    - Family Dromadidae, crab plovers (India to east Africa)
  - Superfamily Burhinoidea, thick-knees
    - Family Burhinidae, thick-knees (cosmopolitan, except North America)
  - Superfamily Glareoloidea, pratincoles, coursers
    - Family Glarrolidae, pratincoles, coursers (old world)
  - Superiamily lhinocoroidea, seed snipe
    - Family Thinocoridae, seed snipe (South America)
  - Superfamily Chionidoitlea, sheathbills
    - Family Chionididae, sheathbills (Tierra del Fuego to southern Indian ocean and Antarctica)
- Suborder Lari, gulls, terns, skimmers
  - Family Stercorariidae, skuas, jaegers (cosmopolitan)
  - " Laridae, gulls, terns (cosmopolitan)
  - " Rynchopidae, skimmers (America, southern Asia and Airica)
- Suborder Alcae, auks
  - Family Alcidae, auks, auklets, murres (northern hemisphere)

Order Columbiformes, sand grouse, pigeons, doves
- Suborder Pterocletes, sand grouse
  - Family Pteroclidac, sand grouse (old world)
- Suborder Columbae, pigeons, doves
  - Family Raphidae, dodos, solitaires (Mauritius, Réunion, Rodrigues)

Family Columbidae, pigeons, doves (cosmopolitan)

Order Psittaciformes, lories, parrots, macaws
Family Psittaiidae, lories, parrots, macaws (cosmopolitan, except northern Eurasia)

Order Cuculiformes, plantain eaters, cuckoos
Suborder Musophagi, plantain eaters
Family Musophagidae, plantain eaters, touracos (Africa)
Suborder Cuculi, cuckoos, road runners, anis
Family Cuculidae, cuckoos, road runners, anis (cosmopolitan)

Order Strigiformes, owls
Family Protostrigidae, *Protostrix* (fossil)
" Tytonidae, barn owls (cosmopolitan)
" Strigidae, typical owls (cosmopolitan)

Order Caprimulgiformes, oilbirds, goatsuckers
Suborder Steatornithes, oilbirds
Family Steatornithidae, oilbirds (northern South America)
Suborder Caprimulgi, frogmouths, goatsuckers
Family Podargidae, frogmouths (India to Australia)
" Nyctibiidae, potoos (new world tropics)
" Aegothelidae, owlet-frogmouths (Australian region)
" Caprimulgidae, goatsuckers (cosmopolitan, except eastern Pacific)

Order Apodiformes, swifts, hummingbirds
Suborder Apodi, swifts
Family Aegialornithidae, *Aegialornis* (fossil)
" Apodidae, swifts (cosmopolitan)
" Hemiprocnidae, crested swifts (India to New Guinea)
Suborder Trochili, hummingbirds
Family Trochilidae, hummingbirds (new world)

Order Coliiformes, colies
Family Coliidae, colies (Africa)

Order Trogoniformes, trogons
Family Trogonidae, trogons (cosmopolitan, except Holarctic region)

Order Coraciiformes, kingfishers, bee eaters, rollers, hornbills
Suborder Alcedines, kingfishers, todies, motmots
Superfamily Alcedinoidea, kingfishers
Family Xlcedinidae, kingfishers (cosmopolitan)
Superfamily Todoidea, todies
Family Todidae, todies (Greater Antilles)
Superfamily Momotoidea, motmots
Family Momotidae, motmots (tropical America)
Suborder Meropes, bee eaters
Family Meropidae, bee eaters (old world)
Suborder Coracii, rollers. hoopoes
Family Coraciidae, rollers (old world)
" Brachypteraciidae, groundrollers (Madagascar)
" Leptosomatidae, cuckoo rollers
" Upupidae, hoopoes (Eurasia and Africa)
" Phoeniculidae, wood hoopoes (Africa)
Suborder Bucerotes, hornbills
Family Bucerotidae, hornbills (Africa and southern Asia)

Order Piciformes, jacamars, barbets, toucans, woodpeckers
Suborder Galbulae, jacamars, barbets, toucans
Superfamily Galbuloidea, jacamars, puffbirds
Family Galbulidae, jacamars (tropical Mexico to South America)
" Bucconidae, putibirds (Central and South Xmerica)
Superfamily Capitonoidea, barbets! honey guides
Family Capitonidae, barbets (tropics)
" Indicatoridae, honey guides (Africa and southern Asia)
Superfamily Ramphastoidea, toucans
Family Ramphastidae, toucans (Mexico to South America)
Suborder Pici, woodpeckers
Family Picidae, woodpeckers, piculets (cosmopolitan, except Madagascar and Australia)

Order Passeriformes, perching birds
Suborder Eurylaimi, broadbills
Family Eurylaimidae, broadbills (tropical Airica and Indo-Malaya)
Suborder Tyranni, ovenbirds, tyrant flycatchers and allies
Superfamily Furnarioidea, ovenbirds, wood hewers and allies
Family Dendrocolaptidae, wood hewers (Mexico to South America)
Family Furnariidae, ovenbirds (Mexico to South America)
" Formicariidae, ant thrushes (Mexico to South America)
" Conopophagidae, ant pipits (South America)
" Rhinocryptidae, tapaculos (Central and South America)
Superfamily Tyrannoidea, tyrant flycatchers, pittas and allies
Family Cotingidae, cotingas (new world)
" Pipridae, manakins (Mexico to South America)
" Tyrannidae, tyrant flycatchers (new world)
" Oxyruncidae, sharp-bills (Central and South America)
" Phytotomidae, plant cutters (South America)
" Pittidae, pittas (old world tropics)
" Acanthisittidae, New Zealand wrens (New Zealand)
" Philepittidae, asities, false sunbirds (Madagascar)
Suborder Menurae, lyrebirds
Family Menuridae, lyrebirds (Australia)
" Atrichornithidae, scrubbirde (Australia)
Suborder Passeres, songbirds
Family Alaudidae, larks (cosmopolitan)
" Palaeospizidae, *Palaeospiza* (fossil)
" Hirundinidae, swallows (cosmopolitan)
" Dicruridae, drongos (old world tropics)
" Oriolidae, old world orioles (old world)
" Corvidae, crows, magpies, jays (cosmopolitan)
" Cracticidae, bell magpies, Australian butcherbirds (Australia)
" Grallinidae, magpie larks (Australia)
" Ptilonorhynchidae, bowerbirds (Australia, New Guinea)
" Paradisaeidae, birds of paradise (Australian region)
" Paridae, titmice (Eurasia, Africa, North America)
" Sittidae, nuthatches (northern hemisphere, Australian region)
" Hypositttidae, coral-billed nuthatches (Madagascar)
" Certhiidae, creepers (Eurasia. North America. Australia)
" Paradoxornithidae, parrotbills, suthoras (Nepal to China)
" Chamaeidae, wren tits (Oregon and California)
" Timaliidae, babbling thrushes (old world)
" Campephagidae, cuckoo shrikes (old world)
" Pycnonotidae, bulbuls (old world)
" Palaeoscinidae, *Palaeoscinis* (fossil)
" Chloropseidae, leaf-birds
" Cinclidae, dippers (northern hemisphere, South America)
Troglodytidae, wrens (cosmopolitan, except Africa and Australia)
" Mimidae, thrashers. mockingbirds (new world)
" Turdidae, thrushes (cosmopolitan)
" Zeledoniidae, wren thrushes (Costa Rica and Panamá)
" Sylviidae, old world warblers (cosmopolitan)
" Regulidae, kinglets (northern hemisphere)
" Muscicapidae, old world flycatchers (old world)
Prunellidae, accentors, hedge sparrows (Europe and northern Asia)
" Motacillidae, wagtails, pipits (cosmopolitan)
" Bombycillidae, waxwings (northern hemisphere)
Ptilogonatidae, silky flycatchers (southwestern United States to Panamá)
Dulidae, palm chats (Hispaniola)
Artamidae, wood swallows (Africa, India and Australian region)
Vangidae, Vanga shrikes (Madagascar)
Laniidae, shrikes (cosmopolitan, except South Xmerica)
" Prionopidae, wood shrikes (old world tropics)
" Cvclarhidae. pepper shrikes (Mexico to South America)
Vireolaniidae. shrike vireos (continental tropical Xmerica)
Callaeidae, wattled crows, huias, saddlebacks (New Zealand)
Sturnidae, starlings, glossy starlings (old world)
" Meliphagidae, honey eaters (Australian region)

Family Nectariniidae, sunbirds (Africa, Asia and Australian region)
" Dicaeidae, flowerpeckers (Africa, Indo-Malaya and Australian region)
" Zosteropidae, white-eyes (Africa, southern Asia and Australian region)
" Vireonidae, vireos (new world)
" Coerebidae, honey creepers, bananquits (tropical America)
" Drepanididae, Hawaiian honey creepers (Hawaiian Islands)
" Parulidae, wood warblers (new world)
" Ploceidae, weaverbirds (Africa, Eurasia and Australia)
" Icteridae, blackbirds, American orioles, troupials (new world)
" Tersinidae, swallow-tanagers (eastern Panamá to tropical South America)
" Thraupidae, tanagers (new world)
" Catamblyrhynchidae, plush-capped finches (northern Andes)
" Fringillidae, grosbeaks, finches, buntings (cosmopolitan, except Australian region)

BIRD BANDING: *see* MIGRATION, BIRD.

BIRD LOUSE, a common name for those species of chewing lice (Mallophaga) that live on birds. They are small parasitic insects feeding on the feathers and sometimes the blood of their hosts. *See* MALLOPHAGA.

BIRD OF PARADISE. Among the most beautiful birds in the world are the birds of paradise, perching birds closely related to the bowerbird (*q.v.*) and crow, and belonging to the family Paradisaeidae. There are about 20 genera and 43 species, of which 17 genera and 35 species are confined to New Guinea and nearby islands; 3 species occur in the Moluccas, while several species of the less spectacular riflebirds (*q.v.*) are native to eastern Australia. The females and young are plain coloured, but the males are frequently rich in orange, yellow, green, blue, brown and red of many shades, with soft, velvety, long or peculiarly shaped plumes. Some are rich black with iridescent colours, as in the riflebirds. Birds of paradise are distributed from the hot swampy lowlands through the forests of oak and beech to the upper tree line at 13,000 ft. on towering New Guinea mountains.

They range in size from that of a small thrush to that of a magpie, and the males' plumes are spread in fantastic displays during courtship. In most species courtship is solitary, *i.e.,* one male woos one female; but communal ceremonies occur in the true plume birds (*Paradisaea*), the flagbirds (*Parotia*) and Macgregor's bird of paradise (*Macgregoria*). Some hang upside down while displaying their beautiful plumes to the female; others, like the flagbirds, sit on a low twig over a cleared "dance floor." Males do not usually participate in nest life, about which little is known. Eggs are generally orange streaked with brown.

The largest and one of the best known of the Paradisaeidae is the great bird of paradise (*Paradisaea apoda*), skins of which first reached Europe on Magellan's ships. It is a beautiful species, rich in cinnamon and fawn, yellow on the head and back of neck, with emerald-green throat, and resplendent golden-whitish plumes, cascading over the back from the sides of the breast. The lesser bird of paradise (*P. minor*) is a somewhat smaller, less brilliantly coloured species, also common throughout New Guinea. Birds congregate on special trees at the beginning of the breeding season, when the males display for the females. They are possibly polygamous. These forms were prized for their beautiful plumes. Plume hunting, each season just after the annual molt, began about 500 years ago, developed rapidly from 1880 to 1910—when 50,000 to 100,000 skins reached the European markets—and was finally prohibited in 1924.

Among the most beautiful are the blue bird of paradise (*P. rudolphi*), with delicate blue plumes spreading like a fan from the sides of the breast; the superb bird of paradise (*Lophorina superba*), a small dark bird with a conspicuous spreading breastshield of glossy green and a huge black velvet cape that can be raised over the head; the king bird of paradise (*Cicinnurus regius*), bright scarlet, with two very long wirelike plumes from the tail with small circular green tips; the beautiful little golden-silky bird of paradise (*Loboparadisea sericea*); the magnificent bird of paradise (*Diphyllodes magnificus*), a small bird with spreading yellow, erectile cape, a glistening velvety breastshield and two long coiled wire plumes from the tail; the long-tailed flagbird (*Parotia wahnesi*), one of the six-wired birds of paradise, with a spreading "skirt" and a pair of triple-wires tipped with bits of feather, upward and forward from behind the eyes; the twelve-wired bird of paradise (*Seleucides ignotus*), with a magnificent large rich dark bib, bright yellow under parts and 12 long recurved wires from the tail; and the King of Saxony's bird of paradise (*Pteri-*

BIRD OF PARADISE

DRAWN FOR THE ENCYCLOPÆDIA BRITANNICA BY H. GRÖNVOLD

MALE BIRDS OF PARADISE

1. Princess Stephanie's bird of paradise (*Astrapia stephaniae*)
2. King bird of paradise (*Cicinnurus regius*), second view showing bird with plumage spread
3. Superb bird of paradise *(Lophorina superba)*
4. Hunstein's bird of paradise (*Diphyllodes magnificus*)
5. Great bird of paradise *(Paradisaea apoda)*
6. Crown, Prince Rudolph's bird of paradise *(Paradisaea rudolphi)* (blue bird of paradise), hanging by feet to display plumage
7. Republican bird of paradise (*Diphyllodes respublica*)

dophora alberti), a small bird with two very long fern-frond plumes growing from the back of the head. These are all inhabitants of the forests of New Guinea.

A. R. Wallace's standard-wing (*Semioptera wallacei*), a native of the northern Moluccas or Spice Islands. has a triangular, brilliant green breastshield and two pairs of pale ribbonlike standards raised from the bend of the uings.

Ten of the genera of birds of paradise are known to crossbreed and produce hybrids. and 4 species of *Paradisaea* have produced species hybrids, resulting in the naming of 17 "rare species" of birds of paradise, usually described each from a single skin found among the tremendous numbers in European shipments.

See also BIRD: *Reproduction.* (G. F. Ss.; X.)

BIRD-OF-PARADISE FLOWER is the name commonly applied to the flowers of species of *Strelitzia,* members of the Musaceae or banana family, but particularly to *S. reginae,* the species so frequently found in conservatories and greenhouses. where it is grown for its bananalike foliage and the very odd, showy flowers. The name *Strelitzia* was given for the wife of George III, Charlotte Sophia, of the family Mecklenburg-Strelitz. who mas a patron of botany. The plants of S. *reginae* attain a height of about three feet. possess large strong roots. require a fertile soil, copious water and good light. The oblong leaves are about a foot in length, stiff and borne on radical leafstalks two to three times as long as the blades. The scapes are higher than the leaves; the spathe is about six inches long, nearly horizontal, purplish at the base, and commonly possesses about six flowers that are orange and purplish in colour. The plant is serviceable for house decoration and may be used also on the porch or lawn in summer. It will withstand much neglect but may fail to bloom regularly when badly handled Seeds may be induced to set if the flowers are hand pollinated. but the usual method of propagation is by suckers and division. The bird-of-paradise flower is an important florist's crop in California and Hawaii, from where it is shipped to market throughout the United States. It is particularly striking when mixed with other flowering plants, especially orchids.

BIRD PROTECTION: *see* WILDLIFE CONSERVATION.

BIRDSEYE, CLAUDE HALE (1878–1941). U S. topographic engineer and first president of the American Society of Photogrammetry, was born on Feb. 13, 1878, at Syracuse, N.Y. He graduated from Oberlin college in 1901, did postgraduate work at Ohio State and Cincinnati universities, and joined the U.S. geological survey, in which service he explored and mapped the regions of Kilauea volcano, Hawaii (1912), and Mt Rainier, Wash. He served overseas during World War I. and in 1923 led an expedition through the Marble and Grand canyons of the Colorado river from Lee's Ferry, Ariz., to Needles, Calif. In 1929 he resigned from the geological survey to become president of the Aerotopograph Corporation of America and in 1930 was in charge of surveys by aerial photography of the sites for Hoover dam He returned to the geological survey in 1932 and was assistant to the director until his death on May 30, 1941, in Washington, D.C.

(D. MN)

BIRD'S NEST, EDIBLE, the nest of a species of swift of the genus *Collocalia,* composed chiefly of the saliva of birds. They are to be found in the East Indies and Australia and are valued by the Chinese for the making of bird's nest soup. *See* SWIFT.

BIRD WATCHING. The development of bird watching as a popular pastime and scientific sport took place almost entirely in the 20th century. The widespread use of the term itself appears to date from Edmund Selous' book, *Bird Watching* (1901). Modern bird watching was made possible largely by the development of optical aids, particularly binoculars, which have enabled people to see and study wild birds better than ever before. Whereas in the 19th century almost all students of birdi used guns and could only identify an unfamiliar species when its corpse was in their hands. thousands of modern bird watchers have brought the accurate identification of live birds in the field to a pitch of skill never before achieved in civilized history.

This newly acquired skill was the basis of the great surge of interest in wild birds that occurred from about the 1880s onward. Though bird watching first became popular in Great Britain, the United States was never far behind. and by the early 1960s it was almost equally popular in Scandinavia. the Netherlands, Germany, Switzerland and the older countries of the British Commonnealth. There are bird watchers and usually some club or society for them, in almost every country in the world.

About 1.000 natural history societies exist in the United Kingdom alone, mainly in England. of which 47 are devoted solely to bird matching: many of the rest have active ornithological sections As a result almost the whole of England is covered by a network of annual reports recording the more unusual birds seen in the district or county during the year and the sifting of these records is one of the most important activities of the societies. The first such annual report appeared for Hertfordshire as early as 1878. Almost every English county also has a book devoted to the history of its avifauna. Middlesex (1866) was the first county to be so treated. In the United States the first illustrated book on the birds of a single state appeared in 1910.

No small part of the credit for increasing the interest in bird watching among the public belongs to the numerous authors of popular bird books, stretching as far back as Gilbert White's *Natural History of Selborne* (published 1788, although dated 1789) and H. D. Thoreau's *Walden, or Life in the Woods* (1854), and culminating in such essential aids to the bird watcher in the field as H. F. Witherby's five-volume *Handbook of British Birds* (1938–41) and Roger Tory Peterson's *A Field Guide to the Birds* (1934), which gives the field marks of all North American birds found east of the Rocky mountains.

Numerous journals and magazines, such as the *Audubon Magazine* (United States). *British Birds, La Terre et la vie* (France) and *De Levende Natuur* (Netherlands). have also played their part; and so have the radio authorities. led by the British Broadcasting corporation, n-hose natural history unit at Bristol was a world pioneer in presenting natural history to mass audiences. One of their earliest, "hits" was the woodpecker film of Heinz Sielmann, the outstanding German ciné photographer.

From about 1930 there was a great increase in field work, including photography, by amateur bird watchers in the Anglo-Saxon, Germanic and Scandinavian countries. whereas in the Latin and Slavonic countries ornithology remained much more the province of the professional zoologist. In Great Britain this movement was led by the British Trust for Ornithology (B.T.O.). founded in 1932 by a group headed by H. F. Witherby, E. M. Nicholson and B. W. Tucker. The B.T.O. organizes co-operative inquiries in which large numbers of amateurs take part, such as sample censuses of herons and great crested grebes and surveys of winter roosts of gulls. The wildfowl counts of the International Wildfowl Research bureau are run as a co-ordinated international effort throughout western Europe.

Bird observatories originated as far back as the 1840s, when Heinrich Gatke began to record the vast numbers of migrant birds that pass every spring and autumn through the island of Heligoland in the North sea. British ornithologists, stimulated by Gatke's work, began in 1880 to organize co-operative observations on migration on their side of the North sea, and this eventually led to the discovery by William Eagle Clarke of the importance as migration stations of Fair Isle and other islands off the coast of Scotland.

The modern phase of bird observatory activity in Europe began in 1935–36, when R. M. Lockley opened the first permanent one on the Pembrokeshire island of Skokholm. By the early 1960s there were about 15 British bird observatories, mainly on islands or promontories along the coast line, closely linked with the British

Trust for Ornithology, while others were scattered around the coasts of Europe from Ottenby (Sweden) in the Baltic to Ushant on the west coast of France and Capri (Italy) in the Mediterranean.

The main activity at British bird observatories as they developed in the 1950s and 1960s was the trapping and subsequent ringing (banding) (see MIGRATION, BIRD) of birds under the national ringing scheme, founded by H. F. Witherby, and run by the British Trust for Ornithology from the British museum (Natural History). Similar ringing schemes are found throughout the world, especially in Europe and North America.

Side by side with the actual watching of birds grew up a strong movement to protect them by legislation and public understanding (see WILDLIFE CONSERVATION). In this the lead was taken in the United States by the National Audubon society and in Britain by the Royal Society for the Protection of Birds.

Starting in Vienna in 1884, there has been a series of international ornithological congresses, which in the 20th century came to be held at four-year intervals. These scientific gatherings are attended by several hundred amateur bird watchers as well as by the leading professionals.

BIRDWOOD, WILLIAM RIDDELL BIRDWOOD, 1ST BARON (1865–1951), British field marshal, who was the first commander of the Australian and New Zealand army corps (Anzac) and is especially remembered for his part in the Gallipoli campaign of World War I. was born at Kirkee, India, on Sept. 13, 1865. Educated at Clifton college, he entered the army through the militia in 1883, passed through the Royal Military college, Sandhurst, and joined the 12th lancers (1885), transferring to the 11th Bengal lancers in 1887. He took part in the Black Mountain (1891) and Tirah (1897) campaigns on the Indian frontier, and in the South African War (1899–1902). In South Africa he first met Lord Kitchener, who became the greatest influence in his military life. Birdwood was on his staff in South Africa and in India from 1902 to 1909. He commanded the Anzac forces in the landing at Gallipoli in 1915 and soon gained the confidence of his troops. As commander of the Dardanelles army he was responsible for the later evacuation of the peninsula, which was praised as a masterpiece in planning and execution. He moved to France with the Anzac infantry in 1916, and in May 1918 took command of the 5th army, in whose victorious advance the Anzacs played a prominent part. After holding the northern command in India (1920–24), he became commander in chief, India (1925–30). From 1931 to 1938 he was master of Peterhouse, Cambridge; he was appointed captain of Deal castle in 1935 and was created Baron Birdwood, of Anzac and of Totnes. in 1938. He was the author of Khaki *and* Gown (1941) and In *My* Time (1946). He died near London on May 17, 1951. (R. G. TH.)

BIRETTA, a square, stiff cap worn by the Roman Catholic clergy, its colour varying with the rank of the wearer; that of the pope is white; of the cardinals, red; of bishops, purple; and of the lower clergy, black. Its use is not confined to liturgical functions. The biretta is descended from the *biretum* or "barret cap," once a common item of headgear, whose other descendants include the *barett* worn by the Lutheran clergy, German lawyers and the deans and rectors of universities; the barrette of French judges and barristers; the black cap of the English judge; and the "college cap" familiar in English and American universities and popularly known as the mortarboard. See VESTMENTS, ECCLESIASTICAL.

BIRGER JARL (d. 1266), the virtual ruler of Sweden from 1248 until his death. Before 1238 Birger had married Ingeborg (d. 1254). the sister of King Eric Ericsson, and in 1248 he was created *jarl* or earl of Sweden (Lat. *dux Svecie*). On King Eric's death in 1250 Birger obtained the election of his own son. Valdemar. to the throne. He secured his dynasty's ascendancy after a bitter struggle with the league of Uppland magnates known at that time as the Folkungar. Birger established closer ties with Denmark and Norway, confirmed by marriage alliances: in 1251 he married his daughter to the Norwegian heir apparent and in 1261 he himself married the Danish queen Mechthild. He extended Swedish influence to southern Finland and attempted to control the trade routes to Russia but in 1256 this policy was thwarted by the Russians under Alexander Nevski. However, to develop Sweden's commercial contacts, Birger concluded a trading treaty with Liibeck which was of great importance in Sweden's future development. In internal affairs, Birger enlisted the church's support for the monarchy against the magnates and the provincial assemblies and developed the king's legislative powers on the concept of the king's peace. Under him Sweden first developed a general meeting of the estates on the western European model and Stockholm finally established its position as the administrative centre of Sweden. (G. T. WE.)

BIRINGUCCIO, VANNOCCIO (1480–*c.* 1539). Italian metallurgist and armament maker, known chiefly for his descriptions of processes for the extraction of metals and the preparation of chemical substances in his book The Pirotechnia, was born in Siena, on Oct. 20, 1480. Biringuccio enjoyed the patronage and suffered the vicissitudes of the Petrucci family. He held a post in the armoury of the Siena commune in 1513 and after periods of exile returned to the service of the Republic of Siena in 1530. In 1538 he became head of the foundry of Pope Paul III.

The Pirotechnia was first published in 1540. Unlike the obscure alchemical writings of the period, it gave clear practical instructions and became a standard reference book. It is now valuable to historians of science as a source of information on the state of chemical knowledge of the time.

See C. S. Smith and M. T. Gnudi, *The Pirotechnia of Vannoccio Biringuccio,* Eng. trans. (1942). (WA. W.)

BIRJAND, the chief town of a district (Shahrestan-e Birjand) of eastern Iran! in the ostan (province) of Khurasan, is built on low hills in a barren treeless valley of the Kuhistan uplands, 4,440 ft. above sea level. The town is divided by the broad and usually dry bed of the Khusf river. Pop. (1956) 13,926. The inhabitants include a strong Sunni element, an Afghan community and some Indian merchants. It was formerly the seat of semi-independent rulers of the Qayenat (Qainat), and a caravan centre on the road from Meshed (Mashhad) to the south which now joins the railhead at Zahedan. Birjand has partly maintained its commercial position in spite of the modern changes in traffic.

The district grows wheat and barley, some cotton and fruits. Water is scarce though cultivation on rainfall succeeds in upland locations. Saffron is a famous product especially in the neighbouring district of Qayen (Qain). The wool is excellent and carpet-making remains important though declining in quality. (H. Bo.)

BIRKBECK, GEORGE (1776–1841). English physician, pioneer in the foundation of classes for working men and first president of Birkbeck college. London, was born at Settle. Yorkshire. on Jan. 10, 1776. In 1799 Birkbeck was appointed professor of natural philosophy in Anderson's institution, Glasgow, where he started a class for mechanics. He then practised medicine in London, also promoting the foundation in 1823 of the London Mechanics' institution. He was president of the institution until his death in London on Dec. 1, 1841, and endowed it with £3,700. In 1907 it was renamed Birkbeck college and in 1920 it was recognized as a school of the University of London for evening and part-time students. The success of the London institution led to the establishment of mechanics' institutions all over Britain, especially in the larger industrial cities. Some developed into technical colleges.

See C. Delisle Burns, *A Short History of Birkbeck College* (1924). (S. J. C.)

BIRKENHEAD, FREDERICK EDWIN SMITH, 1ST EARL OF (1872–1930). British statesman and lan yer, best remembered for his remarkably successful tenure of the lord chancellorship and as one of the most influential members of Lloyd George's post-World War I coalition government, was born at Birkenhead on July 12. 1872, the eldest son of a barrister. Frederick Smith. Educated at Birkenhead school and at Wadham college. Oxford, he made a great mark as an undergraduate debater, and was president of the Union in the Hilary term of 1894. He obtained first

class honours in law in 1895, was called to the bar by Gray's Inn in 1899 and at once began a highly successful common-law practice in Liverpool. In 1901 he married Margaret Furneaux, the daughter of an Oxford don. At an early stage he took a keen interest in politics and in 1906 was elected, despite the prevailing tide of Liberal success, as Conservative member of parliament for the Walton division of Liverpool. His maiden speech on March 12, 1906, was one of the finest pieces of satire and invective ever heard in the house of commons, and made his parliamentary reputation overnight. He took silk in 1908 and for the next few years made a huge income which, however, he habitually anticipated and overspent, for he never had any idea of the meaning of money. His capacity for work was astounding and his energy never flagged, despite a life of strenuous exercise and constant pleasure reminiscent of the days of Charles James Fox.

Smith soon became a leading figure in his party and was prominent in opposition to the Parliament act of 1911 and in the struggle (1912–14) to exclude Ulster from the provisions of the Home Rule bill. On the formation of the first coalition government of World War I in May 1915 he became solicitor general, succeeding Sir Edward Carson as attorney general a few months later. In 1918 Lloyd George offered him the lord chancellorship which he accepted with some misgivings because it effectively extinguished any prospect of becoming prime minister. The appointment was not popular. It shocked the king and many others who knew of Smith's reckless mode of life or had felt the lash of his tongue. In fact he was an excellent lord chancellor, his judgments were sagacious, and he was responsible for one of the greatest law reforms of the day, the Law of Property act (1922). Along with Winston Churchill, his close personal friend, and the prime minister he dominated the coalition cabinet, and played a major part in the negotiations leading to the Irish treaty of 1921. On the fall of the coalition government in 1922 he was created an earl (having previously been made a baronet in 1918 and raised to the peerage in 1919). He declined to serve under Andrew Bonar Law or in Stanley Baldwin's first cabinet but in 1924 he became reconciled to the official Conservatives. He was secretary of state for India from 1924 to 1928 when he resigned to make some much needed money in business. He died in London on Sept. 30, 1930.

One of the ablest lawyers and greatest orators of his day, Birkenhead yet possessed qualities which made him many enemies. Orthodox politicians mistrusted him and politically he was a brilliant failure.

Birkenhead's Life, 2 vol. (1933–35; rev. ed., 1 vol., 1959), was written by his only son and successor, FREDERICK WINSTON FURNEAUX SMITH (1907–), 2nd earl. (R. N. W. B.)

BIRKENHEAD, a municipal, county and parliamentary borough and seaport of Cheshire. Eng.. on the Wirral peninsula facing Liverpool at the mouth of the Mersey, 16 mi. S.N.W. of Chester by road. Pop. (1961) 141.683. Area 13.4 sq.mi. A Benedictine monastery, of which considerable ruins remain. was founded about 1150 by Hamon de Masci (Massey) and drew revenues from tolls at the Mersey ferry. Birkenhead ("headland overgrown with beech") was a hamlet of 106 inhabitants in 1810; its development was largely the result of the establishment of boilerworks and a shipyard on Wallasey pool in 1824 by William Laird, a pioneer of iron ships. Laird also laid out, on a rectangular plan. the nucleus of Birkenhead, with the aid of the architects of the New Town of Edinburgh. Sir Joseph Paxton of Crystal Palace fame laid out Birkenhead park (1847). In Arrowe park was held the third International Boy Scouts' jamboree in 1929, 21 years after the foundation of the movement bv Lord Baden-Powell. James Telford, Alan Stevenson and Alexander Nimmo favoured. in 1828, the conversion into a basin of Wallasey pool. the creek of the Mersey north of the priory where Laird's yard was standing. After parliamentary powers mere obtained the first docks were constructed by James Rendel in less than five years and opened in 1847. Since 1858 they have been controlled by the Mersey Docks and Harbour board. There are nearly ten miles of quayage.

The tonn. nhich could still be described as a beautiful watering place in 1833 nhen it was recognized as a tonnship, was incorporated in 1877, became a parliamentary borough in 1861 and. after an increase of boundaries. a county borough in 1888. Besides sharing in the general trade of the Merseyside port, Birkenhead developed an individual trade in the export of midland manufactures and in trade with the east. The two great floats or main basins of the dock system attracted a gigantic flour milling industry which made Birkenhead the largest milling centre in Europe. A vast cattle and meat trade is carried on at lairages and abattoirs on the river front. Besides the shipbuilding industry, which produced the famous Confederate raider, "Alabama," in 1862 and H.M.S. "Ark Royal," the aircraft carrier. in 1955, there is ship repairing and a variety of industry including heavy and light engineering, food processing and clothing manufacture.

The ferry service dates from 1330. Birkenhead was the first town in Europe to have streetcars. The railway tunnel under the Mersey to Liverpool was completed in 1886 and the Mersey tunnel for road traffic, known as Queensway. was opened by King George V on July 18. 1934. It is more than 2 mi, long and has an internal diameter of 44 ft , allowing four traffic lanes. Its capacity per hour is 4,150 vehicles moving at 20 m.p.h. and spaced 100 ft. apart. The roadway is of cast iron, with rubber paving blocks in various sections, and the interior is lined with a glass dado. Public buildings include the toun hall, the Williamson art gallery (1928). the central library (1934), St. Aidans Theological college. the general hospital and the fine Technical college opened in 1955.

BIRKHOFF, GEORGE DAVID (1884–1944), U.S. mathematician. was born at Overisel, Mich., on March 21, 1884. Following his secondary education at Lewis institute. Chicago, he attended The Gniversity of Chicago and Harvard university (A.B., 1905; A.M., 1906), and returned to The University of Chicago to complete his graduate studies (Ph.D., 1907). He taught at the University of Wisconsin, Madison (1907–09), at Princeton university. Princeton, N.J. (1909–12), then at Harvard until his death. Birkhoff was extraordinarily stimulating as a lecturer and as a director of research. At the middle of the 20th century many of the most productive mathematicians of the United States had either written their doctoral dissertations under his direction or done postdoctoral research with him.

Birkhoff's own research. notable for both breadth and depth. was primarily in the fields of mathematical analysis and analysis applied to dynamics. His dissertation and much of his later work dealt with the solutions of ordinary differential equations and the associated expansions of arbitrary functions. Using matrix methods. he also contributed fundamentally to the theory of systems of differential equations and the analogous theory of difference equations. A striking achievement was his proof (1913) of a geometric theorem having applications to dynamics conjectured by Henri Poincaré. Another of Birkhoff's major contributions to dynamics was the ergodic theorem (1931), which transformed the Maxwell-Boltzmann (see CHEMISTRY: Physical Chemistry: The *Maxwell-Boltzmann* Law) ergodic hypothesis of the kinetic theory of gases (to which exceptions were known) into a rigorous principle that, through use of the Borel-Lebesgue measure theory. placed the exceptional cases in proper perspective. Birkhoff developed his own theory of gravitation. subsequent to Einstein. He also constructed an important mathematical theory of aesthetics, which he applied alike to art, music and poetry. All of this creative work was renowned internationally, and stimulated further scientific discoveries. Birkhoff served as dean of the Harvard faculty of arts and sciences (1935–39); he was president of the American Mathematical society (1924–26) and of the American Association for the Advancement of Science (1936–37). He died Nov. 12, 1944. in Cambridge. Mass.

Among his works are *Relativity and Modern Physics* (1923); *The Origin, Nature and Influence of Relativity* (1925); *Dynamical Systems* (1928); *Aesthetic Measure* (1933); with Ralph Beatley, *Basic Geometry* (1911); and *Collected Mathematical Papers-* (1950).

(J. L. WH.)

BÎRLAD (formerly BÂRLAD), a town in eastern Rumania, is the administrative centre of the district of the same name. Pop. (1956) 31.599. It lies on the Birlad river. which is tributary to the Siret and is navigable by small vessels as far as the town. An old Thracian settlement, first mentioned in documents in 1408, Birlad has few historic buildings except the 17th-century Dom-

neasca church. It has long been a market for farm produce but after 1950 expanded industrially, with factories manufacturing ball bearings, clothing, soap and textiles. The town has a state theatre and museum, and is a junction on the Galaţi-Iaşi railway. Nearby are traces of Palloda, a Roman frontier camp.

BIRLING (LOGROLLING) is a favourite outdoor sport of the North American lumberjack. Its origin can be traced to the spring log drives of the New England states, particularly the state of Maine, during the early lumbering era, from where it moved westward to the Great Lakes region and then to the Pacific northwest. On the spring drives the lumberjacks, turned rivermen, obtained their experience in managing themselves on the moving carpet of logs. Agility and nimble-footedness mere the prime requisites, as well as levelheadedness, since the slightest misstep or miscalculation of the eye might send them beneath the logs into a swirling current of white water to drown.

Clad in "stagged" (shortened) overalls or jeans, which were light and dried quickly, woolen shirts, high-topped calked ("corked" to a real riverman) boots that gripped the soft bark of the logs, with pike poles or peaveys in their hands. they would leap from log to log, pushing, prying and pulling to keep the logs moving and ever striving to prevent jams (the bane of the rivermen, along with low water) at curves in the river, on sandbars, rocky narrows, windfalls and deadheads. From the daily work of the rivermen the sport of birling developed. It required skill and endurance to hop with an opponent on a log, spin it rapidly in the water with the feet, stop ("snub") it suddenly, reverse its motion, and in various ways maneuver an adversary off balance and into the water. Dislodging an opponent constituted a fall; two falls out of three constituted a match. Birling rules became standardized as the sport progressed. Camp championship contests were held. followed by intercamp contests, and eventually they became intersectional, finally culminating in national championship tournaments, called rodeos. The contests were usually held after the drive reached the sawmills. The lumberjacks bet freely on their favourites, and large sums of money changed hands. It was not until 1888 that the first public birling match was sponsored. The first world's championship tournament was held in 1898, at the Omaha, Neb., exposition. Thomas Fleming of Eau Claire, Wis., won the honour of being the first world's champion.

(G. T. S.; X.)

BIRMINGHAM, a city, county and parliamentary borough (which returns 13 members to parliament), in northwest Warwickshire. Eng., lies 113 mi. N.W. of London by rail and 108 mi. by road. Its northern suburbs adjoin Staffordshire and its southern and southwestern suburbs border on Worcestershire. Area 79.9 sq.mi. Pop. (1961) 1,105,651. Birmingham is England's largest provincial city.

Birmingham stands in the centre of an upland area; isolated by the valleys of the rivers Trent, Severn and Avon, and known as the Birtningham or Midland plateau. It is situated in the valleys of three small and unimportant rivers — the Tame. Cole and Rea (which all flow into the Trent) — and on the rising ground between these valleys. The site is undulating, rising from 267 ft. above sea level in the east to 736 ft. in the west, while at the Lickey hills, which form the city's southern extremity, the land rises to 1.000 ft.

The City Centre. — Victoria square is the heart of Birmingham's city centre, flanked on the southwest by the Town hall. a building in the classic tradition modeled on the Temple of Castor and Pollux. It was designed by Joseph Hansom, who invented the Hansom cab and John Welch, and is the principal meeting place and concert hall in the city. Mendelssohn's *Elijah* was given its first performance there in 1846, and since then most of the great orchestras and concert celebrities have appeared. On the north of Victoria square is the Council house. the foundation stone of which was laid in 1874 by Joseph Chamberlain during his mayoralty. The building, in Italian Renaissance style, contains spacious reception rooms, Lord Mayor's parlour, committee rooms and offices, and its clock tower, locally known as "Big Brum." is Birmingham's best-known landmark. Adjoining is the City of Birmingham Museum and Art Gallery, visited by about 2,000 people daily and famous for its pre-Raphaelite paintings and English water colours. It has departments of archaeology and natural history, and nearby in Newhall street, is a Museum of Science and Industry, which includes a collection of veteran cars.

Two of the city's principal thoroughfares radiate from Victoria square — Colmore row and New street. In Colmore row, surrounded by lawns and flower beds, is the cathedral church of St. Philip. Designed in the baroque style by Thomas Archer and consecrated in 1715, it contains some stained glass windows portraying the Nativity, Crucifixion, Ascension and Last Judgment by Edward Burne-Jones, a native of Birmingham. The parish church of St. Martin is in the former Bull Ring, standing on the site of a Norman church and twice rebuilt since the 13th century. Inside are stone effigies of the de Bermingham family and a chapel of the Guild of the Holy Cross dedicated to the memory of an American airman, James Neale Thorne, who fought and died with the Royal Air Force in World War II. Among other notable ecclesiastical buildings in the city centre is the cathedral of St. Chad, built in 1839–41 to the design of Augustus Pugin, the first Roman Catholic cathedral to be built in England after the Reformation. Its interior is made interesting by much fine modern glass. some rare 15th-century carving in the episcopal throne, stalls and lectern from Cologne and an old pulpit from Louvain.

Corporation street, built toward the end of the 19th century as a result of clearing 45 ac. of slum property, was again being redeveloped in the mid-20th. It contains the Victoria Law Courts, built between 1887 and 1891, and designed by Sir Aston Webb nith Ingress Bell; opposite is the Central hall, Birmingham's principal Methodist church, and nearby the modern headquarters of the city's fire and ambulance service.

To the west of Victoria square is the Central library and beyond at the beginning of Broad street is the Hall of Memory, commemorating those citizens who were killed during World Wars I and II, and the first section of the Civic centre (opened 1939). The old Bull Ring, an ancient market area, was demolished and redevelopment began in 1960. Provision was made for retail markets, a self-contained shopping centre, arid parks and open spaces.

Suburbs. — Although primarily an industrial city. Birmingham has many pleasant residential suburbs and more than 4,000 ac. of parks and open spaces. Westward and beginning less than one mile from the city centre is Edgbaston. still with many gracious residences. although now with a number of modern office blocks, including the Chamber of Commerce which moved from New street in 1960, and several hotels. Cannon Hill park on the outskirts of Edgbaston is the city's principal ornamental park of about 80 ac., where the main conservatory containing many interesting tropical plants is open to visitors. Opposite is the County Cricket ground, one of the most up-to-date in the country and of test match standard with comfortable seating for about 30.000 spectators. Beyond Edgbaston is Harborne, a village taken into the city in 1891. David Cox, the painter, is buried in the churchyard of the parish church of St. Peter.

Southwest of the city is Bournville where about 11,000 people are employed in its cocoa and chocolate industry. The adjoining estate, founded by George Cadbury (*q.v.*) in 1879, is still regarded as an outstanding instance of enlightened planning. By the village green are Selly manor and Minworth Greaves house, two splendid examples of medieval building. There is also a unique carillon of 48 bells. Nearby King's Norton, mith its ancient church and half-timbered school house, and Northfield, mith a church with traces of Norman work, are two districts in which evidences of historical associations are still to be seen. Beyond are the Lickey hills. one of the finest stretches of unspoiled countryside in the Midlands, rising to 1,000 ft.

On the other side of the city, where industry is more apparent. Birmingham merges almost imperceptibly into the adjoining county boroughs of Smethwick and West Bromwich (*qq.v.*). On the northwest boundary is Handsworth, where beneath the 500-year-old tower of the parish church lie Matthew Boulton. James Watt and William Murdock (*qq.v.*), pioneers and leaders of the Industrial Revolution in England. Nearer the city is Aston hall, a Jacobean mansion built by Sir Thomas Holte between 1618 and

1635 and later occupied by James Watt, son of the great engineer. Acquired by the corporation in 1864, it is now restored to its former grandeur and furnished as a private house of the period.

To the east of Birmingham, where many municipal houses have been built, is the modern airport at Elmdon, and there the city merges into the more rural area of Solihull (*q.v.*), raised to borough status in 1954 and a popular residential district.

Cultural Life.—Birmingham is the centre of cultural life for a large area. It is one of the few cities in England with a permanent orchestra, and the City of Birmingham Symphony orchestra, while not a municipal enterprise, is generously assisted by the city council. It gives frequent concerts in the Town hall, including a popular summer season of Promenade concerts. Birmingham is well known as the home of the Repertory theatre founded by Sir Barry Jackson, where many plays and players, later world famous, first came before the public.

The Central library in Ratcliff place is the hub of the Birmingham library system, which includes 34 branch libraries. The reference library contains more than 700,000 volumes, many rare and valuable. There the Shakespeare Memorial library, one of the largest of its kind in the world, has more than 35,000 books and pamphlets in more than 70 languages. A Technical library and Commercial and Patents library meet the special needs of industry and of the business community.

The University of Birmingham is at Edgbaston with a medical school adjoining the Queen Elizabeth hospital. It takes its roots from Mason Science college. opened in 1880 through the generosity of Sir Josiah Mason, a local manufacturer, and largely through the influence of Joseph Chamberlain a royal charter was granted in 1900 founding the university, with Chamberlain as its first chancellor and Oliver Lodge (later Sir) as its principal. The university has faculties of science, arts, medicine, commerce and law and has been a centre for much modern research. Music and the arts have in the nearby Barber Institute of Fine Arts a building housing an impressive collection of works of art and a fine concert hall. A new university library was built and the latest addition is a building for the faculty of commerce and social science.

The oldest educational institution in Birmingham is the grammar school of King Edward VI which, after its foundation in 1552, stood in New street until 1936, when it moved to Edgbaston near the university. The girls' high school, founded in 1883, is also at Edgbaston, and the foundation also controls a number of branch grammar schools. There are more than 500 schools under the control of the local education authority, covering educational requirements from nursery schools to advanced levels in technology, commerce and art. Educational facilities are also provided at the Birmingham and Midland institute with its school of music, the Selly Oak group of colleges for the study of ecclesiastical and social subjects, Saltley Church of England Training college for men teachers, a Methodist theological college and a Roman Catholic college. Private schools include preparatory and high schools for boys and girls and schools specializing in business training, music, dancing and drama. Since the end of World War II more than 100 new schools and colleges have been built.

Communications.— Birmingham's situation at the heart of England makes it a natural centre for road, rail, canal and air communications. It is on two main British railways services, and road developments, particularly the motorway (M.1) and improvements to routes to Wales, have been made.

The city owns a modern airport at Elmdon (7 mi. from the city centre on the main Coventry road) with direct air services to several continental cities and to Dublin and Belfast. It serves a traffic area containing a population of about 5,000,000, and has a main instrument runway of 5.000 ft. Birmingham is also the centre of an extensive canal system.

Industry.— The city claimed more than 1,500 different trades in the early 1960s and this diversity of industry is one of the main reasons for its uninterrupted industrial prosperity. By the end of the 19th century, although the older-established trades of gun-making, jewelry. goldsmithing and silversmithing continued. the engineering trades had greatly increased in importance; the bicycle trade was by then established and the motor and electrical industries were beginning their spectacular careers. The automobile industry, established in the early 1900s, employed about 22.000 workers in the early 1960s, and produced on average 7,000 vehicles weekly. Although some of the world's largest and most modern factories are located in Birmingham, the city's industrial pattern is not made up entirely of mammoth concerns. and the characteristic industry is still the small firm. The latter, often a family concern, number at least 1,600, each employing less than 100 workers. To meet the needs of small firms the corporation built two "flatted" factories in which the whole or part of a floor is rented to a small firm.

Birmingham's manufactures include practically everything in metal, from pen points and fine jewelry to railway rolling stock. The city is probably best known for its automobiles, motorcycles and bicycles and their component parts and accessories. brassware, silvernare and electroplated goods, buttons and badges, electrical equipment, machine tools, paints, plastics, chocolate, sporting guns and such unusual manufactures as handcuffs, police whistles, ceremonial maces and chains of office. Many firms admit visitors to their plants upon application.

History.— Birmingham is of far more recent growth than most other large British cities. It has no ancient cathedral or medieval castle, and although little is known of the origin of Birmingham, it seems certain that the settlement did not exist as such before Anglo-Saxon times. In Roman times an important road, the Ryknield street, crossed what is now the city, and traces of a Roman camp were found near the site of the Queen Elizabeth hospital at Edgbaston. At the time of Domesday (1085–86) Birmingham lay in the heart of a sparsely populated area, a small community "worth 20 shillings" and having nine tenants living under the lord of the manor probably near the spot where St. Martin's church now stands. At that time several villages, now part of the modern city, were larger and more important than Birmingham.

Its first market charter (possibly confirming earlier rights) was granted in 1166, followed in 1250 by a concession of a four-days fair at Whitsuntide, but it was not until the early 14th century that Birmingham emerged as a centre of any significance: in 1327 only Warwick and Coventry had more taxpayers. There uas a reference to a "goldesmythe" in Birmingham in 1460 and in 1538 the historian Leland described it as "a good market towne . . . with many smithes . . . that use to make knives and all manner of cuttynge tooles and many lorimers that make byts and a great many naylors." The tradition of working in metal thus appears early in Birmingham's history, and during the Civil War its people demonstrated their manufacturing resources and a sturdy independence by providing 15.000 sword blades for the parliamentary forces and by declining orders for weapons for royalist forces, so showing, it was said, "as great fame for hearty, wilful, affected disloyalty to His Majesty as any place in England."

The 18th century saw the foundation of a daily newspaper, *Aris's Gazette*, the establishment of Taylors and Lloyds bank, later to become Lloyds bank, the cutting of the Birmingham canal linking the town with the coal fields of south Staffordshire and. from an industrial point of view most important of all, the partnership of Matthew Boulton and James Watt and the establishment in 1762 of the Soho manufactory. Invention and experience, coupled nith a desire to raise the standard and reputation of Birmingham-made goods, nere the preoccupation not only of Boulton and Watt but of Joseph Priestley, who discovered oxygen. William Murdock, who invented gas lighting. John Baskerville, the printer, and many others nho did so much to lay the foundation of Birmingham as a great industrial centre. These scientific thinkers and industrialists. along with others such as Erasmus Darwin and William Small, Josiah Wedgwood, the potter. Sir William Herschel, the astronomer, John Smeaton, engineer and designer of the Eddystone lighthouse, and Samuel Galton, mere members of the Lunar society, notable for its meetings at which scientific and philosophical questions and problems were discussed.

Later in the 18th century, theatres, schools and libraries and a hospital were opened, and the inauguration of the well-known music festivals mere further indications of the growth of Birmingham,

the population of which increased from 15.000 in 1700 to about 70.000 a hundred years later.

So far, Birmingham's development had been concerned mainly with industry. and "local government" remained unaltered. and indeed until the second half of the 18th century Birmingham was still very much under the rule of the lord of the manor. "very nearly as the Saxons left it." Neither had Birmingham in its earlier history played any prominent part in parliamentary affairs. hut early in the 19th century the question of the corn laws and later parliamentary reform aroused the town with far-reaching effects. Mass meetings were held on Newhall hill. and in 1830, at a public meeting called by Thomas Attwood. J. Scholefield and G. F. Muntz. the Birmingham Political union was formed. the main object of which was to obtain "by every just and legal means such a reform in the Commons House of Parliament as may ensure a real and effectual representation of the lower and middle classes of the people in the House." The movement spread to other parts of the country and Birmingham's lead stimulated a aidespread demand for reform, resulting in the Reform act of 1832. Afterward. it was said that the Birmingham union with its motto "Peace, Law and Order," saved the country from disaster. After this long struggle for political expression, Birmingham, recognizing the great part played by Attwood and Scholefield, returned them both unopposed as its first members of parliament.

Even with political representation obtained, however: local government in Birmingham was in a rudimentary state. In li69 a body of Street commissioners was appointed. but although they acquired the market rights from the lord of the manor and built the Town hall, they "worked in the dark. unseen by the public eye and irresponsible to the public voice," which for a town now of considerable importance with a population of well over 100,000 left much to be desired. The town eventually received a charter of incorporation in 1838. despite objections "that the trading interests of the town would be seriously injured by the annual excitement of a muncipal election." A mayor. 48 councilors and 16 aldermen were soon elected and officials appointed. and for the first time in its history Birmingham enjoyed a representative form of local government. It soon became apparent that the charter did not give the council all the powers it had hoped to possess. and there was still divided control and responsibility with the Street commissioners. and a government enquiry in 1349 revealed a sorry state of affairs with polluted wells, open servers in streets. crowded lodging houses and stagnant ditches.

As a result, an Improvement act was passed in 1851, which abolished the Street commissioners and gave the council supreme control of the civic administration of the town. Even then, local "economists" succeeded for years in producing a period of stagnation in local affairs, but the election of Joseph Chamberlain marked the beginning of a new era in civic administration in Birmingham. Chamberlain was elected mayor in 1873 and twice re-elected to that position. and his association with municipal affairsis still remembered far beyond the bounds of Birmingham. The year 1875 is particularly worthy of note, when an improvement scheme swept away a congested slum area and gave the town Corporation street, and in the same year the gas and water undertakings were acquired.

In 1889 the town was elevated to the rank of city, and in 1896 Queen Victoria conferred the title of lord mayor upon the chief magistrate.

In 1891 the area of the city was increased to 12,365 ac., and in 1911 by the Greater Birmingham scheme the borough of Aston Manor and the urban districts of Erdington and Handsnorth, King's Norton and Northfield. and the rural district of Yardley, comprising most of the residential suburbs, were incorporated into the city, increasing its area to 43,601 ac.

Administration. — Birmingham is a county borough controlled by a council of 152 members, and provides a wide range of public services. Its water supply comes from mid-Wales, 73 mi. away. The corporation carried on large-scale housing projects between World Wars I and II and building since then has included many blocks of multistory flats. Twenty-one homes for old people are provided and 19 children's homes and 5 residential nurseries are maintained. The public health department maintains more than 50 child welfare centres and a number of day nurseries. The city's first health centre with accommodation for six doctors was opened in May 1960. Local transport services are provided by the corporation. which also runs a civic restaurant and catering service. the municipal airport (which after government requisition reverted to the corporation in April 1960) and the only municipal bank in the country.

BIRMINGHAM, the largest city in Alabama, U.S., and the leading industrial city of the south, is in the north central part of the state. It is the seat of Jefferson county and a port of entry in the Mobile customs district. Population (1960) 340,887. (For comparative population figures see table in ALABAMA: *Population.*) The standard metropolitan statistical area (Jefferson county), including Bessemer (*q.v.*), Fairfield and other suburban communities, had a population of 634.864 in 1960.

In 1871. on the site where the east-west and north-south railroads met in a cotton field the year before, the city was founded by a land company backed by railroad officials. It was named for Birmingham, Eng. In the census of 1880 the population mas 3,086; in 1890 it was 26,178. The United States Steel company bought out the main local steel company in 1907 and Birmingham continued to develop as an industrial centre throughout the 20th century. The city adopted a commission form of government in 1911.

Located in the narrow Jones valley, it is protected by mountains to the southeast and northwest. Its residential environs spread over the mountain slopes and into the valleys bevond.

All the materials needed for making steel are found in close proximity and the industrial development of the city is based largely on immense mineral deposits: coal (approximately 66,000,000.000 tons), including good coking varieties; limestone and dolomite, used in fluxing steel; and iron (approximately 1,700,000.000 tons of red ore and 27,000,000 tons of brown ore). Graphite, marble, barites, bauxite, pyrite, quartz, millstone, cement rock, clays, sand and gravel and others are found in smaller quantities. Electric energy is supplied by hydroelectric and steam plants.

Pig iron and steel have always been the city's leading products. The city's varied industries manufacture more than 3,000 different commodities. ranging from acetic acid to zinc sulfate. The district produces several million tons of coal and coke annually, most of it in by-product ovens yielding vast quantities of coal tar and helping to supply the city's mains nith gas The area produces about 5,000,000 tons each of pig iron and steel every year. Other important products are cast-iron pipe (60% of the national supply of pressure pipes), aircraft, wire, nails, steel cars, rails, stoves, cotton gins, machinery for coal mining, brick, cement, lumber and lumber products, cottonseed oil and meal, corn meal, textiles, rubber tires, chemicals, mattresses, meat products, soft wood, especially yellow pine, and explosives.

Birmingham-Southern college, a coeducational Methodist institution, occupies 250 ac. on a hill overlooking the city. It was created in 1918 by the consolidation of Birmingham college, opened in 1898, and Southern university, established at Greensboro, Ala., in 1859. Howard college, a Baptist coeducational institution which was opened at Marion in 1842 as an academy and moved to Birmingham in 1887, occupies a campus of 400 ac. near the city. Daniel Payne college, maintained by the African Methodist Episcopal church and established there in 1889, and Miles college. founded in 1907 and supported by the Methodist church, are Negro institutions.

The medical and dental colleges of the University of Alabama are located in a 12-block $50,000,000 medical centre near the heart of the city. Near them are located the crippled children's

clinic, eye clinic, veterans' hospital, nutritional clinic, University hospital, public health building and the University of Alabama centre where evening undergraduate courses are offered. Three blocks away is the Southern Research institute.

Adjoining Birmingham's business district is the civic centre, including the city hall, county courthouse. Birmingham Museum of Arts, which houses the Kress collection, a city auditorium and the public library, which includes the large Tutwiler collection of southern history. In other sections of the city are the beautiful old ante-bellum home, Arlington, built in 1842 and maintained as a historic shrine, and the large iron statue of Vulcan, the Roman fire god, on top of Red mountain. (H. T. SH.)

BIRNEY, JAMES GILLESPIE (1792–1857), U.S. politician and abolitionist, was born in Danville, Ky., Feb. 4, 1792, of Scotch-Irish parents. He graduated from the College of New Jersey (now Princeton university) in 1810, studied law in Philadelphia, Pa., and passed the bar examination in 1814. He then returned to Danville to practise law and in 1816 mas elected to the Kentucky state legislature. Birney moved to Huntsville, Ala., in 1818, was elected to the state legislature in 1819 and served as alderman and as mayor in Huntsville. While in Alabama he became interested in the American Colonization society and in 1832 became its agent in the southwest. He returned to Danville to devote his full time to the abolitionist cause. In 1834 he freed his slaves and wrote his Letter on *Colonization* which led him into the American Anti-Slavery society. In 183i he became its executive secretary. In the meantime he had abandoned his plan to establish an abolitionist newspaper in a slave state and had moved to Ohio. On Jan. 1, 1836, the Philanthropist began publication; on July 12 the office in Cincinnati was broken into by a mob, one issue of the paper was destroyed and the press was thrown into the Ohio river.

By 1839 Birney felt that an antislavery political party should be formed. This caused a split in the American Anti-Slavery society. Those favouring political action withdrew and were successful in forming the Liberty party. In 1840 and again in 1844 Birney was its candidate for the presidency of the United States. He received few votes in 1840 but in the election of 1844 enough votes were cast in New York state for the Liberty party ticket to defeat Henry Clay and elect James K. Polk. Birney fell from a horse in 1845, suffered a severe paralytic stroke and, although mentally alert and active in writing. could never again deliver a public address. He died in Eagleswood, near Perth Amboy, N.J., Nov. 25, 1857.

See William Birney, James G. Birney and His Times (1890).

BIROM, a small but politically prominent heterogeneous people of the Jos plateau, Nigeria. of about 60,000 population, in many respects representative of the societies that comprise Nigeria's "pagan [*i.e.*, neither Muslim nor Christian] middle belt." Their language is affiliated with the Bantu languages, within the Central branch of the Niger-Congo family, and thus is closely related to the languages of, *e.g.,* the Nigerian Tiv (*q.v.*) and Katab (Atyap), but contrasts with the Hamito-Semitic languages of many of their close neighbours, including the Ron (sometimes confused with Birom), Sura and Angas—peoples otherwise ethnically very similar. (See AFRICAN LAXGUAGES.)

A "naked hill-people," and subsistence farmers, Birom were nonetheless unmatched horsemen, and defended themselves successfully against the Muslim Hausa and Fulani (*qq.v.*) slave raiders through the 19th century.

Under British administration, Birom received particular attention, owing to the wealth of tin in their territory, and to their dignified preservation of austere traditional values while exposed to a measure of alien influence, especially European, but also Muslim, probably unequaled in Nigeria.

The nucleus of a federation of splinter peoples centring approximately about the village of Riyom (8° 45' E., 9° 30' N.), including culturally (and linguistically) related but discrete Rukuba, Irigwe and Aten (among others), Birom came at length to serve as a model among local peoples with a similar cultural tradition—both those that, like Birom, had resisted and those that had submitted to the Muslim states before the advent of the British. Their prestige derived from their seniority in the development of a centralized organization and from their dedication to the principle of "accommodating self-determination," as well as from their nominal wealth from tin royalties.

See H. D. Gunn, Peoples of the Plateau Area of Northern Nigeria (1953). (H. D. GU.)

BIRON, the name of a branch of the house of Gontaut, distinguished in French history, which took its name from the territory of Biron in Périgord.

ARMAND DE GOXTAUT (1524–92), baron de Biron, was born in 1524. As a page of Margaret, queen of Kavarre, he attracted the attention of the marshal de Brissac (Charles de Cossé), who took him to Piedmont. There he commanded the artillery but was lamed by a wound. He brought back to the royal army in France the professional spirit of the Italian soldiers, and, in the battles of 1568–69, won the post of grand master of the artillery, held by Brissac before him. He took La Rochelle in 1573, commanded in Guienne and in 1577 was made marshal of France, with command in the south against Henry of Navarre. In 1581–83 he commanded the duc d'Anjou's forces in Artois. Having been a loyal friend of Henry III, he became in 1589 the chief commander of the army under Henry IV. The latter owed much to his sagacity at the battles of Arques and Ivry and in the many sieges, but Biron was believed to be prolonging the war for his private advantage. He was killed at the siege of Épernay on July 26, 1592. There is an edition of his correspondence by E. de Barthélemy (1874).

CHARLES DE GONTAUT (1562–1602), the first duc de Biron, son of Armand, won the favour of Henry IV by his courage and enterprise at Arques and Ivry and was made admiral of France and Brittany in 1592 after his father's death. He was relieved of that post and made marshal in 1594 on the recovery of Paris, when he was sent to regain Burgundy; and in 1597 he ended the war in the north by the recapture of Amiens. He was made *duc* et pair in 1598 but was discontented with the king's handling of his government of Burgundy. His mission to Brussels (1598) entangled him in intrigue with Spain. as his duties in Burgundy had with Savoy. He commanded the force which gained Bourg in 1600; but his opponent, Charles Emmanuel I, duke of Savoy, was secretly promising him his daughter in marriage. Henry could not decide to take any real action until 1601, when Biron was known to be working with the malcontents led by the comte d'Auvergne (see ANGOULÊME, CHARLES DE VALOIS. DUC D'). Biron was arrested at Fontainebleau, found guilty of treason in sending the duke of Savoy full particulars of the French army and beheaded in the Bastille on July 31, 1602.

The duchy of Biron was revived in 1723 for Charles's brother's grandson CHARLES ARMAND DE GONTAUT (1663–1756), who had been captured at Oudenaarde (1708) and mas made marshal in 1734. His son and successor LOUIS ANTOINE DE GONTAUT (1700–88) commanded the gardes *françaises* in Paris for many years and was also a marshal. His successor was his nephew ARMAND LOUIS DE GONTAUT (1747–93), socially notorious as duc de Lauzun before inheriting his uncle's duchy (see the *Mémoires* published in 1822; new ed., 1858). Armand Louis had military ambitions. He had raised colonial troops and taken Senegal in 1779; he fought in the American Revolution under the comte de Rochambeau; he put his signature to notes on invading England and other military topics. But he was nephew of the Choiseuls and friend of the duc d'Orléans (Philippe Égalité), and he had no favour at court. Even after 1789 he was overshadowed by La Fayette. His chance came with the war in 1792. From Rochambeau's staff he secretly devised with C. F. Dumouriez a plan which gave him the chief role in Belgium. He marched for Mons with 10.000 men who on April 29 fled from a much smaller force at Quiévrain. He was happy to escape from his own men, and this was his only action. Commanding on the Rhine in July, transferred in 1793 to Italy and sent, after Orléans was arrested, to command in the west, he was never present when there was actual fighting. He had accepted every political change, but after 40 days in this last command he was dismissed on July 11 on denunciation by C. P. H. Ronsin and J. A. Rossignol. Robespierre, attacking Ronsin's party, could not

risk the countercharge of leniency to a former peer, and Biron was guillotined on Dec. 31, 1793. (I. D. E.)

BIRON, ERNST JOHANN (1690–1772), German adventurer who became duke of Courland and for a short time regent of Russia through the favour of the Russian empress Anna, was the grandson of a German groom in the service of Duke Jacob III of Courland. Born at Kalnciems (Latvia) on Nov. 23 (new style; Nov. 13, old style), 1690, he received what little education he had at the academy of Konigsberg, from which he was expelled for riotous conduct. In 1714 he set out to seek his fortune in Russia and unsuccessfully solicited a place at the shabby court of the princess Sophia Charlotte, consort of the tsarevitch Aleksei Petrovich. Returning to Mitau (Jelgava), he succeeded in gaining a footing at the court of Anna Ivanovna, then duchess of Courland, through one of his sisters, who was the mistress of the ruling minister, Petr Mikhailovich Bestuzhev-Ryumin (1664–1743), the lover of the duchess. Around 1727 Biron supplanted him in Anna's favour, and from henceforth to the end of her life his influence over her was paramount. On her elevation to the Russian throne in 1730, Biron, who had in the meantime married Fraulein B. G. Trotta von Treiden, came to Moscow, and honours and riches were heaped upon him. He was made grand chamberlain and a count of the empire and was presented with an estate at Wenden (Cesis). He soon made himself detested by Russians of every class. He was mean, treacherous, rapacious, suspicious and vindictive. On the extinction of the line of Kettler, the estates of Courland, in June 1737, elected him their reigning duke. He was almost as much loathed in Courland as in Russia, but large sums of money speedily convinced the electors. On her deathbed Anna appointed him regent during the minority of Ivan VI.

Biron's regency lasted three weeks. At midnight on Nov. 19–20 (N.S., 8–9, O.S.), 1740, he was seized in his bedroom by his ancient rival, B. C. von Miinnich. The commission appointed to try his case condemned him to death by quartering, but this sentence was commuted to banishment at Pelym in Siberia. In 1742 the empress Elizabeth, who felt indebted to him for benevolent treatment while he was in power, permitted him to return and to settle in Yaroslavl. The former regent re-emerged for a brief moment in 1762 when the philo-German Peter III summoned him to court. Catherine II re-established him (1763) in his duchy, which he bequeathed to his son Peter. He died at Mitau, his capital, on Dec. 29 (N.S.; 18, O.S.), 1772.

See R. N. Bain, ***The Pupils*** of ***Peter the Great*** (1897). (Lo. L.)

BIRR (BIORRA), an urban district and market town in Offaly (formerly King's) county, Republic of Ireland, lies on rising ground beside the Camcor river, 82 mi. W.S.W. of Dublin by road. Pop. (1961) 3,872; area 2.5 sq.mi. Trade is carried on in corn, in timber and in beer; there are shoe and moquette factories. An abbey was founded there by St. Brendan of Birr (d. 573), to whom the parish church is dedicated. The district was not included in the county until the time of James I, when Birr castle, the chief seat of the O'Carrolls, and a considerable area of land were granted by the crown to Sir Lawrence Parsons. A descendant, William Parsons, 3rd earl of Rosse, built the famous reflecting telescope which he housed in the castle and first used in 1845. With it he made many important discoveries in astronomy, including that of spiral nebulae. (*See* ROSSE, WILLIAM PARSONS.) One of his sons was Sir Charles Algernon Parsons (*q.v.*), the inventor of the steam turbine.

BIRRELL, AUGUSTINE (1850–1933), British statesman and man of letters, who as chief secretary for Ireland (1907–16) was held responsible for failure to anticipate the Easter rising in Dublin in 1916, was born at Wavertree, near Liverpool, on Jan. 19, 1850. After graduating from Trinity hall, Cambridge, he was called to the bar in 1875. During the 1880s he became a notable figure in literary circles, published two series of essays entitled *Obiter dicta* (1884 and 1887) and a study, *Charlotte Bronte* (1887). He took silk in 1894 and from 1896 was professor of law at University college, London. In 1889 he had entered the house of commons as a Liberal, and except for the period 1900–06 he remained in parliament until 1918. In 1905 he was made president of the board of education in Sir Henry Campbell-Bannerman's government, but in 1907 was transferred to the chief secretaryship for Ireland. There his greatest success was in the Liberal tradition; a convinced believer in religious freedom, he was responsible for the founding of the Roman Catholic National University of Ireland. However, Birrell was temperamentally unfitted to understand the passionate complexities of Irish affairs and although he was not responsible for major decisions of policy, the day-to-day administration of Irish affairs suffered from his *laissez faire* attitude. In 1916 the Easter rising gave as great a shock to the chief secretary as to the house of commons. Amid general condemnation, tempered by respect for his frank avowal of responsibility, Birrell resigned. He died in London on Nov. 20, 1933.

BIRTH: *see* CHILDBIRTH.

BIRTH CONTROL, although literally encompassing all means of preventing live births, including abortion, in this article is used as synonymous with contraception; *i.e.,* the prevention of conception. Some forms of contraception apparently are of very old origin. In *Medical History of Contraception* (1936), Norman Himes cites evidence of the existence of contraception among the Romans, Greeks and the ancient Egyptians and Asians. The Book of Genesis documents Onan's use of a well-known method in early biblical times (Gen. xxxviii, 8–10).

Despite the antiquity of contraception, the birth control movement is of fairly recent origin. Thomas Robert Malthus (1766–1834), English economist and former curate, in his seven editions of *An Essay on the Principle of Population* (first edition 1798, seventh edition 1872) probably provided much of the incentive for this movement although he virtually ignored the possibility of contraception as a means of population control.

Taking as *postulata* man's sex urge and his need for food, Malthus developed the argument that population tends to increase much faster than subsistence. Possibly without intention of rigid accuracy, he put this in striking form by the statement, "Population, when unchecked, increases in a geometrical ratio. . . Subsistence increases only in an arithmetical ratio." Malthus' basic theory, reaching its full development in the second edition of his *Essay,* contained three main points:

(1) Population is necessarily limited by the means of subsistence.
(2) Population invariably increases where the means of subsistence increase, unless prevented by some very powerful and obvious checks.
(3) These checks . . . are all resolvable into moral restraint, vice, and misery.

Malthus has been criticized on two major scores: he did not foresee the future importance of contraception as a means of population control, and he did not foresee the immense possibilities for increasing agricultural and industrial production through discoveries and technical improvements. His defenders point out, however, that his basic tenets are still relevant to the demographic situations in underdeveloped areas.

Some students have argued that Malthus was unaware of contraception. It is true that there is nothing in his writings that is universally accepted as unequivocal evidence of his awareness of the existence of contraception. Some, however, have marshaled at least presumptive evidence that he was not ignorant about these matters. They think it probable that Malthus did not mention contraception as a means of population control because he did not regard it as being of sufficient or potential importance to merit consideration.

HISTORY OF OPPOSITION

Trials of **Neo-Malthusians.**—Whatever may have been the reason for his failure to mention contraception, Malthus unwittingly gave stimulus and name to the 19th century forerunners of the birth control movement, who were called Neo-Malthusians because they seized upon Malthus' essays as an argument for the spread of knowledge of contraception. In 1822 Francis Place, a London tailor, reform politician and father of 15 children, issued a tract endorsing Malthus' views and advocating the use of contraception among the working classes. *Moral Physiology,* by Robert Dale Owen, son of the British social reformer Robert Owen, published in New York in 1831 and in London in 1832, discussed the needs and some of the existing methods of family limitation. **A**

pamphlet on the same subject, *The Fruits of Philosophy* by Charles Knowlton (*q.v.*) of Boston was published in the United States in 1832.

The Knowlton pamphlet was reprinted and sold in England for over 40 years before there was any interference. However, in 1876 a Bristol publisher mas indicted for selling copies of an edition in which, it was alleged, obscene pictures had been inserted. He was found guilty and sentenced. At this juncture two free-thinkers, Charles Bradlaugh and Mrs. Annie Besant, became interested in the matter and carried out a prearranged sale of the Knowlton pamphlet to provide a test case. The famous Bradlaugh-Besant trial of 1877 terminated in no clear-cut immediate legal victory for either side. The pamphlet was adjudged to be obscene but the defendants finally were acquitted on a technicality in Feb. 1878.

A direct result of the Bradlaugh-Besant trial was a great increase in the sale of the publication concerned. There were several subsequent trials but by and large it cleared the way for the free circulation of birth control literature in England. Furthermore, although it may simply have been coincidence, the long-continued decline in the birth rate in England began about this time.

The Malthusian league, formed in 1877, published the journal the *Malthusian* from 1879 to 1921; in 1922 it was succeeded by the *New Grnerntion*. In 1921 Marie Stopes. a zealous leader and author of several books on contraception, started the first birth control clinic in England.

Although the reported year of its founding varies from 1878 to 1882, a birth control clinic established during this period by Aletta Jacobs in Amsterdam, the Netherlands, is generally recognized as the first one in the world. Neo-Malthusian leagues were established for propaganda purposes in the Netherlands and Germany in the 1880s.

Margaret **Sanger.**—Margaret Sanger was the leader of the birth control movement in the United States. Beginning her career as a trained nurse in the Lower East Side of New York city, she soon saw the relation between frequent pregnancies and maternal and infant mortality. In 1913 Mrs. Sanger went to Europe to consult with leaders and workers in the fields of maternal health and contraception. Returning to the United States in 1914 she and some of her friends founded the National Birth Control league From the outset, the avowed purpose of the league was to sponsor the publication of *Woman Rebel,* a periodical devoted to woman's right to plan the size of her family. The first issue of *Woman Rebel* appeared in March 1914. It was barred from the mails. and so were the four following issues. In Aug. 1914 Margaret Sanger was indicted under the federal statutes on obscenity but the case finally mas dismissed in 1916. She opened the first birth control clinic in the United States Oct. 16. 1916. That same year she was arrested for "maintaining a public nuisance" and in 1917 served 30 days in the workhouse. In 1929 her 15th street clinic was raided and the clinic records were confiscated. However, at a subsequent hearing the case was dismissed when prominent doctors and liberals in New York city came to the defense of Mrs. Sanger and her colleagues.

The work begun by Mrs. Sanger is carried on by the Planned Parenthood Federation of America, a national organization composed of state and local affiliates. The International Planned Parenthood federation is composed of national affiliates and holds biennial meetings.

Legal Opposition.— The Comstock act, enacted in 1873. was the first federal law on contraception in the United States. Named for its chief protagonist, Anthony Comstock (1844–1915), founder of the New York Society for the Suppression of Vice (1873). the law was designed mainly to ban the importation. mailing and dissemination in interstate commerce of obscene and pornographic literature and materials: contraceptive literature and devices mere specifically included in the category of obscene materials.

The federal laws are an outgrowth of the Comstock act. However, as interpreted in federal courts, the law is not regarded as broken unless there is intent to use the materials unlawfully and immorally. It is considered legal to ship contraceptives to authorized persons such as physicians and druggists. State laws against contraception have in most cases followed the federal pattern, not only with respect to their original provisions but also with respect to the changes induced by interpretation in the courts.

Approximately three-fourths of the states in the 1960s had laws prohibiting or restricting the giving of information on contraception, or on advertising, display or sale of contraceptive devices. In most of these cases the laws explicitly exempt physicians or druggists, and some explicitly exempt medical schools. medical books and professional journals. Except in two of the remaining states these exemptions probably would be implied even if not expressly stated. The two exceptions are Massachusetts and Connecticut; in these states physicians are prohibited from giving contraceptive advice to their patients for any reason whatever. The U.S. supreme court declined on June 19, 1961, to rule on the constitutionality of the Connecticut ban on contraception.

Medical Opposition.— As might be expected, individual and local attitudes of doctors toward contraception frequently are related to the doctor's own religion, age and cultural environment. Physicians who are themselves Roman Catholic are naturally more likely to espouse the Catholic viewpoint on contraception than are non-Catholics. Within any religious group the older physicians perhaps tend to be more conservative than the younger physicians. Fear of censure may influence local policies regarding contraception. Thus in July 1958 the hospital commissioner of New York city forbade a doctor in a city hospital from prescribing a contraceptive for a Protestant patient even though the doctor believed that another pregnancy would endanger the patient's life. After much protest by various groups the board of hospitals reversed the ban by an 8–2 vote.

In the United States medical opposition has lessened considerably since 1900. This has been caused in part by successes of the birth control movement on the legal front. Opinion polls indicate that most physicians approve of contraception although many may not be very enthusiastic about it. Doubtless in many cases in the past doctors have been uncertain as to the status of the laws. Much of the uncertainty was removed when a decision was handed down by the U.S circuit court of appeals on Dec. 7, 1936. approving the importation of contraceptives by one whose purpose was scientific and legitimate and affirming the right of physicians to prescribe contraceptives "for the purpose of saving life or promoting the well-being of their patients." In 1937 the house of delegates of the American Medical association went on record as acknowledging contraception as a proper part of preventive medicine and the American Medical association's committee to study contraceptive practices reported that there appeared to be no law to prevent physicians from furnishing dispensary patients with any information that lawfully might be furnished to any other patients. "In all cases," the report stated, "the legal justification is the medical need of the patient."

Contraception has been incorporated as an integral part of the public health programs in several states, particularly in the south. The value of contraception for health and economic needs has been stated by the American Public Health association in the *American Journal* of *Public Health* (Dec. 1959):

> The American Public Health Association, retaining cognizance of the principle of religious freedom by all religious groups as expressed, for example, in the First Amendment of the Constitution of the United States, believes therefore that:
>
> 1. Public health organizations at all levels of government should give increased attention to the impact of population change on health.
> 2. Scientific research should be greatly expanded on (a) all aspects of human fertility; and (b) the interplay of biological, psychological, and socioeconomic factors influencing population change.
> 3. Public and private programs concerned with population growth and family size should be integral parts of the health program and should include medical advice and services which are acceptable to the individuals concerned.
> 4. Full freedom should be extended to all population groups for the selection and use of such methods for the regulation of family size as are consistent with the creeds and mores of the individuals concerned.
>
> (American Public Health Association, *American Journal* of *Public Health,* vol. xlix, no. 12 [Dec. 1959], p. 1704.)

Religious Opposition.— On religious grounds, the Roman Catholic Church in particular has opposed the use of contraception, giving its official approval only to the so-called rhythm method of

abstinence during periods of assumed female fertility. The church has condemned the practice of artificial birth control as contrary to the natural law because it is a frustration of the primary end of the sexual act, which is procreation, and therefore is unnatural, contrary to right reason, conduct unbecoming rational beings, and so morally wrong.

Sanction of the use by Roman Catholics of the rhythm method in child spacing and family limitation was given in the encyclical on marriage (*Casti connubii)* by Pope Pius XI in 1930:

. . . . Nor are those considered as acting against nature who in the married state use their right in the proper manner, although on account of natural reasons either of time or of certain defects new life cannot be brought forth.

The rhythm method is expounded in *The Rhythm* of *Stzrility and Fertility in Women* by Leo J. Latz, M.D., first published in 1932 with ecclesiastical approbation.

Many Protestant ministers and laymen may be opposed to contraception, but there is no common doctrine on contraception within any of the Protestant denominations corresponding to that within the Roman Catholic Church. Similarly, none of the other religions of the world opposes contraception in a manner comparable with that of the opposition of the Roman Catholic Church.

The statement of the Roman Catholic bishops of the United States in Nov. 1959 reaffirmed the Roman Catholic stand against artificial contraception and decried efforts to introduce such practices in the underdeveloped areas of the world. The impact of the church on the fertility behaviour of the various predominantly Roman Catholic countries and areas is by no means uniform. Ireland apparently hews close to the line of church doctrine on contraception and the Irish have resorted to postponement of marriage or permanent bachelorhood and spinsterhood to maintain a low birth rate. Because of low proportions of the population married at young ages the general fertility rate is very low. However, the fertility rate of Irish married women is relatively high as compared with that of married women of comparable age in other countries.

In the heavily Catholic Canadian province of Quebec, both general and marital fertility rates are relatively high because marriages are young and fertility is largely uncontrolled.

In France there apparently has long been a gap between Catholic doctrine and practice regarding contraception. For many years France exhibited conspicuously low birth rates and offered the pre-World War II example of a country with fewer births than deaths.

BIRTH CONTROL AND POPULATION CHANGES

To the married couple, birth control is a means of preventing unwanted pregnancies and of spacing births in the interest of the health of the mother and children and of the general welfare of the family. In an impersonal demographic context, birth control is a means of keeping the birth rate in balance with a low death rate.

In 1650 the population of the world was about 500,000,000. By the second half of the 20th century it was about 2,700,000,000,a fivefold increase in three centuries. The increase was especially large for peoples of European origin. In 1650 Europe had about 100,000,000 people or about one-fifth of the world's population. In 1950 the peoples of European origin, in Europe and elsewhere, probably numbered about 800,000,000 or about one-third of the uorld's population. Thus the increase in the population for peoples of European origin was about eightfold and that for peoples of non-European origin only about threefold.

The European peoples increased more than the others during this time because they had the first benefits of the commercial, agricultural and industrial revolutions.

The availability of new lands in the western hemisphere and Oceania provided both a stimulus and safety valve for population growth in Europe. Population growth was especially rapid in the new world where the abundance of land and the relatively large proportion of young men and women stimulated rapid increase of population. The British colonies in the new world furnished to Benjamin Franklin and Thomas Jefferson, as well as to Malthus, examples of areas in which the human population doubled in a generation.

Precise data on early trends in fertility and mortality are lacking but available materials suggest that in England and Wales both birth and death rates were about 35 per 1,000 population around 1650. Whereas death rates began declining shortly thereafter, the birth rates remained at this level until the time of the Bradlaugh-Besant trial in 1877–78. Close interpretation of the data is not warranted. but most students agree that the lag in the decline of the birth rate behind that of the death rate accounted for the great increase of European peoples.

Demographic transition is the term sometimes given to the change from high to low birth and death rates. According to this concept the different countries of the world are in various stages of this transition, or "vital revolution." The modern countries of the west have completed the transition, in that both birth and death rates have declined. Some of these countries, especially the United States and Canada, exhibited marked increases in birth rates after World War II but there is no indication of any return to the large families common at the beginning of the 20th century.

At the other extreme are the countries that were just beginning the transition in the second half of the 20th century. These were largely in the underdeveloped areas of Asia and Africa and they included about one-half of the world's population. Until the end of World War II the high birth rates of these areas were offset by high death rates. However, since World War II the death rates have been reduced with amazing rapidity with the help of new drugs and insecticides. In the meantime, the birth rates have remained high and many of the countries are exhibiting rapid growth. There are some who argue the necessity of encouraging the inhabitants of these countries to find ways and means of reducing their fertility rates in order to facilitate their efforts at economic development and the raising of their levels of living. Others take a different viewpoint for religious, political or other reasons.

Contraception and Fertility.— Prior to the studies of contraception in the late 1920s and early 1930s, there were two schools of thought regarding the reasons for the long-time declines in fertility and the relatively low fertility of the "upper classes" in cities. On the one hand there was the biological interpretation, represented by Oswald Spengler in Germany, Corrado Gini in Italy and Raymond Pearl in the United States. This interpretation attributed the general decline in fertility and the existing differentials in fertility, which were correlated with urban-rural and socioeconomic status, to the relatively low reproductive capacity of urban people of higher socioeconomic status. The growth of cities was accompanied by an increasing proportion of urban white-collar workers in the total population and hence, according to this view, by the decline in the general level of fertility.

The other school of thought held that increased use of contraception was the cause of the decline in fertility rates and that variations in the prevalence and effectiveness of contraception underlay the group differences in fertility.

Subsequent studies of the prevalence and effectiveness of contraception, including those by Pearl himself, confirmed the major importance of contraception. Those studies, which have related to different areas and different population groups, indicate that when the factor of contraceptive practice is held constant the differentials in fertility by socioeconomic status tend to disappear. By indicating very high pregnancy rates among urban groups of high socioeconomic status during periods of noncontraceptive practice, some of the studies also served to cast doubt on any theory that the long-standing decline in birth rates connoted declines in reproductive power. The resurgence in the birth rate itself after World War II suggests that there has been no considerable loss in reproductive power. These increases have been proportionately largest among urban white-collar workers.

Some students have held that in the western countries contraception has tended to originate in the upper socioeconomic groups of cities and to spread outward to rural regions and downward to groups of lower socioeconomic status. If this is the process. differential fertility itself may be a transitional phenomenon which will disappear after the spread of contraception has run its course.

There has indeed been a considerable diminution of class differences in fertility in the United States and other western coun-

tries. During the 20 to 30 years prior to World War II, some trend toward equalization of fertility rates appeared to arise from the more rapid decline in the fertility of the manual workers than of the white-collar workers. During the 1940–50 decade there was a marked narrowing of class differences in fertility in the context of general increases in the level of fertility. This came about because the increases in fertility tended to be proportionately larger for the "upper" than for the "lower" socioeconomic groups. The trends suggest that as family planning becomes more common, class differences in fertility may become less pronounced. However, under conditions of fairly universal planning of fertility greater sensitivity of births to business conditions might occur and hence more short-time fluctuations in fertility levels.

Prevalence of **Contraception.**—A study in 1955 of a representative cross section of approximately 2,700 white married women 18–39 years old in the United States indicated a wide prevalence of knowledge of, and some experience with, contraception. Many of those who avowed no previous attempts at contraception also indicated some form of impaired fecundity: Among the fecund couples (husband and wife physiologically capable of participating in reproduction) 83% reported some past conscious effort at family limitation. By religion of the couple, the percentages were 96% for Jews, 88% for Protestants and 71% for Roman Catholics. By education of the wife the percentages ranged from 68% for those of grade school status to 91% for those of college attainment.

However, in only a minority of the families (29%) was the fertility-planning status classified as "completely planned" in that the couples had no pregnancies except those that occurred when contraception was deliberately discontinued or omitted in order to conceive.

By religion, the proportion of completely planned families was highest for Jews (57%), lowest for Roman Catholics (16%) and intermediate for Protestants (32%). Despite the differences in proportion of completely planned families it should be emphasized that the great majority of the fecund couples of each religion has used or will use contraception.

Contraception in Communist Countries.— A succinct summary of the Communist policy on contraception was presented by Nikita S. Khrushchev in a Radio Moscow broadcast to southeast Asia in Jan. 1955, in which he said the theory of overpopulation is a "cannibalistic" theory invented by bourgeois ideology to cut down the birth rate. In contrast, he said, under socialism a rise in the birth rate is regarded not only as a means of increasing the supply of labour but as essential to the growth of the socialist state.

However, there is much variation among the different Communist countries with respect to actual legislation and practice regarding contraception. The U.S.S.R. has gone through several alternating phases with respect to laws on abortion. Some of its legislation has been intended to discourage high birth rates and some has been intended to encourage them.

Communist China began its existence with a doctrinal opposition to contraception, swung to advocacy of contraception during 1955–57 and later returned to opposition. Even during 1955–57 the attack on Malthus continued; the argument for contraception was that of protecting the health of mothers and children.

THE POPULATION EXPLOSION

During the years since World War II there has been increasing public discussion of the dangers of a "population explosion." Attention has already been given to the fact that for three centuries following 1650 the European peoples increased at a higher rate than others. Growth doubtless will be heavier for the peoples of non-European origin, especially those in Asia and Africa, in the second half of the 20th century. In the past population growth in these countries has been held in check by high death rates. Since World War II, however, the death rates in most of the underdeveloped areas have declined sharply following the use of new drugs and insecticides. Birth rates in most of these have remained high and populations have increased greatly. Furthermore, there are no new continents to help absorb the increase as was the case when Europe had its period of rapid population growth.

There are various interpretations regarding the implications of this situation. Some are very pessimistic about the outlook for underdeveloped areas. The two horns of the dilemma that they see are (1) the difficulty of introducing desires for family limitation in areas in which high value is placed on the large family and (2) the possibility that technical assistance programs will be more difficult or even self-defeating unless declines in death rates are accompanied by declines in birth rates. Continuing population explosions in these areas may mean that the capital needed for development will have to be spent for more food, rather than for schools, roads, dwellings and factories.

Some groups are optimistic. The Marxists hold that with proper political organization increases in production will keep ahead of increases in population. Others admit the seriousness of the problem but maintain hope that production can somehow keep ahead of population growth or that modernization will somehow induce a lowering of fertility levels. It is true that both Japan and Puerto Rico have demonstrated the length to which people may go to control family size when they are sufficiently motivated. Japan's birth rate has declined sharply since 1950, largely by the means of abortion. Puerto Rico has had a much smaller decrease in birth rate than Japan but has managed to minimize population growth partly by migration to the U.S. mainland, partly by sterilization and partly by contraception. In both areas, and also in many larger and more agrarian countries there have been surges of interest in national population trends and in the development of programs of family planning. These stirrings of national interest in the problem may provide some hope to those who believe that the underdeveloped areas have a fighting chance to work out their demographic and family planning problems if these are approached in the context of efforts at improvement in health, education, employment opportunities and levels of living.

BIRTHMARK, a circumscribed new growth on the skin, usually of congenital origin. The scientific term is nevus. It may be present at birth or appear later in life. The most common site of appearance is the face. Birthmarks may be composed of various tissues or combinations of tissues. The more common types are the vascular ones and the pigmented nevi (moles). (For a discussion of pigmented nevi see NAEVUS.)

The vascular birthmarks, which are caused by enlarged small blood vessels or lymph vessels, may be flat, nonelevated, port wine-coloured marks. These appear frequently on the face, where they may extend to the mid-line, or they may involve an extremity or one-half of the body. Such marks on the face may be associated with vascular nevi of the meninges or with other intracranial involvement which through increase of cerebral pressure may produce convulsions or paralyses. Vascular birthmarks on an extremity, especially a lower extremity, may be accompanied by enlargement of the extremity so that it becomes longer and larger than the unaffected leg.

Other vascular birthmarks are elevated above the surface of the skin. These have a tendency to grow during early life and then spontaneously decrease in size or completely disappear. Some, however, do not follow this course and become very large, ulcerated and cause other complications.

Birthmarks composed of a mixture of nerve, fat and connective tissue may be disfiguring. Pendulous overgrowths of these birthmarks may produce unsightly enlargements of the affected parts or may be associated with other congenital defects. (G. C. AN.)

BIRTH RATE, as applied to the human species, is the ratio between (1) the number of babies born alive in a given population during a year and (2) the average number of persons in that population during the year (usually taken as the number living at the mid-point of the year).

Crude Birth Rate.—When the term "birth rate" is used without qualifying adjectives it usually refers to the crude birth rate—the number of babies born alive per 1,000 persons in the total population in a given year—which can be computed for more areas or groups of people than can the more refined rates mentioned below. Crude birth rates for most countries of the world have been published annually by the United Nations in the *Demographic Yearbook* since 1948. Rates for selected countries are shown in Table I. Before making comparisons it is important to read the footnotes indicating whether the data are relatively complete, are affected by irregularities or incomplete coverage, or are not rated. Many births go unrecorded in some of the countries with rates classified under incomplete coverage or not rated and the real rate is much higher than that shown. Among the countries with relatively complete data those with high birth rates (40 or over) are in Latin America or Asia, and those with low rates (less than 20) are in Europe. The crude birth rate of a country which takes a reliable census but does not register births (or fails to record many babies) can be estimated from the number of young children counted in the census, if allowance is made for those dying before the census date.

Trends.—In most of the countries that were economically well developed by the second half of the 20th century the crude birth rate had decreased during the preceding 50 to 100 years (or more) although in some the rates of the 1950s exceeded those of the 1930s. In the United States the rate (adjusted for incomplete registration) decreased fairly steadily from an estimated 54 to 60 per 1,000 in 1800 to a low of 18.4 in 1936, but was between 24 and 27 in each year between 1946 and 1961. A major decline began in France about 1800; in Sweden about 1860; in Ireland, England and Wales about 1870; in Italy about 1890; and in Japan about 1920. (See Table II.)

Effect of War on Birth Rate.—In most of the countries which were deeply involved in World War I the crude birth rate was much loner during the war than before or after. (See Table II.) By 1925–29, however, in most cases it was close to the value that would be expected from a continuation of the prewar downward trend.

Changes associated with World War II were more variable, depending largely on differences in the country's active participation in the fighting, and on the extent of the prewar decline of the birth rate. The birth rate in most countries was higher in the postwar than wartime years, but declined during the 1950s.

Causes of Trends.—In most of the countries with a long-time downward trend the chief cause appears to have been the desire of an increasing proportion of persons to restrict the number of their children so as to improve the living conditions of the family. The most commonly used means of implementing this desire was some type of contraceptive practice (including rhythm or periodic continence). (See BIRTH CONTROL.) Other means included delayed marriage (common in Ireland) and abortion (common in Japan after World War II). The scanty evidence available indicates on the whole that there was not a decrease in fecundity—the physiological ability of couples to have children—but some decline may

have taken place in certain groups. (See FERTILITY AND FECUNDITY; STERILITY.)

The much higher crude birth rates in the United States during 1946–56 than 1930–39 occurred mainly because more women married and started childbearing at younger ages. Studies in later years showed only a small increase in the average number of children among couples having at least one child, but a somewhat larger increase appeared likely to occur. Less was known about the reasons why some other countries had higher birth rates during 1945–56 than during preceding years.

Birth Rates by Age and Marital Status of Mother and Birth Order of Child.—The crude birth rate tends to be high if women aged 17 to 35 make up a large proportion of a population and to be still higher if a large proportion of these women are married. Because such proportions vary from one country to another, and within many countries from one decade to another, crude rates are not precise enough for the accurate measurement of differentials and trends in human fertility. The more specific birth rates which are commonly used are: (1) the general fertility rate, which relates the total number of births to the number of women of reproductive age (ages 10–49 or 15–44 are commonly used); (2) rates like the foregoing except for births of specified order (*i.e.*, first births, second births, etc.); and (3) age-specific rates, which relate the number of births of the women of a given age at childbirth (*e.g.*, 20–24) to the number of women of that age in the population. These rates are occasionally restricted to married women.

The age-specific rate for all women (*i.e.*, single and ever married) usually rises with age to a maximum in the 20s and then declines. (See Table III.) The rise reflects the increasing proportion of women married, and the later decline is due chiefly to measures restricting family size and to the effect of approaching middle age on reproductive capacity. The rates at ages 15–19 and 20–24 are relatively high in the United States because more women marry at younger ages. The age-specific rate for married women usually is highest at ages 15 and 16 (*i.e.*, the youngest ages at which marriage occurs except in countries which permit child marriage), premarital pregnancy being an important factor.

The higher crude birth rate in the United States during 1946–55 as compared with that during 1930–39 reflected mainly an increase in the age-specific rates for women under 35, and in the rates for second, third and fourth births. (See Tables III and IV.) The importance of first and second births in the economically developed countries is illustrated in Table IV, where more than half of the rate for all births comes from first and second births in each country except in Chile.

Birth Rates for Cohorts of Women.—Birth rates for the women born in given years (birth cohorts) or for the women married in given years (marriage cohorts) are available for a few countries. They have the great advantage of describing the fertility of actual groups of women as they proceed through life. In the United States the number of births per 1,000 women living to age 47 (*i.e.*, the cumulative birth rate by age 47) decreased from

TABLE IV.—*Birth Rates per 1,000 Women Aged 10–49, by Birth Order of Child, in Selected Countries*

Country	Year	All births	Birth order				
			First	Second	Third	Fourth and fifth	Sixth and higher
United States*	1936–40	59.5	21.8	14.0	8.1	8.1	7.5
	1941–45	68.7	25.3	17.9	9.9	8.8	6.8
	1946–50	83.2	30.1	23.7	12.7	10.1	6.6
	1951–55	89.0	26.0	25.0	16.8	14.0	7.2
	1956–57	94.3	25.9	24.6	18.4	16.9	8.5
Chile	1952	100.8	28.1	19.6	14.7	18.6	19.7
England and Wales	1953	51.6	20.3	15.6	8.0	5.6	2.1
France†	1953	65.0	19.9	17.4	11.8	10.7	5.0
Netherlands	1953	76.8	22.1	18.7	12.7	13.7	9.5
Yugoslavia	1954	92.3	28.9	23.7	15.1	14.6	9.8
Italy†	1951	57.4	19.6	14.6	8.4	8.2	6.1
Japan	1953	69.0	19.4	17.6	14.7	12.2	5.0

*Adjusted to allow for incomplete registration; birth rates for groups of years are the averages for single years. †Excludes illegitimate live births (and in France infants dying before their birth is registered).

about 3,900 for the women in the cohort of 1875 (born between July 1, 1874 and June 30, 1875) to 2,270 as of age 47 for those in the cohort of 1910. This illustrates the great decline that took place in the average number of children per family in the United States. An increase in family size was under way during the 1950s, however, for the women in the cohort of 1931 who were about 29 years old on Jan. 1, 1960, already had a cumulative birth rate considerably larger than that of the 1910 cohort by age 47. The tendency for more U.S. women to marry and start childbearing at younger ages is illustrated by the large rise in the cumulative birth rate by age 25 from 856 per 1,000 women for the cohort of 1915 to 1,704 for the cohort of 1935.

Socioeconomic Differentials.—Information about the birth rates of women belonging to different socioeconomic groups is available for some of the countries which are more developed economically. As a rule the relationship is inverse—the higher the socioeconomic status the lower the birth rate. For example, the 1959 United States vital statistics report shows that among white women who were 15–44 years old and were (or had been) married, the cumulative birth rate was about 1,780 for college graduates, 1,965 for high school graduates and 3,224 for those with less than eight years of schooling. Similarly, among white women married once and living with husband, the cumulative birth rate by ages 15–44 was about 1,996 for those with husbands in professional. technical and kindred occupations; 2,333 for those with husbands classified as craftsmen and foremen; and 2,649 for those with husbands classified as labourers (excluding mine and farm labourers). The few studies of causes that have been made indicate that the socioeconomic differentials in birth rates have occurred chiefly as a result of differences in the extent and effectiveness of efforts to control family size rather than differences in the number of children desired. In some countries the tendency, beginning in the 1940s, was for differences in birth rates to become smaller as control measures became widespread.

Religious Differentials.—From a world standpoint the size of the birth rates of the major religious groups depends much more on the stage of economic and social development reached by the members of the group than on the religious teachings themselves. In most western countries with important numbers of Roman Catholic and Protestant couples the birth rate of the former is somewhat higher than that of the latter. In the United States a study of a representative sample of white married couples showed that among wives the cumulative birth rate of 1959 (*i.e.*, up to ages 44) was 2,282 per 1,000 for Catholic wives. 2,220 for Protestant wives and 1,749 for Jewish wives. The small difference between the cumulative birth rates of Catholic and Protestant wives is associated with a somewhat older age at marriage and higher proportion in urban areas for Catholic women than Protestant women. Other studies show substantially higher birth rates among Mormons, and much higher rates among a few small groups in rural areas; *e.g.*, the Hutterites.

BIRTHSTONES. From ancient times supernatural powers have been attributed by astrologers to inanimate objects; among these gem stones were early assigned certain occult powers. In Greek and Roman times, the force was thought to be inherent in the stones. Medieval astrology related the effectiveness to the birth date of the individual and different stones were considered propitious depending upon the planetary configuration of the individual's horoscope. The stones now associated with each month have only slight relationship to the ancient beliefs for the list is tempered by availability and cost. Before mineralogy had progressed to the point of chemical analysis. colour was of greater importance than some of the other physical properties, and little distinction was made between emerald and chrysoprase. or topaz and citrine quartz. When it came to healing the eyesight or warding off evil spirits, both were equally effective. Even the names used in ancient times do not necessarily refer to the stones that go by those names in the 20th century; the sapphire of the Bible is much more likely to have been lapis lazuli than what is now known as sapphire. and "adamas" (diamond) was probably white sapphire or white topaz.

With the uncertainty of name and limited appeal of some of the stones of the older selections that were popularly and commercially associated with the different months, it is natural that, from time to time. changes have been made in the accepted list. Originally the stones were considered to be those of the breastplate of the Jewish high priest, but in actual usage the parallelism is not close. In the 20th century the list was supplemented with a series of synthetic stones which were recommended as the equivalents of the rarer. less attractive or less durable of the natural stones. The natural stone list was also expanded to make it more acceptable to both sexes. The list that follows gives the traditional stones and modern variations.

Month	Traditional gem stone	20th century expansion	Synthetic supplement: trade name	Material of synthetic stone
January	Garnet		Garnet	Dark red synthetic corundum
February	Amethyst		Amethyst	Purple synthetic corundum
March	Bloodstone	Aquamarine	Aquamarine	Light blue synthetic spinel
April	Diamond		White sapphire	Colourless synthetic spinel or corundum
May	Emerald		Emerald	Cultured emerald or synthetic green spinel
June	Pearl	Alexandrite	Cultured pearl, Alexandrite	Changeable synthetic corundum (synthetic spinel is rare)
July	Ruby		Ruby	Red synthetic corundum
August	Sardonyx	Peridot	Peridot	Green synthetic spinel
September	Sapphire		Sapphire	Blue synthetic spinel or corundum
October	Opal	Tourmaline (pink or green)	Rozircon	Pink synthetic corundum or spinel
November	Topaz (precious)	Topaz quartz (citrine)	Topaz	Yellow synthetic corundum
December	Turquoise	Zircon	Zircon	Medium blue synthetic spinel

BIRUNI, AL- (ABU-AL-RAYHAN MOHAMMED IBN AHMAD AL-BIRUNI) (973–1048), Arab scholar and scientist, one of the most learned men of his age and an outstanding intellectual figure, was born in Sept. 973 of Persian parentage at Khwarizm (Khiva, in the Uzbek Soviet Socialist Republic, U.S.S.R.). Possessing a profound and original mind of encyclopaedic scope, he was conversant with Turkish, Persian. Sanskrit, Hebrew and Syriac in addition to the Arabic in which he wrote, and applied his talents in many fields of knowledge, excelling particularly in astronomy, mathematics, chronology, physics, medicine and history. He corresponded with the great philosopher Ibn Sina (Avicenna). Some time after 1017 he went to India and made a comprehensive study of its culture. Later, he settled at Ghazni in Afghanistan, where he died on Dec. 13, 1048. In religion he was a Shi'ite, but with tendencies to agnosticism. His most famous works are *al-Athar al-Baqiya* ("Chronology of Ancient Nations"); *Tafhim* ("Elements of Astrology"); *al-Qanun al-Mas'udi* ("The Mas'udi Canon"), a major work on astronomy, which he dedicated to Sultan Mas'ud of Ghazni; *Tarikh al-Hind* ("A History of India"); and *Kitab al-Saydala,* a *materia medica.* In his astronomical works he discussed with approval the theory of the earth's rotation on its axis and made accurate calculations of latitude and longitude. In physics, he explained natural springs by the laws of hydrostatics, and determined with a remarkable degree of accuracy the specific weight of 18 precious stones and metals, while in geography he advanced the daring view that the valley of the Indus had once been a sea basin.

BISAYAN, the name of a people composing 43% of the Christian population of the Philippines and inhabiting the archipelago's central islands, south of Luzon, north of Mindanao. The three major Bisayan cultural-linguistic groups, in order of size, are Cebuano (*q.v.*) of Cebu, Siquijor, Bohol, eastern Negros, western Leyte, southern Masbate and northern Mindanao; Hiligaynon (*q.v.*) of Panay, western Negros, southern Mindoro, Tablas, Romblon, Sibuyan, Guimaras and northwestern Masbate; and Samaran (*q.v.*) of Samar, eastern Leyte and Biliran. Although divided by linguistic and cultural differences of varying degrees, the Bisayans form a basically homogeneous group.

Living representatives of the first settlers of the Bisayas, the Negritos ("little Negroes") still live in the hilly or mountainous regidns of Negros and Panay. Although Bisayan prehistory is inadequately known, evidence indicates Neolithic habitation of the region. In prehistoric times peoples from China, carriers of Neolithic and Bronze Age cultures, moved southward through Luzon into the Bisayas. Archaeological sites of these cultures exist in Panay, Negros and Leyte. One of the oldest-known Philippine manuscripts (*Maragtas*) gives a circumstantial 13th-century account of the arrival at Panay from the Indonesian Buddhistic empire of Srivijaya of a group of Bornean datus ("chiefs") and their followers. In this manner, and also by earlier Indian traders, Vedic, Brahmanistic and Buddhistic elements diffused to the Bisayas and are still evident in their languages, folklore and art.

When Magellan's fleet arrived at Cebu in 1521, according to Pigafetta, the port had a thriving Asian trade. The Bisayans possessed their own system of weights and measurements. calendar and method of writing. They had borrowed selectively and integrated in a unique fashion elements from the great Asian civilizations.

Most Bisayans, tilling the soil and fishing the seas, represent the traditional Bisayan way of life. Located along roads. rivers, on plantations or in the more isolated interiors, the typical Bisayan village consists of two- and three-room bamboo and wooden pile dwellings, thatched with palm. The diet is mainly rice and fish, with some vegetables and fruits. In Cebu and eastern Negros, however, ground cornmeal replaces rice as the staple cereal. Social events centre around baptisms, marriages, funerals, school programs, annual fiestas and the Catholic religious calendar.

A Bisayan elite lives in a highly literate western oriented urban society. The two major Bisayan urban centres are Cebu city (259,194), situated in the Philippines' most densely populated island. and Iloilo city (150,976) in Panay. The most noteworthy Bisayan universities are Silliman (Dumaguete, Negros) and San Carlos (Cebu). Two presidents, Sergio Osmeña (Cebu) of the

commonwealth and Carlos Garcia (Bohol) of the republic created in 1946, have come from the Bisayas. See also BISAYAN LANGUAGE. (D. V. H.)

BISAYAN LANGUAGE, a language of the Philippines belonging to the Malayopolynesian family, is very closely related to Tagalog and Bikol. Bisayan is by far the Philippine language with the largest number of native speakers (8,500,000). These are distributed over the central islands of the Philippines (those south of Luzon and Mindoro and north of Mindanao) and the northern and western coasts of Mindanao.

There are a number of distinguishable dialects. The three major dialects are Cebuano (also called Sugbuhanon; 4,700,000 speakers), Hiligaynon (also called Panayan or Ilongo; 2,300,000 speakers) and Samar-Leyte (also called Samaran; about 1,200,000 speakers). (See also BISAYAN.) There are two minor dialects: Aklan, spoken by about 200,000 in northwestern Panay, and Hantik, spoken by about 2,000 people in small groups on the western coast of Panay.

There is little tendency among Filipinos to learn Bisayan as a second language. Although knowledge of the national language, Tagalog, is increasing, Bisayan continues to be used increasingly in books, periodicals, movies and radio broadcasts. In these, Cebuano is the dialect most used. (I. DN.)

BISCAY (VIZCAYA), a Basque province of northern Spain. Pop. (1960 est.) 630,434; area 2,210 sq.km. (853 sq.mi.); density of population 285 per square kilometre (739 per square mile). Originally one of the tribal territories of the Vascons, it was vested in the crown of Castile and León in 1379; however, the juridical peculiarities of each Basque province, *e.g.,* the "lordship" of Vizcaya and the "county" of Guipúzcoa, indicate the difficulties the central government has always had in ruling these fiercely independent peoples. Privileges toward some form of regional autonomy were granted to the Basque provinces (Vascongadas), notably in the *Concierto Económico* of 1925 signed with the national exchequer. After the Nationalist victory of 1937, however, this agreement was canceled and dreams of a Basque state Euskadi were pushed further into the background. The situation is complicated by the labour force in the industrial centre of Bilbao, whose immigrant population is not Basque-speaking. Indeed, western Vizcaya can no longer be considered truly Basque; a distinctive dialect of Euskera is only spoken now in the eastern districts. (See also BASQUE.)

The confused pattern of mountainous relief, formerly thickly forested and aloof from the interior highways, helped to keep the Vascongadas a distinct ethnic unit. Like Guipúzcoa, Vizcaya lies north of the main watershed and is contained by the drainage basins of the Nervión and Cadagua rivers and centred on the ria (inlet) of Bilbao. It has a corrugated pattern of relief, trending west-northwest–east-southeast in two main mountain alignments. Near the coast is the first range, Monte Aoiz (3,411 ft.), overlooking the border with Guipúzcoa in the Deva valley and extending in headlands seaward from Monte Sollube (2,244 ft.). The second and more extensive range forms an inland arc, connecting near the Peña de Aitzgorri (5,082 ft.) with the Navarrese mountains of Aralat and then swinging northeastward as far as the lower massifs of the Encartaciones. Although it forms the main watershed, it is broken by transverse corridors such as the Valle de Aramoyona and the upper valley of the Nervión, to provide cols of strategic importance to north-south lines of communication. These separate this dissected anticline into a series of broken calcareous cuestas or ridges. Between the coastal and interior ranges the Nervión valley follows a broad synclinal depression, the axis of the province. To the west the transverse drainage flowing into the Nervión near Bilbao presents a more open country with no clear frontier to the neighbouring province of Santander. Consequently Biscay has been affected by Castilian influences such as exposure to the hot, dry air streams of the Meseta in summer, while the mountain trends favour less generous rainfall in the valleys than that of'neighbouring Guipuzcoa. Island stands of evergreen forests therefore mingle with the Atlantic flora of deciduous oaks. Cereal lands and vineyards are there more important than farther east though the pastoral economy was still dominant in the second half of the 20th century. More than three-fourths of the province was under rough pasture or forests, with about 30% cultivated. Maize occupied about one-third of the cropped area and apple orchards were also important. Farms are scattered in isolated *caseríos,* although in the western valleys of Carranza and Lanestosa the Castilian influence of hamlets is clear.

Bilbao (*q.v.*), nine miles from the head of its estuary, is the great industrial centre of the province. A population of more than 400.000 is concentrated along the banks of the Nervión embracing Bilbao and its industrial suburbs including Baracaldo (*q.v.*). Bilbao alone has about 600 factories, mostly engaged in metallurgic and some chemical industries. At its port are important shipyards, and about 35% of Spanish shipping is registered there. Biscay is the most important iron ore producer of Spain. It has been calculated that between 1876 and mid-20th century 212,000,000 tons of iron ore were extracted, approximately 80% being exported to the United Kingdom. An increasing proportion of its diminishing reserves thereafter was extracted to supply its own heavy metallurgic industries.

There are ten fishing ports of some importance along the coast, the chief being Bermeo (12,460) and Ondárroa (6.389). The industry was modernized with fleets of steam trawlers and coastal smacks.

(J. M. HO.)

BISCAY, BAY OF (Sp. GOLFO DE VIZCAYA of which Biscay is a corrupt form; Fr. GOLFE DE GASCOGNE), an extension of the North Atlantic ocean, is bounded on the east and northeast by France and on the south by Spain. It has a maximum depth of 15.525 ft. a little south of its centre. The continental shelf is 100 mi. wide off Brittany but gradually narrows to less than 40 mi. when traced southwestward. Off the north coast of Spain the sea floor is steeply shelving. The Loire, Gironde and Adour are the principal rivers entering the bay. Off the 15th-century mouth of the Adour the Cap Breton submarine canyon penetrates the continental shelf for 30 mi. The canyon walls are cut in consolidated Eocene strata and are vertical in places. The bottom sediment of the bay is largely sand and mud. The salinity averages $35^0/_{00}$ (3.5%), the same as for the North Atlantic in this latitude. Because of its open situation to the west and southwest, heavy seas are frequent, especially in winter when the westerly wind belt moves south.

Principal ports are Brest, Saint-Nazaire, La Rochelle and Bayonne in France and Bilbao, San Sebastián and Santander in Spain; Nantes and Bordeaux are also reached by ocean-going ships. Resorts along the French coast include La Baule, Biarritz and Saint-Jean-de-Luz. (A. H. W. R.)

BISCEGLIE, a coastal town and resort in the province of Bari, region of Puglia, Italy, on the Adriatic, lies 34.5 km. (21 mi.) N.W. of Bari. Pop. (1957 est.) 41,702 (commune). In the medieval part of town there are examples of Roman-Apulian architecture: the cathedral (11th century), and the churches of S. Adoeno and Sta. Margherita (1197), with the Gothic tomb of the Falcone family. There are also the *palazzi* ("palaces") of the Mazzalorsa (15th century), Frisari (16th century) and Tupputi (17th century). The large Piazza Vittorio Emanuele II, with its trees and gardens, is the centre of the modern town. There is progressive and intensive market gardening: cherries, dessert grapes, vegetables, almonds and many kinds of fruit are exported, especially to central and southern Europe. The town contains a harbour for fishing boats, wine- and oil-producing establishments, engineering shops, furniture factories and sawmills for producing packaging material.

The Romans called the town Vigilae, from the many guard towers along the coast. In the 11th century it was conquered by the Normans; Robert Guiscard made it a countship and ceded it to the Norman count Peter II, who began the building of the cathedral (1073), fortified the town and provided it with a high tower, which still remains. The *castello* was built under the Hohenstaufens and enlarged and embellished by the Angevins.

After having had various feudal rulers, among whom was Lucrezia Borgia. Bisceglie became a free city in 1532 under the Demiano regime. In 1536 Charles V gave the town a coat of arms and the title of Città. Bisceglie then became part of the kingdom of Naples, and in 1861 it was joined to the kingdom of Italy.

BISCUIT (U.S. COOKIE or CRACKER), a baked product made from the flour or meal of wheat, or other cereal, together with varying quantities of fat, sugar, leavening agents and other ingredients. Its name is derived from Old French *béscuit* ("twice-cooked") since originally the mixture was hardened by returning it to the oven after baking—a method still used in some home cookery recipes. In the United States some types of biscuits are known as cookies or crackers, and the term biscuit refers to small shapes cut or dropped from a raised bread mixture.

Although biscuits are made in a variety of shapes and sizes they are usually small and flat. They have a low moisture content and a characteristically crisp texture. The main types of biscuit in Great Britain are cream cracker, semisweet (rich tea, marie, petit beurre), sweet (digestive, shortcakes), chocolate-coated (sweet and semisweet), sandwich biscuits (cream-filled), wafer (sugar or cream-filled); in the United States, crackers (soda, graham, oyster), semisweet (lunch or milk), marshmallow-covered cookies, sandwich (cream-filled), wafers (sugar or cream-filled); in continental Europe, semisweet (petit beurre), sweet (sablé shortcake), wafers (sugar or cream-filled).

For thousands of years natives of India have been making a flour and water dough that they roll into thin sheets and cook on both sides to make a *chappatti*. By adding shortening, sugar. essences and aerating agents in various quantities it is possible to produce a variety of biscuits from this basic recipe. There are five main types: (1) Wafers are made simply by adding a very small amount of sugar and colour to flour and water. (2) Crackers are biscuits generally leavened by yeast and containing little, if any, sugar, and a small percentage of fat. The dough is hard and has to be rolled into sheets and laminated (see below) before cutting in order to give texture to the biscuit. It is baked at about 500° F. for approximately $3\frac{1}{2}$ minutes. (3) Semisweet biscuits have more shortening, sugar, leavening, sirup, malt and essences. Because of the extra ingredients, the dough is more pliable than cracker dough but still requires laminating before cutting. It is baked at a lower temperature for about $5\frac{1}{2}$ minutes. (4) Sweet biscuits have a high shortening and sugar content with the result that the dough is pliable and is handled on the cutting machine. It is baked in a moderate oven for approximately $7\frac{1}{2}$ minutes. (5) Specialities, such as ginger nuts, have a high shortening content and an exceptionally high sugar and sirup content. This is a very pliable dough that requires slow baking for 14 minutes.

Ingredients.— Flour forms the largest part by weight of any biscuit. The type of flour used depends upon the type of biscuit required; crackers require a "strong" (high protein and gluten content) flour almost like bread flour, but the sweet shortcake types require a "soft" (low protein and gluten content) flour. English wheat produces an excellent flour for semisweet and sweet biscuits, while American wheat is essentially strong and suitable for crackers.

Sugar is refined from cane or beet, and granulated sugar is ordinarily used in dough. Besides sweetening the biscuit, the sugar adds colour and flavour and helps to give a crisp bite. Other types of sugar, such as invert sugar, molasses, corn sirup, honey and malt extract, are used to give various qualities to the biscuit.

Shortening is the most important ingredient because it determines the eating quality, and in some cases the flavour, of the biscuit. The most important shortenings are butter, lard, oleo and hydrogenated oils such as coconut and palm kernel. Large manufacturers make their own compound.

Baking powders or leavening agents are compounded by each manufacturer to give the effect he desires. Crackers require yeast but the other types of biscuit are usually leavened with a mixture (baking powder) of ammonium bicarbonate, sodium bicarbonate (baking soda) and tartaric or other acids. These agents give off carbon dioxide and water vapour on heating and thus aerate the biscuit. Other ingredients are added either to give special flavours or appearances. The commonest of these are eggs, milk, dried fruit, chocolate. cheese, nuts, spices and essences.

Manufacture.—Mixing machines are all automatically controlled and have capacities of up to 1,300 lb. They have central rotating beaters that knead the dough and can be set to given times on low or high speeds, depending on the type of dough required. Crackers are a speciality since they are made of yeast dough and have to be left to stand twice during the mixing process so that they can "prove," or ferment. All other doughs, however, with the exception of certain manufacturers' own variations, are mixed in the ordinary manner. The dough of crackers or semisweet biscuits is deposited in a laminator when it is mixed.

Continuous mixers are used extensively. These are small machines that handle about 100 lb. of dough and are fed continuously with correctly proportioned ingredients. The machine produces a continuous stream of dough that is regulated to the production capacity of the oven. This method produces a consistent dough whereas the large batches of 1,300 lb. may vary from batch to batch.

The laminator automatically rolls sheets of dough to any given thickness, places several sheets in a pile and dusts the top of every sheet with a small amount of flour and fat. The pile is then rolled out to make one laminated sheet before being fed to the cutting machine. This process gives a light flaky texture, particularly to the cracker biscuit.

Cutting machines consist of a series of rollers that are 32 to 42 in. wide. As the mass of dough is passed from the laminator, it is rolled into a continuous sheet that is gradually reduced in thickness depending upon the type of biscuit being made. As this sheet passes through the cutting machine, the cutter stamps out shapes of dough at the rate of thousands per minute and at the same time pierces holes that allow the steam to escape during baking. Embossed designs can also be made on the dough at this stage. Sweet biscuit dough, being more pliable, is not laminated but passes straight from the mixing process to rotary molders, where it is pressed into molds and deposited upon a web feeding the oven.

Traveling ovens are continuously fed from the cutting machines and can be any length up to 300 ft. The cut shapes of dough travel on steel or wire bands between gas burners or electric elements at temperatures from 250° to 500° F., depending on the type of biscuit. This is called direct firing. The temperature in any section of the oven can be regulated. Indirect firing, a process in which hot air is blown into the baking chamber, is also common. Infrared and high-frequency heating came to be employed in the early 1960s in order to reduce the baking time and thus the oven length.

From the oven, the biscuits are automatically transferred lo a canvas web on which they cool as they are carried to a stacker to be lined up for packaging. If, however, they are required for sandwiching or chocolate coating, this process takes place directly after cooling.

Packaging.— In the United States most biscuits are wrapped and this method of packaging is used generally in Great Britain and Europe. Moistureproof materials such as cellulose film and laminated or coated papers are sealed by heated elements and give an airtight pack. In many factories wrapping is fully automatic: in some cases biscuits are counted, in others they are simply fed by volume into the wrapping machines. A popular American method is to drop weighed quantities of biscuits into a bag that is then sealed automatically. These packets are filled into an outer container that is sealed before being transferred to the warehouse.

Flow production is the essence of modern biscuit manufacturing. Once the ingredients are in the mixing machines the processes are continuous until the filled carton arrives at the warehouse.

Production.— Production methods in the United Kingdom and United States are similar and the efficiency of the industry has been greatly increased by automation. In the United States unsweetened biscuits (crackers) are most popular whereas in Great

Britain sweet and semisweet biscuits account for four-fifths of the production.

The industry in the United States is proportionally smaller and less important than in the United Kingdom, where it has assumed a position of considerable importance since World War II.

(J. C. FI.; R. C. BL.)

BISECTOR, a point that divides a line segment into two equal parts (also used in the Latin feminine form "bisectrix"); a line that divides a plane angle into two equal angles; a plane that divides a dihedral angle in the same way; or, more generally speaking, any line or plane that divides any geometric magnitude (like a parallelogram, sphere, or cube) into two congruent parts. In crystallography, it denotes the bisector of the angle between the optic axes.

BISHARIN: *see* BEJA.

BISHOP, SIR HENRY ROWLEY (1786–1855), English composer and conductor, remembered for the songs "Home, Sweet Home" and "Lo, Here the Gentle Lark," was born in London, Nov. 18, 1786. He began writing theatrical music in 1804 and for many years was closely connected with the theatre, composing the music for many light operatic pieces, productions of Shakespeare's plays and adaptations of Scott's novels and arranging operas by well-known composers. He held appointments at Covent Garden (1810), the King's theatre, Haymarket (1816–17), Drury Lane (from 1825) and Vauxhall (1830).

For Drury Lane he wrote his ambitious and unsuccessful *Aladdin* (1826), his only opera without spoken dialogue, as a rival to Weber's *Oberon* at Covent Garden. He was a founder of the Philharmonic society (1813). He became professor of music successively at Edinburgh (1841) and at Oxford (1848) and was knighted in 1842. His works included oratorios, part songs and glees. His slender talent is seen at its best in the tuneful songs which remain popular; "Home, Sweet Home," an early example of the theme song, from *Clari* (1823), became world-famous. He died in London April 30, 1855.

BISHOP, ISABELLA LUCY (née BIRD) (1831–1904), English traveler and writer whose works caused her to be elected the first woman fellow of the Royal Geographical society (1892), was born on Oct. 15, 1831, at Boroughbridge hall, Yorkshire. She was the daughter of the Rev. Edward Bird and related to the Wilberforces. Delicate and nervous, she took enthusiastically the advice of doctors to go abroad for her health, and became famous as a traveler and author, with strong missionary interests. She was a keen horsewoman and a pioneer of photography. In 1873–74 she visited the Hawaiian Islands and the Rocky mountains, but her reputation was made by later travels in Asia, described in *Unbeaten Tracks in Japan* (1880), *The Golden Chersonese* (1883), *Journeys in Persia and Kurdistan* (1891), *Among the Tibetans* (1894), *Korea and Her Neighbours* (1898). *The Yangtze Valley and Beyond* (1899). In 1881 she married John Bishop, an Edinburgh physician, who died in 1886. In 1901 she rode 1,000 mi. in Morocco and the Atlas mountains. She died in Edinburgh on Oct. 7, 1904.

See Anna *M*. Stoddart, The Life *of Isabella L. Bird* (1906); Dorothy Middleton, "A Lady's Life in the Rocky Mountains," *The* Cornhill, no. *994* (1952–53). (D. MN.)

BISHOP, the title of the highest order in the threefold ministry of the Christian church *(see* HOLY ORDERS; MINISTRY, CHRISTIAN). A bishop is customarily consecrated to his office by a metropolitan (*q.v.*) and at least two other bishops. He normally possesses spiritual power over a diocese (*q.v.*); a bishop without this authority is known as an assistant, auxiliary, coadjutor, suffragan or titular bishop. In addition to the normal functions of a priest. a bishop has power to confer holy orders, to consecrate places and things set apart for holy use and, in the west, to administer confirmation. Of those churches that rejected the threefold ministry at the Reformation and later, certain Lutherans and Methodists have retained the title "bishop." *See* EPISCOPACY; *see* also Index references under "Bishop" in the Index volume.

BISHOP AUCKLAND, an urban district in the Bishop Auckland parliamentary division of Durham, Eng., 12 mi. S.S.W. of Durham by road. Pop. (1961) 35,276. It is an industrial and market town on high ground near the confluence of the Wear and the Gaunless. Though the Romans had a fort (Vinovia) at Binchester nearby, Bishop Auckland did not become important until the bishops of Durham resided there in the 12th century. Their castellated palace, Auckland castle, in an 800-ac. park, containing a deer house, has a 17th-century chapel. It became the official residence of the bishops in 1836. King James I founded the grammar school in 1605. Coal, mined systematically from at least the 18th century, is excellent for coking. Flooded workings caused some of the collieries to close, but an official dewatering scheme, completed in 1954, reopened the coal fields. Other industries were established and the town is also a shopping centre. To the west is Escomb with a Saxon church and south is St. Andrew Auckland with the ancient parish church for Bishop Auckland dating to the 13th century. Farther to the southwest is St. Helen Auckland which, despite its modern industries, preserves a little 12th–13th century church and an 18th-century Palladian house.

BISHOP'S CASTLE, a market town and small municipal borough in the Ludlow parliamentary division of Shropshire, Eng., on a steep hillside above an important lowland route from south Shropshire into Wales, 21 mi. S.S.W. of Shrewsbury by road. Pop. (1961) 1,229. The historic road from Ludlow past Stokesay was controlled, probably from the 8th century, by the bishops of Hereford who built a castle about 1085–1100, where the gap narrows between the mountain lines of Longmynd and the Clun forest. Only a small garrison was required to keep a check on the Welsh and to regulate the town which had sprung up around this strong point on the "road of the castles." The castle is now in ruins and the site partly occupied by the Castle hotel and gardens. The town hall dates from 1608 and there are still some half-timbered houses.

In 1573 Elizabeth I granted the townsmen, on request, a charter confirming their privileges given in nine earlier charters to the bishops. From then until 1832 the borough returned two members to parliament.

Agriculture and stock rearing are the industries; sales of cattle take place regularly. The local railway to Craven Arms, started in 1863, ceased to function in 1935.

BISHOP'S STORTFORD, a market town and urban district of Hertfordshire, Eng., lies on the steep banks of the river Stort, 14 mi. N.E. of Hertford and 31 mi. N.N.E. of London. Pop. (1961) 18,308. The town is largely residential with a variety of schools and colleges. Industries include malting, the preparation of seeds, light engineering, flour milling and matchmaking. There is a large weekly cattle market (Thursday). The manor, mentioned in Domesday Book, was formerly the property of the bishops of London. William I built a church there, and the small Waytemore castle, which he gave to the bishop. Only a vault and a font of the original church survive, but the 14th–15th century St. Michael's church (Perpendicular). high above the valley, has an interesting collection of documents relating to local history. The castle was destroyed by King John, and only a few stones remain; its dungeon, the "Bishop's Hole," was used as an ecclesiastical prison until the 16th century. The town apparently did not become a borough in the full sense, though it was represented in six of the parliaments of Edward II and Edward III. Its commercial importance grew with the opening of the Stort navigation in 1769, and it became a malting centre and a depot for grains and other goods. Cecil Rhodes was born at Netteswell House, which became the Cecil Rhodes Memorial museum in 1938 and was reconstructed in 1952–53. Hatfield forest (National Trust property) four miles east of the town is of great interest to the naturalist.

BISHOPS' WARS, the name given in English history to the two brief campaigns fought between Charles I and the Scots in 1639 and 1640. caused by Charles's endeavour to enforce Anglican observances in the Scottish Church, and by the determination of the Scots to abolish episcopacy. In the first war there was no engagement, but in the second the 'Scots' seizure of Northumberland and Durham made it necessary for Charles to summon the Long parliament (Nov. 1640), and thus precipitated the English Civil War. *See* COVENANTERS; LEVEN, ALEXANDER LESLIE.

BISITUN (BISOTUN or BEHISTUN), a village and a precipitous rock in Kermanshah *ostan* (province), Iran, situated at the foot of the Zagros range, which rises to 4.000 ft. at this point, between Kermanshah city and Hamadan, where there are a number of springs which are favourite camping places for caravans. This was on the old road from ancient Ecbatana to Babylon, and it was there that Darius the Great placed his famous trilingual inscription on the face of the rock *(see* DARIUS). Mention of this is first made by Diodorus Siculus, who stated that it was the work of Semiramis (*q.v.*) and identified the bearded figure of Darius with that of this mythical queen. Darius carved his inscription in bas-relief about 500 ft. above the spring, in a difficult though not inaccessible rock face. The inscription is in Babylonian, Old Persian and Elamite. The Old Persian consists of four and one-half columns, the Elamite of three columns and the Babylonian covers two faces of the overhanging rock immediately below the Elamite version. The inscriptions were first reached and copied by Henry Creswicke Rawlinson (*q.v.*), an officer in the East India company's service seconded for work in Persia. Between 1835 and 1847 he copied all the inscriptions and with his knowledge of local dialects managed to read the version recorded in Old Persian. Rawlinson published his findings in 1849 in the *Journal of the Royal Asiatic Society* and virtually accomplished the task of deciphering the Old Persian cuneiform texts. The Babylonian text was, however. to present far greater difficulties. This task was also largely achieved by Rawlinson with the help of Edward Hincks (*q.v.*), an Irish scholar, and Félicien de Saulcy. a French one, and by 1850 the decipherment of this text was practically completed.

The Behistun inscription was severely weathered and difficult to read, and in an effort to clarify some of Rawlinson's readings A. V. Williams Jackson, an American, mounted the ledge below the inscriptions in 1903. The following year L. W. King and R. Campbell Thompson, working on behalf of the British museum, London, made a complete copy of the texts by means of a kind of boatswain's chair, swinging across the face of the rock. Their copy remained the standard text of the inscriptions until 1948. In that year George Glenn Cameron, working on behalf of the American Schools of Oriental Research and the University of Michigan, led an expedition to recopy the texts. In this they were successful, partly by the aid of Latex squeezes (rubber molds), by photographs, and partly by rechipping the rock face on which a tufa deposit had formed, partially obscuring the cuneiform signs. Other signs were, however, much more eroded than they had been in 1904, because a stream which feeds the springs had washed down over part of the inscription and eroded the signs at the top of the inscription to a depth of between five and six inches. The earlier orientalists had not been able to copy the four columns of writing lying to the right of the relief, although Campbell Thompson had decided that it was in Elamite. It has now been possible to copy all these columns, which were confirmed to be Elamite and actually a copy of the Elamite text which appears below and to the left of the relief depicting Darius with a group of captives. This copy enabled doubtful passages in the other version to be restored. gaps in the text to be more accurately measured. and determination of the year in which these events took place.

The inscription records the way in which Darius after the death of Cambyses killed the usurper, Gaumata, and gained power after defeating the rebels. Decipherment provided an important key for the study of the cuneiform script. Bisitun or Bisotun is a colloquial expression for the site, Behistun being the classical name given by Yaqut, the Arab geographer, and classical Persian authors.

BISK (BIISK or BIYSK), the second town after Barnaul of the Altai *krai* of the Russian Soviet Federated Socialist Republic, U.S.S.R., lies on the right bank of the Biya river 12 mi. above its confluence with the Katun to form the Ob. Pop. (1959) 146,000. At the head of navigation and terminus of a railway from Barnaul and Novosibirsk, Bisk is the starting point of the Chuya highway, a motor road across the Altai mountains to the Mongolian People's Republic. The town manufactures boilers, electric furnaces, food-processing machinery, matches, linen, leather goods, sugar and tinned meat. Nearby is the largest fur farm of the U.S.S.R. (silver fox. sable and mink). (R. A. F.)

BISKRA, a town and commune of Algeria, in the south of Batna *département* and on the northern edge of the Sahara. It lies at about 360 ft. altitude, south of a wide, open depression between the Aurès range and the Tell Atlas (always a route for conquerors and nomads), and is the centre of the Zab (or Ziban) group of oases. Pop. (1954) 52,511, of whom 1,730 were Jews or Europeans. About 19,700 live permanently in the town built in the mid-19th century on a grill plan beside St. Germain fort, itself constructed on the site of the former Turkish kasbah. The rest inhabit about ten villages of sun-baked brick houses, scattered among the palm gardens or on their verges. The new town is a centre of civil and military administration and commerce. The mildness of the winters (52° F. in January) and the beauty of the oasis and the distant horizons have made it a winter resort. The villagers cultivate the 5 sq.mi. of the oasis. with more than 150,000 date palms (many of the *deglat-nour* type for export) and thousands of various fruit trees (olives, apricots, pomegranates). In the cold season the surplus water of the Wadi Biskra irrigates downstream vast fields of wheat and barley which are harvested in April. The town is on the railway from Constantine to Touggourt, and linked by main road to the former, and has an airport. It is also near the oil pipeline from Hassi-Messaoud to Bougie.

Biskra stands on the site of Vescera, a post of the Roman limes (fortified boundary). After the Arab conquest it became a prosperous centre from the 9th to 11th centuries; in the 12th it was the capital of the Zab, almost autonomous in spite of its ties with the dynasties of Tunis or Bougie; and from the 13th to 15th centuries it was the chief centre of the southwestern states of the Hafsids, practically independent of Tunis. The Turks occupied it in 1552 and built a fort, and in 1844 it was garrisoned by the French.

(J.-J. Ds.)

BISLEY, village, Surrey, England, 33 mi. N.W. of Woking and about 29 mi. from London by road. Pop. (1951) 1,071. Bisley common is the site of the ranges of the National Rifle association, which were transferred there from Wimbledon in 1890. The ranges are the scene of important British and international shooting competitions.

BISMARCK, OTTO, PRINCE VON (1815–1898), Prussian statesman, the founder and first chancellor of the German empire, was born on April 1, 1815, at Schonhausen in Brandenburg. His father, Ferdinand von Bismarck-Schonhausen, was a Junker landowner who had served in the Prussian army; his mother. Wilhelmine Mencken, was the daughter of an untitled bureaucrat who had risen high under Frederick William III. The contrast between his parents did much to cause the conflict in Bismarck's own nature. In physical appearance and avowed tastes he was a Junker : powerfully built. devoted to country pursuits and with an enormous appetite for food and drink. Mentally and emotionally, however, he was sophisticated and highly bred, sensitive to the point of hysteria, with a subtle intellect and a gift of expression which put him in the highest class of German writers.

Early Years.—Bismarck went to school in Berlin, living with his mother and developing a romantic nostalgia for the family estates, which he seldom visited. He read law first at Gottingen university and then at Berlin; he was a disorderly student, though he passed his examination. He then entered the Prussian service, and became a judicial administrator at Aachen. There he was drawn into the international society which stopped at the spa on the way to other watering places; and at one time absented himself without leave for some months in order to follow across Germany an English girl with whom he had fallen in love. The adventure came to nothing and the criticism of his official superiors drove Bismarck to resign from the service at the age of 25. He declared, "I will play music as I like it or none at all." The family estates were running into difficulties, and Bismarck took over the manage-

ment of them from his father and to some extent from his elder brother.

Under his mother's influence, Bismarck as a youth had been a deist, indifferent to Christianity. In the country, he came to know his Pietist neighbour Adolf von Thadden; and he was deeply affected by the death of Von Thadden's daughter, Marie. Soon after he fell in love with another girl of this Pietist circle, Johanna von Puttkamer, whom he married in July 1847. To win her hand Bismarck avowed his own conversion, though he was inclined to lay down to God the conditions on which he would acknowledge his existence.

The 1848 Revolution. — In 1847 Bismarck became a member of the united diet, the quasirepresentative body which Frederick William IV summoned in order to authorize a loan for the building of a railway to East Prussia. Bismarck stood out as the provocative spokesman of absolutism and reaction, dismissing the mildest liberal measures with contempt. The diet demanded that it should be summoned regularly; when the king refused this it rejected the railway loan and was prorogued. Before it could meet again the revolution of 1848 swept Germany and Frederick William IV himself capitulated to the revolution in Berlin on March 19. Bismarck wished to organize a military repression and civil war. When the king pleaded that he had been unable to sleep for worry, Bismarck replied, "A king must be able to sleep." He attempted to force the king's abdication and suggested to Princess Augusta, wife of the king's brother William, that her husband, too, should withdraw in favour of his young son, who would then become the helpless figurehead of the reaction. Augusta indignantly refused and remained the mortal enemy of Bismarck throughout her life. In later years he launched the version that Augusta had made the proposal to him and that he had rejected it out of loyalty to the king—one of many instances in which he put the best appearance on failure and sought to mislead posterity.

Bismarck was in eclipse so long as liberalism prevailed in Germany. He was elected neither to the national assembly at Frankfurt nor to the first Prussian parliament at Berlin. In October the army occupied Berlin, and Frederick William IV issued a more monarchist constitution. Bismarck was elected to the new second chamber. In April 1849 the Frankfurt parliament offered the imperial crown to Frederick William. He refused it; and Bismarck was one of the few who welcomed this refusal. Frederick William next attempted to gain the leadership of northern Germany with the co-operation of the princes. This challenge to Austria was opposed by Bismarck; and when open conflict seemed to be approaching in Oct. 1850, he advocated return to Austro-Prussian dualism. He welcomed enthusiastically the Prussian surrender at Olmiitz, when Frederick William's schemes were abandoned, and praised Austria as "a German power that is fortunate enough to rule over foreign peoples." He hoped that, with the defeat of the revolution, Prince Netternich's "system" with its Holy Alliance of Austria, Russia and Prussia would be restored. These views made him an obvious choice to represent Prussia at the federal diet at Frankfurt. He arrived there on May 11, 1851, renewing a career in the service of the state that was to last without interruption for 39 years.

Beginning of the Struggle With Austria: Frankfurt. — Bismarck went to Frankfurt as the leading advocate of co-operation with Austria in German affairs. Within a fortnight, his outlook was revolutionized, and he became convinced that the Austrian statesmen would never treat Prussia as an equal. The men who had defeated the revolution in Austria no longer thought in Metternich's cautious terms. They believed that they could hold the revolution in check without any assistance from their former conservative partners, Russia and Prussia. But if the challenge came from Austria, Bismarck was not slow to take it up. He disputed every formal sign of Austria's leadership, though Austria was in fact "the presiding power" at the diet by virtue of the federal act; and he carried on a relentless personal feud with successive Austrian representatives. Hitherto only the Austrian had smoked at meetings. Now Bismarck, too, pulled out his cigar case. Such trivialities were to reshape the destinies of central Europe. Bismarck soon came to speak with contempt of Frederick William IV and of Otto von Manteuffel, his foreign minister. He believed that they were sacrificing Prussia's greatness to their romantic conception of conservative solidarity. In his opinion "the Holy Alliance mas dead," and Prussia should follow a policy of self-centred realism. It should claim the headship of Germany and make alliances with foreign powers against Austria in order to achieve it; it should even ally itself with "the revolution."

During the Crimean War (1854–56) Bismarck feared that Prussia would support Austria or even join the western powers in war against Russia. He reached the conviction that the Balkans and the lower Danube, however vital to Austria, were no concern of Prussia's; and this view did much to shape his later policy. At the end of the war he believed that Russia and France would soon come together in a "revisionist" alliance — Russia to undo the results of the Crimean War, France to expel Austria from Italy — and he urged that Prussia should make a third in this restless combination. He overrated the dynamism of both Russia and France and insisted that Prussia could gain the headship of Germany only as part of a general European upheaval. His greatest state paper dismissed as impossible the limited reordering of German affairs which he himself carried through 14 years later.

Ambassador at St. Petersburg and Paris. — Bismarck grew increasingly critical of Prussia's official policy in his last years at Frankfurt. He was over 40 and seemed to have achieved nothing. In 1858 Frederick William IV became insane and his brother William took his place as regent. This began the short-lived "new era," when Prussian policy took a liberal turn. Bismarck seemed out of place at Frankfurt with his reactionary reputation, and early in 1859 he was sent as ambassador to St. Petersburg — "put in cold storage" was his own phrase.

In Jan. 1861 Frederick William IV died and the prince regent became King William I. A soldier by training and profession, he wished to increase the army in order to be able to train all those liable to military service. This increase mould, in addition, enable him to cut down the *Landwehr*, or militia, which all Prussian conservatives regarded as a dangerously democratic institution. The liberal majority in the Prussian parliament was ready to increase the grant for the army, but they defended the *Landwehr* and sought to reduce the period of military service from three to two years. In 1861 parliament authorized the increased grant for one year only. Albrecht von Roon, the minister of war, at once organized new regiments, implying that the grant was permanent. In Nov. 1861 a general election strengthened the more advanced liberals, who were now organized as the Progressive party. Roon urged William to make Bismarck prime minister, but the king was alarmed by Bismarck's advocacy of alliance with France and his plans for sweeping away the German princes.

In March 1862 Bismarck was recalled from St. Petersburg. He expected to be made prime minister (minister president); but though William was running into increasing difficulties with the chamber of deputies, he still shrank from an open breach of the constitution, and Bismarck on his side would not take office until the king could be forced to accept a revolutionary foreign policy. He was therefore sent as ambassador to Paris. There he and Napoleon III dangled before each other the idea of alliance against Austria.

Appointment as Prime Minister. — Meanwhile events in Berlin had reached a crisis. The chamber of deputies would authorize the increased military expenditure only if the period of service mas reduced to two years. On Sept. 17 the ministers. including Roon, agreed to this compromise; it was rejected by William, and Roon swung around to his support. Immediately after the meeting of the council Roon sent to Bismarck the famous telegram, *Periculum in mora. Dépêchez-vous* ("There is danger in delay. Hurry up"), meaning that the king's reluctance had been broken. On Sept. 22, 1862, Bismarck arrived in Berlin and was at once made prime minister. It was an uneasy partnership. William wished to defend his independent conduct of military affairs, but still rejected an adventurous foreign policy; Bismarck encouraged the domestic conflict in order that the king should be dependent on him and then be drawn into a foreign policy by no means to his taste.

The constitution laid down that the budget must be agreed upon by the chamber of deputies, the upper house and the king. Bismarck argued that if one of the three rejected the budget, there was "a gap in the constitution" and that the government must collect the existing taxes (and of course spend them) until agreement mas reached. This theory served to promote a conflict. He told the chamber in his first speech, "The great questions of our day cannot be solved by speeches and majority votes—that was the great mistake of 1848 and 1849—but by blood and iron." Time and again the liberal majority offered a compromise; but Bismarck knew that this would destroy his hold over the king and always evaded it. Dissolution failed to shake the liberal majority; this, too, was an advantage for Bismarck, for a conservative chamber would have made him unnecessary.

The German Question.—Bismarck's main interest lay elsewhere—in foreign policy. He had long announced his intention of settling the German question. When he took office a conflict had already started on Austrian initiative. The Austrians proposed to the federal diet a delegate conference at Frankfurt to strengthen the confederation. Bismarck answered by proposing the direct election of a German parliament; and he asked the French government what it would do "if things grew hot in Germany." Napoleon III was in a conservative mood and gave a timorous answer. In Feb. 1863 the diet rejected the Austrian proposal and the alarm blew over.

The Polish Revolt of 1863.—Russia and France had worked together with increasing intimacy since the end of the Crimean War. This intimacy was disturbed by a revolt in the part of Poland ruled by Russia, which broke out in Jan 1863. Napoleon III tried to turn his back on this embarrassing affair and pretended that it was a question of Russian domestic politics. Bismarck, however, sent Graf Gustav von Alvensleben-Erxleben to conclude a convention with Russia (Feb. 8, 1863) for co-operation against the Polish insurgents. Bismarck always regarded Polish national ambitions as the greatest threat to Prussia's existence, and his motive in proposing the Alvensleben convention was principally to silence the advocates of concession to Poland at the Russian court. Certainly the convention did not win Russian gratitude: Prince A. M. Gorchakov, the chief minister, resented the implication that Russia was in any need of help. Moreover, Napoleon III, who was impotent to act against Russia, thought of making a demonstration in favour of Poland by threatening Prussia; and at the beginning of March Bismarck had to ask Gorchakov to allow him to withdraw the convention. Far from being a great stroke of policy, the convention was an impulsive gesture against the Poles which led Bismarck into a position of some danger: he had almost put Prussia as a hostage between Russia and France.

The Frankfurt Meeting of the Princes.—In Aug. 1863 the emperor Francis Joseph invited the German princes to a meeting at Frankfurt to discuss the reform of the confederation. It was the high-water mark of the Austrian attempt to unite Germany by agreement. Its principal element was a "directory" of princes. Bismarck might have been willing to compromise with Austria at the expense of the princes; he would certainly not give the princes authority over Prussia. William I was tempted to attend the Frankfurt meeting, especially when King John of Saxony brought an invitation in person. Bismarck threw all his weight on the other side. It was his first struggle for ascendancy over William and he won it, though at great strain. When the argument was over, Bismarck smashed a large jug of water on the ground and broke into hysterical sobs. William's refusal wrecked the Frankfurt meeting. Though the princes approved the Austrian proposals, they added the proviso that Prussia must approve them too. The princes had, in fact, no interest in German unity and welcomed the conflict between Austria and Prussia as giving them an easy excuse.

In answer to the Austrian policy of working with the princes, Bismarck emphasized his friendship with Russia and with France. In the autumn of 1863 he concluded a commercial treaty with France and imposed this treaty on the *Zollverein*, the German customs union, which Prussia controlled. There was no room for Austria in this arrangement and the economic division of Germany was thus made final, even while the political confederation still existed.

Schleswig-Holstein.—In Nov. 1863 Frederick VII, the last Danish king of the male line, died, and therewith the Schleswig-Holstein question (*q.v.*), which had played a vital part in the German revolution of 1848, was renewed. The two duchies, Schleswig and Holstein, were in personal union with Denmark; Holstein alone was a member of the German confederation, though there was also a German majority in southern Schleswig. In 1848 the German liberals had attempted to "liberate" the two duchies, with the assistance of the Prussian army, but the attempt had been defeated by the protests of the great powers, and the treaty of London (1852) had reaffirmed the personal union. The Danes had subsequently tried to extend their constitution to include the two duchies; and German national sentiment countered by supporting a rival claimant to the duchies, the duke of Augustenburg. Bismarck had no interest in creating another petty German state. particularly on Prussia's border; on the other hand he would not let Austria steal a march on him by appealing to German national feeling.

J. B. von Rechberg-Rothenlowen, the Austrian foreign minister, was a conservative who hated German liberalism and therefore fell in with Bismarck's plans. On Jan. 16, 1864, he signed a treaty of alliance for war against Denmark, not to liberate the duchies but to enforce personal union as laid down by the treaty of London; German nationalism was repudiated. The Danes were soon defeated and Schleswig overrun. A conference of the great powers then met to try to save the settlement of 1852, but the coalition of non-German powers no longer existed. On May 28 Austria and Prussia repudiated the treaty of London and were able to renew the war against Denmark without intervention or serious protest from any foreign power. In August Denmark made peace, ceding the duchies to Prussia and Austria jointly (the definitive treaty was signed at Vienna on Oct. 30, 1864). Later in August Bismarck and William visited Francis Joseph at Schonbrunn. Rechberg was willing to surrender the duchies to Prussia, but asked in return for a guarantee of Venetia and help in recovering Lombardy from Italy; Francis Joseph also wanted compensation in German territory. The terms were logical enough, but they were too high ior Bismarck. He might compromise with Austria; he would hardly go to war with Italy, and perhaps France as well, for Austria's sake. Austria and Prussia therefore agreed to rule the duchies jointly, until something turned up which would make a lasting solution possible.

The Conflict With Austria.—Bismarck still hoped to reach an agreement with the Austrians when their difficulties increased elsewhere—either in Italy or the near east. Instead they concentrated on German affairs and put forward the claim of the duke of Augustenburg to the duchies. On May 29, 1865, a Prussian crown council discussed whether to meet the Austrian challenge by mar. The generals favoured war; Bismarck insisted on alliance with France and an appeal to German nationalism, if war were decided on. He said, "If war against Austria in alliance with France is struck out of the vocabulary of diplomacy, it is impossible for Prussia to have a policy." This idea was still too revolutionary for William, and compromise followed once more. By the treaty of Gastein (Aug. 14, 1865) Austria mas given the administration of Holstein, Prussia of Schleswig. Bismarck, rewarded with the Prussian title of Graf von Bismarck-Schonhausen (Sept. 1865), soon moved again toward an alliance with France. In October he visited Napoleon III at Biarritz. Hitherto he had assumed that Napoleon would repeat in Germany the policy that he had followed with Cavour in Italy: he would join in the war against Austria and expect to receive a territorial reward for his assistance. At Biarritz Napoleon made it clear that he planned to remain neutral and that his reward should be the cession of Venetia to Italy. The Biarritz bargain was negative: Bismarck would not guarantee Venetia to Austria, and Napoleon would not give Austria support.

After promising not to defend Venetia, it was an easy development to promise it to Italy. This was the essential clause of the alliance with Italy, which Bismarck signed on April 8, 1866; in return Italy promised to join in war against Austria if it broke out

in the next three months. In May there was a last attempt at compromise, organized by the brothers Anton and Ludwig von Gablenz—the one a Prussian, the other an Austrian general. Bismarck would have been satisfied with the military headship of northern Germany. Austria was still unyielding and at the beginning of June repudiated the alliance with Prussia by bringing the question of the duchies before the diet. Prussian troops invaded Holstein, and when a majority of the diet condemned Prussia Bismarck declared the German confederation at an end (June 14). War followed against Austria and those German states which took the Austrian side. (See SEVEN WEEKS' WAR.)

The 1866 Settlement.—Two Prussian armies invaded Bohemia, and on July 3 the Austrians were decisively defeated at Sadowa, near Koniggratz (Sadova, near Hradec Kralove). They appealed for French help, but Napoleon III would only mediate. A believer in the national principle. he sympathized with the Prussian purpose and himself urged Bismarck to annex the whole of northern Germany. Bismarck's real struggle was with his own king. William had been gradually taught to believe that the Austrians were the aggressors, and he wished to punish them by annexing some of their territory. Bismarck got his way only after a bitter dispute, in which he called the crown prince to his aid. By the preliminary peace of Nikolsburg (July 26), he excluded Austria altogether from Germany, instead of dividing Germany between Prussia and Austrian zones at the line of the Main as he had proposed before the war broke out. The southern German states were to have "an international independent existence." Bismarck's moderation in 1866 has been much praised; and certainly he wished to preserve Austria as a great power—"we shall need its strength in future for ourselves." But Austria remained intent on revenge until the events of 1870 made it impossible. Moreover, in preserving Austria. Bismarck saddled himself and his successors with "the Austrian problem." The war of 1866 defeated the empire which Metternich had served; but within a few years Bismarck re-created the conservative system of Metternich in a modified form.

The North German Federation.—A general election took place in Prussia on the day of the battle of Sadowa. The Progressive party was much weakened and soon afterward split. The majority formed a new party, the National Liberals, which would support Bismarck in exchange for concessions in home affairs. He agreed to admit that he had acted illegally in collecting the taxes without parliamentary authorization; and the diet passed an act of indemnity.

All the states north of the Main that had fought against Prussia in 1866 were annexed except Saxony; the others had to join a federation under Prussian control. The king of Prussia became its president and commander in chief. Bismarck set up a *Reichstag*, elected by universal suffrage; but he did not propose to allow it any say in the military budget, which was to be written into the constitution; nor was there to be a responsible ministry—the real decisions were to be taken by a federal council, composed of delegates from the states. The National Liberals revolted against this sham and Bismarck met them halfway, perhaps with one eye on liberal feeling in southern Germany. The chancellor became a responsible minister. though the only one; and the military budget was authorized only until the end of 1871. Then, after further dispute, Bismarck agreed in 1874 to authorization only for seven years (the septennate); and this produced a crisis every seven years while he remained in office.

Bismarck and the National Liberals made a genuine compromise. Certainly the chancellor was appointed by the king, or emperor, as the prime minister had been in 18th-century England; but neither Bismarck nor his successors ever infringed the constitution, though Bismarck was often tempted to do so. There was in imperial Germany a true rule of law, and the will of the people could have prevailed if they had known what to will. The Reichstag won the essential point of any constitution: it controlled supply for the military forces, though it could exercise this control only every seven years instead of annually, as in a fully liberal country.

The Conflict With France.—At the time of making peace with Austria, the French ministers—though not Napoleon himself—demanded compensation for Prussia's aggrandisement. Bismarck answered with vague talk of Belgium, but when the French asked for an alliance and the cession of German territory on the left bank of the Rhine he evaded them. In Sept. 1866, Napoleon III, who was wiser than his advisers, declared himself content with the new order in Germany, but French public opinion insisted on some concrete satisfaction. Luxembourg seemed the solution. It had been a member of the old confederation and was garrisoned by Prussian troops. but it was ruled by the king of the Netherlands, and Bismarck did not claim it for his new federation. Indeed he advised Napoleon III to buy it from the king of the Netherlands. The French dallied over these negotiations, and the German public began to protest against the loss of this "old German land." Bismarck himself joined in the protest (April 1, 1867), though finally he accepted compromise at an international conference: the Prussian garrison was withdrawn and Luxembourg was neutralized instead of being annexed to France.

The Luxembourg crisis is one of the most disputed episodes in Bismarck's career. Some writers have seen in it a trap by which he meant to involve France in war; others claim that he was surprised by the strength of German feeling and had to go along with it. Certainly the crisis put an end to all hopes of a Franco-Prussian alliance, such as Bismarck had often discussed. On the other hand although Bismarck regarded war with Austria as one of the only two possible alternatives before 1866 he does not seem to have worked deliberately for war with France in the same way. Even in 1869 he suggested that France might acquire Belgium in return for the addition of the southern German states to the federation.

These states were the point about which Bismarck's policy revolved. In 1866 his renunciation of them had been genuine: he did not want to add Roman Catholic states to a predominantly Protestant federation. But he counted on their liberalism to keep them from alliance with either France or Austria. Instead the liberal parties in southern Germany lost ground to clericalists, who were strongly anti-Prussian. Bismarck was faced with a dilemma. If he rallied the southern liberals by proposals of unification, this would strengthen liberalism throughout Germany; if he did nothing, Austrian, and even French troops might soon be on the Main. His solution was to prepare for unification by increasing the prestige of the Prussian monarchy.

One device to achieve this was the proposal which he put forward unsuccessfully early in 1870, to give the king of Prussia the title of German emperor. Another was to encourage members of the house of Hohenzollern to accept any vacant thrones that might be offered them. In 1866 Prince Charles of Hohenzollern-Sigmaringen went to Rumania on Bismarck's advice. In 1869 his brother Leopold was offered the throne of Spain, vacant after a revolution in 1868. Though Bismarck later established the version that he had no connection with this offer, there is. in fact, no doubt that he repeatedly urged it on the Spaniards until they wore down Leopold's reluctance in June 1870. This does not imply that the Hohenzollern candidature was intended to provoke a war with France. France was to be presented with a *fait accompli*, and Leopold to become king before the French learned of it.

On July 3 the news leaked out prematurely, The French government demanded Leopold's withdrawal; and William, who had always disliked the affair, seconded them. On July 12 Leopold withdrew. Bismarck, though taken by surprise, had wished to reject the French demands and to score a victory of prestige, if not actually to provoke a war. Instead he seemed to have been humiliated. At the last minute he turned the humiliation against the French. He transformed a message which William sent him from Ems from a surrender into a defiance; and the French declared war a week later. Bismarck soon claimed that he had caused the war by means of this "Ems telegram"; but it is likely that the Bonapartists, who dominated Napoleon III, would have insisted on war in any case. (See FRANCO-GERMAN WAR.)

The war of 1870, unlike the war against Austria, had no practical purpose; Bismarck asked nothing of France except to be left alone. But from the beginning of the war he accepted the military proposal to annex Alsace-Lorraine. The generals urged the stra-

tegical advantage; Bismarck thought rather of giving German national feeling some concrete symbol of victory and, as well, he was glad to have some cause for lasting estrangement between France and the German liberals. Later he regretted this estrangement and assured the French that he had been opposed to the annexation of Metz. There is no contemporary evidence of this. His diplomacy during the war was limited to preventing the French from finding allies or provoking a European mediation. He was successful. and in Feb. *1871* imposed upon them an indemnity of 5,000,000,000 fr., as well as the loss of the territory. This became the treaty of Frankfurt in May *1871.*

The German Empire.—A11 the southern German states joined the war against France, but they were still reluctant to enter an empire controlled by Prussia. It would have been easy to drive them on by evoking popular feeling, but Bismarck was determined that Germany should not be made by democratic means—it must be made by the princes, not by the *Reichstag.* He gave some political concessions to the southern German states and, more effectively, bribed the king of Bavaria with large sums from his secret fund. The *Reichstag* merely asked William to deign to accept the imperial crown; the actual offer was made by the princes, and William I was proclaimed German emperor on Jan. *18, 1871.* Two things stand out in this supreme achievement of Bismarck's life. Germany was made without the German people, almost against them; though Germany was technically united. *8,000,000* German Austrians were excluded from the German national state.

Nevertheless, Bismarck was the hero of the German people in 1871, and he was created prince von Bismarck (March *21, 1871)* and appointed imperial chancellor. The National Liberals acted almost as a government party in the *Reichstag.* Bismarck discussed every legislative measure with their leaders before introducing it, and left the conduct of measures through the *Reichstag* to them. In addition, the conservatives also split, and one section, the Free Conservatives: accepted liberal measures so long as Bismarck advocated them. Between *1871* and *1878* Bismarck had a majority in the *Reichstag,* almost in the western parliamentary sense, and he carried through fundamental changes, comparable with the work of the Revolution in France or of the Benthamites in England. Germany was given a common currency and a central bank. A single code of commercial and civil law was created. and a high court of justice set up at Leipzig. The tangle of medieval survivals was swept away in less than a decade, and Germany became the most modern and liberal of states, so far as laws could make it so.

The **Kulturkampf.**—Distrust of political Roman Catholicism mas common doctrine among liberals in the 19th century. Bismarck shared this distrust and it grew stronger in *1871* when a confessional party, the Centre, gained *58* seats in the *Reiclzstag.* Though the Centre claimed to defend strictly Roman Catholic interests, it drew its support from all the elements which had opposed Bismarck's work; for instance, Protestant Hanoverians supported it, while Bavarian nationalists, though Roman Catholic, did not. Bismarck regarded the empire as his own creation and he branded any opponent of his as a *Reichsfeind* (enemy of the empire). He believed, too, that unity was most easily created if there was some object to attack, and the Centre provided that object when Germany had no foreign enemies. He said of Ludwig Windthorst, leader of the Centre, "Everyone needs somebody to love and somebody to hate. I have my wife to love and Windthorst to hate."

The struggle began over the state control of education. When the Roman Catholics claimed the right to choose and license their own teachers, Bismarck attacked the teaching orders and then insisted that the state should train and license priests. Priests and bishops were imprisoned and sees were left vacant. By *1876,* when the struggle reached its height, Bismarck seemed to have committed himself irrevocably to the Liberals; even the Prussian conservatives, though Protestants, were turning against him. It was the climax of the liberal era.

Foreign Policy, 1871–78.—Bismarck assumed in *1871* that, with the defeat of France, a long period of peace would follow. The only danger seemed to be the French desire for revenge. Hence he encouraged republicanism in France, in order to create an ideological gulf between the republic and the two eastern empires. With these empires he revived the conservative partnership of the Holy Alliance in a new form. This was the League of the Three Emperors, or *Dreikaiserbund,* constituted in *1873.* Impressive in title, it was never more than a vague expression of monarchical solidarity in fact. The league implied that the three empires, and especially Russia and Austria-Hungary, would settle their disputes peacefully. In reality it held together only so long as there nere no disputes.

Its weakness was shown in *1875,* even before the eastern question raised its head. Bismarck was on bad terms with the French government whom he accused of patronizing the German Roman Catholics; in addition he was offended at the reorganization of their army. In April a German newspaper published, on Bismarck's instructions, an article entitled "Is War in Sight?" Probably he wished only to shake the French nerve and to underline the Centre's association nith the "foreign enemy." The French, however, raised the alarm and appealed to the great powers. Austria-Hungary did not respond—the first open symbol of Vienna's new dependence on Berlin. Both Russia and Great Britain protested in Berlin and Bismarck had to repudiate his own words. The eastern crisis, which began in July *1875,* raised more serious difficulties. Germany had no direct interests in the near east. and during the Crimean War Bismarck had been the most emphatic advocate of neutrality, or even of giving Russia diplomatic support. But then the main canflict had bren between Russia and the western powers. Sow France kept an attitude of reserve; Great Britain took the lead against Russia, and Austria-Hungary showed an increasing inclination to go over to the British side. Bismarck, at first. followed the French example and turned his back on the crisis. In Dec. *1876* he declared that the whole of the near east "was not worth the bones of a Pomeranian grenadier." His only concern was to keep Russia and Austria-Hungary on good terms and he succeeded until the autumn of *1876.* Then the Russians foresaw that they would be driven to war against Turkey for the sake of the Balkan Slavs; and they appealed to Bismarck to keep Austria-Hungary neutral, as they claimed (with some exaggeration) to have kept that monarchy neutral in *1870.* Bismarck refused: he would not allow either Russia or Austria-Hungary to be destroyed as a great power.

The crisis reached its height in March *1878* when the Russians abandoned their moderate plans and imposed the treaty of San Stefano on the Turks. Great Britain threatened war; Austria-Hungary would not promise peace. Bismarck acted as "honest broker" and brought Russia and Great Britain to a compromise. He could rightly claim to be the main architect of the peaceful settlement between them, which was confirmed by the congress of Berlin (June *1878).* He presided and this seemed to symbolize his paramount position as mediator betneen the great powers. All the same, the congress of Berlin marked the turning point in Bismarck's diplomacy. Hitherto he had believed that Germany could secure peace by keeping out of the combinations of the great powers; after *1878,* he tried to achieve the same aim by having a finger in every pie.

The Austro-German Alliance.—The eastern crisis of 1875–78 destroyed Bismarck's faith in monarchical solidarity. In addition it made him regard Russia as too unstable to make a reliable ally. He decided, with great reluctance. to commit himself to the defense of Austria-Hungary. William held out against the alliance with Austria-Hungary until Bismarck forced his hand by threatening his resignation and that of all the Prussian ministers. The alliance followed logically enough from Bismarck's policy in *1866.* Then he had refused to destroy the Habsburg monarchy; now, therefore, he had to guarantee it against foreign danger. At the same time he still hoped to keep out of Austria-Hungary's Balkan adventures. The alliance was strictly defensive, limited to a direct attack by Russia, and Bismarck even made out (with some truth) that it brought advantage to Russia. in that Austria-Hungary would no longer be tempted to work with Great Britain. He said to the Russian ambassador, "I wanted to dig a ditch between her and the western powers."

The alliance was something of a conjuring trick: it preserved Austria-Hungary without supporting Austro-Hungarian policies. But suppose Austria-Hungary should take the risk of an aggressive Balkan policy, of which Germany disapproved? This was the insoluble problem which Bismarck left to his successors. Previously alliances had only been concluded as preparation for a war, or on its outbreak; now Bismarck tried to make international relations rigid. He himself regretted this later, and advised his successors not to take their treaty obligations literally; every treaty, he said, contains the unwritten clause, *rębus sic stantibus*.

Breach With the Liberals.—The Austro-German alliance was signed on Oct. 7, 1879. It marked the beginning of a new period of conservatism in Bismarck's foreign policy. The same change had already taken place in his policy at home. Until 1877 he continued to work with the National Liberals. Then fiscal, economic and political factors turned him against them. The existing taxes did not cover the cost of the armed forces; and the deficit had to be met by "matricular contributions" from the states. Bismarck wished to escape this dependence; on the other hand, he did not wish to increase the power of the *Reichstag* by introducing direct taxation in the empire. Indirect taxes were voted for an indefinite period; therefore, once granted, the *Reichstag* would have no more control over the military expenditure than the Prussian parliament had had after 1862. The National Liberals foresaw this danger and they would agree to more indirect taxation only if they received "constitutional guarantees." In Dec. 1877 Bismarck invited Rudolf von Bennigsen, the leader of the National Liberals, to become a Prussian minister and virtually his deputy. Bennigsen insisted that the invitation must be extended to two other National Liberals. Bismarck had planned to take Bennigsen prisoner. Instead the National Liberals threatened to turn Bismarck into the figurehead of a parliamentary ministry. He broke off the negotiations and on Feb. 22, 1878, announced his intention (never in fact achieved) of introducing a tobacco monopoly. This was his first breach with the National Liberal policy, and it ended the plan of giving the German empire a parliamentary ministry.

The breach with the National Liberals soon widened. In June 1878 an attempt was made to assassinate William I. Bismarck at once dissolved the *Reichstag* and launched an anti-Socialist campaign designed to hit the National Liberals on the rebound. They either had to renounce their liberal principles or be branded as the supporters of assassins. They lost 30 seats in the election and then tried to get back into Bismarck's favour by voting for the anti-Socialist bill after all. He was, however, intent on destroying them as a political force. In March 1879 he made his peace with Windthorst, the Centre leader, and at once began to undo the measures against the Roman Catholics, despite his early boast that he would never "go to Canossa" (where the emperor Henry IV submitted to the pope in 1077). His basic reason for the *Kulturkampf* had been to create some target for national resentment. Now the Socialists filled the role even better. Furthermore, the Centre drew its main strength from the peasant-farmers of western Germany. They sympathized neither with liberalism nor—what was more important—with free trade. Reconciliation with the Centre was the preliminary to protection, and this was the essential change which took place in Bismarck's policy in 1879.

The initial impulse was the decline in agricultural prices which hit all Europe at the end of the decade. Bismarck was determined to maintain the predominance of the agrarian classes—primarily of the Prussian Junkers, but also of the land workers who were supposed to make the best soldiers. Agrarian protection could not be carried by itself. Bismarck also introduced tariffs on manufactured goods, particularly on iron and steel. This satisfied the great industrialists of western Germany, who were henceforth ready to accept the Junker landowners as partners. The return to protection in 1879 was more than a change of policy. Hitherto protection had been the defensive weapon of backward countries. Germany, the most progressive industrial nation, took it up for aggressive purposes.

Protection completed the estrangement of the National Liberals. They had always cared more for *laissez-faire* than for individual freedom, and Bismarck challenged them at their most sensitive point. In 1880 the party split. the more advanced members gradually drawing toward the Progressives. The National Liberal remnant became purely an interest group, representing the needs of heavy industry.

Bismarck's maneuver was not altogether successful. He had destroyed the National Liberal majority without putting anything else in its place. The remaining National Liberals were in a minority even when the two Conservative groups joined them. In fact the Centre held the decisive position and it could defeat Bismarck's measures if it voted with the Progressives and the Social Democrats. His *Reichstag* policy between 1879 and 1890 all turned on this point: he had no solid party on which to rely, yet would not accept the open partnership with the Centre that was the only alternative. Hence he had to invent alarm cries, imaginary panics with which to stampede the electorate. The "social peril" had been the cry of 1878; it failed to work satisfactorily in 1881. Bismarck had to call in, first, colonial disputes in 1884 and then foreign dangers in 1887. Both were risky expedients which could not be repeated, and in 1890 Bismarck found himself once more without a majority.

Social Security.—Bismarck did not rely only on repression to defeat the Social Democrats. He was the first statesman in Europe to devise a comprehensive scheme of social security, offering the worker insurance against accident, sickness and old age. This Bismarckian "socialism" later became a model for every other country in Europe. It represented in part the paternalist function of the state which Bismarck, as a conservative, had always held. But no doubt its prime function was as a weapon against the Social Democrats. It is commonly held that it failed of this purpose. The Social Democrats continued to increase despite both persecution and state insurance. Bismarck himself confessed in 1890 that he had failed and wished to establish a military dictatorship in order to crush the Social Democrats. But in a deeper sense he succeeded. The Social Democrats ceased to be a revolutionary party; and, when a mortal crisis came in 1918, they alone preserved the empire as Bismarck had created it. This was his last and most unexpected achievement.

Foreign Policy and the Colonies, 1879–85.—Bismarck had not meant to commit himself exclusively to Austria-Hungary when he made the alliance of 1879. Rather he desired to renew good relations with Russia on a conservative basis. This was not difficult. The Russians asked only for security in the near east; and the Austrians gave up hope of alliance with Great Britain when the Liberals came to power there in 1880. The League of the Three Emperors was renewed (June 1881). This was both a conservative partnership, echoing the phrases of the Holy Alliance, and a pact of practical co-operation in the near east. guaranteeing Russia security at the Straits. Austria-Hungary assented to the league unwillingly: Vienna had a deep distrust of Russia which could never be surmounted and would have preferred an anti-Russian alliance with Italy and Great Britain. Bismarck, to satisfy the Austrians, agreed to a Triple Alliance with Italy (May 1882). This gave Austria-Hungary a guarantee at least of Italian neutrality in the event of war with Russia; in exchange Bismarck had to promise to defend Italy against France. This system of alliances—further extended to Rumania in 1883—was strictly defensive and aimed at preserving the general peace of Europe. But, like the earlier League of the Three Emperors, it depended on Russia and Austria-Hungary remaining pacific and conservative in the Balkans; and it threatened to break down when new difficulties occurred there in 1885.

Bismarck's colonial venture was closely connected with his other policies. He had always repudiated interest in colonies. Pointing to Russia and France, with Germany in the middle, he said, "Here is my map of Africa." In 1884, however. he flung himself into colonial disputes with Great Britain and in the course of a single year acquired for Germany the Cameroons, South-West Africa, east Africa and part of New Guinea. His motives have been much debated. He certainly had close connections with the great trading firms of Hamburg and welcomed an occasion to estrange them from England and English liberal ideas. Moreover,

he needed a cry with which to fight the election of 1884, and hostility to England seemed as good as any. He himself, as he grew older, clung ever more persistently to office. The old emperor could not last much longer; and Bismarck feared that when the crown prince succeeded a liberal ministry would be set up. He was constantly on the match for this imaginary "German Gladstone ministry" and sought to drive out of public life anyone who might qualify as a member of it. But the crown prince could not himself be driven out; therefore he had to be isolated and preparations had to be made to discredit him. Since he had an English wife, England had to be presented as hostile to Germany.

Colonial ambitions also served the needs of Bismarck's foreign policy. He made a determined effort to be reconciled to France, while the eastern question was quiescent. He would not, of course, return Alsace-Lorraine, though he made misleading apologies for the annexation; but he offered to support the French anywhere else in the world. They suspected, however, that he was pushing them into conflict with Great Britain; and to lull these suspicions Bismarck trumped up disputes of his own with the British, in order to be able to convince the French that he had common interests with them. This policy had a certain success, so long as Jules Ferry, the great advocate of colonial expansion, was prime minister in France. But even Ferry did not intend a permanent reconciliation with Germany, though he used Bismarck's co-operation to further his colonial plans; and the policy broke down altogether when he fell from power on March 31, 1885. Bismarck then patched up his disputes with Great Britain and soon repudiated all interest in colonies. In 1889 he declared, "I am not a colonial man."

The Army Bill.—The calm which had followed the Congress of Berlin was broken in 1886. In the near east a new crisis was caused by the unification of Bulgaria. In France Georges Boulanger appeared as the leader of a patriotic movement agitating for revenge. Bismarck used this crisis both to strengthen his position in the *Reichstag* and to give his foreign "system" a new form. The septennate, passed in 1880, was running out. Bismarck exaggerated the danger from France in order to justify an increased grant; moreover, by emphasizing the French danger, he could distract attention from Russia, which was his real anxiety. Finally he hoped to secure a new *Reichstag* more favourable to himself and thus get additional security against the accession of the crown prince. The parties in the *Reichstag*, including even the Progressives, were ready to agree to the proposed army increases but would grant them only for three years. This gave Bismarck the excuse for a conflict, which he deliberately provoked. In Nov. 1886 the *Reichstag* authorized the army bill for three years only. It was at once dissolved. Bismarck persuaded the Conservatives, the Free Conservatives and the National Liberals to form an electoral cartel on a so-called patriotic basis. Even Bennigsen, who had retired from politics in despair, was induced to return in order to defend the national cause. These tactics were successful. The Progressives lost half their seats, although the Centre was not shaken. The army grant was duly passed for seven years; and Bismarck had a *Reichstag* ready to support him in anything. As soon as the election was over, Bismarck minimized the danger from France and worked to remove the tension which he himself had largely created.

Austria and Russia: the Reinsurance Treaty.—Bismarck's real anxiety was not an attack from France, which Germany could easily defeat, but a conflict between Russia and Austria-Hungary in the near east. He urged the two countries to partition the Balkans, but Austria-Hungary would never agree to this. Bismarck was determined not to fight a war for Austria-Hungary's Balkan interests, let alone for the preservation of Turkey. He therefore provided Vienna with other allies who would bear the responsibility for him. In 1879 he had worked to separate Austria-Hungary from Great Britain; now he worked to bring them together. The two Mediterranean agreements (March and December 1887) between Austria-Hungary, Great Britain and Italy were made under his auspices. By them the three powers agreed to maintain the *status* quo, particularly in the eastern Mediterranean.

Yet at the same time Bismarck himself made a secret agreement with Russia which deprived this coalition of much of its effect. The League of the Three Emperors, renewed for three years in 1884, ran out in 1887. The Russians, on bad terms with Austria-Hungary, would not again renew it. They suggested a new agreement with Germany alone. Bismarck accepted this, but revealed to them the Austro-German treaty of 1879 by which he would have to aid Austria-Hungary if Russia attacked it. The Russians countered by refusing to remain neutral if Germany attacked France. With these two exceptions, a treaty promising neutrality in the event of mar was concluded in June 1887. This "Reinsurance" treaty had a further clause by which Germany promised Russia diplomatic support in Bulgaria and at the Straits—the points on which the powers of the Mediterranean agreements were combined against Russia.

The Reinsurance treaty may have made the Russians feel less isolated in the near east and so deterred them from any violent impulse; but there is no good evidence that the Russians ever contemplated war there in 1887. Bismarck later made a much greater claim: the Reinsurance treaty, he insisted, had kept Russia away from France, and the failure to renew it in 1890 caused the Franco-Russian alliance. This was an unjustified exaggeration. The Russians had little confidence in German policy even after the treaty; and it was the French who held back from alliance in 1887. Bismarck's economic policy itself helped to defeat his diplomacy. The rising German tariffs on Russian grain estranged the great Russian landowners; and when Bismarck closed the German market to Russian bonds in Nov. 1887, he drove the Russians to look to Paris for money instead.

Frederick III.—In March 1888 there came the catastrophe which Bismarck had long dreaded: William I died, and the crown prince succeeded as Frederick III. The liberal era seemed to have arrived. But the new emperor was already a dying man, and Bismarck had taken his precautions. Frederick III and his wife were surrounded by Bismarck's creatures, who cut them off from contact with the remaining liberal politicians. Bismarck remained securely in office. Only one reactionary minister, Robert von Puttkamer, was dismissed. Yet Bismarck was not satisfied. He launched a violent press campaign against Alexander of Battenberg, the former prince of Bulgaria, in the quite unfounded belief that the emperor was planning to make him chancellor. Bismarck even appealed to the Russian government, though in vain, to threaten war if Alexander were nominated. These pathological alarms were ended only on June 15 when Frederick III died.

William II and Bismarck's Fall.—Bismarck had taken no precautions to make the new ruler, William II, amenable; on the contrary, he had encouraged him in insubordination, as a preliminary to playing him off against his father. Still, Bismarck's position seemed unshakable. He had no political rivals, and in 1886 had made his son Herbert (born 1849; Graf von Bismarck-Schönhausen from 1871) secretary of state, in order to gain unchecked control of foreign affairs. Herbert had all his father's violence without his skill and encouraged him in the worst courses. Bismarck set out to take William II prisoner, as he had taken William I prisoner in 1862. His only method of governing was to raise the cry, "the *Reich* in danger," and he intended to provoke a crisis so grave that a dictatorship would have to be set up, with himself as dictator and William II as a helpless puppet. But William II was a more skilful politician than his grandfather, and he understood the new Germany better than Bismarck. He was not prepared to be estranged from the mass of his subjects; he believed, not altogether wrongly, that the Social Democrats would cease to be dangerous if they were treated with conciliation. He preached a policy of social reform, including factory legislation and recognition of the trade unions. In his own words, he wanted to be a *roi des gueux* ("beggars' king"). He also advocated a demagogic foreign policy. He repudiated Bismarck's cautious policy of keeping Russian friendship and refusing to support Austria-Hungary. Instead he wanted alliance with Great Britain, unrestricted backing to Austria-Hungary, and a large-scale promotion of German economic interests in the near east. Bismarck did not openly oppose this policy.

The crisis centred on the anti-Socialist laws, which were due

to expire in 1890. The Conservatives wished to renew them without alteration; the National Liberals demanded a slight modification. Bismarck made no attempt to reconcile them. In fact, as he admitted, he wanted the bill to be rejected and then "the waves would mount higher and higher until a catastrophe occurred." The National Liberals insisted on their amendment. The Conservatives thereupon voted against the bill as a whole and it was defeated with the aid of the radical and Social Democratic opposition on Jan. 25, 1890. The *Reichstag* was at once dissolved. The general election of Feb. 20 brought defeat to the Bismarckian parties. The Progressives, the Social Democrats and the Centre together had a strong majority. Bismarck welcomed the crisis. He proposed to carry out a *coup d'état*. The German princes, who had made the empire, should now declare that it was dissolved; and a new constitution should be drafted, abolishing universal suffrage and reducing the powers of the *Reichstag*. William II refused to follow this path; he would not, he said, stain the first years of his reign with the blood of his subjects. Bismarck attempted to isolate the emperor. He revived a royal order of 1852, which forbade the ministers to advise the emperor except in the presence of the prime minister, and he appealed to the ministers to threaten a joint resignation, as they had done in 1879. But times had changed. Bismarck was old, William young, and the ministers had their careers before them. Only Herbert Bismarck stood by his father.

At the last moment Bismarck tried to turn foreign policy to his advantage. He claimed that the Russians were willing to renew the Reinsurance treaty only if he remained in office. William II refused to be taken prisoner. On March 18 he demanded Bismarck's resignation. Bismarck drafted a letter of resignation, emphasizing only the differences in foreign policy and blaming William for the estrangement from Russia. He arranged that this letter should be published on the day of his death.

Last Years. — No one but Herbert went with Bismarck into retirement. Bismarck was an implacable foe. He never forgave an injury, even an imaginary one, and refused to use the personal title of duke of Lauenburg that the emperor conferred on him when he retired. His last years were devoted solely to discrediting William, though the emperor made many efforts at reconciliation. Bismarck used every weapon in this last campaign. In a speech at Leipzig in 1892, he criticized imperial influence and urged the German people to make the empire more democratic, although he had spent his life thwarting their democratic wishes. This demagogic appeal did not work. The German masses rightly regarded Bismarck as their enemy, and the left-wing parties even managed to prevent an address of congratulation to Bismarck from the *Reichstag* on his 80th birthday in 1895. Bismarck then swung back to the extreme right and ended up, as he had begun, as a violent Junker. He emphasized his claim that he had built and maintained good relations with Russia which his successors had destroyed. In 1896 he even published the text of the Reinsurance treaty — a breach of official secrecy for which any lesser man would have been prosecuted.

His main energy in these last years went into the composition of his *Reflections and Rerniniscences,* a work of great literary genius though of doubtful historical value. He increased the drama of every event and always presented himself in a favourable light. Bismarck died at Friedrichsruh on July 30, 1898, about three years after the death of his wife. He carried his feud with William II to the grave, for the inscription on his tombstone, which he devised himself, read: "A True German Servant of the Emperor William I."

Herbert Bismarck had entered the *Reichstag* in 1893, where he acted as a member of the extreme right. He advocated high agrarian protection and alliance with Russia, opposed colonial expansion, and became increasingly anti-British. During the South African War he was one of the most unscrupulous pro-Boers. He died in 1904 and with his death the challenge of the "Bismarckians" to William II came to an end.

Estimate. — Bismarck was a political genius of the highest rank, but he lacked one essential quality of the constructive statesman: he had no faith in the future. The revolutions of 1848 convinced him that the old order could not be preserved unchanged, and all his later policy was shaped by this conviction. He went with the modern forces of liberalism and democracy solely to draw their sting. Like Metternich he regarded them as evil; unlike Metternich he turned them to his own purposes. He is sometimes compared with the leaders of the English governing classes, who under Sir Robert Peel also made a compromise with liberalism and democracy. But there was a basic difference. In England there was a genuine compromise; in Germany only a trick. The German people were defrauded, given a shadow instead of the substance.

Bismarck was at his greatest in foreign policy. There he understood, as no one else did, "the art of the possible." He never aspired to dominate Europe; he was content to balance between the great powers. Though he had no moral objection to war, he preferred to get his way by diplomacy and went to war only for limited aims, when it was necessary to his policy. The system of alliances which he built up was designed to secure the peace of Europe; and he played the powers off against each other with matchless skill. In fact, though no believer in eternal peace, he was the principal architect of the halcyon age that gave Europe 30 years of peace after the congress of Berlin.

In domestic affairs his record is less inspiring. He had a lust for power which grew on him with the years. He wanted Prussia to be supreme in Germany. He wanted the king to be supreme in Prussia; but, most of all, he wanted to be supreme over the king. His boasted loyalty to the crown vanished as soon as William II showed signs of independence; but he was equally ruthless, though more subtle, with William I. He spoke contemptuously of the old emperor's intelligence and did not shrink from the most unscrupulous tricks in order to keep his hold. His suspicion of possible rivals was unbounded, and he persecuted them out of public life one after the other. In his latter years all his energies went into the search for the "German Gladstone cabinet," which he was convinced was being prepared against him, a search all the more degrading in that this cabinet was always a creation of his imagination. He battered down any politician who dared to cross him even in trifles, and refused to allow the *Reichstag* to pay a posthumous tribute to Edward Lasker, a sincere National Liberal who had done much for the empire but had shown some independence. Yet Bismarck himself changed course whenever it suited him. He repudiated old friends and old policies without scruple and often showed the disloyalty which he denounced in others. He lived in the age of democracy and German power, and he devoted his life to making these two forces as harmless as possible. Despite his ringing, self-confident phrases, he was at heart a despairing conservative, caring only for the past, dreading the future and trying to retard its arrival. Gladstone said of him, "He made Germany great and Germans small."

BISMARCK, the capital of North Dakota, U.S., and the seat of Burleigh county, on the east bank of the Missouri river in the south central part of the state.

The present townsite, named for the then German chancellor Otto von Bismarck was laid out by the Lake Superior and Puget Sound company in 1873 when the Northern Pacific railroad laid rails as far as the Missouri. It remained the western terminus of that railroad until 1879 and a river steamboat port until commercial navigation ceased on the upper Missouri.

In 1883 the capital of Dakota Territory was moved from Yankton to Bismarck. When the territory was divided and became two states in 1889 Bismarck became the capital of the northern state. The city has retained a governmental and political aspect, and more than one-fourth of the working population is employed by county, state and federal governments.

Situated in a spring-wheat area and ranching country, Bismarck is a centre for the distribution of grain and the marketing of livestock. Many oil companies and firms serving the industry established offices in the city following the discovery of oil in the Williston basin in 1951.

In addition to the public and parochial school systems in Bismarck there are a junior college, a commercial college and an aviation school. It is a regional medical centre with several clinics and hospitals. The local public library, the medical libraries of the clinics, the state law library, State Library commission and State Historical Society library provide service to residents of the city and state.

Points of interest include the skyscraper capitol completed in 1933, the State museum and old Camp Hancock, now a museum. South of Bismarck are "new" Ft. Lincoln and the Annunciation priory. Across the Missouri is Ft. Abraham Lincoln, former headquarters of George A. Custer and the U.S. 7th cavalry.

For comparative population figures see table in NORTH DAKOTA: *Population.* (MA. RO.)

BISMARCK ARCHIPELAGO, a group of islands northeast of (and formingpart of) the Australian Trust Territory of New Guinea (see NEW GUINEA: *History).* Area 19,173 sq.mi. Native pop. (1954 est.) 144,073'. Most of the area and population are comprised in the two islands New Britain and New Ireland. The islands are in general of volcanics or raised coral limestone, and are heavily forested. The main economic resource is copra, with some lumbering and in recent years an important development (largely in native hands) of cocoa. This has taken place especially on the Gazelle peninsula (northeast New Britain), which, with New Ireland, is by far the most developed area. Rabaul, on the drowned volcanic caldera of Blanche bay (Gazelle peninsula), is the chief town. The archipelago, with the northeast of the mainland New Guinea, was annexed by Germany in 1884, and occupied (after token resistance at Rabaul) by Australian forces in Sept. 1914. The area was the scene of a military and naval campaign during World War II leading to the reduction of Rabaul, a Japanese stronghold. (O. H. K. S.)

BISMUTH is the elementary substance of the highest atomic weight in Group V of the periodic table; the other members of the group are nitrogen, phosphorus, arsenic and antimony. Bismuth is the most metallic of the group in both physical and chemical properties and is a coarsely crystalline, brittle metal having a high metallic lustre and is tin white in colour with a slightly pinkish sheen which readily distinguishes it from antimony.

HISTORY

This element, though not abundant, was described in writings attributed to Basil Valentine, who supposedly lived in the 15th century (*see* ANTIMONY) and on account of its brittleness it was regarded as a half metal. Georgius Agricola in the 16th century regarded it as a true metal and distinct from metals such as tin. lead and antimony. J. H. Pott (1739) first demonstrated the characteristic properties of bismuth, and its reactions were later studied by S. F. Geoffrey (1753) and by T. Bergman (1780). The name bismuth is supposed to be derived from the German *Weissmuth,* "white matter."

PHYSICAL AND CHEMICAL PROPERTIES

The symbol of bismuth is Bi. atomic number 83, atomic weight 209. The usual valence is +3 and +5. Its crystals belong to the rhombohedra1 division of the hexagonal system. The constant physical and chemical properties of bismuth are given in Table I.

TABLE I.—Properties of Bismuth

Atomic number	83
Atomic weight	209 00
Boiling point	1,477° C. (2,691° F.)
Crystal structure	Rhombohedral hexagonal
Density at 20° C. (68° F.)	
g./cc.	9.80
lbs./cu.in.	0.354
g./cc. (molten)	10.007
Electrical resistivity (microhm-cm.)	
(solid) 0° C. (32° F.)	106.8
(liquid) 390° C. (572° F.)	129.0
(liquid) 780° C. (1,382° F.)	153.5
Electrochemical equivalent	
Bi +++ (mg./coulomb)	0.433 16
Electrode reduction potential	
Bi +++ (H_2 = 0.0 v.)	0.22
Latent heat of fusion (cal./g.)	12.5
Latent heat of vapourization (cal./g.)	204.3
Linear coefficient of thermal expansion/° C.	13.3×10^{-6}
Mechanical properties	
Brinell hardness	7.0
Modulus of elasticity, p.s.i.	6,000,000
Melting point	271.3° C. (520.3° F.)
Nuclear data	
Stable isotope (320)	I
Thermal neutron cross section (2,200 m/s)	
Absorption (barns)	0.032
Scattering (barns)	9±1
Solidification expansion	3.32%
Specific heat (cal./g./° C.)	
(solid) 20° C.	0.0294
(liquid) 271° C.–400° C.	0.0340
Specific volume (cc./g.)	
20° C. (68° F.)	0.102
Surface tension (dynes/cm.)	
300° C. (572° F.)	376
500° C. (932° F.)	363
Thermal conductivity (cal./sq.cm./cm./° C./sec.)	
20° C.	0.020
300° C.	0.041
700° C.	0.037
Valence	3, 5
Vapour pressure (mm. hg.)	
917° C. (1,683° F.)	1.0
1,200° C. (2,192° F.)	100
1,400° C. (2,552° F.)	490
1,477° C. (2,691° F.)	760

There are 19 recognized isotopes of bismuth ranging in mass numbers from less than 198 to 215. Bismuth as commercially used is isotope 209. Although listed as a stable isotope, it is thought to be a radioactive alpha emitter of extremely long half life (3×10^{17} years). The isotopes from 210 to 214 are members of radioactive decay chains. The natural isotopes 210, 211, 212 and 214 occur in natural chains as shown in Table II. The isotope 213 is a member of the Neptunium series. Its half life is 46 min., major radiation: Alpha 5.9 Mev, Beta 1.2 Mev.

Bismuth is one of the few elements which expand (3.32%) during solidification. It is also the most diamagnetic of all metals. The electrical resistance increases with pressure and decreases with tension. The metal does not become a superconductor at the temperature of liquid helium. The thermal conductivity of solid bismuth is less than that of any other metal except mercury.

Reactions. — Bismuth oxidizes superficially on exposure to moist air, but if heated to high temperature it burns forming Bi_2O_3. Bismuth decomposes steam at a red heat but it is not affected by cold air-free water. The metal unites directly with the halogens fluorine, chlorine, bromine and iodine, and with sulfur. The halides of arsenic, antimony and bismuth are isomorphous. It does not form a hydrogen compound whereas antimony and arsenic form trihydrides. Bismuth is readily attacked by dilute and concentrated nitric acid forming bismuth nitrate $Bi(NO_3)_3$. It is sparingly soluble in hot sulfuric acid forming bismuth sulfate $Bi_2(SO_4)_3$ and sulfur dioxide, and also is but slightly attacked by hydrochloric acid.

TABLE II.—*Natural Isotopes of Bismuth*

The photometer is extensively used for determination of bismuth, whereby thiourea is added to nitric acid solutions of bismuth producing a yellow colour. The method is very accurate for determination of low bismuth values. The spectrograph also serves as a very sensitive means for determination of bismuth and is very accurate for values under .05%. For spectrographic work the lines 3,067.716Å and 2,897.975Å are used for accurate readings.

The analytical separation of bismuth in a complex mixture can be made by precipitation of the bismuth in an acid solution by means of hydrogen sulfide whereby bismuth, copper, lead, arsenic, antimony and tin are precipitated as sulfides.

By means of using an alkaline sulfide the bismuth, copper and lead are precipitated and separated from arsenic, antimony and tin which are removed in solution. The solubility in nitric acid separates it from mercury and subsequent additions of sulfuric acid precipitates any lead present. The bismuth can be precipitated as an oxychloride in the presence of lead by adding hydrochloric acid or salt to a weak nitric acid solution of bismuth. The oxychloride is washed. dried and weighed as the oxychloride and the determination calculated.

The bismuth oxychloride method is used for accurate determination of bismuth in excess of .2%. In determination of bismuth in lead bullions, generally the lead buttons are scorified in order to remove the impurities followed by the oxychloride precipitation method eliminating the use of the sulfide separation.

USES

Pharmaceuticals. — Bismuth is an essential ingredient in many pharmaceutical compounds. Bismuth subgallate is used for skin injuries and infections, bismuth subsalicylate is used for alimentary disorders and bismuth subcarbonate is used to treat intestinal fermentation and irritation. This same compound is used for outlining the alimentary canal for X-ray examination.

Alloys. — Another important use of bismuth is in the manufacture of solder and alloys having low melting points (see also SOLDERING).

In addition to the alloys shown in Table III there is an infinite number of combinations of bismuth with one or more of the metals which may vary in melting range and physical properties.

Prior to 1930 the major use of bismuth alloys was as a low melting point alloy in automatic sprinkler heads and fire door release lines, and as the fusible element in safety plugs for compressed gas cylinders and fire-detection and temperature-control equipment.

Since the early 1930s many applications have been made in industry. such as anchoring complex punches and dies. and producing accurate patterns and intricate shapes and parts that are not efficiently or accurately producible by other means. Electroformed articles whose internal dimensions must be extremely accurate and of high surface finish. require cores, or mandrels. with properties like those possessed by certain alloys of bismuth, that can be melted out after the electroforming process is complete.

The addition of small amounts of metallic bismuth to molten iron. both gray and white iron, is made in order to produce cleaner castings. Small amounts of bismuth are added to corrosion-resistant steels to produce castings of greatly improved machinability.

Bismuth-cadmium alloys have been widely used as the counter-electrode in selenium rectifiers. The alloy is sprayed on the selenium surface and the interface between the selenium and bismuth-cadmium alloy is the locus of rectification and its constitution mainly controls the properties of the rectifier.

Magnets. — A new magnetic material. a chemical compound of manganese and bismuth having the formula MnBi is reported to have ten times the resistance to demagnetization of that of most of its rivals. This resistance. coming from a magnetic property called high coercive force prevents MnBi magnets from being adversely affected by external magnetic fields, suggesting their use in electric meters. It also makes possible a whole assortment of permanent magnets having novel shapes. (See also MAGNETISM: *Permanent Magnets.)*

Tellurium-bismuth-antimony alloys containing small amounts of silver. selenium. etc. have been developed for air conditioning and refrigeration installations, brought about by the so-called Peltier effect. uhich is a reversal of the thermoelectric phenomenon wherein instead of measuring temperature by the electromotive force developed. direct current is applied to the alloy to produce a cooling effect. This type of alloy may be used in converting solar energy directly into electrical form.

Atomic **Energy.**—With the advent of the nuclear age. great strides have been made in new uses for bismuth. In the solid state, bismuth is used in the nuclear field because of its high attenuation for gamma rays and its low capture cross section for thermal neutrons These characteristics permit its use as windows in nuclear reactors when it is desired to bombard external samples or treat patients with neutrons from the core. This is particularly applicable for neutron radiation in medical reactors.

In the liquid state, bismuth retains its low neutron characteristics. Uranium dissolves in liquid bismuth, thus providing the basis for a critical reactor. One of the concepts being developed was the use of bismuth in the Liquid Metal Fuel reactor (L.M.F.R.) whereby bismuth in liquid form acts as the carrier of uranium-235 and as the coolant. The fuel is a .1% solution of uranium-235 or -233 in liquid bismuth. The reactor is moderated with unclad graphite and operated at approximately 500° C. The design is

TABLE III.—*Bismuth Allays of Low Melting Point*

such that when the solvent (bismuth) containing the solute (uranium) is pumped through the graphite moderator. the fission of U^{235} or U^{233} reaches criticality and is therefore self-sustained. The heat generated by these fission reactions is transmitted to the liquid bismuth which is pumped through heat exchangers to produce steam. The fission products which interfere with the self-sustained fission reaction can be removed by continuous processing. The uranium lost in fission is replaced by converting thorium to uranium-233 by neutron capture. The reactor therefore produces its own fuel. (See also NUCLEAR ENGINEERING.)

OCCURRENCE

Bismuth ores are found over a wide area of the world. the early deposits being located in Saxony and Bohemia and the British Isles. In the second half of the 20th century the chief sources of bismuth ores are Korea, China, Bolivia, Argentina, South-West Africa, Union of South Africa, Uganda and Mozambique.

Some minor deposits are found in Mexico and the United States. All of these ores can be classified as sulfide, carbonate or oxide. with the bismuth sulfide ores being in greater supply. It is only on rare occasions that pure bismuth sulfide or oxide ores are available commercially; so-called commercial bismuth ores usually contain from 15% to 40% bismuth, and depending on the source of supply, the usual impurities contained are gold, silver, lead, copper, arsenic, antimony, tin. tungsten and selenium.

The supply of bismuth from commercial ore is relatively small as compared with the bismuth which is recovered from copper and lead ores. There are a number of lead-bismuth ores, copper-bismuth ores and mixed lead-and-copper-bismuth ores: however. in general the bismuth is present in copper and lead ores as bismuth sulfide. (See Extraction, below.)

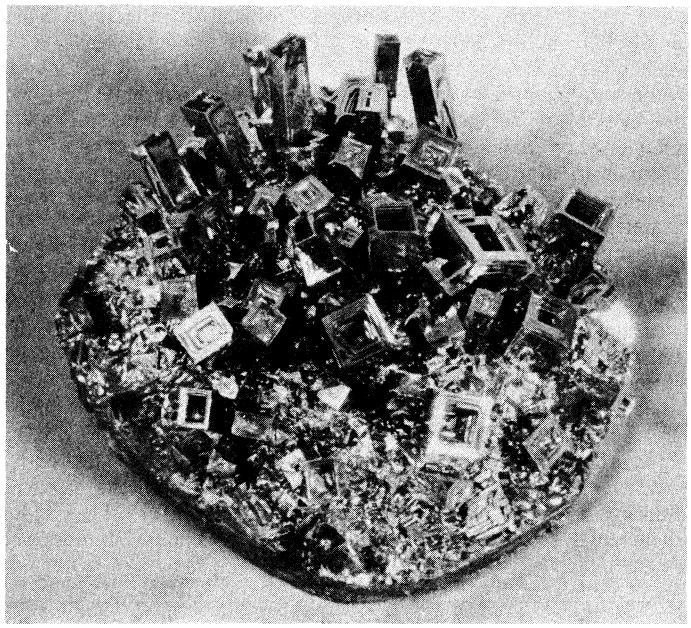
During the reverberatory smelting of copper concentrates the bismuth and lead are collected in the copper matte. During the subsequent copper converting treatment of the copper matte for production of blister copper, the major portion of the bismuth and lead is fumed off and collected as dust in either baghouses or electrical precipitators. The dusts are then transferred to plants smelting lead ores and thus the bismuth from copper ores becomes commingled with bismuth in lead ores and is recovered as an impurity in lead bullion during the lead smelting operations. The bismuth produced by Yugoslavia, Germany, Italy, Sweden, France, Japan and substantially all the bismuth produced in the western hemisphere, which together constitutes the major portion of the world bismuth production, for the most part originates in either lead or copper ores.

EXTRACTION

Recovery From Bismuth Ores.—Bismuth may be concentrated from bismuth ores by means of hydrometallurgical or pyrometallurgical processes. When bismuth is present as an oxide or carbonate, hydrochloric acid and a limited amount of water is employed to dissolve the bismuth in the finely crushed ore, followed by dilution with water whereby the bismuth precipitates as the white bismuth oxychloride. After mashing, redissolving in hydrochloric acid and reprecipitation, the bismuth oxychloride is filtered, dried and smelted with lime and carbon to metallic bismuth. Bismuth produced by this method usually contains small amounts of lead, silver and other impurities which can be removed by further refining. (See also Bismuth Refining, below.)

The bismuth sulfide ores may be roasted in order to remove the sulfur content, followed by smelting with carbon in crucibles or reverberatory type furnaces. Lime, soda ash or salt cake or fluorspar can be used to give further slags, and metallic iron is added to break up any bismuth sulfides. The products of smelting are metallic bismuth, matte or speiss and slag. The matte or speiss is reworked for recovery of occluded bismuth and the bismuth metal is impure and requires further refining.

In more modern installations the finely crushed bismuth sulfide is charged with caustic soda into suitable pots of two or three tons capacity which are externally heated and the molten bismuth is collected in the bottom of the pots, the sulfur reacting with the caustic forming soda mattes which are treated for any entrained bismuth. The impure bismuth again requires further refining.



BY COURTESY OF T. D JONES

BISMUTH CRYSTAL

Recovery of Bismuth from Lead Bullion.--With the exception of lead bullions produced from smelting lead ores from the Tri-State district (Missouri, Kansas, Oklahoma) and a portion of the Coeur d'Alene ore of Idaho in the United States, and Australian lead ores, in general all other lead bullions require debismuthizing in order to meet the bismuth specifications for fully refined lead.

Several debismuthizing processes have been employed over the years since 1900. In 1901 the Betts electrolytic lead process was developed, followed by the Betterton-Kroll alkaline-earth process (calcium plus magnesium) in 1930 and more recently the Jollivet Penarroya process (potassium plus magnesium), developed in France.

Betts Electrolytic Lead Process.—Lead bullion which may contain gold, silver, bismuth, copper, arsenic, antimony and other impurities such as selenium, tellurium, etc. are cast into anode form for electrolyzing. If excess copper and tin are present, these impurities are removed to low limits before anode casting takes place. Excess copper causes drossy lead and complicates the treatment of slimes, and tin will deposit on the cathode with the lead.

The impurities in the lead anodes are insoluble and remain on the anode as a slime blanket. When the corroded anodes have been removed from the electrolytic cells the slimes are removed by scraping, the hardness of the slimes depending on the amount of impurity in the bullion. The slimes are centrifuged and washed free of entrained electrolyte and are partially dried and melted in an oil or gas fired reverberatory furnace. A portion of the arsenic and antimony is removed in the smelting slag and the balance oxidized by blowing the bath with air; the fumes are collected in a baghouse.

When the bath is free of arsenic and antimony, it is transferred to a cupel type furnace where cupellation takes place by blowing air over the surface of the bath and the copper, lead and bismuth are oxidized and removed as a litharge slag, the dork metal (crude silver) remaining in the furnace for the production of gold and silver.

The bismuth-rich cupel slags are then transferred to a second reverberatory furnace and the copper removed either as a copper-antimony speiss or the crushed cupel slags are mixed with sulfur and reduced with carbon to produce copper matte.

The lead-bismuth alloy is then transferred to the bismuth department for production of refined bismuth.

Betterton-Kroll Process.—The Betterton-Kroll, or ASARCO, process has been used extensively since the 1930s for bismuth re-

moval from lead bullion by those plants not favoured with cheap power rates. The lead bullion is first softened, desilverized and dezinced by conventional methods and after dezincing, any zinc and antimony remaining in the lead bath is removed by the use of caustic soda.

The ASARCO process is based on the fact that calcium and magnesium form the higher melting compounds calcium bismuthide (Ca_3Bi_2) and magnesium bismuthide (Mg_3Bi_2), which are removed from the lead bath in the form of a dross. The calcium is added to the molten bath in the form of a 3% to 4% calcium alloy and the magnesium is added in the form of pure magnesium ingots.

The calcium and magnesium are added to the bath in equal amounts and range from 1.2 lb per ton for 0.1% bismuth in the lead to 3.1 lb. per ton when the bismuth is 1%. In actual practice, blocks of dross skimmed from the previous charge are added to the bath at 790° F., melted and mechanically stirred for a short period and thus become enriched and are skimmed off for the recovery of bismuth and transferred to a second kettle for further enrichment by removal of calcium and magnesium and entrained lead and made available for the bismuth refining operations. Following this operation the required magnesium is charged into a perforated basket and submerged beneath the surface of the bath and is slowly alloyed with the molten lead by impinging a stream of lead from a pump on the submerged magnesium. At the same time, the calcium alloy is added to the bath in the form of blocks and allowed to melt. These blocks, because of a lower specific gravity than lead, float on the surface of the bath.

After melting of both calcium and magnesium takes place, the basket is removed and a mechanical mixer is placed in position and the bath at 700° F. is stirred for 30 minutes and the mixer removed. The dross formed is skimmed to blocks and is used as first blocks on the succeeding charge. The metal bath is cooled to the freezing point and all dross removed. At this stage the bismuth in the lead has been removed to the desired limit, and the bath is treated for removal of residual calcium and magnesium.

Jollivet Penarroya *Process.*—This process is used at one plant in France and is based on the fact that potassium and magnesium form a compound with bismuth ($Bi_7Mg_6K_9$) which can be removed from the molten lead bath as a dross.

The reagent potassium (K) is made in a reactor composed of five compartments whereby sodium lead (NaPb) is introduced at one end and KOH at the opposite end. By counterflow, potassium lead and NaOH emerge at opposite ends of the apparatus. In actual practice the lead bullion previously fully refined, with the exception of bismuth removal, flows to a divider where one portion flows to a kettle for alloying nith magnesium: the second portion flons to the five-compartment apparatus named above for production of KPb.

The MgPb and KPb then converge with the third portion from the divider in a separate debismuthizing kettle equipped with a sealed cover. and progressive cooling begins. The dross formed rises to the surface and enters a hinged basket inside the cover. As the cover is raised, the dross is transferred to a second kettle and is treated with KOH formed in the process. A bismuth alloy containing approximately 16% is obtained and transferred for the recovery of bismuth.

BISMUTH REFINING

The alkaline earth bismuth-recovery processes will produce alloys containing from 16% to 40% bismuth and the slimes metal recovered in the Betts electrolytic process contains about 75% bismuth. Alloys recovered from smelting bismuth ores will contain bismuth in direct proportion to the bismuth content of the ore. Final steps in the bismuth refining process are fairly standard regardless of the origin of the bismuth.

The impure bismuth is melted in kettles which may have a capacity of two to ten tons of bismuth and treated with repeated additions of caustic soda and nitre to remove such impurities as arsenic, antimony. tin, selenium and tellurium. All of these impurities are removed to .0001% or less and in most cases to the fifth decimal place. If copper is present in unusual amounts it is removed by sulfur additions and the bath cooled and copper

TABLE IV.—*Typical Analysis of Drossed Lead Blast-Furnace Bullions at Various Smelters*

Constituent	Selby smelter, Selby, Calif.	Chihuahua smelter, Chihuahua, Mex.	Cerro de Pasco Copper Corp., Oroya, Peru	Consolidated Mining and Smelting Co., Trail, B.C.
Gold (oz./ton)	1.35	0.32	0.11	0.057
Silver (oz./ton)	117.02	115.0	90.0	64.9
Lead	95.855%	98.58%	96.8%	98.250%
Copper	0.020%	0.019%	0.21%	0.04%
Arsenic	0.09%	0.267%	0.135%	0.26%
Antimony	3.27%	0.400%	2.07%	1.17%
Tin	0.11%	0.016%	0.0012%	0.004%
Nickel and cobalt	nil	nil	nil	nil
Bismuth	0.25%	0.320%	0.65%	0.054%

removed to approximately .02%.

The above procedure is followed by zinc additions for the removal of gold, silver and remaining copper, and the number of zinc additions depends on the *doré* content of the bismuth metal. The desilverizing operation is very similar to desilverizing lead bullion, although on a much smaller scale. The bath is heated to approximately goo° F. and the calculated amount of zinc is added and stirred in by a mechanical mixer. The zinc drosses formed during the successive stages of cooling are skimmed off until the bath becomes frozen. If the bath is high in *doré* content then two zinc additions may be necessary. In this case the zinc skimmings from the second addition are usually added as first zinc for the next batch or lot of impure bismuth. After a thorough job of desilverizing the bath contains substantially only bismuth, lead and approximately .6% zinc.

The modern practice calls for chlorination of the zinc and lead in the molten bath, and the chlorine first combines with the zinc to form zinc chloride which is skimmed off. Continued chlorine additions are made to form lead chloride until the lead has been reduced to low limits. An operator usually knows nhen the lead has been removed as the chlorine begins to react with the bismuth forming bismuth chloride. which evolves from the bath as a dense fog of fume.

The deleaded bismuth is transferred to a very clean kettle where the bath is again refined with caustic and cast into shapes for market. This method of refining produces bismuth 99.99% pure and in most cases 99.999% pure.

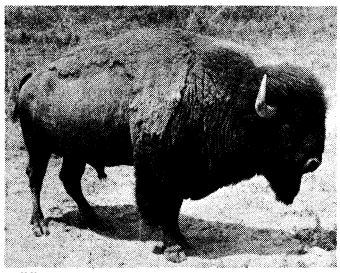
BISON, any member of the oxlike genus Bison of the family Bovidae. The bison differs from typical cattle or oxen by being larger and by having a convex forehead. larger legs, a pronounced hump at the shoulders and 14 pairs of ribs instead of 13. The fur is coarse and especially long on the head. neck and shoulders (the shoulders in winter only in the European species). forming a sort of cape. The head is carried low and cannot be raised to shoulder level. Both sexes bear heavy, curved horns. those of the cows being smaller. Bison are large, ponerful beasts; a mature bull stands 6 ft. tall at the shoulder and weighs more than 2.000 lbs.: a female is about 5 ft. tall and weighs about 700 lb. The coat is a sombre dark brown in colour but on rare occasions a white animal is born. White buffaloes mere once honoured, and even worshiped, by American Indians; their hides became valued tribal possessions.

Bison are long-lived animals; a breeding life of 40 years is common in females. They live in herds. the basic unit of which is a female. several generations of her descendants and one or more bulls Bulls seldom live alone Cons usually give birth to a single calf in May after a gestation of nine to nine and one-half months All members of the band protect the young. Bison will eat tree twigs and leaves. although they prefer grass. They



JOHN H. GERARD

AMERICAN BISON (BISON BISON)

feed in early morning and late afternoon, resting during midday and at night. The herd may remain in one location for several days and then, for no apparent reason, move in a purposeful manner to a new locality. At other times the herd may move more or less constantly in a seemingly aimless fashion. The usual gait is a plodding walk. They also trot, canter in a stiff-legged manner or run with a rolling motion. In spite of their bulk they are surprisingly agile and fast; they have been clocked at 40 m.p.h. Bison are unpredictable animals. Sometimes they can be approached closely without evincing alarm. At other times they stampede with the least provocation. It is never safe to approach them too closely.

There are two living species. The European species, *Bison bonasus* (wisent), sometimes erroneously called the aurochs (q v.), became rare by the 16th century and in the early 1960s only a few wild specimens existed in eastern Poland and Lithuania. It differs from the American species by living in woods, being slightly larger, having thicker, shorter and blunter horns and displaying different skull features. In historic times it lived in small bands in many forests of Asia and Europe including England. The young are born in seclusion in a dense part of the forest. The wisent is also known from Pliocene deposits of India and Java.

The American bison (B. *bison*), commonly called buffalo or plains buffalo, once occurred in great numbers over most of North America; a conservative estimate of their number when the white man arrived is 60,000,000, probably the greatest aggregation of large animals ever known to civilized man. The buffalo formed the mainstay of the economy of the Plains Indians, providing them with meat and hides for food, clothing and shelter. With the westward movement of civilization the "buffalo" was slaughtered with a wantonness seldom matched. First killed for meat and hides, then only for hides, sport and sometimes only for the tongue, they were soon decimated. One hunter alone, William F. Cody (*q.v.*), killed 4,280 animals in 17 months while supplying the beeflike buffalo meat for railroad construction crews and won the name of "Buffalo Bill." Much of the hostility between the Indians and the white man resulted from the depletion of the buffalo. The low point was reached around 1900 when the animals neared extinction. Concerted action by cattlemen and conservationists led by William T. Hornaday resulted in their protection on government preserves. The future of the buffalo now seems secure. The present managed herds now comprise several thousand animals.

The extinct B. *latifrons* occurred contemporaneously with early man in North America at the end of the Ice Age.

(K. R. Kn.)

BISSEXT (Bissextus), the intercalary day in February added every fourth year under the calendar reform of Julius Caesar (46 B.C.), to compensate for the three six-hour periods omitted during the three years of 365 days (the Julian year contains 365.25 days). The 24th day of February, at that time the sixth day before the kalends (or 1st) of March, was designated as *ante diem sextum kalendas Martias;* the intercalation resulted every fourth year in the repetition of this sixth day, *ante diem bis sextum kalendas Martias.* The ecclesiastical calendar preserves the Roman method of intercalation. The gradual acceptance, in medieval Europe, of the numbering of the days of a month in a continuous sequence, up to 30 or 31, led to Latin or vernacular designation equivalent to "the 29th day of February"; the extra day at the end of February became the bissext ("leap") day in bissextile ("leap") years. *See* Calendar; Leap Year. (A. Po.)

BISSOLATI-BERGAMASCHI, LEONIDA (1857–1920), Italian Socialist and statesman, was born at Cremona on Feb. 20, 1857. He mas an active member of the Italian Socialist party from its foundation in 1892 and exercised considerable influence as a journalist, editing the party's official organ *Avanti!* He entered parliament in 1897 and threw himself into the obstructionist tactics by which the Socialists opposed the antidemocratic legislation of Luigi Pelloux (1898). In 1902 he became a leader of the reformist group which criticized his party's abstention from government and wished to see the workers' organizations integrated with the fabric of the state. In 1911 he came into conflict with the party over his support of the war against Turkey and was expelled for refusing to oppose the military credits, whereupon he founded the Reformist Socialist group (1912). At the outbreak of World War I, when the official Socialist party was neutral, Bissolati declared himself an interventionist because he believed that the war would emancipate the subject nations. At the age of 58 he enrolled as a volunteer and was seriously wounded. He entered Paolo Boselli's national cabinet as minister without portfolio in June 1916 and became minister for war aid and pensions in Orlando's government (1917). He resigned in Dec. 1917 because of disagreement over the treaty of London. During the war Bissolati had advocated agreements with the subject nations under Austria; and after the armistice, on the Wilsonian principle of ethnic rights, he opposed the annexation of the Alto Adige and northern Dalmatia while he supported the annexation of Fiume (Rijeka) as a preponderantly Italian town. His attitude on the Tirolese and Dalmatian questions lost him much of his popularity, but his death, in Rome on May 6, 1920, was regretted as that of a true patriot.

See Ivanoe Bonomi, Leonida Bissolati e *il* movimento *socialista* in *Italia* (1945). (N. S. J.)

BITHUR, a former town in Kanpur district, Uttar Pradesh, India, lies on the Ganges 13 mi. N.N.W. of Lucknow, and though now ruined is still notable as a Hindu holy place. Pop. (1951) 2,577. The chief object of worship is a footmark held to be that of Brahma. There also is the Balmiki *ashram* or retreat. believed locally to have sheltered the saintly author of the epic *Ramayana.*

Deposed by the British in 1819. Baji Rao, peshwa (ruler) of the Marathas, kept court-in-exile at Bithur with about 15.000 retainers. But in retaliation for the part played by his adopted son Nana Rao Peshwa in the 1857 revolt (*see* Indian Mutiny), the British largely destroyed the town in 1858, blowing up its chief temple and palaces. (B. Si.)

BITHYNIA, an ancient region of northwestern Asia Minor, comprising part of modern Turkey. adjoining the Sea of Marmora, the Bosporus and the Black sea. On the east it bordered on Paphlagonia, on the west Mysia, and on the south Phrygia and Galatia. The country was divided into two roughly equal parts by the Sangarius (Sakarya) river, the less mountainous western half being the more populated. About the end of the 2nd millennium the region had been settled by Thracian tribes that had crossed from Europe. One of these tribes, the Bithyni, gave the country its name. Greek colonies were later established at various points on the coast, the Thracian peoples continuing in occupation of the interior. The Bithyni of historical times were a warlike people who frequently attacked the Greek settlers and harried the representatives of the Persian king, whose nominal subjects they became in the 6th century. They also became notorious for piratical activities They were led by tribal chiefs who later, in the 3rd century, took the title of king in imitation of Hellenistic practice. This dynasty ruled with considerable success over their small but powerful kingdom until Bithynia became a Roman province in 74 B.C.

Bithynia never submitted to Alexander the Great. When Lysimachus attempted to subdue it he was defeated by Zipoetes (327–*c.* 279 B.C.), who then assumed the royal title (298); later he won a victory over the Seleucid king Antiochus I. After Zipoetes' death his successors, Nicomedes I (c. 279–*c.* 255), Ziaelas (c. 255–230) and Prusias I (c. 230–182). using the methods of war and diplomacy, built up the kingdom into a considerable power. To help him in a family quarrel Nicomedes I in 277 brought over from Europe the Celtic marauders who caused havoc to Asia Minor in the ensuing decades. For Bithynia. however. they served as a useful shield against the Seleucid empire. Zipoetes' assumption of the royal title had been the signal that Bithynia had grown beyond the stage of tribal organization and that her

rulers aspired to take part in international politics. This was shown clearly when Nicomedes I entered into alliance with Ptolemy II of Egypt and with the independent Greek cities of Heraclea Pontica on the southern coast of the Black sea and Chalcedou at the southern entrance to the Bosporus. Later he named Ptolerny and Antigonus Gonatas of Macedonia among the guardians of his heir, Ziaëlas. The latter also professed friendship for the Greek cities. But the next king, Prusias I, made war on Byzantium and annexed the cities of Cius and Myrleia (on the Gulf of Cius; modern Gemlik), which Philip V of Macedonia (whose sister Apama he married) had destroyed in 202; he also took much inland territory from Heraclea. In a war with Pergamum he seized Mysia, and, after the defeat by the Romans of the Seleucid king Antiochus III at Magnesia in Lydia in 190 B.C., he gave refuge to the Carthaginian general Hannibal. He was, nevertheless, astute enough to abandon in time his defiance of Roman policy: Mysia was handed back to Eumenes II of Pergamum and Hannibal had to commit suicide (183). Under this king Bithynia attained to its greatest extent, an area estimated at 18.000 sq.mi. Later the power of the kingdom began to decline under less capable rulers, Prusias II (d. 149 B.C.), Nicomedes II (d. c. 127) and Nicomedes III (d. *c.* 94).

The last king. Nicomedes IV (c. 94–74), allowed himself to be used as a Roman pawn in the struggle between the Romans and Mithradates VI of Pontus. Twice driven from his throne, in 91 and 88, he was finally reinstated by L. Cornelius Sulla in 84. and on his death in 74 he followed the example of Attalus III of Pergamum by bequeathing his kingdom to the Romans. The Roman senate accepted the bequest, and after further conflicts with Mithradates the country was organized as a province. Its later history was comparatively uneventful. The Roman emperor Trajan sent Pliny the Younger to the province c. A.D. 111 as a special legate to check the mismanagement of their affairs by the self-governing Greek cities.

The land was richly wooded in its eastern part, and fertile and well populated in certain western districts. The Bithynian kings founded Nicomedia (modern Izmit) on the coast and Prusa (Bursa) at the northern foot of Mt. Olympus. Under the Romans the limits of the province were frequently varied, and it was often united for administrative purposes with the province of Pontus.

See A. H. M. Jones, Cities of the Eastern Roman Provinces (1937); D. Magie, Roman Rule in Asia Minor (1950). (R. H. Si.)

BITLIS, the chief town of the *il* (province) of Bitlis in south-eastern Turkey, lies 4,700 ft. above sea level and 16 mi. S.W. of Lake Van, in the narrow valley of the Bitlis cay, a tributary of the Tigris. Pop. (1960) 16.562. At the close of the 19th century the population exceeded 30,000, but because of the troubled years of World War I, the Russian occupation and the riots on the part of the Armenian minority it decreased to about 9,000 by 1922, when the Turkish War of Independence ended.

The climate is healthful but snowfalls are heavy, and narrow streets may be blocked for five months in the year. The main part of the town and the bazaars are crowded alongside the stream, while suburbs of scattered houses among orchards and gardens extend up the hillsides along two tributary streams. These houses are solidly built of a soft volcanic tufa. In the centre of the town is an old castle, partly ruined, which, according to local tradition, occupies the site of a fortress built by Alexander the Great. It is apparently an Arab 'building, since the walls carry Arabic inscriptions, and from its position on the main highway between the Van plateau and the Mesopotamian plain it must have been of strategic importance. Some fine old mosques and madrasahs (mosque schools) still exist. Roads link the town northward with Mus and Erzurum, eastward with Van. and southward with the railway at Misric (Kurtalan) (40 mi. S.W.).

Bitlis *il* (area 3.415 sq.mi.; pop. [1960] 129,125) includes the eastern corner of the Mus plain and the plateau west of Lake Van, and contains mild mountain country on either side of Bitlis town. Fruit is plentiful and there are vineyards. Tobacco of an inferior quality is grown and manna and gum-tragacanth are collected. The mountains have been little explored but are believed to be rich in minerals; iron, lead, copper, traces of gold and many mineral springs are known to exist. The chief industries are the weaving of a coarse red cloth and the production of leather goods.

(N. Tu.; S. Er.; E. Tu.)

BITOLA (Bitolj, Monastir), the southernmost town in Yugoslavia, lies below Mt. Perister on an upland plain 2 019 ft. above sea level. The swift mountain Dragor river runs through the town. Pop. (1961) 49,101, including Macedonians. Vlachs and some Albanians. Up to World War II the largest Jewish community in Macedonia existed there. Bitola itself has been identified with the ancient Heraclea Lyncestis, a Roman city on the Via Egnatia. The military advantages of its position led the Turks, about 1820. to make Bitola the headquarters of an army corps, uhich greatly increased its general and commercial importance. Its population reached 50,000. In the Balkan Wars (1912–13), Bitola mas taken from the Turks by the Serbs and was assigned to Serbia by the treaty of Bucharest (1913). Thus Bitola became a border town, cut off from its natural environs. During World War II the town suffered greatly and declined in commerce and population. In 1941 it was occupied by Bulgaria. In 1945, upon the re-establishment and reorganization of the Yugoslav government. Bitola became one of the largest towns in the People's Republic of Macedonia, one of the six Yugoslav republics It is linked by railway to the main Balkan railway from Belgrade to Salonika. Greece. The plain in which it lies affords excellent pasturage for cattle, and wheat, maize (corn), tobacco, madder and the poppy are cultivated; a part of the population of Bitola is actively engaged in agriculture. The chief industries are rubber, tanning and the manufacture of ribbons, carpets and stockings. The old crafts of metalwork, woodwork, needlework and carpet-making still flourish. (V. De.)

BITONTO, an Italian town and episcopal see in the province of Bari, lies 18 km. (11 mi.) S.W. of Bari. Pop. (1957 est.) 37,143 (commune). The old town, with narrow, irregular. arcaded streets, contains remains of Norman and Angevin walls and monuments. a Norman castle, a Romanesque cathedral (1175–1200) which is a fine example of medieval Apulian architecture, and several Renaissance buildings. In the modern to n, with its wide streets are the two Palazzi Gentile, one of which is the community centre and public library. Educational establishments include agricultural institutes The commune is an agricultural one, its principal crops being olives, vines and almonds.

Bitonto (ancient Butuntum, Botontum and other forms) has nearly alnays had juridical autonomy. Many coins have been found dating from the 6th to the 3rd centuries B.C. It was a Roman municipality and the seat of *marchesi.* (D. A. De C.)

BITTERFELD, a regional capital in the German Democratic Republic in the district of Halle, lies about 40 km. (25 mi.) N.E. of Halle and the same distance N. of Leipzig. Pop. (1939 est.) 31,968. The Zwickauer Mulde, a tributary of the Mulde, flows north of the tonn which is in the northern part of the central German brown-coal (lignite) area and its industry is determined by that raw material. The largest enterprise is the nationally owned electrochemical complex. one of the largest enterprises in east Germany. the products of which include polyvinyl-chloride and synthetic jewels. In addition there are several brown-coal opencast mines, metal processing plants, a large power station and potteries. Bitterfeld originated in 1150 as a settlement of Flemish colonists. Some time later it became known for its clothmaking craftsmanship and a brick-kiln provided work for the population. The electrochemical industry had its beginning there about 1900. Bitterfeld is a railway junction for the Berlin-Leipzig, Berlin-Halle and Dessau-Leipzig lines.

BITTERLING (*Rhodeus sericeus*) a little carplike fish, native of central Europe, belonging to the Cyprinid family. In it we have a remarkable instance of symbiosis. The genital papilla of the female acquires a great development during the breeding season and becomes produced into a tube nearly as long as the fish itself: this acts as an ovipositor by means of which the comparatively few and large eggs (3 millimetres in diameter) are introduced through the gaping valves between the gills of pond mussels (*Unio* and *Anodonta*). After being inseminated, the fertile eggs undergo their development and the fry leave their host about a

month later. As the young fish swim away, the mussel throws off its embryos on the fish, in the skin of which they remain encysted for some time. Thus both the bitterling and the host mussels benefit from this unusual arrangement.

BITTERN, generally, the name for wading birds of the subfamily Botaurinae, allied to the heron (*q.v.*), but with shorter neck, stouter body, variegated brown colours and streaked neck. Bitterns are solitary, nocturnal inhabitants of wet meadows, marshes and reedy swamps, where they skilfully spear frogs, small fish, meadow mice, crayfish and other animals.

The true bittern (*Botaurus*) escapes detection by standing upright among reeds, bill pointed upward, camouflaged by its dark streaks. It is well known for its "thunderpumping," or booming during the breeding season. During courtship it erects two tufts of feathers in the shoulder region. Four species occur: *B. stellaris* breeds in temperate Europe and Asia and in South Africa; *B. lentiginosus* in Canada and northern and western U.S., wintering south to Guatemala; *B. pinnatus* from Colombia to southeastern Brazil; and *B. poiciloptilus* in Australia and New Zealand.

PAUL POPPER LTD.

EURASIAN BITTERN (BOTAURUS STELLARIS) WITH YOUNG

The much smaller least bittern (*Ixobrychus exilis*), which builds a nest of reeds smaller than but similar to the nests of other bitterns, lays 4 or 5 eggs more bluish-white than the olive-buff of the larger bittern; it ranges from southern Canada to Paraguay. The little bittern (*I. minutus*) occurs over the old world, while other species are found in South America (*I. involucris*), Africa (*I. sturmii*), China to India and the Malays (*I. cinnamomeus*), central Asia to Japan (*I. eurhythmus*), and eastern Asia and Japan to the Philippines, Guam and Truk (*I. sinensis*).

The South American *Zebrilus undulatus* occurs from the Guianas to central Brazil, while *Dupetor flavicollis* is found in southeastern Asia, the Malays, Australia and Guadalcanal. (G. F. Ss.)

BITTERROOT (*Lewisia rediviva*), a North American plant of the purslane family (Portulacaceae; *q.v.*), native to mountain regions from Montana to British Columbia and southward to Colorado, Arizona and southern California. Crowning its stout root is a thick perennial rootstock from which rise small fleshy leaves and short, jointed stalks, each bearing a beautiful rose-red, cactuslike flower, two inches or more across. In early spring the flowers bloom in immense numbers in stony soil on ridges and in alpine valleys. The large starchy tap root was highly esteemed for food by the Indians.

ERNST C. PETERSON

BITTERROOT (LEWISIA REDIVIVA)

The plant became known to science from specimens collected by Meriwether Lewis, of the Lewis and Clark expedition (1806–07), and the botanical genus *Lewisia* was named in his honour by Frederick Pursh.

The Bitterroot river and the Bitterroot mountains in Montana are named after this plant, which is the Montana state flower.

BITTERROOT MOUNTAINS, a linear Rocky mountain range extending about 300 mi. along the middle border of Idaho and Montana. Peaks average about 9,000 ft.; passes, or saddles, about 7,000. The highest peak is Scott, at 11,393 ft. The upper levels of the range are strongly glaciated with many cirques and U-shaped valleys. The abrupt east slope, a fault scarp, is difficult of access and few main roads cross the range. The forest, which covers all but the highest peaks, includes ponderosa pine on the lower slopes, lodgepole pine, white pine, larch, grand fir and Douglas fir. The range drains to the Columbia river via the Clark Fork river on the east and the Clearwater and Salmon rivers on the west. (S. N. D.)

BITTERS, aromatized and often alcoholic beverages and medicines containing a bitter substance or substances (chiefly alkaloids, glycosides or complexes), used as tonics, appetizers or digestives. The bitterness is imparted by such substances as bitter orange peel, gentian root, rhubarb root, hop flowers, quassia wood chips, cascarilla, cinchona bark and quinine. The aroma is provided by juniper, cinnamon, caraway, anise, nutmeg, camomile, cloves and other flavouring agents.

Bitters are prepared by (1) simple maceration and subsequent filtration; (2) single or multiple percolation; (3) extraction and condensation by a large-scale extractor; and (4) shaking out of a volatile solvent after extraction. Rectification, sometimes required after extraction, is accomplished by fractional distillation and produces a superior product. Alcohol or sugar, or both, may be added.

Early Hebrew history recorded the addition of sweet-scented or bitter herbs to wine in order to improve and give variety to its flavour. The preparation of aromatic liqueurs originated in France around 1533, and their use spread quickly throughout the world.

Bitters are usually sold under the name of the substance that has been used to give the predominant flavour, such as orange or peach bitters. The alcoholic strength of bitters varies but is generally about 40% of alcohol.

Most bitters have no medicinal effect and may be regarded as beverages pure and simple. Medicinal bitters, which are few in number and of minor therapeutical value, include compound tinctures of absinthe and of aloes. (F. A. C.)

BITTERSWEET, a name for the woody nightshade (*Solanum dulcamara*). (*See* NIGHTSHADE.) Also applied in the United States to *Celastrus scandens,* a woody vine, called more properly climbing bittersweet (*q.v.*).

BITUMEN, the name applied by the Romans to the various types of natural hydrocarbons, the word petroleum not being used in classical Latin. Classical and biblical references to bitumen are of frequent occurrence, as in Gen. xi, 3, where reference is made to its use as mortar, and Gen. xiv, 10, where the bitumen pits in the vale of Siddim are noted.

In the modern use of the word, largely because of its commercial application, there is a tendency to restrict its popular meaning to the solid or semisolid hydrocarbons, although in its widest sense it includes all the natural hydrocarbons. In the generally accepted classification, however, gaseous hydrocarbons are excluded.

The solid bitumens are characterized by being fusible and largely soluble in carbon disulfide. Allied to but distinct from the bi-

Bitumens	Liquid petroleum	Paraffin base	
		Mixed base	
		Asphaltic base	
	Native mineral waxes	Ozocerite (called ceresine when refined)	
		Montan wax (extracted from peat)	
	Native asphalts	Vary from a pure solid bitumen to an impure bitumen containing a high percentage of sand, clay, etc.	
	Asphaltites	Gilsonite	Characterized by a higher fusing point than the asphalts
		Glance pitch	
		Grahamite	
Pyrobitumens	Asphaltic pyrobitumens	Elaterite	Infusible and insoluble, derived from petroleum
		Wurtzilite	
		Albertite	
		Impsonite	
		Oil shale	
	Nonasphaltic pyrobitumens	Peat	Infusible and insoluble, derived from vegetable matter
		Lignite	
		Bituminous coal	
		Anthracite coal	
		Lignitic and coal shales	

tumens are the pyrobitumens, a group of solid substances that are characterized by being infusible and insoluble, but that. on heating, generate or become transformed into bodies resembling bitumens in their solubility and physical properties.

In its various forms bitumen is one of the most widely distributed of substances. It occurs, though sometimes only in small quantities, in almost every part of the globe and throughout the whole range of geological strata, from the Laurentian rocks of the Pre-Cambrian, or most ancient, era to the members of the Quaternary, or recent, period.

All the asphalts, asphaltites and asphaltic pyrobitumens, with the exception of oil shale, have probably been derived from liquid petroleum. either by the evaporation of the lighter fraction under atmospheric conditions or by deeper-seated metamorphism. A range of products similar to many of the native solid bitumens is obtained as residues on the distillation of various types of crude petroleum, these forming many of the "asphalts" and "bitumens" of commerce. *See* also ASPHALT; GILSONITE; OZOCERITE.

(J. R.)

BITUMINOUS COAL: *see* COAL AND COAL MINING.

BITURIGES, a Celtic tribe that about 600 B.C. was the most powerful in Gaul. By the middle of the 1st century B.C. they were divided into two groups: the Cubi, clients of the Aedui with a capital at Avaricum (Bourges), in the region later known as Berry; and the Vivisci, west of the Gironde estuary. Against the advice of Vercingetorix, the Cubi insisted on defending Avaricum in the Gallic revolt of 52 B.C., with the result that Julius Caesar stormed the town, captured large stores and massacred the inhabitants. The cubi were included with Aquitania under Augustus (about 27 B.C.) and became a *civitas libera* ("free state"). They developed both iron mining and the manufacture of linen. The Vivisci, also a free state! possessed the great port of Burdigala (Bordeaux), and the vineyards behind it were already in production in Roman times.

See T. Rice Holmes, *Caesar's Conquest of Gaul,* 2nd ed (1911).

(G. E. F. C.)

BITZIUS, ALBERT (1797–1854), Swiss pastor and novelist, better known by his pseudonym JEREMIAS GOTTHELF, was an outstanding narrative writer. Born at Morat, Fribourg, Oct. 4, 1797, he came of an old Bernese family and was the son of a pastor. During his school days and later as a theological student at Berne and Gottingen he held liberal views and subsequently took part in the political activities which brought to an end the rule of the aristocracy in Berne. After becoming pastor of Lützelflüh, Emmental, in 1832, he made great efforts to enlighten the country people and tried to bring about universal education. He also founded an institution for the neglected.

When radical tendencies began to appear in Swiss liberalism Bitzius became more conservative. His desire to preserve Christian beliefs in a world threatened by materialism stimulated him to begin writing. His *Der Bauernspiegel* (1837) was followed by other works dealing with country people, including *Leiden und Freuden eines Schulmeisters* (2 vol., 1838; Eng. trans., *The Joys and Sufferings of a Schoolmaster,* 1864), *Die Armennot* (1840) and *Uli der Knecht* (1841; Eng. trans. *Ulric the Farm Servant,* 1888). Although his purpose was didactic, he showed exceptional literary talent. His 13 novels and more than 50 shorter stories reveal not only his genius as an epic writer and poetic gifts but also his intense interest in people. Psychological observation, imagination and creative power of language enabled him to achieve vivid portraits. His material was drawn from the world of the Bernese country people. Bitzius believed that the constructive forces of mankind were to be found in an undogmatic Christianity centred in family and community life. He died at Liitzelfliih, Oct. 22, 1854.

The complete works of Bitzius, in 24 volumes, were edited by R. Hunziker and H. Bloesch, with supplementary volumes of letters, sermons, political writings and *juvenilia* (1911–).

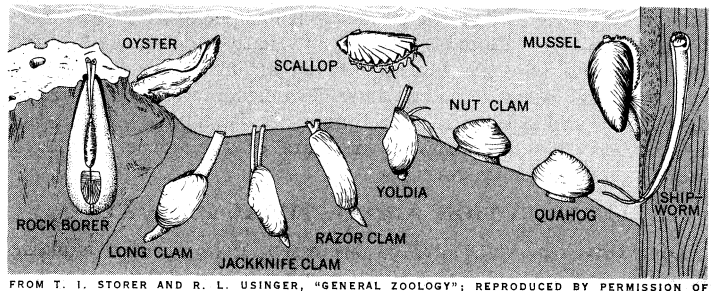
(K. F.)

BIVALVE, a common name for certain molluscan shellfish, such as the oyster, mussel, scallop, clam, etc., that have a calcareous shell composed of two hinged pieces (valves) Scientifically, bivalves comprise the class Lamellibranchia, or Pelecypoda, the former term referring to the thin, platelike gills and the latter to the hatchetlike foot of some of these aquatic invertebrates; the term Bivalvia is also used for the class.



FROM T. I. STORER AND R. L. USINGER, "GENERAL ZOOLOGY"; REPRODUCED BY PERMISSION OF MCGRAW-HILL BOOK CO., INC. (1957)

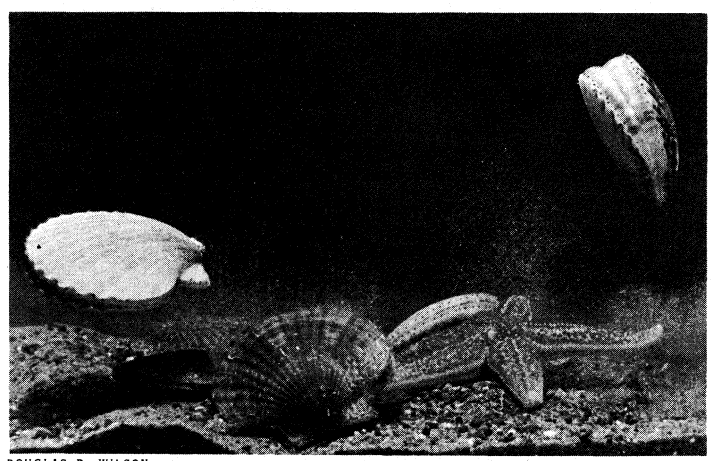
FIG. 1.—MARINE BIVALVES IN THEIR CHARACTERISTIC HABITATS. ROCK BORER (PHOLAS); OYSTER (OSTREA); LONG CLAM (MYA); JACKKNIFE CLAM (TAGELUS); RAZOR CLAM (ENSIS); YOLDIA: SCALLOP (PECTEN) NUT CLAM (NUCULA); QUAHOG (VENUS): MUSSEL (MYTILUS); SHIPWORM (TEREDO)

The majority of the bivalves live in the sea, but a few families of the group have penetrated into brackish and fresh water; some, such as the fingernail clams (Sphaeriidae), can tolerate conditions in moods pools that dry up for periods of the year.

Bivalves are internally and externally symmetrical and are distinguished from other mollusks by the possession of a shell formed in two equal, or nearly equal, valves that are joined by a tough. cuticular ligament and, in most cases, also by a system of interlocking teeth They are further distinguished by the rudimentary development of the head and the presence of two symmetrical gills. Aside from their normal respiratory function, the gills are used in feeding and in reproduction (they often serve to house and provide oxygen for the developing eggs). The foot is usually well developed and modified for burrowing in sand and mud; in many cases it secretes a tuft of adhesive threads (the byssus) by nhich the animal can anchor itself to a solid surface.

With very few exceptions bivalves are sedentary animals that live buried in sand or mud, feeding on minute plankton (floating plants and animals) and organic debris. A few groups have taken to burrowing in rock or wood, and certain genera are permanently fixed by the byssus or by one valve of the shell. There are, however, some very active members in this class; scallops *(Pecfen* and *Chlanzys)*. for example, can actually swim away from such enemies as the starfish. A beautiful bivalve known as the file shell *(Lima hians)* swims with its shell held vertically. The group as a whole, however, shows less diversity of habitat than one of the other large groups of mollusks, the Gastropoda (*q.v.*), which includes the snails, slugs. whelks and limpets.

The bivalves comprise about 7,000 species belonging to more



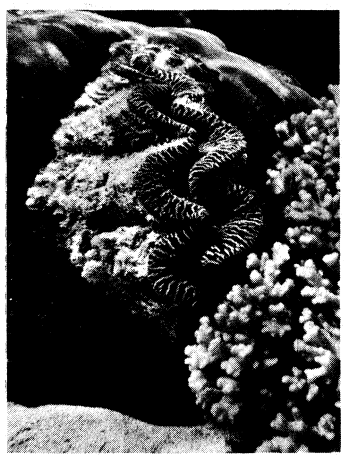
DOUGLAS P. WILSON

FIG. 2.— QUEEN SCALLOPS (CHLAMYS OPERCULARIS) SWIMMING AWAY FROM PREDATORY STARFISH

than 100 families. They range in size from species of *Condylocardia* a millimetre (about 4/100 in.) in length to species of *Pinna* and *Tridacna* (the giant clam) which attain lengths of over a metre (about 40 in.). They have a considerable vertical range in the sea and are of almost universal distribution. Like the Gastropoda they first appear in strata of the lower Cambrian (about 500,000,000 years ago).

DISTRIBUTION AND NATURAL HISTORY

Distribution. — The bivalves are essentially a group of aquatic animals; no authentic record of a permanent terrestrial habitat is known among them. As mentioned above many fingernail clams are occasionally found out of the water: they may survive in soil for as long as several months. This habit. which also occurs among other tropical fresh-water bivalves, appears to be a fortuitous adaptation to the drying up of the temporary ponds and woods pools in which the mollusk lives.



"LIFE" PHOTO BY FRITZ GORO

FIG. 3.— GIANT CLAM (TRIDACNA), SPECIMENS OF WHICH MAY WEIGH OVER 500 LB., WEDGED IN CORAL OF GREAT BARRIER REEF. AUSTRALIA

The majority of bivalves live in the sea, and the subgroups Protobranchia and the specialized Septibranchia are almost exclusively marine in distribution. Among the Filibranchia, *Scaphula* lives in the rivers of India, and among the Eulamellibranchia the Unioniacea. Sphaeriacea and a few isolated genera such as the aloidid *Erodona* and the mytilid *Sinomytilus* are inhabitants of fresh water. The Unionidae, which are a large family of fresh-water mussels, are most plentiful in North America and have a very extensive range there.

There are, in addition, a certain number of forms that constitute a population intermediate between the truly marine and fresh-water bivalves. These are found in brackish water in the estuaries of large rivers and in tidal ditches and lagoons. The cockles (*Cardium*) appear to thrive in a salinity midway between that of the sea and of fresh water and are usually found in estuaries.

Marine bivalves are found in all seas and at almost all depths. As in the case of other marine animals certain areas are characterized by certain genera. For example, the clams *Mya, Yoldia* and *Astarte* are found largely in arctic seas. As regards the vertical distribution, *Solen* (a clam), *Cardium* and *Ostrea* (oysters), for example, live principally in shallow water. The Septibranchia as a whole inhabit deep water and with them are found species of *Pecten, Abra* and *Callocardia.* Species of the two last-named genera have been found at a depth of 2,900 fathoms (17,400 ft.), the greatest depth at which a bivalve has been recorded.

Fresh-water bivalves have been found in all the great river systems of the world. The larger forms (Unionidae) tend to keep to rivers, lakes and large ponds; but the smaller forms (*Pisidium, Sphaerium,* etc.) occur in pools, ditches, streams and marshes. The dispersal of marine bivalves is mainly effected in the free-swimming larval stage during which the larvae drift about in currents. Such fresh-water forms as are parasitic in the larval stage (Unionidae) no doubt owe their dispersal to the fish on which they live. Although it is doubtful that fresh-water mussels are carried from one river or lake to another by birds (H. van der Schalie, 1945), birds and water beetles may carry clams such as *Sphaerium* and *Pisidium,* which have been found clinging by their valves to the legs of those animals (*see* fig. 4).

FIG. 5.—RAZOR CLAM (SILIQUA PATULA) OF THE AMERICAN PACIFIC COAST, WITH SIPHONS EXTENDED

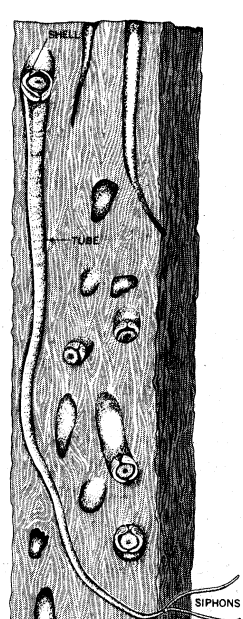
The habitats of the individual species of a genus tend either to be more or less distinct or to overlap to some extent. However, we are far from knowing with certainty to what extent the individual members of a species occupy identical habitats over the whole of their range.

Habits, Food, etc.—C. M. Yonge defined the habits of the Lamellibranchia as follows:

The bivalve molluscs are primitively inhabitants of soft substrata and we shall find them in varied and rich abundance in sand and mud. The broad foot of the snail is an admirable organ for slow progression over a rocky surface or for attachment to this. The laterally flattened foot of a bivalve is as well fitted for movement through sand or mud but not for gripping a hard surface. Hence those bivalves that live between tide marks on rocky shores are attached in other ways, either by cementation as in oysters, or, more usually, by means of tough threads which constitute the *byssus.* In the former case the animal is incapable of movement, but not necessarily in the latter where the foot is not lost although it may be reduced. (C. M. Yonge, ***The Sea Shore,*** p. *132,* William Collins Sons & Co., Ltd., London [1949].)

Most burrowing forms keep within a few inches or less of the surface, the distance to which they burrow being largely determined by the lengths of the siphons, for, as a rule, the openings of both the dorsal (excurrent or exhalant) and ventral (incurrent or inhalant) siphons are kept more or less at the surface. Thus the soft-shelled clam *Mya arenaria,* which has rather long siphons, lives about six or eight inches below the surface. F. Weymouth states that the pismo clam (*Tivela stultorum*) of California usually lies with the hinge line directed toward the oncoming surf and the open edge of the valves toward land. Forms that cannot readily orientate themselves in the unstable bottom of the open beach are found in situations where the substratum is more solid and they can form a semi-permanent burrow. Such conditions are realized in the quieter reaches of slow estuaries or in deep bays where the mud is less liable to disturbance. It is here that *Mya, Scrobicularia, Cardium* and *Macoma* are found in the northern hemisphere.

There are a good many bivalves that burrow into hard substrates and become adapted to this existence. *Pholas, Lithodomus, Saxicava* and *Clavagella* live in holes formed either by the chemical action of acid secretions or by the mechanical action of the shell. In certain places on the southern coast of England the flat slabs of chalk debris at the foot of cliffs are riddled by the holes made by the rock borer *Pholas. Teredo* and *Xylotrya,* worm-like clams called shipworms, burrow in submerged timber in which they excavate long passages; such wood may often be honeycombed with these holes. (*See* TEREDO.)



FROM "CAMBRIDGE NATURAL HISTORY" (MACMILLAN & CO., LTD.)

FIG. 6.—SHIPWORMS (TEREDO NAVALIS) SHOWN IN PASSAGES THAT THEY BORE IN TIMBER

Bivalves live almost exclusively upon

plankton and particles of organic debris ihat float in the water. The mode of feeding characteristic of this group is described below under Digestive System. It is probable that the larger proportion of the food is vegetable matter, but minute animals and the eggs and larvae of larger forms occurring in the plankton are also eaten Yonge found that the stomach contents of clams of the genus *Mya* may contain diatoms, Foraminifera, minute (probably larval) bivalves and ostracods and other small Crustacea, spores and eggs of various kinds, sponge spicules and a large mass of small sand grains. There may also be fragments of organic debris; *e.g.,* strips of algae.

The Septibranchia are usually regarded as carnivores. Living at great depths from which plants are normally excluded by the absence of sunlight, the septibranchs obviously cannot obtain living plant tissue for food. The great modification of their gills deprives them of the apparatus for fine sorting found in other classes of bivalves. Furthermore their intestine is very short and of a carnivorous type. As a matter of fact, they must subsist very largely on animal plankton and coarse particles of animal carrion, though in all probability a good deal of vegetable debris finds its way at least into the less profound depths of the oceanic abyss. Among those bivalves that bore into the solid material the shipworm has been shown to be practically independent of plankton for food and to live upon the wood into which it bores.

The chief defenses of bivalves against their enemies are the valves of the shell and the burrowing habit. Without these adaptations such slow-moving animals with no weapons of active defense would be entirely at the mercy of more aggressive enemies. As it is, bivalves are preyed upon by a great variety of animals, some of which rely almost entirely on them for food and have developed special modes of attack. Various whelks drill holes through the valves by means of an acid secretion and the filelike radula and by the aid of the extensible proboscis feed on the soft animal inside. Scaphander and other Gastropoda, which have gizzards armed with masticatory plates, swallow small bivalves whole and crunch them up in the gizzard. Birds. fish and other aquatic animals deal with them in the same way. Walruses feed on clams of various kinds which they are said to dig up with their tusks.

Fishery investigations have emphasized the importance of bivalves as an element in the food of edible fishes. The work of F. M. Davis (1923) in England on the bottom fauna of the Dogger Bank, where the small clams *Spisula subtruncata* and Mactra *stultorum* exceed in number all other large invertebrate animals of the sea bottom, shows how in a particular area the bivalves are the most important constituent of the food. Davis has shown that Spisula subtruncata occupies rather local patches on the south end of the Dogger Bank. These are of vast extent and dense population.

It is stated that certain carnivorous Gastropoda use the spines of teeth situated on the shell opening for forcing apart the valves of lamellibranchs. Thus a species of *Murex* is said to grasp the clam *Arca* with its foot and to drive one of its spines betneen the valves of the clam. *Sycotypus* is said to use the edge of its own shell for this purpose.

Bivalves are often exposed to other dangers. The special risks run by forms living in sand on open coasts are apparent. Freshwater forms in most areas are regularly exposed to the dangers of low or high temperature. In some cases the water in which they live may freeze, or may be dried up by excessive heat. Bivalves may meet these dangers by drastically reducing all activities, that is, by hibernating (in cold climates) or estivating (in warm, dry climates). The bivalves are probably as tenacious of life as the Gastropoda although less is known concerning them in this respect. An Australian pond mussel is recorded as having lived for nearly 500 days out of water.

Commensalism, or the food-sharing association of one nonparasitic animal with another, is of rather common occurrence among bivalves. Lepton *squamosum* lives thus in the burrows of Crustacea and marine worms. *Jousseaumiella* inhabits the chamber of wormlike sipunculids, and species of *Montacuta* and Scioberetia live attached to echinoderms (starfish and their allies). Other bivalves are more closely embedded in the test (cuticular outer coverings) of sea squirts (ascidians); *Modiolus* is found in the tissues of sponges; Entovalva is parasitic in *Synapta*, an echinoderm.

The age to which these animals live varies considerably. The mussel *Mytilus* and the cockle *Cardium* may attain their fuli size in a year, the common oyster in five years. The oyster is said to live as long as ten years under cultivated conditions The giant clam (Tridacna *gigas*) lives for eight years (probably a very low estimate). The swan mussel (*Anodonta*) is recorded as attaining an age of 20 to 30 years, and Weymouth has calculated that the pismo clam (*Tivela stultorum*) lives as long as 26 years. The European fresh-nater mussel *Margaritana* (or *Unio*) *margaritifera,* which lives in soft waters, is estimated to live 60 to 100 years.

ECONOMIC IMPORTANCE

Like the gastropods, among other mollusks, the bivalves have supplied man with food since a very early stage in his evoiution. Oysters, cockles, mussels and clams have been found in large quantities in Paleolithic and Neolithic kitchen middens in Europe and elsewhere. The oyster was cultivated during the time of the Roman republic, the celebrated beds in the Lucrine lake being established about 100 B.C. During the Roman empire British oysters, which were very much in favour, were brought from Rutupiae (modern Richborough), where there apparently was a fishery. At the present time oysters are cultivated in many countries (see J. H. Orton, Oyster Biology *and* Oycter *Culture,* 1937).

The cockle, scallop and mussel are caught for human consumption mainly in European countries, and a variety of other forms (including those of fresh water) are eaten in most parts of the world. In the Gulf of Naples, *Psammobia, Solen* and *Donax* are fished for the market. The importance of bivalves as food for edible fishes has already been discussed.

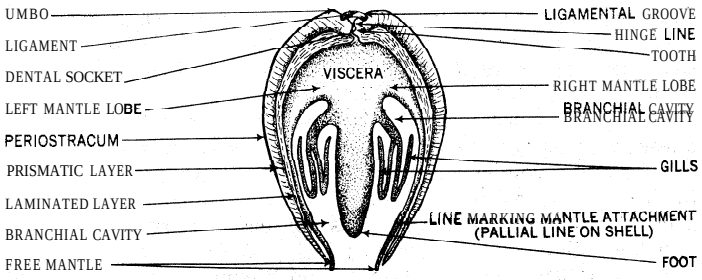
The shells of certain genera are regularly cultivated for mother-of-pearl, which is used for inlaying and for various kinds of ornaments, knife handles. buttons. etc. The oriental pearl oyster *Meleagrina* (or Pinctada) margaritifera, is fished for mother-of-pearl and for the occasional pearls obtained from it. The most important pearl fisheries are in Ceylon, Australia and Japan. In Japan pearls are also produced artificially in the pearl oyster by a grafting operation (see PEARL). From Roman times onward the pearls of the European fresh-water mussel, *Margaritana* (or Unio) *margaritifera,* were sought especially in Scotland, although this industry no longer exists. The large river mussels (Unionidae) of the United States were largely cultivated in connection with button making.

Shell money is made from clams in various parts of the world and the "wampum" of the eastern Xorth American Indians consisted largely of beads made from the shell of *Venus* (or *Mercenaria*) *mercenaria* In southern India and parts of China the "window-pane oyster," *Placuna* placenta, is still used for glazing the windows of houses. The byssus of a large species of *Pinna* was at one time used as a substitute for silk in southern Italy.

Bivalves have also proved themselves obnoxious to man in tno ways: (1) In the past the cultivation of oysters and cockles in unsanitary situations near sewage outfalls has led to serious epidemics of typhoid fever, although better cultivation has practically eliminated this danger in England and the United States (2) The shipworm Teredo and its allies have been from time immemorial a source of considerable loss through their destruction of the timber of ships, piers, jetties, etc.

ANATOMY AND PHYSIOLOGY

General Body Form. — The body of a bivalve is divisible into three main areas — the visceral mass, the mantle and the foot (fig. 7). There is no specially differentiated head such as is found in other mollusks. The animal is bilaterally symmetrical; the main axis is occupied by the visceral mass and the valves of the shell enclose the animal on the sides. The mouth is situated at the anterior end of the visceral mass and. though it is provided nith lips that are generally continued on each side as lobes (labial



FROM R. SHROCK AND W. TWENHOFEL, "PRINCIPLES OF INVERTEBRATE PALEONTOLOGY"; REPRODUCED BY PERMISSION OF MCGRAW-HILL BOOK CO., INC. (1953)

FIG. 7.—SECTION THROUGH A REPRESENTATIVE BIVALVE, SHOWING GENERAL BODY PLAN AND RELATION OF SHELLS TO VISCERA

palps), they are not marked off from the rest of the body. Except in *Nucula* and Poromya, the mouth is not furnished with sense organs and tentacles.

The visceral mass is covered over by a fleshy sheath, the mantle, which hangs down on either side like the skirt of a coat. The area lying between the mantle and the visceral mass is the mantle cavity. The foot projects as a highly muscular prominence from the underside of the visceral mass.

The mantle (and its derivatives) is in a sense the most important feature of bivalve organization, and as such its role is comparable with that of the mantle of the squid, cuttlefish and other decapod Cephalopoda (*q.v.*). Not only does the mantle secrete the shell, but it also forms its edges into inhalant and exhalant siphons; the gills are mantle derivatives that perform respiratory, nutritional and incubatory functions.

The shell first appears in the embryo as a single structure, the prodissoconch. In the course of subsequent development two separate calcified plates are secreted by the right and left areas of the shell gland. With very few exceptions these valves are joined together by a series of interlocking teeth that project from the inner dorsal border of the valves (hinge line) (see fig. 8).

The arrangement, shape and development of these teeth are variously differentiated and afford a basis of classification. The two valves are also fastened by an elastic ligament that is a persistent rudiment of the larval shell. The action of the ligament is to pull the top edges of the two valves together so that the lower edges gape and expose the animal within.

The gaping of the valves is counteracted and the valves closed by the contraction of strong adductor muscles. These muscles, which are usually two in number (anterior and posterior adductors), are developed from the mantle. Their fibres are disposed transversely to the main axis of the body, and they join the mantle lobes to the valves on either side, leaving scars on the inner shell where these muscles attach. As long as the valves are closed, the muscles are in a state of tonus; when the muscles relax the valves are separated by the resiliency of the ligament along the hinge. At times the anterior adductor is reduced in size or may disappear entirely in the adult. In such cases the posterior adductor then enlarges and becomes more central to produce shell forms known as monomyarian (the shell of Pecten, for example).

The shell varies quite considerably in shape. In some genera the two valves are somewhat unequal in size and of a different shape (Pecten, Ostrea), and some forms are permanently fixed on the sea bottom by the adhesion of one valve (Chama, *Spondylus*). In certain species of *Pinna, Anodonta*, etc., the valves are fused along the hinge line. In *Ensis* and *Siliqua* the shell is long and tubular; in Brechites and Teredo it is reduced to a rudiment.

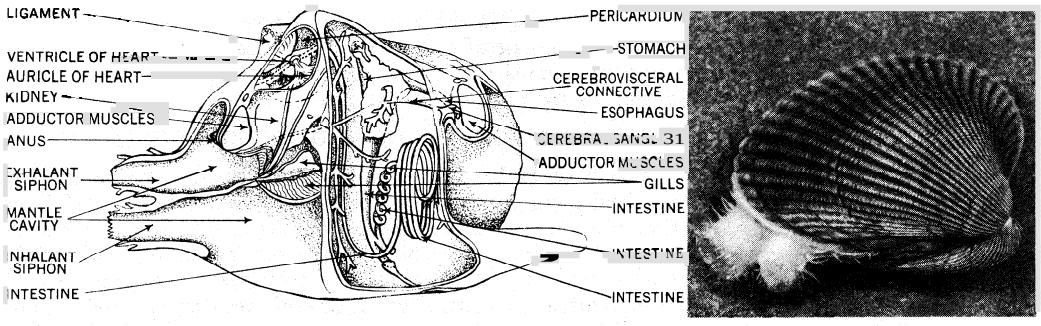
FIG. 8.—**DIAGRAM SHOWING (TOP) THE CLOSING AND (BOTTOM) OPENING** OF VALVES IN **(A)** QUAHOG (VENUS); **(B) SCALLOP (PECTEN); (C) LONG** CLAM **(MYA)**

A variety of ornamentation is formed by the interruption of the growth lines of the shell by ribs radiating from the umbo (apex of the dorsal border) and by development of spines and scales. As in the Gastropoda the mantle may become reflected over the surface of the shell (Galeommatidae) and finally in *Scioberetia* and a few other genera it completely covers the shell.

The mantle hangs down on either side of the visceral mass as two loose folds. In the most primitive bivalves the ventral edges of the folds are entirely free and unattached (Nucula, *Arca*, etc.); in all other members of the class the two lobes of the mantle are united with each other at one or more points below the ventral surface of the visceral mass.

In a large number of the latter group of bivalves there is one junction only, at the posterior end of the animal, and it forms an opening adjacent to the anus. This is known as the exhalant opening and serves for the passage of feces and stale water from the mantle cavity to the exterior. Among a second large group of families there is a second junction close to the first, forming a median inhalant opening through which water is drawn into the mantle cavity. Three openings are thus formed in the mantle edge: the posterior exhalant opening; a median inhalant opening; and the remaining larger anterior pedal opening from which the foot projects. A fourth opening is produced in certain species of



(LEFT) FROM J. JOHNSTONE IN "LIVERPOOL MARINE BIOLOGICAL COMMITTEE MEMOIR" (UNIVERSITY PRESS OF LIVERPOOL); (RIGHT) RALPH BUCHSBAUM

FIG. 10.— COCKLE (CARDIUM): (LEFT) SECTION SHOWING INTERNAL ANATOMY; (RIGHT) LIVING ANIMAL WITH VALVES CLOSED AND SIPHONS EXTENDED

the family Solenidae by a third fusion of the mantle edges. The exhalant and inhalant openings are in many genera prolonged as tubes, or siphons. The elongate siphons characteristic of burrowing forms enable the mollusk, when burrowing below the surface, to maintain communication with the water upon which it depends for food and oxygen and for elimination of its waste products. Forms like Cumingia, *Pholas, Psammobia* and Mactra have very long siphons, two or three times as long as the shell. In Teredo the siphons, which form the larger part of the total bulk, secrete a calcareous tube.

The gills. which are an even more distinctive feature of bivalve organization, are described below.

The foot is usually very muscular and in some primitive forms (Yoldia, Solemya) among the Protobranchia it has a flat sole which allows a creeping mode of locomotion. This flat type of foot, is, however, of rare occurrence, and in Nucula (an otherwise primitively organized protobranch) K. Hirasaka has shown that the foot is, as in most other bivalves, a burrowing organ. The foot of certain more specialized genera, *e.g.*, Lepton and species of *Erycina,* has a creeping surface. Usually, however, it is laterally compressed and its lower edge is keeled so that the whole foot is somewhat like the blade of a hatchet.

In the middle line of the surface of the foot is an opening corresponding to the ventral pedal pore of the Gastropoda. This leads into a cavity in which is secreted, in the form of long bristles or hairs, a substance called conchiolin. which constitutes the organic matrix in the shell. This mass of conchiolin is gradually pushed to the exterior, where it hardens on contact with water and serves to attach the animal to rocks, stones and masses of sand. This anchoring structure; the byssus, is of considerable importance to forms that live on open beaches. It is imperfectly developed in the Protobranchia and is large and highly efficient in *Anomia* (in which it is calcified and passes through a hole in the right valve), Area, *Mytilus,* etc.

Digestive System.— The mouth has already been described. It leads through a short esophagus directly into the stomach. Only in the Nuculidae (Protobranchia) is there any special expansion of a pharyngeal nature. In the embryo of *Cardium,* S. Lovén observed a small protuberance in the stomodaeal wall that may be a vestige of a radular caecum. This observation has never been recorded in other bivalves: and in no adult representative of this class is there a radula (the rasping tongue characteristic of the rest of the Mollusca).

The stomach is thin walled and lined with a hard cuticle. It has a well-marked pyloric caecum that in some forms communicates with the initial part of the intestine by a longitudinal slit, as in certain Gastropoda. This caecum secretes the crystalline style, a gelatinous rod that contains a digestive enzyme.

The physiological action of the style has been studied by several workers. In *Mya* C. M. Yonge shows that it secretes enzymes that digest starch and glycogen. A cellulose-splitting function is recognized in some species.

The liver is bilobed and usually communicates with the stomach by several openings. It contains, in *Mya,* amylolytic, proteolytic and lipolytic enzymes and is the principal organ of digestion. It seems also to have an absorptive function. The intestine, usually long anc provided with a longitudinal fold, tl typhlosole, traverses th ventricle of the heart in most cases, but in *Nucula* and some Filibranchia it passes below the ventricle.

Tracts of cilia on the gills and palps are an important adjunct to the digestive system. By their beating, the cilia sort out food part les drawn t the mantle cavity when water is taken in and drive them toward the palps from which they are passed to the mouth. The intricacy of the ciliary mechanism in sorting and straining food has been shown in studies by Yonge, J. H. Orton, D. Atkins and others.

Circulatory System.— The blood in many bivalves is colourless, but the red pigment hemoglobin is found in several forms that live in sand and mud (Arcidae, *Solen,* etc.) and the blue hemocyanin in some others (species of *Venus* and *Cardium*). The blood is contained in vessels that are usually capacious cavities (sinuses). The heart. situated dorsally, consists of a median ventricle! lying within the pericardial cavity, and two lateral auricles. In most bivalves there are two aortae (anterior and posterior) which carry the blood to the tissues via smaller vessels. The blood, ultimately collected in certain large sinuses, then passes to the gills, where it is oxygenated. After oxygenation it is carried from the gills to the auricles of the heart. As J. E. Morton indicates, the blood in bivalves serves also as a "fluid skeleton" which. with muscular action, changes the shape of the animal, thus aiding in various methods of locomotion.

Gills.— There are two gills in all bivalves except the Septibranchia, and they are situated one on either side of the body as prolongations from the upper surface of the mantle cavity. Each gill is, in its primitive form. comparable with those of other mollusks in that it is composed of a central vascular axis carrying on its opposite sides a series of filaments. From this simple, featherlike structure, found in the Protobranchia, are evolved a number of types of gills that show progressive complexity and remarkable divergences.

The role of the gills in providing an incubatory chamber is discussed in Breeding Habits below.

Coelom and Excretory Organs.— In the Protobranchia, in which the primitive connection between the pericardial cavity and the gonadal coelom is retained, the reproductive organs open into the renopericardial canals. In the Filibranchia, such as *Pecten,* the generative ducts open into the kidneys. and in the Eulamellibranchia they have separate openings. The kidneys are symmetrical and ramified and in certain specialized forms they

communicate with each other. The excretion of hippuric acid is carried out by the pericardial glands.

Most marine bivalves are unable to osmoregulate, that is, regulate the flow of water to and from tissues, at lower salinities; in order to prevent excessive loss of salts they therefore remain tightly closed during such unfavourable periods.

FIG. 12.— GENERALIZED NERVOUS SYSTEM OF A CLAM

Nervous System.—The nervous system consists of pairs of ganglia (connected by commissures), nerve cords and sense organs. With one exception the ganglia are separate from each other; the general fusion of the nervous system, a condition present in Gastropoda and Cephalopoda, is not found.

In the Protobranchia the pleural, cerebral, pedal and visceral ganglia are all distinct. In all other bivalves the cerebral and pleural ganglia are fused and the pedal ganglia are close together. The visceral commissure is always long. The visceral ganglia are usually placed on the surface of the posterior adductor muscle and in most Eulamellibranchia are more or less attached to each other. There is no stomatogastric system such as is found in the Gastropoda, the alimentary canal being innervated from the visceral cbmmissure.

Sense organs consist of eyes, statocysts (balance organs), osphradia (taste and smell indicators) and tactile organs. In a very few genera are eyes found in the head region (*e.g.,* in the Mytilidae); they are, however, found on the siphons and the edge of the mantle. In their simplest form the eyes are merely pigment spots. In certain groups they are more complex: in *Pecten* and *Spondylus* they attain maximum complexity, consisting of a cornea, conjunctiva, lens, retina, deep pigment layer and tapetum.

The optic nerve divides into tuo branches just below the optic cup and one branch passes around the latter to enter the retina. The extremities of the retinal cells (rods) are turned toward the interior of the optic globe (*i.e.,* away from the direction in which the light rays enter the eye).

FIG. 13.—SECTION THROUGH THE PALLIAL EYE OF A SCALLOP (PECTEN)

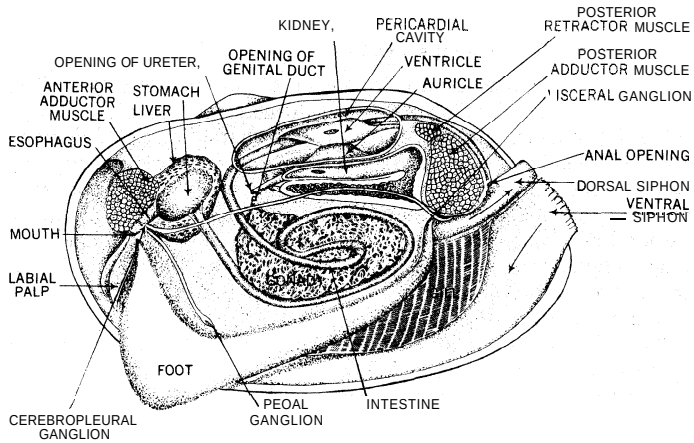
Reproductive Organs. — The sexes are usually separate, but some groups are hermaphroditic, or bisexual, *e.g., Poromya, Kellya* and the parasitic genera, as well as individual species of *Ostrea, Cardium* and the Cyrenidae. W. R. Coe (1943) has given a very good summary of the sexual differentiation in bivalves in which many grades of sexuality are described. However, among some of the fresh-water mussels (Lampsilinae) there is so great a difference between males and females that they were named as distinct species when they were first described. Generally sexual dimorphism is very little developed and is usually evident only as a slight difference of size and shape between males and females. In *Astarte* the border of the male shell is smooth, that of the female shell is undulating.

The reproductive organs are simple and consist of the gonads—ovary in iemales, testis in males and the ovotestis, or hermaphroditic gland, in bisexual forms—together with a generative duct. The generative duct, however, is not found in the Protobranchia and many Filibranchia, the ova and spermatozoa being liberated to the exterior through the kidneys. In the Lucinidae, *Ostrea* and *Sphaerium* the gonads and kidneys open into a common cloaca. In some bivalves the gonads open to the exterior by a genital duct, which is situated either together with the renal duct on a common papilla or in close proximity to the renal duct. In certain hermaphroditic forms the ovary and testis are completely separate from each other and open by separate ducts. There is no copulatory organ in the male and no accessory glands or organs, except in the male of *Cuspidaria.* Fertilization is usually external but may take place in the cloacal chamber or (as in the common oyster, *Ostrea vulgaris)* in the oviduct itself.

REPRODUCTION AND DEVELOPMENT

Breeding Habits. — Marine bivalves usually discharge their eggs and sperm into the water; fertilization occurs externally and the embryo develops as a free-swimming larva. In a few marine forms and in fresh-water bivalves the eggs are retained within the female body or shell, where they are fertilized and incubated.

Incubation is a distinctive feature of fresh-water bivalves, and



FROM M. S. MACDOUGALL AND R. HEGNER, "BIOLOGY, THE SCIENCE OF LIFE"; REPRODUCED BY PERMISSION OF MCGRAW HILL BOOK CO , INC. (1943)

FIG. 14.— INTERNALANATOMY OF A FRESH-WATER MUSSEL (FAMILY UNIONIDAE)

attains a far greater development in this class than in any other molluscan group. In incubatory forms the eggs are retained after fertilization usually in the spaces between the gill lamellae, which are often modified to serve as brood chambers (Unionidae and Sphaeriidae). It has been observed that the embryos eat the epithelial cells of the maternal gills during incubation. In certain species of *Ostrea* the embryos are incubated in the mantle cavity outside the gills. There is not much doubt but that marine bivalves that live in cold seas are more likely to adopt some form of incubation than those inhabiting warm or temperate seas.

Development. — The development of a bivalve is best known from J. Meisenheimer's study of the fresh-water mussel *Dreissena polymorpha.* With two important exceptions (Protobranchia and Unionidae) the course of development in such other forms as have been studied is more or less similar. In *Dreissena* the first two cleavage divisions produce four cells called macromeres of which one is very much larger than the rest. Successive divisions of the macromeres yield "quartettes" of smaller cells called micromeres; the micromeres continue to divide until they form a cap overlying the macromeres. This type of cleavage is spiral, like that found in Gastropoda, but the radial symmetry resulting from cleavage is modified very early in development.

The mass of cells thus formed gives rise to a free-swimming embryo that has now assumed the characteristic form of the molluscan larva known as the trochophore. Among mollusks the trochophore usually develops a special swimming organ, the velum, consisting of a band of heavily ciliated tissue; hence the name veliger for the later stage of the trochophore larva. Most marine mollusks produce such a free-swimming veliger larva, but of the fresh-water iorms *Dreissena* is the only one known to have a free-swimming veliger.

During the veliger stage the nervous system, musculature, statocysts, gills and foot of the adult are laid down. The larva rapidly changes into the adult. The cells of the velum are cast off, the larval musculature disintegrates and the area of the larval mouth shrinks to the proportion characteristic of the adult.

One of the most notable modifications of this developmental

history occurs in the Protobranchia in which the veliger has a disproportionately large velum consisting of rows of large ciliated cells giving the larva a barrel-shaped appearance.

The development of the Unionidae is remarkable in that part of the embryonic life is parasitic. After incubation in the brood chambers the embryos, which have developed into special larvae known as glochidia (sing. glochidium), are ejected into the water. Each glochidium has a minute bivalved shell that may be furnished with teeth or hooks. If the glochidium comes into contact with a specific fish, it may succeed in fixing itself to the gills or fins. Once lodged on the fish, the larva encysts and lives as a parasite in the tissues of the fish. During this phase the glochidium develops into a miniature adult and subsequently escapes from its host by the rupture of the cyst.

EVOLUTION AND PALEONTOLOGY

The recognition of bivalves in the oldest fossiliferous rocks is somewhat difficult owing to their unsatisfactory preservation and the similarity of shells between certain bivalves and ostracod crustaceans. *Glyptarca,* which occurs in upper Cambrian strata, is certainly a bivalve; but the exact position of *Fordilla* and *Modioloides* (lower Cambrian), which have been referred to this class, is uncertain. In the Ordovician period, *Ctenodonta* and *Modiolopsis* are recognizable as representatives of the Protobranchia and Filibranchia. but the class is not well represented at this epoch. In the Silurian, however, there is a rich bivalve fauna containing representatives of all the chief orders except the Septibranchia, and the modern Aviculidae are recognizable. In the lake beds of Devonian age (Old Red Sandstone) are found shells that resemble those of modern fresh-water mussels and are referred to the genus *Archanodon.* These forms and apparently brackish water bivalves are well developed in the Carboniferous, and a good many marine genera represented at the present time are recognizable at this period, *e g., Trigonia, Astarte* and *Lucina.*

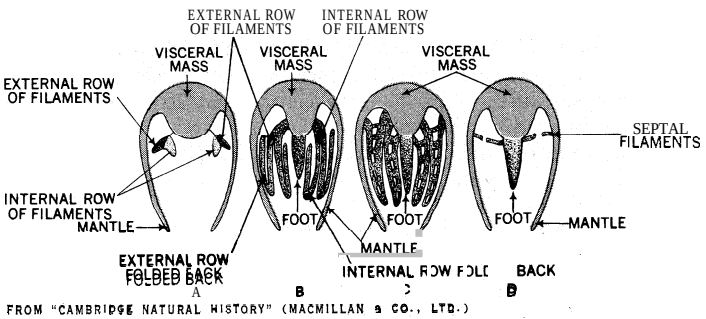
CLASSIFICATION

Some classifications have united the Lamellibranchia with the Gastropoda and Scaphopoda. This association, however, seems to exaggerate resemblances and to attach too little importance to the very marked specialization of these groups of mollusks. Specialization is apparent even in the most primitive members of the bivalves, which seems to suggest very early divergence from the rest of the Mollusca.

One of the outstanding features of the bivalves is the structural uniformity found in many of their internal and external parts. This has made it peculiarly difficult to distinguish satisfactory subdivisions of the group, and its classification has, as a result, been a source of much controversy in the past. Paleontologists and students of living mollusks have differed as to the basis upon which the main subdivisions should be established.

The main groups recognized by zoologists depend upon the structure of the gills. The latter are not preserved in fossil remains; thus. the paleontologist has had recourse only to the shell and its essential features, such as the hinge line and hinge teeth.



FROM "CAMBRIDGE NATURAL HISTORY" (MACMILLAN & CO., LTD.)

FIG. 18.—STRUCTURE OF GILL FILAMENTS IN BIVALVES FROM SECTIONS (SHELL NOT SHOWN): (A) PROTOBRANCHIA; (B) FILIBRANCHIA; (C) EULAMELLIBRANCHIA; (D) SEPTIBRANCHIA

P. Pelseneer's classification (1906), which recognized five orders — Protobranchia. Filibranchia, Pseudolamellibranchia, Eulamellibranchia and Septibranchia — was based primarily upon the structure of the gills. In order to include an ecological aspect as well as a structural and paleontological one J. E. Morton *(1958)* adopted H. Douvillé's classification (1912) which includes: (1) a normal free-living group; (2) a sessile group; (3) a deep burrowing group. A simplified arrangement of the class follows:

LAMELLIBRANCHIA (BIVALVIA, PELECYPODA)

Subclass 1. (Filibranchia + Pseudolamellibranchia)
Order 1. Protobranchia
" 2. Taxodonta
" 3. Anisomyaria
Subclass 2. (Eulamellibranchia)
Order 1. Schizodonta
" 2. Heterodonta
" 3. Adapedonta
" 4. Anomalodesmata (including Septibranchia)

(G. C. R.; H. v. D. S.)

BIWA-KO, largest fresh-water lake in Japan (area 268 sq.mi., circumference 146 mi.) located in central western Honshu in Shiga prefecture. Long (about 40 mi.) from north to south, the lake derives its name from the ***biwa,*** a Japanese musical instrument that its shape resembles. The lake occupies a structural depression and is fed by small rivers flowing from encircling mountains. Although mountains closely parallel the west coast, the east coast has generous alluvial plains that are expanding into the lake. A sole outlet, the Yodo river, flows from Biwa's southern tip past Seta southwest to Osaka bay. Deepest water is in the northwest corner (315 ft.), with depths of over 197 ft. common among the west coast. However, the silting east coast deepens gradually from about 33 ft. near the shore. Biwa's surface rises as much as 10 ft. in spring due to snow melt and spring rains and in the autumn from typhoon rains. Summer brings high water and winter low water.

In early Japanese history, the lake was a principal avenue of movement between the Sea of Japan and the Inland sea, but it now has only a few commercial, fishing and sight-seeing boats. Its lowlands, rich in historical associations and legends, produce large rice surpluses, support such centres as Otsu and Hikone and are traversed by the Tokaido trunk railway line. Famed for its scenic beauties, splendid temples atop Mt. Hiei and the nearby cultural city of Kyoto (*q.v.*), Biwa is one of Japan's greatest tourist attractions. (J. D. EE.)

BIXIO, NINO (1821–1873), Italian patriot who played a notable part in his country's fight for independence, was born at Genoa on Oct. 2, 1821. In his youth he went to sea and, meeting Giuseppe Mazzini and other compatriots in exile abroad, was won over to the cause of Italian unity. In the war of 1848–49 he fought first in the Sardinian army and then in Giuseppe Garibaldi's Italian legion in Rome. After spending several more years at sea, he was at Garibaldi's side again in the Alpine campaign of 1859. In the expedition to Sicily in 1860, leading a battalion, he distinguished himself in action at Calatafimi and was wounded during the capture of Palermo and at the siege of Reggio. The tactical qualities that he displayed at the battle of Volturno brought him promotion to the rank of lieutenant general. In 1861 he was elected deputy for Genoa in the first Italian parliament and tried to reconcile Garibaldi and Cavour. Created a senator in 1870, he commanded a division in the attack on Rome. He died of cholera at Achin bay, Sumatra, on Dec. 16, 1873, on a commercial expedition.

See G. Guerzoni, *La Vie du général Bixio* (1877); A. Codignola, *Birio* (1948).

BIZERTE (BIZERTA), a seaport of northern Tunisia, situated at the edge of rainy lake plains, on a natural channel which links the lake of Bizerte with the sea, and facing an open bay on the strait of Sicily, between Cape Blanc and Cape (Ras) Zebib. Pop. (1956) 44,681, of whom 12,808 were Europeans. Its maritime value was completely transformed at the end of the 19th century by the opening, south of the town and of the natural channel's mouth, of a canal 4,920 ft. long, 787 ft. wide and 32 ft. deep. The lake became a fine roadstead, with depths of 32 ft. as far as the naval port and arsenal of Sidi Abdallah and Ferryville (now Menzel-Bourguiba) at its southwestern end, and depths of more than 29 ft. over half its area. There is a protected outer harbour at the sea end of the canal. The new roadstead and arsenal made Bizerte an important French military base, and the commercial port was established in the bay of Sebra.

The old native town stands at the channel's former sea entrance, which was not filled in and serves as a fishing harbour. On the north side of this is the kasbah. Dredgings from the new canal were used to fill up the old channel and to form building sites on the north side of the canal where the new town now extends. The central point of the modern town is a square, where stand the hôtel de ville (town hall) and the modern church of Notre Dame de France. There are a Franco-Arab school south of the old harbour and a *lycée* to the west of the town. The exodus from the countryside after World War II added some poor quarters to its outskirts. The commercial port has little trade: it exports iron ore from Duaria, lead from local mines smelted in a small foundry, and part of the cement produced in a modern factory, but the grains of the interior go almost entirely to Tunis. Imports are confined mainly to fuels (especially liquid), building materials and metal products for the arsenal. Passenger traffic and fishing are of secondary importance. The town is a limited regional market and Tunis competes strongly for the trade of its hinterland. It is linked by rail and road with Tunis and Tabarka and has an airport. Bizerte was pever of great commercial importance, though it was an early Phoenician outpost and a town of the Carthaginian era (Hippo Zarytus, or Diarrhytus) and one of Rome's first colonies. In medieval times, as Benzert, it was a mediocre fishing village. In the 16th century it was enlarged by an Andalusian quarter of Muslim refugees from Spain. In Turkish times it took part in the piracy of Khair ed-Din (Barbarossa) and was occupied by the Spanish in 1535, and later suffered various bombardments by European fleets. At the time of the French protectorate (1881) it had barely 6,000 inhabitants. It was occupied by the Germans in Nov. 1942 and liberated by the Allies on May 7, 1943. The town and port, severely damaged by the Tunisian campaign, have been reconstructed. In 1961 there were violent clashes betneen French troops and Tunisians in the wake of a Tunisian demand for French evacuation of the base. An agreement was signed on Sept. 29 whereby the French withdrew to positions they held before fighting broke out on July 19.

The governorate of Bizerte had a population (1956) of 258,544. It is a wet region (Satfura) comprising on the west the poor country of Mogod, an area of cork oak bush and pasture, and the hills of the Hedil and Bejawa (grain and pasture); to the south are the rich plains of Bizerte and Mateur (wheat and cattle); on the east is a thickly populated area including about ten large villages, established in market gardening. (J.-J. Ds.)

BIZET, GEORGES (1838–1875), French composer, was one of the foremost dramatic composers of his age, combining a graceful and fluent style in the tradition of Mozart and Rossini with a realism that influenced the *verismo* school of opera at the end of the 19th century.

He was born in Paris, Oct. 25, 1838, and baptized Georges, though his registered names were Alexandre César Léopold. His father, a hairdresser, married a sister of the gifted but eccentric singing teacher F. A. Delsarte, and set up in the same profession. Bizet, their only child, showed precocious musical gifts. He studied at the Paris Conservatoire from 1848 under Antoine Marmontel (piano), Pierre Zimmerman (counterpoint) and

Fromental Halévy (composition), and also received instruction from Gounod, whose music greatly influenced him. He won many prizes, culminating in the Prix de Rome (with his cantata *Clovis et Clotilde)* in 1857. His delightfully fresh Symphony in C major, discovered and first performed in 1935, was written in 1855 within a month of his 17th birthday. His first stage work was the one-act operetta *Le Docteur Miracle,* produced at the Théâtre des Bouffes-Parisiens in 1857.

During his years in Rome (1857–60) Bizet composed the lively *opera buffa Don Procopio* (Monte Carlo, 1906) and the ode-symphony *Vasco de Gama,* and planned a number of other works, including the symphony known as *Roma* (performed 1869). On his return to Paris he supported himself by teaching, scoring dance music and making piano transcriptions, etc. He was a superb pianist who won the admiration of Liszt but shrank from the career of a virtuoso.

In 1862–63 he composed the grand opera *Ivan le Terrible,* probably for the theatre at Baden-Baden, but put it aside when Leon Carvalho, director of the Théâtre-Lyrique in Paris, offered him the libretto of *Les Pêcheurs de Perles.* This opera, produced in 1863, shows the influence of Gounod, Meyerbeer and Verdi, but contains much charming and original music. In 1865 a revised version of *Ivan le Terrible* was rejected by the Théâtre-Lyrique and the Opéra. The surviving score — probably that of 1862–63—was first produced at Mühringen castle, Württemberg, 1946. In this and other works Bizet made the mistake of attempting the grandiose, to which his talents were unsuited. *La Jolie Fille de Perth* (Théâtre-Lyrique, 1867) shows an advance in dramatic skill and orchestration but is hampered by a feeble libretto. During the years 1865–68 Bizet wrote many songs, a few with the vitality of his best dramatic music, and some piano pieces, of which the best is the experimental *Variations chromatiques de concert.*

Bizet's discouragement during the 1860s is reflected in the numerous operas he leit unfinished, and in the constant self-doubts and suspicions, amounting almost to persecution mania, expressed in his letters. When in 1868 the Opéra offered a prize for a setting of *La Coupe du Roi de Thulé,* a libretto with a remarkable likeness to that of Carmen, he submitted an entry; but on failing to win the prize strove to conceal the fact. His score! which survives only in fragments, shows high promise. On June 3, 1869, he married Genevieve Halévy, daughter of his old master. In the same year he completed Halévy's opera *Noé* and eagerly accepted the invitation of Camille du Locle. the new joint director of the Opéra-Comique, to "change the genre of *opéra-comique.*" But his career was interrupted by the Franco-German War, during which he served in the national guard throughout the siege of Paris. and in 1871 *Grisélidis* was refused by the Opkra-Comique on the grounds of expense.

The compositions of Bizet's last four years are nearly all masterpieces. The suite for piano duet, *Jeux d'Enfants* (1871), shows a rare mastery of miniature forms and an insight into the child's mind; the one-act *Djamileh* (1872), though again marred by a weak libretto, contains some of his most seductive music in an oriental idiom; and the incidental music to Alphonse Daudet's *L'Arlésienne* (1872), in which he collaborated closely with the dramatist, is a *locus classicus* for the marriage of music and the spoken word. The last two were both failures; but the orchestral suite (No. 1) irom *L'Arlésienne* won great success as a concert piece. Two further orchestral works were the *Petite Suite* adapted from *Jeux d'Enfants* (1873) and the overture *Patrie* (1874).

Bizet's last and finest work, *Carmen,* with libretto by H. Meilhac and Ludovic Halkvy. based on a tale by Prosper Mérimée, mas produced at the Opera-Comique, Rlarch 3, 1875. It was received with indifference by the public and with hostility by much of the press; only after a world-wide triumph did it come into its own in Paris. Here for the first time Bizet set an excellent libretto (the subject was his own choice and he helped shape the words): and the music reveals all his qualities as a musician — vitality. rich colour, abundant and varied melody; masterly orchestration and. above all, a rare insight into the dramatic manipulation of character. Bizet's best music is spontaneous and exuberant. as was the man himself. In opera he penetrated to the deeper emotions that govern human behaviour, especially jealousy; he observed them with detachment and expressed them through a refined musical craftsmanship. He revitalized *opéra-comique,* but did not live to exploit his success. His last years were darkened by domestic unhappiness and declining health. Soon after the production of *Carmen* he was taken ill with an infection of the throat, from which he had suffered chronically since childhood, and died suddenly at Bougival, near Paris, June 3. 1875.

BJERKNES, VILHELM FRIMANN KOREN (1862–1951), Norwegian physicist and meteorologist, was one of the founders of the modern science of weather forecasting. He mas born in Oslo on March 14. 1862. As a student he assisted his father, Carl Anton Bjerknes, professor of mathematics in Oslo, with experimental verifications of hydrodynamic action at a distance, a field which he generalized and clarified in later years. Under Heinrich Hertz (1890–91) he made a comprehensive study of electrical resonance which was decisive in the development of radio. In 1897, then professor of mathematical physics at the University of Stockholm, Bjerknes discovered his famous circulation theorems. These led him to a synthesis of hydro- and thermodynamics, a physical hydrodynamics, applicable to large-scale motions in the atmosphere and the ocean. In 1904 he presented a farsighted program for physical weather prediction based on the fundamental dynamic principles of physics. Supported by the Carnegie institution in this program, Bjerknes was able to employ a long line of talented "Carnegie assistants." thus founding his "schools" in Leipzig and Bergen. His influence as an inspiring teacher was perhaps as great as his scientific achievements. During the period from 1895 to 1932 he held teaching positions at the universities of Stockholm, Oslo and Leipzig and at the Bergen Geophysical institute. He died in Oslo on April 9, 1951.

JAKOB BJERKNES (1897–), his son, was among his young collaborators in Bergen who in i919 discovered that cyclones originate as waves in sloping frontal surfaces which separate different air masses, the first great success of the elder Bjerknes' program. Its full potentialities are unfolding in modern numerical weather predictions. *See* also METEOROLOGY: *History;* WEATHER FORECASTING.

A comprehensive bibliography of Bjerknes' writing is contained in his book, *Physikalische Hydrodynamik* (1933). (JN. H.)

BJÖRNEBORG: *see* PORI.

BJØRNSON, BJØRNSTJERNE MARTINIUS (1832–1910), Norwegian poet, novelist, dramatist and Nobel prizewinner (1903) who reiashioned the *dvame bourgeois* of his day into a serious realistic drama which inspired Henrik Ibsen (*q.v.*). Bjørnson was also a brilliant journalist and used his rigorous personality to further the causes of radicalism and Norwegian nationalism and to assist oppressed minorities overseas. Born at Bjørgan parsonage. Kvikne (Østerdal), Dec. 8, 1832, he spent most of his childhood—a happy one—in Nesset (Romsdal), where his father was appointed pastor in 1837. In 1838 he went to Christiania (now Oslo) to prepare for the university at a school which Ibsen also attended, but having matriculated in 1852 he leit the university in 1854 to become a dramatic critic. He published his first stories and became editor of a small paper in 1856, publishing *Synnøve Solbakken* (Eng. trans. 1870. 1895) in 1857. This: written during a visit to Copenhagen, was the first of his peasant tales (*bonde-fortaellinger*) in which he is unsurpassed in Norwegian literature. His other peasant tales included *Arne* (1858; Eng. trans. 1890), *En glad Gut* (1860; Eng. trans., *A Happy Boy,* 1896), *Fiskerjenten* (1868; Eng. trans., *The Fisher·Lassie,* 1896) and *Brudeslåtten* (1873; Eng. trans., *The Bridal March,* 1893).

Bjdrnson wished to create a new saga of peasant life, not only in prose fiction but also in popular plays (*folke-stykker*), the first of which was *Mellem Slagene* ("Between the Battles") a one-act historical drama performed in 1857. Later that year he succeeded Ibsen (with whom he was friendly at the time) as director of the Bergen theatre, but left in 1859 to return to journalism in Chris-

tiania. Awarded a government grant in 1860, he traveled widely in Europe until 1863. His early historical plays were produced at this period—Halte-Hulda (1858) and Kong Sverre (1861), the trilogy Sigurd Slembe (1862, performed 1865; Eng. trans. 1838) and *Marie Stuart* i *Skotland* (1864, performed 1867; Eng. trans. 1912), which made him famous as a dramatist. In 1565, when his comedy De Nygijte (Eng. trans., The *Newly Married Couple* in Three Comedies, 1912) was produced. he was appointed artistic director of the Christiania theatre but later resigned (1867) to become editor-in-chief of Norsk Folkeblad, which he made the main organ of Norwegian radicalism.

In the 1860s his political activities increased. He toured Norway agitating for more independence for his country—as well as for some kind of Pan-Scandinavian union: he also favoured Pan-Germanism in later years. Though an admirer of Danish culture, Bjørnson as a fervent nationalist wrote a distinctly Norwegian Danish. Nevertheless, he opposed the full-scale introduction of the synthetic *landsmål* (see NORWEGIAN LANGUAGE).

In 1870 he published a collection of Digte og sange (4th ed. 1903; Eng. trans., Poems and Songs, 1915) including Ja, vi elsker dette landet, which was set to music by his cousin R. Nordraak and is now the Norwegian national anthem. In 1874 Bjørnson settled at Aulestad, Gausdal (Oppland) and began a fresh period of creative activity. In the late 1870s he passed through a religious crisis, finally abandoning his Christian beliefs, and began to preach a code of nonreligious ethics. His three plays *Redaktøren* (1875; Eng. trans., The Editor), En *Fallit* (1875; Eng. trans., The Bankrupt) and Kongen (1877; Eng. trans., The King: all trans. in *Three* Dramas, 1914) are realistic works, reflecting his political views, but have become dated and are not well constructed, though En Fallit—which strongly influenced Ibsen's *Samfundets stötter* (1877; Eng. trans., The Pillars oj Society)—earned him a European reputation. In 1883 he published En *Handske* (Eng. trans., A Gauntlet in Three Comedies, 1912), a drama attacking sexual moral duplicity. This was followed by his two most powerful plays —*Over* Aevne: *første* stykke (1883; Eng. trans., Pastor Sang, 1893, and Beyond Our Power in Plays, 1913), an attack—like his striking short story "Støv" (1882; Eng. trans., "Dust" with *Magnhild*, 1897)—on dogmatic religious belief, which was not performed until 1899, and Paul *Lange* og Tora *Parsberg* (1898; Eng. trans. 1899), a masterly psychological study of weakness, which was founded on the career of a Norwegian politician of the day. In 1889 the comedy *Geografi* og Kjaerlighed (Eng. trans., Love *and* Geography in Plays, 2nd series, 1914) had been published and became a great favourite in Norway. Bjørnson treated the Over Aevne theme twice, setting Over Aevne: andet stykke (1895; Eng. trans., Beyond Human Might, 1914), against the background of a strike, and continued to publish novels—Det Flager i *byen* og *paa Havnen* (1884; Eng. trans., *The* Heritage of the Kzirts, 1892), a long chronicle novel, and Paa Guds Veje (1889; Eng. trans., In *God's Way*, 2 vol., 1907–08).

His later plays included *Når* den ny Vin blomstrer (1909; Eng. trans., When the New *Wine* Blooms, Poet Lore, vol. xxii. pp. 1–78, 1922), a delightful comedy. A positive, confident personality, Bjørnson wrote much that is less significant than anything Ibsen did, but he was far more typically Norwegian than the other was. Bjørnson died in Paris, April 26, 1910.

BJORNSSON, SVEINN (1881–1952), first president of Iceland, was born in Copenhagen, Den., on Feb. 27. 1881. After going to school in Iceland. he received the degree of bachelor of law from Copenhagen university in 1907. He lived in Reykjavik from 1907 until 1920 and was very active both in local and national affairs. He was a member of the althing for Reykjavik for several years, chairman of Reykjavik city council 1918–20, advocate in the high court and supreme court of Iceland until 1920, and a leading spirit in the foundation of many important companies and institutions. Appointed Icelandic envoy to Copenhagen in 1920, he remained there until 1940, except for the years 1924–26, when he was recalled to Reykjavik.

After Iceland became a self-governing kingdom in personal union with Denmark (Dec. 1, 1918), the Danes conducted Iceland's foreign affairs until the beginning of World War II. Then, on May 10, 1940, the day after the German occupation of Denmark, the *althing* decided to delegate to the Icelandic cabinet the powers of the king and to rescind the Danish government's commission to conduct Iceland's foreign affairs. In pursuance of these temporary measures the *althing* in 1941 elected Bjornsson to be regent of Iceland, to which office he was re-elected in 1942 and 1943. On the inauguration of the republic of Iceland (June 17, 1944) he was chosen by the *althing* to be Iceland's first president for one year, but when a plebiscite was held for the presidential office in 1945 he was returned unopposed, as also in 1949. He had acquired his people's trust and affection by his labours over the previous decades for them and their good. He died on Jan. 26, 1952. His memoirs were published in 1957. (T. J.)

BLACK, ADAM (1784–1874), Scottish publisher, founder of the firm of Adam and Charles Black, was born in Edinburgh on Feb. 20, 1784. On leaving school he was for five years apprenticed to an Edinburgh bookseller, afterward spending two years in London. Returning to Edinburgh, he opened his own bookshop (1807) and subsequently began publishing. His business flourished and after some years he took his nephew Charles into partnership. In 1827 the copyright of the *Encyclopædia Britannica* passed into the hands of Adam Black and a few friends (whose interest he shortly acquired) and it was under his direction that its 7th, 8th and 9th editions were published. In 1851 the firm bought the copyright and stock of Sir Walter Scott's Waverley novels for £27,000; and in 1861 they became the proprietors of De Quincey's works. Black was twice lord provost of Edinburgh and represented the city in parliament from 1856 to 1865. He died in Edinburgh on Jan. 24, 1874, and was succeeded by his three sons, who in 1890 moved their business to London.

See Adam *& Charles* Black, *1807–1957:* Some Chapters in the History of a Publishing House (1957).

BLACK, DAVIDSON (1884–1934), Canadian discoverer of Peking man (*Pithecanthropus* pekinensis), was born at Toronto on July 25, 1884. A graduate of the Cniversity of Toronto, he taught at Western Reserve university, Cleveland, O., which he left to join the Canadian army medical corps in 1917. While visiting Manchester, Eng.. to study comparative anatomy with G. Elliot Smith, at that time working on the Piltdown material, his interest was deeply aroused by the problems of man's origin. After World War I he became, and remained until his death, professor of neurology and embryology at Peking Union medical college and subsequently honorary director of the Cenozoic Research laboratory of the Geological survey of China. In the search for early man he worked without success first in Jehol (north China), then in Thailand. After some pieces of quartz, not of local origin, and some apparently hominid teeth had been found at Chou-k'ou-tien, he instigated a thorough investigation of the site, which culminated in the discovery of Peking man (see MAN, EVOLUTION OF: Pithecanthropus). The phylogenetic importance of this fossil was immediately recognized by Black who, when only a single molar tooth had been recovered, gave it a new generic name to indicate that it represented a distinct form of early man. Later discoveries of skulls and other fossil bones, by himself and after his death by Franz Weidenreich (*q.v.*), proved the accuracy of his judgment. Black died at Peking on March 15, 1934. (D. F. R.)

BLACK, GEORGE (1890–1945), English manager and producer of entertainments and a pioneer of the motion-picture business, is chiefly remembered as the originator of the brilliant and long-lived "Crazy Gang" revues at the London Palladium and later at the Victoria Palace, London. Born in Birmingham, April 20,

1890, he helped his father establish the first permanent motion-picture theatres in Great Britain. Later he became proprietor of a circuit of theatres and music halls on the northeast coast. He moved to London in 1928 and became general manager of various music halls there and in Brighton. In 1933 he took over the active management of Moss Empires theatres (extending all over Great Britain) and became joint managing director in 1938. The "Crazy Shows" began at the London Palladium in 1935 with *Life Begins at Oxford Circus,* and continued as an annual event that World War II interrupted only intermittently. He died on March 4, 1915. (A. H. D.)

BLACK, JEREMIAH SULLIVAN (1810–1883), U.S. lawyer and cabinet officer, was born Jan. 10, 1810, in Somerset county, Pa. He attended several schools but was largely self-educated. After three years of study under Chauncey Forward, a prominent Somerset attorney. he was admitted to the bar in 1830. Appointed a judge of the district court in 1842, he was elected to the state supreme court in 1851 and re-elected three years later. In 1857 Pres. James Buchanan appointed Black attorney general oi the United States. In his most significant action he successfully challenged questionable Mexican land grants in California.

After Abraham Lincoln's election Black advised Buchanan to garrison southern forts to protect federal property from the secessionists. His pro-Union influence upon Buchanan increased after he became secretary of state on Dec. 17, 1860. He drafted instructions to U.S. diplomatic representatives to warn foreign governments against recognition of the Confederacy.

When Lincoln was inaugurated, Black retired from office to a lucrative law practice. After the American Civil War he represented opponents of radical Republican reconstruction before the Supreme Court. He capped his career there in the famous Slaughterhouse cases when his arguments led the court to interpret narrowly the rights conferred upon citizens by the 14th amendment. He continued to practise law until his death Aug. 19, 1883, at Brockie. Pa. (R. J. Ro.)

BLACK, JOSEPH (1728–1799), Scottish chemist and physicist. is best known for his enunciation of the concept of latent heat and the rediscovery of "fixed air" (carbon dioxide). He was born on April 16, 1728. at Bordeaux, Fr., where his father—a native of Belfast but of Scottish descent—\\as engaged in the wine trade. He was educated at Belfast, and in medicine and natural sciences at Glasgow university. There he had William Cullen (1712–90) for his instructor in chemistry, and the relation between the two soon became that of professor and assistant rather than of master and pupil.

In 1751 Black transferred to Edinburgh to complete his medical studies. In the thesis *De humore acido a cibis orto, et magnesia alba,* which he presented for his doctor's degree in 1754, he described his investigations in the heating of magnesia alba (magnesium carbonate) and anticipated Antoine Lavoisier and modern chemistry by indicating the existence of a gas distinct from common air, which he detected by using the balance. This gas was carbon dioxide, first described by Jan van Helmont (1577–1644) as "gas sylvestre." A fuller account of Black's studies was published in 1756 as *Experiments Upon Magnesia Alba, Quicklime, and Some Other Alcaline Substances.* In this he proved that the mild alkalies (carbonates) are causticized (become more alkaline) when they lose carbon dioxide and that the absorption of this material converts the caustic alkalies again to mild alkalies. *(See* also CHEMISTRY: *History of Chemistry.)*

It is curious that Black left to others the detailed study of "fixed air." Probably the explanation is pressure of other work. He. however, had found that it behaves as an acid, that it is produced by fermentation. respiration and the burning of charcoal, and inferred its presence in the atmosphere. His only other important chemical discovery was that of the bicarbonates.

In 1756 he succeeded Cullen as lecturer in chemistry at Glasgow, and was also appointed professor of anatomy. though he exchanged that post for the chair of medicine. He also practised as a physician. Moreover, his attention was engaged on studies which ultimately led to his doctrine of latent heat. *(See* also HEAT: *Change of State.)* He noticed that when ice melts it takes up a quantity of heat without undergoing any change of temperature, and he argued that this heat must have combined with the particles of ice and thus become latent in its substance. This hypothesis he verified quantitatively by experiments performed at the end of 1761. In 1764, with the aid of his assistant, William Irvine (1743–87), he further measured the latent heat of steam. though not very accurately. This doctrine of latent heat he taught in his lectures from 1761 onward. and in April 1762 he described his work to a literary society in Glasgow. But he never published any detailed account of it, so that others: such as J. A. Deluc, were able to claim the credit for his results. His friend and student, James Watt. doubtless was influenced by these ideas in his revolutionary construction of the condensing steam engine. In the course of his inquiries Black also noticed that different bodies in equal masses require different amounts of heat to raise them to the same temperature, and so founded the doctrine of specific heats. He also showed that equal additions or removals of heat produced equal variations of bulk in the liquid of his thermometers. In 1766 he succeeded Cullen in the chair of chemistry in Edinburgh. Black died in Edinburgh on Nov. 10, 1i99 (not on Nov. 26 as stated in Robison's life).

Apart from the work already mentioned he published only two papers during his lifetime—"The Supposed Effect of Boiling on Water, in Disposing It to Freeze More Readily," *Phil. Trans.* (1775), and "An Analysis of the Waters of the Hot Springs in Iceland." *Trans. Roy. Soc. Edinburgh* (1794). After his death his lectures mere written out from his own notes. supplemented by those of some of his pupils. and published with a biographical preface by his friend and colleague, John Robison (1739–1805), in 1803 as *Lectures on the Elements of Chemistry, Delivered in the University of Edinburgh.*

See W. Ramsay's biography, *Life* and *Letters of J. Black* (1928); J. R. Partington, *A Short History of Chemistry, 3rd ed.* (1960). (R. E. O.; X.)

BLACKBERRY (BRAMBLE), prickly, fruit-bearing bushes of the genus *Rubus* (family Rosaceae, *q.v.*), natives chiefly of the north temperate regions of the old and new world. They are particularly abundant in the eastern part and the Pacific coast of North America and in the British Isles and western Europe as copse and hedge plants. The bush is characterized by its usually biennial, prickly. erect, semierect or trailing stems, leaves with usually three or five oval, coarsely toothed. stalked leaflets, many of uhich persist through the minter; white, pink or red flowers in terminal clusters; and black or red-purple fruits, each consisting of numerous drupelets adhering to a juicy core. It is a most variable plant, exhibiting many more or less distinct forms. In Europe evidence indicates that the Ice Age brought together two widely different species groups, the northern and southern. When they hybridized, the thousands of pseudogamic blackberries of Europe that come true to seed originated. Because of coming

(LEFT) ROCHE PHOTOGRAPHY, (RIGHT) JOHN H GERARD

BLOSSOMS AND FRUIT OF A CULTIVATED BLACKBERRY

exactly true to seed, they have reproduced themselves down through hundreds and thousands of years and in some cases have become widely distributed. There are relatively few good species. The Evergreen and Himalaya are varieties of European origin that are cultivated in the United States. This type is a pest over large areas of Australia, New Zealand, Chile and other countries.

In North America there are two groups, the Pacific coast trailing one, native from southern California to British Columbia, and the eastern group, both erect and trailing, native from southern Florida to Canada and west to the Great Plains. The Pacific coast group consists of only three to five trailing species that have very high flavour. Species of the eastern group have hybridized freely.

Originally there were probably some 20 species; now there are tens of thousands of hybrids and segregates of various types. Most cultivated erect-growing varieties have been derived from *Rubus allegheniensis,* R. *argutus* and R. frondosus. In the United States there are about 10,000 ac. under blackberry cultivation. In Oregon and Washington, Thornless Evergreen, Logan and Boysen are the chief varieties; in California Olallie, Boysen and Logan; in eastern states Eldorado. Early Harvest, Early Wonder and Lawton blackberries and Lucretia dewberry are the chief varieties.

The erect varieties are propagated by suckers and root cuttings, the trailing and semitrailing varieties by both tip layers (the tips being covered in late summer) and root cuttings (except Thornless Evergreen). The plants are usually set in early spring, the erect-caned varieties four by eight feet, the dewberries five by five feet or five by eight feet, and the Himalaya and Thornless Evergreen 16 by 8 ft. The canes of the dewberries and the Himalaya and Thornless Evergreen are commonly trained to a one-, two- or four-wire trellis, though the dewberry is often trained to stakes set about five feet by five feet. Virus diseases, the orange rust, leaf spots and anthracnose are common diseases. The cane borer and red berry mite are serious insect pests.

About 1,000 ac. of the blackberry are raised in Great Britain and a small quantity on the continent. The Logan (loganberry), Bedford Giant, Himalaya (Theodor Reimers), Evergreen (parsley-leaved or cut-leaf) and John Innes are the principal varieties and are grown chiefly in Kent and Worcestershire. Thornless sports of the Logan and Evergreen are available; they are as productive as the thorny and are preferred. Propagation of all these varieties is by tip layers.

The Boysen, similar to the Logan in habit, has been introduced into France and is well liked there. Logan and Boysen are set about 8 ft. apart in rows 8 ft. distant, the others 12 ft. to 15 ft. in the row and the rows 8 ft. to 10 ft. distant. The canes are trained to three-wire trellises with wires three feet, four feet and five feet high.

See "Blackberry and Raspberry Improvement" in U.S. Department of Agriculture ***Yearbook 1937,*** p. ***496; Farmers' Bulletin 1995, U.S.*** Department of Agriculture; ***Cane Fruits,*** Bulletin 156, British Ministry of Agriculture and Fisheries. (G. M. D)

BLACKBIRD, a name given to several different perching birds of predominantly black plumage. In North America several birds of the family of Icteridae are called blackbirds: the red-winged blackbird (*Agelaius* phoeniceus); the yellow-headed blackbird (Xanthocephalus *xanthocephalus*); and the grackles (*q.v.*).

The European blackbird (*Turdus* merula) is a member of the thrush (*q.v.*) family and a close relative of the American robin. It is one of the commonest of British birds. The males are recognizable by their black plumage and orange bill. The females are more thrushlike, being a dusky brown and the beak is also dark.

The European blackbird is an early nester, often beginning to lay in February, and raises two broods in the year. The nest, usually placed in bushes or hedgerows, is made of hay and coarse grass, neatly interwoven and lined with hair and fine grass. The eggs, three to five in number, are pale blue-green, mottled with brown. The young resemble the female in colour. Its food consists of fruits, buds, insects, worms, snails, etc. The song is mellow and flutelike. The blackbird is widely distributed over Europe and Asia, and, despite occasional raids on fruit trees, is, on the whole, a beneficial species. (G. F. Ss.; X.)

BLACK BODY, in physics. a theoretically perfect absorber and emitter of radiation, invisible as well as visible. The black body has been of great importance in theoretical studies and research. although its practical applications have been limited. Black-body radiation has been employed by physicists to study the fundamental nature of matter, and out of such studies have evolved the wave theory of light and quantum mechanics.

The term black is commonly applied to any substance, such as coal or pitch, that absorbs nearly all the light falling on it and reflects very little. Lampblack or smoke black consisting of very fine particles of carbon is usually taken as a typical example of a black substance. The majority of black substances owe their blackness to the presence of particles of carbon embedded in a binding medium; but even black substances reflect some light at the surface when smooth or polished. For scientific experiments in which complete absorption of the incident light is required, reflection at the surface must be avoided as far as possible. For this reason the internal surfaces of optical instruments, such as telescopes and cameras, are coated with a dead-black varnish having a matte surface to eliminate internal reflections that would obscure or fog the image.

In the case of visible radiation (light), a very small amount can be detected by eye, but the visible rays form a very small proportion of the total radiation from any source of artificial light and are completely absent in radiation from any radiator at a temperature below a red heat. It cannot be assumed that surfaces which appear black to the eye and are practically perfect absorbers of visible light are equally perfect absorbers of the invisible rays. Instruments for detecting or measuring radiation, such as the thermopile or bolometer, depend for their accuracy on the completeness of the absorption of all radiation over a range of wave length about 100 times greater than that of visible light. The sensitive receiving surfaces of such instruments are necessarily metallic and would be very poor absorbers of radiation. They are accordingly coated with a film of smoke black or platinum black to make the absorption as complete as practicable.

An absorption equivalent to 98% of the incident radiation may thus be obtained under favourable conditions. but it is very difficult to estimate the percentage defect and to make sure that it is the same for all wave lengths. Some allowance is usually made for incomplete absorption in modern experiments, but it remains one of the chief sources of uncertainty in accurate measurements. Complete absorption cannot be attained except by the adoption of the black body principle.

The theory of the black body as a perfect absorber is extremely simple. The apparatus consists merely of a chamber or box that is light-tight except for an aperture in one side; the inside of the enclosure is blackened. Any radiation entering through the hole is scattered and absorbed by repeated reflection so that only an infinitesimal fraction can possibly escape.

An example of near-perfect blackness can be seen by removing the lens from a box camera and covering part of the aperture with a card painted with the best dead black. The uncovered part of the aperture will appear of a much higher order of blackness than the most perfect dead-black coating procurable. The advantage of the method lies in the fact that the blackness thus secured is equally perfect for all wavelengths because of the complete elimination of surface reflection at the aperture.

The practical application of the principle to the construction of a perfect absorber of radiation is not quite as easy. With a simple chamber as above described, the radiation entering through the aperture would be scattered over the inner surface and could not easily be collected and measured. The experimental difficulties of this problem cannot be discussed here but are illustrated in the article on HEAT The application of the same principle to the construction of sources of radiation, also termed "black bodies," is described in the same article, but it will be well to explain here how the apparent misnomer "black" has come to be applied to a body emitting radiation.

It follows from the theoretical reasoning of Balfour Stewart (1858) and G R. Kirchhoff (1859), based on the equilibrium of temperature, that a body capable of absorbing radiation perfectly

at any temperature must be equally perfect in the emission of radiation. Further it follows that the intensity of radiation inside a hollow chamber at a uniform temperature depends only on the temperature, is the maximum possible at the given temperature. and is independent of the shape of the chamber or of the materials of which it is composed. Chambers of this kind, provided with suitable heating appliances and with apertures for the emission of the internal radiation, are commonly termed black bodies and are employed as sources of radiation of definite quality and intensity. The radiation they emit is the same as that of a perfectly black surface at the same temperature and is often called "black" radiation. The black-body temperature of a source like the sun is the temperature at which a black body would emit radiation of the same intensity.

See HEAT: "Full" and *Selective* Radiation; Absolute Measurement of Radiation; PLANCK, MAX KARL ERNST LUDWIG; QUANTUM MECHANICS: Black-Body Radiation; THERMOMETRY: Optical and Radiation Thermometry; WIEN, WILHELM.

(H. L. C.)

BLACK BUCK (Antilope cervicapra), the Indian antelope, the sole species of its genus. An adult male stands about 32 in. high at the shoulder. The general colour is brown deepening with age to black; the chest, belly and inner sides of limbs are pure white. as are the muzzle and chin and an area round the eyes. The doe is smaller and yellowish-fawn above. Horns present in males—and occasionally found in aged females—are long, ringed and form spirals with three to five turns. These fast-moving animals, formerly found in herds in grassy districts, are now so scarce that they are protected by law. See also ANTELOPE.

BLACKBURN, GIDEON (1772–1838), U.S. Presbyterian clergyman and Indian missionary, mas born in Augusta county. Va.. on Aug. 27, 1772. Sometime before 1790 his family settled in Washington county. Tenn. (then North Carolina). There Blackburn was educated at Martin academy (later Washington college). About 1794 he became a Presbyterian minister stationed at a military post which later became Maryville, Tenn. Following the Great Revival of 1800–03, in which he took an active part, he went to the general assembly of the Presbyterian Church to plead for the evangelization of the Cherokee Indians. During the next seven years he worked among the Cherokee, preaching, establishing schools and introducing better agricultural methods and new handicrafts.

When his' health began to fail he took up schoolteaching near Nashville, Tenn. There he formed a friendship with Andrew Jackson that continued until his death. In 1823 he became pastor of the Presbyterian Church at Louisville, Ky., and four years later president of Centre college, Danville, Ky. Blackburn was not successful as an administrator. Moreover, he mas a strong supporter of the so-called New School wing of Presbyterianism while labouring in quite strongly Old School territory. In 1830 he left Centre and in 1833 became a fund raiser for the new, decidedly New School. Illinois college. In 1835, turning to the founding of a theological seminary in Illinois, he built up an endowment of 16.656 ac. of land near Carlinville from payment for his services to persons seeking Illinois public lands. He died on Aug. 23, 1838.

(L. J. T.)

BLACKBURN, HELEN (1842–1903), British pioneer in the movement for the emancipation of women, was born on Valencia Island. Ireland, on May 25, 1842. She was the daughter of Bewicke Blackburn (d. 1897), a well-known civil engineer. The family moved in 1859 to London, where Helen Blackburn soon became interested in the movement for women's suffrage. When, in 1874, a National Society for Women's Suffrage was formed, she became its secretary. She was also editor of The Englishwoman's Review from 1881 to 1890. In 1895 however! she gave up most of her public work to look after her father. One of the first to recognize the significance of women in industry. she published on this subject The Condition of *Working Women* (1896) and *Women Under the* Factory Acts (1903). She also wrote *Women's Suffrage:* a Record of the *Movement* in the British Isles (1902). She died in London on Jan. 11, 1903. (M. A. H.)

BLACKBURN, JOSEPH (c. 1700–1774), English-born portrait painter, who had no important competitor during his stay in New England from 1753 to 1763. Research has yielded some authentic information about him. replacing earlier errors. In 1752–53 he painted 17 known portraits in Bermuda. For his American stay about 100 examples are listed. He was back in England by 1764 and the last recorded fact is the payment to him for two portraits in 1774.

Blackburn's manner is English rococo! probably out of Thomas Hudson, and it proved popular with the American colonials desirous of being fashionable. An occasional male portrait, such as that of "Theodore Atkinson" (museum. Worcester, Mass.), manifests some individuality in the features; but the majority, especially of women, emphasize pose and costume at the expense of characterization. More than once a design is repeated even to details of costume and jewelry; an instance of this occurs with the "Margaret Sylvester Chesebrough" (Metropolitan Museum of Art, New York city) and the "Mary Browne Greenleaf" (privately owned). Nevertheless, Blackburn's formula was still superior to those of other workmen at the time in drawing and handling of pigment. These relative merits, together with Blackburn's animated posing and placement of his subjects, exerted an influence upon the youthful John Singleton Copley so strong as to constitute a distinct though brief stage in the latter's development into the more monumental style of his maturity.

See L. Park, Joseph Blackburn, a Colonial Povtrait Painter (1923); J. H. Morgan and H. W. Foote, *An Extension of Lawrence Park's Descriptive List* (1937). (VL. B.)

BLACKBURN, a municipal, county and parliamentary borough of Lancashire, Eng., 10 mi. E. of Preston. Pop. (1961) 106,114. Area 12.6 sq.mi. It lies in the valley of a stream called in early times the Blackburn. For some time the chief town of an area called Blackburnshire. Blackburn was a flourishing market ton-n of about 2.000 inhabitants during the reign of Elizabeth I. Its weaving tradition had beginnings in the 13th-century wool trade; from Elizabeth I's time flax from Ireland was used for making the blue and white "Blackburn checks" cloth. which, in turn, was superseded by a linen-and-cotton fabric known as "Blackburn greys." But expansion did not come until the spinning jenny, invented by James Hargreaves about 1764 at nearby Stanhill. and other textile machinery speeded up cotton spinning. The Leeds-Blackburn-Liverpool canal, completed 1816, helped transport and was a useful source of water. as is shown by the many mills lining it. Coal, lime and building materials abounding in the neighbourhood also helped expansion.

Though about a quarter of the working population is engaged in textiles. especially weaving, there is a variety of other trades. including the making of engineering and electrical equipment. paper, vehicles. beer, animal products and lubricants. Five cattle and horse fairs are held yearly, the oldest dating to 1583. There are many markets. The grammar school (1567) is housed in a 19th-century building. Blackburn diocese was carved out of Manchester in 1926 when the parish church of St. Mary was made the cathedral and extensions were started, the foundation stone being laid in 1938.

Of interest are the Lewis textile museum and the public library, museum and art gallery, which has a collection of Lancashire birds. In 1954 a new municipal technical college was opened. Corporation park (60 ac.) and Witton park belong. with several others, to the corporation. A few miles west-northwest is Samlesbury airfield and to the north is Stonyhurst college. a Roman Catholic boys' school. Blackburn. incorporated in 1851, sends one member to parliament.

BLACKCAP (Sylvia *atricapilla*), a small warbler (*q.v.*), notable for the beautiful song and black cap of the male, the female having the top of the head brown. The rest of the plumage in both sexes is gray. The blackcap is a summer resident in northern Europe and the British Isles, but lives the year round in southern Europe, northwest Africa and nearby islands. The male often helps to incubate the eggs and may betray the nest by singing while sitting. (G. F. Ss.)

BLACKCOCK, male of the black grouse (*Lyrurus* tetrix), the female of which is called grayhen. One of the largest members

of the family Tetraonidae, which includes many notable upland gamebirds, it is about 21 in. in length and has glossy blue-black plumage with white under tail coverts and white wing bar. Its appearance is much enhanced by a lyre-shaped tail and conspicuous scarlet wattles above the eyes. The female is much smaller than the male, measuring about 16 in. and weighing only 2 lb., and has reddish brown plumage, irregularly barred with black.

PAUL POPPER

BLACKCOCK (LYRURUS TETRIX) IN COURTSHIP DISPLAY

The species is widely distributed in England, Europe and northern Asia. A smaller, related species, the Georgian black grouse (L. *mlokosiewiczi*), is restricted to the Caucasus mountains at altitudes of 5,000–9,000 ft.

Little is known of the habits of the black grouse, but the Eurasian species frequents wet woodlands, moors and rocky hillsides, and feeds principally on vegetable matter. Blackcocks are polygamous, and in spring perform remarkable communal dances on special display grounds called leks for the benefit of the assembled grayhens.

The courtship performances begin at dawn and sometimes are continued at intervals through the day. There is much strutting, posturing and jumping accompanied by loud vocalization that includes slurred, wheezing and gobblerlike notes that attract females from a distance. Fighting is largely formalized. but fierce combat sometimes occurs, and victorious cocks are accepted by an ever-changing harem. Eggs of black grouse are yellowish-white! scantily marked with brown, and usually six to ten in number. The nest is a hollow scraped in the ground by the female. Females of other species. especially red grouse (*Lagopus scoticus*) and capercaillie (*Tetrao urogallus*), may also be attracted to the display ground, where random matings with blackcocks have produced the well-known intergeneric hybrids that are often seen. (E. R. BE.)

BLACK COUNTRY, THE, an industrial area containing about 20 towns of the English midlands west and northwest of Birmingham. The towns included are: (in Staffordshire) Aldridge, Walsall, Willenhall, Wednesfield, Wolverhampton, Tettenhall, Sedgley, Coseley, Bilston. Darlaston. Wednesbury. West Bromwich, Tipton, Brierley Hill, Rowley Regis, Smethwick; (in Worcestershire) Dudley, Oldbury, Stourbridge, Halesowen. The name is derived from the murk produced by the collieries. blast furnaces, foundries. etc., set up there during the Industrial Revolution because of the presence of the south Staffordshire coal field with its coal, iron ore, fireclays and limestone. Coal mining had almost ceased by the 1960s, iron ore was no longer worked and the dense network of canals was mostly derelict. Grass grew on old tip-heaps and quarries had been laid out as public parks. However, the Black Country remains intensely industrial.

BLACK DEATH, the name later given to the plague which ravaged Europe between 1347 and 1351 and which proved to be the greatest catastrophe experienced by the western world up to that time. It was also the first widespread epidemic of which sufficient documentary evidence is extant for its course to be tracked and its severity and consequences assessed with any degree of accuracy.

Origin and Incidence.— The Black Death came from Asia, where it had already wrought havoc in China and in Turkistan. It decimated the army of the Kipchak khan Janibeg. while he nas besieging the Genoese trading port of Kaffa (now Feodosiya) in the Crimea (1347), and by catapulting plague-infested corpses into the town the khan contrived to infect his enemies. From Kaffa Genoese ships carried the epidemic westward to the Mediterranean ports. whence it spread inland, halted neither by prayer nor by physic, nor even by mass burnings of Jews, who nere popularly held to have spread the disease by poisoning the wells. Sicily suffered in 1347; North Africa, Corsica. Sardinia, Italy, Spain and France in 1348; Austria, Hungary, Switzerland, southern Germany, the Rhine valley and the Low Countries in 1349. A ship from Calais carried the plague to Melcombe Regis. Dorset, in Aug. 1348; it reached Bristol almost immediately and spread rapidly throughout the southwestern counties of England. London suffered most violently between Feb. and May 1349, East Anglia and Yorkshire during that summer. The Black Death reached the extreme north of England, Scotland, Scandinavia and the countries round the Baltic sea during 1350.

Contemporary descriptions, especially that of Boccaccio in the introduction to his *Decameron,* suggest that the Black Death was probably bubonic plague *(see* PLAGUE). The rate of mortality varied from place to place: whereas some districts, such as the duchy of Milan, Flanders and Béarn, seem to have escaped comparatively lightly, others, such as Tuscany. Aragon, Catalonia and Languedoc were very hard hit. Towns, where the danger of contagion was greater, were more affected than the countryside; and within the towns the monastic communities provided most victims. Neither the great nor the powerful were immune: among royalty, Eleanor, queen of Peter IV of Aragon, and King Alfonso XI of Castile, succumbed, and Joan, daughter of the English king Edward III, died at Bordeaux on the way to her wedding with Alfonso's son. Canterbury lost two successive archbishops, John de Stratford and Thomas Bradwardine; Petrarch lost not only Laura, who inspired so many of his poems. but also his patron, Giovanni Cardinal Colonria. Four of the five councilors of Barcelona died and the staff of the papal court at Avignon was reduced by one-fourth. There also died so vast a multitude of labourers and artisans that enlargement of the cemeteries became an urgent necessity. Whole communities and families were sometimes annihilated; such a fate befell certain Dominican friaries in Tuscany and Languedoc. and the young Francesco di Marco Datini, afterward a merchant in Prato, lost almost his entire family.

The study of contemporary archives suggests a mortality varying in the different regions between one-eighth and two-thirds of the population, and Jean Froissart's statement that about one-third of the world's population died in the epidemic seems a fairly accurate average. A toll so heavy has been taken by no other plague or war.

Consequences.— The consequences of this violent catastrophe were many. and varied from region to region. Some, such as the cessation of wars and the sudden slump in trade, followed immediately but were of only short duration. Many of the more serious economic consequences, the reduction of tillage. the decline in rents, the ruin of the landowning classes and the general rise in wages, proved the more lasting since there were many recurrences of the plague, notably during the years 1361–63, 1369–71, 1374–75, 1390 and 1400. The psychological damage was also great. insecurity and a constant fear of death leading many into curious excesses of mysticism or to an unhealthy morbidity. Some events can be directly attributed to the plague: the Nestorian Christian communities of central Asia, for instance, were almost wiped out; and a turning-point was reached in the fortunes of Catalonia, since its military and economic expansion had depended entirely on a rising birth rate. The expanding economy of Siena received a decisive check; the population, indeed, was so diminished that the citizens abandoned the project of enlarging their cathedral; and the death of many great painters such as Ambrogio and Pietro Lorenzetti, brought the development of the first Sienese school to a premature end. The Dominicans suffered so severely that they were driven to receive postulants of little education or culture; thus the quality of an order, which had constituted the intellectual elite of Christendom, had seriously declined by the end of the 14th century, a fact certainly not unconnected with the subsequent increase in superstitious practice and with the growth of various heresies. In England the immediate effects of the epidemic of 1348–49 seem to have been of short duration, and the economic decline which reached its nadir in the mid-15th century should probably be attributed rather to the pandemic recurrence of the plague. 'Tendencies and movements already discernible were increased and accelerated. The population, estimated at 2,500,000–4,000,000 in about 1300, had already begun to decline by 1348. In 1400, however, it was perhaps half what it had been 100 years ear-

lier. The Black Death certainly caused the depopulation or total disappearance of about 1.000 villages. Moreover there had already been some commutation of villein services and introduction of leasehold before the Black Death. Many oi these changes brought a new fluidity to the hitherto rigid structures of society.

The population of western Europe did not again reach its pre-1348 level until the beginning of the 16th century and some historians consider the development of several countries to have been seriously retarded by endemic plague. F. A. Gasquet. who first drew attention to the violent incidence and the grave consequences of the Black Death in his book *The Great Pestilence* (1893). regarded it as the dividing point between medieval and modern history. However exaggerated his thesis, it has at least the merit of stressing the exceptional importance of the greatest disaster in western European history.

BLACK DROP, in astronomy. an apparent distortion of the planets Mercury or Venus at the time of internal contact with the edge of the sun at the beginning or end of a transit. (A "transit" of Mercury or Venus refers to a passage by either planet between the earth and the sun; *see* MERCURY; VENUS) The black drop has been in the past a source of much perplexity to observers of transits, but is now understood to be a result of an optical phenomenon produced by the atmosphere or by the aberration of the observing telescope.

BLACKETT, PATRICK MAYNARD STUART (1897–), British physicist. received the Nobel prize for physics in 1948 for his discoveries in cosmic radiation. He was born in London on Nov. 18. 1897. After graduating from Cambridge in 1921 he spent ten years as a research worker in the Cavendish laboratory. Early in this period Blackett began to develop the cloud chamber (*q.v.*) of C. T. R. Wilson into an automatic instrument for the study of nuclear disintegrations. Adapting this instrument to the investigation of cosmic radiation. Blackett devised the counter-controlled cloud chamber. The development of this powerful instrument and Blackett's subsequent successful application of it to the gathering of data on cosmic radiation were recognized by the award of the Nobel prize. He was elected fellow of the Royal society in 1933.

From 1933 to 1937, Blackett was London university professor of physics at Birkbeck college. leaving to become Langworthy professor of physics in the University of Manchester. While establishing a school of cosmic ray research that was internationally renowned, Blackett stimulated the development of other research interests. the most notable of which led to the creation of the first chair of radio astronomy and the building of the Jodrell Bank experimental station for radio astronomy.

In 1953 Blackett was appointed professor and head of the physics department of the Imperial College of Science and Technology, London. (N. CE.; X.)

BLACKETT, WILLIAM CUTHBERT (1859–1935), pioneer in the dilution of coal dust with inert rock. or stone dust to render it harmless, mas born at Durham, Eng.. on Nov 18 1859. Following study at the Durham College of Physical Science and mining apprenticeship, he undertook mine management and from 1887, was in charge of all the mines of the Charlaw and Sacriston collieries. He had wide experience of colliery explosions. was one of the first to recognize the danger of coal dust and was the first person in the north of England to use inert dust to render harmless the coal dust in mine passageways. He patented a number of mechanical appliances and safety devices for use in mines and served on many committees dealing with mine accidents Among the honours and awards bestowed upon him were the Royal Humane society's silver medal for gallant rescue work (1903), the Greenwell medal of the North of England Institute of Mining and Mechanical Engineers (1906), presidency of that institute (1912–14), the medal of the Institution of Mining Engineers (1917) and presidency of that institution (1919–20). Blackett died at Durham on June 13, 1935. (C. W. D.)

BLACK-EYED SUSAN. A species of coneflower (*Rudbeckia hirta*), called also yellow daisy, native to dry open grounds from Ontario to Manitoba southward to Florida and Texas and widely distributed east of this area as a troublesome weed. It is a rough. hairy herb, about 2 ft. high, with thick, lance-shaped leaves and long leafless flower stalks with a single large head. 3 in. to 4 in. across. composed of brilliant golden-yellow ray flowers surrounding a dark brown cone-shaped centre (disk). It is a handsome but weedy American wild flower, rarely grown for ornament, and is the state flower of Maryland.

BLACKFISH, the name applied to various dark-coloured fishes. In the United States, it most commonly refers to the tautog (*Tautoga onitis*), but is also used of the black sea bass (*Centropristes striatus*) of Atlantic waters. and a minnow (*Orthodon microlepidotus*) of central California. In Alaska, the blackfish is the small, fresh-water *Dallia pectoralis.* In England, it is *Centrolophus niger,* a fish about 2 ft. long and shaped like a perch. By whalers "blackfish" denotes whales of the genus *Globicephalus,* which includes the ca'ing or pilot whale (G. *melas).*

BLACK FLY, any member of the family Simuliidae of the order Diptera *(see* FLY), regardless of colour. which is generally black or gray, only a few being yellowish. About 300 kinds are known, widely distributed throughout the world. They are also called turkey gnats and buffalo gnats. They are small, hump-backed flies with gauzy wings, stout antennae and legs and rather short mouth parts adapted for blood sucking. Only the females bite; they are sometimes so abundant as to kill chickens, birds and other domestic animals.

Simuliid adults, *Simulium caecutiens* in Africa and *Eusimulium avidum* and *E. ochraceum* in America, are vectors of nematode worms. *Onckocerca volvulus,* causing the disease onchocerciasis in man, is known from Mexico, Central America and Africa, and results in blindness if the worms settle in the eye; otherwise it causes subcutaneous nodules.

The larvae and pupae are aquatic, living only in flowing or moving water, in streams and on wave-washed shores. The larvae occur on stones. dams. weeds, etc.. in fast flowing streams. The adults emerge directly from the water; the pupa frees itself from its cocoon, rises to the surface on a bubble of air. the back splits open, and the adult emerges and flies away. Repellents used for mosquitoes keep them away.

See also ENTOMOLOGY: *Medical and Veterinary Entomology.* (C. H. CN.)

BLACKFOOT, a group of three closely related and allied Algonkian-speaking tribes in Alberta and Montana, also known as Siksika and comprising the Blackfoot proper, Piegan and Blood. In the early years of the 18th century these tribes were pedestrian buffalo hunters living in the Saskatchewan valley about 400 mi. E. of the Rockies. Before 1750 they acquired horses and firearms. Driving weaker tribes before them they pushed westward to the Rockies and southward into present Montana. At the height of their power, in the first half of the 19th century, the Blackfoot held a vast territory extending from the North Saskatchewan to the southernmost headwaters of the Missouri.

The Blackfoot were known to fur traders as the strongest and most aggressive military power on the northwestern plains. For a quarter century after 1806 they prevented Americans from trapping in the rich beaver country of the upper tributaries of the Missouri. At the same time they warred upon neighbouring tribes, capturing horses and taking scalps. Horses were their wealth. Some rich men owned hundreds of these animals.. Poor men had few or none at all. Each Blackfoot tribe was divided into several hunting bands led by one or more chiefs. These bands wintered separately in sheltered river valleys. In summer the scattered bands gathered in a great encampment to observe the sun dance, the principal tribal religious ceremony. Many individuals owned elaborate medicine bundles which they believed would bring success in war and protection against sickness and misfortune.

For three decades after their first treaty with the United States

in 1855, white men's efforts to encourage the Blackfoot to forsake the chase in favour of farming were of little avail When the buffalo were almost exterminated in the early 1880s, nearly one quarter of the Piegan died of starvation. Thereafter the Blackfoot made progress as farmers and cattlemen. In 1950 approximately 5,900 Indians (mostly of Piegan descent) lived on the Blackfoot reservation in Montana. Less than 20% of them were fullbloods. In addition there were 2,600 Indians on the Blackfoot, Blood and Piegan reserves in Alberta. *See* also ALGONKIAN TRIBES; PLAINS INDIANS.

Ewers, "The Horse in Blackfoot Indian Culture," Bureau of American Ethnology *Bulletin 159* (1955), *The Blackfeet, Raiders on the Northwestern Plains,* "Civilization of the American Indian Series" (1958); C. Wissler in *Anthrop. Pap. Amer. Mus.,* rol. v, pt. 1 (1910), vol. vii, pt. 2 (1911), vol. xi, pt. 4 (1913), vol. vii, pt. 2 (1912), and vol. xvi, pt. 3 (1918). (J. C. Es.)

BLACK FOREST (SCHWARZWALD), a highland in southwest Germany, in the Land of Baden-Württemberg, Federal Republic of Germany. Area 2.320 sq.mi.; total length. about 100 mi.; breadth varying from 10 to 25 mi. Structurally and topographically the Black Forest forms the counterpart of the Vosges, which lies west of the sunken valley of the Rhine.

The Black Forest is mainly a granite highland with rounded summit levels, though its northern part consists of forested red sandstones. It drops abruptly to the Rhine plain. It is bordered to the south by a narrow band of lower and more fertile limestone country. It is divided into two parts by the deep Kinzig valley, with the highest summits; *e.g.,* Feldberg (4,905 ft.), Herzogenhorn (4,642 ft.) and Blössling (4,295 ft.). to the south. The northern half has an average height of 2.000 ft. The climate in the higher districts is raw and only hardy cereals are grown; but the valleys are warm, with good pasture land. Oak and beech woods clothe the lower spurs, while stretching up to 4.000 ft. are the extensive forests of fir which have made the terms "forest" and "mountain" synonyms there. The excellent timber is partly sawn in the valleys and partly exported down the Rhine in logs. The manufacture of watches, clocks, toys and musical instruments is typical of this and other forested areas of central Europe.

There are numerous mineral springs and watering places, *e.g.,* Baden-Baden and Wildbad. The towns of Freiburg im Breisgau, Rastatt, Offenburg and Lahr lie under the western slopes. The Black Forest is a favourite tourist and winter sports resort.

(R. E. DI.)

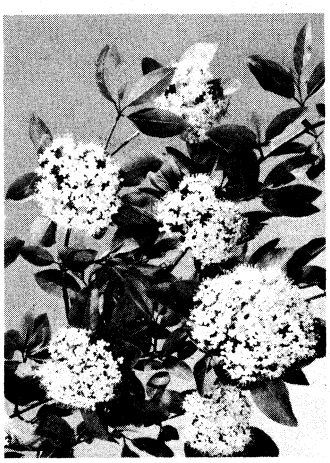
BLACK FRIDAY, a term sometimes applied to Good Friday or to some specific Friday on which a serious crisis occurred. In England the term was used as early as the 18th century to denote the date Dec. 6, 1745, when news of the landing on English shores of the Young Pretender reached London and caused a panic. More than a century later the term was applied to May 11, 1866, when the banking house of Overend and Gurney of London failed and caused widespread financial distress.

In U.S. history, Sept. 24, 1869, came to be known as Black Friday because of the panic in the securities market that occurred then. For some time before that date the balance of trade had been running steadily against the United States and gold was being drained out of the country in tremendous amounts. This situation suggested to Jay Gould, the financier and, speculator, and James Fisk, the Erie railroad magnate, that they might be able to corner the available gold supply, drive the price up and thus make a huge profit. Through the influence of his friend, Abel R. Corbin, who was Grant's brother-in-law, Gould was able to persuade the president not to release any government gold for sale, for that would have prevented his maintaining his corner on gold. In a short time, buying by Fisk and Gould forced the price of $100 in gold up to $140 in paper money, a price that was reached on Sept. 20, 1869. But by this time Grant realized what Gould and Fisk .were doing. Gould learned that the president intended to sell government gold and secretly began selling his own. But he did not inform Fisk, who continued buying until Friday, Sept. 24, when the price of gold touched 163½. Finally, the secretary of the treasury ordered the sale of $4,000,000 in government gold, which quickly reduced the price to 133 and caused a panic in the securities market.

Another financial crisis occurred in U.S. history on Sept. 19, 1873, another Friday. The day before, the firm of Jay Cooke and Co. had failed, and Sept. 19 saw the failure of many other investment firms, marking the beginning of the panic of 1873.

(B. MI.)

BLACK HAW (*Viburnum prunifolium*), a showy North American shrub or small tree of the honeysuckle family (Caprifoliaceae), called also stagbush, and often cultivated for ornament. It grows in dry soil from Connecticut and southern New York westward to Michigan and southward to northern Georgia. Texas and eastern Kansas. Although somewhat bushy in habit, with a short. usually crooked trunk, six to eight inches in diameter, and rigid, spreading branches, it sometimes reaches 30 ft. in height. It bears smooth, ovate, very finely toothed leaves and numerous small white flowers in compact clusters, two to four inches broad, and sweet, edible. bluish-black fruits (drupes), about one-third inch long. each containing a much flattened stone. The similar but larger southern black haw (*V. rufidulum*), sometimes 40 ft. high, with fruit one-half inch or more long and containing a nearly orbicular stone, is found in dry upland woods from Virginia westward to Missouri and southward to Florida and Texas.



ROCHE PHOTOGRAPHY

BLACK HAW (VIBURNUM PRUNIFOLIUM)

The nannyberry or sheepberry (*V. lentago*) in some districts is called also black haw. In the Carolinas the root bark of *V. prunifolium* was once widely collected as a source of the "fluid-extract of black haw." This contains a crystalline glycoside thought to provide an effective depressant of uterine contractions.

See VIBURNUM. (E. S. HR. N. TR.)

BLACK HAWK (Indian MA-KA-TAI-ME-SHE-KIA-KIAK) (1767–1838), a chief of the Sauk and Fox Indians, was born at Sauk village, Illinois, near the Mississippi river in 1767. Naturally antagonistic to Americans who were settling in territory which he insisted his people had not surrendered. Black Hawk joined the British in a number of engagements in the War of 1812. Thereafter U.S. officials cultivated Keokuk, a rival chief, and thus incensed Black Hawk and confirmed him in his hatred of Americans. With other discontented Sauk and Fox Indians he conferred with the British, who encouraged the Indians in their intransigence and gave them medals and supplies. For a time Keokuk's moderation prevailed, but as white men continued to penetrate the disputed territory, taking over the Indians' cornfields and cabins, Black Hawk regained power.

In 1832 Black Hawk and his British band were led to believe that other tribes would aid them, and were at the same time made desperate by hunger for food and for their old homeland. They crossed the Mississippi to the disputed area to plant crops and to resist further white encroachments. That the band of 1,000 included old men, women and children shows the move was not aggressive. Gov. John Reynolds of Illinois, alarmed at the "invasion," called out the militia and the United States despatched troops to repel the redmen. Black Hawk's band first caught the militia unaware and inflicted on them a stinging defeat. But their strength soon waned. The expected aid from other tribes did not materialize; food supplies were quickly exhausted; desertions, malnutrition and illness took their toll. During the Indians' retreat northward through the Rock valley bloody atrocities were committed on both sides. The superior forces prevailed and in the final battle or massacre at the Bad Axe river most of the surviving band were brutally slaughtered. Black Hawk himself escaped but was shortly captured and taken east where he was put in jail. In 1834 he was returned as a hostage to Keokuk's charge, a final blow to his pride from which he never recovered. He died Oct. 3,

1838. A later generation saw Black Hawk as a romantic figure and erected a huge statue of him by Lorado Taft near Oregon. Ill.

Black Hawk's own story was told in *Life of Ma-ka-tai-me-she-kia-kiak* (1833).

See William *T*. Hagan, ***The*** *Sac and Fox Indians (1958).*

(P. W. G.)

BLACKHEATH, an open common and residential district! mainly in the metropolitan boroughs of Lewisham and Greenwich, 6 mi. S.E. of Charing Cross, London, Eng. This high-lying tract was crossed by the Roman Watling street from Kent, on a line approximating to that of the modern Shooter's Hill; and was a rallying ground of Wat Tyler (1381), of Jack Cade (1450), and of Lord Audley, a leader of the Cornish rebels, defeated and captured there in 1497. It mas once the haunt of highwaymen.

At Blackheath the citizens of London greeted Henry V on his return from Agincourt, and the army of the Restoration met Charles II there. The introduction into England of the game of golf is traditionally placed there in 1608, and attributed to King James I and his Scottish followers. Ancient barrows were opened on the heath. The common, with an area of 267 ac. (179 ac. in Lewisham, *q.v.*), is used as a recreation ground.

BLACK HILLS, an isolated mountain range in western South Dakota and eastern Wyoming, U.S. The mountain mass has an elliptical shape; the north-south axis extends for 88 mi. and the shorter east-west axis for 60 mi. The hills rise about 3.000 ft. above the surrounding Great Plains. The highest peak, Harney, has an altitude of 7,242 ft. The Black hills are a result of upwarping of the earth's crust; removal of the higher portions of the dome by stream erosion has produced the present unique topographic features. The broken edges of the sedimentary strata about the ancient core form a concentric pattern; the more resistant strata form ridges and the softer rocks yield to form the concentric valley lowlands.

Scientific explorations began in the area as early as 1849 and some placer gold was worked. Members of a military expedition under George A. Custer discovered rich veins of gold in 1874. This discovery lead to the gold rush days of 1875–76 and the great boom period of the area. One rich vein of gold (Homestake) located at Lead has yielded $500,000,000. In addition to gold, 29 other minerals have been found in the area, including beryllium and lithium, both of which are necessary in the production of atomic energy. Immediately west of Rapid City is Mount Rushmore National memorial (*q.v.*), a noted tourist attraction.

The climate of the Black hills is humid in contrast with the semiarid conditions of the surrounding plains. In response to these climatic differences the short grasses of the plains give way to the cedars and junipers of the foothills and the forests of spruce, ponderosa pine, lodgepole pine and limber pine further up the slopes. From a distance the forested slopes have a dark appearance—thus the name Black hills. Lumbering and grazing under government regulation are important activities of the area.

(H. B. H4.)

BLACK JACK, one of the world's most popular gambling games played with cards. is a version of the French game *cingt*-et-un or twenty-one (as it is known in U.S. gambling houses) and is basically similar to baccarat (*q.v.*). Its aim: to acquire a total card value as near as possible to a given figure without exceeding it, is a principle of gambling games known long before playing cards were invented.

In black jack, the desired total is 21. A player tries to acquire cards which count exactly 21 or to stop closer below it than does the dealer (banker) against whom all betting is done.

Any number may play, using the standard 52-card deck. If there are a large number of players. two decks may be shuffled together and used as one. An ace counts 1 or 11 at the option of the holder, picture face cards count 10 each and all others take their pip or number value.

Play. — First dealer is chosen by cutting for high card or dealing until someone receives the first ace. After the deck is shuffled and cut, dealer exposes the top card and "burns" it by placing it face up at the bottom of the pack. If the top card is an ace. the deck must be reshuffled and another card burned. Dealer then gives each player, including himself, one card face down. Each player looks at his card and places a bet. The maximum bet may be established by agreement before the game begins or by each dealer for his deal.

Dealer then looks at his own card and may, if he wishes, double all bets He then deals to each other player and to himself a second card face up. Cards are always dealt clockwise, beginning at the dealer's left.

If a player's first two cards total exactly 21 he has a "natural" or "black jack," and wins double his bet.

If dealer has a natural he shows it at once and collects double from all players except one with another natural, who pays only nhat he bet.

After all bets on naturals have been settled, dealer offers additional cards to each player in turn. A player may "stand" on his two cards or ask for more by saying "hit me." Additional cards are then dealt to him face up one at a time, until he stands or goes over 21 (busts). If he busts, he pays the dealer immediately.

At dealer's turn. which is last, he may also stand or draw. If he busts, he pays any player with whom he has not already settled; if he hits 21 or stays under, he collects for a tie and from any player having a lower count. but pays to any hand nearer 21.

After each hand, dealer puts all the dealt cards face up at the bottom of the pack. When the "burned" card is reached. the deck is reshuffled and play continues. The deal, which carries a decided betting advantage, passes in rotation to the left after each deal or it may go to the first player to receive a natural.

Players' Options. — If a player's first two cards are a pair. he may turn them face up, duplicate the amount of his bet and play both as separate hands. the next card to each hand being dealt face down.

If a player's first two cards count to 11, he may turn them both face up. double his bet and receive one card face down. But he may draw no more; his bet is settled on his three cards.

Bonus Payments. — A player having a count of 21 or less in five cards can at once collect double his bet, regardless of dealer's total, or he can call for a sixth card and. if he still has less than 21 collects four times the amount of his bet. However, if the sixth card causes him to bust, he loses. A player making 21 with three sevens receives three times the amount of his bet

Twenty-one. — As played in gambling houses the game has somewhat different rules. In gambling houses there is a permanent dealer representing the house or bank. Usually, each player must bet before any card is dealt. The dealer pays a natural one and one half times the bet, but if his own natural is tied, such ties are standoff. The permanent dealer has no option on whether to stand or dram another card; he must stand on a count of 17 or more, but must continue to draw on 16 or less. Bonus payments are not made.

(R. L. FY)

BLACKMAIL, or extortion (*q.v.*) as it is sometimes labeled, is one of the more serious crimes in Anglo-American law. In ordinary language it may be described as the demanding of money or other advantage (1) on the threat of exposure of information, true or false, about the victim; or (2) on the threat of violence to the person or property of the victim or of a third person in whom the victim has an interest. (In some jurisdictions, the term extortion is used to describe only intimidation by one acting under colour of official right.)

Blackmail was a crime at common law, though its exact scope was uncertain. At least as early as 1601, however, it became the subject of legislation and both in the British empire and the United States became generally proscribed by statute In England. the governing provisions are to be found in sec 29, 30 and 31 of the Larceny act of 1916. (Under these provisions, threats to obtain advantages other than money or personal property are not condemned.) In the Cnited States. if the activities of the blackmailer come into contact nith that area of regulation assigned to the national government. for example by using the U S. mails to make the threat, they could constitute a federal crime as defined in sec 871 through 877 of the U.S. criminal code. Generally. however, the crime of blackmail is controlled by the laws of the several states. with the consequent variations in the law which

occur from one jurisdiction to the next.

Insofar as it is possible to generalize from the myriad of governing statutes and decisions, it is the threat which constitutes the essence of the crime of blackmail; it is not necessary that the victim succumb. Some threats are illegal as blackmail although the advantage sought was believed by the threatening party to be due him and indeed was due him. Thus. a threat to use physical violence, or to accuse of wrongful acts other than the failure to satisfy the demand rightfully made, could constitute the crime, although in fact the victim was required by law to perform the very acts which the threatening party demanded of him. Some threats, on the other hand, are improper only because the advantage sought could not reasonably be believed to be due from the victim. Thus a threat to sue or to accuse of not satisfying a liability could constitute blackmail if the threatening party made the threats with knowledge that his demands could not be made in good faith. Most prosecutions for blackmail involve those cases in which the threat is made without any pretension to a right to the money. property or other advantage demanded. It is not blackmail, however, to demand in good faith indemnity for a wrong actually suffered even though legal proceedings to enforce the demand might in fact bring shame and disgrace upon the person addressed.

Some jurisdictions follow the English example of permitting the victim of a blackmailing to prosecute in anonymity. Most jurisdictions. however, do not grant this protection to extortion victims. In these. the victim is put to the very difficult question of whether he should initiate prosecution which may bring about the very publicity with mhich he may be threatened by the blackmailer.

Punishment for conviction for blackmail is usually severe. The law in England draws a distinction between demanding with menaces, demanding with intent to steal. and threatening to publish with intent to extort. In England, where the crime has been appropriately called moral murder, punishment may be as heavy as life imprisonment. In spite of the weight of punishment usually accorded. the incidence of this crime is high. (P. B. K.)

BLACKMORE, SIR RICHARD (1654–1729), English physician and writer, who became physician in ordinary to William III (who knighted him in 1697 for professional services) and Anne. He was born at Corsham. Wiltshire, and died, on Oct. 9, 1729, at Boxted. Essex. Though he regarded poetry as merely the entertainment of his idle hours, he found time to write four epics in ten or more books. *Prince Arthur* (1695), *King Arthur* (1697), *Eliza* (1705) and *Alfred* (1723). He also wrote *Creation, A Philosophical Poem* (1712), designed to counter the spirit of skepticism by demonstrating "the Self-Existence of an Eternal Mind from the created and dependent Existence of the Universe"; this received high commendation in the *Spectator*. To each poem he wrote a preface censuring the lewdness and impiety of modern wits, a subject also treated in his verse *Satyr Against Wit* (1700). These and other writings in prose provoked retorts from Alexander Pope and his friends, and earned Blackmore his reputation as "father of the Bathos. and indeed the Homer of it."

See Richard *C*. Boys, *Sir Richard Blackmore and the Wits* (1949); *E*. Hudson Long, "Notes on Sir Richard Blackmore," *Modern Language Notes,* lviii, 585–9 (1943). (J. E. Bt.)

BLACKMORE, RICHARD DODDRIDGE (1825–1900), English Victorian novelist whose west country romance *Lorna Doone* holds a secure place among English historical novels, was born on June 7, 1825, at the parsonage of Longworth, Berkshire. Educated at Blundell's school, Tiverton, and Exeter college, Oxford. he was called to the bar but withdrew because of ill-health. He married in 1852 and taught classics for five years. Then. upon receiving a legacy, he bought a property at Teddington and settled down to fruitgrowing and novel writing.

After publishing some poems, Blackmore produced *Clara Vaughan,* a first and fairly successful novel, in 1864 and *Cradock Nowell* in 1866. *Lorna Doone* (1869) was his third. Its popularity grew slowly, until the qualities of this imaginative and exciting tale of Exmoor eventually brought it fame. Blackmore himself, a shy, reserved, but kindly man who was prouder of his peach orchard than of his 14 novels, preferred *The Maid of Sker* (1872) but is remembered for *Lorna Doone*. He died at Teddington on Jan. 20. 1900.

See M Elwin, *Victorian Wallflowers* (1934); *Q* G Burris, "R. D. B.: His Life and Novels," *University of Illinois Studies in Language and Literature* (1930), which includes bibliography.

BLACK PLATE: *see* Tin Plate and Terxeplate.

BLACKPOOL, a municipal, county (1904) and parliamentary (1918) borough of Lancashire, Eng., 17 mi. W.N.W. of Preston by road. Pop. (1961) 152,133. Area 13.2 sq mi. This town on the Irish sea was in the 16th century a small hamlet known as Pool Houses, but by the 1780s it was already in vogue as a bathing place consisting of houses and inns scattered along the coastline. When William Hutton, a Birmingham man, visited Blackpool with his family in 1788, he wrote about the resort and his booklet was immediately bought up by enterprising innkeepers. This "infant commonwealth" had a coffeeroom, several hotels and a reputation for the health-giving effects of the sea water. The town's rapid growth was related to that of the Lancashire industrial area. With the development of a fast railway service and places of amusement, Blackpool attracted visitors from all over the country and by the 1960s more than 8,000,000 were being catered for every year in more than 5,000 hotels and boardinghouses. The sea front with its long sandy beach is well laid out; seven miles of promenade have been constructed, often with several tiers. There are spectacular illuminations at night. The front is dominated by a 520-ft. steel tower (built in 1895 and modeled on the Eiffel tower in Paris) containing a large ballroom, winter gardens, an aquarium, etc. There are three piers. five swimming pools, four golf courses and a large amusement park. Stanley park, opened in 1926, provides about 300 ac. of pleasure gardens. Blackpool is a popular centre for conferences.

Besides the tourist trade, industries include the making of biscuits, sweets (candies), prefabricated joinery, aircraft, market gardening and coachbuilding. There is an airfield at Squire's Gate, 3 mi. S.S.E. The town was incorporated in 1876 and returns two members to parliament.

BLACK RIVER, the name of several rivers in the United States.. The major ones include: (1) a 280-mi.-long stream which rises in the Ozarks of southeastern Missouri, flows southeasterly to Poplar Bluff, and then continues southwesterly to a junction with the White river near Newport, Ark. Limited navigation is possible for shallow draft vessels in the lower 15 mi. of its course. Its main tributary is the Current river. Clearwater dam near Piedmont, Mo , was constructed on the Black river as a major flood control project. (2) A 165-mi.-long stream which rises in north-central Wisconsin and flows southwestward to a junction with the Mississippi river near La Crosse. The lower one and one-half mile stretch has a depth maintained at nine feet for seasonal barge traffic delivering coal and petroleum products. There is also a Black river in northwestern Wisconsin. It features the 165-ft.-high Manitou falls of Pattison state park near Superior. (3) A 101-mi.-long tributary of the Red river in central Louisiana, formed by the confluence of the Ouachita and Tensas rivers. It is navigable all year with a depth maintained at 6.5 ft. Traffic consists mainly of chemicals and logs. (4) A 50-mi.-long tributary of the Cape Fear river in southeastern North Carolina. (5) A 235-mi.-long tributary of the Pee Dee river in northeastern South Carolina. (6) A 40-mi.-long river in south-central Vermont which joins the Connecticut river near Springfield. Another Black river in northern Vermont flows into Lake Memphremagog on the Canadian border. (7) A 120-mi.-long stream in northern New York which rises in the Adirondacks and flows northwesterly into Lake Ontario and which furnishes power to local pulp and paper mills. (E. Hg.)

BLACK SEA, a large inland body of water, bounded by the U.S.S.R. on the north and east, by Rumania and Bulgaria on the west, and by Turkey on the south and southwest. Egress is through the Bosporus into the Sea of Marmara and the Dardanelles into the Aegean, and then into the Mediterranean. Rerch strait leads into the enclosed Sea of Azov, a gulflike projection to the northeast.

BLACK SEA, SHOWING INTERNATIONAL BOUNDARIES AFTER WORLD WAR II

Extending 330 mi, in its greatest width and 630 mi, in length, the sea covers an area of about 180,000 sq.mi. Depth increases progressively from north to south. West of Crimea it is nowhere deeper than 500 ft. and much of it is less than 150 ft. South of Crimea it sinks rapidly to 5,000 ft.. reaching a maximum of more than 7,000 ft. northwest of Sinop on the Anatolian coast.

The shape of the Black sea was formed in an early geological period when the connection with the Mediterranean was opened. Previously it had been a deep brackish lake. The consequent rise in level flooded the lowland along its northern coast, drowning the estuaries of the rivers and creating a liman coast. Because of the great volume of water carried to the sea by the Danube, Dnieper. Don (via the Sea of Azov) and other rivers, the surface is relatively fresh. Below 650 ft.. however, it is stagnant. as is evident from the large quantities of hydrogen sulfide and the absence of deep-sea life. The current is counterclockwise and, owing to differences in density, the surface water don-s out through the Bosporus and Mediterranean water enters below 6j ft. There is little tide, but storms are frequent and sudden, causing considerable fluctuation in level along the coasts. The Sea of Azov is shallow. the maximum depth not exceeding 48 ft.

The shores of the Black sea are varied. On the west. from Cape Rumeli to Cape Kaliakra, the land rises to a moderate height around the sea, backed by picturesque mountains. Along the northwest and north the shore is again low, although near Odessa a series of bluffs provide an attractive setting for this major Russian port. At the mouths of the rivers heavy deposition occurs, impeding navigation. The Danube has built a large delta. and long sandspits (*kosy*), such as the Tendra northwest of Crimea, separate quiet lagoons from the sea. Because of shallowness and low salinity, ice is frequent along the coast in winter. The Azov may be frozen up to three months. Mountains parallel much of the south coast of Crimea. Small, deep bays occur, such as at Yalta. but none have the advantages which have made Sevastopol on the west side of the peninsula the best harbour on the entire Black sea. Eastward from Feodosiya, the coast is again low, the lack of elevation also characterizing the shores of the Sea of Azov.

The east side of the Black sea, from Xnapa to Sukhumi (Sukhem-Kalehj, is dominated by the lofty Caucasus mountains which, in places, closely approach the sea. A regular coast, the only major embayment is at Kovorossisk (Novorossiisk) in the north. South of Sukhumi is the broad, poorly drained Colchis lowland, caused by the deposition of rivers descending from the interior uplands of Georgia. The Anatolian coast. backed by the high Pontic mountains. also lacks good natural ports. Exposure to northerly winds has always made navigation difficult.

History.— The sea is said to have received its name from the Turks. who feared the open stormy expanse of water; their epithet for it was the word for black. thus Karadeniz. To the ancients, however, it became, with knowledge, the Pontus Euxinus, or "hospitable sea.!! Across it. according to the story of the Argonauts, Jason sailed to Colchis in search of the Golden Fleece. Seven centuries B.C. the Greeks planted trading colonies on the south coast at Trabzon and Sinop. from which copper and iron. brought from the interior, were shipped to the Aegean islands. Additional colonies were founded about Kerch strait where they could control the trade and fisheries of the Azov region. on Crimea, and at the mouths of the northern rivers. By the 4th century B.C. half the grain imported by Athens originated on the shores of the Sea of Azov. Economic decline set in, due, in part, to the dislocation caused by the migration westward across the open grassland, or steppe, of successive waves of people from central Asia.

With the founding of Constantinople in A.D. 330, the importance of the Black sea increased considerably. From the 8th to the 10th centuries, trade flourished, especially between Byzantium and the Khazars, a people of Turkish origin converted to Judaism and securely in control of the territory east of the Don. In the 9th century, a new element appeared with the establishment of the Eastern Slavs on the Dnieper about Kiev, astride the great trade route which led from the Baltic to the Bosporus. In A.D. 907, Oleg, prince of Kiev, led an expedition against Constantinople and in 911 Byzantium and Kievan Rus signed a treaty of commerce. Slavic traders were everywhere. The attempt of Kiev to dominate the trade of the Black sea was far from successful, however. In the 11th century, Seljuk Turks devastated the southeast coast of the Black sea while Petchenegs and Kumans harassed the steppe dwellers. In the 13th century, Mongol horsemen overran Kiev and severed the Varangian route. Finally. the fall of Constantinople to the Ottoman Turks in 1453 ushered in a new era. For almost three centuries thereafter the sea was a Turkish lake, with commerce in the hands of Italian, French and, later, English traders.

The rise and expansion of Muscovy brought changes to the political complexion of the lands draining into the Black sea. Peter the Great, sea-minded and determined to westernize his country, recognized the need for a strong Black sea fleet to protect his growing commerce from Turkish attack. Campaigns against the remnants of the Mongol horde in the Crimea and the Kuban led to the construction of arsenals in the Sea of Azov and the laying of the foundations of future naval power. Under Peter's successors, Russia's growing ambition to gain control of the straits leading to the Mediterranean brought the new empire of the north into repeated collision with the Ottoman empire. Success led Russia to annex the territory between the Bug and the Dniester (1789) and Bessarabia (1812). Expansion also occurred into the Trans-Caucasus.

Economic development ensued, necessitating the construction of ports. Nikolayev on the Bug was founded in 1788, and Odessa was established in 1794. The Sevastopol naval base was begun in 1784. During the 18th and 19th centuries, weakened Ottoman control of the territory southwest of Bessarabia led to the emergence of independent Rumania and Bulgaria. A major setback to the growth of Russian power in the Black sea came in the treaty of Paris, which ended the Crimean War in 1856. However. Russia repudiated the restrictions in 1870 and until 1914 remained free to develop its resources in the Black sea. For the U.S.S.R. the Black sea, navigable throughout the year, is a waterway of major importance. In the coasting trade. oil is shipped from Batumi (Batum) and Novorossisk, manganese from Poti. coal from Zhdanov on the Azov sea. iron ore from Kerch. cement from Kovorossisk. and grain from Odessa. Nikolayev, Kherson and Novorossisk. Oil and cement are also transported from the Black sea to Leningrad and the Soviet far east.

Sinop and Trabzon never recaptured for modern Turkey their ancient importance, but Zonguldak. to the west, ships local coal to domestic markets elsewhere. Constanța in Rumania and Varna and Burgas in Bulgaria have local significance.

BLACK SNAKE, in America, a name usually applied to *Coluber constrictor constrictor,* also called the northern black racer. a common harmless colubrine snake, black above and lighter beneath with a white chin. It ranges from southeastern Canada through the eastern United States. Subspecies occur across North America south to Guatemala: the most familiar are the blue racer of the central states, olive to bluish gray above with a bluish to yellow belly, and the southern black racer of the southeastern states.

The black snake is slender, usually 4 to 5 ft. long, rarely larger. It is alert. active and diurnal, and climbs and swims well. When alarmed it vibrates the tip of the tail, producing a buzzing sound. Mating occurs in spring; 10 to 35 eggs, laid from May through

WALTER DAWN FROM NATIONAL AUDUBON SOCIETY

BLACK SNAKES (COLUBER CONSTRICTOR SUBSPECIES) MATING

July! hatch in seven to nine weeks. The eggs are coated with granules resembling salt grains. The young are gray with reddish brown blotches. Food of the black snake includes insects, frogs. reptiles. birds. eggs and small mammals.

The Australian black snake (*Pseudechis porphyriacus*), bluish black with a red belly and four and one-half to five and one-half ft. long. is venomous, but not highly dangerous. In Egypt. the middle east and northern India various cobras are sometimes called black snake. (S. A. M.)

BLACKSTONE, SIR WILLIAM (1723–1780), the most famous of English jurists. was born in Cheapside on July 10, 1723, the posthumous son of Charles Blackstone. silkman. citizen and bowyer. of London. From Charterhouse school he went at the age of 15 to Pembroke college. Oxford, and was entered at the Middle Temple in 1741. He was elected a fellow of All Souls in 1744, devoted himself ardently to the interests of the college. became bursar and prepared his *Essay on Collateral Consanguinity* to defeat the claims to fellowships of people n-ho were of any degree of kin to the founder, claims which threatened to lower the prestige and efficiency of the foundation of Archbishop Chichele. Called to the bar in 1746. he was chosen by the ancient borough of Wallingford as its recorder in 1749. He tried to practise at the bar during this period. but with so little success that in 1753 he was minded to quit London altogether and devote himself to an academic life. In Michaelmas term 1753 he began to read law lectures at Oxford. His hearers were captivated by the lucidity and charm of his style and by the simplicity with which he presented the subject, slurring over the difficulties and contrarieties of the law, giving the whole subject an air of completeness and mutual interdependence as if it were a uniform logical system. suppressing or ignoring the archaic learning and putting forward the English law as the embodiment of 18th-century wisdom.

But from the first he antagonized his rival for the position of the greatest English jurist. Jeremy Bentham, who seemed to dislike him as much as a man as he mistrusted him as a teacher. Bentham wrote of him that he was "a formal. precise and affected lecturer. just what you would expect from the character of his writings. cold. reserved and wary. exhibiting a frigid pride"; he. however. qualified to some extent this mordant censure when he also wrote: "correct, elegant, unembarrassed, the *style* is such as could scarce fail to recommend a work still more vicious in point of *matter* to the multitude of readers. He it is. in short, who, first of all institutional writers! has taught jurisprudence to speak the language of the scholar and the gentleman." In 1758 the lectures were first delivered in their present form. Blackstone having been elected to the newly founded Vinerian professorship, delivered the introductory lecture "On the Study of the Law," which is prefixed to the first volume of the *Commentaries.* It was some years before the author decided to present the *Commentaries* as a finished work; but notes of the lectures were in circulation, so in Nov. 1765 the first volume appeared, and the three remaining parts were published in the four succeeding years.

On May 5, 1761, he had married Sarah, daughter of James Clitherow of Boston House. hfiddlesex; on July 28 in the same year the earl of Westmorland, the chancellor of the university, made him principal of New Inn hall.

Professional advancement came side by side with academic. On May 6, 1761, the very day after his marriage, he received a patent of precedence giving him the rank of king's counsel. In 1763 he was made solicitor general to the queen, the first to hold that office under Queen Charlotte, to whom he dedicated the *Commenturies;* and about the same time he became a bencher of the Middle Temple where his well-known portrait by Gainsborough hangs. In that year his success at the bar led him to resign the professorship and the headship of New Inn hall. two positions which he is said by his anonymous biographer to have intended to use for the foundation of a law school. His career in parliament, to which he was elected first (1761) for Hindon, afterward for Westbury, was somewhat inglorious. He took the ministerial side in the controversy about the Middlesex election and drew a severe criticism from Junius, who boasted that he had answered "Dr. Blackstone" out of his own *Commentaries* and seemed to have completely silenced him.

Blackstone disliked attendance in parliament; this aversion, no doubt, determined him to refuse the solicitor generalship in 1770 and in February of the same year to accept a judgeship in the court of common pleas. In the ten years of his judgeship he administered the law satisfactorily but attained no special distinction. and his career is not associated with any famous trial. He seems to have given signs of rather premature decay toward 1780, attributed to his sedentary habits and avoidance of physical exercise. and on Feb. 14 of that year he died in London. Two volumes of his *Reports of Decided Cases,* with a brief m'emoir by his brother-in-law James Clitherow. appeared in 1781, but added little to his fame either as reporter or judge; the reports of his nephew Henry Blackstone are thought better of by the profession.

The Commentaries.— The famous *Commentaries* deserve some detailed account and criticism. Their design is exhibited in his first Vinerian lecture printed in the introduction to them. The author there dwells on the importance of noblemen, gentlemen and educated persons generally being well acquainted with the laws of their country; and his treatise, accordingly, is as far as possible a popular exposition of the laws of England. Falling into the common error of identifying the various meanings of the word law, he advances from the law of nature (being either the revealed or the inferred will of God) to municipal law, which he defines to be a rule of civil conduct prescribed by the supreme power in a state commanding what is right and prohibiting what is wrong. On this definition he founds the division observed in the *Commentaries.* The objects of law are rights and wrongs. Rights are either rights of persons or rights of things. Wrongs are either public or private. These four headings form respectively the subjects of the four books of the *Commentaries.*

Blackstone was by no means a scientific jurist. He had only the vaguest possible grasp of the elementary conceptions of law. He evidently regarded the law of gravitation, the law of nature and the law of England as different examples of the same principle—as rules of action or conduct imposed by a superior power on its subjects. Hc propounds in terms the doctrine that municipal or positive laws derive their validity from their conformity to the so-called law of nature or law of God. "No human laws." he says,

"are of any validity if contrary to this." His distinction between rights of persons and rights of things. implying, as it would appear, that things as well as persons have rights. is attributable to a misunderstanding of the technical terms of the Roman law. In distinguishing between private and public wrongs (civil injuries and crimes:) he fails to seize the true principle of the division. John Austin. who accused him of following slavishly the method of Sir Matthew Hale's *Analysis of the* Law, declares that he "blindly adopts the mistakes of his rude and compendious model; missing invariably, with a nice and surprising infelicity, the pregnant but obscure suggestions which it proffered to his attention, and which would have guided a discerning and inventive writer to an arrangement comparatively just." By the want of precise and closely defined terms, and his tendency to substitute loose literary phrases, he falls occasionally into irreconcilable contradictions. Even in discussing a subject of such immense importance as equity, he hardly takes pains to discriminate between the legal and popular senses of the word. and, from the small place which equity jurisprudence occupies in his arrangement! he would scarcely seem to have realized its true position in the law of England. Subject, however, to these strictures. the completeness of the treatise, its serviceable if not scientific order. and the power of lucid exposition possessed by the author demand emphatic recognition. Blackstone's defects as a jurist are more conspicuous in his treatment of the underlying principles and fundamental divisions of the law than in his account of its substantive principles.

Blackstone did not confine himself to the work of a legal commentator. It was his business. especially when he touched on the framework of society, to find a basis in history and reason for all the most characteristic English institutions. There is not much either of philosophy or fairness in this part of his work. Whether through the natural conservatism of a lawyer, or through his own timidity and subserviency as a man and a politician. he is always found to be a specious defender of the existing order of things. More undeniable than the political fairness of the treatise is its merit as a work of literature. It is written in a most graceful and attractive style, and although no opportunity of embellishment has been lost. the language is simple and clear. Whether because of its literary graces. or its success in flattering the prejudices of the public to which it was addressed. the influence of the book in England was extraordinary. Not only lawyers. and lawyers perhaps even less than others, accepted it as an authoritative revelation of the law. It performed for educated society in England much the same service as was rendered to the people of Rome by the publication of their previously unknown laws. It is more correct to regard it as a handbook of the law for laymen than as a legal treatise: and as the first and only book of the kind in England it was received with somewhat indiscriminating reverence. To this day Blackstone's criticism of the English constitution probably expresses the most profound political convictions of the majority of the English people.

Although Blackstone was much criticized for his superficiality and lack of the historical sense, he showed signs of the recognition of the duty of research. His two volumes of *Law Tracts* (1762) give a better impression of him as a student than the more eloquent *Commentaries* and seem to be the outcome of deeper learning and thought. But his inability to place himself in the position of legislators of remote times and his habit of justifying everything as reasonable come out very markedly in his treatment of the famous rule of the *bastard eigné* and *mulier puisné*. In the *Commentaries* themselves his account of the Revolution of 1638 exhibits these defects in the most pronounced form. as in his optimistic description of Edward VI as an amiable prince. in "the short sunshine" of whose reign England enjoyed a peculiar felicity. And his shallowness appears in his justification of the penal laws or apology for them. Instead of condemning them he says: "these laws are seldom exerted in their utmost rigour and indeed if they were it would be very difficult to excuse them." He did. however. go so far as to say in his first edition that he was not sure that some of the sectaries did not hold principles which made them as dangerous as the papists themselves. but in deference to an outbreak of indignation from the sectaries he softened or got rid of this expression in subsequent editions.

In the English law institutional writers are not recognized. The most famous and approved treatises have no such rank as is accorded for instance in Scotland to the works of James D. Stair, Henry Bell and the like. Consequently Blackstone is seldom or never referred to as an authority. His *Commentaries* are recommended for their literary value, and they have experienced the singular fate of being used as the framework upon which all the additions made to the law by statutes or decisions since his day have been attached for the use of students preparing fpr examiñations, his original text being printed with the new matter interpolated in successive layers, producing in the result textbooks swollen out of all proportion into portents of ugliness. These monstrosities now, happily, are failing to attract as of old. And there is a reaction in favour of regarding Blackstone's great work from the standpoint of true historical and literary criticism as a complete work of art of the greatest literary merit, inadequate in deep learning, unscientific in arrangement. often mistaken in very elementary matters, but a genuine outcome of 18th-century culture and a true exposition of the 18th-century standpoint. This reaction is really the just tribute to Blackstone's greatness. (F. SH.)

Blackstone in the U.S.—The fame of Blackstone in the 19th century was greater in the United States than in Blackstone's native land. After the Declaration of Independence the *Commentaries* were the chief source of the knowledge of English law for the commonwealth of the west. A book which in the old country was and is a textbook became in the new an oracle of law. The results were not always good. What was a true exposition of the spirit of the law in 18th-century England was unreal in the Illinois of Abraham Lincoln. Fortunately, living law in America was being shaped through local institutions. Legislators and judges were practical men in spite of the *Commentaries*. Nor did U.S. lawyers after 1850 try to copy Blackstone. With the advent of the law school reviews legal scholars escaped from Blackstone. They began to nrite extensively and critically. and they produced monographs in specialized areas. By the middle of the 20th century few Americans had read Blackstone even as a classic. Nevertheless. Blackstone is a symbol American lawyers remember. When the American Bar association met on its first official visit to London in July 1924. U.S and Canadian lawyers presented to the law courts of London a plaster cast of a statue of Blackstone to be executed in marble. The sculptor was Paul Bartlett, who died before the finished statue was placed in position in June 1928. The sculptor's wife presented a bronze cast of the original statue to the United States in 1943. Ten years later this statue was placed before the United States courthouse for the District of Columbia in Washington.

Sir William Blackstone, with Memoirs of His Life* (1781); Jeremy Bentham, *A Comment on the Commentaries: a Criticism*, ed. by C. IV. Everett (1928); David A. Lockmiller, *Sir William Blackstone* (1938); L. C. Warden, *Lifr of Blackstone* (1938); D. J. Boorstin, *The Mysterious Science of the Law (1941)*. (V. X. M.)

BLACK STONE OF MECCA (AL-HADJAR AL-ASWAD), built into the eastern wall of the Ka'ba at Mecca, consists of three large pieces and some fragments of stone, surrounded by a stone ring and held together with a silver band: total diameter is about 12 in. The stone. an object of veneration by Muslim pilgrims to Mecca. probably dates back to the pre-Islamic religion of the Arabs.

BLACK VARNISH (or JAPAN), a class of oil varnishes in which bitumen replaces the natural gums or resins used as hardeners in clear varnish. Bitumens used include blown or unblown petroleum bitumen. natural asphalts such as gilsonite, and pitches, as from coal tar.

Because bitumen forms a protective coating against atmospheric corrosion. black varnish is widely used for ironwork, both exterior and interior, such as pipework, tanks, marine applications, stoves and roofing. and for tarpaulin.

The process of manufacture is similar to that used for clear varnish except that. as bitumen is soluble in oil. "running." or preheating the bitumen, is not necessary. Bitumen, in small pieces:

is simply added to hot linseed or other drying oil together with driers such as red lead and lithnrge, or manganese dioxide, and the mass heated to about 450° F. until stringy. After cooling a solvent. usually turpentine substitute (white spirit), is added until the varnish is of the desired consistency. The cheapest black varnish (Brunswick black) is merely a solution of bitumen in white spirit. In coachbuilders' black japan only the purest grades of asphalt or pitch are used, together with a hard gum such as copal. A variety of black varnish known as Berlin black has a matte or eggshell finish; this is achieved by the incorporation of a proportion of vegetable or other carbon black. (E. G. Es.)

BLACKWATER, a river in the Republic of Ireland, 104 mi. long, noted for its trout and salmon, rises in the carboniferous uplands, sometimes called the Munster coalfield, which are dreary, almost coalless plateaus, 1,000 to 1,400 ft. high. The main headstream of the river forms the boundary between the counties of Cork and Rerry. In its upper course the Blackaater flows between the uplands and a spectacular east-west Devonian sandstone ridge with summits over 2.200 it. East-west lines of mountains mark the whole course of the Blackwater to Cappoquin, County Waterford, where the river suddenly bends southward for the last 15 mi of its journey. Much of its course is through a valley oi rich pastures and plentiful woodlands. and in the 18th and 19th centuries a large number of demesnes (*q.v.*) were established there, notably the Devonshire estates at Lismore (*q.v.*). Beyond the river the farm lands generally extend to a height of 800 ft. or more.

There are a number of tributaries including the Finnow, which has Millstreet as its market centre and the Dalva, which drains the southeast part of the Leinster coalfields and has two tonns. Kanturk with hosiery making, and Newmarket. Twelve miles downstream. the main railway from Dublin to Cork crosses the valley at Mallow (*q.v.*), an active and attractive commercial and grain milling town, and the river flows east. gathering from the north the Awbeg, to Fermoy 20 mi. farther on. Twenty miles more of fine valley scenery carries the river to Lismore and Cappoquin, and then the river's whole character changes as it cuts across the grain of the land in a series of gorges and depressions to meet the sea at Youghal (*q.v.*), a town associated with Sir Walter Raleigh.

(T. W. Fr.)

BLACKWATER FEVER, the most serious and least understood complication of malaria. in which hemoglobin appears in the urine. *See* Malaria: *Blackwater Fever.*

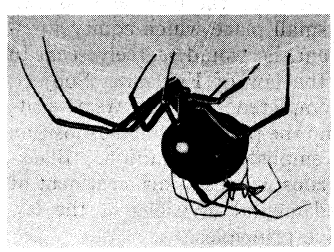
BLACKWELL, ELIZABETH (1821–1910), the first woman doctor of medicine. was born at Counterslip. Bristol, Eng., Feb. 3, 1821, the daughter of a sugar refiner who migrated to New York in Aug. 1832. Elizabeth sought admission in vain to the medical schools of Philadelphia, Pa., and New York city, but eventually secured admission to the medical class at Geneva, in western New York state, graduating M D. in 1849. She then studied at St. Bartholomew's hospital. London, and on the continent. After her return to the United States she established in New York city in 1857, in spite of much opposition, a hospital entirely staffed by women. In due course she succeeded in founding there a full course of medical education for women, Sophia Jex-Blake being among the first students. Dr. Blackwell returned to England in 1857 and in 1869 settled there permanently. She died at Hastings on May 31, 1910.

See her *Pioneer Work: Autobiographical Sketches (1895).*

BLACKWELL, THOMAS (1701–1757), Scottish professor of wide learning. was born at Aberdeen on Aug. 4, 1701. He was educated at Aberdeen grammar school and Marischal college. where in 1723 he was given the chair of Greek. which he retained on his appointment (1748) as principal (a post also held by his father, the Rev. Thomas Blackwell). He was a stimulating teacher, and when principal carried out reforms in the curriculum. His *Enquiry Into the Life and Writings of Homer* (1735) was designed to explain "why no poem either formerly heard oi, or now extant, was or is comparable to the Iliad and the Odyssey." He also wrote *Letters Concerning Mythology* 11748) on "the opinions of the ancients concerning the rise and government of the world," and the overrated *Menzoirs* of *the Court of Augustus* (1755–64), of which most of the 3rd volume was compiled from his notes after his death in Edinburgh on March 8, 1757.

BLACK WIDOW, a common name applied in the United States to spiders of the genus *Latrodectus* (family Theridiidae). The mature female black widow is about one-half inch long, is shiny black and has a scarlet hourglass-shaped mark on the underside of the globular abdomen. The immature females may have a row of red spots along the back and some are without any red markings at all. The male is smaller (one-seventh to one-sixth inch long) and usually has a red hourglass figure on the underside of the abdomen. Dorsally there often is a variable pattern of red spots flanked by white lines.

In temperate areas of the United States the black widow survives the winter in an immature stage and the young forms appear in the spring. The mature females appear in April; the males, though not as commonly seen, mature at about the same time.



BY COURTESY OF GEORGE ELWOOD JENKS

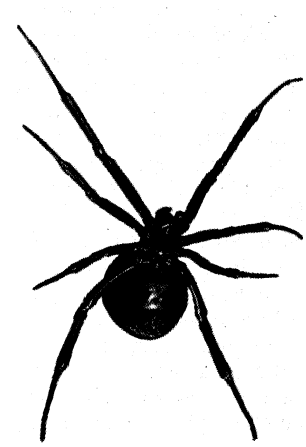
FIG. 1.—FEMALE BLACK WIDOW (LATRODECTUS MACTANS) HANGING FROM WEB WITH MALE CLINGING TO HER BACK

Before mating, the male spins a delicate web upon which the seminal fluid is placed; he then collects the semen in a sac on the second pair of appendages (palpi). During mating one of the palpi is introduced into the genital opening of the female. As the male is smaller than the female, he runs the danger of being eaten by the female ii he does not escape immediately after mating. While the male may mate more than once, the female apparently mates only once. The female places the eggs in silken globular cocoons about one-half inch in diameter. These may be found from late July until September. Each cocoon contains from 250 to 750 or more eggs. The numerous young remain in the cocoon until after the first molt, a period which varies from 14 to 30 days after the eggs are laid.

Males molt from four to seven times before maturing, and live irom 28 to 40 days aiter maturing; females molt from seven to nine times, and live from a few months to a year and a half after maturing.

Their webs are formed of a dense crisscross of threads. One side has a silk sheet which serves as a retreat. The web is found under loose bark, in crevices, in holes, in hollow stumps and other similar places. The silk is quite strong though the diameter of the threads is small. The black widow catches a variety of different insects in its net. Like all spiders, it makes small punctures into the body of the captured insect and sucks the liquid contents. The spider in turn is attacked by mud-dauber wasps, insect parasites and predators which attack the young forms.

Like all spiders, black widows have fangs and poison glands by which they kill their prey. They do at times bite humans, and their poison often produces such symptoms as severe pain and nausea and mild paralysis of the diaphragm. Although most of the bite victims recover without complications and deaths are rare, bites of these spiders should be regarded seriously. Possibly different species vary in the toxicity of their poisons, and individuals bitten vary greatly in their reactions to the poison.



JOHN H. GERARD

FIG. 2.—BLACK WIDOW (LATRODECTUS MACTANS) SHOWING HOURGLASS ON UNDERSIDE OF ABDOMEN

H. Levi recognizes six species of *Latrodectus:* L. *geometricus,* possibly native to Africa; *L. curacaviensis,* of the Americas; *L. hystrix,* of Yemen; *L. dahli,* from Iran and Sokotra; *L. pallidus,* from Turkmen to North Africa; and *L. mactans,* from warm areas all over the world.

Several geographical subspecies are recognized in L. *mactans;* they differ in colour pattern. carapace shape, leg length and spination as well as in other characters.

Latrodectus mactans, *L. curacaviensis* and *L. geometricus* are found in the United States. *L. geometricus* is encountered infrequently in Florida, and the females are usually gray. Of the other two species, L. *curacaviensis* is more abundant in temperate areas of both North and South America and is absent from Mexico, Central America and the greater Antilles. L. *mactans,* while present in most of the United States. is more abundant in warmer sections of the Americas. In areas where these two species occur together. they often occupy different habitats. In the northern part of its range. L. *mactans* is found most often in trash and near dwellings, while L. *curacaviensis* lives under logs and stones and in rvoods and fields. In Florida *L. curacaviensis* lives in trees and shrubs above the ground. while *L. mactans* lives on the ground.

BLACKWOOD, WILLIAM (1776–1834), founder of the publishing firm of William Blackwood and Sons. Ltd., was born at Edinburgh. Scot.. on Nov. 20, 1776, and died there on Sept. 16, 1834. After learning antiquarian bookselling, in 1804 he set up a business in Edinburgh.

By 1810 Blackwood was acting in Scotland for John Murray and other London publishers. and publishing on his own account. In 1816 he brought out Walter Scott's *Tales of My Landlord.* In 181; he founded the *Edinburgh Monthly Magazine,* later called *Blackwood's Edinburgh Magazine,* as a Tory counterblast to the Whig *Edinburgh Review.* It achieved notoriety with its "Chaldee Manuscript," a satire in Old Testament language on the Edinburgh Whigs, and attacks on the Cockney school of poets, as it chose to designate Leigh Hunt and his circle. Then it became more respectable, and secured a wide and steady influence. Scott, J. G. Lockhart, John Wilson. James Hogg. De Quincey and William Maginn were among its contributors. As "Christopher North," Wilson (*q.v.*) wrote most of the *Soctes Ambrosianae* for it.

William Blackwood was succeeded by his sons Alexander (1806–45), Robert (1808–52) and John (1818–79). They added a London ofiice to the business in 1840, and an Edinburgh printing office in 1837. After them the conduct of the firm passed, in turn, to William Blackwood (1836–1912), George Blackwood (1876–1942), James Blackwood (1878–1931) and George Douglas Blackwood (1909–) great-great-grandson of the founder. Blackwood's published serially and then in book form works by George Eliot. Bulwer-Lytton, Charles Lever. Anthony Trollope and Joseph Conrad. They have also printed much material about British history and achievements in the empire and commonwealth.

See F. *D.* Tredrey, *The House of Blackwood, 1804–1954* (1954). (F. D. T.)

BLADDER, the membranous and muscular sac in animals that receives the urine secreted from the kidneys. The word is also used for any similar sac, such as the gall bladder. the swim bladder in fishes, or the small vesicle in various seaweeds. *See* URINARY SYSTEM; UROLOGY; BLADDER AND PROSTATE. SURGERY OF; *see* also Index references under "Bladder" in the Index volume.

BLADDER AND PROSTATE, DISEASES OF. *(See* also URINARY SYSTEM; UROLOGY: *Urologic Diseases.)*

DISEASES OF THE BLADDER

Any disease that partially occludes the urinary passages below the bladder outlet will lead to dilatation and hypertrophy of the bladder wall. Pouchlike pockets. called diverticula. also balloon outward from the bladder cavity because of the increased pressure within it. Soon the bladder no longer empties completely but leaves a residual urine after voiding that predisposes to hladder infection and stone formation. Often. hon-ever, infection of the bladder occurs quite apart from urinary obstruction when microorganisms gain admission to the bladder by way of the urethra. kidneys or blood stream. Such a simple acute cystitis is especially common in females. The bladder rapidly becomes intensely irritated. urination becomes frequent and painful, and the urine contains pus and blood. Prompt cure and relief of symptoms follow treatment with various antibiotics. On the other hand, a chronic. persisting cystitis suggests a more basic underlying condition, usually some kind of obstructive disease at the bladder outlet or chronic infection of the kidneys. A common and nonserious condition. chronic trigonitis, must not be confused with bacterial infections of the bladder. It leads to similar though less severe symptoms. but the urine remains free of pus. This disease. occurring only in women. is caused by tiny soft growths on the floor of the bladder near its neck. They are not true tumours, nor do they give rise to serious secondary effects.

Tumours of the bladder arise as papillary growths of the lining of the bladder projecting out into the bladder cavity as they grow. Unfortunately, only a minority of bladder tumours are benign in their behaviour: the majority are malignant cancers, though the degree of malignancy varies greatly. As the cancer grows, it invades the bladder wall and ultimately penetrates adjacent organs. Meanwhile, the tumour surface bulging into the bladder cavity becomes eroded. leading to the characteristic symptom of blood in the urine. Noninvasive. benign papillomas may be successfully treated by open surgical operation or by special instruments operated through the urethra. Treatment of malignant cancer has not been entirely satisfactory. and recurrence and progressive extension are common. Cancers of the bladder are sometimes removed n-ith transurethral instruments, while at other times excision by open operation of the tumour-bearing portion of the bladder is preferred. The most radical operation involves removal of the entire bladder. This necessitates deviation of the urine by connecting the ureters either to the skin, large intestine. or to an "artificial bladder" constructed from a segment of the small intestine.

Bladder calculi (stones) occupy a special position in the history of surgery because they were recognized even in antiquity, and operations for removal were among the earliest surgical procedure devised. Calculi are composed primarily of precipitated calcium oxalate. calcium phosphates. uric acid or cystine (rarely). For reasons not known, the frequency of bladder calculi varies markedly according to geographic location. In certain parts of the world bladder calculi are extremely common as a primary disease: in other areas bladder calculi ordinarily form only as a secondary complication of bladder infection and urinary retention. Symptomatically, calculi manifest themselves by irritating the bladder lining, giving rise to lrequent painful urinations and bloody urine. Large stones require open operation for removal. but many smaller stones can be treated adequately n-ith transurethral crushing instruments (lithotrites). On rare occasions calculi have been dissolved by prolonged catheter irrigation with special solutions. but attempts to dissolve stones by diet or oral medications have not been successful. The widespread belief in the efficacy of stone-dissolving medicaments. though common among all peoples for centuries, is without scientific foundation.

Urinary incontinence, or involuntary urination, may be of several types. It sometimes occurs in disease or injuries of the nerves to the bladder where the mechanism for periodic emptying and filling is interrupted or paralyzed ineurogenic bladder). In other instances a partial urinary obstruction leads to a gradual distention of the bladder until a certain point is reached when small amounts are passed involuntarily at frequent intervals (overflow incontinence'). Older women, usually those who have borne several children, leak small amounts of urine on heaving. lifting or coughing because of weakness and relaxation of the perineal niuscles (stress incontinence). Bed-rvetting in children (enuresis') is often simply a bad habit though it occasionally is caused by a more basic abnormality.

Bladder fistula is an abnormal communication between the bladder and some other organ such as the vagina, rectum or intestines. These communications form when cancers or chronic inflammatory diseases penetrate into the bladder from other organs

or, conversely. when disease of the bladder spreads and perforates into neighbouring structures. Perforation or rupture of the bladder occasionally occurs as a serious complication of fractured pelvis. With rupture. urine leaks into the tissues of the pelvis and abdomen. resulting in cellulitis and peritonitis if prompt surgical intervention and drainage are not performed.

DISEASES OF THE PROSTATE

Cancer of the prostate and treatment in its far-advanced stages led to one of the most brilliant discoveries in the attack on the cancer problem by C. B. Huggins in 1942. Prostatic cancer often spreads widely throughout the body (especially to the bones of the pelvis and spine) even before there is any local evidence of disease. Most cases therefore remain undiagnosed until the disease is already widespread. Frequently the first signs of the disease are general wasting and weakness, or pains in the back, hip or leg resulting from bone metastases. Huggins found that in such cases the cancerous tissue may undergo profound and striking regression as the result of castration or treatment with female sex hormones. This treatment has relieved the symptoms of even widespread and otherwise hopeless prostatic cancer for periods of ten years or more. Huggins concluded that prostatic cancer tissue requires the presence of male sex hormones if the cancer is to continue its growth. The results stimulated the hope that similar methods might be found to suppress other types of cancer. If the diagnosis of prostatic cancer can be made prior to spread of the disease, cure may be obtained by total removal of the prostate. Earlier diagnosis would be made if all men over 50 years of age submitted to periodic rectal examination. See also CANCER.

Benign prostatic hypertrophy is probably the commonest prostatic disease of older men. The enlargement is caused by the development of spherical benign tumour growths (adenomata) within the gland. They gradually encroach upon the bladder outlet and lead to increased frequency and difficulty in urination, incomplete emptying and ultimately to complete urinary retention. Secondary bladder infection and stone 'formation often follow as complications. Uremia from back pressure upon the kidneys is especially serious. Even in far-advanced cases, however, surgical removal of the obstructing adenomata is successful in relieving symptoms and restoring function. The operation may be accomplished either by open surgery or by special instruments (resectoscopes) introduced through the urethra.

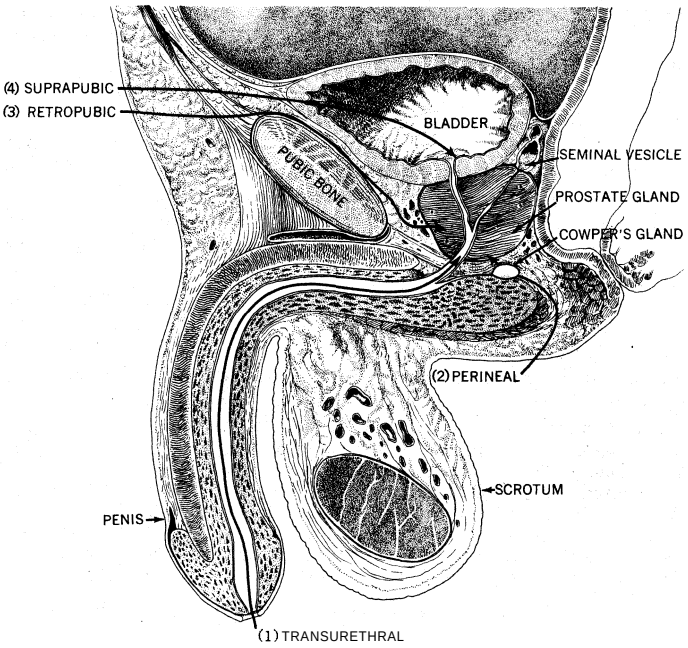
Infection of the prostate may lead to an acute prostatitis and eventually to abscess formation. More commonly it merely sets up a smouldering inflammation or chronic prostatitis. Infection reaches the prostate either from the urethra (*e.g.*, in gonorrheal or other urethral infections) or from the blood stream. Chronic prostatitis produces a sense of fullness and discomfort in the perineum, mild irritability of the bladder and sometimes a slight urethral discharge. Except for abscess, surgical treatment is not needed for inflammations of the prostate. In acute prostatitis treatment with appropriate antibiotics ordinarily suffices to bring the inflammation under control very promptly. On the other hand, systemic medication is of little or no value in chronic inflammations of the prostate except for tuberculous prostatitis where medical therapy is often curative.

See Meredith Campbell (ed.), *Urology*, 3 vol., with extensive bibliographies (1954). (C. W. V.)

BLADDER AND PROSTATE, SURGERY OF. The four basic surgical approaches to either the bladder or prostate are illustrated in the figure. Each has specific advantages, and the indications for its use are determined by the nature of the disease in the individual patient.

Transurethral surgery (1) of the bladder and prostate represents a major surgical advance. Instruments that make this possible result from a combination of the incandescent lamp, multiple lens optics and high frequency electrical currents capable of precise cutting of tissues under water.

The perineal incision (2) was first used in Greece (c. 200 B.C.) for removal of stones in the prostate and bladder. Radical prostatectomy for cancer, removal of large adenomata or calculi of the prostate. drainage of prostatic abscesses and repair of fistulas or



VERTICAL SECTION THROUGH PELVIS. SHOWING FOUR SURGICAL APPROACHES TO BLADDER AND PROSTATE GLAND

traumatic rupture of the bladder orifice are commonly performed by this approach.

The retropubic incision (3) is limited to removal of benign adenomata of the prostate, certain forms of prostatic cancer and plastic repair of strictures of the bladder neck and prostatic urethra.

The suprapubic incision (4) is the most direct approach for operations involving the body and interior of the bladder. The prostate, calculi and tumours are removed from within the bladder; and creation of an opening (cystostomy) for prolonged drainage is established through this approach.

The functional regenerative capacity of the urinary bladder is unequaled by any other abdominal organ. This has led to many ingenious procedures in which large portions of the bladder are utilized to replace diseased segments of the ureters, to construct new urethras or remove neoplasms that are limited to a segment of the bladder. Partial removal of the bladder is often a necessary accompaniment to removal of large diverticula, which are remnants of the embryological allantois; part of the bladder also may be removed in repairing fistulas between the bladder and bowel, vagina or other organs. Functional closure of congenital exstrophy, in which the anterior wall of the bladder and lower abdomen fail to develop, remains an unsolved problem in the surgery of this organ.

Complete surgical removal of the bladder may be necessary in patients with advanced cancer. A substitute is usually supplied from a length of small bowel (ileum) or transplantation of the ureters to the skin. These procedures result in incontinence and require appliances for collection of the urine. Transplantation of the ureters to the colon creates a cloacalike situation in which continence of urine and feces is maintained by the anal sphincter.

Advances in the surgery of these organs have resulted in prolongation of useful life for many individuals, especially the aging male.

(1947); R. H. Flocks and David Culp, *Surgical Crology* (1954); Henry M. Weyrauch, *Surgery of the Prostate* (1959). (WI. H. B.)

BLADDER WORM, a stage (technically called *cysticercus*) in the life cycle of tapeworms (class Cestoda), intestinal parasites of vertebrates, including man. See TAPEWORMS.

BLADDERWORT, the common name for an aquatic plant that traps in its numerous and small spherical bladders such various animals as larvae, crustaceans) small worms and protozoa that inhabit shallow water. These animals die, decompose and serve as

nitrogenous food for the plant. See also CARNIVOROUS PLANTS; UTRICULARIA.

BLADENSBURG, a suburb of Washington, D.C., northeast of the capital in Prince Georges county, Md., about 32 mi. S.W. of Baltimore on the Anacostia river. The site of Bladensburg was originally a trading post known as Garrison's Landing, at the northern end of the navigable portion of the Anacostia. In 1742 Bladensburg was founded and named after Thomas Bladen. then governor of Maryland. The town achieved early prosperity because of its position on the river and on the main north-south highway through the colonies, but by the middle of the 19th century the Anacostia had become too shallow for large ships and the road was supplanted in importance by railroads; in addition, Washington, the national capital, had been established close by. After mid-20th century its population was less than 5,000.

During the War of 1812 it was the site of the battle of Bladensburg, in which an outnumbered army of British soldiers on Aug. 24, 1814, defeated an American force, which retreated, leaving Washington undefended. The British marched on the capital and sacked it, burning many important buildings. Just outside Bladensburg is the Bladensburg dueling field, where Washingtonians of the early 19th century, in order to avoid the stringent antidueling laws of the District of Columbia, fought their duels. Commodore Stephen Decatur was killed there in 1820.

BLAGOEVGRAD, a town in southwest Bulgaria, 102 km. (63 mi.) S. of Sofia. is situated in the valley of the Bistritsa river, a tributary of the Struma. Pop. (1956) 21,833. A settlement known as Scaptopara existed there around the warm mineral springs in Thracian times. The town was known during the Turkish occupation as Djumaya or Dzhumaya, later as Gorna Djumaya, but since 1950 it has been known as Blagoevgrad, after Dimiter Blagoev, founder of the Bulgarian Communist party. It was formerly a farming centre, producing and trading in oriental tobacco. It is now an important tobacco processing centre with the largest tobacco-fermentation factory in the Balkans; the wood processing industry (plywood, parquet flooring) and the canning, textile and craft industries have also been developed. The mineral springs are still significant. (L. DI.; S. H. BR.)

BLAGOVESHCHENSK, a town and administrative centre of the Amur oblast (province) of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands at the confluence of the Amur and Zeya opposite Aigun, Heilungkiang province (China). Pop. (1959) 94.000. Founded in 1858 after the Russian occupation of the Amur basin, Blagoveshchensk has always been one of the major centres of the Russian far east. Communications are good—the Amur is navigable, a branch line links the town to the Trans-Siberian railway and roads run to Svobodny on the Trans-Siberian and to Khabarovsk. Its industries are food processing (flour milling, oilseed milling, meat packing, etc.), timber working (sawmilling, furniture and matchmaking), the making of woolens and leather goods and the building and repair of river craft. (R. A. F.)

BLAINE, JAMES GILLESPIE (1830–1893), U.S. congressman, senator, secretary of state and presidential candidate, was an outstanding leader of the Republican party in the decades following the Civil War. He was born on Jan. 31, 1830, in West Brownsville, Pa. After graduating from Washington college (now Washington and Jefferson college) in Washington, Pa., in 1847, Blaine taught school for six years, first as an instructor in mathematics at a military academy in Kentucky and later as an instructor in the Pennsylvania Institute for the Blind in Philadelphia. In 1850 he married Harriet Stanwood, a native of Augusta, Me. Four years late' he moved to Augusta to assume the editorship and part ownership of the Kennebec *Journal,* a crusading Republican newspaper, and began to assume political identity. In 1856 he attended the first national convention of the newly organized Republican party. Two years later, at the age of 28, he was elected to the Maine state legislature. There his mastery over the intricacies of parliamentary maneuvering and his political acumen enabled him to succeed, in 1860, to the speakership of the house, a post he held until his election to the U.S. house of representatives in 1862.

As a member of congress, Blaine supported a hard money policy, high protective tariffs, railroad subsidies and the radical reconstruction program. Though at odds with actions of the radicals in his party on some issues, Blaine joined with them to advocate a strict reconstruction policy toward the South. Throughout his career he generally held to the proposition that the southerners were traitors and rebels. Yet, convinced that a stable, prosperous South was vital to the financial well-being of the entire nation, he was willing to compromise on matters which did not weaken reconstruction and Republican control of the South.

In 1868 Blaine was elected to the powerful position of speaker of the house, a post well suited to his abilities and temperament. A superb speaker and a shrewd debater, Blaine had remarkable insight into political situations and could sway an audience with great skill. To his role of speaker he brought great energy and tact. His conception of the role differed considerably from that held by many of his predecessors in that he rarely descended from his chair to participate in the debates on the floor. Blaine developed a strong, loyal and devoted body of followers who gave him support throughout his long and varied career. To his followers he was known as the "Plumed Knight," an appellation given him by Col. Robert G. Ingersoll of Illinois who offered his name in nomination at the national Republican convention of 1876.

It was during the period of Blaine's speakership that disclosures were made of graft, corruption and improprieties of high officials in President Grant's administration. In 1876, immediately prior to the nominating convention, came the sudden and disquieting accusation that Blaine had used his office to profit from a financial transaction involving the Little Rock and Fort Smith railroad. Though Blaine made a brilliant speech on the floor of congress in an attempt to exonerate himself, the publicity which the incident received plus a heatstroke suffered on the eve of the convention adversely affected Blaine's chances in the close nominating race. On the seventh roll call, Rutherford B. Hayes defeated Blaine by a margin of 25 votes.

Immediately after the election Blaine was appointed to the senate to fill a vacancy and was soon elected for a full 6-year term. In 1880 he was again a candidate for the presidential nomination but was defeated by his friend. James A. Garfield. He then gave his support to Garfield and was active in his behalf throughout the campaign. Upon Garfield's victory Blaine resigned his senate seat to accept appointment as secretary of state. In this capacity he demonstrated both creativity and initiative and achieved some degree of success. His policies represented a modification of the long-standing Monroe Doctrine; rather than waiting until called upon to mediate disputes, Blaine broke tradition by extending the nation's good offices to Mexico in its boundary controversy with Guatemala and to the governments involved in the War of the Pacific (*q.v.*). The results, however, were disheartening. Most of the Latin American countries were already suspicious of the motives of the United States. Blaine's actions served merely to alienate them further.

Blaine envisaged a system of inter-American arbitration which might relieve international tensions, prevent future conflict and strengthen the Monroe Doctrine. He also hoped to increase commercial relations between the United States and its southern neighbours and to create a more favourable balance of trade. In 1881, therefore, he attempted to realize the idea—conceived earlier in the century—of inviting the independent nations of South America to an inter-American conference to discuss and consider a comprehensive system of arbitration designed to prevent future wars in the western hemisphere. This marked the beginnings of the Pan-American movement. Unfortunately, however, Blaine was forced to resign following the assassination of Garfield (1881) and his Pan-American conference was quickly shelved by his successor. (See PAN-AMERICAN CONFERENCES.)

During this term of office as secretary of state, Blaine also sought to modify or abrogate the Clayton-Bulwer Treaty of 1850. The treaty provided that the United States and Great Britain should have equal control of any canal across the isthmus of Panama. Blaine's diplomacy sought to reach an agreement by which a canal entirely under U.S. control might be constructed. His plans

were realized, though not in his lifetime, with the Hay-Pauncefote treaty of 1901. *(See* PANAMA CANAL.)

Blaine was finally nominated for the presidency in 1884 only to lose by a narrow margin to Grover Cleveland in an issueless and sordid campaign. His defeat in an election that had appeared to promise certain victory has since stirred speculation regarding the causes. One interpretation attributes the outcome to the loss of the Irish Catholic vote in New York city, for Blaine lost the state of New York by only 1,149 votes. The phrase "Rum, Romanism and Rebellion" was used by Rev. Samuel D. Burchard to characterize the Democratic party in a campaign speech made in Blaine's presence at the Fifth Avenue hotel, New York city. on Oct. 29. Blaine did not disclaim the phrase; whether he heard the statement at all is open to question. There is considerable doubt, moreover, as to the effect of the remark on the Catholic vote. A second interpretation of the election results holds that Blaine's impugned character made him unacceptable to the public. It would appear, however, that the Republican vote in 1884 actually represented an increase in the proportion of total votes cast as compared to 1876 and that Blaine's candidacy helped to check the political resurgence of the Democratic party.

Blaine was given a second opportunity in 1889 to bring his foreign policy to fruition. Appointed secretary of state by Pres. Benjamin Harrison, he assumed the chairmanship of the first Pan-American conference, which had been authorized by congress the previous year. The conference, though in accord on many important political and economic problems, could not reach agreement on several far-reaching proposals to which Blaine was dedicated. The project for an American customs union failed to win the support of the majority of the committee studying the problem. Recommended in its stead was the negotiation of separate reciprocity treaties. Blaine's proposal that arbitration be compulsory for all controversies except those in which, in the opinion of the nations involved, sovereignty would be compromised, suffered a similar defeat.

Several other thorny problems which confronted Blaine while secretary of state were not solved: the controversy with Great Britain regarding the right of Canadian vessels to hunt seals in the waters of the Bering sea; the conflict with Great Britain and Germany concerning the disposition of Samoa; and the strained relations with Chile following the killing of several U.S. sailors in Valparaiso.

The question of reciprocity raised in the Pan-American conference was of particular concern to Blaine. Though an ardent protectionist, he nevertheless foresaw that reciprocity was essential to the improvement of trade relations with Latin America. He fought hard to include a reciprocity clause in the high-tariff McKinley bill of 1890. His plea for greater reciprocity mas heartily endorsed by midwestern farmers who desired an enlarged market for their produce. Blaine's stand prevented the wholesale defection of the midwestern vote in succeeding elections.

Blaine resigned as secretary of state in June 1892, partly as a result of failing health, but also to block a movement by his friends to place his name before the 1892 nominating convention. He died in Washington, D.C., on Jan. 27, 1893.

BIBLIOGRAPHY.—The essence of Blaine's political philosophy and his views of the political occurrences of his era can be found in his two works: *Twenty Years in Congress: From Lincoln to Garfield*, Vol. *I* (1884) and II (1886), and *Political Discussions: Legislative, Diplomatic and Popular* (1887). The best biography of his life and career is David Saville Muzzey, James G. *Blaine, a Political Idol of Other Days* (1934).

(JO. B.)

BLAIR, FRANCIS PRESTON (1791–1876), U.S. journalist and politician, was born at Abingdon, Va., on April 12, 1791. He graduated in 1811 from Transylvania university, then entered journalism and politics at Frankfort, Ky. A loyal supporter of Andrew Jackson, he established in 1830 and owned until 1845 the Washington *Globe*, a party organ, and also published the *Congressional Globe*. He was a political journalist of the first rank, a member of Jackson's "kitchen cabinet" and a skilful party organizer. He was an expansionist, but opposed the territorial extension of slavery and in 1848 supported the Free-Soil presidential candidate, Martin Van Buren. One of the founders of the Republican party, he assisted materially in Lincoln's nomination in 1860 and became an influential adviser in the Lincoln administration. The president approved Blair's unofficial and unsuccessful mission to arrange peace at the Hampton Roads conference in Feb. 1865. After the war, Blair supported Pres. Andrew Johnson's plan of Reconstruction, opposed the radical Republicans and rejoined the Democratic party. He died at Silver Spring, Md., on Oct. 18. 1876.

His son, MONTGOMERY BLAIR (1813–83), lawyer and politician, was born in Franklin co., Ky., on May 10, 1813. He left Transylvania university to enter West Point, graduating in 1835 and serving briefly in the army. He then studied law and began practice in 1837 in St. Louis. A leading supporter of Sen. Thomas Hart Benton, he became, successively, U.S. attorney for Missouri, mayor of St. Louis, a judge of the court of common pleas and a leading lawyer. In 1853 he moved to Maryland where he practised extensively in the federal courts and served as one of the attorneys for Dred Scott in 1856–57. He was a Free-Soil Democrat and an advocate of western extension without slavery. Blair left his party to become a Republican and advocated the candidacy of Abraham Lincoln in 1860. Appointed postmaster general in 1861, he supported the policies of the Lincoln administration, but his moderation incurred the hostility of the radical Republicans who forced his resignation from the cabinet in 1864. His administration of the post office department was distinguished by the establishment of free city delivery, a money order system and other improvements. After the war he supported Pres. Andrew Johnson's policies, returned to the Democratic party and resumed the practice of law. He died at Silver Spring. Md., on July 27, 1883.

Another son, FRANCIS PRESTON BLAIR. JR. (1821–75), soldier and political leader, was born in Lexington, Ky., on Feb. 19, 1821. After graduating from Princeton in 1841, he studied law at Transylvania university and began to practise in St. Louis in 1842. Convinced that the institution of slavery was morally wrong and an economic hindrance to western development, he became a Free-Soil Democrat, a supporter of Thomas Hart Benton and an advocate of gradual compensated emancipation. He served from 1852 to 1856 in the Missouri legislature, assisted in organizing the new Republican party and was a member of congress for two terms, 1857–59 and 1861–63. His services in 1861 were probably significant in preventing the secession of Missouri, although his domineering and aggressive methods aroused opposition. As chairman of the military affairs committee of the house of representatives he rendered loyal and effective service. A general and corps commander in the Union army, he won recognition for competent military leadership. He opposed the congressional reconstruction policy, rejoined the Democratic party and in 1868 was the Democratic candidate for vice-president. In 1870 he was elected to the U.S. senate from Missouri to fill an unexpired term but was not re-elected in 1872. He died in St. Louis on July 8, 1875.

BLAIR, JAMES (1656–1743), American ecclesiastic and founder of the College of William and Mary, Williamsburg, Va., was born, probably in Edinburgh, Scot., in the year 1656. He was educated at the University of Edinburgh, receiving the degree of M.A. in 1673'. Blair received ordination in 1679 but was deprived in 1681 for refusing to take a test oath imposed by the Scottish parliament for the purpose of securing the succession of the duke of York as James II. Unable to obtain any ecclesiastical appointment, he served for three years as clerk in the office of the master of the rolls in London. In 1685, through the recommendation of the bishop of London, Henry Compton, he was elected rector of Varina parish, Henrico county, Va. He was appointed commissary or ecclesiastical representative of the bishop of London in Virginia on Dec. 15, 1689, and it was in this capacity that in April 1691 he proposed the founding of a college. With the endorsement of the assembly, he went to England and secured from William and Mary a charter and grant of funds for the college, which was named in honour of its royal patrons. He became its president, in addition to being commissary, and saw it through all the vicissitudes of its early history. Though Blair, whose influence with the home government enabled him to secure

the recall of three governors, became one of the most powerful men in the colony, his career outside the college was marked by frustration. This was partly the result of his personal limitations, but more the consequence of the ambiguity of his official position. The bishop of London's jurisdiction in the American colonies mas never officially defined, and that of his commissaries was still more vague. Blair began by attempting to maintain some discipline over the laity, but gave it up after being rebuffed by the governor and council. His continuing effortsto exercise some authority over the clergy. to raise their salaries and to stabilize their tenure involved him in endless disputes with the governors, the assembly, the parish vestries and the clergy themselves. Most of the issues were still unresolved when he died on April 18, 1743.

BLAIR, ROBERT (1699–1746), Scottish poet, whose poem *The Gsave* achieved great popularity and influence by appealing to the morbidity underlying 18th-century rationalism. was born at Edinburgh in 1699. Educated there and in Holland, he was ordained in 1731 and appointed to Athelstaneford, East Lothian, where he died on Feb. 4, 1746. He was happily married, had six children and devoted his leisure to poetry, botany and optical experiments.

The Grave (1743) is his only important work. It is an uneven poem in blank verse which, while often macabre and melodramatic, sometimes rises to the level of true poetry. It inspired William Blake to make 12 illustrations which appeared in the 1808 edition.

The standard edition of Blair's *Poetical W7Orks* was edited by R. Anderson in *Poets of Great Britain,* vol. viii (1794), with a biographical introduction.

BLAIR ATHOLL (Gaelic BLAIR, "a plain"), a village and civil parish in Perthshire, Scot., 34 mi. N.N.W. of Perth by road, lies at the confluence of the rivers Tilt and Garry. Pop. of civil parish (1951) 1,870. Blair castle: a seat of the duke of Atholl (chief of clan Murray), which dates in part from 1269, was considerably enlarged in the 1740s. The marquess of Montrose raised his standard there in the cause of Charles I in 1644. The castle was held for James II in 1689 at the time of the Battle of Killiecrankie. Viscount Dundee. killed in that engagement, was buried in the church of St. Bride. Old Blair, in which a tablet was erected to his memory 200 years later. Prince Charles Edward stayed at the castle in Aug. 1745 and Feb. 1746. Soon afterward occupied by government forces, it was besieged by Lord George Murray (the duke's brother) lieutenant general of the Jacobite forces. The Atholl gathering, in abeyance since 1913, was a famous event held annually in September to commemorate Queen Victoria's presentation of colours in Sept. 1845 to the duke's ceremonial bodyguard, still in existence and now called the Atholl Highlanders. The fine falls of Bruar are 4 mi. W. of Blair Atholl.

BLAKE, EDWARD (1833–1912), Irish-Canadian lawyer and statesman, was born in Metcalfe township, Ont., on Oct. 13, 1833. Blake was called to the bar in 1856, created a queen's counsel in 1864, and, following Confederation, became a leading authority on the Canadian constitution. In 1867 he was elected as a Liberal to both the Ontario legislature and the Canadian house of commons. He mas prime minister of Ontario, 1871–72, and minister of justice, 1875–77, in Alexander Mackenzie's Dominion cabinet. In the latter position he was instrumental in settling controversial questions regarding the powers of the governor general. Following the defeat of Mackenzie's government in 1878 and his resignation as Liberal leader in 1880, Blake was elected his successor and led the party until 1887. Ill-health and discouragement at Liberal defeats in two general elections then caused him to resign the leadership. and in 1891 a temporary disagreement with his party over trade policy ended his Canadian political career.

From 1892 to 1907 Blake was an Irish nationalist member of the British house of commons, giving valuable advice on constitutional and financial matters, such as the drafting of the Home Rule bill of 1893 and the study of the financial relationship between Britain and Ireland. His greatest contribution, however, mas in raising funds in Canada and the United States for the lrish parliamentary party which, through his efforts. was saved from collapse. He retired in 1907 and died at Toronto on March 1. 1912.

BLAKE, ROBERT (1599–1657), English admiral, fought on the parliamentary side in the English Civil War and subsequently rendered valuable services to the Commonwealth through his reorganization of the navy and by his victories at sea. Born at Bridgwater in Somerset, the eldest son of a well-to-do merchant, he entered St. Alban hall. Oxford, in 1615, but soon moved to Wadham college, from which he graduated in 1623. From that date until his election for Bridgwater to the Short parliament in 1640 nothing certain is known about him. He is said to have visited the Ketherlands and probably had some experience of the sea.

At the outbreak of the Civil War in England he declared for parliament and soon distinguished himself as a general. He defended Bristol against Prince Rupert in 1643 and became famous as a result of his defense of Lyme the next year. In July 1644 he took Taunton by surprise and held the town against the Royalists for the next two years. In 1645 he re-entered parliament as member for Bridgwater. In 1618. during the second phase of the Civil War, he organized the forces in Somerset.

In Feb. 1649 he was appointed with two other "generals at sea" —Richard Deane and Edward Popham—as "commissioner to command the fleet." In April he was sent against Rupert's squadron at Kinsale, where he blockaded the prince for six months. When Rupert escaped to Lisbon, Blake followed him into the Tagus but was refused permission by the king of Portugal to attack him. He made reprisal by capturing six ships and burning three of the returning Brazil fleet and brought his prizes home. Blake then sailed again to pursue Rupert into the Mediterranean. where he destroyed the Royalist squadron at Cartagena in Nov. 1650. For this service he was thanked by parliament and awarded a grant of 151.000. In May 1651, in conjunction with Sir George Ayscue, he captured the Scilly Islands which were held by Royalist. privateers. Shortly afterward he was made a member of the council of state.

On the outbreak of the first Dutch War in 1652 he was appointed to the command of the fleet in the channel. In May, Martin Tromp's fleet of 42 ships appeared off Dover. Though Blake had only about 20 ships, he insisted on demanding the salute to the English flag and, when this was refused, attacked Tromp and forced him to withdraw with the loss of two ships. War was formally declared in July, and Blake was sent to capture most of the Dutch fishing fleet in the North sea; a gale prevented another battle with Tromp. On Sept. 28, 1652. Blake and William Penn encountered a Dutch fleet commanded by Michael de Ruyter and Cornelius de Witt off the Kentish Knock. The Dutch were defeated in a two days' battle and withdrew to Goree. In November Tromp was reinstated in command and met Blake off Dungeness with a superior force, compelling the English fleet to retreat into the Thames and originating the legend of Tromp lashing a broom to his masthead in triumph as a sign that he would sweep the English from the sea. On Feb. 18, 1653, an indecisive action was fought off Portland in which Tromp, with 80 warships and about 200 merchantmen, was engaged for three days but managed to escape; in this battle Blake was severely wounded. On June 3 another battle was fought off the Gabbard in which Richard Deane and George Monck had the worst of it until Blake appeared with 13 sail, whereupon Tromp retreated to the Texel. This was the first battle to be fought in line-ahead formation.

The effects of his wound compelled Blake, now aged 53, to retire from the sea for the next few months. though he took his seat as a member of the Barebone's parliament. The conclusion of peace with the Dutch in 1654 enabled Cromwell to turn his attention to the French and the Spanish. In Nov. 1654 Blake was given the command of a fleet of 24 ships to make English influence felt in the Mediterranean. Having exacted compensation from the grand duke of Tuscany, he sailed against the corsairs of Tunis,

who constantly threatened English shipping in this area. When the bey refused to release his English slaves, Blake attacked his fleet at Porto Farina and destroyed the fortresses there.

War having been declared on Spain in 163'6.Blake was sent with 48 ships to cruise off Cadiz and capture Gibraltar if opportunity offered. His force was not strong enough to attempt the latter task, but one of his captains. Richard Stayner, intercepted the plate fleet in September and captured treasure estimated at 5.000.000 pieces of eight. In April 163'7Blake, then in ill-health: heard that another plate fleet and its escort lay in the bay of Santa Cruz. Tenerife. The Spanish fleet consisted of 16 ships protected by six forts. In spite of their strong position. Blake ordered Stayner to lead into the attack on April 20 and in one of the most vigorously fought actions in naval history he totally destroyed the Spanish fleet and its defenses. There is a story that the wind shifted to enable him to withdraw at the conclusion of the action. but he himself states that "the wind was all the while blowing into the bay." The English only lost one ship and 50 men killed. "The whole action," says the earl of Clarendon, "was so incredible that all men who knew the place wondered that any sober man, with what courage soever endowed, would ever have undertaken it; and they could hardly persuade themselves to believe what they had done; while the Spaniards comforted themselves with the belief that they were devils and not men who had destroyed them in such a manner."

Since his health was seriously deteriorating. Blake was compelled to make for home before the end of the summer. He died on Aug. 7, 1657, one hour before his victorious fleet entered Plymouth sound. His body was embalmed and lay in state, like Nelson's, at Greenwich before a state funeral at Westminster abbey. In 1661 Charles II ordered the exhumation of his body, together with those of other leading members of Cromwell's regime, and it was flung into a pit north of the abbey.

Apart from his services at sea. Blake played an important part in the organization of the Commonwealth navy. He was the author of the Fighting Instructions which founded the tactics of the next century and he was responsible for the introduction of the Articles of War, the basis of naval discipline. He was a humble man, simple and sincere in his religion. brave in action and devoted to "the services of this Commonwealth." Clarendon. the royalist, bears this testimony to his example: "He betook himself wholly to the sea: and quickly made himself signal there. He was the first man that declined the old track, and made it manifest that the science might be attained in less time than was imagined; and despised those rules which had long been in practice. to keep his ship and his men out of danger. . . . He was the first man who brought the ships to contemn castles on shore. which had been thought ever very formidable. He was the first that infused that proportion of courage into the seamen, by making them see by experience, what mighty things they could do. if they were resolved; and though he hath been very well imitated and followed, he was the first that drew the copy of naval courage."

BLAKE, WILLIAM (1757–1827), English mystic. poet and artist. was born in London, Nov. 28, 1757. His father, James Blake, of whose family and origin nothing is known. was a hosier. living at 28 Broad street. Golden square. His mother's maiden name was Catherine Harmitage. The family consisted of four sons and a daughter. William was the second son, and the only one to achieve distinction. The eldest, James. succeeded his father in the hosiery business. The third, John, died young, after a life of dissipation. The youngest, Robert. who showed considerable capabilities as an artist. was greatly loved by his brother William, and was nursed by him through the illness of which he died at the age of 21. Another son. Richard, died in infancy.

William began to show his artistic leanings at an early age. His father wisely decided to encourage this side of his nature, and sent him at the age of ten to Henry Pars's drawing school in the Strand. He also gave him casts from which to draw and allowed him to buy prints after the old masters at the sale rooms. In Aug. 1772 he was apprenticed to Basire the engraver and served his time faithfully in learning the conventional styles of engraving. He also made drawings of the monuments in Westminster abbey and these were engraved for Gough's *Sepulchral Monuments*. His mind was profoundly influenced by the surroundings in which he worked, and the Gothic style was to him the ideal, the "living form," for ever after. At the same time he was cultivating his mind in other ways and is known to have read Burke, Locke, Bacon and Fuseli's translation of Winckelmann. His creative faculty found its outlet in the early years in poetry, some of which has survived in the thin volume of *Poetical Sketches*, printed for Blake by his friends in 1783., These pieces were composed between his 12th and 20th years. .Although they show the influence of contemporary poetry. notably Ossian, they owe something too, to the Elizabethans and the poets of the later 17th century; yet they have a pure strain of lyrical inspiration which sets them apart as a landmark in English literature. They remained unknown and so had no influence on the poetry of their time, but nevertheless were the forerunners of the freer age in poetry which began some 20 years later.

In 1779 Blake had completed his apprenticeship, and at the age of 21 set out to earn his living as a professional engraver. He executed many commissions for the booksellers and publishers, and during the next 20 years supported himself largely by this means. His circle of friends about the year 1780 included T. Stothard. J. Flaxman and H. Fuseli, all of whom played a large part in the course of his later life. In this year he first exhibited at the Royal Academy pictures admired by Romney.

In 1781 he met his future wife, Catherine Boucher. the illiterate daughter of a Battersea market-gardener. They were married in hug. 1782, and lodged at first at 23 Green street. Leicester Fields. The name of Catherine Blake will go down to posterity as that of an almost perfect wife. She learned to draw and paint well enough to be able to help Blake in his work. She remained childless, and survived her husband only four years, dying in 1831.

During the years 1783–87 Blake met a number of distinguished people at the house of the Rev. A. S. Matthews, who had helped in printing the *Poetical Skefches;* but this society soon disgusted him, and he ridiculed it in a satire, or burlesque novel, now known as *An Island in the Moon* written about *1785*. One interest of the piece now lies in the fact that it contains early drafts of three of the *Songs of Innocence*. In 1784 Blake had started a print shop in partnership with a former fellow apprentice, Parker, at 27 Broad street. but this did not succeed and was soon abandoned. Meanwhile he was earning a livelihood by engraving ordinary copperplates for the publishers, and in 1788 he began to experiment with a new method of printing from etched copperplates. It is related that the secret of this process was revealed to him in a vision by the spirit of his brother Robert. More probably he had received a hint of it some time before from his friend. George Cumberland of Bristol. who had been working on it as early as 1784. Both words and decorations were drawn on the copperplate with a resistant medium, and the copper was then etched with acid. Text and design remained in relief and could be printed in any tint that pleased the artist. The print could then be left plain or be coloured by hand with water colours or printed as a monotype in opaque pigments. The first results of this process were the small dogmatic works. *There Is No Natural Religion*, and *All Religions Are One*. It developed further with the production of *Songs of Innocence*, which consisted of simple lyrical poems etched on copper with decorations coloured by hand. The volume was finished in 1789 and was sold for a few shillings. This was the prelude to the remarkable series of books in "illuminated printing" which occupied Blake in some degree for the remainder of his life. Blake was now living in Hercules road, Lambeth, and here he completed the works entitled *The Book of Thel*, 1789; *The Marriage of Heaven and Hell*, 1793; *Songs of Experience*, 1794 (a companion volume to *Songs of Innocence*); *America*, 1793; *Visions of the Daughters of Albion*, 1793; *Europe*, 1794; *Urizen*,

1794; *The Book of Los*, 1795; *The Book of Ahania*, 1795; and *The Song of Los*, 1795. In *Songs of Experience* the lyrical and mystical elements were intimately mingled. This book had been preceded by *Thel*, and by a prose work, *The Marriage of Heaven and Hell*, in which mysticism and philosophy began to gain the upper hand. In the succeeding works Blake's visionary powers overwhelmed him, and they were wholly devoted to an elaboration of his mystical and metaphysical systems, which have proved a stumbling block to many of his readers, but have now been largely elucidated by a better understanding of his complicated symbolism and its sources. They are written in an irregular verse form which entitles Blake to be regarded as the forerunner of the *vers libre* of recent times.

Meanwhile Blake's output as an artist was very large. About the year 1795 he produced his stupendous series of large colour prints, which can scarcely be matched in the whole history of art for imaginative content and magnificence of colouring. These include "Nebuchadnezzar," "The Elohim Creating Adam" and "Newton." By 1797 he had completed his series of 537 water-colour designs for Young's *Night Thoughts*. He had also made numerous separate paintings in water colour and tempera, but never painted in oils.

Blake's circle of friends had widened somewhat, and now included Thomas Butts, chief clerk in the office of the muster-master general. It was chiefly Butts's patronage which enabled Blake to earn a livelihood while expending much time and energy on his symbolical works, which never produced any adequate return by their sales. He even laboured at a long poem which never was, and was never intended to be, produced in its original form. This was *Vala* or *The Four Zoas*, a poem of the greatest significance for the understanding of Blake. though the manuscript (now in the British museum) was not properly transcribed and edited until 1925, nearly a century after the author's death. The poem was begun about 1795 and was elaborately revised five years later, some passages from it being used in later works.

During the seven years from 1793 to 1800 his creative output was almost greater than can be believed. Periods of mental and physical exhaustion were the inevitable result, and it was probably a fortunate event that in 1800 introduced Blake to the notice of William Hayley in order that he might execute copperplates for various works on which Hayley was engaged. As a result of this introduction, brought about by Flaxman, Blake paid a visit in the early part of 1800 to Hayley at Felpham in Sussex, and later in the year he rented a cottage in the village, so that he might work under Hayley's eye at the engravings for the projected *Life of Cowper*. Blake removed to Felpham with his wife and sister, intending to stay there for an indefinite period. Three years later he returned with a great sense of relief to London. At first he had been able to work happily enough at Felpham, but as time passed he became increasingly irritated by Hayley's patronizing ways and lack of understanding, and his feelings found relief in the scurrilous doggerel and epigrams scribbled in his notebook. At length he realized that the best way of keeping Hayley's friendship was to leave his company, so he returned to London. Part of the three years at Felpham were charged with spiritual discomfort. Blake obtained no respite from the visions which crowded ceaselessly upon him. He was forced to lead a double life, pandering on the surface to Hayley's vanities and forced to develop in secret his own imaginative faculties. The Felpham period was, therefore, a strangely mixed output of second-rate engravings for Hayley, of fine paintings, and of mystical poetry of great power, which was mostly embodied in the poem *Milton* first printed from copperplates in 1808. Thomas Butts bought most of Blake's paintings, and to this faithful friend he confided his difficulties in his letters. An additional trouble was the well-known incident following a misunderstanding with a soldier, John Scofield, whom Blake forcibly turned out of the garden of his cottage. Scofield afterward fabricated evidence against Blake, accusing him of using treasonable words against the king. He was tried at Chichester sessions in Jan. 1804 and was triumphantly acquitted of the charge.

After his return to London he lived at 17 South Molton street, determined to devote his life to art without further hindrance from the outside. He believed that he had learned from Hayley the way to obtain worldly success and riches as a publisher of his own works, but in this he was disappointed, and he found the means of livelihood more precarious than ever. Butts continued to buy his pictures and he was given some work as an engraver, but for his own books he was unable to find a market. He refused, however, to be discouraged for long, and in 1805 he entered with zest into a scheme with the engraver Cromek for the production of a series of engravings for Robert Blair's *The Grave*. Here he was again deceived. Cromek paid him a small sum for the designs, and then contrary to his agreement employed another to engrave them. The book containing them was published in 1808. Blake, already embittered by neglect, became still more embittered by incidents such as this and suffered from fits of depression. He reacted, however, about 1808 when he decided to hold an exhibition of his works at the house of his brother James in Broad street, Golden square. Sixteen pictures only were exhibited, including his large painting of Chaucer's Canterbury Pilgrims, and each visitor to the house received for his entrance fee of 2*s*. 6d. a copy of the now celebrated *Descriptive Catalogue*. The exhibition was opened in May 1809, and attracted very little notice, the only criticism of it, which appeared in Leigh Hunt's *Examiner*, being spiteful and unfair. The few visitors included Charles Lamb and Henry Crabb Robinson, the barrister and diarist, who has left a valuable account of his acquaintanceship with Blake during his later years. Blake was again disappointed of the recognition which he knew he merited, and was further ruffled by what he believed to be dishonesty on Stothard's part concerning his picture of the Canterbury Pilgrims. Probably the knavery was Cromek's, who, having seen Blake's design. suggested the idea to Stothard and so made him an innocent plagiarist. Stothard's commonplace picture was a popular success—a cruel blow to Blake's pride.

During the years following his exhibition Blake sank into an obscurity from which it has been difficult to disinter the bare facts of his existence. For the years 1810–17 only a few scattered references remain, and it is uncertain how he found the means of earning his living. It has even been suggested that for part of this time he was confined in an asylum. but it is now certain that there is no foundation for this rumour. Some of Blake's acquaintances, such as Robert Southey, who had visited him in 1811, did regard him as insane. But the testimony of his more intimate friends is of greater value, and they have repeatedly stated their conviction that he was anything but mad. Samuel Palmer, a close friend of his later years, wrote of him as "the most practically sane, steady, frugal and industrious" man he ever knew. Moreover there are facts enough to show that Blake was living from 1810 to 1817 merely in retirement, having accepted his fate like

"JOB'S DESPAIR." A DRAWING FROM ILLUSTRATIONS OF THE BOOK OF JOB BY WILLIAM BLAKE

the wise man that he was. Throughout this period he was occasionally selling copies of his illuminated books. In 1812 he showed several pictures at the last exhibition of the Associated Artists in Water Colour. In 1815 he called on the Rev. Thomas Dibdin, probably in connection with some illustrations to *Milton* which he had made. During most of these years he was still executing engravings for various employers, including a number of plates for Josiah Wedgwood the younger. Finally in the years 1808–18 he was engaged upon the 100 etched plates of his greatest symbolical poem, *Jerusalem*. This magnificent work can have brought him very little financial return, as only six copies issued by him are known to exist, and the only one of these that he coloured was still in his possession in 1827.

In the year 1818 Blake entered upon the last phase of his life, and until his death in 1827 was probably happier in his friends and in his work than he had been at any other period. This was due primarily to his friendship with John Linnell, portrait and landscape painter, to whom he was introduced by his old friend, George Cumberland. Blake was still living in South Molton street, and under Linnell's guidance began to move more freely in society. He was enabled to obtain more work, and became the centre of a circle of young artists who regarded him with affection and veneration. The chief of these were Palmer, Calvert, Richmond, Finch and Tatham, some of whose names are still well known. Frederick Tatham is of little note as an artist, but is remembered as the author of a short life of Blake, and as the owner of most, perhaps also the destroyer of some, of Blake's effects after the death of Mrs. Blake in 1831. Another friend introduced by Linnell was John Varley, the water colourist. He was greatly interested in astrology, and at his instigation Blake drew his visionary heads of historical personages, an occupation which was clearly much less serious to him than to Varley.

In 1821 Blake moved from South Molton street to 3 Fountain court, Strand, and here he executed his most widely known work in creative art, the *Illustrations of the Book of Job*. He had previously made 20 water-colour paintings which had been bought by Butts. Linnell commissioned a duplicate set, and later suggested that he should make engravings of these subjects. The initial expense was borne by Linnell, and the copperplates were engraved in the years 1823–25, the book of 21 uncoloured prints being published in March 1826. Though superficially illustrations of the Bible story, the engravings actually form one of the most important of Blake's symbolical books. Their mystical content has not prevented the designs from being the most widely known and generally appreciated of Blake's works. From about 1824 Blake had been suffering from symptoms of the gallstones which eventually caused his death. He was a frequent visitor at Linnell's country home at Hampstead, but as time passed he found it increasingly difficult to make the journey there. He was still, however, to make one more great effort in his art. In Oct. 1825, Linnell commissioned him to make illustrations to Dante's *Divine Comedy,* and to engrave them. He completed 100 water-colour designs, of which seven were engraved, and was still at work upon these when he died on Aug. 12, 1827. He was buried in an unmarked grave in Bunhill Fields cemetery, the approximate place being now indicated by a tablet placed there on Aug. 12, 1927.

Blake had lived for nearly 70 years and for more than 50 had worked unremittingly as creative artist and as journeyman engraver. His position in the history of the art of England is peculiar owing to his double achievement as poet and as painter. It is moreover impossible to determine his place in either poetry or painting separately, the two being interdependent both in his own mind and in the forms he used for their expression. His impulse as a lyrical poet had shown itself before the age of 14 and was not quite exhausted until more than 30 years later. It is seen at its best in the volume of *Poetical Sketches,* printed in 1783, in the *Songs of Innocence* and *Songs of Experience,* produced in the years 1789 to 1794, and in some of the later poems from manuscripts and letters, and this part of his writings has justly been the chief source of his present popularity. Gradually this faculty gave way, as his mind developed, before a rising tide of mysticism which strove to find expression through an increasingly complex system of symbolism. In the *Songs* some symbolism and simple pictorial designs were added to lyrical poetry. In his latest poems, *Milton* and *Jerusalem,* the symbolism became predominant and its pictorial representation more elaborate. As a painter he was entirely uninterested in realism, his favourite subjects being taken from the Bible or from writers such as Shakespeare and Milton. He sought to express in a picture the things of the mind as much as in a poem, and it is to the mind of the observer that they appeal. It is useless therefore to look in Blake's pictures for accuracy of detail. He laid great store by firmness of outline, but abhorred copying nature. His pictures live by their qualities of design, colouring and imaginative content, and his mystical poetry by the vigour of the intellect which produced it.

It cannot be disputed that Blake suffered from the defects of his qualities. His mind was never systematically cultivated, just as his hand was never intensively trained to draw from the living model. He was therefore apt to be intolerant through ignorance, and inaccurate through lack of observation. It is doubtful, however, whether he would have achieved more or have had a greater influence at the present time if he had possessed the academic virtues. His qualities isolated him from his contemporaries and drove his mind in upon itself, so that the interpretation of his message to mankind cannot be made with precision. But through all his mental turmoil and difficulties in dealings with his fellow men he kept his intellectual integrity, and he never prostituted his art. Throughout his life he sought to exalt the things of the mind, and for him the imagination was man's highest faculty. Ceaselessly he fought against materialism and attempted to gain his own spiritual regeneration through struggles against self. He was deeply religious, though in no conventional sense. In his later years Christ became identified in his mind with Art, and this fact provides many clues for the understanding of his doctrines. In his symbolic writings his own mental experiences were described without regard to the difficulties of his readers. Late in his life he made some attempt to embody his view of Christianity in more direct language, but his poem *The Everlasting Gospel,* written about 1818, was never finished, and exists now only in disconnected fragments. Perhaps the most illuminating revelation of his mind for most readers are the aphorisms and didactic statements which he engraved about the year 1820 around a representation of the Laocoön group.

It is not surprising, therefore, that Blake was incomprehensible to his contemporaries. He influenced them as little as he was influenced by them, and for many years after his death his name was unknown. His first full biography, written by Alexander Gilchrist, was published in 1863, and was reprinted under the supervision of D. G. Rossetti in 1880. Since that time his power and originality have gained fuller recognition, and he now holds a position as one of the greatest figures in English poetry and art. A bronze bust of him by Sir Jacob Epstein was placed in the Poet's Corner in Westminster abbey in Nov. 1957 to mark the bicentenary of his birth. Many of his pictures are to be seen in the Tate gallery, London, and collections of his illuminated books in the British museum and the Fitzwilliam museum, Cambridge.

BLAKELOCK, RALPH ALBERT (1847–1919), U.S. painter, whose powerful impasto paintings of lunar scenes convey a mysterious romanticism, was born in New York city on Oct. 15, 1847. He graduated at the College of the City of New York in 1867. In art he was self-taught, original and a prolific worker. His subjects included pictures of North American Indian life and landscapes derived from a trip to the far west in 1869. His early works are related to the Hudson River school.

Under the strain of continual failure. with his large family in a condition of abject poverty. Blakelock broke down in 1899. His work ceased and almost all of the remainder of his life was spent in an asylum. During his confinement his fame burgeoned, and his paintings brought high prices. In 1916 the Toledo Art museum paid $20,000 for his "Brook by Moonlight," a work which he had been forced to dispose of for a humiliating amount 17 years before. He died near Elizabethtown, N.Y., on Aug. 9, 1919.

See L. Goodrich, *Ralph Albert Blakelock* (1947).

BLAKENEY, WILLIAM BLAKENEY, BARON (1672–1761), British soldier, best remembered for his defense of Minorca during the Seven Years' War, was born at Mount Blakeney, Limerick, Ire. He joined the army in 1702 and served throughout the War of the Spanish Succession under the duke of Marlborough. He commanded a brigade in the expedition to Cartagena in 1741 and was governor of Stirling castle when it was besieged by the Highlanders in 1745, but dispersed them by a vigorous sortie. He became lieutenant governor of Minorca in 1747. At the beginning of the Seven Years' War (1756), the island was attacked by a strong French force. Its defenses were dilapidated and the garrison too small to man them effectively, but Blakeney's resolution so inspired his men that they held out for 70 days, despite the failure of Adm. John Byng's attempt to drive off the French fleet. This gallant defense made Blakeney a popular idol and he was created Knight of the Bath and an Irish baron. His health was undermined by the hardships of the siege, however, and he died on Sept. 20, 1761. He was a true "soldiers' officer," always in close touch and sympathy with hi's men. Of a frugal nature, he lived on his army pay, leaving his brothers to reside on the family estate in Limerick. His Memoirs were published in 1756.

(E. W. SH.)

BLAKESLEE, ALBERT FRANCIS (1874–1954), U.S. botanist and geneticist. whose chief contribution to science resulted from his extensive investigation~with the genera Dafura (Jimson weed), *Mucor* (molds), Rudbeckia and Portulaca, was born at Geneseo. N.Y., on Nov. 9, 1874. He graduated from Wesleyan college in 1896 and obtained his Ph.D. degree from Harvard university in 1904. After teaching botany at several institutions, including Harvard and the Connecticut Agricultural college, he joined the department of genetics of the Carnegie institution of Washington. D.C., in 1915, working as its director from 1935 until his retirement in 1941. In that year he established the genetics experiment station at Smith college, Northampton, Mass., and directed it until his death on Nov. 16, 1954.

Blakeslee's Ph.D. thesis on sexual reproduction in the genus *Mucor* received wide recognition. His investigations on Datura genetics contributed new knowledge concerning cytogenetics, gene and chromosome mutations, effects of radiation, polyploidy and hybridization between species. He also studied the differences among individual persons in the senses of taste and smell.

(S. SA.)

BLAMEY, SIR THOMAS ALBERT (1884–1951), Australian soldier who commanded the Australian military forces in World War II. was born on Jan. 24, 1884, at Wagga Wagga, New South Wales. where his father was a storekeeper. He was commissioned in 1906 and before World War I served in India. where he attended the Quetta staff college. During 1914–18 he served in Egypt. in the Gallipoli campaign and in France. He was awarded the Distinguished Service Order and was created companion of St. Michael and St. George in 1918 and companion of the Bath in 1919. After a period as Australian defense representative in London, he returned to Australia in 1923 as second chief of the general staff. In 1925 he retired from the army and became chief commissioner of police in Victoria, combining this office with territorial army activities. Soon after the outbreak of World War II he was recalled and flew to Palestine in 1940 as commander of the Australian I corps. In 1941 he was promoted to full general and appointed deputy commander in chief, middle east, under Lord Wavell. Early in 1942 he returned to Australia to become commander in chief of all Australian ground military forces, and was later appointed commander in chief, Allied land forces, southuest Pacific area, under Gen. Douglas MacArthur. In June 1950 Blamey was promoted to field marshal, the first Australian to attain the rank. He died in Melbourne on May 27, 1951.

BLANC, (JEAN JOSEPH CHARLES) LOUIS (1811–1882), French political leader and historian whose ideas have had a great influence on the development of socialism. was born on Oct. 29. 1811. in Madrid, where his father was inspector general of the Spanish finances under Joseph Bonaparte. As C. A. Pozzo di Borgo, his mother's uncle, did nothing to help him, Louis Blanc lived in poverty in Paris after the Bourbon restoration, studying law and writing for various journals. In 1839 he founded the Revue *du progrès,* in which he published his famous essay "L'Organisation du travail." The principles laid down in this essay form the key to Blanc's whole political career. Attributing all social evils to the pressure of competition whereby the weaker are driven to the wall, he demanded the equalization of wages and the merging of personal interests in the common good, with an economy based on the principle "To each according to his needs, from each according to his abilities." This was to be effected by the establishment of "social workshops," a sort of combined co-operative society and trade union, in which the workmen in each trade were to unite their efforts for their common benefits.

In 1843 Blanc joined the committee of *La Réforme,* the journal of the extreme left-wing Republicans. In 1847 he was prominent in the banquets campaign for electoral reform (see FRANCE: History). After the revolution of 1848 he became a member of the provisional government of the second republic. On his motion, on Feb. 25, 1848, the government undertook "to guarantee the livelihood of the workers by work" and "to guarantee work for every citizen." Next, though his demand for a ministry of labour was refused, the government agreed to shorten working hours and authorized an assembly of Paris workers' delegates to make recommendations for the reorganization of labour and industry under the supervision of Louis Blanc and Albert (*q.v.*) "the Worker." This assembly. the celebrated Luxembourg commission (so-called because it met in the Luxembourg palace), became an arbiter in trade disputes and a centre of socialist propaganda. Blanc's increasing popularity, however. alarmed the more conservative members of the government, so that when the national assembly met at the beginning of May, he was not re-elected to his post, and the recommendations of the Luxembourg commission were ignored. Furthermore, the government had already set up a rival organization, the "national workshops" (*q.v.*), conducted on a parody of Blanc's principles and denounced by him, under the supervision of A. T. Marie, minister of public works and one of Blanc's political enemies. Forced to flee to England after the defeat of the workers in the revolt of June 1848, Blanc did not return to France until the fall of the second empire (1870). He was elected a deputy for Paris in Feb. 1871, but he would not join the Communards. whom he tried to reconcile with the government at Versailles in March. Under the constitution of 1875 he was elected deputy for Saint-Denis in 1876. He was opposed to the extreme left-wing republicans but introduced a proposal, for the amnesty of the Communards in Jan. 1879. He died at Cannes on Dec. 6, 1882.

Louis Blanc had not only a vivid and picturesque style but also

considerable power of research, exemplified for instance by his studies of English affairs during his exile from France. His books include *Histoire de dix ans, 1830–1840,* five volumes (1841–44), an attack on the July monarchy; *Histoire de la Re'volution française,* two volumes (1847–62); *Lettres sur l'Angleterre,* two volumes (1866–67); *Histoire de la Re'volution de 1848,* two volumes (1870); *Dix ans de l'histoire de l'Angleterre,* ten volumes (1879–81); and *Questions d'aujourd'hui et de demain,* five volumes (1873–84). There is also a collection of his speeches, *Discours politiques, 1847–1881* (1882).

BLANCHARD, JEAN PIERRE (1753–1809), French aeronaut who, together with the American, John Jeffries, made the first aerial crossing of the English channel, and who was also the first man to make balloon ascensions in England and in America, was born in Les Andelys on July 4, 1753. Within a year following the first balloon ascensions of the Montgolfier brothers *(see* BALLOON), Blanchard began his career, making his first balloon flight in Paris on bfarch 2, 1784. Later that year. he made his pioneer ascension from English soil. Accompanied by Jeffries, he took off from Dover in a balloon and made a successful landing on the French coast near Calais on Jan. 7, 1785. The first international airmail was carried on this flight. In that same year in England, Blanchard made the first use of a parachute (*q.v.*), dropping a dog (or, according to another authority, a cat) in a basket to which a parachute was attached from a balloon. Blanchard was one of the first balloonists to attempt to achieve "dirigibility" in balloons by using sails or "oars," but had no success. (The practical dirigible airship came many years later when propellers and lightweight power plants became available; *see* AIRSHIP.) After making many exhibition flights in Europe, Blanchard went to the United States and made the first balloon ascension in the North American continent on Jan. 9, 1793. He took off from the Washington prison yard in Philadelphia and landed in Gloucester county. N.J. Pres. George Washington was an interested spectator. Blanchard returned to Europe and made many other successful flights. Following an accident in which he fell from his balloon at The Hague, Neth., he died in Paris on March 7, 1809.

(S. P. J.)

BLANCHE, JACQUES ÉMILE (1861–1942), French painter and writer, was born in Paris on Feb. 1. 1861. He was an elegant and witty portraitist of innumerable contemporary English and French artists and writers, in both prose and paint. Blanche's painting developed under the successive inspirations of Manet, of his close friends Degas and Sickert, and of Fauvism and of Expressionism. His "Arthur Symons," "Thomas Hardy" and others are in the Tate gallery, London, and he is represented in the Rouen museum, the Art Institute of Chicago and elsewhere. He died on Oct. 3. 1942.

See Jacques Émile Blanche, *Portraits of a Lifetime* (1937), *More Portraits of a Lifetime* (1939).

BLANCHE OF CASTILE (1188–1252), queen consort of Louis VIII of France and twice regent for Louis IX, was born at Palencia in Old Castile, the third daughter of Alfonso VIII, king of Castile, and Eleanor, daughter of Henry II of England. In consequence of a treaty between Philip II Augustus of France and her uncle John of England, she was betrothed to Philip's son Louis and brought to France, in the spring of 1200, by John's mother, Eleanor of Aquitaine On May 22, 1200, the treaty was finally signed, John ceding with his niece the fiefs of Issoudun and Graçay together with certain fiefs in Berry. The marriage was solemnized the next day, at Portmort. in John's Norman domains, as Philip's domains lay under an interdict. Blanche first displayed her great qualities in 1216, uhen Louis, who on John's death claimed the English crown in her right, invaded England. only to find a nation united against him. As Philip Augustus refused to help his son, Blanche established herself at Calais and organized reinforcements, but all her energy was in vain.

Although it would seem that her masterful temper exercised a sensible influence on Louis's gentler character. Blanche's role during his reign (1223–26) is little known. On his death he left Blanche regent and guardian of his children, including Louis IX (Saint Louis), the heir, who was only 12 years old. During this first regency (1226–34) Blanche had to bear the whole burden of affairs alone. to break up a league of the barons (1226) and to repel an English attack (1230). She gained the support of one of the confederate nobles, Thibaut IV of Champagne, protected him from the attacks of his former allies and, when he inherited the throne of Navarre, obtained from him the countships of Blois, Chartres and Sancerre. By judicious marriage treaties she secured Toulouse and Provence to the royal house. Louis IX. indeed. owed his realm to his mother, who brought him up strictly and according to devoutly Christian principles, and he always remained somewhat under her influence.

In 1248 Blanche again became regent, during Louis's absence on the crusade, a project she had strongly opposed. In the disasters that followed she maintained peace, while draining the land of men and money to aid her son in the east. She fell ill at Melun in Nov. 1252 and was taken to Paris, where she died a few days later.

Apart from general histories of the reigns of Louis VIII and Louis IX (*qq v*), *see* Élie Berger, "Histoire de Blanche de Castille, reine de France," *Bibliothèque des écoles françaises d'Athènes et de Rome,* vol. lxx (1895); M Brion, *Blanche de Castille, femme de Louis VIII, mère de Saint Louis* (1939).

BLANDRATA (BIANDRATA), **GIORGIO** (c. 1515–1588), Italian physician and an important figure in the history of unitarianism, was born at Saluzzo in Piedmont about 1515. He studied at the university of Montpellier and in 1533 graduated as a doctor of medicine. His writings on the diseases of women gained him a wide reputation, and in 1540 he was called to the court of King Sigismund of Poland, to be the personal physician of his queen, the Milanese Bona Sforza. After 12 years he returned to Italy and practised at Mestre and at Pavia. He became involved in the antitrinitarian movement and had to flee to Geneva to escape from the Inquisition. His relations with Calvin were at first friendly. but later they quarrelled, and Blandrata had to flee to Poland The remainder of his life was marked by frequent changes in his religious opinions and by equally frequent changes of domicile. His polemical activities brought him into grave danger, from which he was saved by his professional reputation and his courtly manners. His end is obscure, but he is said to have returned to Rome with a fortune and to have renounced his heresies. According to contemporary gossip he was murdered by a nephew in May 1588.

See also UNITARIANISM.

See E M Wilbur, *A History of Unitarianism* (1945) (W J. BP)

BLANE, SIR GILBERT (1749–1834), Scottish physician ahose reforms in naval hygiene and medicine included the use of lime juice to prevent scurvy, was born at Blanefield, Ayrshire, on Aug. 29, 1749. He studied medicine at Edinburgh university but took his M.D. degree at Glasgow in 1778. He then became private physician to Admiral (later Lord) Rodney. whom he accompanied to the West Indies in 1779. He improved the health of the sailors by adding lime juice and other fresh foods to their diet and by enforcing a number of sanitary measures, and it was through him that the use of lime juice was, in 1795, made obligatory throughout the navy.

He returned to London and became physician to St. Thomas' hospital (1783–95). and physician-in-ordinary to George IV (both as regent and as king) and to William IV. He was made a baronet in 1812 in reward for his services in connection with the return of the ill-fated Walcheren expedition. He died in London on June 26, 1834.

His published works include *On the Most Effectual Means for Preserving the Health of Seamen* (1780); *Observations on the Diseases of Seamen* (1785); and *Elements of Medical Logick* (1819) (W. J. BP.; X.)

BLANK VERSE, so called because it lacks rhyme, is the unrhymed iambic metre which has 9. 10, 11 or 12 syllables in each line nith five main stresses. Classical heroic verse, which was the model for later European epic and dramatic poetry, is generally unrhymed *(see* RHYME). When the revival of interest in classical

metre led to the development of a modern unrhymed verse, it took the form of ten syllables (in general) in a line divided into five iambic feet, instead of following the pattern of the classical hexameter (*q.v.*). Introduced in 16th-century Italy, blank verse reached its fullest development in English literature. The skill in using it lies in the variation of the stress, and of the pause or pauses within the line, and in the musical sonorous upbuild of lines into paragraphs.

The Italian humanist Francesco Maria Molza was the first to attempt the writing of consecutive unrhymed verse in his translation of Virgil's *Aeneid* (1514). Other experiments in 16th-century Italy were the tragedy of *Sofonisba* (1515) by *G.* Trissino, who developed a strictly classical form, and G. Rucellai's didactic poem *Le Api* (published 1539). Rucellai's was the first use of the term *versi sciolti*, which became translated as blank verse. Renaissance Italy quickly adopted the form and the comedies of Ariosto, the *Aminta* of Tasso, and the *Pastor Fido* of Guarini are all in unrhymed verse. Italian poets used an 11th syllable or feminine ending to complete the line.

Henry Howard, earl of Surrey (*q.v.*), took the measure from Italy to England. Making the line stronger by omitting the final syllable, Surrey translated two books of the *Aeneid* (1557) in the "straunge meter." He soon found imitators. Thomas Sackville and Thomas Norton used blank verse for the first time in English tragic drama in *Gorboduc* (1562). John Lyly in *The Woman in the Moone* and George Peele in *The Arraygnement of Paris* sought to combine rhyme with blank verse. Christopher Marlowe's use of blank verse is important: in *Tamburlaine, Doctor Faustus* and *Edward II* his "mighty line" occasionally combines the music of Edmund Spenser's poetry with the emotional power of Shakespearean drama.

It was Shakespeare who transformed the line and the instrument of blank verse into the vehicle for the greatest English dramatic poetry. In his early plays, such as *Love's Labours Lost, Romeo and Juliet* and *The Two Gentlemen of Verona*, Shakespeare used prose as well as a ten-syllabled rhymed couplet. After Marlowe's death he used a blank verse, dependent, as Robert Bridges has said, on stress rather than on syllabic length. Shakespeare's verse in *Hamlet, King Lear, Othello, Macbeth* and *The Winter's Tale*, is supple, approximating to the rhythms of speech, yet capable of conveying the subtlest human delight, grief or perplexity:

> To be, or not to be, that is the question—
> Whether 'tis nobler in the mind to suffer
> The slings and arrows of outrageous fortune;
> Or to take arms against a sea of troubles,
> And by opposing end them?

After Shakespeare, blank verse fell from its high place. Beaumont and Fletcher, authors of *The Knight of the Burning Pestle* and *The Maid's Tragedy*, made excessive use of the feminine ending. Thomas Middleton was long-winded. John Webster was violent. Philip Massinger's verse approached the tenuous borderline where poetry meets prose. Cyril Tourneur, George Chapman, Thomas Kyd, Ben Jonson, John Ford, James Shirley and Thomas Heywood were in no sense masters of blank verse.

John Milton's blank verse stands next to Shakespeare's. He used it in the three great epic poems, *Paradise Lost, Paradise Regained* and *Samson Agonistes*, as Shakespeare had used it in drama. In the preface of 1668 to a reissue of the first edition of *Paradise Lost* (1667) Milton wrote:

> The measure is English Heroic Verse without Rime, as that of Homer in Greek, and of Virgil in Latin; Rime being no necessary Adjunct or true Ornament of Poem or good Verse, in longer Works especially, but the Invention of a barbarous Age . . . . . it rather is to be esteem'd an example set, the first in English, of ancient liberty recover'd to Heroic Poem from the troublesome and modern bondage of Rimeing.

Milton's verse is intellectually complex yet flexible, using inversions, latinized words and all manner of stress, line length, variation of pause and paragraphing to gain descriptive and dramatic effect. After Milton, dramatists returned to the use of blank verse and John Dryden, with Nathanial Lee and Thomas Otway, regained for it some of the Shakespearean magnificence.

In the 18th century James Thomson used the measure in his long descriptive poem *The Seasons*, and Edward Young's *Night Thoughts* gained power and passion from its use. Wordsworth wrote his great autobiography of the poetic spirit *The Prelude* (1805) in a blank verse which is capable both of high tension and of pedestrian flaccidity. Shelley's drama *The Cenci* (1819) was written in the form. Keats used it in *Hyperion* (1820). In *The Princess* (1847), Tennyson employed alliteration to offset the lack of rhyme. Both Robert Browning and Elizabeth Barrett Browning attempted blank verse.

Of 20th-century writers of blank verse, Lascelles Abercrombie, Robert Bridges, and Robert Frost in *A Masque of Reason* (1945) are notable. In his plays, *The Family Reunion, The Cocktail Party* and *The Confidential Clerk*, T. S. Eliot has offered what he himself has called a "trickle" of unrhymed lines that flows somewhere between blank verse and dramatically utilitarian prose.

BLANQUI, (LOUIS) AUGUSTE (1805–1881), French socialist and revolutionary, was born on Feb. 1, 1805, at Puget-Théniers, where his father (a former member of the Convention) was a subprefect. He studied both law and medicine but early became interested in politics. He fought in the revolution of 1830, receiving a decoration for his services. Rapidly disillusioned by the conduct of the new government of Louis Philippe, he began to organize secret republican societies and was twice imprisoned (1831 and 1836). In 1838 he organized a new "Society of the Seasons," with Armand Barbès and Martin Bernard as colleagues. Its attempt at insurrection on May 12, 1839, was a fiasco, and Blanqui, with his colleagues, was arrested and sentenced to death, commuted to imprisonment for life. Later he was granted a formal pardon in the belief that he was dying, but he could not leave the prison hospital until just before the revolution of Feb. 1848. He found himself the chief republican club leader. having set up the Société Républicaine Centrale, and continually pressed the government to follow a more socialist and Jacobin policy. As the most skilled tactician, he might have momentarily succeeded in this object had not Barbès ruined his influence by sponsoring a baseless charge of treachery. Unable to prevent the senseless attack on the assembly on May 15, Blanqui suffered its consequences, being sentenced to ten years' imprisonment.

During these years he thought out his political philosophy, advocating the dictatorship of the proletariat (exercised through Paris) as the only means of achieving communism. He maintained that the proletariat must fight the rule of the *bourgeoisie* by forming trade unions, by strikes and, above all, by revolution, and must overthrow the existing political structure before it could achieve its social aims. In Blanqui's philosophy, revolution meant progress. As time went on, Blanqui became more concerned with revolution and less with a social program. He refused to countenance an attack on property after a revolution had been achieved, but wanted gradual economic evolution from capitalism. Released from prison in 1859, Blanqui resumed his organization of secret societies. Again imprisoned in 1861, he escaped to Belgium in 1865 and directed operations from there. By 1870, when he returned to France for good, he was at the head of a secret, armed and drilled force of about 4,000 men in Paris; he also had many adherents who were not included in his army. On the news of the disaster of Sedan the Blanquist army formed the "hard centre" that directed the energies of the indignant crowd, so that the downfall of the empire was secured. It was not, however, able to influence the composition of the new government except by forcing the inclusion of Henri Rochefort.

Blanqui, who was ardently patriotic, was infuriated by the slackness of the government left behind in Paris by Léon Gambetta to conduct the war. He believed that it was more hostile to the left-wing battalions of the national guard than to the Prussians. On Oct. 31. 1870, the battalions that followed his lead came into conflict with the orthodox regiments, and for a few hours Blanqui was at the head of a provisional government; he came, however, to an arrangement with the expelled government and withdrew. On the signing by Louis Adolphe Thiers of the armistice of Jan. 27, 1871, Blanqui retired to Lot to recover his health, broken by exer-

tion and disappointment. There, by order of Thiers, he was arrested on March 17, just before the outbreak of the Paris Commune (*q.v.*), for his part in the revolution of Oct. 31, 1870. Though elected to a seat on the commune, which mas led chiefly by his followers, he was held a close prisoner until after its defeat, when he was again sentenced to imprisonment for life. As a result of agitation, culminating in his standing as deputy for Bordeaux, he was released after the amnesty of 1879 and ended his life in peaceful propaganda. His published works include: *La Patrie en danger* (1871); *L'Éternité par les astres* (1872), a philosophical work strongly tinged with mysticism; *L'Armée esclave et opprimée* (1880); and. most important, *Critique sociale,* 2 vol.. published posthumously in 1885. He died in Paris on Jan. 1. 1881. The Blanquist party was absorbed in the unified French Socialist party by negotiation in 1904–05.

BLANQUI, JEROME ADOLPHE (1798–1854), French economist, whose *History of Political Economy in Europe* (translated in 1880) was the first major study of the history of economic thought. Born Nov. 21, 1798, at Nice, he succeeded J. B. Say, under whom he had studied, to the chair of political economy at the Conservatoire des Arts et Métiers. Blanqui's writing blended both theoretical and empirical approaches in an analysis of industry and commerce. He devoted himself primarily to an examination of the conditions of the working class. Though he advocated government action in the protection of the worker, Blanqui remained a liberal in the tradition of Adam Smith. He died Jan. 28, 1854, in Paris. (L. N.)

BLANTYRE, a town in Lanarkshire. Scot.. lies 9 mi. S.E. of Glasgow and is made up of the previously independent villages of Auchintibber, High Blantyre, Stonefield and Low Blantyre. Pop. (1951) 17,769. The main industries are coal mining and engineering; there is also an industrial estate. In 1813 David Livingstone (*q.v.*) was born in a small single-roomed house in Low Blantyre and he was later employed in the cotton mills there. The Livingstone National memorial, which includes this house and the surrounding grounds, contains a complete record of Livingstone's life and African journeys, together with a scale model of the original village and mills. Scanty remains of Blantyre priory (13th century) stand on the left bank of the Clyde adjacent to the memorial. Opposite, the towers and walls of Bothwell castle crown a red sandstone cliff.

BLANTYRE-LIMBE, a town in the Southern province, Nyasaland, lies in the Shiré highlands at an altitude of about 3,600 ft. It is the largest town in Nyasaland. covering an area of approximately 16 sq.mi., and was formed in 1956 out of the adjoining townships of Blantyre and Limbe. Pop. (1956) 40,498. The altitude gives it a temperate climate with a rainy season from December to March.

By the early 1960s the town showed all the signs of rapid growth including the construction of a new township for Africans. Kindergarten, primary and secondary education are provided, and there is a school for Europeans and one for Asians. There are Roman Catholic and Anglican cathedrals, a public library, hospitals for Africans and Europeans as well as for all races. four public parks and two markets. Blantyre-Limbe is connected by rail with Beira (Mozambique) 330 mi. distant, and a main road links it with Salisbury (380 mi.). Chileka, 7 mi. N., is an airport for services from Southern Rhodesia, Northern Rhodesia and east Africa and the base for local air services in Nyasaland. Blantyre-Limbe is the chief commercial and distribution centre of Nyasaland. Its industries include saw mills and the manufacture of cement, tobacco and mineral waters (effervescent drinks:). It is also the centre for visiting the Mlanje mountain area to the south and Lake Nyasa to the north.

Blantyre, originally a Church of Scotland mission station, was named after David Livingstone's birthplace in Scotland and dates its foundation from 1876. The town was constituted a municipality in 1895 and is therefore the oldest municipality in the Federation of Rhodesia and Nyasaland. The Livingstonia Central Africa company (now the African Lakes corporation) has its headquarters at Blantyre. Its trade was mainly in ivory for which it developed communications, thus laying the foundations of the town's commercial importance. Limbe (founded 1909), five miles anay, grew round the headquarters of the Nyasaland railways. The area between them was built over, and in 1956 the two tonns were amalgamated. (K. H. J. V.)

BLARNEY (BLÁRNA), a village in County Cork, Republic of Ireland. well known for its castle, lies in wooded country 5 mi. N.W. of Cork. Pop. (1956) 1,001. Tweed is manufactured there. Blarney castle, built about 1446 by Cormac Laidhiv McCarthy, lord of Muskerry, has walls 18 ft thick. Below the battlements on the southern wall is the "Blarney Stone," reputed to confer eloquence on those who kiss it, an operation performed only by hanging head downward. Unknown in the early 18th century, there is no legendary explanation of how the stone became invested nith its remarkable properties. The word blarney has come to mean smoothly flattering or cajoling talk. The castle played an important part in the history of the area. being besieged both by Cromwellians and by the troops of William III.

BLASCO IBÁÑEZ, VICENTE (1867–1928), Spanish writer and politician whose early regional novels are vividly descriptive but who achieved spectacular success at the expense of literary quality. He was born at Valencia in Jan. 1867, and at 17 went to Madrid to study law, there beginning his career by incurring the first of many terms of imprisonment for a republican poem. After visiting Paris he returned to Valencia, founded (1891) a republican journal. *El Pueblo,* and in 1901 was elected to the *cortes,* to which he was returned seven times before his voluntary exile at the beginning of the Primo Rivera regime in 1923. Restless energy and political hazards often drove him abroad: into exile for supporting the Cuban nationalists in 1896, and to Argentina and Paraguay, where he tried to found colonies in 1909.

His early novels—Flor *de Mayo* (1895). *La barraca* (1899) and *Cañas y barro* (1902)—depict with intense realism the tragic lives of Catalan farmers and fishermen and excel in the creation of vigorous, elemental characters and the description of nature. In *La catedral* (1903) ideology began to swamp character and action, and although he wrote powerful novels on serious social themes—*La bodega* (1905). *Luna Benamor* (1909)—, his sensibilities gradually became blunted. In *La maja desnuda* (1906). *Sangre y arena* (1909) and the best-selling *Los cuatro jinetes del Apocalipsis* (1916; filmed as, *The Four Horsemen of the Apocalypse* with Rudolph Valentino), energy degenerated into sensationalism. Detailed description lost significance when applied to places only superficially known, and such works as *Los Argonautas* (1914) and *Mare nostrum* (1918), although popular, did not enhance his literary reputation. He amassed a fortune: went on a world tour, built a mansion on the Riviera and exploited his exile to create publicity. He died at Menton, Jan. 28. 1928.

See his *Obras completas* (1947); J. A. Balseiro, V. B. *Ibáñez, hombre de acción y de letras* (1935).

BLASHFIELD, EDWIN HOWLAND (1848–1936), U.S. genre and mural painter. whose academic adaptations of symbolism and allegory were much admired. was born in New York city on Dec. 1j. 1848. From 186; he studied in Paris with Léon Bonnat, exhibited genre there (salon of 1874 and later) and in New York from 1881. His decorative work began at the Chicago exposition of 1893. Typical among his numerous commissions thereafter were those for the capitol. St. Paul. Minn.; the courthouse. Baltimore. Md.; and City college, New York. His extensive organizational activities included the presidency of the National Academy of Design (1920–26). With A. A. Hopkins he edited Vasari's *Lives* (1897); with his first wife. Evangeline Wilbour. he wrote *Italian Cities* (1900). His principal publication was *Mural Painting in America* (1913). His many honours included the gold medal of the National Institute of Arts and Letters (1923). He died on Cape Cod. Mass., Oct. 12, 1936. (VL. B.)

BLASIS, CARLO (1795–1878). a distinguished Italian ballet dancer, teacher and writer on the technique, history and theory

of dancing. He was the first to codify and publish an analysis of the classic ballet technique, in his *Traîté élémentaire, théorique, et pratique de l'art de la danse* ("Elementary Treatise Upon the Theory and Practice of the Art of Dancing"; 1820).

Born in Naples on Nov. 4, 1795, he studied under Jean Dauberval in Bordeaux, France, danced briefly at the Paris Opéra and appeared in Salvatore Viganò's ballets at La Scala, Milan. In 1837 Blasis was appointed director of the ballet school at La Scala, where he trained many brilliant dancers, including Amalia Ferraris and Giovanni Lepri.

See also BALLET: *The Italian School.* (LN. ME.)

BLASIUS (BLAISE, BLAIZE), **SAINT,** bishop of Sebaste (modern Sivas, Turkey), was martyred early in the 4th century. He is said to have been torn with wool combers' irons before he was beheaded, and, perhaps for this reason became the patron saint of wool combers. Because of a miracle which he is alleged to have worked on a child suffering from a throat affection, St. Blasius' aid was held sovereign against throat and lung diseases. The Roman Catholic Church keeps his festival on Feb. 3, the Orthodox on Feb. 11.

BLASPHEMY is a word that has been used with different and often not very precise meanings at different times. By moral theologians blasphemy is regarded as a sin; St. Thomas Aquinas described it as a sin against faith. It has points in common with heresy, but must, nevertheless, be differentiated: heresy consists in holding a belief contrary to the orthodox one; blasphemy imports the idea of irreverence and profanity. Thus it is not blasphemous to deny the existence of God or to question the established tenets of the Christian faith unless this is done in a mocking and derisive spirit. For a Muslim it is blasphemy to speak contemptuously not only of God but also of Mohammed.

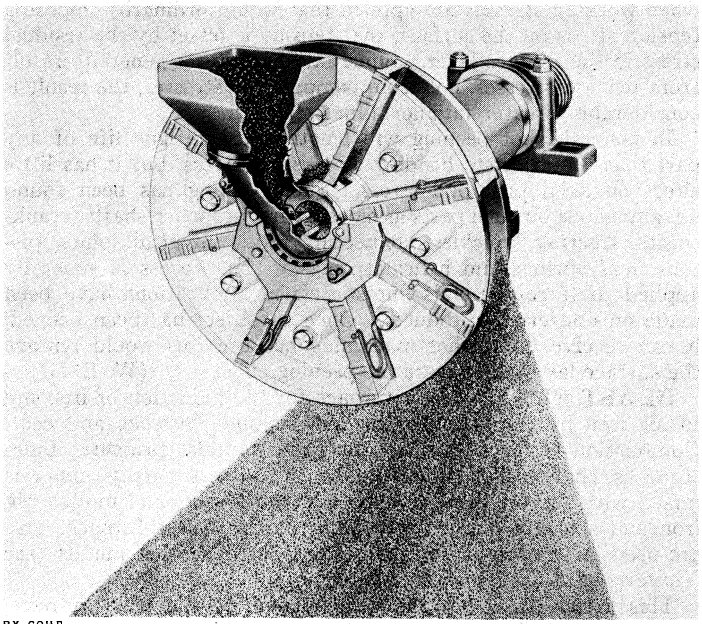
Among many peoples blasphemy in some form or another has been an offense. The Mosaic law decreed death by stoning as the penalty for a blasphemer, "the sojourner as well as the native" (Lev. xxiv, 16). The extent to which sins have been treated also as crimes by the secular power has varied from age to age and place to place. Under Justinian I the death penalty was decreed for blasphemy. The French code for Cambodia made mockery of an idol an offense. Many states of the United States have legislation aimed at blasphemy. In Scotland until the 18th century it was punishable by death. In England it is both a statutory and a common-law offense. Recognized as the latter in the 17th century, in theory it must be taken to have been such from time immemorial, the underlying idea appearing to be that an attack on religion is necessarily an attack on the state, for in the words of Chief Justice Hale, in *Taylor's Case* (1675, *1* Vent. 293), "the allegation that religion is a cheat tends to the dissolution of all government." This idea probably has been the reason why penalties have been laid down for blasphemy in some secular legal codes.

See J. Hastings (ed.), *Encyclopaedia of Religion and Ethics,* vol. ii, pp. 669–672 (1909). For blasphemy in English law *see* G. D. Nokes, *A History of the Crime of Blasphemy* (1928). (E. G. Mo.)

BLAST CLEANING AND SHOT PEENING. Blast cleaning is a process in which a stream of solid particles is propelled with sufficient velocity against a surface to cause a cleaning action. There are two means of propelling the abrasive—compressed air and centrifugal force. Although some types of work require the use of compressed air—*e.g.,* complex internal holes in castings—centrifugal force has generally replaced air in most applications.

The centrifugal blasting wheel was developed in the early 1930s. Usually it is an eight-bladed wheel about 20 in. in diameter and from 2 to 5 in. wide. The abrasive is fed to the centre of the wheel and metered to the blades which turn at more than 2,000 r.p.m. The major advantage of centrifugal force as opposed to compressed air is reduced operating cost. A blasting wheel will throw 300 lb. of abrasive per minute while requiring only 15 h.p.; five $\frac{3}{8}$ in. air nozzles are required to throw the same quantity at 80 lb. per square inch pressure, consuming 190 h.p.

The first use of the process was by the metalworking industry. In particular, the foundry and forging industries are major users of the process. It is also widely used in steel mills, structural fabricating shops, pipe mills and die-casting shops.



BY COURTESY OF WHEELABRATOR CORP.

CUTAWAY VIEW OF CENTRIFUGAL BLAST CLEANING WHEEL. SHOWING ABRASIVE PATTERN

A wide variety of materials are used as the abrasive, including many types of metal, vegetable matter and sand. The first abrasive used was sand, but because it was very short lived, other abrasives were sought. Cast chilled iron was the first metallic abrasive to be generally used. Extremely hard, it is far superior to sand in any cleaning operation where the abrasive can be recovered. Malleable iron shot and grit, and steel shot and grit, are generally considered superior to chilled iron for most applications. Other metallic abrasives include cut wire, nail clippings and many of the nonferrous metals such as copper, aluminum, etc. Vegetable matter, such as crushed corncobs, walnut shells and peach and apricot pits, is used in many applications where a softer abrasive is needed. Sand is seldom used in the metalworking industry as a cleaning abrasive, but it is employed in cleaning stonework on buildings and other structures. The plastics industry is also a large user of blasting equipment for mechanical deflashing and finishing of molded plastic parts; vegetable abrasives are widely used in this work.

Industrial blast cleaning equipment is constructed in many different forms. The tumbling machine, which utilizes an endless belt conveyor in the blast chamber, is used for batch cleaning of parts that can be tumbled. This type of machine ranges in capacity from 1 cu.ft. to more than 100 cu.ft. For parts that are either too large or too fragile to be tumbled, the table-type machine is used. In this machine the table is loaded with work and then revolved in the blast. The table can be an integral part of the machine with only a quadrant exposed to the blast at any one time or it can be enclosed to permit blasting the entire table surface at once.

Shot Peening. — Shot peening is a cold-working method accomplished by pelting the surface of a metal part with round metallic shot thrown at a relatively high velocity. Each shot makes a small dent in the surface of the metal and stretches the surface radially as it hits. The rain of shot causes a plastic flow of the surface fibres beyond their yield point in tension. The fibres underneath the top layer, however, are not stretched to their yield point and therefore retain their elasticity. The under fibres are bonded to the stretched surface layer, and after the peening action the inner fibres force the outer fibres to return to a shorter length than that at which the stretched fibres would tend to remain. In the equilibrium which results, the surface fibres are in residual compression while the inner fibres are in tension. The surface compression stress is several times greater than the tension stresses in the interior of the section, so that

when working stresses are applied that would ordinarily impose a tension stress on the surface, that tension is offset by the residual stress in the surface layer. Since fatigue failures generally result from tension stresses, not from compressive stresses, the result is considerably greater fatigue failure strength.

In general, shot peening will lengthen the fatigue life of any part that is subject to bending or twisting stress, but it has little effect on axial push-pull stress. Shot peening has been found advantageous on such parts as axles, gears, propeller shafts, crankshafts, steering knuckles, connecting rods, universal joints, pistons, leaf springs and helical springs. The process is generally applied to ferrous metals but successful applications have been made on nonferrous products. Once an object has been peened, it can receive no further machining because this would remove the surface layer and negate the peening effect. (W. E. N.)

BLAST FURNACE, a furnace for the reduction of iron ore to pig iron by the action of carbon, supplied by coke and heat. Combustion is forced by a current of air under pressure; limestone is charged into the furnace to convert earthy minerals mixed with the ore and the coke ash into a slag; and molten pig iron and slag are drained from the hearth. Blast furnaces also are used in the production of lead, copper and other metals (see *Nonferrous Blast Furnaces,* below).

This article discusses the development of the blast furnace, the process of obtaining pig iron from ore, furnace construction and operation and blast furnaces for nonferrous metals. For the history of the manufacture and use of iron *see* IRON AND STEEL INDUSTRY: *Early* History.

Development. — In the middle ages iron was made in furnaces of relatively small size, in which pure ore was reduced to a pasty mass by means of charcoal: and this was subsequently hammered to get rid of the impurities. About the 15th century the type of furnace was altered by the addition of an upper portion, or stack, in which primary preparation of the materials took place. This revision made possible the melting of the metallic product, so freeing it from earthy impurities and giving a material, pig iron, altogether different from the forged metal formerly made. Thus the blast furnace first came into use.

Until the 18th century only charcoal was the furnace fuel. An acre of forest mould furnish only from 7 to 12 tons of charcoal which was less than the amount needed for the production of a ton of iron per day for a one week period. This depletion of the forests caused grave alarm and stringent laws were enacted in 1558, during the reign of Queen Elizabeth I, which forbade the cutting of trees for conversion into charcoal and the making of iron, except at Kent. These laws caused such ironmakers as Simon Sturtevant (1612), John Rovenson (1613) and Dud Dudley (1622) to turn their efforts toward the use of "sea-coale, pit-cole, etc." for ironmaking. By the early 1700s iron smelting with coke had been accomplished by Abraham Darby I at Colebrookdale (see also SHROPSHIRE: History). The first cokes were made by methods similar to charcoal (*q.v.*) burning. After the Civil War when cokes were made from the Connelsville, Pa., coals they were very strong and did not crush under heavy burdens thus permitting blast furnace stacks to be raised to 95 ft. in height, an advance known as the "Duquesne revolution."

In 1892 James Gayley reported that in Germany carbon brick refractories had already been developed for lining furnace hearths and this along with his work on furnace design and construction presaged the modern practice of using carbon blocks in preference to the firebrick construction of earlier days. Both practices became common.

Julian Avery (1938) suggested that high pressure blast furnace operation could be accomplished by controlling the outflow gas—a method subsequently developed at Cleveland, O. The first actual pressure operation started on April 26, 1944, and the top pressure was raised one half pound each day until ten pounds was reached. This development was reported in May, 1947 by J. Slater who operated the furnace. Modern blast furnaces are over 100 ft. in over-all height with hearths over 30 ft. in diameter, and may produce as much as 3,000 tons of iron in one day.

The Process.—Minerals containing iron in amounts permitting their use as economic ores are widely distributed in nature. The common ores most suitable for direct use in the blast furnace are the reddish hematite, Fe_2O_3, the yellow to brown limonitic ores, $Fe_2O_3(H_2O)$, and the black magnetite, Fe_3O_4. The bulk of these natural impure ores is made up of ferric oxide, Fe_2O_3, with iron and oxygen atoms combined in the ratio of 2 to 3. Rleans, therefore, must be provided to abstract oxygen thus leaving the metallic iron, a process knoun technically as reduction. This reduction requires both high temperatures and the use of suitable reducing agents, such as carbon and carbon monoxide. These conditions are readily ensured by the combination of oxygen of the air nith the hot carbon in the furnace hearth in the ordinary process of combustion wherein ample heat is generated and reducing gases are liberated.

Ores are never pure iron oxides but contain a portion of earthy materials made up of silica, alumina, lime, magnesia. soda and potash, etc , nhich must be removed in the process as molten slag. At sufficiently high temperatures, the basic oxides, lime and magnesia, derived from the flux stone charged into the furnace combine with the acidic oxides, silica and alumina, and other earthy materials to form a molten slag. The ratio of these basic to acidic oxides in the slag is carefully controlled as it affects both the operation of the furnace, the composition of the iron, the removal of impurities such as sulfur from the iron, the fluidity of the slag and its melting temperature range. The slag does not mix with the iron as it is of a lower density and floats on top.

Pig iron is by no means pure iron. It contains a total of from 5% to 9% of carbon, silicon, manganese, phosphorus and usually rather small amounts of sulfur. Each of these constituents has an important effect on the quality of the pig iron.

In order that the product should be the quality required the mass of material, or "burden" as it is called technically, from nhich the pig iron is made must contain. in addition to iron, the requisite proportions of the other constituents mentioned. There is charged into the furnace therefore: (1) the burden which includes the iron ore, fluxes for forming the slag, and any other additions. *e.g.,* manganese ore or phosphoric rock, needed to give the proper manganese and phosphorus contents; (2) the fuel, which is generally coke; (3) the air blast. which is injected above the hearth of the furnace to burn the fuel and maintain a sufficiently high temperature to render both metal and slag freely molten.

The section of a modern furnace is shown in fig. 1, the parts of the interior known as the stack, bosh and hearth respectively

TABLE I.— Examples of Blast Furnace Operation in Various Parts of the World

Technical Details	England Appleby-Frodingham, Scunthorpe	U.S. Republic Warren, O. (high top pressure)	Sweden Stora Kopparberg, Borlange	Japan Imperial Steel Works, Yawata
Height of furnace tuyères to stock line (in ft.)	76′	74′	40′	61′–3″
Diameter of hearth (in ft.)	31′	28′	15′	15′–5″
Output of furnace (in net tons of iron per day)	1,400	1,630	536	270
Quality of iron made	basic	basic	Bessemer blowing	acid Bessemer
Analysis of iron (in %)				
Silicon	.70	.84	.30	1.57
Phosphorus	1.38	.267	1.80	.10
Sulfur	.050	.038	.050	.04

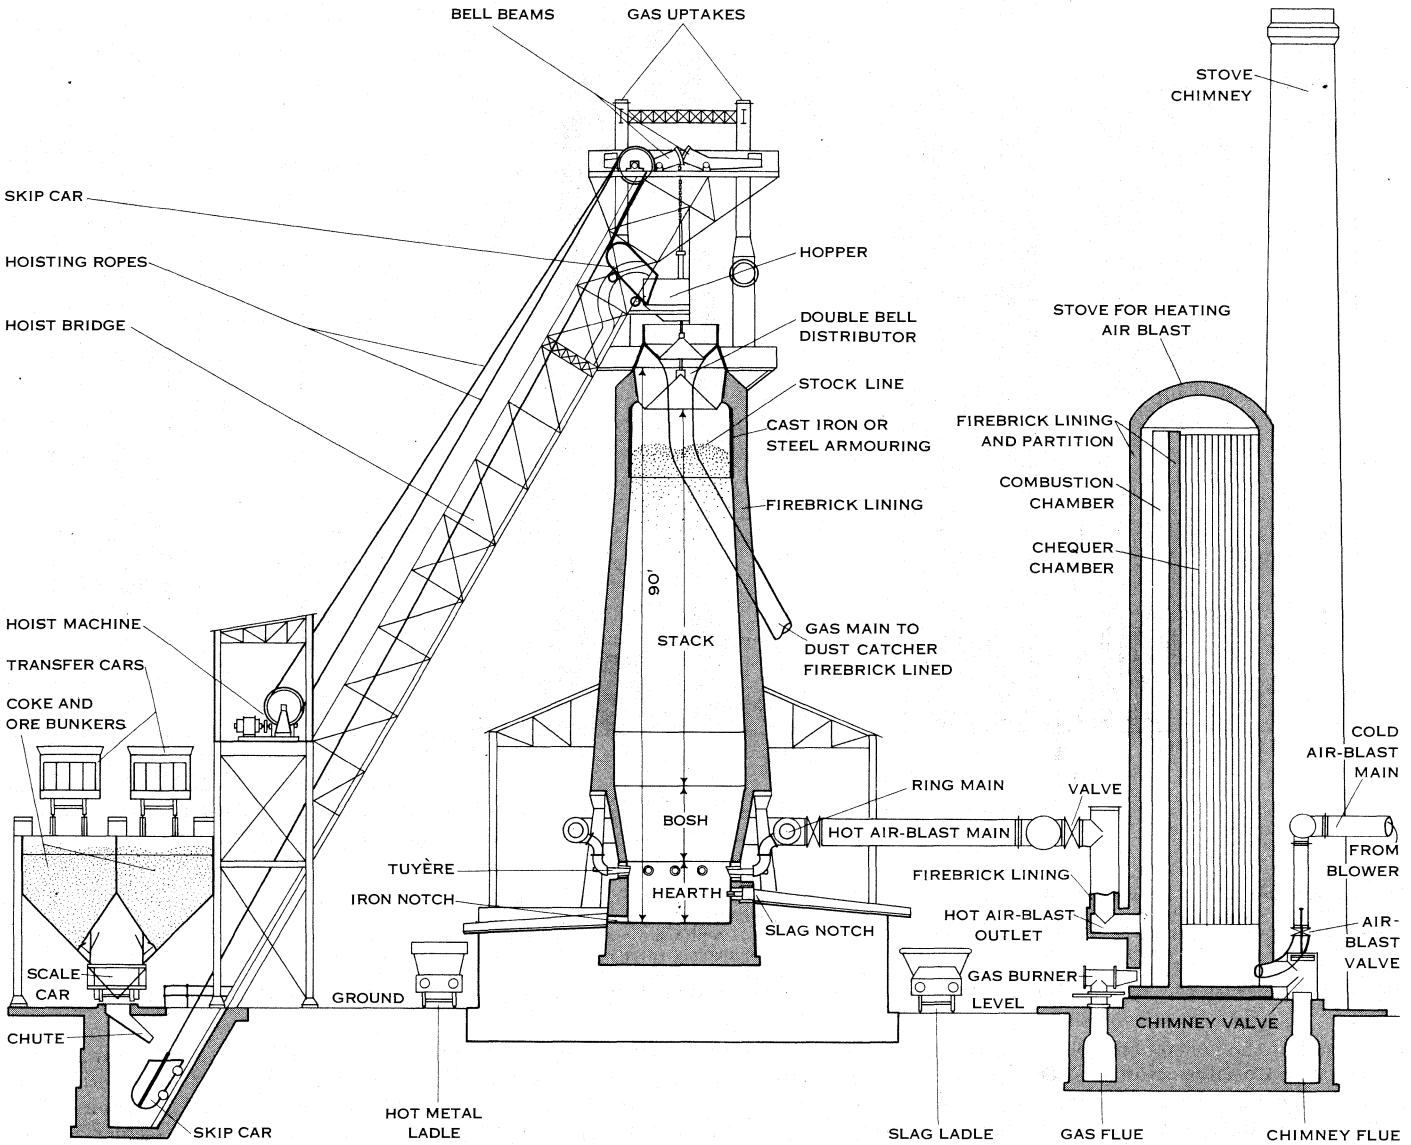

FIG. 1.—DIAGRAMMATIC SKETCH OF A SECTION OF A MODERN BLAST FURNACE

being indicated. The solid materials are charged into the top of the furnace while the air blast is blown through tuyères (nozzles) into the hearth where the highest temperature (about 3,400° F.) is generated. The oxygen of the air combines with the carbon of the coke, momentarily forming carbon dioxide, but as the hearth is full of incandescent coke, a reverse reaction rapidly takes place, the carbon dioxide being converted into carbon monoxide which is a powerful reducing agent. The hot gases composed of the carbon monoxide and the nitrogen of the air, along with some hydrogen derived from the dissociation of the moisture carried in the air, pass upward through the column of solid materials, their temperature being progressively reduced as a result of direct contact and chemical reaction, until they leave the top at about 460° F. The constituents of the burden pass through the furnace in 8 to 16 hours, while the gas passes upward through the burden in three to five seconds. When charged the constituents immediately come into contact with the hot gases and any moisture is quickly driven off. As they slowly descend the stack, the temperature increases and the carbon monoxide in the gases combines with the oxygen of the iron oxide to form carbon dioxide, leaving metallic iron in a finely divided form, or as iron sponge. The nonferrous materials are mixed intimately with the reduced iron, and separation does not take place until near the top of the bosh, where both the iron and the slag begin to melt. The coke passes through the furnace with only a light solution loss and a constant increase in temperature, until it reaches the tuyère zone. where intense combustion takes place with the oxygen of the air blast. The bosh and hearth however are filled with coke and, as the slag and iron melt, the liquids trickle down until they reach the well, in the bottom of the hearth, where they slowly accumulate and separate. the slag layer being on the top. The iron and slag are tapped from the furnace through separate tapholes at intervals timed in accordance with the capacity of the furnace.

TABLE 11.—*Analysis* of Top Gas
(per cent of volume)

Carbon monoxide (CO)	24–27
Carbon dioxide (CO_2)	13–16
Hydrogen (H_2)	1–2
Methane (CH_4)	0.25
Nitrogen (N_2)	56–59

As the iron runs from the iron notch it passes into a trough, thence beneath a skimmer block or dam and on down the runner into the awaiting ladles. Toward the end of the iron tapping or runoff. slag comes from the furnace along with the iron. The molten iron acts as a seal beneath the skimmer dam and prevents thk slag which floats on top of the iron from flowing down the iron runner thus separating the slag from the iron. The slag accumulates until it fills the trough and overflows into a slag runner and finally into the slag ladles.

A large volume of gases, sufficiently rich in combustibles to be of value, is produced during the process. The combustible gases are the carbon monoxide and hydrogen, but the major volume is

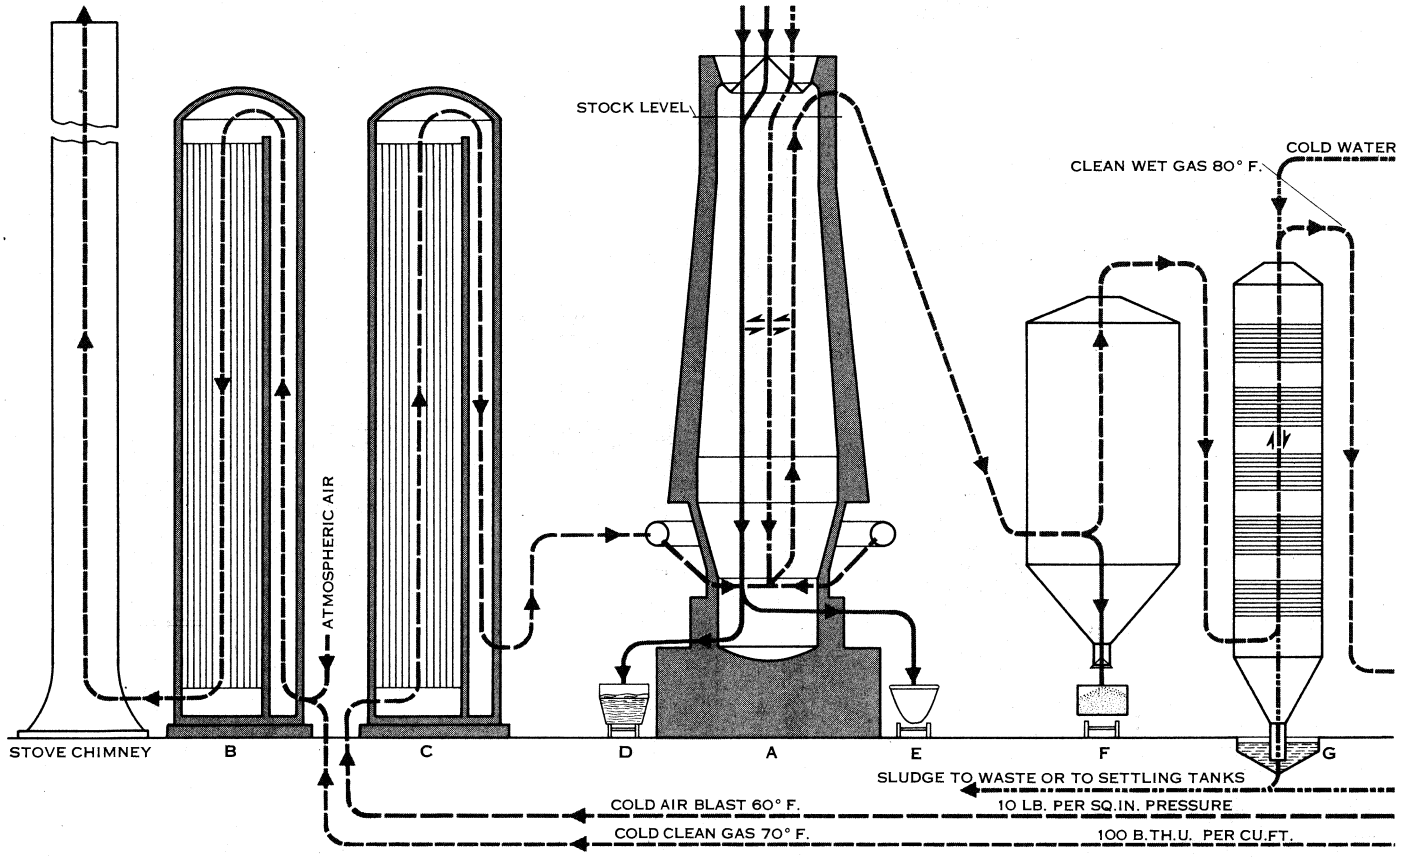

FIG. 2.—DIAGRAM OF A BLAST-FURNACE PLANT.

Ore, flux and coke (fuel) are charged into blast furnace (A) from top, up to stock level. As the burden descends thermal and chemical interchange takes place with ascending gases until they arrive at the hearth in a reduced form. Metal and slag are melted by combustion (temp. about 3,2000 F.) of coke burned with preheated air (temp. about 1.4000 F.) supplied by air-blast stoves (B and C) which are heated by burning blast-furnace gas. The stoves are on gas and air blasts alternately; and a steady supply of air passes through a heated stove to the tuyères (nozzles) of the furnace. The molten metal (temp. about 2,6500 F.) and slag (temp. about 2,7700 F.) trickle down to the furnace hearth, where they separate naturally, the slag being on top. They are tapped out through suitable holes and troughs into hot-metal ladle (D) and slag ladle (E). Meanwhile gases (temp. about 450° F.) formed by combustion of the coke, after passing through and inter-

composed of the noncombustibles, nitrogen and carbon dioxide.

Furnace Construction and Operation. — The furnace shown is composed of a firebrick lining encased in a steel shell.

In the hearth the firebrick is frequently replaced by carbon or graphite block refractories. Everything is of a substantial nature since it has to withstand strenuous work. The weight of the materials in the furnace may approach 1,000 tons while that of the lining and structure is about 1,200 tons. Those parts of the furnace which are subjected to high temperatures are protected by water cooling. The life of a furnace lining is about five years, during which a quantity of iron up to 2,000,000 tons may be made. The raw materials are discharged from trucks into bins, from which they are drawn as required into a scale car. After weighing they are emptied into a skip which is hoisted electrically on an inclined track to the top of the furnace, where it is automatically tipped and stopped. The materials are received on a bell which is capable of being mechanically revolved to any point in the complete circle, and after moving to the proper position are lowered onto a second and larger bell. When the latter is fully loaded by a series of deliveries from the upper bell, it is lowered and the materials slide into the furnace. The level of the solids is about eight feet below the large bell, and the intention of the arrangement described is to distribute the incoming charge evenly over the stock line without allowing any gases to escape to atmosphere through the furnace top.

Air blast at the requisite pressure is provided by a blower, which may be a steam-driven reciprocating engine, a steam-driven turboblower. or a gas-driven reciprocating engine. In any case the blast furnace gases are used as the source of motive power. James Neilson of Scotland in 1828 discovered that increasing the temperature of the air blast before entry into the furnace resulted in a marked fuel economy, and air blast temperatures up to 1,800° F. or more are employed. High pressure blowing and the use of oxygen enrichment of the air blast have resulted in further increases in furnace productivity and fuel economies. The use of oxygen was patented in 1876 by Henry Bessemer and developed at Oberhausen. Ger., in 1933–40.

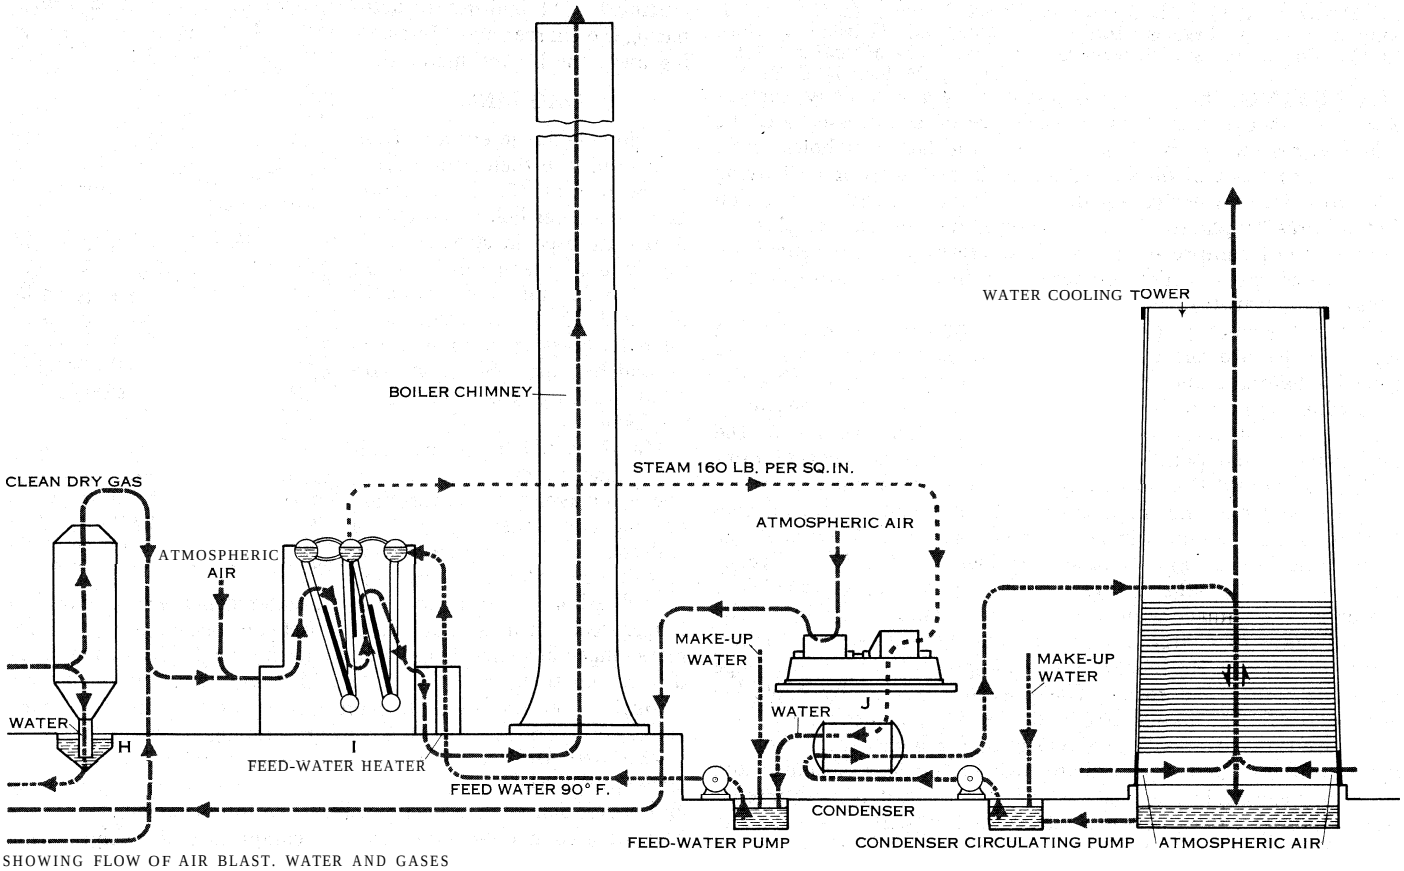
Hot blast stoves are used for heating the air blast and each unit is composed of a mass of brickwork, arranged as chequer work, contained in a steel casing. The temperature of the brickwork is raised to the required intensity by the combustion of blast furnace gases. The gases are then shut off and the air blast allowed to pass through the stove on its way to the furnace. Two or more stoves are required in order that the process may be continuous.

TABLE 111.—Qualities of Pig Iron

Class of iron	Analysis (per cent)				
	Total carbon	Silicon	Sulfur	Phosphorus	Manganese
Basic	4.4	1.0	.03	.25	1.8
Thomas	3.8	.7	.10	2.10	2.0
Malleable	4.1	2.0	.04	.15	0.8

The gases leaving the furnace are passed through primary dust catchers and ultimately through towers where they are washed with water before use in the hot blast stoves. The remainder of the gases are utilized in raising steam, or as direct fuel in blast furnace gas-driven engines. The distribution of the available gases is approximately as follows:

Hot blast stoves	27%
Power for air blast	15
Wastage	3
Available for other purposes	55
	100%



SHOWING FLOW OF AIR BLAST. WATER AND GASES

acting with the burden, leave the furnace into a gravity dust catcher (F); then into a washer (G), where they are cleaned with water, and ultimately into a dryer (H). A portion of the clean gas (temp. about 80° F.) is used for firing water-tube boilers (I) in which steam is generated for the turboblower (J). The blower, which may be a steam-driven reciprocating engine, a steam-driven turboblower or a gas-driven reciprocating engine, forces air at a suitable pressure to heating stoves, while exhaust steam from the turbine is condensed and returned to boiler. A part of the remaining furnace gas is used in heating stoves while surplus is available for use in other processes

The diagram in fig. 2 shows a skeleton arrangement of a blast furnace plant and the data for typical practice are indicated.

Many different qualities of pig iron are made. representative examples being shown in Table III.

(F.C.; J. M. SN.; D. E. BK.)

Nonferrous Blast Furnaces. — Blast furnaces are used for the production of some of the nonferrous metals, particularly lead but to a lesser extent also for antimony, tin. copper and zinc. Such furnaces are much smaller than an iron blast furnace and are normally rectangular in plan. Furthermore. they do not use a hot blast and so do not have the large stoves that are such a prominent part of an iron blast furnace plant.

Modern lead blast furnaces will vary from 17 to 28 ft. in height from the tuybres where the air is introduced near the bottom of the furnace to the charge floor at the top of the furnace. The inside length at the tuybres will be about 16 ft and the width j ft., although larger furnaces have been built both at Trail, British Columbia and Port Pirie, Australia.

The walls of the furnace are of water cooled steel jackets resting on a crucible of refractory brick and extending upward to a rectangular brick shaft that forms the upper part of the furnace. The steel jackets on the sides slope out so that the furnace has a greater area at the top.

Feed to the furnace consists chiefly of lead oxide formed by sintering lead sulfide concentrates. fluxes to form a proper slag, and coke to act as fuel and as a reducing agent. As the charge is heated in the furnace the lead and slag are formed and settle in the crucible with the slag on top of the metal. Normally the lead overflows continually into a pot from a channel to the bottom of the crucible, while the slag is tapped at intervals of a few minutes through a hole in the end of the furnace. Dust, fume and gases leave through a connection to the flue from the top or near the top of the furnace.

The use of the blast furnace for the production of antimony and tin is very similar to that described for lead, but there are other competing methods.

Copper blast furnaces are much the same as those for lead although usually all of the liquid contents are tapped through one hole and then allowed to separate in a container known as a forehearth. However, the reduction of copper oxides with coke in a blast furnace to form metallic copper is not common practice, because the simultaneous reduction of any iron oxides will form an alloy known as black copper. Blast furnaces are more likely to be used to melt a mixture of copper sulfide minerals and fluxes to form a slag and a liquid sulfide phase called a matte. The matte is subsequently converted to metallic copper in a Bessemer type converter.

The production of metallic zinc in a blast furnace is an unusual process first achieved in 1950 at Xvonmouth. Eng. The process and furnace differ from those previously described in that the zinc is produced as a vapour and leaves the furnace with the gases. The zinc vapour is then condensed by a spray of molten lead and the zinc subsequently separated from the molten lead-zinc alloy. Molten slag and any liquid lead resulting from a mixed zinc-lead ore are tapped from the bottom of the furnace.

Furnaces even smaller than those described and usually cylindrical in shape are used for the melting donn of both lead and copper scrap. . (A. W. S.)

(F.C.; J. M. SN.; D. E. BK.)

BLASTING, the process of fragmenting a solid body, such as rock, with an agent such as an explosive or compressed air, the former either in or upon the rock and the latter in holes only; also, the processes of displacing soil or tree stumps or destroying structures with explosive agents. In military usage, destruction of structures by placed charges is termed demolition. Explosions and the use of compressed air are characterized by the generation or release of gases at high pressures and, in the case of explosives at high temperatures, the kinetic energy of the gaseous molecules producing the energy to do the work of breaking and displacing material. Before the application of explosives, rock was excavated by hammer and chisel or by fire setting; *i.e.*, heating the rock, which split and flaked upon rapid cooling. The discovery and use of explosives in mining and excavation was one of the key advances that permitted the exploitation of the world's mineral resources and the construction of great dams, canals, etc.

For primary blasting (breaking rock from the solid) an explosive agent is usually confined in holes, thus making more efficient use of the explosive energy. In secondary blasting (breaking of rocks or boulders into smaller pieces) the charge is usually placed in a hole or on the surface with a cover of mud (mud capping). The size and shape of charge and depth from the nearest free surface to accomplish efficient breakage depend upon the properties. shape and structure of the rock. The pressure exerted by explosive agents varies from about 10,000 lb. per square inch (p.s.i.) for compressed air to about 1,500,000 p.s.i. for high explosives, and several million pounds per square inch for nuclear (atomic) and thermonuclear explosives. The shock of the blast is most intense near the charge. Compressed air, because it presents no fire hazard, is usually employed in bituminous coal mines to break the coal in large fragments. Black powder and high explosives may cause crushing immediately around the hole, but at the limit of the crushed zone the strain wave proceeds radially, diminishing rapidly in intensity. The shock from nuclear explosives produces melting and vaporization of rock in the immediate vicinity, then a crushed zone and finally a fractured zone if the charge is near enough to a free surface.

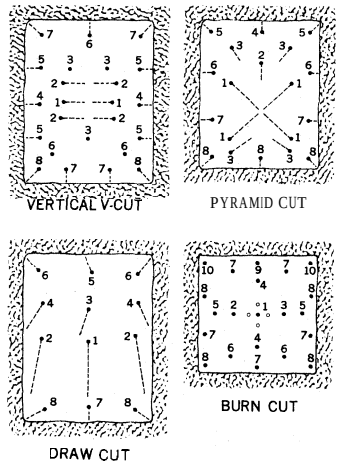
Fragmentation may be caused by compression, tension and perhaps occasionally shear stresses. If the rock near a high-energy explosive is compressible enough, it may break because of compression near the charge. When a charge of a given size is placed at an optimum distance from a free surface, compressive waves generated in the rock by the explosion will be reflected from the free surfaces as tensile waves, because the acoustic impedance (density times sound velocity) of the rock at the rock-air interface is much greater than that of air. Slabbing proceeds from the surface inward because of tensile failure of the rock, inasmuch as rock is much weaker (usually only one-tenth as strong) in tension than in compression. Energy in waves not impinging upon free surfaces proceeds outward in the ground in the form of waves and may cause damage to nearby structures. Poorly confined explosives may cause sufficient air blast, sometimes reflected from layers of the atmosphere of different temperatures, to break windows. The crater broken by a spherical charge at the proper depth theoretically should be conical in shape. However, the heterogeneity of rocks causes craters of irregular shapes to be formed.

The amount of explosive required to break a mass of rock effectively is proportional to that mass. Thus, the volume of rock broken is proportional to the weight of explosive, W; the surface areas of the crater are proportional to $\sqrt[3]{W^2}$; and the linear dimensions are proportional to $\sqrt[3]{W}$. This is the much-used cube-root scaling law, stating, inversely, that the amount of explosive required is proportional to the cube of the charge depth for similar size and shape.

Usual blasting operations (cycles) are composed of several phases: (1) drilling holes; (2) placing a charge and detonator in each hole; (3) tamping and stemming the charge (compacting the explosive and filling the remainder of the hole with clay or rock cuttings); (4) igniting or detonating the charge; and (5) clearing away the broken material.

DRILLING

Drill-hole diameters vary from 1 to 12 in. and their depths from a few feet to 100 ft. or more. Large diameter holes (more than 3 in.) are used in surface blasting, with an average diameter of about 6 in. and average depth of about 30 ft. Shorter, small diameter holes are used in underground blasting. Since the late 1800s drilling has been done mechanically.



DRILL ROUNDS FOR SMALL TUNNELS. DOTTED LINES INDICATE INCLINATION OF HOLES: NUMBERS. THE FIRING ORDER. BURN CUTS) OPEN HOLES (FOR ARE NOT LOADED

Hand Drilling — The old-style miner's hand drill, or steel, usually octagonal in cross section, had one end forged into a chisel and could be used by either one or two men. One steel was used to drill a hole about 12 in., and if greater depth was required, a longer steel with a narrower width chisel end was employed. Hammers ranged in weight from $3\frac{1}{2}$ to $4\frac{1}{2}$ lb. for single-hand (one man) drilling, up to 8 or 10 lb. for double-hand (two man) drilling. Enough water was used to make a mud of the cuttings which could be "spooned" out of downward sloping holes.

Machine Drills. — The introduction of machine drills in the latter part of the 15th century increased the efficiency of blasting and excavation work tremendously. The following types of drills have been commonly employed: (1) compressed-air reciprocating or piston drills; (2) hammer drills; (3) electric auger drills; (4) electric reciprocating drills; (5) hydraulic drills; (6) rotary drills; (7) rotary air-blast drills; (8j cable (churnj drills and (9) jet-piercing drills. The compressed-air drills are obsolete and have been replaced by hammer drills. Electric auger drills are used in relatively soft materials, but these and the electric reciprocating and hydraulic drills are relatively unimportant although hydraulic drills are used to some extent in Europe. In these, hydraulic cylinders, driven by water pressure, operate a hollow bit with a serrated edge at about 6 r.p.m.; the bit, under a pressure of 800 to 1,000 p.s.i., crushes and grinds the rock, which is carried from the hole by a stream of water that also cools the bit. Rotary drills are used for hard abrasive material, employing diamond-set, tungsten carbide or roller-cone bits; they are also used extensively in oil well drilling. Rotary air-blast drills were first introduced in 1950; they use compressed air as a cooling medium for the drill bit. Cable drills will produce only vertical holes and have limited application. Jet-piercing drills were introduced commercially in 1549 and use thermal energy in the form of a very hot flame to heat and spall certain types of rock. The flame is generated by combustion of liquid petroleum fuels with oxygen. The impinging of the flame jet on a rock surface causes a thin fiake to expand and break away. The gases of the jet plus the vapour formed by a cooling jet of water carry the spalled fragments out of the drill hole. Fusion of the rock is undesirable and rocks must have certain characteristics to make jet piercing more economical than other types of drilling. The efficient operation of the process also demands the proper combination of heat transfer rates for rapid spalling and high kinetic energy of the flame to keep the cutting face clean. See also DRILLING MACHINERY.

LOCATION OF HOLES

Successful fragmentation for a minimum powder factor (pound of explosive per ton of rock broken) is dependent upon the proper placement of holes. Several configurations are used depending upon whether the blast is to be on the surface or underground and, if underground, the type of opening being blasted. Fragmentation is most easily obtained if there is a large number of free surfaces within an optimum distance of the charge. Thus, a sphere with a

charge at the centre would provide the maximum of free surface, while the face of a tunnel would provide only one free surface. Also. a cylindrical hole loaded along most of its length will break the rock more effectively if the hole is aligned parallel to a free surface. Most blast-hole patterns are based on these two principles.

Surface Blasting. — In most quarries, as well as for such construction projects as highways and canals, vertical holes are drilled parallel to a vertical face nith several rows of holes spaced according to the charge size, hole diameter and "burden" (amount of rock the explosive in the successively outermost hole is to break). Holes are arranged in a rectangular or triangular pattern and charges are usually fired in rows with millisecond delay caps (see below) which are claimed to give better fragmentation and reduce possible vibrational damage to nearby buildings and other structures.

Open pit mines employ sloping benches instead of vertical faces. Large-didmeter holes are drilled from the top of the benches in some mines, while in others small hole drills of hammer type may he used to drill either a series of holes into the toe of the bench or a combination of toe and top holes. The small holes are enlarged (sprung) at the bottom with small charges of explosive to form a chamber large enough to hold the main charge Stripping of relatively loose overburden in surface coal mines is accomplished by exploding charges of suitable size, usually in widely spaced holes unless the rock overlying the coal is hard to blast.

Very large blasts, in which the explosive is loaded in tunnels usually about 4×5 ft. in cross section for the purpose of furnishing broken rock for dams or fills, have employed well over 1,000,000 lb of high explosive in a single blast. Ripple Rock, a navigational hazard in the inland water route to Alaska, was removed by one of the largest nonnuclear blasts in history..

Underground Blasting. — Tunnels, drifts, shafts and similar openings have only one free surface into which the holes can be drilled and from nhich rock fragments can be broken A "round" of holes in openings up to about 10 ft. high or wide consists of: (1) cut holes; (2) relief holes; (3) breast or enlarger holes; and (4) trim holes, including "lifters." The cut portion of the round is fired first to provide additional free surface to which the remainder of the round may break. Cut holes are either drilled at an angle to the face to make a V-cut, a pyramid cut or a draw cut. or several holes are drilled close together perpendicular to the face and only part of them are loaded, the unloaded holes providing free surface to form a "burn cut." The relief, breast and trim holes are spaced and aligned with respect to the cut portion of the round so that the rock will break to the desired shape of opening without placing too much burden on any one hole. A blast hole about which the rock fails to break is called a "bootleg." Some deep rounds employ large centre holes, up to 6 in. or more in diameter, with four or more blast holes slanted slightly inward toward the large hole. The blast holes must be carefully located and aligned for successful breakage. In large tunnels. small pilot tunnels may be driven first and the remainder of the large tunnel broken by bench blasting.

Mining of ore in rooms or stopes in a mine is usually performed with a modified type of bench blasting, or with holes drilled at an acute angle to a free surface to "slab off" the rock or ore.

In Sneden. where parallel openings are driven. holes are drilled from one tunnel into the face in the adjoining one so that the holes are parallel to the face of the unblasted tunnel. This method has very limited application.

EXPLOSIVES

Three types of explosives are used for blasting: (1) low explosives; (2) high explosives; and (3) nuclear explosives. Energy is released from low explosives (black powder) by chemical reaction by very rapid burning called deflagration. The release of energy from high explosives (dynamites and military explosives such as TNT) is by a process known as detonation, which is characterized by the propagation of a shock wave through the explosive supported by the chemical reaction accompanying the shock wave.

Black powder, which is used only where a slow explosive of low power is required to avoid shattering, as in building-stone quarries and some nongassy coal mines, was supplanted as an explosive when Alfred Nobel invented dynamite in 1867 by mixing sensitive nitroglycerin with kieselguhr (powdered SiO_2), making it safe to handle. Combustible absorbents such as wood pulp were later found to be more effective and still safe to handle. Part or all of the nitroglycerin may be replaced with blasting gelatin or ammonium nitrate. Salt or a similar inert substance is often added to dynamites to reduce their flame temperature and make them safer to use in gassy coal mines; they are then classed as permissible explosives.

For commercial blasting a wide range of dynamites is employed. These are mechanical mixtures of an oxidizing agent. a reducing agent and other substances. The most common grades of dynamite are ammonium nitrate dynamites for dry work and gelatins for wet work. Gelatin dynamites are made of nitroglycerin and nitrocellulose and are mixed with other substances to yield water-resistant dynamites of various strengths. These are made into cartridges, usually about $1\frac{1}{8}$ in. in diameter by 8 in. long. In general, higher strength explosives are required for harder rocks. Nonfreezing dynamites are made by the addition of ethylene glycol dinitrate or other antifreezing agent.

Although it was known in the late 1800s that ammonium nitrate (NH_4NO_3), an oxidizing agent. mould explode when alone or when mixed with a fuel. it was not until the production of inexpensive fertilizer grade ammonium nitrate took place in the 1940s that mixtures of NH_4NO_3 and fuel oil became popular explosives for use in large (over 3-in) diameter holes because of their low cost and safety in handling. The most common mixture is approximately 94% NH_4NO_3 and 6% No. 2 fuel oil. which gives a maximum strength explosive. Its performance. sensitivity to detonation and detonation velocity are all markedly dependent on particle size, density of mixture. particle density and the fuels or sensitizers employed with it. The above percentages are calculated from an oxygen balanced mixture; *i.e.*, one in which there is just enough oxygen to convert all of the hydrogen to water and all of the carbon to CO_2, assuming fuel oil to contain carbon and hydrogen in the ratio of 1 to 2:

$$NH_4NO_3 + \tfrac{1}{3}(CH_2) = N_2 + \tfrac{1}{3}H_2O + \tfrac{1}{3}CO_2$$

Ammonium nitrate-TNT-water slurries have also proven effective in wet holes in which ammonium nitrate-oil mixtures will not detonate because of the high solubility of NH_4NO_3.

Blasting With High Explosives. — Explosions are initiated in high explosives with detonators. more commonly called blasting caps, either of fuse or electric type, or with detonating fuse. Either type of cap is embedded in a cartridge, called a primer. which is usually placed at the bottom or top of the explosive column in a hole while detonating fuse is threaded through the primer. Timing of hole blasts with fuse is fixed by the fuse length, while timing with electric caps is done with timing elements in the caps themselves. Holes must be fired in proper order even if there are only few thousandths of a second delay between them. Electric caps may be connected in series or parallel, and regular (one second) delay or millisecond delay caps (usually $\frac{50}{1,000}$ of a second between caps or groups of caps) are used depending upon the particular application. The amount of explosive in each hole depends upon hole spacing and toughness of rock, and is usually determined by actual test. Electricity for detonators may be obtained from a regular power source or from a blasting machine, which is a small hand-operated electric generator.

Since World War II several nuclear charges have been detonated at varying depths under the surface of the ground. Many of these tests were designed to ascertain the possibility of employing nuclear explosions to perform excavation as well as breakage of rock. Others were designed to test the amount of burden necessary to completely confine a nuclear explosion. Research has been undertaken to test the possibility of employing nuclear explosives in mining large ore bodies, excavating canals and harbours, and fracturing oil-bearing strata for recovery of the oil contained in them.

Shaped jet charges of high explosives are used for perforating

oil well casings and tap hole facings (jet tapping) of blast furnaces; cylindrical charges are shaped so that the detonation front encloses a concavity, producing in it a convergent shock wave (the Munroe effect, discovered by Charles E. Munroe in 1887), are used to achieve deep penetration, a principle used in the bazooka and other armour-piercing projectiles *(see* AMMUNITION, ARTILLERY: *Artillery Ammunition Ajter World War I: Armour-Piercing Projectiles).*

BLAVATSKY, HELENA PETROVNA (1831–1891), founder of the Theosophical society, was born at Ekaterinoslav, Russia. Her father was Col. Peter von Hahn, descended from the counts Rotenstern-Hahn of Mecklenburg who settled in Russia. Her mother was a noted novelist who advocated the emancipation of women. In her 17th year she married a man much her senior, Nikifor V. Blavatsky, but separated from him in a few months. She traveled for many years, visiting Turkey, Greece, Egypt and Canada, crossing the U.S. in a covered wagon, going on to Central and South America, and to India and Java. After spending some time in Tibet in 1856, she returned to Russia for several years before setting out on further extensive travels in the near east and Asia, visiting Tibet again in 1868 and Egypt in 1872. In 1873 she went to New York city, where, with the assistance of Col. H. S. Olcott, William Q. Judge and others, Mme Blavatsky founded the Theosophical society in 1875. Its aims were defined: (1) to form a nucleus of the universal brotherhood of humanity without distinction of race, creed, sex, caste or colour; (2) to promote the study of comparative religion, philosophy and science; and (3) to investigate the unexplained laws of nature and the powers latent in man. The publication of Mme Blavatsky's *Isis Unveiled* in 1877 attracted wide attention and criticism.

In 1879 she and Colonel Olcott went to India where they established the permanent headquarters of the Theosophical society at Adyar, near Madras, in 1883. In 1885 she left India and settled first in Germany and then in London, where the European headquarters of the society was established. She died on May 8, 1891.

Mme Blavatsky's *Collected Writings* were published at Adyar in seven volumes, completed by 1938. In addition to *Isis Unveiled,* her works include *The Secret Doctrine* (1888); *The Key to Theosophy* (1889); *The Voice of Silence* (1889). *See* also THEOSOPHY.

See Charles J. Ryan, H. *P. Blavatsky and the Theosophical Movement* (1937); Mary K. Neff (ed.), *Personal Memoirs of H. P. Blavatsky* (1937). (K. W. Mo.)

BLAYDON, an urban district and manufacturing town in the Blaydon parliamentary division of Durham, Eng., on the Tyne near its junction with the Derwent, 5 mi. W. of Newcastle. Pop. (1961) 30,615. The town, still a hamlet in the 18th century with local lead mining and iron smelting, developed with the Northumberland and Durham coal field. Many of the inhabitants are engaged in mining, but a feature of the region is the development of coal by-products. Apart from coking, there is iron founding, general and sanitary engineering, brickmaking and some smaller industries. Axwell hall (1760) is an approved school. Nearly half a mile upstream is Stella, where there is a beautiful Elizabethan mansion, with later additions, and a chapel. The song "Blaydon Races," by Geordie Ridley (d. 1864), has become the "anthem of Tyneside."

BLEACHING, the process of whitening textiles or other materials by removing natural colouring and other unwanted substances. Although a considerable amount of bleaching was performed in the home in the early 1960s, including the whitening of clothing during laundering and the decolouring of human hair for cosmetic purposes, the main use of bleaching was in industry, especially in the bleaching of textile fibres and fabrics. Among the textiles usually bleached during processing were cotton, linen, wool, silk and synthetic fibres. Other materials often decolorized included paper pulp, waxes and oils, flour and sugar. This article deals with the bleaching of textile fabrics with emphasis on bleaching of cotton, which accounts for most industrial bleaching. Other articles on bleaching will be found under the titles PAPER: *Bleached Cellulose;* OILS, FATS AND WAXES: *Bleaching;* FLOUR: *Bleaching;* HYDROGEN PEROXIDE: *Uses of Hydrogen Peroxide and Its Derivatives.*

History.—The art of bleaching textile fabrics is very ancient, having been practised by all the early civilizations. Egyptians, Phoenicians, Greeks and Romans produced white linen goods, but little is known of the methods they employed. Pliny refers to the use of plants and the ashes of plants, mentioning especially the "Struthium," which was probably the plant *Saponaria officinalis.* The Dutch established a great reputation as linen bleachers after the last of the crusades and retained a near monopoly of the industry until the middle of the 18th century.

In England, bleaching grounds are said to have existed near Manchester as early as 1322, and there was a bleachworks at Southwark near London in the middle of the 17th century, but the bulk of the brown linen manufactured in Scotland was sent to the Haarlem region of Holland to be bleached. The brown linen was shipped in March and the bleached product was returned at the end of October. In 1728 the Scottish Board of Manufacturers accepted a proposal by James Adair to open a bleachfield in Galloway and voted £2,000 as premiums for establishing bleachfields throughout the country.

The British bleachers (who were sometimes called whitsters) appear to have been taught, or to have copied, the Dutch methods, which consisted of steeping the linen in lyes for several days and washing it clean (called bucking), then spreading it on the grass (crofting) for some weeks. Bucking and crofting were repeated alternately five or six times. The cloth was next steeped in sour milk or buttermilk for several days, washed clean and again crofted. The processes were repeated until the material acquired the requisite whiteness. In 1736 an act was passed in England permitting the use of cotton in cloth; this law resulted in the manufacture of larger quantities of cloth and a greater demand for bleaching.

A far-reaching change occurred in the bleaching industry in 1787 when the use of chlorine for bleaching was introduced at the Macgregor works in Glasgow at the suggestion of James Watt, inventor of the steam engine and son-in-law of the owner. Watt learned about oxygenated muriatic acid, as chlorine was then called, from Claude Berthollet, who was the first to record the bleaching effect of chlorine on linen. Berthollet reported his observations in a paper read before the Academy of Sciences at Paris in 1785 and published that year in the *Journal de physique* (vol. xxvi, p. 325). Further reports appeared in the *Journal* in 1786. Thomas Henry was the first to bleach with chlorine in the Manchester district. At that time, the bleacher made his own chlorine and exposed the fabrics to the gas in chambers or steeped them in an aqueous solution. The process was inconvenient, disagreeable and, worst of all, detrimental to the health of the workers, so it was not surprising that, in spite of the rapid bleaching action, the chlorine method did not gain great favour. The disadvantages were reduced with the introduction in 1792 of *euu de Javelle,* which was made near Paris by absorbing chlorine in a solution of potash until effervescence began. In 1799 Charles Tennant of Glasgow suc-

cessfully prepared chlorine in the even more workable form of a bleaching powder by passing chlorine over lime and was able to supply bleachers with a solid reagent one-third of nhose neight was available chlorine.

In the 1920s hydrogen peroxide began to be used as a bleaching agent after it became available in large amounts and at favourable prices as a result of the development of nen electrolytic methods of production. By the 1960s. after many refinements in production processes, hydrogen peroxide was used for bleaching most cotton goods.

THE BLEACHING OF COTTON

General. — Cotton is bleached in several physical forms — as loose fibre ("raw stock"). yarn or thread, and knitted or woven fabric. The main object of bleaching cotton is to remove as much colour and as many impurities as possible without damaging the fibre. A secondary aim is to produce uniformly absorbent, easily wettable fibre that can be satisfactorily dyed. printed or otherwise finished as desired. It is possible to produce cotton with a high degree of whiteness. or almost complete absence of colour. Whiteness is expressed according to the amount of light bleached cotton reflects. using the reflection from magnesium oxide as 100. Commercially bleached cloth is considered suitably white if it reflects in the range 85–90.

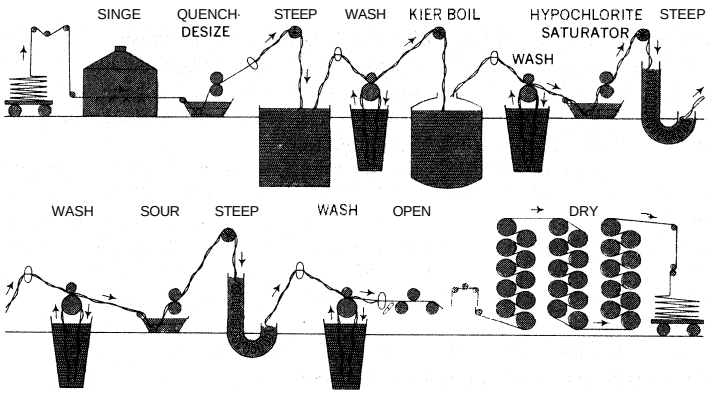
Other tests are made on bleached cotton for absorbency and for damage to the fibres. The test for fibre damage is commonly made by determining the viscosity of a solution of the bleached fibre in a cellulose solvent, usually cupriethylene diamine; viscosity (ordinarily expressed in units of fluidity as "rhes," or reciprocal poises) has been shown to be related to the extent of chemical damage to the fibre.

Choosing a Bleaching Method. — There are a variety of methods for bleaching cotton goods, including continuous flow and discontinuous or "batch" methods. In all of them. the bulk of the impurities other than colour must be removed before bleaching can be carried out satisfactorily. Impurities include those naturally present in the cotton and those added for one reason or another while the yarn and fabric were being manufactured. The preliminary purification is considered part of the over-all bleaching operation. Impurities associated with the mechanically cleaned but otherwise unprocessed dry cotton fibre are shown in the following table:

In addition. a fabric just removed from the loom after weaving may also contain 5% to 10% of starch and other agents used in preparing the narp to withstand the operation of weaving The fabric also may contain a small amount of mineral oil used in yarn manufacturing, plus dye used as tints for identification purposes. After the bleach is completed all that remains is about 0 3% wax, 0.25% ash, and traces of the other original constituents so small as to be negligible.

If normal care is taken. excellent results can be obtained by any of the standard bleaching processes. The choice of process usually depends on: (1) the physical form in which the goods are to be handled; and (2) the volume of similar goods to be bleached. The bleaching agents most often used are hypochlorite (usually sodium hypochlorite. NaOCl, often called the "chlorine" bleach), and hydrogen peroxide (H_2O_2). Considerable progress has also been made, particularly in Europe, in utilizing sodium chlorite ($NaClO_2$) as a bleaching agent

The Batch and *Continuous* Flow *Methods* —In the discontinuous or batch method, loose cotton fibre or stock and yarn wound on packages (a single strand weighing one to three pounds wound



BY COURTESY OF U.S. DEPARTMENT OF AGRICULTURE

FIG. 1. — FLOW DIAGRAM FOR SEMICONTINUOUS HYPOCHLORITE BLEACH

on a perforated tube) or on beams (several hundred strands n-ound side by side on a large perforated core). as well as cloth, may be processed. Most cotton fabric is bleached, except when hypochlorite is the bleaching agent, by the continuous flow method. To allow time for the required chemical action to take place in the continuous flow method. a large rectangular tank shaped in the form of the letter J is used for steeping the fabric saturated with the bleaching agent. The enclosure, called the J-box. usually holds 2.500 to 5.000 lb. of fabric. depending on the production speed and the time required for steeping. The fabric usually remains in the J-box about one hour, moving slowly all that time.

Both batch and continuous methods can he carried out with the fabric in a loosely folded strand or "rope" form, or with the material held at open width, free of folds. The weight of the cloth and tightness of the construction determine whether the rope form can be utilized; heavier. firmer goods cannot be uniformly processed while folded. Processors prefer the rope form because it is easier and less expensive to handle.

The continuous methods of processing are adapted to large-volume bleaching of a limited variety of fabric styles. Continuous production methods became possible when hydrogen peroxide became available for use as a bleaching agent. Hydrogen peroxide can be used at high temperatures under alkaline conditions. In contrast. hypochlorite is used at room temperatures, requires a more severe preliminary scour (cleansing with a detergent') than does peroxide and consequently does not permit the use of a continuous scour; prolonged boiling under pressure in a kier is needed when hypochlorite is the bleaching agent. The latter method. *i.e.*, kier boil followed by hypochlorite bleach. is still widely used with excellent results where space and production requirements permit, (*See* fig. 1.)

Methods utilizing both sodium hypochlorite and hydrogen peroxide in successive steps in the same continuous process have been advocated and adopted to a limited extent; likewise, sodium chlorite has won some acceptance for both batch and continuous work.

Bleaching in *Kiers*.—Cotton raw stock and yarn are ordinarily bleached in closed kiers that heat the processing liquor and circulate it uniformly through the mass of fibres. Usually the kiers can be sealed and the temperature of the circulating liquor raised to between 240° and 250" F., although atmospheric pressures and temperatures of 200°–210° F. are frequently used. The first stage is treatment in a 1%–2% solution of sodium hydroxide for one to six hours, depending on the quality of the fibre and the effect desired. After thorough rinsing in fresh water. the goods may be given either a hypochlorite or a peroxide bleach; the former is more common in England and Europe. the latter in the C.S. When hypochlorite is employed it is used in the form of a cold solution containing 0.1% to 0.3% available chlorine and at an alkalinity of pH 9.5 to 11. The bleaching time may be from 30 min. to several hours. After bleaching is completed. the goods are washed thoroughly and given an antichlor to neutralize and remove all residual hypochlorite. which would degrade the fibre if left in. Sodium bisulfite solution or sulfur dioxide gas introduced into water may

be used as the antichlor. Sometimes a treatment with dilute mineral acid (the so-called white sour) is used to decompose the last of the hypochlorite. The white sour also removes any water-insoluble calcium salts if calcium hypochlorite (bleaching powder) solutions have been used. After acid treatment a neutralization with sodium carbonate is recommended.

When peroxide is used, kier bleaching requires from 45 minutes to 6 hours of circulation in a 0.5%–1.0% solution of 35% hydrogen peroxide at 180°–190° F. with the pH maintained between 10.3 and 10.6. The bleaching solution usually includes sodium silicate to slow the breakdown of the peroxide and sometimes may include small amounts of sodium hydroxide when needed for pH adjustment.

Singeing and Desizing.—When fabric is bleached by batch procedures the scouring and bleaching treatment is essentially the same as that for stock and yarn. However, two preliminary steps are necessary for fabric. These are: (1) singeing. in which the short hairy or fuzzy surface fibres on the yarns are burned off to produce a clean, smooth appearance: and 12) desizing in which the starch size on the warp yarns is chemically removed to prevent its interference with subsequent processing.

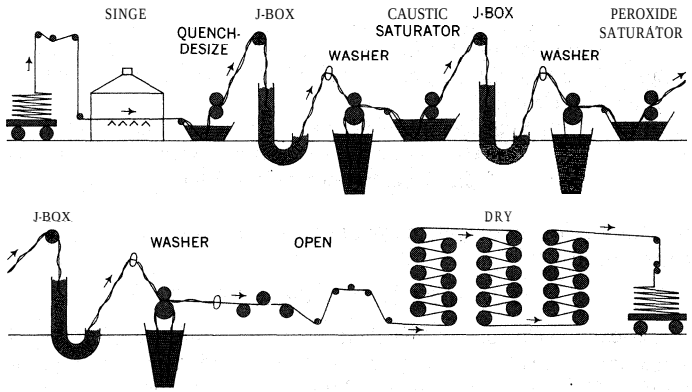
In singeing, the cloth is passed at high speed between rows of gas burners (either or both sides of the fabric may be singed) and then fed directly into a quench box. which can be almost any kind of mangle or padder and which serves the double purpose of saturating the fabric with a desizing agent while extinguishing any sparks on the fabric.

Several distinct methods are used in desizing. All of them serve to hydrolyze the starch: *i.e.*, split it into simpler compounds, such as dextrins and sugars, that are soluble and easily washed out of the goods. Care must be taken in desizing to keep the hydrolysis from extending to and degrading the cellulose. For many years, starch has been removed by steeping the fabrics in weak acid. A typical procedure is to saturate the material with a 0.5%–2.0% solution of sulfuric acid for three to four hours at room temperature, with provision to prevent any part of the fabric from drying out. thereby weakening the fibre.

The most popular and effective means of removing size is by the use of enzymes. These chemicals are complex, nitrogen-containing substances secreted by certain plant cells and produced by several species of microorganisms and having the power to accelerate specific chemical changes to a pronounced degree. Enzymes specific for dextrinizing and solubilizing starch may be obtained from malt and other sources. To remove the starch, the goods are saturated with a solution of the selected enzyme, then held at a temperature best suited for enzyme action and the type of equipment used. After being impregnated with enzyme, the goods may be piled in pits or bins for several hours! steeped in kiers or other vessels at elevated temperatures for a shorter period. or processed continuously at high temperatures if certain heat-resistant enzymes are used. At the higher temperatures, desizing requires only a few minutes or seconds. After desizing, the goods are washed thoroughly.

At one time a lime (calcium hydroxide) boil in an open kier followed by a soda (sodium carbonate) boil was employed for scouring fabric after desizing and prior to bleaching. Later an acid sour was used between the lime and soda treatments. The purpose of these three steps was: (1) to saponify the waxes, forming lime soaps; (2) to decompose the insoluble lime soaps into free fatty acids; and (3) to convert the fatty acids into soluble soaps. Later, the use of a single boiling under pressure in a closed kier with caustic soda (sodium hydroxide) was introduced and has replaced the old, lengthy, three-step treatment.

Technique of Continuous Flow.—In spite of advances in the technology of bleaching, batch processing of fabric still often requires 10 to 20 hours for the scouring and bleaching alone. For this reason, persons responsible for new plant construction and old plant expansion or modernization consider continuous equipment carefully if the production per week is intended to be 200,000 yd. or more. It is now possible. making use of continuous methods, to bleach many fabric constructions quite satisfactorily in less than three hours, including all steps from singeing through final drying. In fact, under certain conditions it may be possible to complete the entire operation in less than one hour.



BY COURTESY OF U.S. DEPARTMENT OF AGRICULTURE

FIG. 2.— FLOWDIAGRAM FOR CONTINUOUS HYDROGEN PEROXIDE BLEACH

Rapid processing requires a special layout of equipment similar to that pictured in fig. 2. The large J-boxes are constructed of stainless steel and insulated to maintain temperatures close to 212° F. The commonest arrangement for continuous peroxide bleaching allows for two stages: (1) an alkaline scour; and (2) an alkaline peroxide treatment. These steps may be carried out in two routings through a range consisting of a saturator, a J-box and a set of wash boxes, or, if greater production capacity is required, in one routing through two ranges in tandem. The saturator for the scour contains a 3%–4% solution of sodium hydroxide; the saturator for the peroxide stage contains 1.5%–2.2% of sodium silicate and 0.75%–1.5% of 35% hydrogen peroxide. The alkalinity of the bleach bath is approximately pH 10.5. The conventional storage period (or dwell time) in each J-box is about one hour; it has been found possible with special bleach formulas, however, to reduce the dwell time to seven or eight minutes. Another variation that has had some commercial acceptance is a one-step combination scour and bleach in a single J-box. Both the combined scour-bleach and the special bleach methods are more expensive than the slower methods, but the extra cost is offset by lower labour, utilities and initial equipment costs and smaller space requirements. The final operation in the continuous bleaching process is a thorough washing to remove residual chemicals.

When fabric containing coloured yarns (ordinarily dyed with vat and naphthol dyestuffs) is to be bleached. the preliminary scour with caustic is not used because of possible colour damage Two successive bleaches, sometimes using less concentrated peroxide and a loner pH, are substituted A hydrogen peroxide bleach liquor that contains free caustic soda tends to promote the bleeding of some dyes; so soda ash is preferred under these circumstances.

Optical Whiteners.— The use of so-called optical whiteners (brighteners or fluorescent white dyes) to enhance the appearance of bleached goods to be sold as whites is quite common. Optical whiteners improve the uniformity of reflectance over the visible portion of the spectrum, resulting in greater apparent whiteness. Fluorescent brighteners do not replace bleaching; they may, however, reduce the length or severity of the bleach required. Optical whiteners are absorbed by the fabric like dyes. Some resist oxidation and can be added to the bleach bath, while others are subject to oxidation and must be applied in a separate bath, or in the last rinse after bleaching. Generally a solution of about 0.05% brightener based on the fabric weight is sufficient.

BLEACHING FIBRES OTHER THAN COTTON

Bleaching is of considerable technical importance for a number of fibres other than cotton, including rayon. linen, jute, hemp, ramie. wool, silk and synthetic fibres, although the amount of these fibres that are bleached is very small compared with the volume of cotton bleached.

Rayon (a regenerated cellulose) seldom needs bleaching because

it is quite white when produced. But if the ultimate in whiteness is desired, a mild bleach with either sodium hypochlorite or hydrogen peroxide or simply a treatment with a substantive optical bleach may be given.

Bast fibres, among which linen is of the most interest as far as bleaching is concerned but which also include jute. hemp and ramie, contain a much larger percentage of noncellulose material than does cotton; the object of bleaching bast fibres is to whiten the fibre while removing only part of the noncellulose matter. Bast fibre bleaching usually involves scouring followed by extended bleaching with either alkaline hypochlorite or hydrogen peroxide; in general the treatment is much longer but milder than for cotton.

Wool and silk are both scoured in a comparatively mild alkaline solution to remove the rather large quantities of impurities associated with the raw fibres. Temperatures used for wool are generally below 140° F., while silk may be boiled. The bleaching of wool was originally carried out by an operation called "stoving" in which moist wool was exposed overnight to fumes from burning sulfur; the sulfurous acid formed bleached the wool. However, modern methods utilize hydrogen peroxide made alkaline and stabilized with sodium silicate and employed at a temperature of about 120° F. Hypochlorites degrade wool and tend to yellow rather than whiten it; for these reasons hypochlorites are not used for bleaching wool.

Nylon and the newer synthetic polymer fibres such as the polyesters (*e.g.,* Dacron and Terylene) and the acrylics (*e.g.,* Orlon and Acrilan) generally do not require bleaching. For an unusually high degree of whiteness, however, nylon may be bleached at 180" F. with peracetic acid adjusted (with sodium hydroxide) to a pH of about 6 or by the use of sodium chlorite at a pH of 3.5 (with formic acid) at 205°–210° F. Polyester fibre and acrylics may require boiling with sodium chlorite plus oxalic acid and nitric acid.

BLEACHING POWDER, also known as chloride of lime, is a white solid having the odour of chlorine. It is formed by the combination of chlorine with slaked lime. Used as a bleaching and disinfecting agent, it has the same effect as chlorine with the advantage of easier handling. It was introduced by Charles Tennant of Glasgow in 1799 and was soon produced in large quantity for the textile and paper industries. Its disadvantages are its instability and the large proportion of inert material present. It decomposes at high temperatures and reacts with moisture and carbon dioxide from the atmosphere, gradually losing its strength.

In the older method of manufacture, still largely used, the slaked lime is spread, in layers of 2 in. or 3 in. deep, on the floor of large rectangular chambers made of lead or of concrete protected with an inside coating of tar; these chambers are from 6 ft. to 7 ft. high, 10 ft. to 20 ft. wide, and up to 100 ft. long. The lime is raked into ridges in order to increase the surface exposed to the gas. The chamber, or series of chambers, is then closed and chlorine admitted. The gas is readily absorbed and, if it is concentrated, so much heat may be generated by the reaction that in hot climates cooling coils are necessary in the floor of the chambers to prevent decomposition of the bleaching powder. A later method dispenses with chambers and employs mechanical means to propel the lime through a horizontal tube or series of tubes. The gas is fed into the plant in a direction opposite to that in which the lime travels.

While bleaching powder is commonly represented by the formula $CaCl(OCl)$, it is not a pure substance, its composition approximating $CaCl(OCl).Ca(OH)_2$. There is some doubt as to the existence of $CaCl(OCl)$. C. W. Bunn, L. M. Clark and I. L. Clifford in 1935 reported on the basis of X-ray analysis that bleaching powder consists of a mixture of the true hypochlorite, $Ca(OCl)_2$, with a basic chloride of the composition $CaCl_2.Ca(OH)_2.H_2O$. The strength of bleaching powder is commonly expressed in terms of "% available chlorine," the maximum being about 40%.

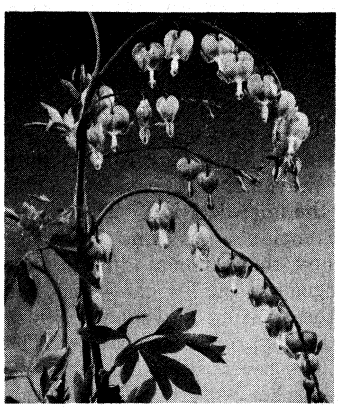
In oxidizing or bleaching capacity 100 lb. of such bleaching powder would be equivalent to 40 lb. of pure chlorine.

The bleaching action is ascribed to the hypochlorous acid which is formed by the reaction of bleaching powder in an acidic medium. Any hypochlorite undergoes the same reaction, $OCl^- + H^+ = HOCl$, and thus has the ability to bleach. Chlorine, by its reaction with water, $Cl_2 + H_2O = H^+ + Cl^- + HOCl$, forms hypochlorous acid and may also be used for bleaching. Although still produced on a large scale. the relative importance of bleaching powder was decreasing by the 1960s because of the advantages enjoyed by other bleaching agents. Liquid chlorine in steel cylinders appeared on the market in 1909 and replaced bleaching powder in many large-scale operations. Later calcium hypochlorite was made commercially available. This material, largely $Ca(OCl)_2.2H_2O$, has about 70% available chlorine. It is produced by treating a suspension of lime in water, rather than the dry material. with chlorine or chlorine monoxide. The solid calcium hypochlorite, in addition to its greater oxidizing capacity, is more stable than bleaching powder. A large amount of sodium hypochlorite solution is consumed as a household bleach because of its convenience.

A later competitor of bleaching powder in the bleaching trade was sodium chlorite ($NaClO_2$) which appeared in 1940. When added to an acid solution. sodium chlorite reacts to produce chlorine dioxide (ClO_2) which is the active bleaching agent. Chlorine dioxide is reported to be less injurious to textile or paper fibres than hypochlorous acid. *See* BLEACHING.

(R. P. S.)

BLEEDING HEART, a common name, in reference to the flower shape, for certain species of Dicentra, low or stemless perennial herbs of the fumitory family (Fumariaceae). A few of these natives of Asia and North America are cultivated for their attractive deeply cut or dissected foliage and handsome irregular flowers. The familiar bleeding heart (D. spectabilis) of the gardens, with showy rose-red, heart-shaped flowers, an inch or more long, is a native of Japan. The eastern bleeding heart (D. eximia), with pink, narrow, heart-shaped flowers, about three-fourths inch long, of the Allegheny mountain region; and the western bleeding heart (D. *formosa*), with similar rose-purple flowers, of mountain woods from California to British Columbia, are both more or less cultivated.



ROCHE

BLEEDING HEART (DICENTRA SPECTABILIS)

Other noteworthy American species related to the bleeding heart are the Dutchman's-breeches (*q.v.;* D. *cucullaria*); and the golden eardrops (*D. chrysantha*), with large panicled clusters of yellow flowers, widely distributed in California.

BLEEK, WILHELM HEINRICH IMMANUEL (1827–1875), German philologist, studied at Bonn and Berlin, where he first noted the philological peculiarities of the South African languages. In his doctor's dissertation (1851), he endeavoured to show that the Hottentot language was of North African descent. Toward the close of 1856 he settled at Capetown, and in 1857 was appointed interpreter by Sir George Grey, who appointed him librarian of the Sir George Grey collection in 1860. He introduced into European philology the word Bantu.

His works are Vocabulary of the *Mozambique* Language (1856); Handbook of African, Australian and Polynesian Philology (1858–63);

Comparative Grammar of the South African Languages, vol. i (1869); *Reynard the Fox in South Africa, or Hottentot Fables and Tales* (1864); *Origin of Language* (1569).

BLEKINGE, a county **(lan)** of southern Sweden, lies between Småland and Skåne and the Baltic. Pop. (1960 est.) 134.568. Area 1,173 sq.mi. The coast is much indented, while the interior is smooth. sloping up toward the Småland plateau. The agriculture is much poorer than that of Skåne because of the light soils: potatoes are a leading crop. being used as a source of starch and alcohol as well as food. Ronneby is the chief commercial centre but Karlskrona. with a magnificent anchorage, has been the Swedish naval base since 1650. It only freezes one year in three and can then be kept open by icebreakers. The *län* was ceded to Sweden by Denmark under the treaty of Roskilde (1658).

(A. C. O'D.)

BLENDE: *see* SPHALERITE.

BLENHEIM, BATTLE OF. On Aug. 13. 1704, during the War of the Spanish Succession, English and Austrian forces under the duke of Marlborough and Prince Eugene of Austria defeated the Bavarians and French under the elector of Bavaria and Marshal C. Tallard and Marshal F. Marsin at Blenheim (Ger. Blindheim) on the left bank of the Danube near Höchstädt, Bavaria. This battle that saved Austria was Marlborough's most notable victory, and Blenheirn palace in Oxfordshire mas erected for him by a grateful English parliament.

To prevent an Austrian collapse before strong French pressure, Marlborough had marched his army to the Danube (*see* SPANISH SUCCESSION, WAR OF THE), and Tallard, knowing the desire of Marlborough and Eugene to protect Vienna. did not expect to be attacked by this slightly weaker force.

The French and Bavarians were strongly placed just behind the Nebel river with their right wing resting on the Danube at Blenheim and their left on hilly country bounded by the town of Lutzingen. In the centre were the hamlets of Oberglauheim and Unterglauheim. the former on the French side of the Nebel. The day of battle saw the French initially unprepared to fight but by noon they were reasonably ready. though basically drawn up as two separate armies with a resultant weakness in the centre. Eugene faced Marsin and the Bavarian elector at Lutzingen and Marlborough opposed Tallard at Blenheim. Against about 60.000 French and Bavarians the allies opposed about 52,000 infantry and cavalry.

Prince Eugene pushed a strong containing action on his flank while Marlborough's general Lord Cutts mounted the main assault against Blenheim. Two fierce infantry attacks were completely unsuccessful before a halt was called in that sector. Cutts' attack, however, had forced Tallard to concentrate more good troops in Blenheim than he had originally intended and the threat of a third attack held them there. Since Eugene kept Marsin fully occupied. Marlborough began the movement of cavalry across the Nebel in the centre that led to the final decision. The movement was hotly contested. Twice French charges came very close to throwing the allies back and only the personal direction of the duke and the selfless loan by Eugene of the Fugger-Kürassiere cavalry corps served to maintain the massing movement. Once successfully launched. however, the attack proved irresistible. The allied cavalry broke through the enemy centre, dividing the army of Marsin from that of Tallard, and wheeled left, sweeping Tallard's forces into the Danube. Although Marsin was able to retreat and escape in some order. 24 battalions of infantry and 4 regiments of dragoons were pinned in Blenheim and eventually surrendered. Tallard himself was taken prisoner.

While the Anylo-Austrian forces lost about 4,500 killed and 7,500 wounded. the French total losses, including prisoners, numbered about 38.000 men (the figure is disputed, however, and contemporary accounts indicate about 29,000). The battle set the seal on that near-perfect co-operation that marked the relationship between Marlborough and Eugene for the remainder of their association in this war. It demonstrated that the armies of Louis XIV were not irresistible and served notice that English soldiers and generals were not to be disregarded in continental diplomatic and military calculations.

(D. M. Sc.)

BLENNY, a name generally given to any blennioid fish. a fish in which the pelvic fins are jugular in position and have the rays reduced in number. The wolf fish, like the viviparous blenny (*Zoarces*), is a blennioid.

The families Blenniidae and Clinidae contain numerous small species in tropical and subtropical seas, mostly shore fishes that lurk under stones and weeds in shallow pools. The shanny (*Blennius pholis*) is the commonest British species. Giant kelpfish (*Heterostichus rostratus*), which may grow to two feet, live on the Pacific coast of North America. See also FISHES.

(C. Hu.)

BLÉRIOT, LOUIS (1872–1936), French aviator who, on July 25, 1909, made the world's first overseas flight in a heavier-than-air craft when he piloted a small 25-h.p. monoplane of his own design across the English channel from Calais to Dover. This feat won him lasting fame and a prize of £1.000 offered by the *London Daily Mail.* Blériot was born in Cambrai, France, on July 1. 1872. He amassed a modest fortune as an inventor of automobile lights and accessories and took an early interest in aviation. He experimented first with toned gliders on the Seine river. Then. as lightweight engines became available, he developed a series of airplanes, one of which was the channel-crossing machine. Bleriot was active in building aircraft for the French government during World War I, first with trainers of his own designs! then associated with the makers of the famous SPXD fighter. After the war his interest turned to commercial aircraft development. He was one of the group to greet Charles A. Lindbergh on his arrival in Paris, May 21, 1927. He died of a heart attack in Paris, Aug. 2, 1936.

(S. P. J.)

BLESBOK (BLESBUCK), an African antelope (*Damaliscus albifrons*) allied to the hartebeest (*q.v.*). *See* ANTELOPE.

BLESSINGTON, MARGUERITE, COUNTESS OF (1789–1849), Irish writer chiefiy remembered for her *Conversations with Lord Byron* and for her London *salon,* was born near Clonmel. County Tipperary. on Sept. 1. 1789. Her father sold her into marriage at 1j to Capt. Maurice St. Leger Farmer. a sadist from whom she fled after three months. He died in a drunken brawl in 1817, whereupon Marguerite, who had been the protégée of Capt. Thomas Jenkins in England for some years, married Charles Gardiner, Viscount Mountjoy and earl of Blessington. Of rare beauty, generosity and wit, "the most gorgeous Lady Blessington," who at 18 had been painted by Lawrence. formed a brilliant *salon* and began to write essays and sketches of London life.

In 1822 the Blessingtons went abroad. accompanied by the young Comte d'Orsay, who married the earl's daughter by his first wife. They spent two months in Genoa in close intimacy with Byron, and lived in Italy, and then in France, until the earl's death in May 1829. Their extravagant tastes had drained his fortune and, returning to London accompanied by D'Orsay. whose marriage had broken up and who remained with her all the rest of her life regardless of scandal, the countess began to support herself by writing. Her first novel, *Grace Cassidy or The Repealers* (1833), was a success. Her journals furnished material for *Conversations with Lord Byron* (1833) *The Idler* in *Italy* (1839–40) and *The Idler in France* (1841), all of which enjoyed popularity for their personal gossip, easy style and sense of humour. She wrote several other novels and edited two annuals. *Tlze Book of Beauty* and *The Keepsake,* to which she contributed.

In spite of her literary successes Lady Blessington could not keep out of debt and in April 1849 she and D'Orsay fled to Paris to avoid ruin. She died there on June 4, 1849. and is buried with D'Orsay at Chambourcy.

BLETCHLEY, an urban district and market town of Buckinghamshire, Eng., lies 11 mi. E. of Buckingham by road and 46 mi. N.W. of London. Pop. (1961) 17,093. Area 7.0 sq.mi. Between Fenny Stratford. where Watling street crosses the river Ouzel, and Old Bletchley, 2 mi. W., the modern town developed after the building of a big railway junction on the main northern line.

After 1911 the three places were joined and renamed Bletchley. Through it pass the main road from London to north Wales and the Grand Union canal. Under the Town Development act, 1952, Bletchley had received about 7,000 Londoners by 1961. Industries include railway workshops, brickmaking, brushmaking. light and electrical engineering and tea and coffee blending, and there is a weekly livestock market. The church of St. Martin, Fenny Stratford, was largely rebuilt (1726–30) by Browne Willis, in whose memory small cannon called "Fenny poppers" are fired every St. Martin's day. St. Mary's, the church of the original village of Bletchley, still contains parts dating from the 12th century.

BLEULER, EUGEN (1857–1939), Swiss psychiatrist who made a number of lasting and unique contributions to the field of psychiatry, was born at Ziirich on April 30. 1857. After completing his medical training, he became director of a hospital in Ziirich and professor of psychiatry at the university there. His early thinking was influenced by Wilhelm Wundt and Sigmund Freud. whose orientations were diametrically opposed, and Bleuler's writings show his attempts to reconcile the rigorous laboratory approach of Wundt with the philosophical approach of Freud in studying the problems of the mentally disordered. He also could never decide whether mental disorders could be explained best on an organic or on a psychogenic basis.

Bleuler introduced the term schizophrenia as a substitute for dementia praecox. He showed the part that autistic thinking plays in the development of paranoia; he was a student of the language of the schizophrenic; he was concerned with possible regressive behaviour exhibited by schizophrenics, and believed that the discrepancy between the aspiration level and moderate ability of the individual sets the stage for the development of delusions. His best-known writings are collated in *Dementia Praecox or the Group of Schizophrenias* (1911; reprinted 1950); *Affectivity, Suggestibility, Paranoia* (1906; 2nd ed., 1926); and *Textbook of Psychiatry* (1924; later ed., 1930). He died on July 1j. 1939.

(R. M. D.)

BLICHER, STEEN STEENSEN (1782–1848), Danish poet and writer of short stories describing with realism and humour the people of Jutland, was born in Vium, northern Jutland, Oct. 11, 1782, the descendant of a line of country parsons. He himself became a country parson in his native district in 1819. During a short period as a schoolmaster in 1810 he married the 17-year-old widow of his uncle, but the marriage was unhappy, and much debt and many children did not help. His wife's unfaithfulness caused him to consider divorce, but his financial situation made this impossible. He spent most of his life out of doors, shooting. walking, talking to gypsies, peasants, farmers and squires. and devoted much time to practical and political questions. often taking part in public debates. As his private life became increasingly unhappy he took refuge in drink, and his death (at Spentrup. March 26, 1848) came as a release.

As a student at Copenhagen. Blicher read Ossian, and he taught himself English in order to translate Ossian into Danish (2 vol. 1807–09). His first volume of original poems appeared in 1814 and he gradually developed his own muted style, expressing with equal felicity a melancholy acceptance and humour. His finest collection is *Trækfuglene* (1838), with its sad self-portrait of a caged bird longing for freedom: in the opening "Prelude." Many of his best poems are in Jutland dialect; in these he describes great events with characteristic irony and understatement.

Blicher's fame rests primarily on his many *noveller,* the first of which, En *Landsbydegns Dagbog* (1824), is a masterpiece of prose style, and convincing in its psychology. He ranges from resignation to humour and irony, and most of his stories. notably his brilliant dialect story *Æ Bindstouw* (1842), are about Jutland. The general feeling of his narrative style is antiromantic and realistic; life is seen as the great shatterer of illusions since it never keeps its promises. In his style Blicher was influenced by Pope, Sterne and Goldsmith, whose *Vicar of Wakefield* he translated into Danish (1837). *Samlede Skrifter,* 33 vol. (1920–34) is the authoritative Danish edition of his work. There is also an English translation of *Twelve Stories by Blicher* (1945).

(E. L. Bf.)

BLIDA, a town of Algeria and centre of a commune of the same name in the *département* of Algiers, lies 32 mi. S.W. from Algiers by rail. Pop. (1960) 87,000 (metropolitan). It lies 630 ft. above sea level at the base of the Tell Atlas mountains, on the south edge of the fertile Mitidja plain and on the right bank of the Wad al Kebir affluent of the Chiffa, which supplies the town with water for its numerous fountains and gardens, and provides power for mills and factories. Ft. Mimich stands on a steep hill left of the river. The town was formerly enclosed within walls, with six gates, but has spread widely outside, and new quarters have been built, especially in the villages of Joinville and Montpensier; the village of Dalmatie contains schools, a church and a religious institution.

The modern town is French in character and one of the pleasantest spots in Algeria, surrounded by orchards and gardens. It has a flourishing trade, mainly in oranges and flour, and its industries include aircraft and other workshops.

Blida (*i.e., bolcida,* diminutive of the Arab word *belad,* "city") occupies the site of a Roman military station, but the present town appears to date from the 16th century. A mosque was built by order of Rhair ed-Din Barbarossa, and under the Turks the town attained some importance. In 1825 and again in 1867 it was badly damaged by earthquake, but was rebuilt. After 1838 it was held by the French. The important French military air base was seized by the Allies on Nov. 9, 1942.

BLIGH, WILLIAM (1754–1817), English admiral, who was captain of H.M.S. "Bounty" at the time of the famous mutiny, was born on Sept. 9, 1754. He entered the navy in 1762 and was chosen by James Cook in 1776 to be master of the "Resolution" on Cook's last expedition. Bligh was appointed to the command of the 220-ton "Bounty" in 1787, when the vessel was engaged in a scheme for transplanting breadfruit trees from Tahiti to the West Indies. Having sailed from Tahiti as far as the Friendly Islands. the ship was suddenly seized by Fletcher Christian, the master's mate, on April 28, 1789, and Bligh and 18 others were turned adrift in the longboat. The causes of this famous mutiny have been much discussed; Bligh was no stricter disciplinarian than Cook, whose example he always followed, but he had undoubtedly insulted many of his officers. His account of the affair is probably correct: the crew "had assured themselves of a more happy life among the Otaheitans than they could possibly have in England, which, joined to some female connections: has most likely been the leading cause of the whole business." Bligh eventually reached Timor in the East Indies on June 12, 1789, after a remarkable voyage of nearly 4,000 mi. in an open boat. Captain Edwards in the "Pandora" was sent out in search of the mutineers in 1791, but by the time he reached Tahiti, Christian and eight others had taken the "Bounty" to Pitcairn Island, where the small colony they founded was undiscovered until 1808 and where their descendants still reside. Of those found at Tahiti, three were later hanged in England.

The mutiny made little difference to Bligh's career. He visited Tahiti again and successfully transported breadfruit trees to the West Indies (1792). As captain of the "Director," he was put ashore when his crew joined the mutiny at the Nore (1797). However, he commanded this ship with distinction at the battle of Camperdomn that year, as he did the "Glatton" at Copenhagen (1801). He was sent to New South Wales as governor in 1805, but complaints of his "oppressive behaviour" led in 1808 to a mutiny under George Johnston. the deputy governor, who sent Bligh to England under arrest. but the mutineers were subsequently found guilty of conspiracy. Bligh was promoted rear admiral (1811) and vice-admiral (1814). He died in London on Dec. 7, 1817.

Bligh's character has been variously interpreted. He does not seem to have been unduly tyrannical, but an abusive tongue and an overzealous and overbearing manner made him unpopular as a commander. He possessed undoubted courage in action and skill as a navigator.

BLIMP: *see* AIRSHIP

BLIND, TRAINING AND WELFARE OF. For practical purposes, such as determining compensation for eye injury or establishing the need for assistance, a person is commonly classified as blind when vision is insufficient for use in tasks in which eyesight is essential. More exact definitions vary from country to country. This lack of a uniform definition of blindness (*q.v.*) throughout the world presents difficulties in determining the total number of the blind and in comparing figures from various countries. However, the most informed sources estimated that the total blind population of the world numbered about 14,000.000 in the 1960s.

The main subdivisions of this article are as follows:

I. HISTORY

1. Early Developments. — From early historical times there are reports of gifted blind persons who achieved fame. but the history of organized efforts to help the blind can he traced to the enlightened philosophy of compassion toward the handicapped as exemplified by such religions as Christianity and Buddhism. Thus, in the 4th century. St. Basil opened a hospice for blind persons at Caesarea in Cappadocia. In the 5th century the hermit, St. Lymnaeus, established a refuge for blind persons at Syr in Syria, with special cottages being erected for their use. Two hundred years later in France St. Bertrand, bishop of Le Mans, founded an institution near Pontlieu. In the 11th century William the Conqueror, in expiation of his sins, it was said, founded several hospices in Normandy for blind and other infirm persons. In 1260 Louis IX of France took under his protection an institution for the care of the blind in Paris, the Hospice des Quinze-Vingts; this institution has continued to this day (see PARIS: Hospitals). Simultaneously, in the far east, the development of Buddhism as a leading religion resulted in efforts to improve the condition of the blind in countries such as China and Japan.

It was not until the close of the 18th century, however, that any real attempt was made to educate or train those without sight. Valentin Hauy (1745–1822), the man to whom the title "father and apostle of the blind" afterward was given, had his attention attracted to the problem by the contrast afforded by the public performance of Maria Theresa von Paradis, the noted Austrian blind pianist, and the spectacle presented by some untrained and illiterate blind persons who, tricked out in fantastic attire, were trying to attract custom by making mock music. Hauy opened the Institution Nationale des Jeunes Aveugles in Paris in 1784 and a philanthropic society sent him 12 blind children as his first pupils. News of Hauy's success in teaching these children to read spread, the Academy of Science examined and approved the raised print he invented, and he was received by the king. When the French Revolution broke out. Hauy's school was taken over by the state and later incorporated with the Quinze-Vingts.

The education movement soon spread to other European countries. Schools for the blind were opened in Liverpool (1791), London (1799), Vienna (1805) and Berlin (1806). Hauy was invited by Tsar Paul to come to St. Petersburg to found a school, but his experiences in Russia were discouraging, and only after many years was he able to open an institution. Other countries, however, were showing interest in the blind, two schools being opened in 1808, in Amsterdam, Neth., and in Stockholm, Swed.; another was founded in Zurich. Switz., in 1809, and many more followed. In the United States three schools were founded practically simultaneously. One of these. the New England Asylum for the Blind (1832; now called Perkins School for the Blind). was directed by Samuel Gridley Howe (*q.v.*). The two other schools, in New York (1832) and Philadelphia, Pa. (1833), were headed by John D. Russ and Julius R. Friedlander, respectively. These schools were at first supported by private means. The first entirely state-supported U.S. school for the blind was opened in Ohio in 1837.

2. Systems of Reading. — The earliest authentic records (1517) of tangible letters for the blind describe a plan of engraving the letters upon blocks of wood, the invention of Francesco Lucas, a Spaniard. In 1640 Pierre Moreau, a French notary, cast a movable leaden type for the use of the blind. Pins inserted in cushions

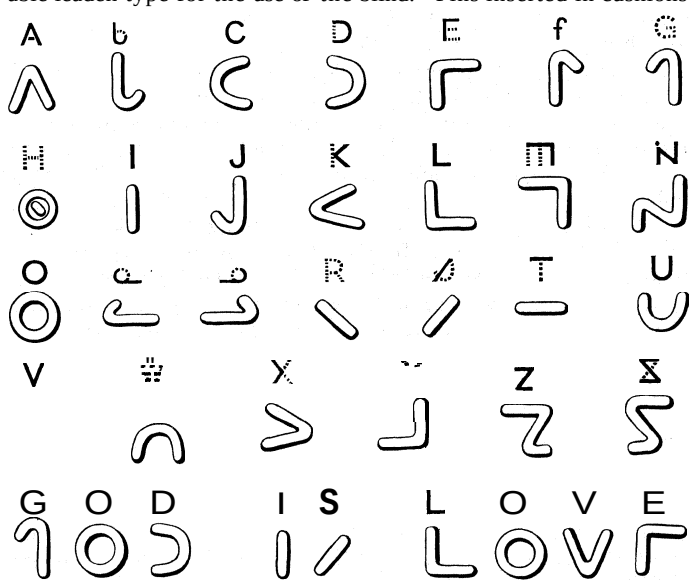

FIG. I.— WILLIAM MOON'S ALPHABET WHICH IS BASED ON ROMAN LETTERS

were next tried, and also large wooden letters. Cast metal letters folloned, and in Germany R. Weissembourg made use of letters cut in cardboard, and afterward pricked maps in the same material. To Hauy, however, belongs the honour of being the first to emboss paper as a means of reading for the blind; his books were embossed in large and small italics, from movable type set by his pupils. Haüy's first pupil, François Lesueur. was sorting the papers on his teacher's desk and came across a card strongly indented by the types in the press. The blind lad showed his master he could decipher several letters on the card. Immediately Haüy traced with the handle of the pen some signs on paper. The boy read them and the result was printing in relief, the greatest of Haüy's discoveries.

The first book for the blind produced in Great Britain was by James Gall of Edinburgh in 1827; it was printed in a triangular modification of the common alphabet.

In 1833 the first American book for blind people was turned out in Philadelphia in a system invented by Friedlander. Howe also worked out a system of his own, and many books were printed at his school in Boston. Most of these early systems, which appeared in England as well as in the United States. were adaptations of the regular Roman alphabet and were cumbersome to handle and difficult to learn. With one exception, they are no longer in use. The exception is the Moon type (see fig. 1), invented by William Moon of Brighton, Eng., which partly retains the Roman outlines and is easily learned by those who have become blind late in life. Books in this type are still in limited use by elderly persons throughout the English-speaking world.

All these types utilized raised lines and therefore could not be easily written by the blind. Louis Braille (1809–52), a blind teacher in the Institution Nationale des Jeunes Aveugles, realized this shortcoming and, inspired by a 12-cell dot system produced by Capt. Charles Barbier, developed a dot system that could easily be written with a simple instrument. Braille first published his type in 1829. and in 1837 he published a more complete elaboration of the system. It was not officially adopted by his school until 1854, two years after his death.

The braille system spread slowly at first. In the United States, in the 1860s, another dot system known as New York point was developed by William B. Wait at the New York Institute for the Education of the Blind, and in the 1870s a modification of braille called American braille was invented by a blind teacher, Joel W. Smith, of Boston, Mass. These codes were used by most of the schools for the blind in the U.S. until 1916, when Braille's alphabet and a series of contractions was officially adopted. Adoption of a universal braille code for the English-speaking world. however, did not come until 1932, when representatives of agencies for the blind of Great Britain and the United States met in London and agreed upon a braille system known as Standard English braille, grade 2. In 1957 U.S. and British experts again met in London to further clarify the system.

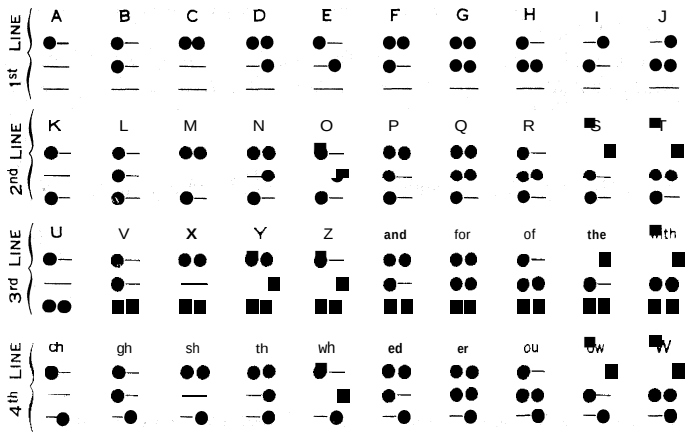

FIG. 2.—THE BRAILLE ALPHABET. ONE OF THE MOST WIDELY USED ALPHABETS FOR THE BLIND

The braille alphabet consists of varying combinations of one or more raised dots in a six-dot oblong. known as the braille cell, which is three dots high and two dots wide. There are 63 possible combinations of dots. and after the letters of the alphabet have been supplied, the remaining signs are used for punctuation, contractions, etc. (see fig. 2). Combinations of dots also have been worked out to signify mathematics, music and other specialized codes. Braille is written with the aid of a metal slate or on a specially constructed braille typewriter.

In 1893 Frank Hall of Jacksonville, Ill., invented a stereotyping machine for embossing on metal plates. Later, this stereotyping machine was electrified and a method devised for shifting the folded zinc plates, which serve as masters, so that they could be turned over and brailled on the reverse side as well (interpointing). Paper is inserted into the folded master, which is then run through a roller proof press; or the master is mounted in a flat-bed press, or cut apart and mounted in large rotary presses. on which many pages can be run off simultaneously, as in regular printing. Efforts are being made to carry mechanization of the process still further.

Many blind persons find it difficult to read raised type with their fingers. A survey made in the U.S. in the late 1920s revealed that less than 15% of the blind population read braille well enough to make reading a pleasure. In order to prevent the remaining large group of blind people from being shut off from a world of literature, the American Foundation for the Blind developed a new reading medium, called talking books. These are books and other reading material recorded on long-playing 12-in. vinylite phonograph disks. A printed book of average length can be recorded on 13 double-faced disks—a reading time of about 12 hours. Longer books fill many more records; the Bible, for example, runs to 170 records. The U.S. government set up under the Library of Congress a series of libraries for the blind from which braille and talking books may be borrowed. Similar library systems for the blind were developed in the British commonwealth and in other parts of the world.

3. Appliances. — Before the establishment of schools for the blind. tools such as calculating boards were frequently devised for individual use, but there was no continuity of effort. The first regularly produced apparatus were directed primarily toward the solution of educational problems. One of Hauy's first efforts was a guide for writing script. which, however, proved inadequate; for generations thereafter it was assumed that persons born blind could not be taught script. With improved guides, it has been established that such skills can indeed be taught. Raised maps have called on the ingenuity of many minds, as have mathematical aids, music devices and materials for use in handicrafts. Braille slates and braille typewriters have multiplied in variety of design.

Since the majority of blind people lose their sight as adults, and many of them have the potential of carrying on in the work for which they have been trained, the need for a richer variety of devices has been recognized. There exist micrometers, electrical measuring apparatus, thermometers, scales, slide rules and timers, in addition to household aids, clocks, collapsible canes and other less special-purpose devices. Moreover, catalogues tend to include commercial tools that, while not devised for people without sight, help solve problems resulting from blindness; pressure cookers equipped nith audible signals rather than dials are an example. The typewriter, radio and telephone are other examples of commercial equipment that is especially helpful to persons without sight.

4. Optical Aids.—As the conviction grew that residual vision safely can be used up to its limits, there was a rapid increase in interest in optical aids. Australia. Great Britain and the United States took the leadership in this direction. Persons formerly regarded as having no useful vision have been enabled to read again with the aid of powerful magnifying devices, of which the variety steadily increases. Use of these requires the development of skill in holding material at the proper focus and in learning to interpret the enlarged optical cues.

5. Recreation. — Despite broadening employment opportunities, too many blind persons find time hanging heavily on their hands, so that recreational opportunities are essential. Especially among voluntary agencies, recreational programs often are emphasized.

Wrestling, bowling (with special guide rails), swimming! boating, hiking, skiing, golf, horseback riding and fishing are among the more active sports in which the blind can participate. Sprinting (often with guide wires), jumping, shot-putting and modified forms of baseball also are carried on, especially in residential schools.

Checkers, chess, Chinese checkers, bingo, cards and Scrabble are among the games that have been adapted for blind persons. Among hobbies, amateur radio, recording, cooking, sewing and even some phases of photography are followed with enthusiasm. Social and folk dancing, amateur theatricals and music are other group activities. Blind people can and do take active part in political and service organizations with sighted persons, and in this way not only serve their fellow members but also serve blind people by helping to overcome prejudiced thinking about blindness.

6. Social Adjustment. — There are situations in which the totally or almost totally blind person needs assistance from sighted people. These are fewer, however, than is commonly thought. Blind persons may be taught techniques for carrying on such routine tasks as housework, grooming. typing, handling of money and foot travel. After World War II a trend developed toward the establishment of rehabilitation centres where groups of blind people might learn such techniques. Permanent facilities for handling blinded veterans came into operation in various countries. and civilian centres were more or less patterned on experiences in these programs. An important offshoot was a systematic method for teaching cane travel techniques, especially in the United States. This involves some effort to teach the use of auditory and other nonvisual cues. as well as the safe and efficient use of the cane.

7. Dog Guides for the Blind. — Historically. many blind people are known to have relied in varying degrees on dogs for guidance and protection, but not until World War I, when the German government established a school for training such dogs. did this become an established method of travel. Only a fraction of the blind population, however, can use a dog guide successfully. Too much useful vision; advanced age or poor health. or unsuitable temperament are reasons for rejection of an applicant for a dog guide.

Dog guide schools exist in Great Britain, Italy, Switzerland, Germany and the United States (where the pioneer Seeing Eye, Inc., in Morristown, N.J., remains the best known). and trainees usually spend about a month in training with the already trained dog in order to achieve a good working relationship. In most schools the cost to the blind person is only a nominal part of the over-all cost of the dog and its training, and sometimes no charge is made to the individual.

II. UNITED STATES

The term blindness as commonly used in the United States means "central visual acuity not exceeding 20/200, as measured by the Snellen chart, in the better eye with correcting lenses; or central visual acuity greater than 20/200 accompanied by a limitation in the field of vision such that the widest diameter of the visual field subtends an angle no greater than 20 degrees." Stated simply, this means that a person is defined as blind if at a distance of 20 it. he can see what a person with normal vision sees at a distance of 200 ft., or if his field of vision is diminished to the point where the remaining sight is of limited value.

1. Prevalence of Blindness. — Because of difficulties in securing complete reporting in cases of blindness, and in providing medical diagnosis in each case to determine the existence of blindness, no exact statistics are available as to the prevalence of blindness in the U.S. On the basis of studies made in various representative areas, however. it is estimated that there are at least 330.000 blind persons. The number of children is comparatively small, less than 10% of the total; more than 50% of blind persons are over 65 years of age. Most studies show a larger number of males than of females among the blind. These figures indicate to some extent the problems facing those in charge of the education and the rehabilitation of the blind.

2. Education of Blind Children. — The young blind child requires special training before he reaches school age. Formerly there were residential nursery schools to which blind children were sent for such training. Later, emphasis came to be placed on keeping the child in his own home, if the home environment was at all satisfactory, so that the parents could provide the training needed. In a number of states trained workers are employed to advise parents on methods of training; in several states institutes for mothers of blind children are held, providing courses of lectures, consultation service on special problems, and demonstrations. In many localities, day nursery and kindergarten training are available to blind children, either in groups of other blind children or, preferably, together with sighted children.

Blind children of school age are educated in residential schools for the blind or in public or private schools with sighted children. In the 1960s about 55% of the country's blind children attended residential schools and the balance regular schools. The latter system was first introduced in 1900 in the public schools of Chicago, Ill., and it came to be accepted as an alternative educational system in all parts of the country. In some schools a special teacher is available during the entire school day; other school systems provide teaching service at intervals.

Some special educational methods and devices are necessary for the education of a blind child — the substitution of embossed type (read by touch, for reading and writing by visual methods, special mathematical apparatus. embossed and bas-relief maps. etc. In recognition of this fact, the U.S. congress in 1879 passed a law providing a federal grant to the American Printing House for the Blind in Louisville, Ky., to furnish books and tactual apparatus to blind school children on a quota system according to the number of children enrolled. The original appropriation was increased considerably over the years.

3. Higher Education. — Blind students seeking higher education attend regular colleges, universities and professional schools. The only special provision they need is some arrangement for having printed textbooks or other material read aloud to them. Most states provide funds for the payment of readers ior blind students. Of great importance also is the recording of textbooks done by organizations such as Recording for the Blind in New York city. Through the efforts of this and similar volunteer groups, student libraries of recorded textbooks are available. Some material in braille also is made available by volunteer transcribers.

4. Rehabilitation of the Adult **Blind.**—Work with the adult blind in the United States is of comparatively recent origin. Although there were a few workshops and boarding homes for the adult blind in the 19th century, little or nothing was done for the blind in their own homes and little recognition was given to those who lost their sight after reaching maturity. After the turn of the century it became increasingly recognized that with proper help in adjusting to their handicap, blind persons could lead normal active lives, could become self-supporting and need not be subject to segregation and dependency. This attitude was progressively strengthened through the interest taken by the federal government, which passed a number of legislative measures to enable the state governments to carry out a program of benefit to the adult blind.

The first state commission for the blind was established in Massachusetts in 1906, and eventually all states had agencies responsible for the welfare of the adult blind. These agencies are sometimes independent and sometimes divisions within the welfare or education departments. In addition, most large cities have privately supported agencies for the blind, which undertake to provide such services as the states cannot render effectively; their functions vary, but in general they supplement the activities of the tax-supported agency.

5. Vocational Opportunities. — It is commonly felt that at least 25% of the blind are employable and with appropriate training can become self-supporting. There are no special jobs for the blind. On the contrary. tens of thousands of blind persons are gainfully employed in all kinds of occupations. as farmers. salesmen. factory workers, secretaries, teachers. physicists. lawyers. etc. The choice depends primarily upon the qualifications of the individual—his abilities, aptitudes, education, personality and work experience.

The Vocational Rehabilitation act of 1920, amended in 1943 and in 1954, provides for federal funds to be expended for vocational

training and placement of physically handicapped persons, including the blind. The program is operated by the state under the administration of the office of vocational rehabilitation in the United States department of health, education, and welfare. Each year several thousand blind persons are placed in gainful employment.

There are, however, some blind persons who because of age or other limitations cannot compete in the general labour market. For them are provided special workshops or a home industries program. To facilitate the marketing of products made in workshops for the blind, congress in 1938 passed the Wagner-O'Day act, which requires that federal departments purchase brooms, mops and some 40 other approved articles from workshops for the blind at a fair market price determined by a committee appointed by the president of the United States.

6. Financial Assistance. — Blindness is so widely recognized as a cause of poverty that provision for financial aid to needy blind persons from public funds was one of the earliest forms of relief for the blind, the first state law being passed in Illinois in 1903. State after state followed the example, and in 1935 the federal government in title X of the Social Security act provided federal funds to help the states make adequate financial provision for their needy blind. Under this law each state enacts its own legislation and sets up its own administrative plan. Provided the state plan meets certain minimum requirements, the federal government pays four-fifths of the first $30 of the individual grants and 50%–65% of the balance within the federal maximum of $65 per month. In addition, the federal government pays half the administrative cost. In the early 1960s more than 100,000 blind persons received financial aid under this program. The average grant was $66 per month, but the amount varied considerably from state to state. The number of blind persons who receive direct financial aid is actually much higher, since many of them are included in the general old-age assistance program.

7. Other Provisions. — In recognition of the special expenses that blindness may entail, the federal government permits a blind person to take an extra exemption of $600 on his federal income tax and an added $600 exemption if his wife is also blind. Some states allow a corresponding extra exemption on the state income tax. and in many cases exemptions are allowed the blind person on his property tax. Some blind persons use a white cane as a mark of identification, and legislative measures in each state give a blind person carrying a white cane the right of way in traffic. In addition, a blind person with a guide may travel at the cost of one fare on most railroads and bus lines.

8. The Deaf-Blind. — It is estimated that about 6,000 persons in the United States have a serious hearing defect in addition to blindness. Deaf-blind children are educated in special departments in seven schools for the blind and one school for the deaf. Many adult deaf-blind persons are active in the professions or in industry. and many are employed in special workshops.

9. War-Blinded Veterans. — The federal government assumes full responsibility for veterans with service-connected blindness. A central physical medicine and rehabilitation unit is maintained at the Veterans Administration hospital at Hines, Ill., and domiciliary care is given at a number of Veterans administration hospitals throughout the country. The blinded veteran is entitled to receive vocational training, counseling and placement in a job, as well as a disability compensation according to degree of disability.

10. National Agencies. — The professional workers for the blind are represented by two national associations, the American Association of Instructors of the Blind and the American Association of Workers for the Blind. The National Federation of the Blind is an organization of blind people established to promote and improve social and economic conditions among the blind.

The American Foundation for the Blind, located in New York city, is a national nonprofit agency created to help those handicapped by blindness to achieve the fullest possible development of their capabilities and the maximum integration into the social and cultural life of the community. It serves as a clearinghouse on all information relating to blindness and co-ordinates the activities of other agencies for the blind. Among its activities are research, consultation and field services; publications of professional literature; special library service; and public education.

III. GREAT BRITAIN

In the United Kingdom there are two statutory definitions of blindness: (1) that applicable to children under the age of 16 is contained in s. 69 of the Education act, 1921, defining the word "blind" as meaning "too blind to be able to read the ordinary school books used by children"; (2) that applicable to adult blind persons is contained in the National Assistance act, 1948, defining "blind" as "so blind as to be unable to perform any work for which eyesight is essential." Interpreted in medical terms the latter definition means that a person is blind if his visual acuity by the Snellen tests is less than 3/60. Persons with vision from 3/60 to 6/60 may be blind if the field of vision is restricted or other complications are present.

By the early 1960s more than 90,000 blind persons were registered in England and Wales; 2,200 of these were under the age of 16; 77,000 were over 50 years of age, including 49,000 who were 70 years of age and over. The number of registered blind in Scotland was about 10,000. of whom 200 were under 16 years of age. In Northern Ireland approximately 2,600 were registered as blind. Thus it can be seen that blindness is especially associated with old age; and this is borne out by the fact that although after 1950 approximately 12,000 names were added annually to the blind register, the actual total of living persons on the list increased by an annual average of little more than 3,000.

The Blind Persons act, 1920, placed responsibility for the welfare of blind persons upon the state and local authorities (county councils and county borough councils) assisted by national, regional and local voluntary agencies, all working in close cooperation. This responsibility was reaffirmed and further amplified by the National Assistance act, 1948. The Blind Persons act, 1920, gave blind persons in need a noncontributory pension at the age of 50 similar to that received by the seeing at 70 and subject to the same means test. The age was subsequently lowered from 50 to 40. National assistance grants were made payable to those blind persons whose resources were inadequate, and such grants were made at a higher rate than those to the seeing in recognition of the extra living costs of blindness.

The National Assistance act further required that blind persons be given "instruction in their own homes or elsewhere in methods of overcoming the effects of their disabilities" and also that "recreation facilities shall be provided for them." Qualified home teachers visit the blind in their homes, ensure that they receive pensions and allowances, instruct them in the reading of embossed type, teach them handicrafts and assist in the disposal of the finished goods, arrange social gatherings and try in a variety of ways to brighten their lives. Home teachers are required to pass the examination of the College of Teachers of the Blind, which body also conducts examinations for school teachers, craft instructors and blind piano tuners.

Blind persons in need of residential accommodation were provided for under part III of the National Assistance act, 1948, such accommodation being provided either by local authorities or by voluntary agencies.

Blind persons who use a dog (which may be specially trained) as a guide or who possess a radio set were exempted from the obligation to pay for a licence; and the cost of the combined television-and-radio licence was reduced for them to the extent of the cost of a radio licence. (The British Wireless for the Blind fund, so far as its resources permit, provides a radio set on free permanent loan to every adult blind person in need of one.) Blind persons also were given permission to vote by mail in parliamentary or local elections or alternatively to have the help of a seeing person to mark their ballot. There are special postal rates for transmission of braille literature and apparatus for the use of the blind; and there are certain special travel facilities.

Members of the armed forces of the crown and the civil defense services who lost their sight on active service came under the special care of St. Dunstan's (founded in 1915 by Sir Arthur Pearson), which in the early 1960s was caring for about 2,000 blind men and women in the United Kingdom and about 600 overseas.

Braille plays an important part in the lives of the blind in both education and recreation. In addition to the various braille libraries and publishing houses in many parts of the world, there is also in London a students' library for the blind where a blind person who requires a specialized book for the purpose of pursuing his studies or following his profession may have it specially transcribed into braille.

Talking books are increasingly used by many blind persons. Books are recorded on long-playing records and issued as a library service for use on specially designed reproducing machines.

1. Education. — There were about 600 blind children under the age of five in the early 1960s. For the early training of those remaining in their own homes. parents are assisted by home teachers of the blind and by the Royal National Institute for the Blind (R.X.I.B.). A child who cannot be satisfactorily cared ior at home may be admitted to one of the nine residential Sunshine Home Nursery schools, maintained by the institute. Two of these schools cater especially to retarded blind children.

The education of blind children from age j to 16 was made compulsory in England and Wales in 1893 and in Scotland in 1890; it is also compulsory in Northern Ireland. The first British school for the blind was opened in Liverpool in 1791, and there were 13 residential schools in the United Kingdom after World War II. In these the education given conforms as nearly as possible to that in a school for the seeing. Braille is used for reading and writing, and special apparatus is supplied for teaching mathematics and geography. Physical education plays an important part in the curriculum. As in schools for the seeing, there is a break at age 11 or above. the child of average ability passing to a senior school and the boy or girl of exceptional promise going on to one of the two residential grammar schools, Chorleywood college for girls and Worcester college for boys, administered by the R.N.I.B. At these two grammar schools general education normally continues until the age of 18 in preparation for entrance to a university or for professional training. There is also a senior selective school, the Royal Normal college, where general education is continued up to the age of 16 and then succeeded by trainirig in some branch of music, piano tuning or shorthand and typing. The blind child who is also deaf. crippled, maladjusted or mentally or physically retarded may receive education between the ages of 8 and 16 at a special residential school established by the R.S.I.B. in 1948 Mentally defective blind children were provided for under the National Health Service act of 1946.

For a blind boy or girl leaving school at 16 or 18 years of age the education authority normally offers training, retaining responsibility for such training up to the age of 21. For the further education of blind adolescents. a first establishment was opened in 1956, with the purpose of "bringing the adolescent to a point at which a definite choice of a vocation could be made."

2. Rehabilitation, Training and Employment. — During World War II, when many civilians lost their sight as a result of enemy action, three residential centres of rehabilitation were established for the newly blind in England. A fourth was opened in Scotland in 1952. At these centres any newly blinded civilians may undertake a period of either prevocational or social rehabilitation.

Responsibility for vocational training and employment of the blind was made jointly that of the local authority and the ministry of labour under the Disabled Persons (Employment) act of 1944. In the case of those destined for sheltered employment, training is usually carried out at a workshop for the blind; in the case of those entering industry. commerce or one of the professions, it is provided at one of the ministry of labour's government training centres, at a school for blind shorthand-typists and telephone operators, at a school for physiotherapy or, sometimes, at a sighted professional training college. Local authorities frequently delegate the task of placing blind persons in industry, commerce or the professions to a specialized national placement service such as that operated by the R.N.I.B. In addition, a number of sheltered workshops for the blind carry on such trades as the making of baskets, brushes. mats, mattresses, wire goods. woodwork, soap and plastic moldings; they also carry out chair caning. piano tuning, shoe repairing, machine knitting and weaving. Trained workers living at a distance from a workshop are sometimes given employment in their own homes at piecework rates plus augmentation of wages. By the early 1960s about 12.000 blind persons were in employment: about one-third of these were engaged in sheltered employment in workshops and as home workers. the remainder in a variety of professional, commercial or industrial occupations (*e.g.*, lecturers. lawyers, ministers of religion, teachers. physiotherapists. home teachers of the blind, musicians, shorthand-typists. telephonists or factory operatives).

IV. COMMONWEALTH OF NATIONS

In the commonwealth, outside of the United Kingdom, for obvious reasons, there has not been a similar tradition of voluntary social service; nor has the development of local government followed any set pattern. In some of the dominions blind welfare work is hampered by the wide distribution of the blind and by the difficulty of correlating welfare agencies over great distances.

1. Canada. — In Canada, several residential schools have been established for the education of blind children, and some blind children also receive instruction in special day-school classes in the public schools. The dominion and provincial governments give financial aid to the needy blind.

The Canadian National Institute for the Blind is organized to give every possible type of service.to the adult blind, including the training and aftercare of the war-blinded. By the early 1960s it had registered more than 22.000 blind persons and administered nation-wide library services, home teaching, workshops, home-workers' schemes, vocational training and placement service. The institute was organized in 1918 in Toronto, Ont. An Ontario division and national headquarters were first set up in that city, and gradually the work was expanded through the establishment of two divisions to cover the four western provinces, one division in the province of Quebec and a division covering the three maritime provinces. Later a Newfoundland division was organized, and a British Columbia division was made independent of existing western divisions. A common administrative pattern is observed by all divisions. Each of the provincial divisions is represented on a central national council. A board of management comprising local men and women, both blind and sighted, interested in the blind of their community. voluntarily give advice, guidance and support to the work. It is the responsibility of the board in each division to see that every possible service is rendered to the blind, and to arrange for funds to meet the cost. A divisional superintendent and staff are employed for each division.

In order to make sure that the blind in smaller places or rural districts receive the same service as those in the larger centres, field secretaries are informed and local voluntary advisory boards and committees have been set up. It is the duty of the field secretary to familiarize each blind person in his district with his legal entitlements and the services available from the institute and to arrange for the services that might be beneficial.

The Canadian Council of the Blind is an organization cooperating with the Canadian National Institute for the Blind. Clubs of the blind in all principal cities of Canada are members and are represented on the parent body. Financing of individual club activities is met by the various divisions; that of the council is met by the national headquarters of the Canadian National Institute for the Blind.

2. Australia and New Zealand. — In New Zealand, where national voluntary activity is centred in the New Zealand Foundation for the Blind. and in Australia, where voluntary organizations exist in most states, pensions for the blind have been enacted as part of the general social security legislation. In 1953 most of the statewide and local organizations in Australia entered into a voluntary agreement for co-ordination of their activities through the creation of the Australian National Council for the Blind. while those specializing in the education of blind children formed the Australian Association of Teachers of the Blind.

3. Ceylon.—A 1953 United Nations survey estimated that there were at that time 14.000 blind persons in Ceylon. A government-recognized National Council for the Blind and Deaf maintains a

school for blind children, which was originally operated under missionary auspices, in Colombo, and a branch of the school in the northern province of Jafna. Adult services under the council's administration include vocational training, sheltered workshops, co-operative housing schemes and home industries.

4. India. — Blindness constitutes a vast and complex problem in India. which has a blind population estimated at 2,000,000. The central government's responsibility for the education and rehabilitation of the blind rests with the ministry of education, which expanded its budget during the 1950s and made further increases within the framework of the second and third five-year plans. The major purposes for which central government funds are used are (1) operation of a training centre for blind adults at Deradun; (2) maintenance of a printing plant and manufacturing centre for braille appliances at the same location; and (3) provision of cash grants to schools and agencies for the blind operated by state governments and voluntary agencies.

By law each state is responsible for providing or arranging for educational services for blind children. Under the terms of the law, many of the schools originally established by missionary bodies or other voluntary agencies were taken over by state governments, which continue to operate them, using state funds plus subsidies from the central government. Most of the services for blind adults (with the exception of the central training centre) are operated by voluntary agencies, some of which receive limited assistance from state governments and occasionally the central government, particularly for building purposes. The major portion of their funds, however, are obtained from public contributions.

The total of state and voluntary organizations throughout India exceeds 50 in number. In an effort to provide a means of national co-operation, an All India Conference on Work for the Blind was called in 1952, and this led to the creation of the National Association for the Blind (N.A.B.). Most of the agencies for the blind are affiliated with the N.A.B., which is responsible for promoting interest in the problems of the blind and in prevention of blindness, as well as for the maintenance of international contacts.

5. Pakistan. — Pakistan, with an estimated blind population of 400,000, has several schools for blind children and one centre for the training and employment of blind adults. Although most of these societies are recognized by and receive subsidies from the central or provincial governments, all are operated voluntarily. On recommendation of a United Nations survey completed in 1955, plans were made for the formation of the West Pakistan Blind society, to discharge certain centralized functions such as the production of braille. In 1957 first steps were taken toward the creation of the All Pakistan Federation for the Blind, to provide national co-ordination and to represent the blind welfare interest of Pakistan internationally.

6. Malaya. — Malaya, with an estimated total of 14.000 blind citizens, maintains schools for blind children at Penang (opened in 1926) and Johore Bahur (founded in 1955). The work of governmental and voluntary bodies is co-ordinated by a blind-welfare officer within the department of welfare. This joint activity led to the creation of the Gurney Training centre for blind adults at Kuala Lumpur, two smaller training centres in outlying districts and a large agricultural training centre outside Kuala Lumpur.

7. Other. — In the newly independent dominions and the non-self-governing territories of the British commonwealth most schools and other activities for the blind were originally launched under missionary auspices with little or no governmental or local support. Following a survey of the British colonies under the joint sponsorship of the colonial office and the Royal National Institute for the Blind, it was recognized that governmental and voluntary authorities in the United Kingdom should join in partnership with private groups in the colonies to promote more effective, co-ordinated services. In 1950 the Commonwealth Society for the Blind (then known as the British Empire Society for the Blind) was created to meet these objectives, and in the succeeding years great progress was made. Joint action was undertaken in countries of Africa, the Caribbean, the Mediterranean and the near and far east, with local participating organizations bearing a considerable proportion of financial and administrative responsibility. Approximately 1,000,000 blind persons reside in the British territories, with the greatest concentration in west Africa, where there are an estimated 335,000.

In the nonself-governing territories where formerly there was little organized work for the blind, the foundations have been laid for permanent systems of blind welfare, and many new schools and training centres have been established. The number of blind students and workers has multiplied, braille alphabets have been devised for practically every written language, and blind welfare workers from 25 countries have gone to the United Kingdom for training. Surveys to reveal the extent and causes of blindness have been conducted in areas containing 27,000,000 inhabitants, and research work has brought within reach methods of controlling blinding diseases.

With the emergence of former colonies to the status of self-governing dominions, recognition was given in 1957 to the need for constructing an interlocking framework of services for the blind throughout the commonwealth. Ghana, for example, which became an independent republic in 1960, had a population including 65,000 blind persons. A plan therefore was approved for the introduction of a program of mutual assistance. with some of the more highly developed dominions joining with the United Kingdom in providing funds, experienced workers, special appliances and other forms of technical assistance to certain of the younger dominions and those colonies whose total emergence had not yet been achieved.

In the former member of the commonwealth, the Republic of South Africa, work for the African and European blind is undertaken by a number of voluntary organizations, whose work is co-ordinated through the South African National Council for the Blind in Pretoria. The largest single organization is the Transvaal Society for the Care of the Non-European Blind, whose voluntary activities are maintained by societies located in some of the states of the union. A large eye hospital and ophthalmic research centre is maintained in Johannesburg under the direction of the Order of St. John of Jerusalem. Considerable emphasis in the national program is placed on prevention of blindness and restoration of vision where possible. The work of large eye hospitals in principal cities is supplemented by that of clinics in strategic locations and the operation of mobile eye units. Efforts are also being made to expand services for the training and resettlement of blind Africans in rural occupations and for integrating them into normal life.

V. OTHER COUNTRIES

A. Europe

1. Austria. — Austria, with a blind population of approximately 4,000, has several residential schools for the education of blind children. Great interest has been shown in industrial placement and in opening up of new vocational avenues for the blind. The Federation of Austrian Organizations for the Blind mas established to unify the work of the various agencies as well as to conduct other cultural and practical activities. Work for the blind and its physical facilities suffered severely after the German *Anschluss* and during World War II. among the casualties being the world-famous library on blindness in Vienna.

2. France. — France, which observes a stricter definition of blindness than that of most western countries, has a blind population of approximately 45.000 within its definition. Under an ordinance of July 3. 1945, "those whose central vision is nil or less than 1.20 of normal" are considered blind. There were in the early 1960s, 35 schools for the blind in France; most of them may be defined as charitable institutions furnishing general education and vocational training to the blind of school age. The nationally supported school is the Institution Nationale des Jeunes Aveugles in Paris.

Traditionally the principal effort for aid of the adult blind in France has been the maintenance of residential homes and the operation of sheltered workshops in which the blind are employed principally in the manufacture of brooms and brushes. Approximately 50 institutions of this type are located throughout France, mainly under voluntary or ecclesiastical support. Many French workshops for the adult blind have facilities for permanent shelter

for a certain number of blind persons who cannot become self-supporting. The American Foundation for Overseas Blind, Inc. (A.F.O.B.), extends cultural and vocational aid to the blind through the publication of a braille magazine and the manufacture of braille slates and other equipment. Under the auspices of the A.F.O.B., a Central Committee for Blind Workers was established in Oct. 1946 to co-ordinate the distribution of raw materials to workshops and blind workers and to promote the sale of blind-made products.

A growing recognition of the ability of the blind to compete satisfactorily with the sighted in open employment led to the creation in Paris of an industrial vocational training centre where blind adults are trained for occupations in industry and commerce, particularly for light engineering, braille shorthand-typing and telephone switchboard operation. Maintained under the joint sponsorship of the French department of labour and voluntary organizations, this program also provides placement and post-placement follow-up services.

The National Committee for the Social Protection of the Blind co-ordinates the work of public and private agencies. Representatives of the most active national and regional organizations working on behalf of the blind serve on this committee.

In the field of service to the adult blind the three French organizations with national responsibility are: (1) the Valentin Haüy association, founded in 1889 by a blind man, Maurice de la Sizeranne, which boasts a library of 125,000 volumes, mostly hand-copied books; (2) the Federation of Civilian Blind of France and Colonies, including about 30 provincial associations forming a representative group of blind people; and (3) the Union of French War Blind, founded in 1918, for the benefit of those who lost their sight in combat.

3. Germany. — In 1954 responsible authorities in west Germany indicated that there were 35,000 blind persons among the residents of the German Federal Republic. Scant information is available on the German Democratic Republic, but it is estimated that the blind community there numbers approximately 15.000.

Prior to World War II Germany had a well-organized educational and welfare system for its blind citizens. Education of blind children was carried on in 25 publicly supported residential schools for about 2,700 pupils. There was also a special institution for blind university students, combined with a braille library. The two largest braille libraries were located in Hamburg (39,000 volumes) and Leipzig (26,000 volumes). World War II completely changed the status of the blind. Many schools and workshops were entirely destroyed (Diiren, Soest, Hamburg), others were heavily damaged and only a few remained intact. After the war, educational authorities as well as associations of the blind became active in reconstruction work for the blind. As a first step regional organizations were created in the U.S., British and French zones of occupation, these later becoming a national organization when the Federal Republic was established. Schools, training centres and workshops were reconstructed, and great strides were made in providing legislation to meet the economic needs of the sightless and to encourage the placement of the blind in industrial and commercial occupations. The principal organizations with national responsibility in the Federal Republic are the Union of the War Blind of Germany, the Union of the German Blind, the Association of Blind Intellectual Workers and the German Association of Teachers of the Blind.

4. Italy. — The Italian blind population was estimated by national authorities to be 50,000 in 1954. The Unione Italiana dei Ciechi (founded in 1920), which works in co-operation with various government departments and maintains branches in all regions of the country, is the chief agency. The union participates in the direction of services for employment of the blind through the Ente Nazionale di Lavoro per i Ciechi. National co-ordination of programs for the education and vocational and professional training of the young blind is provided by the Federazione Nazionale delle Instituzion Pro-Ciechi. In 1955 the Opera Nazionale per i Ciechi Civili was created by the Italian government to implement statutory policies related to services for the blind.

5. Netherlands and **Belgium.**—In the Netherlands (5,000 blind population) and Belgium (6,000) work for the blind is of a generally high standard. Well-organized institutes for the blind are found in Amsterdam, Zeist, Grave, Brussels, Bruges, Mons and Liège.

In 1956 the Netherlands government adopted legislation providing for extended economic assistance to the blind and for more complete facilities for the location, registration, rehabilitation and placement of the sightless. These services are maintained in co-operation with the Netherlands Foundation for the Blind and the Union of the Blind, which are the country's principal voluntary organizations. In Belgium the principal voluntary organization is the Ligue Braille.

6. Scandinavia. — In Sweden (6,000 blind population), Norway (2.500) and Denmark (4,000) the generally advanced state of work with the blind is attributed in a large measure to the initiative and energy of the blind themselves. In all three countries and in Finland (4,200 blind) there exist strong associations of blind persons that advise and co-operate with the government authorities. In Sweden grants to the blind are given as old-age pensions (for those who are over 67 years of age) or as invalidity pensions (for persons under 67 years who are unable to work because of physical conditions). The amount given as invalidity pensions varies according to the blind person's income over and above a certain sum. In addition there is a flat blindness compensation and a residence subsidy to offset regional differences in the cost of living.

In Denmark a similar system is maintained, invalidity pensions being granted to all categories of severely handicapped citizens, including the blind, with a fixed amount being paid to all blind persons to offset increased living costs imposed by the handicap. In 1957 refinements to the law were adopted, including the creation of an appeals board to review grievances. In Finland the handicap allowance increases as the pensioner returns to active life and ernployment, thus serving as an incentive to speedy rehabilitation.

7. Spain. — In Spain (28,000 blind population) all agencies for the education and welfare of the blind were merged into a National Organization for the Blind, which serves as the official agency of the ministry of the interior. This organization conducts regular national lotteries, the majority of the blind population being employed in lottery offices or as ticket sellers. All profits are used for the operation of training centres, workshops, braille printing departments, schools and welfare facilities for the blind.

8. Switzerland. — In Switzerland (blind population 3,000) the schools and residences for blind children and adults are operated almost entirely by private agencies, although some receive governmental subsidies. Efforts toward expansion of vocational opportunities, dissemination of braille and recorded literature and improvement of economic provisions for the blind are carried on by two national organizations composed of blind members, the Swiss Central Union for the Blind and the Swiss Federation of the Blind.

9. **U.S.S.R.**—According to available information, the government of the U.S.S.R. has shown great interest in its blind citizens, including the large number who lost their sight during World War II. Special efforts have been made in regard to vocational training and placement in jobs.

B. Far East

In the far eastern countries blindness is much more prevalent than in most of Europe and America. Statistics are unreliable, but it is estimated that 75% to 80% of the world's sightless people reside in the countries of Asia. Modern blind welfare work has affected only a minute section of this blind population. The initial work was started in the latter part of the 19th century by missionaries and philanthropists. After World War II, however, an encouraging growth of interest and initiative on the part of governments was noted.

1. Burma. — St. Michael's School for the Blind, the first to exist in Burma (estimated blind population 50,000), was established in 1914, when a small group of blind children was gathered in the mission compound; in 1917 Father William Henry Jackson, a blind Anglican missionary, arrived to supervise the establishment of a school, which he guided until his death in 1931. Prior to World War II its services had expanded by the introduction of a voca-

tional training department. the operation of sheltered industrial workshops and the creation of a school for the education of blind girls at Maektilla. This latter school was destroyed during the war, while others were seriously damaged Another voluntary organization, St Mary's Workshop for the Blind. was founded in 1955 to expand employment opportunities. Under government sponsorship the National Council for the Blind was created in 1957 to prepare plans for extending national services for the blind by governmental and voluntary action. These plans were based upon recommendations resulting from a United Nations survey of blindness in Burma in 1953.

2. China.--Many of China's vast blind population, estimated at 2 000.000 to 3,000,000. have traditionally lived by practising fortune telling. Some blind persons have been able to obtain a place for themselves as musicians and in the professions, while a comparative few are known to be employed at manual operations in sheltered workshops. The larger number, however, have turned to begging.

The first school for the blind in China was started in Peking in 1876 by William Hill Murray of the Scottish Bible society. Murray was the inventor of a Chinese system of braille, but his system was later supplanted by the Union Mandarin braille which has been accepted nherever Mandarin is spoken. A unique braille system for the Cantonese dialect later evolved by Mary West Niles is in use.

In 1947 a survey of the condition of the blind mas made for the government of China and recommendations were submitted for a national program of education and welfare. This survey revealed that at that time only about 30 schools and agencies for the blind were in operation throughout China, with a total enrollment of less than 3,000 blind persons. Among the most active' in addition to the Peking school, were the Ming Sum School for Blind Girls in Canton the David Hill School for Blind Boys in Hankow and the Institution for the Chinese Blind, founded in Shanghai in 1912 by John B. Fryer.

Little reliable information is available from the Chinese People's Republic.

The government of the Republic of China in Formosa assumed responsibility for education of blind children maintaining provincial schools at T'ai-pei and T'ai-nan. Under the voluntary Committee for the Blind of Formosa. programs for the training and employment of the blind in industrial and agricultural occupations and for the manufacture of braille literature mere introduced. Braille library services and welfare activities were maintained by the Taiwan Association of the Blind. An effort to reduce the incidence of blindness by elimination of trachoma among children was undertaken in the 1950s and 1960s by co-operation among the Nationalist government. the United Nations Children's fund (TSNICEF), and the World Health organization (WHO).

3. Indonesia.— A 1953 United Nations report stated that according to accepted medical opinion the number of blind in Indonesia was approximately 600,000. This figure places Indonesia among the countries with the highest incidence of blindness in the world In 1902 the Institute for the Blind in Bandung was founded by the Society for Improvement of the Fate of the Blind in Indonesia. Under a Dutch board of directors. the institute during its first 40 years offered a basic program of education and training in a compound accommodating both children and adults. Later the institute became a colony for the destitute and a haven for many blind beggars, and this led to many difficulties in management. A number of professional workers trained abroad in the 1950s began, with government assistance, to endeavour to improve the general standard. and training centres for the adult blind were opened in eight inland cities.

4. Japan.— The condition of the blind in Japan, conservatively estimated to number more than 150.000. perhaps has been happier than anywhere else in the east. This is largely attributed to the fact that the professions of massage. moxibustion and acupuncture became a monopoly of the blind in the 9th century. when Prince Hitoyasu, the young son of the 54th emperor. lost his sight and influenced his father in favour of the blind. These special privileges were abolished with the Meiji restoration in 1868, but the tradition persisted and the number of blind masseurs is still large. Blind Japanese are often gifted musicians, and the blind musicians' guild as well as the blind masseurs' guild has held considerable power. The pioneer modern school for the blind mas opened in Kyoto in 1876, followed by the Tokyo School for the Blind (later called the National School for the Education of the Blind) four years later. By the 1960s there were about 90 schools for the blind in Japan. In the most progressive of them, students are taken from kindergarten through high school; in several, normal school training is also offered. In 1932 by edict of the emperor the education of the blind was required to conform to that available to sighted children, and in 1948 the education of the blind became compulsory by law. By the 1960s there were more than 70 residential schools. with an enrollment of over 5.000, and several other organizations, including three government rehabilitation centres, providing training and welfare facilities for blind adults. Financial provisions for the needy blind were made under the 1948 act for welfare and rehabilitation of the handicapped. Many problems persist. particularly the need for exploiting new areas of employment to supplement the traditional arts of music and massage. Three national organizations were created: (1) the Japanese United Association of the Blind. composed of blind persons resident in all parts of the country; (2) the Association of Educators of the Blind, made up of representatives from almost all of the country's schools; and (3) the Association of Welfare Institutions, whose membership contains those specializing in the care and rehabilitation of the adult blind. Delegates from each of these organizations comprise the National Committee for the Welfare of the Blind of Japan. which, together with the American Foundation for Overseas Blind, sponsored the Far East Conference on Work for the Blind. held in Tokyo in 1955. Two centres for manufacturing aids and appliances, two national braille libraries and three university courses for training teachers of the blind contributed substantially to the growth of Japan's service program for the sightless.

5. Korea.——Nearly 100,000 blind persons live in Korea, about 60.000 being located in the Republic of Korea. Modern work for the blind in Korea was started with the establishment of a school at Pyongyang city. In 1945 the Taegu school for the blind and deaf was founded and has grown substantially; it serves as the national centre for braille book production. In the 1950s other schools, some also providing for vocational training of adolescents and adults. came into being at Chunju, Pusan, Iri, Mokpo, Quanju and Chaejudo. A feature of the expanding program in South Korea is the vocational training and employment project at Taejon, where a school and other welfare facilities for the blind also are maintained. The Advisory Committee on International Aid to the Blind nas formed in 1957 to further and co-ordinate the Republic of Korea's program for the blind and to expand the country's international participation.

6. Philippines.— In 1955 the government of the Philippines reported a blind population of 50.000. The country's first service to the blind. a school providing for the education of deaf as well as blind children, mas established in 1908. This school later found it practical to emphasize the education of the deaf, and this caused the government to give consideration to a plan for the admission of blind children to the general education system, such pupils receiving special services from trained itinerant teachers.

In 1957 an adjustment centre for the blind and other severely handicapped persons was opened in Manila by the government social welfare administration, with direction provided by the American Foundation for Overseas Blind. The centre offers a program of training and work experience for more than 60 blind persons and is serving the far east as a teaching and demonstration unit for preparing instructors. With establishment of rehabilitation services for the blind in Manila, active steps were taken to create commissions for the blind in each province of the republic. Such provincial commissions are in operation in several cities.

7. Thailand.— Thailand, with an estimated blind population of 65,000, has only one school for blind children and no organized program for the training, employment or welfare of the adult

blind. The school in Bangkok. founded in 1937 by a blind American. Genevieve Caulfield, is administered by a Foundation for the Welfare and Education of the Blind and in the early 1960s had an enrollment of 130 pupils.

8. Vietnam. — Itis estimated that the blind population of North and South Vietnam totals more than 60 000. Prior to the division of the country in 1954. Hanoi served as the national centre of work for the blind. a good residential school for blind children having been maintained there under the French colonial administration. In South Vietnam the school for the blind has an enrollment of about 50 students and provides academic studies, music and vocational training. Late in 1957 plans were completed for opening a small school in Saigon for the education of blind girls, the government providing assistance to this voluntary project.

C. Middle East

A relatively high incidence of blindness has been recorded in many areas of the middle east, and it is estimated that there are approximately 500,000 blind persons living in the region, including those in Egypt and Turkey.

As in the far east, the introduction of services for the blind in the middle east during the late 19th and early 20th centuries is mainly traceable to western missionaries. During the decades after 1940 a noticeable growth of interest among government and local groups was noted. such schools as the Ala-Iya School for the Blind in Jordan, the Queen Huziymah Institute in Iraq. the Ankara Blind School in Turkey and several in Egypt being placed under the jurisdiction of government educational and social welfare agencies. In other cases—such as the British Syrian and Swiss Armenian schools in Lebanon, the School for the Blind in Isfahan, Iran, and three small institutions in Jordan—the work of voluntary and missionary groups continued, although in most instances a degree of government recognition or subsidization was enjoyed.

A particularly significant development was the creation of a middle east demonstration project for the blind in Cairo. Opened in 1953 under the joint auspices of the Egyptian government and the United Nations, with assistance from international voluntary groups, the project serves as a focal point of the Egyptian program while being utilized as a training centre for professional workers from other Arab countries. The operation of this project caused acceleration in developments in other countries, particularly Lebanon and Syria.

In Israel (blind pop. 4,500), a residential school for blind children has existed in Jerusalem for many years, and sheltered workshops for the employment of adult blind are maintained by voluntary organizations in several cities.

Turkey also developed its training program for teachers of the handicapped, including the blind. Braille printing centres supplying school textbooks and other literature for the region are located in Egypt, Jordan and Turkey and in Jerusalem.

D. Latin America

Although few of the countries of Latin America publish reliable statistics on the incidence of blindness, it is estimated that close to 500,000 blind persons live in the area that includes Mexico, the Central American republics and the continent of South America. The earliest-known services to the blind in the region were introduced under government auspices, while certain orders of the Roman Catholic Church have made and continue to make noteworthy contributions to the operation of such services, particularly in the education of blind children. The schools having longest history of service in this region are the Instituto Benjamin Constant in Rio de Janeiro, Braz. (1854), the School for the Blind in Mexico City (1866), the School for the Blind and Deaf in Buenos Aires (1888) and the National School for the Blind at Santiago, Chile (1890).

While existing services are inadequate to meet the total need, many new activities were launched after the 1920s and every country of the region maintains some service for the sightless. There is a tendency toward co-operation among the countries, exemplified by the 1954 Pan-American Conference on the Welfare of the Blind and the Prevention of Blindness, held in São Paulo, Braz.. at which resolutions were adopted for region-wide activities to meet the most pressing needs. Subsequently a regional program for the training of teachers of the blind was introduced at the University of Chile, Santiago, in April 1955.

In Brazil there are two braille printing plants, one in Rio de Janeiro at the Instituto Benjamin Constant and the second and most active, operated by the Fundação Para o Livro de Cego no Brasil, in São Paulo. These organizations publish only Portuguese braille. Argentina has one large plant that publishes a braille magazine and a few books. Uruguay manufactures machine-made books, and Peru has a small hand-operated plant that can supply enough books for classroom use in the national school but does not have the capacity for publication of a wide variety of literature for adults. Both Chile and Bolivia have small hand-operated presses.

The Centro Editorial Braille in Mexico City, with the assistance of the Kellogg foundation and the American Foundation for Overseas Blind, improved and enlarged its printing plant in the 1950s. The dissemination of braille literature in Latin America mas greatly facilitated by a uniform braille code evolved during a United Nations Educational. Scientific and Cultural organization (UNESCO) braille conference held at Montevideo, Urug., in Dec. 1951.

Braille library services are maintained in Argentina, Mexico and Brazil. Services for the training and employment of the adult blind have traditionally followed the early European pattern and the Spanish practice of using the blind as lottery ticket salesmen. After 195j Brazil endeavoured to expand employment opportunities and particularly to encourage placement of the blind in industry. In 1957 an International Labour organization (ILO) consultant was assigned to accelerate the pace of this development. Simultaneously new services for the social and vocational rehabilitation of the newly blind were introduced in Chile and Mexico. It being recognized that many Latin-American countries are non-industrialized, sheltered employment will doubtless continue to provide most job opportunities for the blind. Existing workshop practices require modernization, and an interesting program to that end has been introduced in Guatemala.

VI. INTERNATIONAL CO-OPERATION

After World War II many important international developments helped in the progressive development of services for the welfare of the blind throughout the world. As a result of a resolution adopted at the 1949 International Conference of Workers for the Blind at Oxford, Eng., the World Council for the Welfare of the Blind (W.C.W.B.) came into being in July 1951; its purpose was to provide the means of consultation among organizations of and for the blind in different countries, and wherever possible to promote joint action toward the introduction and improvement of minimum standards for the welfare of the blind in all parts of the world.

In the same year the World Braille council was formed at the conclusion of UNESCO's exploratory work for the unification of braille throughout the world. This council later became part of the World Council for the Welfare of the Blind as did the International Conference of Educators of Blind Youth, which arranged world conferences of educators in 1952 and 1957. World Council for the Welfare of the Blind, with over 40 countries in membership, also maintains standing committees on technical appliances, prevention of blindness, professional and urban employment, services to the deaf-blind, rural activities. far east, south and southeast Asian affairs and Pan-American affairs.

The council enjoys consultative status with the United Nations, UNESCO, ILO and UNICEF, and as a member of the Conference of World Organizations Interested in the Handicapped plays a part in the United Nations co-ordinated program for rehabilitation of the handicapped. In co-operation with international governmental and nongovernmental organizations and the local governments concerned, regional conferences on the welfare of the blind were held in São Paulo for the Pan-American region in 1954 and in Tokyo for the far east region in 1955; a seminar on rehabilitation of the blind for European countries was held in London in 1956. An international conference was held in Paris in 1954 for the purpose of evolving a world-wide system for the application of braille

to music of all cultures; UNESCO, World Braille council and World Council for the Welfare of the Blind co-operated in this venture, the latter publishing its international braille music manual in 1957.

The American Foundation for Overseas Blind, established in 1915, a United States private philanthropic organization, maintains a continuing program of aid to governmental and nongovernmental agencies for the blind throughout the world, including consultant service, fellowships, production of literature in braille and talking book form, establishment of demonstration projects and provision of technical equipment. With its world headquarters in New York city, the American Foundation for Overseas Blind maintains regional offices in France, Chile and the Philippines. Similar services are extended to colonial and former colonial territories by the Commonwealth Society for the Blind, established in 1950, whose headquarters are in London.

BLINDNESS, the inability to see. This article is confined to a discussion of the causes of blindness and agencies whose purpose is to combat it. The entire subject of sight and its mechanisms is discussed in the article VISION OR SIGHT. Diseases of the eye are discussed in EYE, HUMAN, as is the anatomy of the eye. See also articles on diseases sometimes responsible for blindness—as DIABETES MELLITUS; LEPROSY; TRACHOMA; etc.—and on related subjects: as COLOUR BLINDNESS. Blindness as a sociological and educational problem is discussed in BLIND, TRAINING AND WELFARE OF.

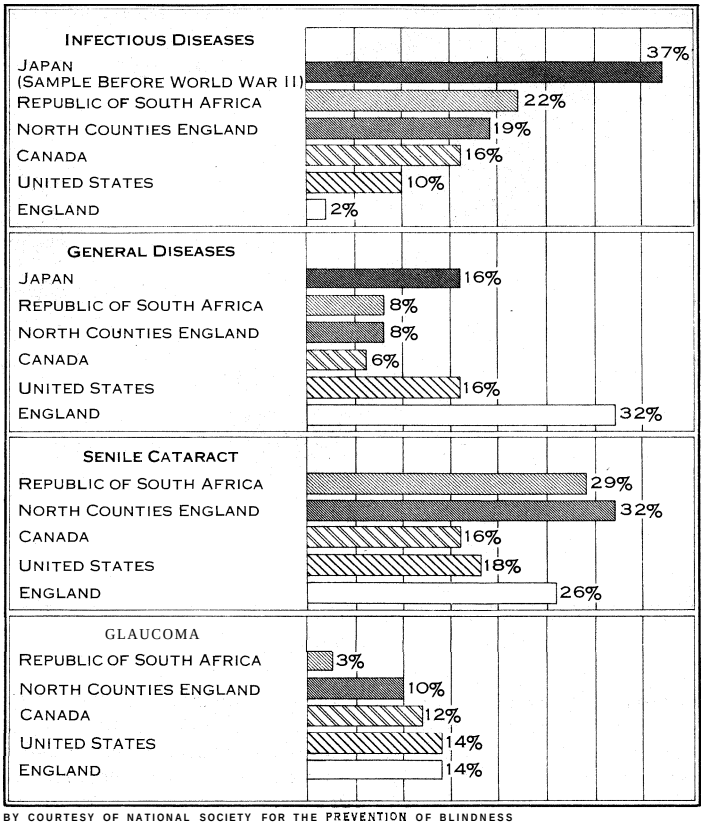
The eye functions as a mechanical device, like a camera taking pictures, but at the same time it is a living organism. As a mechanical device it must contain all essential parts, properly constructed, placed and interconnected so that it may function efficiently as the organ of sight. As a living organism, the eye is composed of parts that are actually tissues, blood vessels, muscles and nerves, similar to those found elsewhere in the body. Their vitality, and hence their function, is maintained by proper nourishment and protection from disease or injury.

Affections of the eye are diagnosed both in terms of what happens to the eye (where it is affected and the nature of the affection) and what causes it to happen (etiology). In general. the part affected and the nature of the condition determine the amount of sight lost; the underlying cause is important both in treatment and in determining the methods of prevention by which individuals or groups may be protected from loss of sight. Etiological factors are of major importance in the prevention of unnecessary blindness.

CAUSES OF BLINDNESS

The causes of blindness, like causes of illness or death, may be classified under a few general groupings. Blindness may be due to an infectious disease, to some general systemic disease, to injury or poisoning, to a tumour or to heredity or some other influence operating before birth. There are some eye diseases the causes of which are unknown. Further, only in more advanced countries can the average blind person be examined by an ophthalmologist (eye physician) to determine the cause of his blindness. In spite of the scarcity of statistics on causes of blindness, however. it is possible to bring together facts from many sources and to determine the nature and approximate size of the more important problems.

The amount of blindness, as well as the relative amount due to various causes, differs markedly in time and place (see fig. 1). As medical science provides knowledge of how to control certain diseases, blindness from these causes decreases. Climate, terrain and availability of good medical care also influences rates. The effect of both time and place can be seen in comparisons of causes of



BY COURTESY OF NATIONAL SOCIETY FOR THE PREVENTION OF BLINDNESS

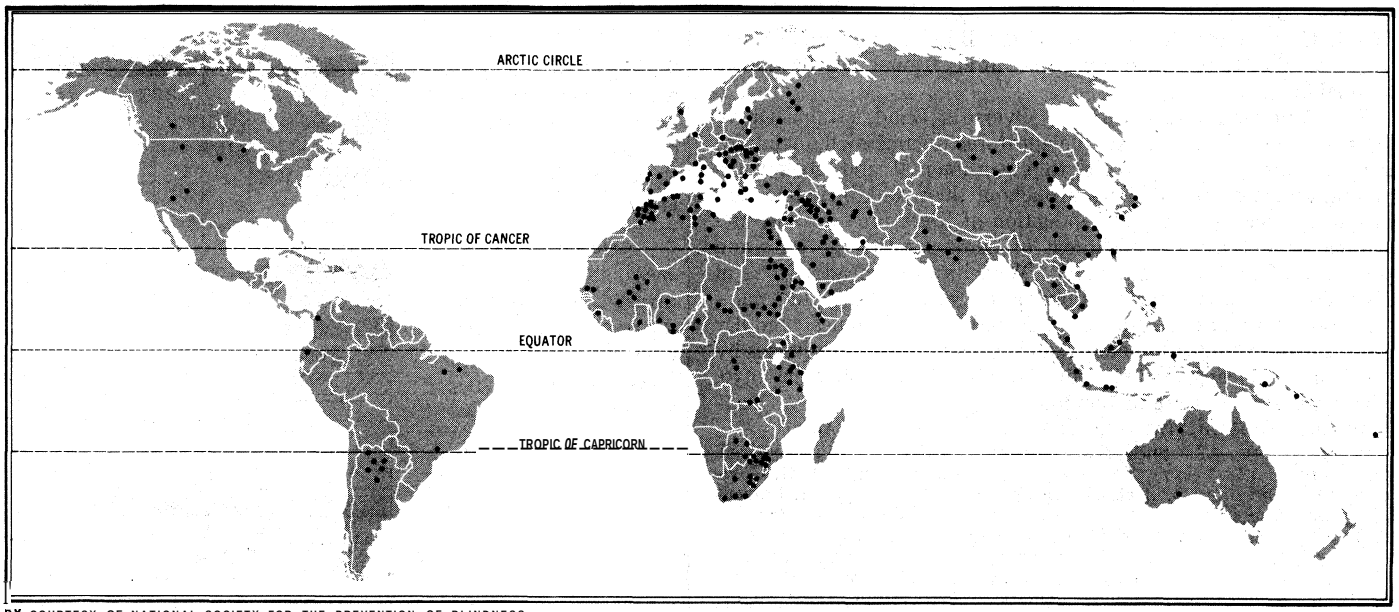
FIG. 1.—VARIATIONS IN PERCENTAGES OF BLINDNESS DUE TO SELECTED CAUSES

blindness in an underdeveloped versus an advanced country. Reports from the former will be found to show high prevalence of blindness. The high rate will be seen to be due largely to infectious diseases, but other causes may be high also because of dietary deficiencies, scarcity of medical care facilities or both. For example, a medical missionary. reporting in 1957 on his personal experience, mentioned that vitamin deficiency, trachoma, smallpox and leprosy as well as cataract are common causes of blindness in India.

In contrast, periodic studies of causes of blindness in England, Canada and the United States (all countries of high economic and health status) show the effect of advances in medical knowledge and safety measures. In these countries there have been conspicuous decreases in blindness due to infectious diseases and injury. Not all medical advances tend to reduce incidence of blindness, however. Some merely extend the life span. Thus persons affected with inadequately treated diabetes or chronic vascular disease live longer but may not avoid the serious eye complications of these diseases. Many more persons now live to an advanced age, when glaucoma may and cataract is almost certain to develop. The introduction of a new technique to save life may sometimes prove disastrous to eyes (as when excessive oxygen in incubators produced gross maldevelopment of the retina—retrolental fibroplasia—blinding thousands of premature babies between 1940 and 1954, when the cause was established).

Among other factors affecting blindness rates, age is most significant. Except in countries having exceptionally high rates of blindness due to the infectious diseases (which can be contracted at any age), the blindness rate increases with age. For example, in England as of 1954 the population aged 50 years and over was less than 10% of the total but accounted for 52% of the register of the blind and 69% of the new cases registered in that year. Estimates for 1957, believed to be a typical year, in the United States, based on samples for several states, showed between 50% and 60% of the blind in the age group 65 years and over.

Infectious Diseases.—Infectious diseases are a potential hazard to sight. The eye may be invaded directly by the living organisms that cause infection, or it may be affected indirectly by infections



BY COURTESY OF NATIONAL SOCIETY FOR THE PREVENTION OF BLINDNESS

FIG. 2.— TRACHOMA ENDEMIC AREAS OF THE WORLD. THE RATE OF BLINDNESS IS HIGH AMONG AFFECTED POPULATION

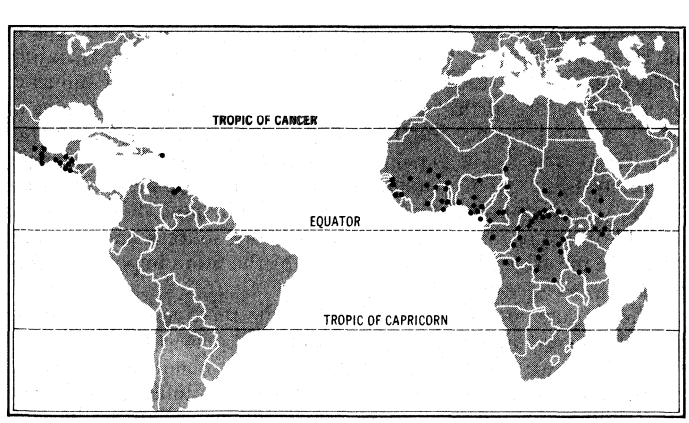
originating elsewhere in the body when the organisms or their toxic products are carried to the eye through the blood stream. The organism breaks down normal tissues of the body in order to maintain its own life and reproductive processes. If this degenerative process cannot be arrested, the eye tissues may be partially or entirely destroyed, with corresponding loss of function. Fortunately, medical science has made most notable progress in combating infections through development of antiseptics, sanitation, immunization and new drugs for effective treatment.

Trachoma.—Trachoma is actually the only infection affecting the eyes exclusively. It attacks the lining of the eyelid (conjunctiva) and the cornea (the transparent front portion of the eyeball). Its known history dates back at least 3,000 years. Starting in Asia, it spread into some areas of all five continents, causing the greatest damage among peoples having low standards of living and hygiene. Because little is known of the nature of the infecting organism except that it is a virus, trachoma remained the most important cause of blindness in underdeveloped countries up to the middle of the 20th century. The outlook for its eventual elimination was changed, however, with the discovery in 1937 that some of the sulfonamide drugs and antibiotics provide effective treatment. Real advances in its control were made after 1951, when the World Health organization of the United Nations set up an expert committee on trachoma. The Aug. 1956 issue of the Chronicle of WHO listed country after country in the far east and middle east where the organization had sent project teams or provided consultant services for mass treatment of affected peoples. The results were impressive: check-up examinations of hundreds of thousands of school children showed 75%–80% cured, for example, and it was stated that the affected population in some areas had taken over responsibility for checking on preventive sanitation and hygiene in homes and for some portions of their own treatment. The map (see fig *2*) shows areas in which high prevalence of trachoma was noted within the decade 1949 to 1958; it is inaccurate, however, because data were not available for some countries (*e.g.*, the U.S.S.R.) and could not be adjusted properly to show the effect of recent control projects in other places.

Onchocerciasis.—This disease ranks with trachoma in seriousness because of high blindness rates in areas where it is prevalent. It is a general infection transmitted to human beings by the bites of a species of fly found only in certain areas of Mexico. Guatemala and Venezuela and in larger areas stretching across central Africa (see fig. 3). When it bites, this fly (*Simulium;* see BLACK FLY) deposits filarial (worm) parasites under the skin; these tend to migrate in the blood stream to the eyes, causing severe destruction to the choroid and retina. For this disease, too, WHO appointed an advisory committee. Under its expert guidance a series of surveys was conducted and a method of attack on the disease was developed, involving "denodulization" (surgical removal of the swollen areas of skin where bites occur), use of special drugs for the patients and elimination of or other protection from the flies. (See also FILARIASIS.)

Smallpox.—Smallpox, once an important cause of blindness, has disappeared in areas where vaccination is compulsory. but the Epzdemiological and Vital Statistics Reports of WHO showed 17 countries reporting more than 1,000 cases of smallpox in 1953 or 1954.

Ophthalmia Neonatorurn.—Babies' sore eyes, or ophthalmia neonatorum, acquired from gonorrhea organisms in the birth canal of the mother, was a major cause of blindness in children in the early years of the 20th century. At that time it was responsible for approximately 30% of blindness among children entering schools for the blind in Great Britain and the United States. As the public became informed of the seriousness of this preventable condition, the use of silver nitrate drops in the eyes of infants immediately after birth was introduced, and compulsory immediate reporting of cases of babies' sore eyes was required so that adequate treatment would be assured. By 1955 the number of cases of ophthalmia neonatorum among new pupils entering schools for the blind in the United States represented only 0.1% of the total. Similarly, no new cases of blindness from this cause were reported in England after 1945. In Denmark a report on blindness among pupils in schools for the blind showed no new admissions from this cause after 1934.



BY COURTESY OF NATIONAL SOCIETY FOR THE PREVENTION OF BLINDNESS

FIG. 3.—ONCHOCERCIASIS ENDEMIC AREAS

Syphilis.—Syphilis is another cause of blindness that is decreasing in importance due to improvement in methods of diagnosis and treatment and promotion of their use where health facilities are adequate to enforce the regulations. In the United States. for example, the estimated blindness rate per 100,000 for syphilis dropped 4j% between 1940 and 19j7. Among approximately 31,000 cases of blindness registered between 1951 and 1954 in England. only 1% was due to syphilis; the percentage for new cases estimated from samples in the United States was 2%.

Others.—Leprosy (*q.v.*), which almost always affects the eyes, is an important cause of blindness in all areas in which the disease is found. Such other infectious diseases as tuberculosis, meningitis, measles. diphtheria and scarlet fever also can cause blindness. Many underdeveloped countries are also plagued by seasonal recurrence in "fly season" of acute eye infections among children. These are often sufficiently severe as to cause blindness in some and to reduce resistance to trachoma in others.

Eye Injuries.— Injuries cause considerable loss of sight, not only in manufacturing but also in mining, logging, forging, farming. in play and in the home. Instruments most likely to injure the eyes are explosives. sharp or pointed objects, flying particles of metal and stone, hot substances; acids and blows or falls affecting the head. When infection follows the injury. the danger of sympathetic inflammation in the uninjured eye is great. Safety measures have been developed to combat these hazards, notably the use of goggles. protective devices on machinery, adequate illumination and restrictions on the use of fireworks and air rifles by children.

Damage to the eyes may be caused by the use of ill-advised family or tribal remedies or by the malpractice of quacks. This type of injury is high among causes of blindness in India and China and is frequently reported from other areas.

Changing industrial processes can involve new eye hazards (*e.g.*, new chemicals and radiations), but in spite of this the percentage of blindness due to injury is no longer high in England and the United States (1% and 3%, respectively).

General Diseases Affecting the Eye.—General diseases of the body often affect the eyes; hence it is important to discover and treat general systemic disease in order to keep the eyes in good health. Among the general diseases that may cause blindness are diabetes. arteriosclerosis. diseases of the central nervous system, nephritis (Bright's disease). anemia and nutritional deficiencies. Because the nerves and blood vessels of the eye are linked with the entire body, a disturbance of the body metabolism caused by diabetes is likely to cause opacity of the crystalline lens within the eye (cataract) or serious retinal disease. Direct causal relationships between other eye conditions and diseases occurring elsewhere in the body can similarly be demonstrated.

Blindness from arteriosclerosis, a vascular disease of elderly persons. is increasing because degenerative changes in the blood vessels of the eyes progress with age and are not likely to be reversed by any known treatment.

Nutritional deficiencies: particularly those of high degree, are not only directly responsible for certain eye diseases such as keratomalacia (in which the cornea. which is the crystal-clear front portion of the eye, becomes soft and cloudy) but also may increase the susceptibility of the person to infections or other diseases of the eye. Nutritional deficiency ranks high among causes of blindness in children in many countries of the east and of South America.

Congenital Blindness.— Blindness of prenatal origin. or congenital blindness. comprises those cases in which the eye defect or a tendency to development of the defect is present at birth. It includes, but is not synonymous with, inherited defects, since other factors may affect the health of the pregnant woman and hence the development of the eyes of her infant. In some cases the cause may be classified. as in maldevelopment due to the presence of syphilis or of German measles in the mother during pregnancy, but often it is not known. The need for basic research into the prenatal factors producing blindness is demonstrated in studies of the causes of blindness among children in Great Britain and the United States, which show that the rate of blindness for this group remains high, whereas blindness from known causes is declining.

Other Causes.—There are other types of eye affection, the cause or causes of which are still unknown, that are responsible for a large percentage of blindness. For example, in the United States, senile cataract (opacity of the crystalline lens within the eye) is responsible for 18% of blindness, glaucoma (hardening of the eye due to high pressure within the eyeball) for 14% and malignant myopia (nearsightedness associated with diseased eye tissues) for 3%. Blindness from eye affections of unknown cause is likewise high in Great Britain. Research to establish the underlying causes is essential to the prevention of these conditions. However, proper medical and surgical treatment can prevent much loss of sight from catpract and glaucoma. To this end it is important that persons be informed of the need for prompt diagnosis and treatment when such symptoms appear as blurring or cloudiness of vision in either eye. seeing a mist or rainbow-coloured halo around distant lights; discomfort or pain about the eyes, blurring of print or eye pain associated with reading.

Problems of Prevention.— The communicable diseases, and to a lesser extent injuries. are rapidly disappearing as causes of blindness in countries where understanding and means of putting preventive measures to effective use are available. Research, however, is needed, to determine methods of preventing blindness from causes about which too little is known. These are chiefly the developmental eye defects of infancy. two progressive eye diseases (cataract and glaucoma) in which blindness can be prevented but not the onset of the disease itself, and the chronic systemic diseases (diabetes, arteriosclerosis) causing progressive degenerative changes in the eye that cannot be arrested.

Underdeveloped countries need to attack the problems of elimination of the communicable diseases—trachoma, onchocerciasis, smallpox. leprosy, venereal diseases and tuberculosis. It is essential that services be developed on a scale large enough to eliminate sources of infection. Studies made by WHO have developed patterns for community projects involving case finding, treatment, immunization, sanitation, health education, etc. Most of these countries require the services of experienced foreign workers, at least in the initial stages, and many need substantial financial aid.

AGENCIES TO COMBAT BLINDNESS

In 1958, based on available medical knowledge and on statistics on causes of blindness, it was estimated that more than half the world cases of blindness were preventable. In areas where infectious eye conditions are widespread, the proportion is much larger.

Activities for combating blindness are carried on by various governmental and voluntary organizations. Departments of public health are concerned with control of communicable disease, provision of public health nursing services, maternal and child health facilities and dissemination of information on health. Several state health departments and some state education departments in the United States employ consultants on vision screening for school children and assist in arrangements for eye care. The British ministry of health and certain health departments in the United States are responsible for various aspects of medical eye care, particularly for children. Also, in the United States many state departments of social welfare make provision for medical care of indigents who have serious eye conditions.

The World Health organization stimulates and assists in programs for the control of trachoma in many parts of north Africa and the middle east, under the general supervision of an expert committee on this problem. Also under the supervision of WHO, the problem of onchocerciasis in Central America and in Africa has been attacked. In Bengal, India, a traveling eye dispensary provided by the Association for the Prevention of Blindness, a voluntary agency organized in 1930, takes eye treatment to the most remote villages, where surgery is performed in tents. Likewise, in South Africa the National Council for the Blind has provided traveling teams, including an eye surgeon, to bring the best possible care to rural areas.

Voluntary citizens' groups have played a large part in the dissemination of information, which is essential to the prevention of blindness movement. In 1882 the London Society for Prevention

of Blindness was founded, and similar agencies later developed in other countries. including in the C.S. the National Society for the Prevention of Blindness, organized originally as a New York state committee in 1908. This society has a staff that works, through its state affiliates, with public health authorities. social workers, educators, vocational counselors and safety engineers. Similar activities are carried on by the Canadian National Institute for the Blind, in Brazil by the National Society for the Prevention of Blindness and in other countries by similar organizations. The International Association for the Prevention of Blindness, established in *1929* with headquarters in Paris. stimulates development of preventive services throughout the world.

BLIND SPOT, the place of entry of the optic nerve into the retina, an area insensitive to light, in man having a diameter of about one-twelfth of an inch, lying about *15°* from the fixation point on the temporal side. In binocular vision the spot is not noticed, because the part of the visual field covered by the blind spot of one eye is covered by a sensitive area in the other. In monocular vision objects that fall entirely within its area are not seen, but this is unnoticed because the eye is not fixed but unsteady. *See* EYE, HUMAN.

BLIND STAGGERS, often mistaken for a disease entity, is a symptom represented by a staggering gait in which the animal affected seems to be blind. Such a symptom may have many causes, such as poisoning by the ingestion of seleniferous plants (certain plants that have a tendency to accumulate selenium from soils high in that element) or of paspalum grasses infected with the fungus *Claviceps paspali;* magnesium or calcium deficiency; or inflammation of the brain (encephalitis) or brain coverings (meningitis). (NA. BR.)

BLINDWORM: *see* SLOWWORM; LIZARD.

BLINK MICROSCOPE, an auxiliary astronomical instrument. Two photographic plates of the same star-field taken at different epochs are placed in the machine and viewed one with one eye and the other with the other eye, and adjusted as in a stereoscope so that a single visual impression is given. An arrangement is provided by which the plates are alternately, in rapid succession, hidden from sight. Attention is at once called to any star image which has changed in the interval between the two epochs by the corresponding flicker. In this way variable stars and stars with large proper motion are detected.

Proper motions can also be detected without the flicker arrangement, since the displacement of the star image gives a stereoscopic effect, the star appearing to stand out in relief in front of or behind the plane of the other stars. When used in this manner the instrument is called a stereocomparator.

See also BINOCULAR INSTRUMENT.

BLISS, SIR ARTHUR (EDWARD DRUMMOND) *(1891–*). a distinguished and versatile English composer, also active in public musical life, was born in London, Aug. *2, 1891.* He studied under Charles Wood at Cambridge, graduating in *1913,* and later under Stanford, Holst and Vaughan Williams in London.

His first successes were three works for chamber ensemble with solo voice or voices. *Madame Noy, Rhapsody* and *Rout* (1918–19). These nere followed by the more substantial *Colour Symphony* (1922), the four movements of which are intended to suggest the characteristics of purple, red, blue and green. Thereafter Bliss essayed most of the major musical forms and media—chamber music, choral music, ballet, concerto and opera. The ballets *Checkmate* (1937) and *Miracle in the Gorbals (1944).* the violin concerto. clarinet quintet and two string quartets are among his most admired works. His opera. *The Olympians* (libretto by J. B. Priestley) was produced at Covent Garden (1949) but mas coolly received. A television opera. *Tobias and the Angel,* was shown by the BBC in *1960.* His piano concerto was commissioned to represent British music at the New York World's fair in *1939.* He was musical director of the BBC (1942–44), received a knighthood in *1950* and was appointed master of the queen's music in *1953.*

See A. Robertson, "Arthur Bliss," *British Music of Our Time,* ed. by A. L. Bacharach (1946). (Co. MA.)

BLISS, CORNELIUS NEWTON (1833–1911), U.S. textile merchant. manufacturer and politician, was born at Fall River. Mass., on Jan. *26, 1833.* He rose from the position of clerk in a prominent Boston commercial house. J. M. Beebe & Company, to that of junior partner. Moving to New York, he later organized the large textile manufacturing firm of Bliss, Fabyan & Company. As an advocate of a protective tariff! he was an organizer of the American Protective Tariff league and. for many years, its president. He was active in Republican party politics, but had no desire to hold office. He twice declined to be his party's candidate for governor of New York and only reluctantly served in President McKinley's cabinet as secretary of the interior, 1897–99. In New York, he was chairman of the Republican state committee in *1887* and later served as Republican national committee treasurer, *1892–1904.* He died in New York on Oct. *9, 1911.* (C. F. McI.)

BLISS, NATHANIEL *(1700–1764),* fourth astronomer royal, was born at Bisley, Gloucestershire, on Nov. *28, 1700.* He graduated as B.A. in 1720 and M.A. in 1723 at Pembroke college, Oxford, and succeeded Edmund Halley as Savilian professor of geometry in 1742. A correspondent and sometime assistant of J. Bradley's, he acted for him at the transit of Venus in *1761* and succeeded him as astronomer royal in *1762.*

Bliss held that post for only two years, dying at Oxford on Sept 2. *1764* (O. J. *E.)*

BLISS, TASKER HOWARD (1853–1930), U.S. army officer, mas born at Lewisburg, Pa.. on Dec. *31, 1853.* He graduated from West Point in *1875,* and from *1885* to *1888* was professor of military science at the Naval War college. In *1897* he went to Madrid and was military attaché at the U.S. legation. He served through the Puerto Rican campaign during the Spanish-American War and from *1898* to *1902* was in charge of Cuban customs and collector for the port of Havana. In *1903* he became commandant of the Army War college. From *1903* to *1905* he was a member of the joint army and navy board and also of the general staff. From *1905* to *1909* he held various commands in the Philippines. During the latter half of *1909* he was president of the Army War college, afterward becoming assistant chief of the staff, to which post he returned in *1915* after four years' service in command of military departments. In *1917* he was made chief of staff and promoted to the rank of general, but he retired later in the year, having reached the age limit. He was a member of the Allied conference *(1917).* of the Supreme War council *(1918)* and of the American Commission to Negotiate Peace *(1918–19).* He died in Washington, D.C., Nov. *9, 1930.*

BLISTER, a vesicle filled with serous fluid raised on the skin by a burn, by rubbing on a hard surface, as on the hand in rowing. or by other injury; the term also is used to describe a similar condition caused artificially, by the application of mustard. of cantharides and of other vesicatories. Similar swellings, filled with fluid or air, on plants and on the surface of steel or paint are also called blisters.

BLISTER RUST, or white-pine blister rust, the most destructive disease of white (five-needle) pines *(see* PINE) in North America, causes an estimated annual loss of about 650,000,000 board feet of saw timber and more than twice that volume in immature trees in the United States. Despite control efforts costing millions of dollars per year, this disease threatens to eliminate white pine species from many areas of the Cnited States and Canada. Blister rust does occur in other countries of the temper-

ate zone. but in these it is of less economic importance.

The causal organism, *Cronartium ribicola,* is a parasitic fungus requiring two different host plants to complete its life cycle: white pines and members of the genus *Ribes* (currants and gooseberries). On pine the fungus is perennial. growing in the bark where it causes a canker that girdles and eventually kills the affected branch or trunk. In the third or fourth spring following infection, orange blisters about the size of navy beans erupt through the surface of the canker. These blisters contain minute spores (asexual reproductive bodies) that may be carried hundreds of miles by wind to the alternate host *(Ribes* species). where they germinate and infect the leaves, causing tiny, orange, leaf spots characteristic of the "currant-rust" stage. In summer or early fall, spores produced on the undersurface of the leaves of the *Ribes* host are blown back to the pines, where infection occurs through the needles and young twigs, initiating new cankers. This spread from *Ribes* to pine rarely exceeds a few hundred yards. as contrasted with the hundreds of miles that the disease may spread from pine to *Ribes.*

Pines do not become infected unless the temperature remains below 70° F. and the air remains moist throughout the one to two day period necessary for dispersal and infection. Thus the disease on the pine host is restricted to areas with cool, moist weather in summer and early fall.

Blister rust is apparently of Asiatic origin and was introduced into North America on white pine planting stock imported from Europe. From its introduction on the east coast in the late 1800s and on the west coast in 1910, the disease spread rapidly throughout the extensive white pine forests of the northern U.S. and southern Canada. This rapid spread was due largely to the abundance of wild *Ribes* species throughout this region and to the favourably cool. moist climate Commercial production of white pine species in much of this region is no longer feasible without direct control efforts.

The most important means of controlling blister rust (except in climatic areas extremely favourable to the disease) is through the eradication of all *Ribes* species within and surrounding (to at least 900 ft.) a stand of white pine. Infected ornamental pines can be saved by surgical or chemical treatment The disease can be avoided by (1) selecting planting sites free from *Ribes* species; (2) concentrating white pine production on sites that are too warm or too dry for serious infection; or (3) by planting resistant varieties of white pines. The U.S. department of agriculture maintains an extensive program of *Ribes* eradication. and state and federal quarantine regulations governing the cultivation and the movement of white pines and of currant or gooseberry plants are strictly enforced.

BLITHEMAN, WILLIAM *(c.* 1525–1591), English organist and composer of motets and organ music.. The earlier part of Blitheman's career appears to have been associated with Oxford, where he was master of the choristers at the cathedral (Christ Church) in 1564. He was appointed a gentleman of the Chapel Royal in 1585, and obtained the degree of B. Mus. at Cambridge in the following year. In 1588 his more brilliant pupil. John Bull, was appointed to assist Blitheman as organist in the Chapel Royal. and succeeded him upon his death in London, on Whit Sunday, 1591.

The fact that two of Blitheman's motets appear in a set of part-books (British Museum Add. Manuscripts No. 17802–05) probably compiled in the reign of Mary Tudor suggests that he may have been born about 1525. In style his music closely resembles that of Thomas Tallis, though it lacks the intensity that makes Tallis pre-eminent among his generation. Blitheman's surviving organ pieces are contained in the *Mulliner Book* (1951), edited by D. W. Stevens as vol. i of "Musica Britannica."

(J. J. N.)

BLITZKRIEG, literally "lightning war." a term first used in connection with the German attack on Poland in 1939 and later popularized during the rapid German drive between Dinant and Sedan in the Belgian campaign of 1940. Gen. Heinz Guderian first outlined the basis for blitzkrieg tactics in *Achtung Panzer,* published in 1938. Guderian, how-ever, recognized his indebtedness to the British military theorists, B. H. Liddell Hart and J. F. C. Fuller, and derived some of his organizational concepts from Gen. Hans von Seeckt.

Three basic features characterize blitzkrieg as a form of war: surprise, speed and superiority in matériel or firepower. Surprise, as achieved by the Germans in 1940, was calculated to create a condition of psychological shock and resultant disorganization in the enemy forces. The employment of armour in deep, sustained operations. without pause for regrouping, enabled German columns to advance at a speed of over 30 mi. a day during the invasion of France in 1940. Superiority in applied firepower was gained by the rapid concentration of tanks and self-propelled artillery on a narro front at the point where the enemy position was to be ruptured; it was maintained by the motorization and rapid displacement foraard of all neapons.

Originally blitzkrieg was conceived as a tactical formula for applying the speed and firepower of the modern tank arm. The classic blitzkrieg operations of 1940, however, saw a degree of teamwork and tactical co-ordination between assault air forces and mobile ground forces never before achieved in war. Thereafter, the use of fast. low-flying attack aircraft against enemy troops, fortifications and lines of communications was considered a necessary ingredient of blitzkrieg tactics. The tactical formations normally employed in the German blitzkrieg campaigns consisted of a collection of "battle groups" made up of tanks, self-propelled guns, infantry in trucks or armoured carriers and mechanized engineers, the whole supported by motorized supply and bridge trains.

The tactics of blitzkrieg consisted of a splitting thrust by armoured columns on a narrow front. complete disruption of the main enemy battle position at the point of attack, followed by wide-swinging sweeps by the armoured spearheads that created large pockets of entrapped and immobilized enemy forces (the so-called *Keil* and *Kessel—or* "wedge" and "kettle"—technique). Blitzkrieg tactics were improved by Rommel during the desert campaigns in north Africa, particularly in their logistics and in the extension of the radius of operations. It remained for General Patton of the U.S. army to bring blitzkrieg to its most successful form in the European operations of 1944. (H. M. CE.)

BLIZZARD, a popular term, probably derived from the German *Blitz,* used especially in North America for a snowstorm accompanied by strong winds or winds blowing loose snow through the air along the ground. (H. R. B.)

BLOCH, ERNEST (1880–1959), Swiss-U.S. composer, was born at Geneva, July 24, 1880. He studied harmony under Emile Jaques Dalcroze, violin with Eugène Ysaÿe and composition with Iwan Knorr.

The performance of his opera *Macbeth* at the Paris Opéra-Comique (1910) brought Bloch to the attention of the musical world. In 1916 he went to the United States where he became a U.S. citizen (1923), director of the Cleveland (Ohio) Institute of Music (1921–25) and of the conservatory in San Francisco (1925–30), and in 1939 professor of music at the University of California. As a teacher Bloch exerted a vital influence on musical development in the United States.

Of Bloch's early works, *Macbeth* best reveals the gradual emergence of a strong individuality, which flowered fully in the works of the "Jewish Cycle," in which Bloch aimed not to reconstruct Jewish music but to embody the aspirations of the Jewish people. The *Trois poèmes juifs,* the symphony *Israel,* settings of three Psalms (114, 137 and 22) and his rhapsody *Scheldmo* for violoncello and orchestra date from 1913 to 1917. The *Jewish Sacred Service* (1933) brings this phase to a monumental climax.

However, Bloch was not content to remain a purely Jewish composer. The First Violin Sonata (1921) and Quintet (1923) reveal a highly personal style and strong feeling for classic form. Noteworthy are five string quartets, a violin concerto, a piano concerto, three suites for solo violoncello and *Last Poems* for flute and orchestra.

Bloch died in Portland, Ore., July 15, 1959. (RO. SE.)

BLOCH, FELIX (1905–), U.S. physicist, was joint recipient of the 1952 Nobel prize for physics. He was born in Zurich, Switz., on Oct. 23, 1905. His higher education was obtained at the Eidgenossische Technische Hochschule, Zurich, and at the University of Leipzig, from which he received the degree of doctor of philosophy in 1928. Working with several of Europe's leading theoretical physicists, he became known for his theoretical researches in solid state, magnetism and the stopping of charged particles in matter. In 1934, after accepting a position at Stanford university, Calif., he conceived a method for polarizing neutrons, with which he and L. Alvarez measured the magnetic moment of the neutron in 1939. After working during World War II on atomic energy and radar countermeasures, he returned to Stanford in 1945 and developed the principle of nuclear induction, which he, with W. W. Hansen and M. E. Packard. detected experimentally by observing radio-frequency signals from nuclei precessing in magnetic fields. He shared the Nobel prize with E. M. Purcell of Harvard, who simultaneously and independently discovered the same phenomenon. After serving for a year in 1954–55 as director of the Conseil Européen de la Recherche Nucléaire in Geneva, Switz., he resumed his professorship at Stanford. Later researches extended nuclear induction to studies of nuclear and molecular structure, and he generalized his original underlying theories of the effect. (G. E. PE.)

BLOCH, JEAN RICHARD (1884–1947), French essayist, novelist, playwright and journalist active in the cause of socialism, was born in Paris, May 25, 1884. In 1910, while teaching in Poitiers, he started *L'Effort libre,* a "review of revolutionary civilization." His essays, from *Carnaval est mort* (1920) to *Naissance d'une culture* (1936), expressed his faith in a new civilization and a new art which would associate the democratic tradition with a proletarian culture. The tales in *Lévy* (1912) included penetrating studies of Jewish psychology; his Balzacian novel . . . *et Cie* (1918; Eng. trans. . . . *And Co.,* 1930) told how a family of Jewish cloth manufacturers left Alsace in 1870 and created a flourishing business in Normandy. *La Nuit Kurde* (1925; Eng. trans. *A Night in Kurdistan,* 1930) gave his imagination free scope and he paid lyrical homage to the grandeur of the east. His plays included a modern legend, *Le Dernier empereur* (1926), and a popular fairy play, *Dix filles dans un pré* (1930). Bloch, one of the "Clarté" group of socialist writers, spent most of World War II in Moscow (1941–45). He died in Paris, March 15, 1947. (RE. L.)

BLOCH, JOSEPH SAMUEL (1850–1923), rabbi and publicist. was among the first to carry the fight against anti-Semitism into the camp of the anti-Semites. Born in Dukla. Galicia, on Nov. 20, 1850, he received a good rabbinic education and a doctorate from the University of Zurich. He was rabbi in several small communities, going finally to Florisdorf, a workers' suburb of Vienna. When August Rohling, professor at the University of Prague, claimed that he could prove the truth of the blood libel (the charge that Jews use the blood of murdered Christians in some rituals; *see* RITUAL MURDER) in connection with a notorious accusation of this sort against the Jews of Tisza-Eszlar (1882), Bloch accused Rohling of ignorance and deceit. Rohling was compelled by public opinion to sue Bloch for libel. but withdrew his suit just before it came to trial. This victory made Bloch into a hero among Jews and liberals. Bloch published the documents he had prepared for the trial and subsequently included them in a volume called *Israel und die Völker* (1922), translated into English as *Israel and the Nations* (1927). From 1884 to 1921 he published a meekly. *Österreichische Wochenschrift,* financed by a Christian, in which anti-Semitism was fought with single-mindedness and courage. Bloch carried on the same fight on a nation-wide platform in the Austrian parliament. of which he was a member, 1883–85 and 1891–95. Two volumes of his uncompleted memoirs appeared in 1922 under the title *Erinnerungen aus meinem Leben,* translated the following year as *My Reminiscences.* He died in Vienna, on Oct. 1, 1923. (SN. GI..)

BLOCKADE has been defined as "an act of war carried out by the warships of a belligerent, detailed to prevent access to or departure from a defined part of the enemy's coast." It differs from a pacific blockade inasmuch as the latter is not strictly an operation of war and cannot rightly be enforced against neutrals. The former may be either military or commercial. A military blockade is one undertaken to attain some specific military objective; *e.g.,* the capture of a naval port. A commercial blockade has no immediate military objective but is designed to cause the enemy to surrender or come to terms by cutting off all commercial intercourse by sea. A belligerent may, if it can, blockade the whole of the enemy's seaboard, but the mere proclamation of a blockade of the whole or any part of the enemy's coast, without anything more, is of no legal effect. Such proclamations were formerly common and were known as paper blockades. A belligerent may not blockade neutral territory unless it is in the actual control or occupation of the enemy, nor may it blockade enemy territory in such a way as to prevent access to neutral territory.

The common law of blockade rests mainly upon the principles laid down by the Anglo-U.S. prize courts, the more important of which are summarized in the judgments of Stephen Lushington and of the privy council in *The Fransiska,* Spinks 111; 10 Moo. P.C. 37. In order, therefore, to render a blockade valid under the common law and to impose penalties upon neutral vessels for breach of it, the following facts must be proved.

(1) A blockade must be duly established; *i.e.,* it must be instituted under the authority of the belligerent government. Usually the officer in command of the naval force institutes the blockade under express instructions, but if he does so without them—an unlikely occurrence in modern times—his action must be ratified by his government. In either case, although in the British view an official notification is not necessary, neutral powers are notified in practice through diplomatic channels and the blockade is officially proclaimed. The officer in command must also notify the local authorities and the foreign consuls. (2) It must be effective. Paper blockades were declared illegal by the Declarations of the Armed Neutralities of 1780 and 1800. and it was to suppress their subsequent continuance that art. 4 of the Declaration of Paris (1856, *see* PARIS, DECLARATION OF) provided that "blockades in order to be binding must be effective"; *i.e.,* maintained by a force sufficient really to prevent access to the coasts of the enemy. The continental view demanded a stricter standard of sufficiency than the Anglo-U.S. The latter, however. ultimately prevailed. (3) It must be continuously maintained and impartially enforced against all vessels alike. If interrupted—except when temporarily interrupted by adverse weather—it must be duly re-established. Certain classes of vessels are exempt from the latter part of this rule, viz., neutral warships and neutral vessels carrying distressed seamen of their own nationality sent home by the resident minister of the neutral state, and neutral vessels compelled by stress of weather, need of provisions or repairs to put into the blockaded port.

Under the Anglo-U.S. practice vessels which have received a special licence from the government of the blockading state or the commander of the blockading force are also exempt. (4) There must be some violation either by egress or ingress by the vessel. At the London Naval conference of 1909 it was generally agreed that there must be some notice, either actual or presumptive. In respect of egress the fact of blockade is sufficient. In respect of ingress, if the blockade has been officially notified notice will be presumed, if there has been sufficient time for the vessel to receive it, since it is the duty of the neutral government to communicate such notice to its subjects. If the blockade is *de facto,* express notice must be given to the vessel by the blockading force and endorsed on the ship's papers. (5) There must be actual or constructive knowledge of the blockade by those responsible for the conduct of the vessel.

A blockade terminates (1) if it is expressly raised by the blockading government or by the officer in command of the blockading force; (2) if it ceases to be effectively maintained; (3) if the blockaded place is actually occupied by the blockading state.

The penalty for breach of blockade was the loss of the ship in any event, and of the cargo if at the time of shipment the blockade was known or might have been known by the shipper: *The*

Paneghia Rhomba, 12 Moo. P.C. 168; Scott, 951 (1858).

At the London Naval conference, 1908, an attempt was made to codify the law of maritime warfare. The provisions in the Declaration of London, 1909, relating to blockade are substantially merely declaratory of the common law. Two important amendments, however, were made. By art. 17 neutral vessels may only be captured for breach of blockade "within the area of the warships assigned to render the blockade effective." Under the customary law they are liable to capture during any part of the outward or return voyage. By art. 19 the doctrine of continuous voyage was declared inapplicable to blockade. Although the declaration had not been ratified by any state, it was, subject to some additions and modifications, adopted by all the belligerents at the commencement of World War I. On Feb. 4, 1915, Germany declared its submarine blockade against Great Britain, and on March 1, the British government announced that it was the intention of the Allied governments as a retaliatory measure "to seize all ships carrying goods of presumed enemy destination, ownership or origin." Although in effect blockades, neither of these measures was legally a blockade, since they did not conform to the provisions of the law of blockade. By the withdrawal of the declaration and subsequent orders by the Maritime Rights Order in Council, July 17, 1916, and by reliance upon the law of contraband (*q.v.*), the situation was regularized for the Allied governments. (H. H. L. B.)

IN NAVAL SCIENCE

A nation fighting for its existence and depending for success on its maritime superiority cannot afford to see one of the main objects for which its naval strength was developed largely discounted by neutrals who. ostensibly taking no part in the struggle. supply its enemy with the sinews of war. The ultimate aim of a sea power is to protect its own sea communications while denying oversea supplies to the enemy. The right of a belligerent to stop contraband of war from going to its enemy has always been admitted, but it is not unnatural that the weaker maritime powers and neutrals should prefer that goods carried in neutral ships should be secure from capture, that is the principle that "the flag covers the goods" or "free ships. free goods." During the hundred years that followed Napoleon's downfall Great Britain was almost invariably a neutral and its own commercial interests found profit in this latter view. Its statesmen. who might have had longer vision, sacrificed this vital belligerent right by signing the Declaration of Paris in 1856. "I believe," said Lord Salisbury speaking in the house of lords on March 6, 1871. "that since the Declaration of Paris. the fleet, valuable as it is for preventing an invasion of these shores. is almost valueless for any other purpose."

A further check on the use of Britain's sea power for preventing supplies from going to the enemy was the Declaration of London (1909). Of the two descriptions of articles enumerated in this instrument, the absolute contraband list was small, being confined to articles of exclusive military value such as guns. explosives, etc These nere liable to capture when destined to the enemy in neutral ships either directly or through neutral territory and in this case the doctrine of continuous voyage was recognized.

The conditional contraband list was composed of articles necessary to the civil population as well as to the military forces, such as food, fuel and clothing. Such articles were liable to capture only if shown to be destined for the armed forces or to a government department of the enemy state, and if they went directly to an enemy port. They could not be touched if discharged in a neutral port for transmission by rail or inland waterway. The evidence required by the declaration to prove the innocence of a cargo could be evaded so simply as to render this class of goods practically immune from capture, and in this case even the doctrine of continuous voyage (*q.v.*) mas disallowed.

BLOCKADE IN WORLD WARS I AND II

World War I.—In World War I Britain sought to justify its interference with trade between neutrals, when such trade might have an enemy destination, on the ground of changed conditions of warfare. Sir Edward Grey's note to Secretary Robert Lansing of July 23. 1915, explained that Germany's "territories are covered by a network of railways and waterways, which enable her commerce to pass as conveniently through ports in . . . [adjacent] neutral countries as through her own." The tactical disadvantage thus faced by a belligerent was not a novel geographical situation, historically speaking. In the Napoleonic wars water transportation by river and canal through the ports of the Baltic was as substantially effective in supplying France as was the "network of railways and waterways" supplying Germany in World War I. Nevertheless, the modes of application of naval blockades and the effectiveness of blockading naval operations had been greatly changed by conditions of warfare in both World Wars I and II. The extended range of shore batteries, the use of torpedo-boats and similar craft, the action of submarines and mines, and the employment of aircraft for bombing and machine-gunning surface craft had made any close blockade or any blockade by stationary vessels impossible. The blockading squadron was accordingly now constrained to operate at some distance from the enemy coast. On the other hand, the efficiency of the blockading forces was increased by the ability of the modern naval vessel to be independent of the weather, to communicate by wireless with other vessels of the squadron and with the command. to operate at high speed, to utilize radar, naval aircraft and submarines for scouting purposes, and to employ radar and searchlights for night operations.

Blockades may be breached by aircraft and submarines as well as by surface vessels. The *Report* of The Hague jurists of 1923 stated that "where a blockade has been established and an aircraft attempts to pass through into the blockaded area within the limits of the blockade, it should be liable to capture." The goods carried in any aircraft so captured, and the aircraft itself, would be subject to condemnation. This power of capture and condemnation was nevertheless subject to the rule, as the Naval War college pointed out in 1935, that "a blockade maintained by surface vessels only without means of preventing or rendering dangerous the passage of aircraft or submarine would be 'a paper blockade' in so far as such craft were concerned even though proclaimed to include these." The fact that a blockade might be ineffective as against aircraft or submarines, and therefore illegal for such purpose, would not preclude the legality of a blockade effectively maintained by surface craft against surface craft.

Retaliation.— Shortly after the outbreak of World War I belligerents began to resort to the practice of mine-laying on the high seas with a view to cutting off access by ships to enemy coasts. On Nov. 3, 1914, Great Britain declared "that the whole of the North Sea must be considered military area" within which "merchant shipping . . . will be exposed to the gravest dangers from mines." On Feb. 4, 1915, Germany countered by declaring the entire English channel and the waters surrounding Great Britain and Ireland to be "an area of war" within which it would "endeavour to destroy every merchant vessel that is found." This action was sought to be justified as an act of retaliation, "just as England has designated the area between Scotland and Norway an area of war." Retaliation was likewise relied on as the basis for the British Order in Council of March 11, 1915, whereby neutral ships carrying goods of presumed enemy destination, ownership or origin mere to be taken into port, the goods there to be discharged and detained for the duration of the war. On Jan. 31, 1917, Germany and Austria-Hungary announced a policy of unrestricted submarine warfare in certain zones, which Germany again sought to justify as a means of meeting "the illegal measures of her enemies." Great Britain retaliated by an Order in Council of Feb. 16, 1917, which declared that any vessel found at sea on its way to or from a port in any neutral country affording a means of access to enemy territory, without having first called at a British or Allied port, should be presumed to be carrying goods with an enemy destination or of enemy origin until the contrary was established.

The British measures lacked the essential characteristics of a blockade and the Orders in Council carefully avoided the use of this term. Rather they appeared to be the assertion of an enlarged right of capture. not limited to contraband, but dependent on the

test of enemy origin or destination. Belligerents did not seek to uphold the legality of their practice independently of retaliation. Neutrals uniformly protested the application of such measures to their shipping and to the goods of their nationals and refused to admit their legality but were unable to thwart the imposition of such measures. The intervention by the United States in World War I, and its resort to stringent measures of economic warfare, instead of reliance on its traditional attitude of "neutrality" (*q* v.), prior to World War II, tending to establish in practice a blockade of the axis powers, strengthened this tendency to obliterate the traditional limitations on the exercise of the right of blockade.

Blockade through Exercise of Sovereign Rights.—In World War I Great Britain found that its strategic control of shipping facilities. including bunker supplies and ships' stores, furnished a powerful means of subjecting neutral shipowners and traders to conformance with the basic British policy that "no vessels owned, chartered or controlled by them (*i.e.*, neutrals) should carry any cargoes proceeding from. or destined to, an enemy country." These shipping facilities could be granted or withheld in the exercise of sovereign discretion, or they could be granted subject to compliance with desired conditions. Examples of this technique of blockade will be found in the succeeding paragraphs.

Bunker Control.—Nearly all the bunker depots in the world, except the U.S., were in Allied territory or were dependent an supplies from such territory in World War I. This fact was made the basis for an effective system of licensing supplies of fuels to neutral vessels in Allied ports. Among other things, such supply was made subject to the condition that the vessel should not trade with any port in an enemy country or carry cargo to black-listed persons. A black list of vessels to be refused bunkers at British ports was established as was also a white list of ships which were to receive bunkers freely, their owners having agreed to observe the various conditions stipulated by the British.

Embargoes.—Embargoes on the export of specified commodities were announced by Germany and France on July 31, 1914, and by Great Britain on Aug. 3, 1914. The practice rapidly expanded both as to commodities affected and territories prohibited. The belligerents evidenced a willingness to relax the embargoes as to specific strategic commodities desired by neutrals, by Germany with respect to such commodities as chemicals. dyestuffs and medicines, and by Great Britain with respect to such commodities as rubber, jute, chrome, manganese and tungsten ore, upon guarantees by such neutrals that they would not re-export such commodities to the opposing belligerent. A co-operative system of enforcement was accordingly established by agreements with the neutral importer. Private organizations such as the Netherlands Overseas Trust and the merchants' guild of Copenhagen assisted the Allied Powers in carrying out their plans.

Black Lists and the Financial Blockade.—In the exercise of its sovereign power over British subjects, Great Britain prohibited all transactions by them with neutral merchants "known or suspected to be furnishing supplies to the Central Powers." Various firms in neutral countries, including the United States, were so black-listed. The consequences of such a loss of trade constrained many neutral firms to a policy of co-operation with the Allied Powers and further cut off Germany from access to neutral sources of supply and trade. A so-called financial blockade accompanied this practice under which British subjects were prohibited from having financial as well as commercial relations with black-listed persons.

Rationing.—Since neutral coasts were not subject to blockade, neutrals facing the sea and also having land boundaries adjacent to belligerent territory could be made a source of supply for such belligerents in avoidance of a blockade. A system of rationing such neutrals was accordingly worked out by the British war cabinet in World War I whereby "rationing schedules showing the normal requirements of all the European neutrals in respect of all the more important commodities which they obtain from overseas" were implemented by agreements with neutral shipowners and traders containing rationing clauses under which the British government could automatically terminate many of the excessive shipments. The rationing system sought to limit neutral imports only to such stocks as would be needed for home consumption.

World War 11.—The most important instance of a formal blockade in World War II occurred with the Soviet Union's announcement of a blockade of the Finnish coast and adjoining islands in Dec. 1939. Finland questioned the Soviet Union's right as a belligerent to establish the blockade since Russia had previously denied the existence of a state of war with Finland. The effectiveness of the blockade was also questioned. The issues thus raised were not, however, resolved before the war ended.

In April 1940. Germany announced its intention to destroy all neutral ships sailing to British ports and in Xug. 1940 proclaimed a total blockade of the British Isles and the establishment of a zone of military operations off the North Atlantic coast within which every ship would be sunk. Submarine and air warfare were used to carry out these policies. A British Order in Council of Nov. 27, 1939, assertedly based on the right of retaliation, required that all goods laden in an enemy port, as well as all goods of enemy origin or ownership, be discharged in a British or Allied port and placed in the custody of the marshal of the prize court. Such goods were to be detained or sold or requisitioned by the crown. These retaliatory measures were thereafter extended to Italy and Japan and also made applicable to civil aircraft.

An Order in Council of July 31, 1940, substituted condemnation in place of detention for goods of enemy origin or ownership, including condemnation of the ships carrying such goods as well as the goods themselves. The order was primarily important for "regulating a system of passes for approved cargoes and ships." The order changed the rules for establishing the existence of enemy ownership, origin or destination by creating a rebuttable presumption of such status where the ship or goods were not covered by the appropriate "navicert," which the shipowner or trader could obtain by voluntary application. "Ships' warrants" could also be obtained applicable to whole shipping lines and companies which were willing to enter into agreements to utilize the system of "navicerts." In the absence of a "ship's warrant" every ship of the company in question was denied access to British shipping facilities. Breach of any agreement pursuant to which a warrant was granted subjected the vessel to liability to seizure and the company to exclusion from trading at any British port. "Ships' warrants" and "navicerts" were also withheld from vessels and goods insured with enemy companies as a means of injuring the enemies' finances.

With regard to the voluntary subjection by neutrals to such. measures of control, the German prize courts ruled in the Ole Wegger that: "A ship which is subjected to such control thereby directly furthers and facilitates the military and economic war effort of the enemy government, and, save in exceptional circumstances in individual cases, is therefore guilty of hostile assistance."

Though the Cnited States objected to the order of Nov. 27, 1939, and reserved its rights in the premises, it soon adopted measures of supporting the British government (see NEUTRALITY) and ceased to object to the British blockade measures. It will be observed, however, that World War II further demonstrated the relative unimportance of the traditional form of blockade and again led to the attempt of belligerents to apply the doctrine of continuous voyage to blockade and to utilize their sovereign powers as a means of compelling neutral compliance with policies which, if carried out by naval power exclusively, would constitute a violation of international law.

See ECONOMIC WARFARE; see also Index references under "Blockade" in the Index volume.

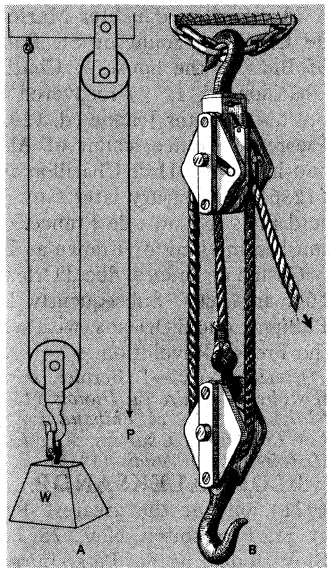
BLOCK AND TACKLE, a most useful and extensively applied mechanical device. The principle is represented by A in the diagram, showing the load W suspended by two "parts" or "falls" of rope so that a weight of 1 lb. applied at P will pull a load of 2 lb. at W; this assumes friction to be absent and the rope perfectly flexible. By increasing the number of pulleys and falls of rope, in the manner shown by B the mechanical advantage is increased according to:

$$W = nP$$

n being the number of parts of rope that support the movable block. If, for instance, there are three pulleys in the top block and two in the moving block, then the weight is supported by five parts of rope; therefore, a force of 120 lb. will hoist a load of 600 lb.



PRINCIPLE OF BLOCK AND TACKLE

(A) Two falls of rope used to increase mechanical advantage; (B) block and tackle with brake (see text)

Block and tackle arrangements are used for lifting loads, rigging, tightening guys and hauling. The objection that the load is not held, as it is in the differential pulley blocks and worm-geared types, may be obviated by fitting a friction brake. The top block in B is of this self-sustaining form, the act of moving the hand rope outward or to one side applying the brake.

BLOEMAERT, ABRAHAM (1564–1651). Dutch painter and engraver, born at Gorinchem, the son of an architect, was first a pupil of Gerrit Splinter (pupil of Frans Floris) and of Joos de Beer, at Utrecht. He then spent three years in Paris studying, and on his return to his native country received further training from Hieronymus Francken. He settled finally at Utrecht, where he became dean of the Guild of St. Luke. He painted and etched historical and allegorical pictures, landscapes, still life, animal pictures and flower pieces.

Among Bloemaert's pupils were his four sons. Hendrick. Frederick, Cornelius and Adriaan (all of whom achieved considerable reputation as painters or engravers), the two Honthorsts and Jacob Cuyp.

BLOEMEN, JAN FRANS VAN (1662–c. 1748), Flemish painter, born at Antwerp, studied and lived in Italy. At Rome he was styled Orizzonte because of his painting of horizons in his landscapes, which are reminiscent of Gaspard Dughet. His brothers Pieter (1657–1719), styled Standaert (from his military pictures). and Norbert (1670–1746) were also painters.

BLOEMFONTEIN, the capital city of the Orange Free State and judicial capital of the Republic of South Africa, lies 4,568 ft. above sea level on the Free State plateau and is the geographical hub of South Africa's rail. road and air transport systems and a focal point of distribution. Pop. (1960) 140,924, of whom 61.213 were Europeans. It has clear air and a dry, invigorating climate. Spread over hills and kopjes (hillocks), its natural and man-made beauties justify its name which means "fountain of flowers."

Founded in 1846 by Maj. Douglas Warden as a fort and residency, it became the capital of the Orange Free State republic. Its open spaces include the Franklin Game reserve, within the city; King's park and zoo; a modern sports stadium; Prince's Rose garden; and the Mazelspoort, the republic's premier inland holiday resort. Buildings include the City hall; the Court of Appeal, with its fine stinkwood paneled courtroom; the Raadsaal, the former Free State parliament house, now seat of the provincial council; the Old Raadsaal, a one-roomed house, now a national monument; the Presidency, former house of the republic's president; the residence of the former governors general, in old Cape Dutch style; and a modern civic theatre and art gallery. The National Women's monument, sculptured by Anton van Wouw, is a memorial to the women and children who died during the South African War. Many national conferences are held annually in the City hall; the Central Agricultural society's annual show draws visitors from all parts of the republic. Bloemfontein has an Anglican cathedral and a Moeder Kerk (oldest Dutch Reformed church) among other churches. There are extensive new housing. modern railway workshops and industrial sites, with ample power and water supplies.

It is the seat of the University of the Orange Free State (founded in 1855 as a constituent college of the University of South Africa), and there are also technical, industrial and agricultural schools. The public library receives copies of all national publications and there is a unique Central Drama library. The National museum contains important collections of skulls, including Africanthropus Helmei Dreyer, discovered 30 mi. N. of the city. The archaeological collection includes items representing all the Stone Age cultures of South Africa. There are also two important observatories, the American Lamont-Hussey (University of Michigan) on Naval hill and the Boyden station (partly maintained by Harvard university) at Mazelspoort.

Bloemfontein is within 24 hours by rail of any point in the republic: Johannesburg is 263 mi. distant, Durban 505 mi. and Cape Town 749 mi. A direct road links the city with the Free State gold fields. The J. B. M. Hertzog national airport. 3 mi. E. of the city, has one of the most modern terminal buildings in the republic. (P. R. Jo.)

BLOIS, capital of the *département* of Loir-et-Cher, central France, is 56 km. (35 mi.) S.W. of OrlCans by road. Pop. (1954) 24,352. First mentioned by Gregory of Tours in the 6th century, Blois, was, in the earlier middle ages, the home of a powerful line of counts from whom the Capetian kings sprang (see BLOIS, COUNTSHIP OF; CAPET). At the end of the 14th century Blois was acquired by Louis, duc d'Orléans. It was from Blois that in 1429 Joan of Arc set out to raise the siege of Orléans. In 1498 the son of Duke Charles and grandson of Duke Louis succeeded to the throne of France as Louis XII and from then until the end of the 16th century Blois was almost a second capital of France. At the beginning of the 17th century the teachers of the French language at Blois were famous, among them was Claude Manger who had a kind of French university in London known as "Little Blois." Blois was occupied by the Germans for a short time in 1870–71 during the Franco-German War, and again in World War II from June 1940 to Sept. 1944.

Known from its association with the French royal house as the "city of kings," Blois is the centre of the Loire chbteau country. The city lies on the slopes of hills on the right bank of the Loire and is dominated by the chbteau and the cathedral. The oldest part of the chbteau, the main hall, was built in the 13th century, and there the states-general met in 1576 and 1588. The northwest wing, erected by Francis I, contains the room where Henry, duke of Guise, was murdered by order of King Henry III on Dec. 23, 1588. This wing is also famous for its staircase tower with its graceful sculpture. The northeast wing, which is the entrance to the château and contains a museum, was built by Louis XII and is connected with a gallery and chapel on the southeast side of the great courtyard. On the southwest side is the wing erected by Gaston d'Orléans in 1635–38.

The Gothic cathedral was largely rebuilt at the end of the 17th century on the site of an ancient Carolingian church; it has a 10th–11th century crypt. The church of the 10th-century abbey of St. Lomer, founded by monks fleeing before the Normans, was refashioned in the 12th–13th centuries and rededicated to St. Nicolas after the French Revolution. The convent buildings (17th century) are now a hospital. Of the ancient houses in Blois the Renaissance Hôtel d'Alluye is a good example. The picturesque streets include the Rue du Chant des Oiseaux, the Rue du Lion Ferré, and the Rue Pierre de Blois, whose steep and twisting surface is paved with rose-coloured bricks. The terraces of both the chbteau and the 18th-century episcopal palace (now the town hall), adjoining the cathedral, give views over the city and the wide Loire valley. Near the château is the pavilion where Anne of Brittany, the first wife of Louis XII, had her oratory. An 18th-

century bridge (built, as was the episcopal palace, by J. J. Gabriel) connects Blois with its suburb of Vienne, on the left bank of the Loire, where are the church of St. Saturnin (15th–16th centuries) and the *camposanto,* whose elegant 16th-century galleries now house some old stones and sculptures, relics from buildings destroyed in World War II. There is the ancient portal of the house where Cassandre, a heroine of the poet Pierre de Ronsard, was born. Though the beauty of Blois is chiefly due to its Renaissance buildings, there are some fine modern ones, among which is the basilica of the Franciscans, completed in 1949, with a carillon of 48 bells, carvings of the Stations of the Cross by Jean Lambert-Rucki and stained-glass windows by Louis Barillet.

Blois is on the main line from Paris to Bordeaux and Spain. There is an airport at Breuil, 14 km. (9 mi.) N.W. The town is a market centre for the corn-producing region of Beauce on the north of the Loire and for the Sologne to the south, where asparagus, wines, fruits and flowers are grown. Chocolate, sweetmeats. boots and shoes, clothing, furniture, caravans, toys, tapestry, saws. machine tools, cardboard and carbon paper, etc., are made, and printing is carried on. (J. M.-D.)

BLOIS, COUNTSHIP OF, a feudal title that rose to great importance in medieval France as its holders came to possess not only Blois (*q.v.*) itself and its immediate vicinity, the Blésois, but also other domains. The first recorded counts of Blois, William (d. 834) and his son or nephew Eudes (d. 865 or earlier), seem to have been only governors, individually appointed rather than hereditary. The next count, however. was Robert (*q.v.*) the Strong, duke of the whole region betneen the Seine and the Loire and ancestor of the royal house of Capet. He and his early successors appointed viscounts in Blois, but about 940 the title of count mas assumed by Thibaut I the Old or the Cheat (d. about 975 or 977). This Thibaut, founder of the hereditary house, held moreover. not only a large part of Sologne around Romorantin to the south, but also the countship of Chbteaudun and its vicinity (Dunois) to the north, and beyond that, the countship of Chartres, while to the west he was count of Tours (see TOURAINE), so that his domain stretched from the Indre to the Eure rivers.

From 987, when the accession of the Capetians to the French crown was finally established, the counts of Blois were the king's immediate vassals, and Thibaut I's successors Eudes I (d. 995), Thibaut II (d. 1004) and Eudes II (d. 1037) were the new royal dynasty's most dangerous rivals. Eudes I obliged Hugh Capet to grant him the countship of Dreux. north of Chartres, in return for help against Charles of Lorraine. Eudes II, though he lost much of Touraine to the Angevins (*see* ANJOU) in 1016 and had to restore Dreux to Robert II of France in 1017, began the rise of the house of Blois to even greater power by the acquisition of the countships of Sancerre in 1015 and of Champagne (*q.v.*), as Eudes I, in 1019 or 1020 (or perhaps c. 1023). The latter acquisition meant that the royal domain was threatened both west and east by the Blois-Champagne power. Thibaut III of Blois (d. 1089) did not at once succeed Eudes in Champagne and lost Tours itself to the Angevins in 1044, but in 1063 became himself count of Champagne (as Thibaut I). His death was followed by another partition, Blois, Chartres, etc., with Meaux in Champagne. passing to his son Stephen (Estienne) Henry (d. 1102). while Troyes and the rest of Champagne went to another son. Stephen Henry's sons were Thibaut IV (d. 1152), Henry, who became bishop of Winchester in England, and Stephen (q v.), the future king of England. Thibaut IV, who reunited Champagne (as Thibaut II) nith Blois in 1125, was considered the second person in France, being alternately the ally and the enemy of Louis VI and Louis VII. The countship was then at the zenith of its power. Fortunately for the Capetians, Blois and Champagne were finally divided betneen Thibaut IV's sons in 1152. Thibaut V (d. 1191), who inherited Blois, Chartres, etc., sided generally nith Louis VII (his brother-in-law and father-in-law), became grand seneschal of France and fought against the Angevin king of England. Henry II. Under Louis I (d. 1205) and Thibaut VI (d. 1218) the countship began to decline. When Thibaut VI died childless, Chartres and Romorantin passed to his aunt Isabelle, while her elder sister Marguerite and her husband Gautier d'Avesnes retained Blois and Châteaudun.

Marguerite's daughter Marie was married in 1225 to Hugues I de Chbtillon, count of St. Pol, and this brought the countship of Blois to the house of Chbtillon in 1230. Their son Jean de Châtillon (d. 1279) recovered Chartres by marrying the heiress, but his daughter Jeanne (d. 1291), after the death of her husband, Pierre de France, count of Alençon, in 1283, sold Blois to her cousin Hugues II de Chbtillon and Chartres to Philip IV of France (1286). A century later Guy II, the sixth successor of Hugues, sold Blois to Louis de France, duc d'Orléans. The latter's grandson became king of France as Louis XII (1498).

Gaston de France, duc d'Orléans, held Blois as an appanage from 1626 to 1660. Subsequently Louis XIV gave it to his brother Philippe, duc d'Orléans, with whose descendants it remained until the French Revolution.

BLOK, ALEKSANDR ALEKSANDROVICH (1880–1921), one of the greatest Russian poets of all times. Born in St. Petersburg, Nov. 28 (new style; 16. old style), 1880, Blok studied at St. Petersburg university. One of the younger Russian Symbolists, he was influenced by the mystic writings of the philosopher Vladimir Soloviev (*q.v.*), but worked in the Russian romantic tradition of Vasili Zhukovski, Mikhail Lermontov and Afanasi Fet (*qq.v.*). The three volumes of his collected works of 1911–12—Stikhi o Prekrasnoi Dame ("Verses About the Fair Lady"), *Nechayannaya* radost ("Unexpected Joy") and *Snezhnaya noch* ("Snowy Night")—reflect the stages of his poetic development—mystic idealism, romantic irony and disenchantment, and finally grim awareness of the surrounding "terrible world." In his later poetry the image of Russia became important. Closely related to the poems are his lyrical dramas (1906–08), *Balaganchik* (Eng. trans. "The Puppet Show," Slavonic and East *European* Review, vol. xxviii, no. 71. 1950). *Neznakomka* (Eng. trans. "The Stranger," Slavonic and East *European* Review, vol. xxvii, no. 68, 1948), *Korol na ploshchadi* (Eng. trans. "The King in the Square," Slavonic Review, vol. xii. no. 36, 1934) and Pesnya *sudby* (Eng. trans. "The Song of Fate," Poet Lore, vol. xliv, no. 1, 1938). Another play. *Roza* i krest (1913; Eng. trans. "The Rose and the Cross," Slavonic and East European Review, vol. xiv, no. 42, 1936), set in medieval France, is also concerned with Blok's major poetic themes. The remarkable unfinished narrative poem *Vozmezdie* ("Retribution"), begun in 1910, has for its themes Russia and the doom of Blok's own generation. Blok responded to the Revolution of 1917 with the poem Dvenadtsat (1918; Eng. trans. The Twelve, 1920). A description of a group of Red army soldiers marching through Petrograd by night during the winter of the Revolution. this strange balladlike poem, extraordinary in its rhythmic polyphony though ambiguous in its message, has a harsh, disturbing power. It was Blok's last major work. He wrote almost no poetry after 1918 but in Feb. 1921 delivered a striking speech on the mission of the poet at a meeting in commemoration of Pushkin.

Blok died in Petrograd, Aug. 7, 1921, from the aftereffects of malnutrition, apparently deeply disillusioned by the Revolution he had welcomed as a spiritual renaissance.

BLOMFIELD, CHARLES JAMES (1786–1857), bishop of London and a Greek scholar of great repute, was born on May 29, 1786, at Bury St. Edmunds. After a brilliant career, which included the editing of Aeschylus' *Prometheus Vinctus* (1810) and Euripides (1821), at Trinity college, Cambridge, he held a succession of benefices and became bishop of Chester in 1824, retaining the rich benefice of St. Botolph, Bishopsgate, *in com-*

mendam. In 1828 he was translated to the see of London, where he threw himself into the task of church building with such vigour that about 200 new churches were consecrated there during his episcopate. He co-operated with the government in carrying through far-reaching schemes of church reform, through the newly formed ecclesiastical commission. He keenly supported the plan for an Anglican bishopric in Jerusalem and the colonial bishoprics fund. He raised the standards of his clergy and helped to smooth over the early tractarian disputes. In 1856 he resigned because of ill-health and died at Fulham on Aug. 5, 1857.

See his memoirs ed. by Alfred Blomfield (1863). (N. S.)

BLONDEL, DAVID (1590–1655), French Protestant theologian of considerable critical faculty, was born at Châlons-sur-Marne on Sept. 25, 1590. He studied at Geneva and later became a pastor at Houdan. In 1619 appeared his *Modeste de'claration de la sincerité et verité des Églises réformées*, a reply to Catholic attacks on Protestant doctrines. He published various other works, including *Pseudo-Isidorus et Turrianus Vapulans* (1628), in which he discredited the so-called "False Decretals," and *Éclaircissement familier de la question: Si une femme a été assise au siège papal de Rome* . . . (1646), which successfully refuted the myth of Pope Joan. to the indignation of some fellow Protestant polemicists who regretted this disposal of a useful piece of scandal. In 1650 Blonde1 became professor of history at Amsterdam, where he died on April 6, 1655.

BLONDEL, JACQUES FRANÇOIS (1705–1774), French architect, began life as an architectural engraver. He was among the earliest founders of schools of architecture in France, but he is now best remembered by his voluminous work *L'Architecture française*, a collection of views of famous buildings.

BLONDIN, CHARLES (real name JEAN FRANÇOIS GRAVELET) (1824–1897), French tightrope walker and acrobat, was born at St. Omer, France, on Feb. 28, 1824, and died in London on Feb. 19, 1897. When five years old he was sent to the École de Gymnase, at Lyons, and after six months' training as an acrobat, made his first public appearance as "the Little Wonder." He especially owed his celebrity and fortune to his idea of crossing Niagara falls on a tightrope. 1.100 ft. long, 160 ft. above the water. This he accomplished a number of times, first in 1859, always with different theatric variations: blindfolded, in a sack, trundling a wheelbarrow, on stilts. carrying a man on his back, sitting down midway while he made and ate an omelette. In 1861 he appeared in London at the Crystal Palace. turning somersaults on stilts on a rope stretched across the central transept. 170 ft. from the ground. His final performance was given at Belfast in 1896.

BLOOD. The blood is a fluid, circulating tissue found in all higher animals and in many invertebrates; it is a tissue, as epithelium, muscle and bone are tissues, because it contains living cells and has specific functions, chief among them being the conveyance of materials from one part of the body to another. The general principle on which the chemical life of the body is conducted is that each living cell carries out in its own substance all the chemical processes necessary to its existence. Therefore all the materials which it requires must be carried to it. and those which it discards must be removed. Throughout the body of higher animals a system of transport—the blood vascular system—has evolved, affording an efficient route for the blood and providing the necessary, intimate contact with every living cell; this system has become highly specialized in the vertebrates. *See* CIRCULATION OF BLOOD and CIRCCLATORY SYSTEM for a discussion of blood transport in the body.

The principal materials which a living cell—whether it is a muscle fibre, a nerve cell or a gland cell—requires are sugar, amino acids, fat, vitamins, oxygen, salts, hormones and water. The organs of digestion convert the solid constituents of the food to such a form that the blood can absorb them and deliver them to the cells of the body. The principal substances which the cell must dispose of are carbonic acid and simple soluble compounds of nitrogen—compounds of ammonia, etc.. or, in the case of the liver, urea. These are conveyed by the blood to the various organs functioning in an excretory capacity, ridding the body of noxious wastes.

In all the higher animals blood consists of a fluid part, the plasma, in which are suspended corpuscles of various kinds: the red blood cells (erythrocytes), the white blood cells (leukocytes) and the blood platelets.

PLASMA

The plasma has a faint straw colour and is clear unless a meal containing fat has been eaten recently, in which case it is somewhat milky because of the minute globules of fat which it transports. The two materials dissolved in greatest quantity are albuminous substances (proteins) and common salt.

The general nature of plasma resembles that of raw egg white, diluted with 0.9% solution of salt. In detail, its composition is roughly as follows: water, 90%; proteins (fibrinogen, globulins, albumin), 9%; salts (of Na, K, Ca, Mg, Fe. Cu, etc.), 0.9%; sugar, urea, uric acid and creatinin, traces. Water is present primarily in order to dissolve the other substances and to afford the blood a degree of fluidity sufficient to secure its easy flow through the minute capillaries.

Protein.— The chemical basis of all life is protein in a watery medium. All the cells with which the blood is in intimate relation are composed of it. The protein formed within these cells is retained, and among its properties is that of attracting water to itself; *i.e.*, osmosis. If proteins were present only in the cells and not in the blood, water would always be passing from the blood into the cells, until the latter became swollen and dropsical. The protein in the blood balances that in the cells and so the water equilibrium is maintained. The case is different with salts; they can pass to and fro with the water and therefore do not set up any permanent stream of water in any direction.

A second purpose of at least one protein, fibrinogen, is to enable the blood to clot. The clot is the first aid to the healing of a wound; it at once plugs the wound and forms a scaffold on which new tissue is built. Thus, if the chin is cut in shaving, the solidification of the blood results not from drying or exposure but from coagulation, a chemical process in the plasma in which the fibrinogen (hitherto in solution) separates out as a spongy network of fibrin which connects the edges of the wound and prevents the further passage of blood cells. (See *Platelets [Thrombocyta]*, below.)

From the chemist's point of view the protein molecule consists of a great number of special organic acids (amino acids) held together in a particular way by links (peptide bonds; *see* PROTEINS) of which ammonia is the basis. When digestion takes place in the alimentary canal the protein is broken into the individual amino acids. These form molecules small enough to pierce the walls of the capillary vessels within the intestines, and so they are picked up by the blood and conveyed to the tissues. If the protein molecule of a cell in one of the tissues has lost a particular amino acid, the appropriate one can be acquired from the assortment which the blood carries.

Similarly. when the protein molecule of a cell loses an amino acid, the lost matter does not appear in the blood as such, but as a salt of ammonia. It is carried to the liver, where it is turned into urea and thrust back into the blood and eventually excreted.

Salts.--Sodium chloride (as sodium and chloride ions, or electrically charged atoms) in blood serves primarily to effect protein dissolution. Since most proteins in the blood do not dissolve in pure water, and since protein can form the basis of living material only if it is in solution, salt is essential, Many salts might serve equally well to dissolve the protein but they are not as innocuous as sodium chloride in other respects. For example. potassium chloride would stop the heart and ammonium chloride might cause convulsions.

The body is capable of regulating the percentage of sodium chloride in the blood with great accuracy. If it is not taken into the body in sufficient quantity, the kidney, acting to maintain the proper salt balance, ceases to excrete it, and the urine, which normally contains a considerable quantity of sodium chloride is almost free from it. The result of a deficiency of this salt may be felt by persons who carry on sustained and heavy work in very

hot surroundings (deep mines or furnaces of ships). Such persons may lose several pounds of sweat (practically a pure solution of sodium chloride) by perspiration in a few hours. By drinking water they make up the deficiency of fluid but not of salt. The concentration of sodium chloride in the blood drops to critical levels, resulting in agonizing cramps in various muscle groups. These cramps do not occur if the chloride loss is made up by taking salt tablets or other materials containing salt.

Although calcium, potassium and magnesium ions are present in much smaller quantities than sodium ions. it is not to be supposed that they are correspondingly valueless. The proper working of the heart appears to depend upon a fine balance between calcium and potassium ions. Calcium ions also have a special function related to the clotting of blood; they are essential to the reactions immediately preceding the formation of the fibrin clot from fibrinogen (see Platelets [Thrombocytes] below). Among the salts in plasma, sodium bicarbonate holds a special place: it helps to transport carbonic acid from the tissues to the lungs, and to maintain the blood within very narrow limits, just on the alkaline side of neutrality.

The concentration of hydrogen ions in normal plasma equals 0.4×10^{-7} g. of hydrogen per litre (pH = 7.4). Any considerable increase in hydrogen ions (lowering of the pH value, acidosis) causes increased and violent breathing; this in turn enhances the expulsion of carbonic acid from the plasma into the air, thereby tending to raise the pH value of the blood to its normal level. (See RESPIRATION.) On the other hand, should the blood become unduly alkaline (alkalosis) the kidney will relieve this condition by secreting an increased quantity of alkali in the urine. This balance of acid and alkali, the maintenance of which preserves the reaction of the blood at a pH of 7.4, is called the acid-base equilibrium of the blood. To give a single instance of the way in which it is maintained: when a considerable meal is eaten, acid is secreted in the stomach for the purpose of effecting its digestion. Collaterally, acid is withdrawn from the blood. which in itself would make the blood more alkaline; the kidney then secretes sodium; hence, the so-called alkaline tide in the urine.

Among fluids, blood is remarkable in that addition of either acids or alkalies produces only trifling alterations in the hydrogen ion concentration — much less than if the same acids or alkalies were added to water. This fact is expressed by the phrase "blood is very highly buffered." The buffering of blood is achieved principally by the interaction of the sodium bicarbonate in the plasma with the pigment substance, hemoglobin, in the red cells. If carbonic acid is added to the plasma. sodium is withdrawn from the sodium chloride, liberating chlorine ions; these tend to pass into the red cells and unite with some of the sodium which had previously been in combination with the hemoglobin.

Hormones. — Large numbers of very potent chemical substances called hormones are secreted into the blood by such organs as the thyroid, the suprarenal (adrenal) gland, the islets of the pancreas, the pituitary body, etc. These substances are carried by the blood from their origin to areas more or less remote where they assert their specific physiologic action.

CELLS OF THE BLOOD

The cells of the peripheral blood (blood outside the bone marrow) are divided into two groups: the red blood cells (erythrocytes) and the white blood cells (leukocytes). The latter, in turn, are subdivided into nongranular leukocytes (agranulocytes) and granular leukocytes (granulocytes). The agranulocytes consist of two subtypes: (1) the lymphocytes; and (2) the monocytes, while the granulocytes consist of three types: (1) the heterophile leukocytes (neutrophile leukocytes in man); (2) the eosinophile leukocytes; and (3) the basophile leukocytes. The names are largely based on the staining characteristics of small granules present in the cell body. The granulocytes are also called polymorphonuclear blood cells, because of the segmentation of their nuclei. In addition to these cellular elements, the blood contains the so-called blood platelets (thrombocytes).

Blood Cell Formation **in** Man. — The blood cells do not originate in the blood stream itself but arise in specific blood cell-forming organs. In the adult organism the following obtains: the bone marrow produces the red blood cells as well as the granulocytes; the lymphatic tissues produce the lymphocytes; and the reticulo-endothelial tissues of the spleen, bone marrow and liver produce the monocytes. (See also BONE MARROW; LIVER; SPLEEN.)

In the embryo, the first site of blood formation is the yolk sac. There large nucleated red blood cells are formed from basophilic cells which are descendants of the embryonic tissue cells (mesenchymal cells). Later in embryonic life the liver becomes the most important red blood cell-forming organ. The liver is soon succeeded by the bone marrow, which in adult life is the only source of both erythrocytes and granulocytes.

The erythrocytes arise in the bone marrow through a series of gradual transformations from primitive stem cells called either hemocytoblasts or myeloblasts. The different names are related to differences of opinion regarding the precise nature of the stem cell (see BONE MARROW). The intermediate forms preceding the mature erythrocytes are called successively polychromatophile erythroblasts and normoblasts, depending on the degree of maturity.

The white cells or granulocytes are derived from the same primitive stem cells which form the erythrocytes. The intermediate forms between the stem cell and the mature granulocytes are called myelocytes.

RED BLOOD CELLS

The primary object of the red blood cell is to transport oxygen. Its efficiency as such depends upon the quality and quantity of hemoglobin it contains. The number of red cells in a human adult male ranges normally from 4,500,000 to 6,000,000 per cubic millimetre of blood. In 100 ml. of blood 12–17 g. of hemoglobin are normally found. This amount of hemoglobin carries 21 volumes of oxygen — more than 50 times the quantity which could be dissolved in the blood in the absence of hemoglobin. The intense oxidation in the tissues of warm-blooded animals has been made possible only by the existence and utilization of hemoglobin. The number of red cells per cubic millimetre of blood varies in different animals as shown in Table I. There is a definite sex variation,

TABLE I.—*Number of Red Blood Cells in Animals*
(in millions **per** cu.mm. of blood)

and in the same individual the size may vary according to the conditions of stress under which they are produced. The red cell in man consists of a minute, disclike, biconcave body having an average diameter of 7.5μ and a greatest thickness of 2μ near the edge. It is very elastic and in the small vessels may be forced into other shapes.

The red cell consists of about 60% water and 40% solids, the latter being composed almost entirely of the red pigment hemoglobin. In the larger vessels they tend to pile up in rouleaux (like rolls of coins)—an arrangement which is likely to occur in the case of any series of disclike bodies with fatty surfaces, floating in an aqueous fluid. Although in mammals the red cells are normally nonnucleated, under abnormal conditions; *e.g.* in severe anemia (*q.v.*), nucleated types may appear in the circulating blood.

The fine structure of the red cell has been a matter of much controversy, some regarding it simply as a bag of fluid and others as consisting of a spongework or stroma. In the absence of certain knowledge of the correctness of either view it may be said that discussions on the chemistry and physics of the red cells are usually carried out on the basis of the former, the cell being regarded as fluid material surrounded by a membrane possessing certain definite chemical and physical characteristics. The membrane is permeable, for instance, to water and to acid radicals, but less so to sodium ions, potassium ions, etc. These facts form the basis of complicated readjustments of equilibriums between the constituents of the cells and those of the plasma when the latter are altered. Among the materials which may pass through the membrane is water; therefore the cell may swell and shrink. Normally it swells if the medium in which it is placed is made more acid or is made hypotonic (by diluting the medium, thereby lowering the osmotic pressure in relation to that in the corpuscule).

Hemolysis.—The passing of water into the red cell may take place on such a scale as ultimately to burst the membrane. The solution of hemoglobin previously enclosed escapes into the surrounding fluid, and the structures which contained the hemoglobin are left as "shadows" or "ghosts." This process is known as laking or hemolysis and may be induced by the addition of distilled water to blood. The red cells may also be ruptured in other ways; for example, by freezing and thawing and by the addition of saponin or bile salts. More remarkable is the fact that if the red cells of one species are injected into the vessels of another they are destroyed, their contained hemoglobin being liberated. This phenomenon is not a result of osmotic or similar changes, but of some specific substance—a hemolysin—in the plasma which attacks the foreign red cells. It is one of several substances on which the immunity of the body against disease depends *(see* IMMUNITY).

Blood Groups.—The red blood cells of all normal human beings, whether their skins are white, black, yellow, brown or copper-coloured. all have an identical appearance. However, they contain materials called agglutinogens which vary in type in different individuals and to some extent in different races. The agglutinogens are probably of carbohydrate structure and have the capacity of combining with other materials called agglutinins. The latter are present in the blood plasma or serum, causing red cells to clump together (agglutinate) like bunches of grapes. Like a lock and its specific key. each agglutinogen in a red cell can be acted upon only by its specific agglutinin (see AGGLUTININ).

In 1900 and later, Karl Landsteiner found by studying these reactions that human beings could be divided into four large classes according to the type of agglutinogen contained in their red cells; some contained agglutinogen A, others agglutinogen B, others both A and B and still others neither A nor B; the latter type was called type O. Following the discovery of the ABO blood group system, several other systems were found, chief among them being the MN and Rh groups; these along with the more recently discovered groups are discussed in the article BLOOD GROUPS. *(See* also *Individuality of Human* Blood below.)

Life Span of the Red Cell.—The longevity or life span of the red blood cell may be determined in various ways, the simplest and most commonly used being the blood-grouping methods, the basis of which was introduced by W. Ashby in 1918. If type O blood cells are transfused into the circulation of A or B persons it is possible to follow along the O cells by using anti-A or anti-B testing serums. The O cells will not be agglutinated and can be counted. By this method, the lifetime of the red cell has been found to be approximately 110–120 days. More recent methods employing natural and radioactive isotopes to "tag" the red cell in the bone marrow have set the life span of the human red cell at about 127 days.

The red cell, which is in reality a chemical envelope containing, among other substances, hemoglobin. is gradually worn out by its numerous passages through the circulating blood and by its thousands of chemical exchanges. It probably becomes fragmented, chiefly through physical forces, following which its various constituents are liberated and either reutilized or discharged from the body. The hemoglobin fraction of the red cell is broken up into its constituent portions of globin, iron and porphyrin. Upon the opening of the ring structure of porphyrin, a yellow bile pigment called bilirubin may be formed.

Fragility of the Red Blood Cells.—All red cells are not disrupted with equal ease by hemolytic agents. Thus, while all or nearly all cells are disrupted by distilled water, salt solutions of less saline concentration than plasma will disrupt some and not others; the "fragility" of the cells differs. Thus, in the case of man, for various percentage concentrations of salt solution, hemolytic disruption of red cells is as shown in Table III. The resistance of the red cells of some animals is greater than that of others. If different animals are graded according to the resistance of their red cells to the hemolytic agent saponin, the following order (in decreasing resistance) is observed: lamb, goat, ox, cat, gray mouse, pig, gray rat, dog, white rat, rabbit and guinea pig. However, based upon the resistance of their red cells to hypotonic salt solutions the animals are listed in precisely the reverse order.

Blood Pigments.—The pigment of the red blood cells which is responsible for their capacity to carry oxygen is called hemoglobin. It consists of a compound of a protein, globin, with a pigment complex called heme.

Heme and Hemoglobin.—Heme has the formula $C_{34}H_{32}O_4N_4Fe$. Its principal chemical characteristics are: (1) it contains iron in the ferrous state (Fe^{2+}); (2) it contains four pyrrole groupings, a fact which gives it a superficial relationship to chlorophyll; (3) it is easily oxidized by chemical reagents to hematin, in which the iron is in the ferric state (Fe^{3+}). In small quantities, heme is widely distributed both in the animal and vegetable kingdoms. In the hemoglobin molecule, four heme molecules are attached to the globin molecule. Heme forms compounds other than hemoglobin with proteins; a conjunction of three such compounds is frequently found both in animals and plants and is called cytochrome. This material is of great importance in the numerous enzyme systems of the body cells. A pigment related to hemoglobin—myohemoglobin or muscle hemoglobin—functions as an oxygen reservoir in muscle fibres.

Unlike cytochrome, hemoglobin can easily be crystallized, the red cells of different animals yielding crystals of different forms. These hemoglobins present specific differences in solubility, in their power of uniting with gases and in the position of the bands in their absorption spectra. Such differences are believed to be due to the specific characters of the globin.

Oxyhemoglobin.—In the body hemoglobin is oxygenated. The reaction is reversible and is not a true oxidation; it more closely resembles a physical process rather than a chemical one. Heme, influenced by the globin portion of the molecule, combines with oxygen forming a compound—oxyhemoglobin—of so loose a nature that (1) it can be completely broken down in a vacuum and (2) the proportion of the whole hemoglobin oxygenated is a function of the partial pressure of oxygen (oxygen tension) to which it is exposed. On this property depends the value of the pigment as a carrier of oxygen.

$$\underset{\text{(as in the lungs)}}{\text{High oxygen tension}}$$
$$\text{Hemoglobin} + \text{oxygen} \rightleftarrows \text{oxyhemoglobin}$$
$$\underset{\text{(as in metabolizing tissues)}}{\text{Low oxygen tension}}$$

The valency of the iron in hemoglobin appears not to be affected; it remains in the ferrous condition throughout.

Carboxyhemoglobin.—Hemoglobin unites with carbon monoxide in a manner similar to that of its union with oxygen, but the affinity of the pigment for carbon monoxide is much greater than for oxygen: at the body temperature in man it is about 250 times as great (for carbon monoxide poisoning, see HYPOXIA).

Other hemoglobin compounds normally not found in blood are the pathological products nitric oxide hemoglobin (hemoglobin + nitric oxide gas) and sulfhemoglobin (hemoglobin + hydrogen sulfide gas).

Methemoglobin.— In all the above hemoglobin compounds the iron is in the ferrous state. A compound found in small amounts in normal blood, but occurring in greater concentration in certain cases of poisoning (see HYPOXIA). is methemoglobin, which differs from ordinary hemoglobin in that it contains iron in the ferric condition. It is formed by the action of potassium ferricyanide, nitrites, acetanilide, etc., on the hemoglobin of the blood.

Bilirubin.— 'This pigment is formed by opening up of the heme pigment molecule which has already been freed of iron. Bilirubin is a yellow pigment which is probably derived from the hemoglobin in the phagocytic cells of the reticulo-endothelial system, notably in the spleen, bone marrow, liver and lymph nodes. This yellow pigment colours the blood plasma a faint yellow and is normally present in a concentration of approximately 0.5 mg. per 100 of blood. From the blood, where it is present in a combined form, it goes to the liver cells which secrete it as "free" bilirubin into the bile. 'The golden-yellow colour of bile is caused largely by this pigment. Some of the bile is stored in the gall bladder, the remainder going into the intestines, where it undergoes various conversions to a pigment called urobilinogen, excreted in the stools. An index of the amount of blood destruction may be obtained from study of the fecal urobilinogen, which is normally 100 to 150 mg. per day. Trace amounts of this pigment are excreted by the kidneys and found in the urine.

Hemochromogen.—Of the other derivatives of hemoglobin which do not occur in blood, perhaps the most important is hemochromogen, in which heme is associated not with native globin but with another protein formed by the action of strong alkali on globin and known as denatured globin. The practical importance of hemochromogen lies in two facts: (1) it is easily made from old blood by the action of alkali in combination with a reducing agent; and (2) of all the blood pigments it is the one whose spectrum can be recognized in the greatest dilution. Therefore, in medicolegal cases. stains suspected of being due to blood can be tested by attempting the conversion of the pigment into hemochromogen and the observation of the material obtained with the spectroscope.

WHITE BLOOD CELLS

The blood of an adult human being contains 5,000 to 10,000 white blood cells per cubic millimetre. Thus, there is only one white cell to 400–500 red cells. The actual number varies greatly from hour to hour in the same person. Lowest counts being observed in the morning and highest in the afternoon and, particularly, after unusual muscular activity.

In man the neutrophile leukocytes constitute 60%–70% of the total number of leukocytes; in these cells contained granules are small and stain purplish with Giemsa, Wright or similar dyes. (In other mammals similar leukocytes are called heterophils; in these the size and stainability of the granules varies from species to species.) The eosinophile leukocytes contain relatively coarse granules which stain red with any of the above-mentioned stains. These cells constitute 1%–4% of all leukocytes. The basophile leukocytes form 0%–1% of all leukocytes. Their granules stain intensively with basic dyes. In addition to the differences in the granules, the three groups of granular leukocytes differ chaiacteristically in the configuration of the nucleus. In spherical condition, the granulocytes have a diameter of 9 to 10 μ. When flattened out. as is the case in blood smear preparations, their diameter varies from 10 to 12 μ.

The lymphocytes number 20%–30% of the total number of leukocytes in adults. Infants and young children have about 30%–60% lymphocytes. These cells are generally smaller than the granulocytes. Spherically, their diameter is 6 to 8 μ, though larger ones are encountered. It is a characteristic of the cytoplasm of the lymphocytes to stain deeply with basic dyes. This is the result of the presence of nucleoproteins in the cytoplasm.

The monocytes number 2%–6% of the total number of leukocytes. They are larger than the lymphocytes and have an oval or horseshoe-shaped nucleus and a grayish cytoplasm. Because of the presence of intermediate forms between the lymphocytes and the monocytes it is sometimes difficult to determine whether a cell is a lymphocyte or a monocyte.

Role During Inflammation.— Leukocytes are an important factor in the cellular defense mechanism of the body. All of them are capable of active movement (essentially the same as the movement of an amoeba). which they exhibit only when they are outside the blood stream; *e.g.,* during inflammation. Experimentally, it has been shown that granulocytes have the ability to move toward a chemical gradient (chemotaxis) notably of carbohydrates. Upon a noxious stimulus such as a bacterial invasion, the leukocytes migrate from the blood vessels and enter the injured connective tissue. The neutrophile leukocytes, after taking up some of the bacteria or other particulate matter, die soon after they have left the vessels. The nongranular leukocytes (lymphocytes and monocytes) increase in size within a couple of days and transform into large phagocytic cells (macrophages), which engulf the particles at the site of invasion as well as the degenerated neutrophiles. The blood cells are joined in this phagocytic process by macrophages already present in the connective tissue. The functions of the eosinophils and basophils are not definitely known. *(See* also PHAGOCYTOSIS.)

Differential Counts of White Blood Cells.—The absolute and relative number of the various types of leukocytes present in the peripheral blood may undergo important changes from the normal during certain diseases. Counts of white blood cells are important clinical procedures in the diagnosis of leukemia and infectious diseases. In the so-called differential count the relative proportion of the different types of white blood cells is determined.

PLATELETS

The blood platelets are very small cellular bodies (not actually cells) which are derived from the largest cells of the bone marrow, *i.e.,* the megakaryocytes. They vary in size from one to three microns, have a small amount of light blue cytoplasm and a deeply staining inner structure. They number normally about 200,000 to 400,000 per cubic millimetre of blood, although their enumeration is rendered difficult by their tendency to stick together. This agglutinating tendency is of great importance since it quickly plugs small loopholes in the blood vascular apparatus. When the plate-

TABLE 111.—Normal Values of the Blood

Total blood volume	
Adult male	5,000 ml.
Adult female	4,000 ml.
Red blood cell volume	
Adult male	2,250 ml.

lets are greatly diminished or completely lacking the blood tends to seep out of the circulation into the skin and mucous membranes, resulting in black-and-blue areas (ecchymoses) and in tiny blood spots or petechiae. The platelets have other functions as well: production of the clotting factor thromboplastin, which initiates the series of chemical reactions that produce the fibrin clot; and aggregation about foreign particles, including bacteria, within the circulation.

BLOOD VOLUME

The body of an adult male contains about five litres of blood, that of a woman or child less. The quantity may be measured in one of two ways. Each depends upon putting a known quantity of some substance into the body, and, after it has been distributed uniformly in the whole circulating fluid, measuring the degree of dilution which has taken place. The two substances most commonly used are carbon monoxide and Evans blue dye, T-1824.

Carbon monoxide to the extent of about 250 cu.mm. (the exact quantity being known) is inhaled from a special apparatus; the gas unites with the hemoglobin of the blood, producing a compound the concentration of which can be measured spectroscopically.

Evans blue dye, T-1824, is a pigment which in the amounts ordinarily injected does not leave the blood for some time but in its entirety remains dissolved in the plasma. A known quantity of the dye is injected into a vein, blood samples are withdrawn and centrifuged, the plasma is tinted blue with the dye, and the depth of the tint is a measure of the degree to which the dye has been diluted and thus of the blood volume.

Probably different species, and indeed different individuals in the species, differ considerably in the quantity of blood contained in their vessels. As a very rough estimate the blood volume is about one-fifteenth to one-seventeenth the body weight in man. It is believed to increase at great heights, under tropical conditions and in polycythemia.

Considerable loss of blood may take place without serious ill effects, but if the volume decreases beyond a certain point the blood pressure commences to drop and a condition of shock supervenes. Besides the blood which actually circulates in the arteries, veins and capillaries, the body possesses reserves which can be mobilized. One such is known to be located in the spleen. At the onset of hemorrhage the spleen shrinks, squeezing blood as from a sponge into the circulation. Thus some animals may lose one-fifteenth of their blood without the volume of that fluid in circulation suffering any appreciable decrease, the spleen contributing as much as is lost by the hemorrhage.

The blood volume may diminish from causes other than hemorrhage; *i.e.*, through severe injury (traumatic shock), especially to the visceral organs. In this condition, the capillary walls appear to become unduly permeable and dilated; the plasma then escapes into the tissue spaces, and the number of corpuscles per cubic millimetre of blood increases. Ultimately the volume of blood becomes so small that the arterial pressure cannot be maintained. This condition is known as surgical shock, and it is distinguished among other features by a great reduction in plasma volume. The introduction of human plasma in states of shock is often life-saving and was of extreme importance in the treatment of war casualties in World War II and the Korean war (see SHOCK).

(W. DK; P. P. H. DE B.)

INDIVIDUALITY OF HUMAN BLOOD

Evidence of the individuality of human blood originated in 1900 with the discovery of the ABO blood groups and was followed in 1928 by descriptions of factors M, N and P. Beginning about 1940. numerous agglutinable properties or factors (antigens) in normal human red blood cells were discovered, among which Rh was, medically speaking, the most important (see BLOOD GROUPS). The term Rh is derived from "rhesus" to indicate a particular blood property common to man and the rhesus monkey. The combination of Rh positive father and Rh negative mother was shown to be the most frequent cause of a disease of the newborn infant, erythroblastosis fetalis or preferably hemolytic disease of the fetus and newborn. The destruction of the infant's blood results from transfer in utero of an antibody produced by the Rh negative mother whose fetus is Rh positive. The application of this fundamental phenomenon — transplacental isoimmunization — resulted in the discovery of many new blood factors, because in the smaller group of affected infants at least 30 differentfactors other than Rh are responsible for maternal antibody production and its subsequent destructive effect on the infant's red blood cells.

With the aid of these antibodies, as well as those produced by transfused patients or others that may be physiological for certain normal persons, it is possible to identify a variety of blood factors by simple agglutination or clumping reactions.

With each blood factor there are two variations; *i.e.,* presence or absence of agglutination with its particular antibody. Assuming independence of the blood factors, the number of individual variations is an exponential function of the number of different factors. Thus, given ten factors, there are 2^{10} or 1,024 different combinations, or with an additional ten blood factors 2^{20} or 1,048,576 combinations.

In the early 1960s, 11 independent blood group systems were known, in addition to many low (private) and high (public) incidence antigens (see BLOOD GROUPS). Since about 70 antigens have been detected and 20 or more are assumed to exist, the number of combinations possible among the general population is truly staggering. And it has been said that some of these possible combinations have not even occurred yet in all the time that man has existed. The individuality is still greater if one takes into account the 78 Rh genotypes listed by R. R. Race and Ruth Sanger.

Some of the blood factors exhibit striking racial differences. The type Fy(a−b−), which has not been found in Caucasoids as yet, has an incidence of 68% in New York Negroes and about 90% in West African Negroes. The antigen V is found in 27% of New York Negroes, but its presence in pure Caucasoids is still to be established. The Diego blood antigen is absent in Caucasoids and is found only in American Indians, Japanese and Chinese. Numerous other examples are cited in the text by Mourant (see Bibliography).

Aside from their importance in studying racial differences (population genetics), blood factors are useful in the determination of monozygotic (identical) twins and are employed in medicolegal matters such as the exclusion of paternity or maternity and the accidental interchange of infants. Some blood factors are present also in leukocytes. platelets, sperm cells, epithelial cells of the skin and mucous membranes of the mouth.

Individual differences in blood proteins such as hemoglobins, haptoglobins and gamma globulins have been observed. Using paper electrophoresis. a method of analysis based on the movement of colloidal particles in an electrical field, it is possible to demonstrate about 18 different types of hemoglobin, of which only hemoglobin A is the normal form; all the others are associated with diseased states called hemoglobinopathies. Some of these abnormal hemoglobins (*e.g.,* S and C) are commoner in Negroids. They are inherited as single genes.

Hemoglobins A, C and S differ from each other in the position of only one of nine amino acids in a particular peptide chain. Glutamic acid of hemoglobin A is replaced by valine in hemoglobin S, and by lysine in hemoglobin C.

Three types of haptoglobins can be demonstrated by differences in the capacity of part of the a, globulin to bind hemoglobin; these are types 1–1, 1–2 and 2–2. Another type more frequent in Negroes is 1–2m, a modified form. The incidence of types 1–1, 1–2 and 2–2 in the Caucasoid population is 15%, 50% and 35% respectively. The incidence varies in Negroids. There are three genes and six genotypes, two of them not identifiable by current methods. These are normal variations genetically independent of Gm groups (see below) or hemoglobin types.

The serological test used in diagnosing rheumatoid arthritis (*i.e.,* agglutination of red cells sensitized with antibody bearing globulin) revealed a specific difference in normal human serum. About 60% of normal human serums can inhibit this agglutination. These are known as Gm(a+) and the remaining 40% that failed to inhibit agglutination are called Gm(a−). The letters Gm refer to gamma globulin, which may or may not inhibit the reaction. The two

groups are inherited according to simple Mendelian laws, Gm(a+) being dominant over Gm(a−). Recent studies reveal additional hereditary differences in normal gamma globulins called Gm(x+) and Gm(x−). These studies reveal also normal hereditary differences of transferrin, the iron binding protein present in the β_1 globulin fraction.

BLOOD, DISORDERS OF. The disorders of the human blood are pathological conditions that involve the cellular elements of the blood and the tissues in which they are formed.

The blood is composed of a watery fluid, the plasma, in which are dissolved various essential and nutritive substances, salts and wastes. Suspended in the plasma are three types of corpuscles: the red cells (erythrocytes), the white cells (leukocytes) and the blood platelets (thrombocytes). The chief function of the red cells (formed in the bone marrow) is the containment of hemoglobin, a pigment especially adapted to combining with oxygen in the lungs and releasing it in the tissues, and to combining with carbon dioxide in the tissues and releasing it in the lungs. The white cells are composed of three types: granulocytes, monocytes (both formed in the bone marrow) and lymphocytes (formed in the lymph glands); all three types of white cells are involved mainly in the resistance of the body to infection and in the repair of tissues. The blood platelets (formed in the bone marrow) are cellular particles concerned with the clotting of blood. *(See* BLOOD; BONE MARROW.)

In some blood disorders, one type of corpuscle is affected; in others, two types or all three types are influenced.

Methods of Study.—The study of any disease in a patient involves an inquiry into the circumstances of its development, the symptoms produced and the course of the illness (the history). A thorough physical examination coupled with specific laboratory tests are essential prerequisites for an intelligent approach to the treatment of most diseases.

In the case of disorders of the blood, certain features of the physical examination are especially important in diagnosis. These include the presence or absence of pallor or, the opposite, an excess of colour; the presence or absence of small purple spots or larger bruises in the skin; enlargement of lymph glands (nodes); enlargement of the spleen; and tenderness of the bones.

Laboratory studies particularly valuable in diagnosis include: (1) determination of the existence of anemia or polycythemia *(see* below); (2) a study of the white corpuscles, their number and their proportions as to type; (3) enumeration of the blood platelets and a study of the blood clotting process; and (4), in many instances, a study of the bone marrow. Further, it is sometimes necessary to remove a lymph node for microscopic examination, and X-ray examinations may be necessary for the detection of organ or lymph node enlargement or bone abnormalities. Rarely, it is found desirable to measure the total volume of red cells or the volume of hlood plasma.

DISORDERS AFFECTING RED CELLS

The quantity of red blood cells in normal human beings varies with age and sex as well as with external conditions, primarily air pressure. At sea level an average normal male adult has 5,400,000 red blood cells per cubic millimetre of blood. These carry an average of 16 g. of hemoglobin per 100 millilitres of blood. If such blood is centrifuged so that the red blood cells are packed in a specially devised tube known as the hematocrit, they are found to occupy 47% of the volume of the blood. In the average female, the normal figures are lower than this (red cell count 4,800,000; hemoglobin 14 g., volume of packed red cells 42%). In the newborn they are higher but decrease in the course of several weeks to levels below those of the normal female; thereafter, they rise gradually. The differences in male and female blood begin to appear about the time of puberty. It should be noted, however, that these figures represent average values; the values found in normal persons range approximately 15% on either side of this mean.

Changes in Numbers of Red Cells.—A temporary increase in the number of red cells (erythrocytosis) is observed under conditions of high altitude (the increase is directly proportional to the altitude), unusual muscular exertion, increased environmental temperature, certain emotional states and shock. The sustained increase in red cells in persons who reside permanently at high altitudes is a direct result of the diminished oxygen tension in the environment.

Reduction in the number of red cells normally occurs in situations of high barometric pressure; *e.g.*, in areas lower than sea level such as deep mines, etc.

A pathological increase in red cells is called polycythemia; a pathological decrease is called anemia.

Polycythemia.—A consistent pathological excess of red cells. or polycythemia. is indicative of a serious disruption of the normal condition in the body. Primary polycythemia is a blood disease of unknown cause; polycythemia resulting from an existing pathological condition is termed secondary polycythemia.

Primary polycythemia, also known as polycythemia vera (*q.v.*) or erythremia, is a condition in which the number of red cells, and often white cells and platelets, is increased and the spleen often enlarged. Because of the excessive quantities of red cells, the blood is unusually thick and its flow retarded; it sometimes clots in the vessels (thrombosis) of the heart, the brain or the extremities with very serious consequences. Patients with this disease have an unusually ruddy complexion and may complain of headaches, dizziness, a feeling of fullness and other symptoms. The simplest method of treatment is to remove the blood, one pint at a time, from a vein until the cellular level approaches normal and the symptoms disappear. Another useful method involves the injection of radioactive phosphorus; this material is carried to the bones, where the radioactivity acts directly upon the blood-producing elements in the bone marrow and impairs their production capacity. The administration of the isotope is repeated, when necessary, at intervals of three months or longer.

Secondary polycythemia results from other organic disorders and certain types of poisoning. This condition represents the response of the bone marrow to low oxygen tension in the arterial blood. It is observed in patients with certain types of congenital heart disease in which part of the blood is shunted out of its normal path in such a way that all the blood does not pass through the lungs and therefore fails to renew its full supply of oxygen, resulting in a deficiency of oxygen in the tissues (hypoxia). The body attempts to make up for the hypoxia by producing more red cells. Other conditions associated with secondary polycythemia include various types of lung disease that impair aeration (*e.g.*, emphysema) and excessive consumption of certain drugs (phenacetin, acetanilid, etc.) that convert hemoglobin to pigments incapable of carrying oxygen (methemoglobin, sulfhemoglobin, etc.). The treatment of secondary polycythemia involves the correction or alleviation of the primary pathological disturbance, thereby relieving the polycythemia.

Anemia.—Anemia is a pathological reduction in the number of red cells, in the quantity of hemoglobin and in the volume of packed red cells to levels below normal according to the age and sex of the patient. In essence, anemia is not a disease-but a symptom of disease. There are many different types of anemia,

each of which is treated according to its cause. (See ANEMIA.)

DISORDERS AFFECTING WHITE CELLS

White cells include granulocytes (neutrophiles, eosinophiles and basophiles), lymphocytes and monocytes. Normally, the white cell count in an adult ranges from 5,000 to 10,000 cells per cubic millimetre of blood. (See BLOOD: Cells *of the* Blood.)

The granulocytes as a group make up between 61% and 75% of the uhite cell total. The three subgroupings are based on the type of dye absorbed by the cytoplasmic granules when the cells are stained in preparation for microscopic examination. Neutrophiles, which absorb neutral dyes, are the largest group, numbering 3,000 to 7,000 per cubic millimetre of blood in an adult, or about 60% to 70% of all the white cells. Eosinophiles, which take up acidic dyes such as eosin, number from 50 to 400 in an adult, or 1%–4% of the total. Basophiles, which take up basic stains, number from 0 to 50 in an adult. or up to 1% of the total.

Lymphocytes, of which there are from 1,000 to 3,000 in an adult (20% to 30% of all white cells), possess a round nucleus that occupies most of the cell. Monocytes, which number from 100 to 600 (2% to 6%), have a lobulated nucleus and are the largest of all the white cells.

Changes in Number of White Cells.—Variations in the number of white cells occur normally from hour to hour, the highest counts being recorded in the afternoon and the lowest in the early morning. Temporary increases also normally occur during muscular exercise, menstruation, pregnancy and childbirth as well as in emotional states.

Abnormal changes in the count, appearance or proportion of the various white cells are indicative of pathological conditions in the body.

Leukocytosis.—The condition in which white cells are present in greater numbers than normal is termed leukocytosis. It is usually due to an increase in the number of granulocytic leukocytes (especially neutrophiles), many of which are immature (myelocytes). Most often leukocytosis is the result of the presence of an infection, usually caused by pyogenic (pus-producing) organisms such as the streptococcus, staphylococcus, gonococcus, pneumococcus or meningococcus. Examples of leukocytosis are found in association with inflamed appendix, lobar pneumonia, meningitis or a boil. Leukocyte counts of 12,000 to 20,000 per cubic millimetre during infections are not unusual, but values greater than this are less common. As the number of cells increases, the proportion of immature cells usually rises, perhaps because the demands on the leukocyte-producing tissues in the bone marrow have increased to the point at which there is an insufficient number of mature cells for delivery into the circulation. This picture of immaturity is referred to as a "shift to the left." As the infection subsides, the number of younger forms and the total white cell count decrease and ultimately return to normal. During the period of repair following an inflammatory reaction, the monocytes may increase in number, and subsequently the lymphocytes become more numerous.

Lymphocytosis.—Certain types of infection are characterized from the beginning by an increase in the number of small lymphocytes unaccompanied by increases in monocytes or granulocytes. Such lymphocytosis is seen in whooping cough and occasionally in infectious lymphocytosis, a benign disorder probably of viral origin. Moderate degrees of lymphocytosis are encountered in certain chronic infections such as tuberculosis and brucellosis.

Monocytosis, an increase in the number of monocytes in the blood, is encountered in association with certain infectious processes, especially subacute bacterial endocarditis and malaria.

Eosinophilia, an increase in the number of eosinophilic leukocytes, is encountered in many allergic reactions and parasitic infections. It is especially characteristic of infestation by trichina larvae ingested when infected, poorly cooked pork or pork products are eaten.

Leukopenia.—Abnormally low leukocyte counts (below 5,000 per cubic millimetre) are encountered in certain types of infection such as typhoid fever, malaria and measles. In persons sensitive to chemical agents such as aminopyrine, severe leukopenia occurs on taking the drug, and a very serious syndrome known as agranulocytosis (*q.v.*) may develop. If exposure to the toxic agent is not stopped immediately and any developing infection is not treated effectively, death will ensue. Leukopenia is also encountered in various diseases involving the bone marrow, such as aplastic anemia, leukemia and multiple myeloma, as well as in certain disorders that affect the spleen.

Infectious Mononucleosis.—This disorder, seen frequently in young persons, is of unknown cause but most probably is due to a viral infection. It is accompanied by fever, sore throat, enlargement of the spleen, grippelike symptoms and enlargement of the lymph glands; at the same time, there is a leukocytosis, primarily an increase in the number of lymphocytes. The lymphocytes in infectious mononucleosis (*q.v.*) have a characteristic appearance, being larger than normal and often having vacuoles in their cytoplasm. Leukocyte counts of 15,000 to 30,000 per cubic millimetre are common. There is no accompanying anemia or alteration in platelets (rarely, the latter may be decreased in number). The condition can be further identified by demonstration in the blood serum of a characteristic antibody that causes the red cells of sheep to clump together (sheep cell agglutinin or heterophil agglutinin). The disease is mild, recovery taking place, as a rule, within several weeks. It has been mistaken for acute leukemia, the symptoms of which are sometimes similar.

Leukemia.—This term means "white blood" and arose from the discovery of very large numbers of white blood cells in the blood of certain patients; counts as high as 500.000 per cubic millimetre and even 1,000,000 per cubic millimetre may be found in some instances. Leukemia (*q.v.*) is a very serious and ultimately fatal disorder of the blood that is characterized by unrestrained, morbid new (neoplastic) growth of white blood cells and ultimately by changes in various tissues, such as in the spleen and lymph glands, as well as by the development of anemia and a reduction in the number of blood platelets. The course of leukemia varies greatly, ranging from the acute type that may cause the untreated patient to die in a few weeks or months (rarely six months or a year) to the chronic type, which may produce little or no ill-health for ten or more years.

The cause of leukemia is unknown. Although hereditary transmission is known to occur in mice, it appears to be of no importance as an etiologic factor in man. Irradiation seems to play a role; there is a higher incidence of leukemia in the survivors of atom bombings than in the general, unexposed population. Attention also has been called to the higher incidence of leukemia in radiologists, as compared with other physicians. This has been attributed to improper shielding of X-ray apparatus, resulting in exposure to undue amounts of scattered radiation. Experimentally produced leukemia in animals indicates that many additional factors are influential in the development of leukemia, among them chemical agents and hormones such as the estrogens (the female sex hormunes). For some time attention has focused on the search for a possible viral agent as the cause of leukemia. Fowl leukemia has been known for decades to be due to the presence of a virus, and a viral agent in the development of mammalian leukemia (mice) has been demonstrated. To what extent these observations apply to man has yet to be determined.

Acute leukemia, of which there are three types, may be associated with an unrestrained development of lymphoblasts, which are immature lymphocytes; this variety (acute lymphoblastic leukemia) is commonest in children. Another type, acute myeloblastic leukemia, is characterized by an overgrowth of cells thought to be related to myeloblasts, the immature polymorphonuclear leukocytes. A third, and the least common, variety is acute monocytic leukemia; this is characterized by the presence of very immature forms of monocytes. Myeloblastic and monocytic leukemia occur more commonly in adults than in children. In general, acute leukemia occurs in young persons, but no age group is exempt.

Although the total white cell count is usually increased, often greatly, in acute leukemia, it is not uncommon for the count to be normal or lower than normal (leukopenic). In cases of normal

or below-normal counts, nevertheless, the blood will often show the presence of a few leukemic cells, and such cells can be demonstrated in great abundance when the bone marrow is examined.

Acute leukemia is often associated with symptoms such as unusual fatigability, fever, sore throat and lymph gland enlargement and may at first be mistaken for a common infection. Usually by the time the diagnosis is made, anemia has already developed. and frequently the number of platelets (thrombocytes) is reduced as well. When the thrombocytopenia (see below, Bleeding *Disorders*) becomes severe, bleeding manifestations occur; there may be serious bleeding from the nose and gums and bleeding into the skin.

Two types of agents have been found beneficial in the treatment of acute leukemia. (1) In acute lymphoblastic leukemia the administration of steroids such as prednisone causes all evidences of the disease to disappear in approximately 65% to 80% of cases. These agents have little or no value in the other types of acute leukemia. (2) Effective in all types are two antimetabolites (*q.v.*), "amethopterin," an antifolic compound, and 6-mercaptopurine, which may be an antipurine; they interfere in the chemical processes necessary for the growth and development of white blood cells. Patients are usually treated with one of these agents at a time. since ultimately the patient fails to respond to one agent but may still be responsive to another. These agents have substantially prolonged life in acute leukemic patients, keeping them in good condition for many months. Permanent cures, however, have not been achieved.

Another approach to the treatment of acute leukemia is total irradiation (using X-rays and/or radioactive substances) of the body to destroy all the leukemic cells. In the process, all the normal blood cells are also destroyed, and the body's capacity to form new cells in the bone marrow is lost; other tissues, especially the gastrointestinal tract, may be damaged as well. To make up for the bone marrow damage, normal marrow is transplanted in the victim following irradiation. This method of treatment appeared, in the early 1960s, to be of no value since hemorrhage, infection, damage to other tissues and failure of the grafted marrow to function always interfered with recovery.

Chronic leukemia is of two main varieties, myelocytic and lymphocytic. Chronic myelocytic leukemia is a disorder characterized by the appearance in the blood of large numbers of myelocytes, immature white cells of the granulocytic series. At the same time the spleen becomes enlarged (ultimately, very greatly), anemia develops and the patient loses weight. This disease is most commonly encountered in persons between the ages of 20 and 45. The disorder can be alleviated temporarily by X-irradiation of the spleen or by the administration of certain chemical agents, particularly busulfan. By these methods the size of the spleen can be greatly reduced, the leukocyte count falls to normal and the anemia is relieved. Ultimately, however, all treatment fails and death ensues in about three and one-quarter years after onset of the disease. There is considerable individual variation, however, some patients dying sooner and others living as long as ten years.

Chronic lymphocytic leukemia is the most benign form of leukemia. It occurs most often in people over 50 years of age and is characterized by an increase in the number of lymphocytes, by lymph gland enlargement and. to a lesser extent than in chronic myelocytic leukemia. by splenic enlargement. There may be some weight loss, but patients often may carry on for years without treatment and without any major symptoms developing. In this disorder, as in chronic myelocytic leukemia, X-ray treatment of the lymph glands and spleen is useful, as is the administration of various chemical agents such as chloramhucil and triethylene melamine. Under treatment, the patient can be kept in reasonably good health for many years; the life span in this disease is measured in terms of 5, 10 and even 15 years, occasionally longer. Ultimately, honever, severe anemia develops, accompanied by a reduction in blood platelets and hemorrhagic manifestations, and death ensues.

Other forms of leukemia are encountered rarely.

Other Neoplasms: The Lymphomas. — Disorders related to leukemia, *i.e.*, associated with neoplastic growth of cells formed in the blood-forming organs, lymph glands and elsewhere, are reticulum-cell sarcoma. lymphosarcoma and Hodgkin's disease, each of which also represent overgrowths of other types of cells found in the blood-forming organs and lymph glands. (See LYMPH AND LYMPHATIC SYSTEM.) In these disorders there may be no striking abnormalities in the blood even though large tumours develop in the lymph glands, spleen, bone and other tissues and in organs such as the stomach, liver, etc. Like all malignant growths they advance relentlessly into normal tissues. Their rate of advance varies, however. In general. the course of reticulum-cell sarcoma is brief, the patient succumbing in months or a year or two. The course of lymphosarcoma may sometimes be slower than this, while the course of Hodgkin's disease may vary greatly, ranging from six months in the rare case to several years in the majority and to many years in a few. Like chronic leukemia, these conditions are subject to treatment by irradiation as well a5 by certain chemical agents. Nitrogen mustard has been particularly valuable in the treatment of Hodgkin's disease.

Hodgkzn's disease is the commonest of these conditions and differs from the others in that its course sometimes resembles that of an infectious disease rather than a tumour. There may be fever as well as glandular enlargement; leukocytosis often occurs. The disease generally starts as a painless lump, often in the neck. However, glands in many locations in the body, such as the chest cavity and the abdominal cavity, ultimately enlarge, as does the spleen. Anemia and weight loss eventually ensue, and death ultimately occurs.

Multiple Myeloma. — Another neoplastic disorder, probably related to the above conditions, is multiple myeloma, which is characterized by a malignant overgrowth of plasma or plasmalike cells within the bone marrow. This severely painful disorder causes bony defects in the skull, the ribs, spine and pelvis that ultimately result in fractures. As the bone marrow becomes more and more involved, anemia develops and hemorrhages occur: leukopenia may develop, and abnormal myeloma or plasma cells can be demonstrated in the bone marrow. This disorder is associated with a peculiar disturbance in protein metabolism. Certain globulins may be found greatly increased in the blood, and the urine often contains a peculiar type of protein called the Bence-Jones protein. A type of chronic kidney disease often develops, probably as result of the high concentration of Bence-Jones protein in the kidney tubules; this frequently is the ultimate cause of death. Multiple myeloma does not respond well to chemical agents, although cortisone and urethane may sometimes be helpful. In some cases the condition remains quiescent for a time, but death is inevitable.

BLEEDING DISORDERS

Several different agents keep blood from flowing out of the blood vessels and into the tissues: the lining of the blood vessels, the blood platelets (thrombocytes) and certain compounds and enzymes in the blood that tend to promote the formation of a clot.

The capillaries (minute blood vessels in intimate contact with the tissues) are elastic and have smooth linings; when the capillaries are cut, the linings normally retract about the injured area, serving to prevent further blood loss. The blood platelets are very small cellular particles (not actually cells) derived from the largest cells of the bone marrow--the megakaryocytes. The platelets number normally 200,000 to 400,000 per cubic millimetre of blood. (See BLOOD: Platelets.) They plug small leaks in blood vessels and participate in the clotting process. Disintegrating platelets release substances that take part in a series of complex chemical reactions in the blood that result in the production of a firm blood clot.

Causes of Bleeding Disorders. — Vascular Weakness. — In cases of vitamin C (ascorbic acid) deficiency (*see* SCURVY), capillary integrity is lost, and blood oozes into the tissues; under these conditions. *i.e.*, widespread capillary injury, the normal number of platelets (which tend to plug small breaks in blood vessels) is not sufficient.

Thrombocytopenia.—Reduction in the number of blood platelets is termed thrombocytopenia and accompanies various disorders of the blood such as aplastic anemia and leukemia. In such cases

thrombocytopenia is accompanied by changes in red cells and white blood cells. Thrombocytopenia may occur also in the absence of other changes in the blood: (1) it may be the result of sensitivity to some chemical agent. such as allylisopropylacetylurea, quinidine, various antihistamines, tranquilizers and other agents in common use; (2) it may be the effect of the action of chemical agents such as benzol or arsenic; or (3) it may result from irradiation. There is also a form of thrombocytopenia of unknown cause (idiopathic). Thrombocytopenia, if sufficiently severe, is accompanied by spontaneous bleeding from the capillaries; this causes either tiny purplish spots (petechiae) or larger black and blue areas (ecchymoses) to appear in the skin; bleeding occurs commonly from the nose and gums and occasionally from other sites such as the urinary tract and the intestines. When hemorrhage occurs in the brain, it is usually fatal.

Faulty Coagulation.—Deficiencies in any of the chemical and enzymatic factors involved in coagulation result in hemorrhages following minor injuries. In some of these disorders a specific deficiency is due to a heritable defect (*e.g.*, hemophilia) ; in others, a pathological condition may be responsible for the deficiency (*e.g.*, hypothrombinemia, etc.).

Purpura.—The general clinical disorder associated with the appearance of petechiae or ecchymoses is called purpura (*q.v.*). If it is associated with thrombocytopenia it is known as thrombocytopenic purpura; if it is associated with inherent vascular weakness it is termed a vascular purpura. Idiopathic thrombocytopenic purpura occurs not uncommonly in children; it is often self-limiting and may follow an infection. In some instances in children, and usually in adults, it is persistent. In such cases the removal of the spleen has been found to be effective in curing the disorder in about two-thirds of the cases.

Purpura also may occur in the absence of thrombocytopenia; it may be mild or quite serious. It is not unusual, especially in women, for black and blue spots to appear spontaneously, often on the thighs and to some extent on the arms. These ecchymoses, which may be painful, may be related to the menstrual cycle.

In Schonlein-Henoch purpura (allergic purpura) there may be associated joint or abdominal pain; this condition may be the consequence of some sensitivity, *e.g.*, to certain foods, drugs or infectious organisms. Recurrent streptococcal infection is a common cause of such a sensitivity reaction. Purpura may also occur in association with various infections such as meningitis and in scurvy.

Coagulation **Disorders.**—*Hemophilia* and *Related* Disorders.—In addition to the purpuras mentioned above, bleeding disorders due to various defects in the process of coagulation may occur. The best known of these is hemophilia, which is due to an inherited defect transmitted by the female but expressed only in the male. The abnormal bleeding, sometimes spontaneous but often the result of slight injuries, occurs as a consequence of a lack of antihemophilic globulin and may threaten the life of the victim or cripple him as a result of hemorrhages into joints.

The term "bleeder" once was considered to be more or less synonymous with hemophilia. Now that many other causes of abnormal bleeding besides deficiency of antihemophilic globulin have been discovered, the term "bleeder" has no specific meaning.

A closely related disorder is PTC (plasma thromboplastin component) deficiency, or "Christmas disease." The inheritance of this bleeding disorder is like that of hemophilia, but a different substance is lacking. As more knowledge has been gained concerning the intricate process of coagulation of blood, more and more bleeding disorders have been discovered. These include PTA (plasma thromboplastin antecedent) deficiency and various types of prothrombin deficiency. Many of these conditions are due to inherited defects, but others occur as result of action by toxic agents or other factors.

Hypoprothrombinemia, a deficiency in prothrombin, occurs most commonly in cases of obstructive jaundice, in which the flow of bile into the bowel is interrupted. Bile is necessary for the absorption of vitamin K, which is needed in prothrombin formation. When biliary obstruction is prolonged, vitamin K deficiency occurs and hypoprothrombinemia develops. Similar changes may take place when absorption of vitamin K is impaired, as in chronic diarrheas such as sprue (*q.v.*). Hypoprothrombinemia also occurs in the newborn as hemorrhagic disease of the newborn. This form of prothrombin deficiency can be prevented by administering vitamin K to the mother during labour. Hypoprothrombinemia can also be produced deliberately by the use of agents such as bishydroxy-coumarin and heparin in attempts to prolong clotting time.

Fibrinogenopenia refers to a reduction in the amount of fibrinogen (a plasma protein) in the blood. Fibrinogen is another substance necessary for coagulation. Fibrinogenopenia is seen in rare instances as a heritable disorder, but more commonly it is found as a complication of labour following pregnancy.

See M. M. Wintrobe, Clinical Hematology, 5th ed. (1961).

(M. M. WE.)

BLOOD BANK. The blood bank, a key organization in medical care, collects, stores, processes and transfuses blood. The safety of stored blood was demonstrated by Oswald H. Robertson of New York while working with the British army in World War I. The first U.S. blood bank was established in 1937 at Cook County hospital. Chicago, by Bernard Fantus. Previously, the physician typed the patient's relatives and friends until the proper type was found, performed the crossmatch, bled the donor and transfused the patient. The discovery of many new blood types important in transfusions, and of several new crossmatching techniques, led in the 1940s to the rapid developnlent of blood banking as a specialized field and to a gradual shift of responsibility for the technical aspects of transfusion from practising physicians to skilled technicians and clinical pathologists.

The practicality of storing fresh blood for future needs made possible such dramatic innovations as exchange transfusions of "Rh babies," artificial kidneys and heart-lung pumps for open-heart surgery. Unfortunately, fresh blood can be stored only for a limited time; this creates the difficult problem of maintaining a steady supply of donors.

At some of the first blood banks, plasma was sometimes separated from the red corpuscles and used separately. Other fractions of blood subsequently became available. These included platelets to control bleeding; concentrated red corpuscles to correct anemia; and plasma fractions, such as fibrinogen to aid clotting, gamma globulin to prevent or modify measles and albumin to augment the blood volume in shock. Thus a single pint of blood might serve the varying needs of five or more patients.

See BLOOD: Individuality of Human Blood; BLOOD TRANSFUSION; BLOOD GROUPS. (F. H. A.)

BLOOD FEUD, a continuing series of killings and counterkillings among members of two consanguinal kin groups. It exists among many primitives and also in some folk communities within civilized societies where there is an absence of legal forms and procedures that lead to the punishment of an original homicide in a way that is acceptable to both parties.

Among most primitives the consanguinal kin group is characterized by a strong sense of collective solidarity which functions to protect its individual members against assault and injury by outsiders. It holds all the members of any other such group collectively responsible for any injury it suffers at the hands of the members of that other group. Thus a killing by a member of a particular group may mean that any member of this group may be killed in retaliation by his victim's kinsmen. If the counterkilling is done by "due process" and is by custom universally acknowledged as just and proper, there will be no blood feud. If, however, the counterkilling is not accepted as right and proper, and in consequence touches off a counter-counterkilling, blood feud is under way.

Institutional devices to forestall blood feud or to bring it to a close seem to have been developed in most primitive societies. Even though many peoples, such as the Trobriand islanders in Melanesia and the Nuer of the African Sudan, profess that honour demands revenge, composition for the homicide is the rule rather than the exception. Regulated combat was frequently used by the Australian aborigines as a substitute for blood feud. The establishment of a strong centralized political authority generally results in the suppression of blood feud.

In general, it may be said that the existence of blood feud represents a condition of internecine warfare contingent upon an absence of law or a breakdown in legal procedures. The threat of feud may also be seen as a factor inducive of legal settlement of serious wrongs. See also VENDETTA.

BLOOD GROUPS. Blood groups are biological categories found in man and many other animals. Members of a particular group have in common certain specific substances (antigens) on the red blood cells. The name was applied originally to the four categories of human blood discovered first—those with antigen A, those with antigen B, those with both A and B and those with neither. These are the four classical blood groups A, B, AB and O discovered by Karl Landsteiner in 1900 and found to be of great importance in blood transfusion. Subsequently many other blood group systems, each based on different antigens on the red blood cell. have been discovered. An individual's blood group is determined by the genes he inherits from his parents. Since the groups are not normally alterable in healthy people, they have assumed considerable importance in forensic medicine (*e.g.,* cases of disputed parentage, identification of blood stains), in the analysis of genetic variability, and in the study of human genetics (*q.v.*) and anthropology. (See BLOOD: Individuality *of Human Blood; HE*REDITY.)

Blood groups are discussed in this article in three main sections: Blood Groups in Man; Blood Groups and Human Disease; and Blood Groups in Animals.

BLOOD GROUPS IN MAN

Blood consists of two phases; one includes the red cells, white cells and platelets: the other is a colloidal suspension—the plasma. When blood is taken from the body it separates into a solid clot and liquid serum. Serum contains all the circulating elements of plasma except those used up in the formation of the clot.

The red cells, which transport oxygen and carbon dioxide. also incidentally carry a number of antigenic substances that characterize the blood groups of the individual. An antigen has been defined as a substance that reacts, under suitable conditions, with another substance called its antibody. Antibodies are present in plasma. Blood group antibodies may occur naturally—that is. they may be present in an individual without artificial stimulation—or they may be of an immune type—that is, produced by artificial stimulation (by exposing the individual to an antigen he lacks). Artificial immunity may be produced deliberately, as in immunization to prevent disease, or unintentionally, if fetal red cells enter the maternal circulation in pregnancy. (See IMMUNITY.)

The reaction between an antigen and its corresponding antibody takes several forms, but the basis of blood group determination is the agglutination reaction, in which red cells clump together when they are treated with an antibody.

There are nine well-established major blood group systems in man. They are, in chronological order of discovery, ABO, MN, P, Khesus, Lutheran, Kell, Lewis, Duffy and Kidd. As far as is known these blood group systems are inherited independently of one another. The independence of the more recently discovered Diego and Js systems is not yet fully established. In addition, a number of blood group antigens have been described that are called "private" because they are possessed by only a few people, usually members of the same family. When a new antigen is discovered care must be taken to exclude the possibility that it fits within a previously discovered system.

Antigens possessed by the majority of people are called "public." Two such antigens have not yet been fitted into a known blood group system; they are Vel (L. N. Sussman and E. B. Miller, 1952) and Yt^a (B. R. Eaton et al., 1956).

ABO Blood Group System.—The naturally occurring antibodies in the plasma of one person may be capable of agglutinating the red cells of another person. These individual differences were discovered by Landsteiner. who formulated the classical ABO blood group system. Human beings may have either of the antigens A and B on their red cells, they may have both (type AB) or they may have neither (type O). The antibody corresponding to the antigen(s) which a person lacks is present in his blood plasma (see Table I). Exceptions to this rule occur in babies under six months old and in extraordinary cases.

TABLE *I.—The Antigens and Antibodies of the ABO Blood Group System*

Blood group	Antibody in serum	Antigen on red cells
A	anti-B	A
B	anti-A	B
O	anti-A and anti-B	neither
AB	neither	A and B

ABO Groups in Blood Transfusion.—In transfusion the important factor is the reaction between the donor's red cells and the recipient's antibodies. Thus, group O blood may be given to people of all groups. A blood may be transfused into A and AB recipients and B blood into B and AB recipients. Blood that is considered to be safe for transfusions is said to be compatible. An ABO incompatible transfusion can result in the death of the recipient, because of intravascular hemolysis and kidney failure Before a transfusion is given it is standard practice to do a crossmatch test in which the donor's cells are tested against the recipient's serum. If there is no reaction in the crossmatch test the transfusion will be a safe one. This test also screens the recipient for antibodies, other than those of the ABO system, which could also influence the safety of the transfusion. In general the anti-A and/or anti-B present in the donor's blood does not adversely affect the safety of the transfusion, but occasionally the titre (*i.e.,* strength) of a donor's anti-A may be so high that his blood should not be given to group A recipients. (See also BLOOD TRANSFUSION.)

The ABO antigens have been found both in a fetus a few weeks old and in aged persons. The antibodies are not present in an infant at birth, but they begin to develop during the first year of life If the blood from the umbilical cord contains any anti-A or anti-B this is maternal in origin.

Inheritance of **ABO.**—It has been established that the blood groups of children are determined by the genes passed on from the parents. The material that carries the inherited information is contained in the chromosomes. The chromosomes are present in all nucleated cells. In man there are two sets of 23 chromosomes in the ordinary cells, but in the reproductive cells only one set. The double number is restored at fertilization when the egg fuses with a sperm, the resulting cell being called a zygote. All inherited characters are determined by chromosomal units kncwn as genes. each of which has a definite locus (position) on a chromosome. Genes that may occupy the same locus are termed alleles; thus, for instance, the, genes of the ABO system form an allelic series, since only a single *A, B* or *O* gene is present at the locus on its particular chromosome. A person having type AB blood has received an A determining gene from one parent and a *B* from the other; such a person is heterozygous. A person who has received the same type of gene from each parent, *e.g., OO,* is homozygous. If a child receives a dominant gene from one parent this will be expressed in the child regardless of the contribution from the other parent; since both *A* and *B* are expressed in the heterozygote one is not dominant to the other. If a child receives an *A* or *B* gene from one parent and an *O* gene from the other, only the A or *B* gene will be expressed so both A and B are dominant to the recessive *O.* The *OO* "genotype" is homozygous recessive. A child's phenotype can be defined by a laboratory test, but the genotype can be described only if the contribution from both parents can be deduced. The four phenotypes and six genotypes of the *ABO* system are shown in Table II.

In 1911 a subdivision of the A phenotype into A_1 and A_2 was described. The A, gene is dominant to A_2 and A_2 is dominant to *O,* so that there are six phenotypes and nine genotypes. The presence of B does not prevent the detection of A_1 or A_2. It is not usually necessary to consider the A_1, A_2 differences in blood transfusion.

TABLE II.—*ABO Blood Group System*

Phenotypes	Genotypes	
	Homozygous	Heterozygous
A	AA	*AO*
B	*BB*	*BO*
AB	—	*AB*
O	*OO*	—

ABO Groups and Anthropology.— In different populations the number of persons belonging to each phenotype of a particular blood group system is not the same. The results may be expressed as a simple percentage that gives the phenotype frequency. From this may be computed, if the sample is adequate, the percentage of persons carrying a particular gene; *i.e.,* the genotype frequency.

In the ABO system a high frequency of group O is found in northwestern Europe, southwest Africa, parts of Australia, and in the Indians of south and central America. Proceeding eastward across Europe into Asia the frequency of B rises and the maximum is reached in central Asia and northern India. The frequency of A is high in Europe, western Asia and among the aborigines of the southern part of Australia, and is highest of all in certain American Indian tribes. The distribution of ABO groups among white Americans reflects their European origins—0, 4570, A, 41%; B, 10%; AB, 4%.

The distribution of the ABO groups may show very local variations that can be detected by large sample surveys. For example, in England there is a slight fall in A and rise in O from the south to north. The frequency of the ABO groups in one survey in southern England was found to be: O, 45%; A, 43%; B, 9%; AB, 3%. In the Cnited Kingdom 20% of A individuals belong to the A_2 phenotype.

Secretion of Blood Group Substances.— As they occur on the red cells, the ABO blood group substances are in an alcohol-soluble form, In the United Kingdom and among white Americans about 75% of the population secrete ABO blood group substances in a water-soluble form in the tissue fluids and giandular products such as saliva, gastric juice and tears. Persons whose secretions do not contain ABO blood group substances are called nonsecretors. The secretor phenotype is determined by the presence of at least one Se gene. A person. if a secretor, produces only the ABO substances present in his own red cells: thus. an A secretor secretes A substances, a B secretor secretes B substances and an AB secretor secretes both. The substance secreted by O secretors is called H substance, and it is not peculiar to group O individuals. H substance occurs in the secretions of secretors of all groups, and so it cannot be regarded as the specific product of an *O* gene. The secretor system is inherited independently of the ABO system, indicating that the genes of the two systems are probably on different chromosomes.

MNSs Blood Groups.— In 1927 Landsteiner and P. Levine described the MN blood group system. The antibodies anti-M and anti-N were produced in experimental animals by immunization with human blood; in general they do not occur naturally. All human blood can be classified as M, MN or N. The antigens are determined by two independent genes, *M* and N. At this uncomplicated stage the groups provide a simple example of Mendelian inheritance in man (see Table III).

In 1947 the Ss subgroups of MN were discovered by R. Sanger and her co-workers. Both S and s antigens can now be identified in a positive may because both anti-S and anti-s antiserums (serums containing antibodies) have been discovered. A parent hands on to his child *MS, Ms, NS* or h[s] as a unit so that, for example, the children of an MSNs father receive either MS or Ns from him, but not *NS*-or Ms. The genetical interpretation is either that the MNSs locus is occupied by a single complicated gene or that two genes with adjacent loci are involved.

TABLE III.—*MN Blood Group System*

Parents		Children
Phenotype	Genotype	Genotype
M×M	*MM×MM*	All *MM*
M×MN	*MM×MN*	½*MM* ½*MN*
M×N	*MM×NN*	All *MN*
MN×MN	*MN×MN*	¼*MM* ½*MN* ¼*NN*
MN×N	*MN×NN*	½*MN* ½*NN*
N×N	*NN×NN*	*All NN*

The MNSs blood groups are not important in transfusion except in special cases. Other rare antigens belonging to the MN system are known, besides those discussed above.

The P Blood Group System.— Landsteiner and Levine discovered the P blood group system concurrently with the MN system in 1927. The first antibody was made in an experimental animal, but the same antibody can occur naturally in man, horses, rabbits, pigs and cattle.

The P groups are not important in transfusion. P subgroups have been identified.

The Rhesus Blood Group System.— The Rhesus (Rh) blood group system was discovered by Landsteiner and A. S. Wiener in the United States in 1940. Rabbits and guinea pigs formed an antibody in response to immunization with red cells from the Rhesus monkey. The agglutination or nonagglutination of human red cells in vitro with this anti-Rh antibody made possible the recognition of two phenotypes, Rh-positive when the red cells agglutinated and Rh-negative when they did not. The frequency of the Rh-negative type in western Europeans is about 15%. (Subsequently antibody uith the same specificity as the original anti-Rh was found in the serums of Rh-negative women who had had Rh-positive children, and among Rh-negative recipients of Rh-positive blood. (See Blood *Groups* and Human Disease, below.)

In the present state of knowledge a full understanding of the genetics of the Rh system is not possible. The question of nomenclature is also controversial. There are two alternatives: first, the nomenclature of R. A. Fisher based in the first instance on his interpretation of the findings of R. R. Race and others in the United Kingdom; secondly, the notation of Wiener, which is in use in laboratories in the United States. It is not the facts that are disputed, but the interpretation of the reactions of certain critical antiserums, and the properties of the various Rh antigens.

A large number of different antigens that certainly belong to the Rh system can be detected on the red cells. These antigens are detected by antiserums, formed through immunization in human subjects, which have a different specificity from that of the original anti-Rh antibody. It is possible to explain most of the experimental observations made up until 1953 on the basis of a series of allelic genes arranged in three pairs at adjacent loci.

All Rh-positive persons have D antigen on their red cells; the D antigen is absent from the cells of Rh-negative individuals who are assumed to be genotype dd. The antigens C, C^w, c, E and e can be recognized in a positive way with the corresponding specific antibodies; d antigen cannot be positively identified. The Rh gene complexes that are common in western Europeans are shown in Table IV.

Wiener regards the Rh system as being controlled by a single locus with multiple alleles.

Rave *Rh* Antigens (in *Fisher Notation).*—D^u antigen gives some but not all of the reactions of a regular D antigen. Certain forms of D^u antigen are due to the presence of rare alleles at the D locus. C^x, C^u, c^v are rare alleles at the C locus. E^u and E^w are rare alleles at the E locus.

A Rare *Rh Chromosome.*—Several examples of blood that appear to lack all antigens of Cc and Ee series have been described. (The genotype is represented — D — / — D — in the Fisher notation.) A small loss of genetic material has been postulated as an explanation. In the homozygous form the D antigen is extremely powerful. Heterozygotes can be detected.

Developments After 1953.— After 1953 R. E. Rosenfield and his co-workers discovered two additional antiserums, the reactions of which cannot be satisfactorily explained by postulating additional allelic pairs on the Rh chromosome. The first of these, anti-hr (f or ce), reacts with a compound antigen presumed to be the product of the genes *c* and C but only when they are together on the same chromosome. The second antiserum, anti-rh_i (Ce), reacts with the products of C and *e* when they are on the same

TABLE IV.—*The* Rh *Chromosomes Common in Western Europeans*

	Shorthand British notation	Wiener's notation	Frequency (in England)
. .	R_1	R^1	40.7%
. .	r	r	38.9%
cDE . .	R_2	R^2	14.1%
cDe	R_0	R^0	2.6%
C^wDe	R_1^w	R^{1w}	1.3%
cdE	R''	r''	1.2%
Cde	R'	r'	1.0%
CDE	R_z	R^z	0.2%

**CdE*, C^wDE and C^wdE are also known to exist.

chromosome. Thus it would appear that the genetic sites that determine the C and E antigens overlap.

An Rh antigen called G, discovered in 1957 (F. H. Allen), threw into question the specificity of serums that are mixtures of anti-C and anti-D.

Rh Antigens Rare in Europeans.—The antibody anti-V was discovered by A. DeNatale and co-workers in 1955. The V antigen is extremely rare in whites, but about 40% of West Africans and 26% of New York Negroes have the antigen. The antigen has been detected only in combination with cDe and cde.

Certain peculiarities that have been found in Negro blood samples in connection with their reactions with anti-C have been attributed to racial differences in compound Rh antigens.

Genetic Linkage.—Genes that are on the same chromosome are said to be linked. During the process of formation of gametes (cells for sexual reproduction) there is often an interchange of genetic material between partner chromosomes. Genes that are on the same chromosome in the parent may by this process of recombination be separated in the offspring. Genes that are very close together will rarely, if ever, be separated. If a gene is regarded as a unit of recombination it has not been proved that the Rh genes occupy more than a single locus. The concept of the gene is changing so rapidly that all that may safely be said is that the Rh complex is determined by a certain section of genetic material on a particular chromosome. Genetic linkage exists between the Rh locus and the locus of one type of inherited oval red cells (normal red cells are round) (S. D. Lawler, 1953).

Other Blood Group Systems.—Lutheran.—This blood group system was described by Race and S. T. Callender in 1946. The anti-Lutheran (anti-Lu^a) antibody was an immune one. There are two phenotypes Lu(a+) and Lu(a−). The genes are Lu^a and Lu^b. Anti-Lu^b has been described by M. Cutbush and I. Chanarin. The Lu(a+) phenotype has a frequency of about 7% in western Europeans. The Lutheran blood group does not normally need to be considered in transfusion. The Lutheran blood group locus is genetically linked to the secretor locus (J. Mohr, 1931).

Kell.—This system was discovered by Race, R. R. Coombs and A. E. Mourant in 1946. The antibody (anti-K) was immune; about 9% of western Europeans are Kell positive. The gene K has a positively identified allele k. The Kell system has been complicated by the discovery, by F. H. Allen and co-workers in Boston, Mass., of new antigens that belong to it.

Lewis.—The Lewis system was originally described as a blood group system by Mourant in 1946. There are now two Lewis antibodies anti-Lea and anti-Le^b. Four different phenotypes may be identified when testing red cells. Le(a+b−), Le(a−b+), Le(a− b−)in adults and children and Le(a+b+), which is found only in young infants. Everyone with Le(a+b−) red cells is a nonsecretor of ABH substances, and everyone who is Le(a−b+) is a secretor. Le(a−b−) persons may be secretors or nonsecretors. The Lewis substances are not only present in the red cells but also in the secretions. A Lewis positive individual is best defined as one who secretes Lewis substances in the saliva. The Lewis locus in this sense is inherited independently of the ABH secretor system, but the expression in the phenotype depends on the interaction with the Sese genes. The Lewis groups are not usually important in transfusion.

Duffy.—This system was discovered by Cutbush, P. L. Mollison and D. Parkin in 1950. There are now two antibodies, anti-Fy^a and anti-Fy^b, and four phenotypes: Fy(a+b−), Fy(a+b+), Fy(a−b+) and in Negroes Fy(a−b−). The genes Fy^a and Fy^b are alleles, and there may be a third allele common in Negroes.

Kidd.—This system was discovered by Allen et al. in 1951. There are two antibodies, anti-Jk^a and anti-Jk^b, and the phenotypes are Jk(a+b−), Jk(a+b+), Jk(a−b+); an example of Jk(a−b−) has been described. The groups are technically difficult to determine but the families that have been studied support the hypothesis that Jk^a and Jk^b are alleles.

Diego and Js.—The Diego system (M. Layrisse et al., 1955) has been shown to be independent of most of the known systems. The Di^a antigen has been found only in the blood of American Indians, Japanese and Chinese. The independence from the known systems of a new antigen called Js, found in the blood of Negroes (E. Giblett, 1958), was not fully established by 1960.

BLOOD GROUPS AND HUMAN DISEASE

During pregnancy a mother may be exposed to antigens that she herself lacks because fetal red cells may leak into the maternal circulation. If this results in the formation of antibody then the action of this on the red cells of the fetus may produce the disease known as hemolytic disease of the newborn. This disease, also called erythroblastosis fetalis, is usually caused by the Rh antibody anti-D (anti-Rh,) and occurs once in about 166 births in the United Kingdom and the United States. Slightly more than half the infants born with this disease require treatment, consisting of partial replacement of the child's blood. An adequate maternity service should test the blood of every Rh-negative mother for Rh antibodies. Since hemolytic disease of the newborn is almost unknown in a first pregnancy in the absence of previous exposure to the Rh antigen D (Rh,), care must be taken that Rh-negative females do not receive Rh-positive blood, which would sensitize them to the Rh antigen D. A Rh-negative woman who is married to a Rh-positive man usually does not produce Rh antibodies until after her first or second pregnancy. (See FETAL DISORDERS: *Erythro*blastosis Fetalis; PREGNANCY: *Rhesus* Factor.)

Hemolytic disease also can occur as the result of the formation of "immune" anti-A in the group O mothers of A, children. ABO incompatibility between mother and fetus usually does no harm. Anti-Kell antibody has been the cause of severe hemolytic disease on many occasions.

It has been shown in large sample surveys that there is an association between the ABO blood groups and certain diseases. For example, individuals of group A are about 20% more likely to develop cancer of the stomach than persons of groups O and B.

BLOOD GROUPS IN ANIMALS

Blood group differences between animals of the same species have been described in birds and mammals including chickens, doves, rabbits, pigs, horses, sheep, cattle, goats, cats, dogs, rats and mice. The blood groups of cattle, in particular, have been extensively investigated.

Hemolytic disease of the newborn, due to incompatibility between female parent and offspring, has been described in mules, pigs and thoroughbred foals. Substances similar to human A and B are found in many living organisms from bacteria upward. The blood groups of Primates can be determined with human anti-A and anti-B serums. All chimpanzees belong to groups O or A, orangutans are group B, gorillas may be B, and gibbons of groups A, B and AB have been described. The lower Primates have no antigens on their red cells, but they secrete ABO antigens in saliva. Old-world monkeys are mostly group A and so are new-world monkeys, except for a few that have a B-like antigen in their saliva. Antigens resembling human M are found in some Primates. The chimpanzee has been found to possess M and N. Rh antigens are found in Primates.

BLOOD INDIANS: *see* BLACKFOOT.

BLOOD PRESSURE is the force exerted by the blood against the walls of the blood vessels. It is created by the pumping action of the heart. For an understanding of the term. a brief consideration of the conditions under which the blood circulates in the body is necessary. The blood passes from the heart throughout the body by way of a system of tubes. blood vessels, that eventually return the blood to the heart. This movement through the various vessel circuits is so rapid that a given drop of blood usually requires less than one minute to complete a circuit from and back to the heart.

A single tube leading from the heart divides into smaller and smaller vessels! the arteries. Finally, the smallest arteries branch into the most minute blood vessels, the capillaries. Through the thin walls of the capillaries the blood supplies the body with oxygen from the lungs and food materials from the intestine and collects the waste products of the body for subsequent removal by the kidneys and other avenues. Beyond the capillaries the branching process is reversed. The capillaries unite to form slightly larger tubes, which in turn join to form larger vessels, known as veins, and eventually the blood is returned to the heart by two large veins.

The blood is moved through this system of vessels chiefly by the heart, which, by its rhythmic pumping action, creates within the arteries pressure that is gradually spent in moving blood through the vessels back to the heart. The blood pressure is, of course, greatest in the arteries and least in the veins.

In common medical usage, however, blood pressure means the pressure of the blood in the arteries and specifically the pressure in the large artery of the arm where it is usually measured. The greatest pressure. which occurs during contraction of the heart, is known as the systolic, and the lowest pressure, during the relaxation or rest period, is known as the diastolic. In normal man. the average systolic blood pressure is equal to the pressure exerted by a column of water 5½ ft. high or a column of mercury 120 mm. high. The average diastolic pressure is 80 mm. of mercury.

The blood pressure varies frotn one individual to another and in the same person from time to time. Thus it is lower in children than in adults and increases gradually with age. The blood pressure of women is slightly less than that of men. It is slightly increased in those who are overweight. During sleep the pressure is decreased slightly; during exercise it is increased. Likewise, a rise in pressure frequently occurs during emotional excitement—the basis for the recording of blood pressure as part of the so-called "lie-detector" test. These increases are temporary and simply reflect normal adjustment of the heart and blood vessels to meet an emergency.

High Blood Pressure.—When the blood pressure remains persistently or permanently above the normal range, the condition is known as high blood pressure (hypertension). High blood pressure and hardening of the arteries are the principal causes of heart and kidney disease in later years. While the exact cause of the common form of high blood pressure remains unknown, there is evidence that the nervous system, the endocrine glands and the kidney are involved. In some way these organs cause constriction or narrowing of the smallest or microscopic arteries of the body. As a result. the heart must pump more forcefully to move the blood through the narrowed vessels into the capillaries, thereby increasing the blood pressure. High blood pressure has been produced experimentally in dogs by partial constriction of the renal arteries supplying the kidneys.

Certain drugs, under medical direction, are efficacious in the treatment of high blood pressure. A low salt diet is effective in about 10% of patients treated. Overweight should be combated by a moderate reducing diet. A nerve-sectioning operation produces what is tantamount to a cure in about 10% of patients, but it is used only infrequently because of the effectiveness of drug treatment.

Low Blood Pressure.—Low blood pressure (hypotension) usually means a condition in which the pressure remains persistently below normal without any evidence of disease. Persons with this condition have a longer life span than those' with normal blood pressure because they are less likely to develop hypertension.

BLOODROOT *(Sanguinaria canadensis),* a North American plant of the poppy family, Papaveraceae. called also red puccoon, common in rich woods in eastern North America. It is a low, smooth, bluish-green perennial which blossoms usually before its own leaves or those of its native woodland unfold. The showy white or pinkish flowers. about two inches broad are usually borne singly on stalks about eight inches long. The flower stalks and the large, rounded, many-lobed leaves rise from a horizontal rootstock, often an inch thick and several inches long. The rootstock, together nith other parts, is surcharged with an acrid, orange-red juice, whence the name. The plant contains an alkaloid, sanguinarine, used in medicine. Throughout its range the bloodroot is one of the most attractive early bloomers and is often transplanted for ornament.

PHOTOGRAPH J HORACE MCFARLANO CO

BLOODROOT (SANGUINARIA CANADENSIS) **IN BLOOM**

In Great Britain the name bloodroot is sometimes applied to the tormentil *(Potenfilla tormentilla)* and the crimson cranesbill (*Geranium sanguineum*).

BLOODSTONE (HELIOTROPE) is a dark-green variety of cryptccrystalline silica or quartz, having nodules of bright red jasper or impure opaque quartz distributed throughout its mass. Polished sections therefore show red spots on a dark-green background, and from the resemblance of these to drops of blood it derives its name.

The aord heliotrope is derived from the Greek *helios,* "sun," and *trope,* "turning," in reference to its supposed power to turn the sun's rays red.

It was greatly prized in the middle ages and used in sculptures representing flagellation and martyrdom; it later became of small importance. On heating. the red spots turn black and the green background changes to gray.

BLOOD TRANSFUSION. The development of blood transfusion, from the vague illusions in the early mythologic period to the modern scientific and therapeutic procedure. forms one of the most fascinating chapters in medical history. The fairly late advances in this field and the simplificdtion of apparatus and methods make blood transfusion so easy that in most modern hospitals, instead of having an expert or a specialist—the transfusionist, formerly called upon to perform all necessary blood transfusions—the youngest intern usually is responsible for the transfusions performed each day.

The antiquity of the concept of blood as a therapeutic agent is difficult to establish. It began with the origin of medicine itself. Ancient Egyptians used blood baths for resuscitation and recuperation. and Romans were said to have rushed into the gladiatorial arena to drink the blood of dying victims as a method of rejuvenating themselves. Probably in all such cases the blood was taken by mouth rather than by vein and therefore had very little beneficial effect. Certainly blood transfusion as it is now understood could not have been practised at a time when the circulation of the blood was not recognized. So it is difficult to determine exactly nhen transfusion in the modern sense (injection into the circulation of the patient) was first performed, and con-

siderable controversy exists regarding claims of priority. For example, there is the oft-quoted and supposed transfusion of Pope Innocent VIII in 1492. In an effort to bring the elderly pontiff out of a state of coma, he was supposed to have received the blood from three young men, but to no avail. Not only did he succumb promptly but so did the donors. Quite probably here, too. the blood was administered as a drink.

In the evolution of the modern practice of blood transfusion there are certain outstanding historical landmarks, first in 1628 when William Harvey announced his theory of the circulation of blood. His discovery made possible a clear idea of blood transfusion as a therapeutic measure and led to devising means of transferring blood from a vigorous to a debilitated subject; it started energetic experiments on the injection of various substances into the blood stream. However, it was not until after the middle of the 17th century that authentic references to blood transfusion are found. Descriptions of four or five different methods, using hollow goose quills, hollow metal tubes (mostly of silver) and even crude valves are found in medical literature. One of the first authenticated reports is that of Richard Lord, who performed a successful transfusion in 1665. Quills were used by Lord at first, and later silver tubes, to convey the blood from the artery of one dog to the vein of another. Two years later, he transfused a healthy but mildly insane man with the blood of a lamb. This is described in the Pepys' ***Diary;*** a demonstration was given before the Royal society in London. Apparently there was little effect, either in disturbing the recipient's good physical state or mending his poor mental one.

At about the same time in Paris, Prosper S. Denis, physician to Louis XIV, performed the first authentically recorded successful transfusion on human beings. The story is that a young patient who had obscure fevers had been treated by the common prevalent method of repeated bloodletting from his veins until he was in a state of extreme exhaustion and profound anemia. Denis administered about a half pint of blood of a lamb and the boy made a "remarkable" recovery. In view of modern knowledge that the blood of one species cannot be transfused into another without fatal or near-fatal reaction, this is indeed remarkable if true. Denis performed several more transfusions, one of which. however, was fatal. Charges were preferred against the physician and following a long legal battle he was exonerated of murder but remained in such disrepute that both he and the procedure of transfusion were decreed criminal by the Faculty of Medicine in Paris and banned, supposedly forever. A short time later, the English parliament also specifically prohibited the operation and the magistrates of Rome followed suit. Interest in transfusion thereafter quickly lapsed throughout Europe.

Reintroduced in England. — It was not until early in the 19th century that transfusion of blood was once more considered as a possibly useful therapeutic procedure. An English obstetrician, James Blundell, revived interest in it because he was overwhelmed by his helplessness in combating serious and often fatal hemorrhage during childbirth. After many experiments on animals, he devised a special apparatus for performing transfusions and saved a certain number of anemic patients by his efforts. Many physicians followed his lead.

During the third quarter of the 19th century, transfusion was performed with increasing frequency. Until this time there had been only 347 human blood transfusions and 129 cases in which animal blood was used. Then, new and more practical needles, syringes, valves and apparatus in general were devised. With a better understanding of physiology, more physicians and scientists became aware of the possible dangers of the use of blood from animal sources in human transfusions and emphasized the fact that the serum of one species "may be a direct poison for the blood cells of another." The lack of knowledge of blood groups and incompatibilities had resulted in severe reactions and increased fatalities. This again resulted in the eventual consideration of transfusion as a hazardous procedure to be used only as a last resort. Moreover, salt solution was introduced at about this time and its safety and efficacy for injection were demonstrated, so that blood transfusion again was virtually abandoned and not considered seriously until the beginning of the 20th century.

Probably the greatest achievement and the most important single discovery in the history of blood transfusion was the demonstration by Karl Landsteiner in 1900 of the blood groups in humans and their practical significance in helping to choose blood compatible for transfusion. The adoption of an international nomenclature as proposed by Landsteiner using the letters A, B and O overcame the difficulties of numerical classification used in many countries.

Asepsis had been perfected with the advent of improved surgical techniques, thereby making injection of materials into the body much safer. Apparatus was devised as the need arose and in the modern period the development of transfusion became dependent upon the recognition of mechanisms of blood clotting and attempts to prevent blood from clotting so that its transfer could be effected from one individual to another. The next great advance was the use of an anticoagulant chemical, sodium citrate. which permitted blood to be taken into a container during constant mixing with a solution of the citrate and transfused without danger of clotting through delay of only a few minutes. This addition of a chemical was called the indirect method of transfusion; as its simplicity and safety were appreciated the former direct method consisting of connecting the blood vessel of the donor with that of the recipient became outmoded. In 1915 Richard Lewisohn perfected the technique and standardized the dosage addition of sodium citrate to blood, thereby rendering transfusion extremely simple and practical. Its standardized use in military medicine during World War I increased its popularity. Later, the difficulty of preserving blood for longer than a few days was solved by the introduction of new diluent solutions composed of sodium citrate, citric acid and glucose, which permitted the storage of blood at ordinary refrigerator temperatures up to 21 days with a survival of 70% or more of the red cells and thereby made the modern blood bank a practical life-saving asset in most hospitals.

In the 1930s the plasma, or fluid part of the blood, first began to be used as an effective weapon to combat serious shock, particularly when whole blood itself might not be needed. Since 70% to 80% of battle wounds are accompanied by shock, it was realized at the very beginning of World War II that the fluid part of the blood would be extremely useful in treatment of the wounded. Plasma has important advantages over whole blood for such treatment, since once the red cells have been removed, typing of the blood is less necessary because plasma from one individual can generally be given to anyone else regardless of the blood groups. Another advantage is that plasma can be stored for months since it does not deteriorate as do the blood cells and can be kept well preserved either in a frozen state or dried to a powder that can be dissolved in sterile water when needed for injection. The British began collecting blood needed to produce plasma for the battle fronts in 1939. In 1941 the American Red Cross, at the request of the army and navy and under guidance of the National Research council, began to collect blood for preparation of plasma for the U.S armed forces. Most of the blood collected was converted to dried plasma, although late in the war a considerable amount was flown to the battle fronts and used as whole blood in the treatment of battle casualties.

Cohn's Fractionation. — A significant advance in the use of blood and portions of the blood was the result of the work of Edwin J. Cohn and his associates at Harvard university. Through the development of methods of separating and purifying the various protein fractions of plasma in unaltered form, they were able to extend the usefulness of portions of the blood and to indicate the path of future progress in treating specific diseases and deficiencies of the body with special blood derivatives. The first practical application of Cohn's new methods of separation or fractionation of the plasma was the development of serum albumin. This fraction accounts for 50% of all the protein in the plasma and is mainly responsible for the shock-combating value of plasma, since it helps to hold Auid in the blood stream. During World War II, several pharmaceutical firms produced serum albumin, by Cohn's methods, from plasma collected by the American Red Cross. Serum albumin had the great advantage of being

five times as concentrated as the plasma; being bottled in liquid form, it did not need reconstitution with water as did the dried plasma; it could be transported ready for use in a much smaller package. Finally. through a method of pasteurization, it could be freed of contamination by the virus of serum hepatitis, which was a serious complication occurring in a small percentage of plasma-treated patients.

Serum albumin was thus the first of a series of products from blood that are specific and better for certain medicinal uses than is whole blood. Other fractions of blood that came into common usage and have specific value included immune serum globulin. fibrinogen and antihemophilic globulin.

Immune serum globulin, or gamma globulin, is a relatively small portion of the plasma that contains the antibodies or chemical substances that help fight disease caused by invading bacteria and viruses. Most of these antibodies are highly specific and have developed in the human body as the result of former contact with a specific organism or virus. Thus, the individual who has had an attack of measles develops specific antibodies or chemicals that attack the germ causing the measles and thereby prevent its usual recurrence. Or when such antibodies in gamma globulin are injected into a susceptible person, they protect the recipient for three or four weeks.

Gamma globulin was also found useful in the treatment of the form of liver disease called infectious jaundice, or infectious hepatitis. Later, following field trials in epidemic areas, it was thought that infantile paralysis may be temporarily prevented or extensive crippling avoided by injection of gamma globulin into susceptible contacts. It was found that by collecting plasma from individuals with a recent specific disease such as mumps and fractionating this plasma into the gamma globulin portion, a serum could be obtained to modify certain diseases and possibly protect against them for a short period of time. This was of special value in certain epidemic diseases like mumps and German measies (which may be serious for women in the early stages of pregnancy because it may harm the fetus).

Fibrinogen is a plasma protein that is specifically necessary in the clotting of blood and thereby stops hemorrhages or fills breaks in blood vessels following injury. In certain disease states where the fibrinogen level of the blood becomes depressed or the body is unable to produce sufficient fibrinogen to prevent bleeding. the injection of this blood fraction may be life-saving or may restore to normal activity an individual whose low fibrinogen level had produced hemorrhages and danger of bleeding. Fibrinogen also proved of value when prepared in a solid form and used locally as a sponge or as a film to' control bleeding and to protect denuded areas.

A little-known fraction of the plasma was found to be most important in speeding up the clotting of individuals suffering from the hereditary bleeding defect called hemophilia. This fraction, called anrihemophilic globulin, must be prepared from fresh plasma shortly after blood is removed from the body because of the fragility of this protein and its rapid rate of deterioration. The fraction, injected intravenously into patients suffering from hemophilia. controlled the tendency to bleed.

The greatest handicap to the long-time preservation of whole blood was the relatively rapid deterioration of the red cells after collection through rubber-tubing into glass bottles; this technique permitted the cells to undergo more rapid destruction after three to four weeks of storage even at constant refrigerator temperatures. In the early 1950s, plastic tubes and plastic containers were developed. These presented a nonwettable surface to which blood would not stick and cell degeneration was less rapid. At the same time, methods of quick-freezing red cells were introduced, and, for the first time, truly prolonged storage and stock-piling of blood became possible, thereby making economy in the use of blood a reality. It was necessary, however, to develop refrigerated centrifuges to separate plasma from red cells rapidly and then by addition of glycerol to protect the cells from damage as they were brought to a temperature of −80° C. or lower. In numerous tests, it was found that at this low temperature, even at the end of many months, most of the red cells were normally viable after removal of the glycerol and transfusion. Multiple units suitably prepared and crossmatched mere given to recipients with the expected benefit and no untoward reactions.

New Surgical Techniques. — In the late 1950s, complicated surgery on the heart and great vessels became possible; part of its success was due to the availability of large amounts of relatively fresh, as well as stored. blood. Open-heart operations, in which the circulation of blood through the body is taken over by a variety of mechanical pump-oxygenators while the heart's action is stopped by drugs and the interior exposed for various repair and shunting operations, requires the use of large amounts of blood, often from 5 to 20 pints per patient.

Surgical procedures on the heart, blood vessels. lungs, brain and other delicate organs, previously considered impossibly lengthy or dangerous, could then be undertaken. These operations introduced new problems: in blood procurement, the need for large amounts of rare types for patients with unusual blood types; in use of other anticoagulants such as heparin and chelating agents (which remove all the calcium from the plasma and thus prevent clotting) instead of citrate solutions formerly used safely for single or smali volume transfusions but toxic in large quantity; in crossmatching not only the recipient's blood sample against the blood of each donor but also that of each donor against all other donors.

Thus, blood transfusion came to serve much more than its earliest purpose, which was to save the life of a bledout patient. It developed as important replacement therapy for shock and protein deficiency through the use of plasma or albumin. for chronic anemia through the use of red cells without plasma, for clotting-factor deficiencies remediable by plasma and special plasma fractions like fibrinogen and for lack of antibodies through injection of gamma globulin. With the need for large pools of blood for extensive surgery and extra-corporeai circulation (the function of the heart and lungs being replaced by a mechanical pump and oxygenator), transfusion services with their complicated laboratory procedures and a variety of blood-banking methods became not just an important but a truly vital part of modern hospital operations.

See BLOOD BANK; BLOOD GROUPS; HAEMORRHAGE.

BLOOD VESSELS, SURGERY OF. Surgery of blood vessels consists of various operative procedures directed toward cure of vascular abnormalities of congenital origin or produced by injury or disease. Such surgery was envisioned from the earliest times, and beginning in the 18th century a number of methods of treatment were proposed; most of these were palliative rather than curative and the results were generally poor. Lack of knowledge of asepsis, anesthesia and blood transfusion precluded performance of this type of surgery past the experimental stage, and even such pioneers as Alexis Carrel and R. Matas in the late 19th century were hampered in their efforts to suture blood vessels successfully. It was not until the early 1950s that an aggressive approach was directed toward cure by extirpating the lesion and restoring normal function of the vessel.

Congenital lesions include such anomalies as coarctation of the aorta (constriction of the largest blood vessel in the body, which impedes the flow of blood to vital parts; fig. 1[A]). The commonest and most serious of acquired diseases are aneurysm (swelling due to destructive weakness of the vessel wall; fig. 1[B]), arteriosclerotic occlusive disease (fig. 1[C]) and injuries. All these may be considered to have a poor prognosis, associated with progressively disabling symptoms and ultimately lethal complications.

The stimulus for modern interest in blood vessel surgery was probably provided by the reports of R. E. Gross and of C. Crafoord and G. Nylin in 1945 of successful treatment of a case of coarctation of the aorta by resection and re-establishment of continuity of the vessel by sewing the cut ends together. Developments from that time were rapid and led to the use of homografts

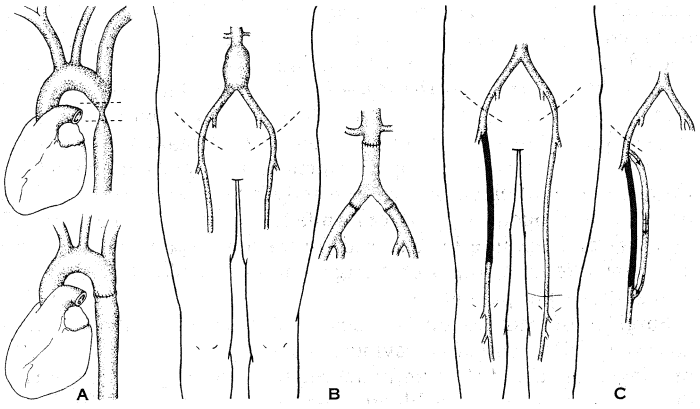

FIG. 1.— SURGICAL REPAIR OF (A) COARCTATION OF AORTA. (B) ANEURYSM OF ABDOMINAL AORTA; (C) ARTERIOSCLEROTIC OCCLUSIVE DISEASE

and later to tubes made of nylon, Dacron or Teflon fabric to replace excised segments, thereby permitting application of this form of therapy to various lesions.

In general, three operative methods may be employed depending upon the nature and extent of the disease:

1. Excision of the diseased segment and restoration of continuity by end-to-end anastomosis or by means of a graft. This is illustrated in fig. 1. The constricted segment of aorta between

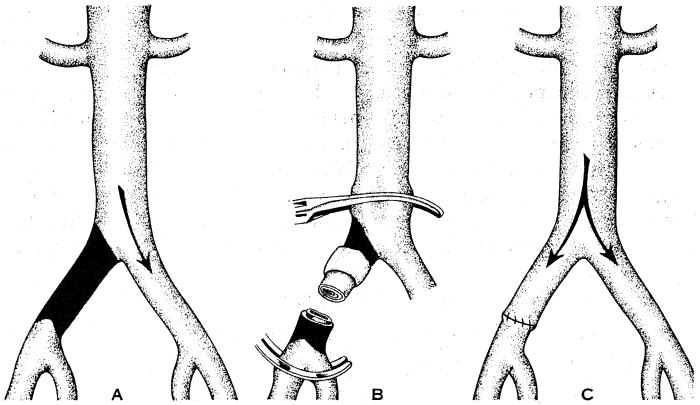

FIG. 2.—THROMBOENDARTERECTOMY

(A) Shaded area represents obstruction in common iliac artery produced by arteriosclerosis. (B) Clamps are applied to vessels above and below obstruction to arrest circulation temporarily and, after dividing artery, outer wall is "peeled" away from inner diseased segment and removed. (C) Upper and lower open ends of vessel are then joined together by silk sutures and clamps removed permitting normal blood flow

the interrupted lines in the upper drawing (fig. 1[A]) is excised and the upper and lower ends are joined together by fine silk sutures, as shown in the lower drawing, to restore normal lumen and blood flow. In some instances in which the constricted segment is much longer, a graft may be used to replace the defect. In fig. 1(B), illustrating graft correction of aneurysm of the abdominal aorta, the operation consists in clamping the vessels above and below the aneurysm to arrest circulation temporarily while the aneurysm is removed and then replaced by graft (drawing on right).

2. Use of a bypass graft, which may be attached by end-to-side anastomoses to the normal artery above and below the obstructed diseased segment, thereby shunting blood around it. Fig. 1(C) illustrates this in a case of arteriosclerotic occlusive disease, represented by the shaded area in the femoral artery in the right thigh (drawing on left). On the right a bypass graft has been attached to the sides of the artery above and below the obstruction to restore normal blood flow into the lower leg.

3. Thromboendarterectomy, which may be used in arteriosclerotic arterial obstruction, consists in the removal of the occlusive lesion from within the vessel (fig. 2).

See ARTERIES, DISEASES OF; VEINS, DISEASES OF.

(M. E. DE B.)

BLOODWORM, the slender, red-coloured. aquatic larvae of certain midges of the dipterous family Chironomidae *(see* FLY). Their coloration is due to the presence of the respiratory pigment, hemoglobin, by means of which the larvae extract dissolved oxygen from water. The term is also applied to red-blooded marine polychaete worms (phylum Annelida) of the genus *Glycera,* occurring along the middle Atlantic coast of the United States. They are six to eight inches long. Dug from sand or mud, they are used as bait in fishing. (G. W. Bs.)

BLOODY ASSIZES, the name given in English history to the commission conducted by Chief Justice Jeffreys after the Monmouth rebellion in the west of England in 1685. About 320 persons aere condemned to death; and about 800 were transported to Barbados. Although modern research has acquitted Jeffreys, in certain cases, of any technical irregularity, the trials generally were conducted with a ferocity which has, with reason, made his name notorious. *See* JEFFREYS, GEORGE JEFFREYS; LISLE. ALICE.

BLOOMER, AMELIA (née JENKS) (1818–1894), U.S. dress-reformer and women's rights advocate, was born at Homer, N.Y., on May 27, 1818. She married Dexter C. Bloomer in 1840. In 1849 she took up the idea—previously originated by Mrs. Elizabeth Smith Miller—of a reform in women's dress, and the wearing of a short skirt, with loose trousers, gathered around the ankles. The name of "bloomers" gradually became popularly attached to any divided skirt or knickerbocker dress for women. Until her death on Dec. 30, 1894, Mrs. Bloomer took a prominent part in the temperance and woman suffrage movements.

BLOOMFIELD, LEONARD (1887–1949), U.S. linguist, whose book *Language* was the most important general treatment of linguistics published in the first half of the 20th century and the one which almost alone determined the course of linguistic science in the U.S., was born on April 1, 1887, at Chicago, Ill. He was educated at Harvard, Wisconsin, and Chicago (Ph.D., 1909). Bloomfield taught successively at the universities of Wisconsin, Cincinnati and Illinois, Ohio State university, The University of Chicago, and Yale university, where he was Sterling professor of linguistics from 1940 until his death.

Behaviouristic—and thus nonmentalistic—in general theory, *Language* (1933) presented a complete synthesis convincingly; it stated the view and demonstrated the fact that linguistic phenomena could properly and successfully be studied scientifically only when isolated from their nonlinguistic environment. Dedication to this principle has given linguistics in the United States an astringent scientific austerity productive of results more clear and certain than those achieved in any other social science but open to the charge of an excessively pragmatic and gradual approach to large problems of human linguistic behaviour.

Trained as an Indo-Europeanist and Germanist, Bloomfield turned in the second half of his life to the study of other language families, among them Malayo-Polynesian and Algonkian. Of Algonkian in particular he wrote many descriptive and comparative studies. It was no doubt this first-hand acquaintance with languages of widely differing structure that gave him the breadth of view so apparent in his masterwork; but his devotion to science and his belief in it as a means to the bettering of man's condition arose from a depth of humanity which far transcended his professional interests. He died on April 18, 1949, at New Haven, Conn.

The list of Bloomfield's publications is long (a bibliography is published in the journal *Language*, vol. 25, No. 2, April-June, 1949); but it is certain that his greatest work and the one on which his fame most firmly rests is his book *Language.*

(MY. F.)

BLOOMFIELD, MAURICE (1855–1928), U.S. Indological and philological scholar, best known as a student of the Vedas, was born on Feb. 23, 1855, in Bielitz, Austria. He went to the United States in 1859, studied at The University of Chicago, Furman university, Greenville, S.C., Yale university and at Johns Hopkins, to which he returned as professor of Sanskrit and comparative philology in 1881 after a stay of two years in Berlin and Leipzig. He translated, for Max Müller's *Sacred* Books of *the East,* the "Hymns of the Atharva-Veda" (1897);

contributed to the Buhler-Kielhorn *Grundriss der indo-arischen Philologie und Altertumskunde* the section "The Atharva-Veda and the Gopatha Brahmana" (1899); was first to edit the Kaucika-Sutra (1890); published in conjunction with Richard von Garbe of the Tübingen university a chromophotographic reproduction of the Paippalada version of the Atharva-Veda (1901). In 1906 he published, in the Harvard "Oriental Series," *A Vedic Concordance;* in 1905 *Cerberus, The Dog of Hades,* a study in comparative mythology; in 1908 *The Religion of the Vedas;* in 1916 *Rig-Vida Repetitions;* in 1919 *The Life and Stories of the Jaina Savior, Parcvanatha.* The bulk oi his work is laid down in articles on Indic and linguistic and ethnological subjects printed in the journals of the U.S. and Europe. He died in San Francisco, Calif., June 13, 1928.

See the bibliography at the end of the foreword to *Studies in Honor of Maurice Bloomfield, by a* group of his pupils (1920).

BLOOMFIELD, ROBERT (1766–1823), English poet, author of *The Farmer's Boy,* a long poem in heroic couplets, owing much to 18th-century pastoralism, was born at Honington. Suffolk! Dec. 2, 1766. His father died soon afterward: leaving a large family. His mother, who kept the village school, taught him to read and write, and at 11 he went to work on his uncle's farm. Proving too frail, at 15 he joined his brothers in London to learn the trade of shoemaker. A fellow lodger in the garret where they lived lent him *Paradise Lost,* and also Thornson's *Seasons,* which inspired him to write of the Suffolk countryside. He composed *The Farmer's Boy* while making shoes with several other men, keeping the lines in his head until he could write them down. It was refused by several publishers but published in 1800 by Capel Lofft, with woodcuts by 'Thomas Bewick. It harmonized with the new mood of Romanticism and in two years sold 26.000 copies. Essentially the work of a simple countryman who loved nature, it was criticized by Lamb, but praised by Hazlitt. Bloomfield followed up his success with *Rural Tales* (1802), *Good Tidings* (1804), *Wild Flowers* (1806) and *The Banks of the Wye* (1811). *He* lost his savings in a publishing venture and died in poverty, at Shefford, Bedfordshire, Aug. 9, 1823. His Remains—verse and an essay on the making of aeolian harps (in which he was expert)—were published in 1824, with a biography by J. Weston. *Selections From the Correspondence of* R. *Bloomfield* was edited by W. H. Hart (1870); *Selections of Poems by R. Bloomfield* was edited by R. Gant (1947). (P. M. Y.)

BLOOMFIELD, a town of Essex county, in northern New Jersey, U.S., is a residential and industrial suburb of Newark. It received its present name in 1796 in honour of Joseph Bloomfield, a general in the American Revolution and later governor of New Jersey. It was set apart from Newark in 1812, and from its territory have been taken Montclair, Belleville, Glen Ridge and Nutley. It was among the first U.S. towns and cities to produce papermaking machinery using the Fourdrinier. process invented in France. During the Civil War large quantities of cloth for Union uniforms were produced there. The development of electrical equipment at the end of the 19th century gave impetus to Bloomfield's expansion. Industries are highly diversified and include the preparation of automobiles for export, the production of projectors for motion-picture theatres, pharmaceuticals and phonographs. Pop. (1960) 51,867. For comparative population figures *see* table in NEW JERSEY: *Population.* (E. R. D.)

BLOOMINGTON, a city of an agricultural area of rich prairie land, in central Illinois, U.S., and the seat of McLean county since 1831, is 125 mi. S.W. of Chicago. First settlement was in 1822 at a site known as Keg Grove, later as Blooming Grove, and in 1831 as Bloomington when the town was platted. Bloomington was incorporated as a city in 1850, and in 1953 established council-manager government. The city is headquarters of the Illinois department of the American Legion, of the Illinois Agricultural association and of a large mutual insurance company. Illinois Wesleyan university (1850) is in Bloomington, and Illinois State Normal university (1857) and Illinois Soldiers' and Sailors' Children's home are in contiguous Normal.

An annual spring event since 1923 is the production of the American Passion Play. Bloomington is the birthplace of the author Elbert Hubbard and was the home oi the U.S. supreme court justice and senator David Davis, of the U S. vice-president Adlai E Stevenson, and of the Illinois governors John Hamilton. Joseph Fifer and Adlai E. Stevenson. Abraham Lincoln delivered a famous speech on slavery at a convention there in 18.56 when the Illinois Republican party was organized.

Many of its products are farm-related, and Bloomington is a transportation centre of the state corn belt. Industrial products include candy, communications equipment, electrical appliances, refrigerators and heating and air-conditioning equipment, For comparative population figures *see* table in ILLINOIS: *Population.* (T. J. C.)

BLOOMINGTON, a city and the seat of Monroe county, in southern Indiana, U S, is 49 mi S W of Indianapolis It is the home of Indiana university which was founded in 1820 (*see* INDIANA: *Education*) Bloomington is the centre of the great Indiana limestone belt with extensive lime and cut stone quarries and mills, and within 25 mi of six of the state parks and forests According to tradition the flowers were in full bloom when the first settlers arrived and it was named Bloomington Of the early immigrants. Kentuckians were the more numerous When the first lots were laid out and sold in 1818, there were about 140 inhabitant? It nas incorporated as a city in 1877 The public library extends contract service throughout the county Bloomington has several parks and a children's swimming pool Industries include meat packing, railroad shops, and the manufacture of radio television. electronic and electrical equipment For comparative population figures *see* table in INDIANA: *Population* (E W H L.)

BLOOMSBURY GROUP, the name given to a number of English writers and artists who frequently met between about 1907 and 1930 at the houses of Clive and Vanessa Bell and of Vanessa's brother and sister Adrian and Virginia Stephen (later Virginia Woolf; *q v.*) in the Bloomsbury district of London near the British museum. They discussed artistic and philosophical questions in a spirit of honest agnosticism and were strongly influenced by G E Moore's *Principia Ethica* (1903) and by A N Whitehead and Bertrand Russell's *Principia Mathematzca,* three volumes (1910–13) in the light of which they searched for definitions of the good, the true and the beautiful and questioned accepted ideas with a "comprehensive irreverence" for all kinds of sham.

Nearly all the "Bloomsberries" as they were nicknamed had been at Trinity or King's college, Cambridge. with Leslie Stephen's son Thoby (1880–1906), who had introduced them to his sisters Vanessa and Virginia Most of them had been "apostles" *i e,* members of the "society," a select semisecret university club for the discussion of serious questions, founded at Cambridge in the late 1820s by J. F D. Maurice (q *v*) and John Sterling Tennyson. Arthur Hallam, Edward Fitzgerald and Leslie Stephen had all been apostles and in the early 1900s, when those who later formed the core of the Bloomsbury group were elected to the society the literary critic Lowes Dickinson, the philosophers Henry Sidgwick (*q v*), J M. E McTaggart, A N. Whitehead (*q v*) and G E Moore and the art critic Roger Fry (*q v*), who became one of the Bloomsbury group himself, were members

The group included the novelist E M Forster the biographer Lytton Strachey (*qq v*), the art critic Clive Bell the painter Duncan Grant, the economist John Maynard Keynes (qq *v*) and the Fabian writer Leonard Woolf and his wife Virginia, who together founded the Hogarth press (1917). Other members were Desmond Macarthy Arthur Waley, Saxon Sidney-Turner Robert Trevelyan, Francis Birrell J T Sheppard (later provost of King's college) and the critic Raymond Mortimer and the sculptor Stephen Tomlin both Oxford men Bertrand Russell. Aldous Huxley and T S Eliot were sometimes associated nith the group, as was the economist Gerald Shove It survived World War I but by the early 1930s had ceased to exist in its original form having by that time merged with the general intellectual life of London, Oxford and Cambridge Although its members shared certain ideas and values. the Bloomsbury group did not constitute a school. Its significance lies in its being an extraordinary constel-

lation of talented persons whose achievements were in many instances both distinguished and influential.

BLOSIUS, FRANCISCUS LUDOVICUS (LOUIS DE BLOIS) (1506–1566), Benedictine monastic reformer and mystical writer. was born a member of the Wallonian nobility at Donstienne in Hainaut. As a page at the court of the future emperor Charles V he received his early education from the future pope Hadrian VI. In 1520 he entered the Benedictine order at Liessies. becoming abbot ten years later. His concern for the renewal of monastic spirit occasioned his writings, which, for a time rivaled the *Imitation of Christ* in popularity. Doctrinally Blosius was a successor to the earlier Lowlands mystics, without however their speculative interests, and a forerunner of St. Francis of Sales.

The best edition of Blosius' writings is that of De Winghe, *Ludovici Blosii opera omnia* (1632), to which must be added Berlière's edition. the first complete one, of the *Statuta monastica* (1029). The more important treatises are translated in B. Wilberforce and D. R. Huddleston, *The Works of Louis de Blois* (1925–26).

The anonymous *Vita*, still the basic biographical document, is given in De Winghe as well as in the Bollandist *Acta sanctorurn*, vol. i, pp 430–456. *See* also Georges de Blois, *A Benedictine of the Sixteenth Century* (1878). (E O'B)

BLOUNT, CHARLES (1654–1693), English writer on deism (q *v.*), was born at Upper Holloway, Middlesex, on April 27, 1654. His father, Sir Henry Blount, personally supervised his education and arranged for his marriage at 18. Blount admired Dryden and Hobbes and his first publications were two pamphlets, *Mr. Dryden ?'indicated* (1673) and *Last Sayings and Dying Legacy of Mr. Thomas Hobbs* (1679), the latter consisting chiefly of extracts from *The Leviathan*. He also contributed to Dryden's translation of Lucian (1711).

An extreme Whig in politics, in religion Blount followed the deistical tenets of Lord Herbert of Cherbury (*q.v.*). In 1679 he published *Anima Mundi*, expressing such unorthodox views on immortality that it was suppressed by the bishop of London. *The First Two Books of Philostratus Concerning the Life of Apollonius Tyaneus* . . . (1680) was banned in 1693 because, in its notes, Blount supported natural rather than revealed religion.

Although not an original thinker, Blount cared sincerely for freedom and materially contributed to that of the press by two pamphlets, signed "Philopatris" (1693), based on Milton's *Areopagitica*, which caused the downfall of the licenser, Edmund Bohun. Blount committed suicide in Aug. 1693 because he could not marry the sister of his deceased wife. A collection of his letters and pamphlets was published by Charles Gildon, entitled *The Oracles of Reason* (1693). *Miscellaneous Works* (1695) is a fuller edition, with a preface by Gildon defending suicide.

See A. Kippis, *Biographia Britannica* (1780); J. Leland, *View of the Deistical Writers (1837)*; Lord Macaulay, *History of England*, ch. xix (1855).

BLOUNT (BLUNT), **EDWARD** (fl. 1578–1632), English publisher and translator who, with Isaac and William Jaggard, printed the First Folio of Shakespeare's plays, was the son of Ralph Blount, merchant tailor of London. On June 24, 1578, he was apprenticed to William Ponsonby, the publisher of Sidney and Spenser. In 1588 he became a freeman of the Stationers' company and opened a bookshop "in Paul's Churchyard at the signe of the Black Beare."

His early publications include Giovanni Florio's Italian-English dictionary (1595) and his translation of Montaigne's essays (1603), and Marlowe's *Hero and Leander* (1598) with a dedication to Sir Thomas Walsingham in which he claims close friendship with the dead poet. He translated *Ars Aulica, or the Courtier's Arte* from the Italian of Lorenzo Ducci in 1607, and *Christian Policie* from the Spanish of Juan de Santa Maria in 1632. In 1612 he published Thomas Shelton's translation of *Don Quixote*, the first English version. The First Folio of Shakespeare's plays, entitled *Mr. William Shakespeares Comedies, Histories and Tragedies. Published According to the True Originall Copies*, appeared in 1623. It had been produced by Shakespeare's colleagues at the Globe theatre, Henry Condell and John Heming, but Blount probably acted as editor though not as an entirely accurate one. In 1632 Blount published the first collected edition of *Sixe Court Comedies* by John Lyly. Nothing is heard of him subsequently. His dedicatory prefaces reveal wide education and a pleasant sense of humour.

BLOUNT, SIR THOMAS POPE (1649–1697), English author whose painstaking collections of critical opinions are of some interest in the development of critical theory, was born at Upper Holloway, Middlesex, on Sept. 12, 1649. He represented St. Albans in parliament under Charles II and later became knight of the shire, having been created a baronet in 1679. He compiled for his own use a bibliographical dictionary of eminent European writers, recording their opinions of one another, and finally allowed its publication in 1690 as *Censura celebriorum authorum*. A version translating the quotations into Latin for the benefit of foreign scholars was published in 1694. In 1693 he wrote *A Natural History, Containing Many Not Common Observations Extracted Out of the Best Modern Writers*, and in 1694 *De re poetica, or Remarks Upon Poetry, with Characters and Censures of the Most Considerable Poets*, which included comments on Shakespeare, Milton, Spenser and Ben Jonson, all of whom had been omitted from the *Censura*. His gifts as an original writer are best revealed in *Essays on Several Subjects* (1692), written in a mood of cheerful cynicism. He died at Tittenhanger Park, Hertfordshire, on June 30. 1697. He was the elder brother of Charles Blount (q *v*).

See A. Kippis, *Biographia Britannica*, vol. ii (1780). For an account of Blount's family *see* Robert Clutterbuck, *History and Antiquities of the County of Hertford*, vol. i, pp. 207–212 (1815).

BLOUNT, WILLIAM (1749–1800), U.S. political leader, was born in North Carolina, March 26, 1749. He was active from the beginning in the American Revolution, serving in the continental congress and in the Constitutional Convention of 1787. From 1790 to 1796 he was superintendent of Indian affairs for the region known as the "Territory south of the Ohio River." When Tennessee became a state, he was elected one of its U S. senators. Implicated in an American conspiracy to seize Spanish-owned Florida and Louisiana for England. then at war with Spain, he was expelled by the senate on July 8. 1797. He was impeached by the house of representatives in the same year, but the impeachment trial, the first to come before the senate, was terminated in Jan. 1799, when the senate decided it had no jurisdiction. Blount then resumed his political career in Tennessee. He died at Knoxville. Tenn., on March 21, 1800. (E. E. R)

BLOW, JOHN (1649–1708), English organist and composer, remembered for his church music and for *Venus and Adonis*, which may be regarded as the first true English opera. Born at Newark-on-Trent, Nottinghamshire, where he was baptized on Feb. 23, 1649, he was probably educated at the Magnus Song school there, and in 1660 became a chorister at the Chapel Royal. There he composed several anthems, including the so-called *Club Anthem* with William Turner and Pelham Humfrey. His voice broke in 1664, and after a musical apprenticeship he was appointed organist of Westminster abbey (1668). In 1669 he became one of the king's musicians for virginals and in March 1674 was sworn in as a gentleman of the Chapel Royal, succeeding Humfrey in July as master of the children. He held this position until his death, and had great influence on the choristers under him, among them William Croft. Jeremiah Clarke and Daniel Purcell, and also on Henry Purcell, who was taught by him at this time. In 1676 or 1677 he became one of the Chapel Royal organists, and in 1677 the dean and chapter of Canterbury conferred on him a doctorate of music —the first reference to what became known as a Lambeth degree in music.

In 1679 Blow was succeeded as organist at Westminster abbey by Purcell; he was reappointed after Purcell's death in 1695. The years 1680–1700 were the most productive and prosperous of his life. He acquired several London properties; at his death he

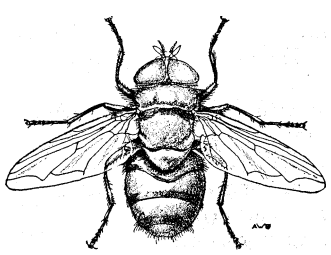
owned at least eight houses, in one of which, in the Great Sanctuary, Westminster, he and his family lived (he had married in 1674 and had five children). In 1687 he became master of the children of St. Paul's, a position he held for 16 years, and in 1699 he received his last appointment, as first composer to the Chapel Royal. He died at Westminster, Oct. 1, 1708, and was buried in the abbey.

Blow's official positions entailed the writing of much ceremonial music, both religious and secular. Fourteen services and more than 100 anthems are extant and many remain in regular use. He was at his best in the writing of full anthems in a simple chordal or contrapuntal style with melodies of great strength and sweetness developed over a ground bass. In his verse anthems his style is quieter than that of Purcell; he lacks the brilliance and sustained power of invention needed for complete success in that most baroque of musical forms. His style is seen at its best in the motet for six voices, "Salvator mundi"; in the verse anthems "I Was Glad When They Said Unto Me" (for the opening of St. Paul's cathedral, 1697) and "Lift Up Your Heads, O Ye Gates"; in the "Ode for St. Cecilia's Day" (1684); the "Ode on the Death of Mr. Henry Purcell" (1696) and "Awake, Awake My Lyre" for the University of Oxford; and in the full anthems "My Days Are Gone Like a Shadow" and "Be Merciful." He excelled also in the writing of services: outstanding is his Service in G. His *Venus and Adonis,* written between 1680 and 1685 for performance at court and called by him *A Masque for the Entertainment of the Kzng,* has an important place in the development of English opera. It is the first dramatic work in which the whole text is set to music without either dialogue or extraneous musical entertainment. His songs for one, two, three and four voices, which appear in many contemporary collections, and also in his own *Amphion Anglicus* (1700), are notable for their charm of melody. Purcell's comment on him, that his "character is sufficiently known by his works. of which this very instance (the Gloria from his *Jubilate in C major*) is enough to recommend him as one of the greatest masters in the world," may be taken as the tribute of a grateful pupil rather than as a considered critical comment, but it reveals an appreciation of the debt he owed to Blow, which in itself would ensure his fame.

BIBLIOGRAPHY —Modern editions of Blow's works include the Oiseau Lyre editions of *Venus and Adonis* (1939), of *Six Songs,* ed by A Lewis (1938) and of two sonatas for two violins, viola da gamba and bass, ed by W. G. Whitaker (1936); *Harpsichord Pieces,* ed. by J. A Fuller Maitland (1921); *Awake, Awake My Lyre, Salvator mundi* and the 1684 *Ode for St Cecilia's Day,* ed by H Watkins Shaw (1949–50) and the Schott edition of the *Complete Organ Works* (1958). *See* also W H. Cummings, "Dr John Blow," in *Proceedings of the Musical Association,* vol xxxv (1909); H. Watkins Shaw, *Blow, Doctor of Music* (1937); E J Dent, *Foundations of English Opera* (1928); *E* H Fellowes, *English Cathedral Music* (1941). (B P.)

BLOWFLY, the common name for large flies of the family Calliphoridae; they are metallic blue, green or bronze in colour and very noisy in flight Their habits and life cycles are like those of the common house fly except that they breed chiefly in carrion and excrement. Several genera are important, among them *Calliphora,* called bluebottles, and *Lucilia,* green-bottle flies.

Although the larvae of blowflies feed on decaying meat, they sometimes infest open wounds; while they prevent infection (by cleaning away dead flesh), they mill also eat healthy tissue. *Lucilia sericata* and *L. cuprina* commonly infest sheep. The most dangerous species in America is *Callitroga hominivorax,* the larva of which, called screwworm, attacks livestock and other animals in the southern United States and tropical regions. Several species of *Calliphora* are the most serious offenders in Australia; sheep are frequently killed as a result of attack. *Chrysomya megacephala* is widely distributed in the Pacific, oriental and Australian regions, occurring in enormous numbers, breeding in decaying vegetation, manure, human excrement and carcasses. It is a most important vector of dysentery and probably of jaundice and anthrax. Treating latrines with sodium arsenite, garbage disposal, use of screens and baited flytraps are employed in control.



FROM CURRAN, "INSECTS OF THE PACIFIC WORLD" (THE MACMILLAN CO.)

CHRYSOMYA MEGACEPHALA, A DANGEROUS CARRIER OF DYSENTERY IN THE PACIFIC AREA

Species of *Protocalliphora,* small bluebottle or green-bottles, attack nestling birds, particularly the American robin and bluebird; the larvae live in the nests and suck blood, often being so numerous as to kill the nestlings. The cluster fly. *Pollenia rudis,* of Europe and North America, is a parasite of earthworms; the adults often enter houses to hibernate within the walls or in attics and on warm days may cause a loud buzzing sound; they return outdoors in spring. (For the plant bluebottle *see* CORNFLOWER.)

The closely related flesh flies *(Sarcophaga)* have black and gray stripes on the thorax and a checkered abdomen. They mostly deposit living maggots on dead animals but also may infest wounds. *See* FLESH FLY.

BLOWGUN (sometimes called BLOWPIPE) is a hunting weapon made of a wooden tube 7 to 16 ft. long through which is blown a small dart by means of a sudden puff of breath at the mouthpiece of the tube. Blowguns were used by the aboriginal peoples of eastern South America, the Antilles, the southeastern United States and southeastern Asia.

Among the Indians of the tropical forests in South America the blowgun was usually 8 to 10 ft. long, but sometimes as much as 16 ft. It was made of suitable wood or cane and consisted of two complete tubes, one within the other or of an inner tube within a casing of two split halves or of a single tube composed of two halves.

Darts, usually of palmwood the thickness of a knitting needle, were 9 to 16 in. long and wrapped at their butt ends with a fluffy plant fibre to trap the blown air that propelled the dart through the tube. The sharpened points of these wooden darts were smeared with curare, a lethal poison. The darts were kept in quivers made of basketry or sections of bamboo.

In the South American forests and the Antilles the blowgun was used only for the hunting of birds and small tree-climbing animals. It had an effective range to 120 ft. and mas noiseless enough to allow the hunter to kill a number of animals in one small area.

The blowgun of southeastern Asia was a wooden tube about seven feet long with a bore of about one-third of an inch and an external diameter diminishing from about one inch at the mouth to three-quarters at the outer end. The tube was made of a light rigid wood found commonly throughout Borneo and Malaya. A piece free from knots having been selected, it was roughly shaped, then bored with an iron rod, eight feet long, having a cutting edge at one end. From 8 to 10 hours were necessary to bore through the pole. Although the sharpened iron rod did fine work, the inside was polished with a rattan. When the bore was satisfactory, the outside was whittled away to the required size and smoothness.

The darts were made of splinters of palmwood eight to ten inches long, sharpened at one end. At the butt was a cone of soft pith, having the same size bore as the blowgun. The pointed end of the dart was smeared with a poison that was either *Strychnos* or *Antiaris.* Small baked clay pellets were sometimes used in marginal areas.

Except in the southeastern United States where it was unimportant, the blowgun depended upon the use of poison for its effectiveness. It seems moreover to have been limited in use to tropical forest regions where birds and small arboreal animals are abundant. (G. I. QY.)

BLOY, LÉON HENRI MARIE (1846–1917), French Catholic writer who preached the virtues of poverty and suffering. Born in Périgueux (Dordogne), July 11, 1846, he worked as a railway clerk and fought in the Franco-German War (1870–71), becoming a fervent Catholic after meeting Barbey d'Aurevilly (*q.v.*). The only masters he acknowledged besides Barbey (his most constant friend) and Villiers de L'Isle-Adam (also a friend), were Ernest Hello and Thomas Carlyle, whom he called his "cousin german, in literature." He described himself as "a very humble, artless clamourer," not to be judged "from any human point of view," because he was "writing for God only." An apocalyptic Catholic, he declared in his last years that he was only awaiting

"the advent of the Cossacks and the Holy Ghost." Although he was a visionary rather than a true mystic, his savage onslaught upon the lukewarm Christians whom he "vomited" resulted in the conversions of Huysmans (*q.v.*) and Jacques Maritain. The source of his undeniable power lies in his style, coarse and filthily abusive when he was inveighing against Ferdinand Brunetibre and Paul Bourget *(Les dernibres Colonnes de l'eglise, 1903)* but hauntingly beautiful when he expressed his thirst for justice and his faith in the redeeming virtue of suffering. The outstanding works of this "entrepreneur de démolitions," as he called himself, are his autobiographical novels, *Le Désespéré (1887)* and *La Femme pauvre (1897;* Eng. trans. *The Woman Who Was Poor,* 1939), and his *Journal* from *1892* to 1917, in eight books: *Le Mendiant ingrat* (1898), *Mon Journal (1904)*; *Quatre ans de captivité à Cochons-sur-Marne* (1906), *L'Invendable* (1909), *Le Vieux de la montagne* (1911), *Le Pèlerin de l'absolu* (1914), *Au Seuil de l'Apocalypse* (1916), *La Porte des humbles (1920).* He died at Bourg-la-Reine (Seine;), Nov. *3, 1917.*

See J. Bollery, *Lion Bloy,* 3 vol. (1947–54). (RE. L.)

BLÜCHER, GEBHARD LEBERECHT VON (1742–1819), Prussian field marshal famous as a commander during the Napoleonic wars, was born at Rostock, Mecklenburg-Schwerin, on Dec. *16, 1742.* His early career was unusual: against the wishes of his family he enlisted at the age of *14* in a Swedish cavalry regiment. His first campaign was against the Prussians who took him prisoner, but later he joined the Prussian army and served in the Seven Tears' War with the hussar regiment responsible for his capture. Disgruntled at being passed over for promotion he resigned and took up residence in Silesia, where he became a very successful farmer. On the accession of Frederick William II he returned to his regiment as a major and greatly distinguished himself in the campaign of 1793–94. In 1794 he was promoted to major general and was given a command on the lower Rhine. The years *1805–06* found him on active service again. After the Prussian defeat at Jena (Oct. *14, 1806)* Blucher commanded the rear guard with great courage and devotion. It was in these circumstances that he first met Scharnhorst and, although they were both forced to surrender at Rakau, near Liibeck, the meeting started one of those almost traditional German military partnerships, typified later by Nindenburg and Ludendorff, Mackensen and Seeckt and others.

Bliicher was described by a contemporary as a rough, ill-educated man, but endowed with common sense, fiery energy and indomitable courage. He was the first Prussian officer to appreciate the value, to a commander such as himself, of a highly trained chief of staff.

Soon after his capture at Rakau, Blucher was exchanged for the French marshal Victor. After the peace of Tilsit he was employed for a time in the war department and was subsequently given command in Pomerania; but Napoleon succeeded in getting him deprived of this appointment and he again went into retirement.

In *1813* war between France and Prussia broke out again and Blucher, although *71* years old, returned to the colours. He distinguished himself at Liitzen (May *2, 1813)* and was responsible for a heroic resistance at Bautzen (May *20, 1813*). Three months later, at Katzbach, lie decisively defeated the French under Marshal Macdonald, capturing *18,000* prisoners and more than *100* guns. For his part in the battle of Leipzig (Oct. *16–18,* 1813) he was made a field marshal.

Bliicher crossed the Rhine on Jan. *1, 1814,* and after much hard fighting entered Paris, with other victorious allied troops, on May *31, 1814.* Soon after he retired to his estates, but was soon back in service again on the news that Napoleon had escaped from Elba. He at once assumed command of the Prussian troops in Belgium and, together with Gneisenau his chief of staff, began coordinating the employment of his force with that of the British and allied forces under the duke of Wellington. At Ligny (June *16, 1815)* he was defeated by Napoleon; but, in order to ensure cooperation with Wellington later, he withdrew his army toward Wavre although by so doing he endangered his own communications. Blucher was in the thick of the fighting at Ligny and barely escaped with his life. His troops took no part in the early stages of the battle of Waterloo (June *18, 1815);* but, urged on by the veteran field marshal, they carried out an exhausting countermarch and appeared on the French right flank in the late afternoon, at a critical stage of the battfe. This, together with a general advance by the British, completed Napoleon's defeat. Blucher's cavalry continued the pursuit in the direction of Paris throughout the night. The allied powers heaped honours on him for his service in this, his last campaign, and his own sovereign named him prince of Wahlstadt. Blucher was a man uith little knowledge of the higher art and science of war and required a good chief of staff to guide him. On the battlefield his determination and personal courage and example was worth its weight in gold. He died at his chateau of Kriblowitz in Silesia on Sept. *12, 1819.*

See C A L Varnhagen von Ense, *Leben des Fürsten Blucher* **(1827)**; E **F.** Henderson, *Blücher and the Uprising of Prussia Against Napoleon,* **1806–15 (1911).** **(C. N. B.)**

BLUEBEARD, the villain of a story entitled *La Barbe bleue* and included in the collection by Charles Perrault (*q.v.*), first printed in *1697* as *Contes de* ma *mkre l'Oye (Mother Goose's Tales).* The story has parallels in European, African and eastern folklore, but Perrault's version probably derived from Brittany, and it has been suggested that it was based on the career of Gilles de Rais (q v), or of Comorre the Cursed, a Breton chief of the 6th century.

In Perrault's story Bluebeard is a rich *seigneur* who, soon after his marriage, goes away, leaving his wife the keys to all the doors in his castle, but forbidding her to open one of them. She disobeys and finds in the locked room the bodies of his former wives. On his return, Bluebeard discovers on one of the keys a telltale spot of blood and threatens to cut off her head as a punishment for disobedience. She persuades him to delay and sends her sister to the top of a tower to look out for help: her pathetic question "Sister Anne, sister Anne, do you see anybody coming?" is perhaps the best remembered part of the story. Her brothers arrive in the nick of time and kill Bluebeard.

The essentials of the story in folklore are the locked room, the curiosity which tempts the wife to her fate and the 11th-hour rescue. Bluebeard is a typical "folk villain" in his strength and repulsiveness, his wealth and power and his barbaric cruelty. .In an Estonian version he is credited with having already killed *11* wives, and the 12th is rescued by a gooseherd (or sometimes a page), a friend of her childhood, who kills her husband and marries her. In a legend included in Grimm's *Hausmärchen* three sisters are the intended victims, the first two being rescued by the third, nho in turn is rescued by her brothers. Perrault does not give the number of Bluebeard's former wives and sister Anne is not herself an intended victim. The identification in some stories of Bluebeard with the devil and of the locked door as the gate of hell are probably later additions.

See Andrew Lang's edition of Perrault's *Contes* **(1887)** for a close comparison with other folktales and details of the careers of Gilles de Rais and Comorre.

BLUEBELL, a descriptive name for several unrelated plants, based on the bell-like shape of the flowers. The wild hyacinth (*Scilla nonscripta*) of England, and the harebell of Scotland, the United States and Canada commonly receive this designation. In the United States the Virginia cowslip (*Mertensia virginica*) and the bellflower *(Campanula rotundifolia)* are called bluebell; on the Pacific coast various species of *Phacelia* plants of the waterleaf family [Hydrophyllaceae) are known as the California bluebell. See CAMPANULA; GRAPE HYACINTH; HAREBELL; HYACINTH; VIRGINIA COWSLIP.

BLUEBERRY *(Vaccinium),* the name given in North America to certain shrubs of the heath family, Ericaceae (*q.v.*), prized for their sweet, edible fruits. The British species of the genus are called bilberries and bear their fruit singly, in contrast to the many-fruited clusters of the American blueberries.

The most important North American forms are: *(1)* two high-bush or swamp blueberries of the north *(V. australe* and *V. corymbosum), 4* to *12* ft. high, native to moist soils from Maine, Quebec and Michigan south to southern Georgia, the fruit blue with a thirk bloom; (2) the rabbit-eye high-bush blueberry of the south

ROCHE

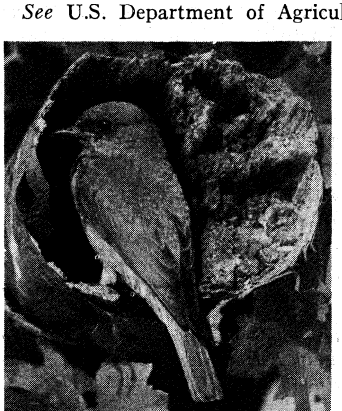
HIGH-BUSH OR SWAMP BLUEBERRY (VACCINIUM CORYMBOSUM)

(V. ashei), mostly 8 to 16 ft. high, found in swamps and pine barrens in southern Georgia and Alabama and northern Florida, the fruit black, rarely blue; (3) the low-bush blueberry (V. *lamarckii*), 1 to 2 ft. high, supplying the bulk of the canned blueberries, abundant on barrens, heaths and mountain lands from Newfoundland to Saskatchewan and south in the mountains to Virginia, the fruit blue usually with a bloom; (4) the Canadian blueberry (*V. myrtilloides*), similar in size and range to *V.* lamarckii but with more acid and later fruits; (5) two dry-land lorn,-bush species (I·. *pallidum* and *V.* vacillans), 1 to 3 ft. high, of sandy or rocky places from Maine to Wisconsin and south to Georgia and Kansas, the fruit blue with a heavy bloom (part and possibly most of the berries gathered are from tetraploid forms known as *V.* altomontanum); (6) the evergreen blueberry (V. *ovatum*), 6 to 20 ft. high, near the coast from central California to British Columbia, the fruit black or slightly blue, of value also for its long-keeping foliage, called evergreen huckleberry; and (7) the mountain blueberry or bilberry (*V. membranaceum*), 3 to 6 ft. high, in the Sierra and Cascade mountains, especially from northern Oregon to British Columbia, the fruit deep maroon to black, borne singly in the leaf axils, a very drought-resistant species. All the above species, and to a lesser extent other species, are gathered in large quantities in the wild.

Blueberries grow only in very acid (pH 4 to 5), well-drained but moist soils. About 20.000 ac. of the high-bush blueberry (V. *australe*) are cultivated in New Jersey. southwestern Michigan and eastern North Carolina and to a slight extent elsewhere. One selected native variety and many from breeding work are raised; the largest bear fruits about seven-eighths inch in diameter Recommended varieties are, in order of season, Earliblue. Blueray, Bluecrop, Berkeley, Herbert and Coville for Maryland and north, and Angola. Wolcott, Croatan and Murphy in North Carolina. The most highly flavoured varieties are Blueray, Herbert and Coville. Propagation is by hardwood cuttings. Plantings are usually set five by eight feet in the fall or early spring. Superior varieties of the rabbit-eye are Callaway, Coastal, Homebell, Tifblue, Garden Blue and Menditoo. They are hardy from eastern North Carolina to southern Arkansas. Propagation is by softwood cuttings. Plantings are usually set 10 by 15 ft. during the winter. The fruit begins to ripen about a month later than the New Jersey type and ripens over a period of four to six weeks.

Blueberries are seriously damaged by the "stunt" virus disease, canker, leaf spots and a rust disease. A bud mite, stem borers and fruit worms are serious pests. See also BILBERRY; VACCINIUM.

See U.S. Department of Agriculture, *Farmers'* Bulletin *1951* (rev. 1957). (G. M. D)



ESTHER HEACOCK FROM NATIONAL AUDUBON SOCIETY

BLUEBIRD (SIALIA SIALIS) AT NEST IN HOLLOW STUMP

BLUEBIRD, a North American thrush of the genus Sialia, with much blue in the plumage of the male. There are three species, all about seven inches long and all living in thinly wooded areas. They feed on insects that they catch on the wing or drop down to the ground to seize, and on fruit in season; the femalelays about five pale-blue eggs in a hole in a tree. in a crevice about a cliff or building, or in a nest box.

The eastern bluebird (*Sialia* sialis). which inhabits the eastern part of the North American continent, is migratory in the north. Its very early spring arrival, liquid notes, plaintive song, beautiful bright blue upperparts, reddish-brown breast and gentle appearance have endeared it to many persons. It often lives in orchards. and will nest in bird boxes with entrances 1½ inches in diameter.

The western bluebird (S. *mexicana occidentalis*) of the mountains from British Columbia to western Mexico is of a deeper blue, and has a reddish-brown breast and back. The mountain bluebird (S curroides) of the western part of the continent has a pale-blue breast and upperparts and is a remarkably silent bird. (A. L. RD.)

BLUEBONNET (*Lupinus* subcarnosus), a North American plant of the pea or pulse family (Leguminosae; *q.v.*), native to the plains of Texas. It grows about a foot high, has silky haired leaves composed of five leaflets and bears handsome clusters of purplish-blue flowers, marked in the centre with uhite or yellow. As early as March the plant in bloom covers immense areas in southern- and western Texas with a blue carpet. The bluebonnet is one of the most popular wild flowers of the southwest and has been adopted as the state flower of Texas. In Scotland the name is given to the bluebottle (Centaurea *cyanus*) and also to the blue scabious or devil's-bit (Succisa *pratensis*). See LUPINE.

BLUEFIELD, a city of Mercer county, W.Va., U.S., in the Appalachian mountains is the southernmost city in West Virginia, and at an elevation of 2,558 ft. the highest city of the United States east of Denver, Colo. Bluefield, and its companion city, Bluefield, Va., were named for fields of blue floners that grew there.

Bluefield, W.Va., was incorporated in 1889 when the Norfolk and Western railway established yards, shops and a division point there. The city adopted a council-manager form of government in 1921. The name of Graham, Va., a suburb of Bluefield in Tazewell county (founded in 1880), was changed to Bluefield in 1924. They make one continuous city. Bluefield is the outlet for the nearby coal fields. The annual Southern Appalachian Industrial exhibit or "coal show," held each spring in Bluefield, is the only display of its kind in the United States.

Bluefield State college, founded in 1895, enrolls about 500 students annually. Across the state line in Bluefield, Va , Bluefield college (Baptist), a junior college founded in 1920, enrolls about 300 students.

For comparative population figures see table in WEST VIRGINIA: *Population.* (K. K. McC.)

BLUEFISH (*Pomatomus* saltatrix), a relative of the sea basses (Serranidae), lives in the tropical or temperate oceanic waters away from the coasts. It is the only member of the family Pomatomidae. Bluefish congregate in large schools and consume or kill large numbers of small fish. They grow to about four feet in length; the larger individuals, which may weigh over 20 lb., are commonest in the Atlantic ocean off Africa. They are a prized game fish and are also caught commercially for food. Bluefish breed during the spring and summer. The young grow rapidly, attaining the length of about one foot when one year old. (C. HU.)

BLUEGRASS, a common name applied to about 200 species of Poa, most of which are found in the temperate regions. The exact origin of the name bluegrass is unknown, but it could refer either to the fact that bluegrass fields have a bluish cast when in flower, or to the bluish leaf colour of Canada bluegrass (*Poa compress~*). Kentucky bluegrass (Poa *pratensis*), also called June grass and smooth-stalked meadow grass, a valuable lawn and pasture grass in North America and Europe, is the most widely known species. Kentucky bluegrass is native to Eurasia.

It is a long-lived perennial characterized by a spreading growth habit and soft leaves with boat-shaped tips. The plants tolerate moderate drought, but will not thrive in the shade. Kentucky bluegrass grows best on heavy, well-drained, nonacid soils of good fertility. Applications of nitrogen and phosphorus improve sod formation and colour. It becomes established slowly from seed and hence fall seeding is recommended where practical. The seeding rate for lawns is about 3 lb. per 1,000 square feet. An imprpved lawn variety, Merion, is resistant to the destructive purple spot disease. Kentucky bluegrass lawns should not be

mowed closer than one and one-half inches.

Other important bluegrasses are: Canada bluegrass which competes with Kentucky bluegrass as a pasture grass on poor dry soils; the shade-tolerant rough bluegrass (Poa *trivialis*); the valuable range species, big bluegrass (Poa *ampla*); mutton grass (Poa *fendleriana*); and Texas bluegrass (Poa arachnifera). See also LAWNS, CAKE OF; GRASSES. (A. A. H.)

BLUE JAY: see JAY.

BLUE LAWS, in U.S. history, a term applied to a series of strict enactments ascribed to the New Haven Puritan government in the 17th century; some were enactments of other New England colonies, and some were pure invention. Among the 45 "blue laws" which the Rev. Samuel A. Peters listed in his General History of Connecticut (published in 1781) that were wholly or substantially true are the following: "The judges shall determine controversies without a jury"; "married persons must live together or be imprisoned"; "a wife shall be good evidence against her husband"; "no minister shall keep school"; "the selectmen, on finding children ignorant, may take them away from their parents and put them into better hands, at the expense of their parents." Among those in the same list which are wholly or in part spurious are: "No woman shall kiss her child on the Sabbath or fasting day," and "No one shall travel, cook victuals, make beds, sweep house, cut hair or shave on the Sabbath day." Examples of "blue laws" could be found in all the American colonies but they generally disappeared after the American Revolution.

BLUE MOUNTAINS, part of the eastern highlands of New South Wales, Austr., really a plateau falling from about 3,500 ft. in the west to about 1,200–1,800 ft. along the steep eastern scarp overlooking the Sydney lowland, about 40 mi. inland. Basically the plateau is formed of massively bedded Hawkesbury (Triassic) sandstones, interbedded with softer sandstones and shales, strikingly dissected by deep canyons. For 25 years it acted as a barrier to exploration inland, until in 1813 Gregory Blaxland penetrated it along the ridges. (See also AUSTRALIA, COMMONWEALTH OF. History.) (O. H. K. S.)

CITY OF BLUE MOUNTAINS, a local government area of New South Wales, comprises 22 townships. Pop. (1954) 23.089. The main tourist centres are Katoomba. Leura. Mount Victoria. Blackheath. Springwood, Wentworth falls and Hazelbrook, all of which lie on both the railway line and the Great Western highway betueen Sydney and Lithgow. The City of Blue Mountains, whose amenities include hotels, camping areas, scenic walks and golf courses, is visited by about 500,000 tourists annually. The highest point within the area is Mt. Boyce (3,576 ft.). (R. GA.)

BLUE MOUNTAINS, a range curving northeastward from central Oregon to southeastern Washington, U.S.. with a length of 190 mi. and up to 68 mi. wide. comprises an uplifted, warped and dissected lava plateau, above which rise several higher mountain ridges, including Aldrich, Strawberry and Elkhorn. Elevations range from 1,000 to over 10,000 ft. At lower elevations basins or flats—the Grande Ronde, Baker valley and many others—are cultivated, some with irrigation. Lava flows cover much of the region but erosion has exposed older and harder rocks. Mining of gold, copper, chrome and other metals, formerly important, declined. Rainfall varies from 10 in. (in the west) to 40 in. (in the north), and the natural vegetation, includes grass used for grazing, pine and Douglas fir for timber and brush land. Much of the forest is stunted and noncommercial. The region is drained by tributaries of the Columbia river, the Deschutes and the John Day in the west, and the Grande Ronde on the northeast. (S. N. D.)

BLUE NILE PROVINCE (AN NĪL AL AZRAQ), a province of the Republic of Sudan, lies on the country's eastern border with Ethiopia in part between the Blue and the White Niles. Area (54,879 sq.mi.) is comprised mostly of black clay ("cotton soil") plains which are a quagmire in the rainy season and crack in the dry. The average altitude is 1,300 ft., sloping gently from the Blue to the White Nile. Outcrops of basement complex form isolated groups of hills stretching north-northwest from Kurmuk in the southeast. Most major streams rise outside the region because of the low rainfall, absorbent clays and the level topography. West of the White Nile and occasionally near its eastern bank are found *qoz* (mainly fixed sand dunes). Along the rivers and the stream beds are alluvial silts and sands. The unreliability of the rainfall, which comes from the southwest monsoon, is an agricultural hazard throughout the province. In the north the annual average is below 10 in., falling in three months (July–September); southward the season lengthens to eight months (April–November), and near the Ethiopian border the fall exceeds 40 in. This variation affects temperatures: in the north the coolest period is January (mean 75° F.) and the hottest May–June (93°); closer to the equator the coolest period is August (76°) and the warmest April (88°), with a subsidiary warm season during October–November and a short cool season in January because of the northerly winds.

Vegetation follows the rainfall distribution; there is acacia desert scrub in the north and acacia tall grass forest in the south. In the centre there are gum gardens (Acacia *senegal* and Acacia seyal). Along the Ethiopian border is bamboo forest, and "goat desert" is found around large settlements. Wild animal life was much reduced in the 20th century by the spread of settlements, but there is the Dinder game reserve. Crops are frequently damaged by birds and locusts.

Population.—The province was enlarged in 1939 by inclusion of the former Fung and White Nile provinces and its present boundaries were determined in 1951. Its population at the 1955–56 census was 2,069,646. Principal towns are Wad Medani (47,677) the provincial capital, Kosti (22,688), Ed Dueim (12,319), Singa, Rufa'a. Sennar, Tendelti. Es Suki, Hasaheisa, Er Roseires (a railway terminal) and Kurmuk, the administrative centre for the south Nearly three-quarters of the inhabitants are Arabs and more than 85% speak Arabic as their first language. Nail-Arabs include Nilotics in the south, and west Sudanese and west African tribes elsewhere. Of the total population 93% are settled and 7% truly nomadic. Settlements concentrate along rivers and around hillfoot water points. There is some seasonal migration to and away from the Niles.

The Economy.—The gainfully employed are engaged in farming (86%) and stockbreeding (10%). Crops are mainly subsistence; cash crops are of greater significance in the north and on irrigated land. The staple food crop is durra (sorghum millets), and on unirrigated land in the north precarious farming is based on this quick-maturing crop. Southward crops become more varied, with two durra harvests (quick and slow-maturing), sesame on clays and peanuts on sands. Large-scale mechanized agriculture has been started. Irrigation is mainly along the Niles, the largest scheme being served by gravity from the Sennar dam. There was expansion after 1946 of pump schemes for cotton, with durra and lubia (Dolichos *lablab*), a bean fodder, as subsidiary crops. Some government controlled schemes were financed out of compensation from Egypt for Sudanese affected by the Jebel Aulia dam, which stores water for Egyptian use. Small pumps, shadoofs and Persian wheels irrigate fruit and vegetables. Maize (corn), vegetables and watermelons grow on the *gerf* (land uncovered as the floods recede). The province provides about 85% of Sudan's long staple cotton exports and 17% of gum. Pastoralism is an important subsidiary occupation, with cattle, sheep and goats, and some camels; the largest owners are nomads. There is fishing on the river banks. Gold was formerly of importance along the Ethiopian border. Industries include cotton ginning, brickmaking and local crafts.

Sennar is a railway centre with connections to Khartoum, Nyala, Er Roseires and Port Sudan. Roads are closed during the rainy season. Regular steamer services on the White Nile are centred on Kosti; the Blue Nile is rarely used.

BLUEPRINT, the popular name applied to both the blueprint and whiteprint methods for copying drawings, letters and similar material by exposing sensitized paper to light.

The blueprint method, used principally for copying house plans

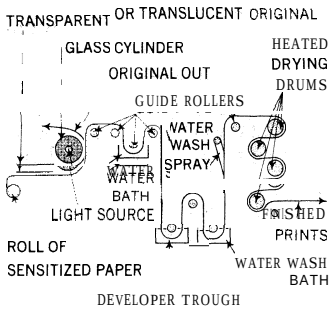
and other drawings, employs paper sensitized with a mixture of ferric ammonium citrate and potassium ferricyanide and produces a blue-coloured print that actually is a negative since the darks and the whites of the original are reversed on the blueprint.

The whiteprint method uses paper sensitized with diazo compounds (*q.v.*) that form a dye when exposed to light. A diazo compound is a complex chemical whose identifying unit is a carbon atom attached to two nitrogen atoms. The whiteprint process, widely employed in the early 1960s in office copying machines, produces a positive print of the original, that is, the darks and whites of the original appear as darks and whites on the whiteprint.

Since they differ in the type of print produced and in other technical aspects, despite being based on the same photoprinting principles, the two methods are discussed separately below.

Blueprints. — The blueprint method was originated by Sir John Herschel in 1842. The method was used first for printing photographic negatives but later came to be used chiefly for making copies of drawings. Cheapness of materials, permanence of prints and simplicity of method are advantages of the blueprint process. In making blueprints, the drawing to be copied, which is made on translucent tracing cloth or paper, is placed in contact with the sensitized paper and exposed to light. After exposure the sensitized paper is removed and washed in clean water, producing a clear negative print with the dark lines of the drawing appearing as white lines on a background of prussian blue.

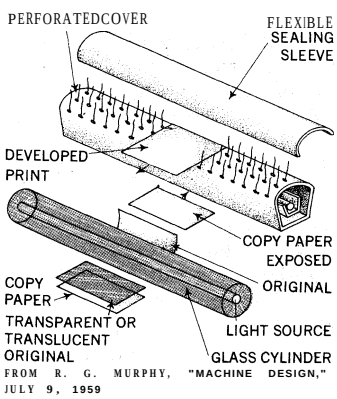
In the early days of blueprinting, prints were produced individually in frames by exposure to sunlight. Coating the paper and exposing and developing the print were all done by hand until a machine was developed that combined all these operations. In the machine, a continuous strip of sensitized paper (see fig. 1) passes around a rotating glass drum carrying the drawing on its surface and a light source in its interior. After exposure the print is separated from the drawing and then moved through a water bath, a developing bath of potassium dichromate (to improve contrast between white lines and blue background), another water bath and then over drying drums. The finished print is then trimmed off the continuous roll.



FROM R. G. MURPHY, "MACHINE DESIGN," JULY 9, 1959

FIG. 1.—SCHEMATIC DIAGRAM OF PROCESS FOR MAKING BLUEPRINTS WITH A CONTINUOUS ROLL MACHINE

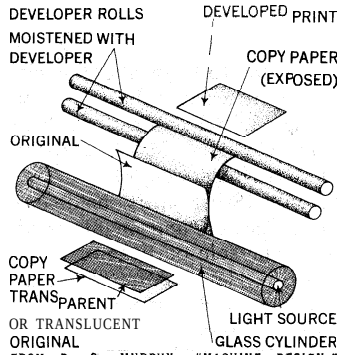
Whiteprints.—The whiteprint method, developed in 1917 by Gustav Kogel. employs either a dry or semimoist technique. In both, the print produced is an exact copy of the original and the chemistry is based on a diazo compound. In addition to a light-sensitive diazo compound, each technique uses a coupler that forms the colour, an acid that prevents coupling of the diazo and coupler before development, and an alkaline agent that combines the diazo compound and coupler to form the image. By changing the coupler, the colour of the print is changed. Materials used in both processes are fundamentally the same; the only differences are in the materials used for coating the paper and the method for developing the print.



FROM R. G. MURPHY, "MACHINE DESIGN," JULY 9, 1959

FIG. 2.—SCHEMATIC DIAGRAM OF DRY PROCESS OF WHITEPRINTING

In the dry (or ammonia) process (see fig. 2) the paper or other material used for printing is sensitized by a coating of diazo compound, coupler and acid. After exposure the print is developed in ammonia vapours; the ammonia neutralizes the acid and permits the diazo compound and coupler to unite and form the azo dye that produces the image. Prints are delivered dry immediately after development.



FROM R. G. MURPHY, "MACHINE DESIGN," JULY 9, 1959

FIG. 3.—SCHEMATIC DIAGRAM OF SEMIMOIST PROCESS OF WHITEPRINTING

In the semimoist process (*see* fig. 3) the material. used is sensitized with the diazo compound and acid. After exposure the print is developed by running it between two rollers that apply a thin film of developer, which consists of the coupler and alkaline agent. Wetting the exposed print with this solution causes the diazo compound and coupler to unite and form the azo dye that produces the image. After developing, the print passes over a drying drum.

In both the dry and semimoist processes, the print is exposed by placing the sensitized material in contact with the original as the latter moves around a glass drum containing the light source. After exposure. the original is separated from the print and removed. The exposed copy is then moved through the developer section, over a heated section and out either the front or back of the machine.

In the original whiteprint process, the print was exposed in one machine and developed in another. The two steps later mere combined in one machine, and by the early 1960s the whiteprint process was more widely used than was blueprinting.

BLUE RIDGE, a range of mountains in southeastern U.S., the southwesternmost portion of the older Appalachian mountains (*q.v.*). The Blue Ridge is a relatively narrow ridge, 5 to 65 mi. wide and 615 mi. long., extending from Carlisle, Pa., through parts of Maryland, Virginia, North Carolina and South Carolina to Mt. Oglethorpe, Ga. Included in the Blue Ridge system are the Black mountains. with Mt. Mitchell (6,684 ft.), the highest peak east of the Mississippi river; the Great Smoky mountains; and the Unaka mountains. Geologically the Blue Ridge is composed principally of ancient Pre-Cambrian metamorphic rocks strongly folded, occasionally faulted, and containing igneous materials of more recent age. The whole region has been subjected to intricate dissection by numerous small streams. On the eastern front range, commonly referred to as the Blue Ridge. the altitude is between 2,000 and 4,000 ft. Several peaks are included in this section: Mt. Rogers (5,720 ft.), highest peak in Virginia; Sassafras mountain (3.560 ft.), highest peak in South Carolina; Brasstown Bald (4,784 ft.). highest peak in Georgia. Others are Stony Man (4,010 ft.) and Hawks Bill (4.049 ft.) in Virginia and Grandfather mountain (5,939 ft.) in North Carolina. Three major rivers have cut gaps through the ridge—the Roanoke, James and Potomac, all in Virginia. The Skyline Drive highway begins south of Front Royal, Va., and runs 97 mi. through the Shenandoah National park (*q.v.*). The drive connects with Blue Ridge parkway at Rockfish Gap in Virginia and runs south to the Great Smoky Mountains National park (*q.v.*). The famous Appalachian trail (for hikers) follows the crest of the Blue Ridge range from Mt. Oglethorpe, Ga., into Pennsylvania. Over 700 varieties of trees and plants have been catalogued, including azaleas, rhododendrons, mountain laurel and galax. Long noted for its isolation. the region in the 1960s still contained numerous small farms with picturesque log cabins. Intensive truck farming, tobacco production and cattle raising are important farm activities. The main nonfarm resource of the region is its hardwood forests; some minerals are available.

(M. C. P.)

BLUE SKY LAW, a term popularly applied in the United States to statutes and regulations enacted in almost all the states

to protect purchasers of stocks and bonds from fraud. See SECURITIES REGULATION.

BLUESTOCKING, a word which came to be used derisively to describe a woman who affects literary or learned interests. It derives from the name given to the group of English literary ladies, including Mrs. Elizabeth Montagu, Mrs. Chapone, Mrs. Elizabeth Carter (*qq.v.*), Mrs. Vesey, Mrs. Ord, Mrs. Boscawen. Mrs. Crewe and Miss Mary Monckton, who, in the mid 18th-century, held *conversaziones* to which they invited men of letters and members of the aristocracy with literary interests. The sole purpose of these parties, according to Hannah More (*q.v.*), whose poem "The Bas Bleu, or Conversation" provides valuable inside evidence about them, was conversation, and they were a deliberate attempt to replace card playing by something more rational. The origin of the term bluestocking, or bas *bleu,* is probably to be found in an anecdote told by Mme d'Arblay (Fanny Burney; *q.v.*), perhaps the most famous "bluestocking." Mrs. Vesey had asked the learned Benjamin Stillingfleet to one of her parties, and he declined because he lacked appropriate dress for the evening. She persuaded him by telling him to come "in his blue stockings"—the ordinary worsted stockings he was wearing at the time. He did so, and Bluestocking (or Bas *bleu*) society became a nickname for the group, which was never a society in the formal sense.

According to Mme d'Arblay, the first party was given by Mrs. Vesey at Bath, but when she moved to London a rivalry developed with Mrs. Montagu, who became the leader. Among frequent attenders at the parties were Dr. Johnson, Garrick, the earl of Bath, Mrs. Delaney, Mrs. Thrale, Lord Lyttleton, Horace Walpole (who called them "petticoteries"), William Mason and Sir William and Sir Lucas Pepys.

See W. S. Scott, *The Bluestocking Ladies* (1947); and, for contemporary references, the bibliographies to the articles on the most notable members of the group.

BLUETHROAT, a bird, *Cyanosylvia* svecica, allied to the nightingale, but with a blue throat and a dark brown and chestnut tail. In habits it is shy and skulking; even its song, though musical, is weak. It haunts tangled hedges and thickets of birch and willow, especially when swampy, and nests close to the ground. Five to seven gray-green eggs, speckled with red-brown, are laid in early summer. The bird breeds in northern Europe and Asia, to the Arctic circle, migrating to Africa and India in minter. Two forms are common: the white-spotted bluethroat (C. s. *cyanecula*) of Scandinavian countries and the central European red-spotted bluethroat (C. *s.* svecica).

BLUETS (*Houstonia* caerulea), a popular North American wild flower of the madder family (Rubiaceae; *q.v.*), known also as innocence, eyebright and quaker-ladies. It is native to grassy places and wet rocks from Nova Scotia to Wisconsin and south to Georgia and Missouri. This early spring favourite, which grows perennially in matted tufts, with smooth stems three to seven inches high. is aptly described by Asa Gray as "a delicate little herb producing in spring a profusion of light blue flowers fading to white, with a yellowish eye." In the southern United States there are about 20 other species of *Houstonia,* some of which are known as bluets, as the thyme-leaved bluets (H. serpyllifolia), the least bluets (H. *minima*), the small bluets (H. patens) and the purple bluets or Venus-pride (H. purpurea) which grows 18 in. high. In Great Britain the bluebottle or cornflower (*q.v.; Centaurea cyanus*) is sometimes called bluet.

BLUM, LÉON (1872–1950). French politician, first Socialist premier of France, was born on April 9, 1872, at Paris, a member of an Alsatian Jewish family. Educated at the École Normale Supérieure, he proceeded to study law at the Sorbonne, graduating in 1894 with the highest honours, and thereafter he made his name as a brilliant literary and dramatic critic. The Dreyfus affair (see DREYFUS, ALFRED) brought him into active politics on the side of the republican Dreyfusards, and his close association with Jean Jaurès, whom he greatly admired, led to his joining the Socialist party in 1899.

Blum was first elected to the chamber of deputies in 1919. His first task was to reconstruct the Socialist party after the split of Dec. 1920, when the Communist section of it won a majority at the congress of Tours and so inherited the party machinery, funds and press. Blum ranks in history as the maker of the modern French Socialist party and of its chief journal, Le *Populaire.* He led the opposition to the governments of Alexandre Millerand and Raymond Poincaré and in 1924 supported Edouard Herriot's Cartel des Gauches (Radical coalition), though refusing to participate in the ministries of Herriot and Aristide Briand. In the elections of 1928 the Socialist party won 104 seats in the chamber. but Blum himself was defeated. A year later he was returned for Narbonne, which also returned him in 1932 and again in 1936.

After the riots in Paris in Feb. 1934 Blum worked for solidarity between Socialists, Radicals and all other opponents of fascism. These efforts contributed to the formation of the electoral alliance of the left known as the Front Populaire which, in the elections of April and May 1936, won a large majority in the chamber. Blurn, its chief architect, became premier as leader of the Popular front government of June 1936. He was the first Socialist and the first Jew to become premier of France. His government introduced, against considerable opposition, the 40-hour week; it nationalized the chief war industries and the Bank of France, and carried out a program of social reforms. Its most intractable problem was national defense against the growing power of the Rome-Berlin axis, and its policy of "nonintervention" in the Spanish civil war was denounced as appeasement. His social reforms aroused bitter hostility among French industrialists and financiers, who refused to co-operate with his government, and it nas at this time that sections of the right wing adopted the ominous slogan, "Better Hitler than Blum."

In June 1937 Blum resigned after the conservative majority in the senate refused to grant him emergency decree powers to tackle the country's financial difficulties. Modified Popular front governments were formed by Camille Chautemps, in which Blum served as vice-premier, and by Blum again in March 1938. He refused office under his successor, Edouard Daladier. In Oct. 1940, after the French collapse in World War II, Blum was indicted by the government of Vichy on charges of war guilt, and in Feb. 1942 nas brought to trial at the court of Riom. The powerful defense put up by Blum and the others accused so greatly discomfited the men of Vichy and so irritated the Germans that in April the hearings were suspended indefinitely, and Blum was returned to prison. He was freed by U.S. forces from a German concentration camp in May 1945.

After the liberation of France he emerged as one of France's leading veteran statesmen, and in the spring of 1946 he negotidted a U S credit to France of $1,370,000,000. In Dec. 1946 he formed a "caretaker government," the first all-Socialist French ministry, pending the election of the first president of the new fourth republic. Though the ministry lasted little more than a month, its vigorous policy left a deep impression on France Blum retired from public life in Jan. 1947, but served as vice-premier in André Marie's ministry of Aug. 1948. He died on March 30, 1950.

Blum's many writings include La *Réforme gouvernementale* (1936); *Souvenirs sur l'Affaire* (1935); *A l'échelle humaine* (1945), Eng. trans. by W. Pickles, For All Manktnd (1946).

See *L'Oeuvre de Léon Blum,* 2 vol. (1954–55); G Fraser and T. Natanson, *Lton Blum, Man and Statesman* (1937; 1938). (D. TN)

BLUMENBACH, JOHANN FRIEDRICH (1752–1840), German physiologist and comparative anatomist who proposed one of the earliest racial classifications, was born at Gotha on May 11, 1752. After studying medicine at Jena, he received a medical degree at Gottingen in 1775 and was appointed extraordinary professor of medicine there in 1776 and ordinary professor in 1778. He died at Gottingen on Jan. 22, 1840. He was the author of *Institutiones* Physiologicae (1787) and of a *Handbuch* der *vergleichenden* Anatomie und Physiologie (1824), but he is best known for his work in physical anthropology, of which he has been called the founder. He was the first to show the value of comparative anatomy in the study of man's history, and his craniometrical research led to his division of mankind into five great families—the Caucasian or white, the Mongolian or yellow, the Malayan or brown, the Ethiopian or black and the American or red. His most important anthropological work was his collec-

tion of 60 human crania of various physical types, described in his *Collectionis suae craniorum diversarum gentium illustratae decades* (1790–1828).

A selection of Blumenbach's writings is given in Earl W. Count (ed.), *This* Is *Race* (1950).

BLUNT, WILFRID SCAWEN (1840–1922), English poet whose impulsive, generous nature found expression also in anti-imperialism based on sympathy for small or oppressed nations. Born on Aug. 17, 1840. at Petworth house! Sussex, he was educated at Stonyhurst and Oscott, and entered the diplomatic service in 1858, serving successively at Athens, Madrid, Paris and Lisbon, and in South America. He retired on his marriage with Lady Anne Noel, daughter of the earl of Lovelace and a granddaughter of Byron. In 1872 he succeeded to the estate of Crabbet park, Sussex, where he established a famous stud for the breeding of Arab horses. With his wife he traveled frequently in northern Africa, Asia Minor and Arabia, two of their expeditions being described in Lady Anne's *Bedouin Tribes of the Euphrates* (2 vol., 1879) and *A Pilgrimage to Nejd* (2 vol., 1881).

Blunt became known as an ardent sympathizer with Muslim aspirations, and in *The Future of Islam* (1882) he directed attention to the forces which produced the movements of Pan-Islamism and Mahdism. He was a violent opponent of British policy in the Sudan. and in *The Wind and the Whirlwind* (in verse, 1883) prophesied its downfall. He supported the national party in Egypt, and took a prominent part in the defense of Arabi Pasha. *Ideas About India* (1885) was the result of two visits to that country, which, by rousing his sympathy for the poverty of the people, confirmed his distrust of colonialism as "exploitation." In 1885 and 1886 he stood unsuccessfully for parliament as a Home Ruler; and in 1887 he was arrested in Ireland while presiding over a political meeting in connection with the agitation on Lord Clanricarde's estate. and was imprisoned for two months in Kilmainham. His best-known volume of verse, *Love Sonnets of Proteus* (1880). reveals his real merits as an emotional poet. *The Poetry of Wilfrid Blunt* (1888), selected and edited by W. E. Henley and George Wyndham, includes these sonnets together with "Worth Forest, a Pastoral," "Griselda" (described as a "society novel in rhymed verse"), translations from the Arabic and poems which had appeared in other volumes. Blunt published a complete edition of his poetical works in 1914 and two volumes of *My Diaries* (1919 and 1920). He died at Newbuildings, Sussex, on Sept. 12, 1922.

See Edith Finch, *Wilfrid Scawen Blunt, 1840–1922* (1938); Lord Lytton, *W. S. Blunt* (1961).

BLUNTSCHLI, JOHANN KASPAR (1808–1881), Swiss writer on the laws of war. was born at Zurich, March 7, 1808. He studied law at Zurich, Berlin and Bonn (under Friedrich Karl von Savigny), became a professor at Zurich university and a member of the Great Council of Ziirich (1837–45). In 1848 he was appointed professor of German private and public law in Munich and in 1861 in Heidelberg.

His outstanding contribution, the *Lehre vom modernen Statt* (3 vol. 1875–76), was translated into French and English. Bluntschli is probably best remembered for his contributions to international lam-. *Das vzoderne Kriegsrecht* (1866), based on Francis Lieber's code, contributed to the eventual codification of the laws of war *(see* HAGUE CONFERENCES), and *Das moderne Völkerrecht* (1868), presented, in the form of a code, a deceptively complete system. Bluntschli, equally interested in codification and progressive development of international law to satisfy the growing needs of mankind. filled gaps in positive law without drawing a line between existing law and what the law ought to be. Immediately an outstanding success, this book, translated into many languages, became a reference work for diplomats. Bluntschli was cofounder of the Institute of International Law (1873) which has made substantial contributions to the development of international law. He died on Oct. 21, 1881, at Karlsruhe.

Of Bluntschli's numerous publications the following may be mentioned: *Allgemeines Staatsrecht* (1851–52); *Über die Communisten in der Schweiz* (1844); *Deutsches Staatswörterbuch* (co-editor; 11 vol. 1857–70); *Das Beuterecht im Krieg* (1878); *Privatrechtliches Gesetzbuch fur den Kanton Zurich* (4 vol., 1854–56); *Deutsches Privatrecht,* 2 vol. (1853–54).

BIBLIOGRAPHY.—Bluntschli, *Denkwürdiges aus meinem Leben,* 3 vol. (1884); F. von Holtzendorff, *Bluntschli und seine Verdienste um die Staatswissetzschaften* (1882); A. Rivier, *Revue de droit international,* 13:612 (1881). (L. Gs.)

BLY, NELLIE (pen name of ELIZABETH COCHRANE) (1867–1922). U.S. newspaper writer. whose around-the-norld race against a theoretical record made the name one of the most celebrated of the era, and a synonym for the feminine star reporter. She was born at Cochran's Mills, Pa.. on May 5, 1867, but after her father's death moved to Pittsburgh, where she obtained a job at the age of 18 as feature writer on the *Dispatch.* There she did a series of articles on such subjects as divorce. slum life and conditions in Mexico. She was employed by the *New York World* in 1887. Feigning insanity to get into the asylum on Blackwell's Island, she wrote an expose which brought about needed reforms. Later she exposed tenement conditions, "mashers' " methods, the Albany lobby, and the like. On Nov. 14, 1889, she sailed from New York to beat the record of Phileas Fogg. hero of Jules Verne's romance, *Around the World in Eighty Days.* The *World* built up the story by daily articles and a guessing contest in which whoever came nearest to naming Nellie's time in circling the globe would get a trip to Europe. There were nearly 1,000.000 entries in the contest. Nellie rode on ships and trains, in jinrickishas and sampans, on horses and burros. On the final lap of her journey the *World* brought her from San Francisco to New York by special train; she was greeted everywhere by brass bands. fireworks. etc. Her time was 72 days. 6 hours, 11 minutes and 14 seconds Miss Cochrane married millionaire Robert Seaman in 1895; but after his death and financial reverses she returned to newspaper work on the *New York Journal* in 1920. She died in New York city on Jan. 27, 1922.

See Mignon Rittenhouse, *The Amazing Nellie Bly* (1956). (F. L. MT.)

BLYTH, a municipal borough (1922) and seaport in the Blyth parliamentary division of Northumberland, England, at the mouth of the Blyth, 17 mi. N.N.E. of Newcastle by road. Pop. (1961) 35,933. The area around this short river that runs past tree-covered banks to a sandy shore has been occupied at least from Saxon times. The flourishing salt pans on the coast mere gradually displaced by sea trade in coal from the hinterland. About 6,000,-000 tons of coal are shipped yearly from the harbour which has ample quays, five dry docks and shipbuilding yards. Timber is largely imported; industries include ropemaking, electroplating and textiles. Blyth has also become a seaside resort along the grassy dunes south of the harbour. To the southwest is Seaton Delaval hall, designed by Sir John Vanbrugh in 1718.

B'NAI B'RITH ("Sons of the Covenant") is the oldest and largest Jewish service organization in the world, with men's lodges, women's chapters and youth chapters in countries all over the world.

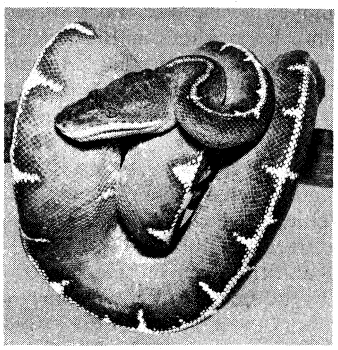
Founded in New York city in 1843. B'nai B'rith defends human rights; promotes intercultural relations; provides for the religious and cultural needs of Jewish college students; sponsors Jewish education among adults and youth groups; supports hospitals and philanthropic institutions; provides vocational guidance; sponsors welfare projects in Israel; assists victims of natural disasters; and carries on a broad program of community service and welfare, civil defense and service to veterans. It confers with government leaders on such issues as civil rights, immigration. abuses of freedom by totalitarian states. the position of Israel and problems affecting Jews throughout the world. B'nai B'rith is represented at the United Nations through its membership in the Coordinating Board of Jewish Organizations.

The order is headed by a president elected at triennial meetings of the supreme lodge (made up of representatives of district grand lodges), a board of governors and an administrative committee. (ME. B.)

BNEI BRAK (BNEI BRAQ), the modern Israeli name of the biblical Beneberak, a town allotted to the Israelite tribe of Dan (Josh. xix, 45). The ancient site has been identified as Arabic Al

Kheiriyeh (Ibn Ibraq), 5 mi. E. of Tel Aviv-Jaffa (Yafo), and the present town is north of the ancient site. Bnei-Brak appears among the captured cities of the Assyrian monarch Sennacherib who defeated Sidqia, king of Ascalon (Ashkelon) and suzerain of Banai-Barqa (*i.e.,* Bnei Brak), in his third campaign, 701 B.C. The name. which means "sons of lightning," is similar to an attested Canaanite (Ugaritic) personal name Bn brq. The Mishnah records a famous Passover seder at Bnei Brak wherein five rabbis expounded all night on the story of the exodus from Egypt. A modern village was established in 1924 by Polish immigrants. which quickly became an industrial centre of some importance. Pop. (1956 est.) 30,000. (J. S. I.)

BOA, the popular name of snakes of the subfamily Boinae of the family Boidae. All boas kill their prey by constriction, have no poison fangs, give birth to live young: have a vestigial pelvis and hind limbs that can be seen externally as small spurs on either side of the vent, have no teeth in the premaxillary bones and lack supraorbital bones. They range in length from 8 in. to 30 ft. The only larger snakes are the pythons of the related subfamily Pythoninae. A python (*q.v.*) closely resembles a boa, differing only by laying eggs and possessing supraorbital bones. The boas and pythons, since both have vestigial hind limbs, are believed to be the most primitive of living snakes.



ISABELLE H CONANT

EMERALD GREEN BOA (BOA CANINA)

Most boas are either terrestrial or arboreal and feed upon birds and mammals, killing them by constriction; the smaller species may hold their prey with the teeth and without constriction until it is swallowed. In colour, most boas show patterns of browns, tans and yellows arranged in rhombuses, diamonds, blotches and other disruptive figures that blend into the natural coloration of the habitat.

There are about 35 living species of boas, 32 of which occur in tropical America, nearby temperate regions and the West Indies. The largest new world boa is the anaconda (*q.v.*), which reaches a length of about 30 ft. The second largest is Constrictor constrictor, whose technical name once was Boa constrictor, a term now used popularly to describe any large constrictor snake; C. constrictor averages 11 ft. in length and ranges from near the U.S. border in Mexico to central Argentina and the West Indies. The rubber boa (*Charina* bottae), reaching 18 in., is found in the western U.S. and extreme southwestern Canada, and two species of *Lichanura* occur in southern California and Arizona and northwest Mexico. The last genus includes the California boa, which reaches 24 in. Other new world species include the rainbow boa (*Epicrates cenchris*), found from Costa Rica to Argentina; the Cuban ground boa *Tropidophis semicinctus;* the emerald green boa (Boa canina); and members of the dwarf genera *Ungaliophis* and *Trachyboa.*

Boas of the old world include the sand boas (Eryx) of the dry regions of central Asia, southeast Europe and northeast Africa; the Pacific boas (*Enygrus*), found from the Celebes through New Guinea to the Society Islands; and two genera in Madagascar.

See also SNAKES: Boidae. (A. SC.)

BOABDIL (ABU 'ABD ALLAH MOHAMMED XI) (d. 1527) ruled over Granada (*q.v.*) as the last Nasrid sultan during 1482–92. The son of Mulay Hasan, his succession was endangered by the rivalry between his mother, the sultana Aisha and the sultan's favourite Zoraida, a Christian captive. Proclaimed sultan by popular insurrection in 1482 in place of his father, he was taken prisoner by the Castilians at Lucena in 1483 and was released after secretly consenting to surrender Granada city upon demand to the Catholic sovereigns of Aragon and Castile, Ferdinand and Isabella. The next few years were spent in civil war with his father and his uncle, al-Zagal ("the valiant"), who had usurped the sultanate in Boabdil's absence. The Castilians profited from these diversions to capture the chief strongholds of their kingdom.

In 1491 Boabdil was summoned to fulfill his promise to the Catholic sovereigns, and on his refusal Granada was subjected to the celebrated siege. It fell on Jan. 2. 1492, and Boabdil left for lands he was allowed to hold in the Alpujarras district of southern Spain. He crossed to Africa in 1493 and is reported to have been killed in 1527 fighting for his kinsman, the Marinid ruler of Fez.

A romantic figure, Boabdil has survived in many local folk tales, such as those collected by Washington Irving in his *The Alhambra* (1832). The hill from which he looked for the last time on the palaces and pleasure-gardens of Granada is known as "the last sigh of the Moor." There his mother Aisha is said to have taunted his tears with the words "You do well to weep like a woman for what you could not defend like a man."

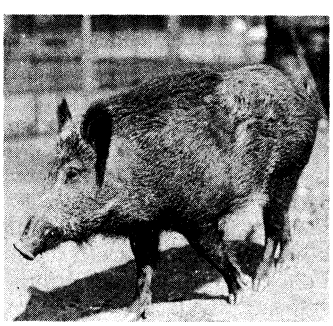
See W. H. Prescott, ***A History of*** *the Reign* ***of*** *Ferdinand and Isabella,* 8th ed. (1887). (K. GA.)

BOACO, a department in Nicaragua extending from the northern end of Lake Nicaragua eastward across the central highlands; and a town, capital of the department. Pop. (1959 est.) 59,353; area, 2,085 sq.mi. The population is concentrated in highland valleys in the western third of the department. Despite rather rugged relief, the department is important agriculturally, producing especially cattle, swine, hides and skins, dairy products, corn, beans, other vegetables and fruits. The town of Boaco, a very old settlement, is connected by a new road 38 mi. long with the Inter-American highway at San Benito, which is only 23 mi. from, Managua. (C. F. J.)

BOADICEA (properly BOUDICCA), a British queen who in A.D. 60 led a revolt against Roman rule. Her husband, Prasutagus, ruled the Iceni (in what is now Norfolk) as a client king under Roman suzerainty. On his death in A.D. 60 without male heir, he had left his private wealth to his two daughters and the emperor Nero, trusting so to win imperial protection for his family. Instead. his kingdom was annexed. his family humiliated and the chief tribesmen plundered. While the provincial governor Suetonius Paulinus was absent in north Wales and Anglesey in 60. Boudicca and her people rose, and with them the rest of East Anglia. They burned Colchester. Verulam, the mart of London, and several military posts, massacred (according to Tacitus) 70.000 Romans and friendly Britons and cut to pieces the 9th legion marching from Lincoln to the rescue. Paulinus, concentrating his army, met the Britons at a point thought to be near Fenny Stratford on Watling street. In a desperate battle Rome regained the province. Boudicca took poison or died of shock; thousands of Britons fell in the battle or were hunted down in the ensuing warfare.

In the end Rome adopted a milder policy, and Britain became peaceful. But the retarded development and modest character of Romano-British remains in Norfolk suggest the severity with which the Iceni were crushed. (I. A. RD.)

BOAR, generally speaking, the name given to the male of the domestic pig (*q.v.*) and to the males and females of some wild species of the family Suidae. The European wild boar refers to *Sus* scrofa, the largest of the wild pigs, distributed over Europe, northern Africa and central and northern Asia. Long extinct in the British Isles. it is still found in marshy woodland districts in Spain, Austria, the U.S.S.R. and Germany.



BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

EUROPEAN WILD BOAR (SUS SCROFA)

From the earliest times, because of its great strength, speed and ferocity when at bay, the boar has been one of the favourite beasts of the chase. In some parts of Europe and India the wild boar is still hunted with dogs, but the spear, except when used in emergencies and for giving the coup de *grâce,* has been replaced by the gun. The wild boar of India (S. *cristatus*) is slightly taller than *S. scrofa,* standing about 30 to 40 in. at the shoulder. It is found throughout India. Ceylon and Burma. There the horse and spear are used for hunting it (see PIG-STICKING).

The boar is one of the four heraldic beasts of the chase, and was the distinguishing mark of Richard III, king of England. As an article of food the boar's head was long considered a special delicacy.

BOARD GAMES are games of skill and chance played by two or more players with "men," or pieces, on a restricted field, or board. Man has been playing board games for thousands of years; the first "boards" no doubt consisted of lines drawn on the ground, the first pieces, stones, bones or shells. Ancient game boards have been found in Egyptian tombs and at Ur; a diagram for Nine Men's Morris (*q.v.*) was engraved on the steps of an ancient Cretan temple. An ivory and ebony veneer board with ivory pieces for an Egyptian game, "Hounds and Jackals," dates from the reign of Amenemhet III (*c.* 1842–1797 B.C.) in the 12th dynasty. The origins of the oldest games, such as backgammon and chess, are in doubt; all may have descended from a common, earlier ancestor. Primitive man may have evolved games from playing with materials at hand, or repeated magical rites, funeral games or military lessons. Board games imitate, symbolically, the activities of men—the battle, siege, hunt. race or territorial conquest. They undergo evolutionary development and the invention of variants, especially when rules are transmitted orally. The Japanese game of Go, for example, is quite different from its Chinese parent, wei-ch'i, and there are many variants of checkers (*q.v.*).

EGYPTIAN BOARD GAME "HOUNDS AND JACKALS," WITH IVORY AND EBONY VENEER BOARD AND IVORY PLAYING PIECES, 12TH DYNASTY

In the earliest board games moves were controlled by instruments of chance such as staves (sticks or straws), cowrie shells, knucklebones or early forms of dice: modern games use dice. cards or spinners. Proprietary board games have been known since the 18th century. Many modern proprietary games are built around popular television, literary or comic characters; favourite themes have been detecting, news reporting, treasure-hunting, quiz contests and travel. Two modern innovations in skill games have been Monopoly, a buying and selling game, and Scrabble, a combination of crossword puzzles and anagrams.

BOARDING-OUT SYSTEM, the placing of destitute children in families where they would be treated as members, evolved from the apprenticeship provisions of the early English and American poor laws into foster home programs for children in need of care outside their own homes. *See* CHILD WELFARE: *Children Away From Home: Foster Care.*

BOARD OF GUARDIANS: *see* POOR LAW.

BOARD OF TRADE, in Great Britain a department of the government (*see* GOVERNMENT DEPARTMENTS) and in the United States a term occasionally, and especially in earlier times, used as a synonym for chamber of commerce (*see* TRADE ORGANIZATION). The typical chamber of commerce consists of business and professional men of a city, state, country or other locality who have an interest in industrial development, legislation affecting business and the like, and are also concerned with charitable causes and general civic improvement. Board of Trade has another important meaning as the corporate name of an organized market for grain in the city of Chicago. Incorporated by an act of the legislature of Illinois in 1850, it is a self-governing exchange on which grain, grain futures and certain other commodities are traded.

See also COMMODITY MARKET. (FK. L. K.)

BOARD OF TRADE UNIT, the unit of energy adopted by the British Board of Trade. It is equal, in electrical units, to one kilowatt-hour. *See* PHYSICAL UNITS.

BOAS, FRANZ (1858–1942), one of the most influential of U.S. anthropologists, was a specialist in the cultures and languages of American Indians. Born July 9, 1858, at Minden, Westphalia, he studied physics and geography at Heidelberg and Bonn before receiving. his Ph.D. from the University df Kiel (1881). His interest in primitive culture was aroused by observations of the Eskimos made during a scientific expedition to Baffin Island (1883–84). In 1886 he made the first of many trips to the north Pacific coast to study the Kwakiutl and other tribes of British Columbia, on which he later specialized. In 1887, having become a permanent resident of the United States, he joined the staff of *Science* as editor. He began his academic career as instructor at Clark university, Worcester, Mass., in the following year. In 1896 he became instructor, and in 1899 professor of anthropology at Columbia university. During his long tenure at Columbia, where he remained for the rest of his life, Boas built up one of the foremost departments of anthropology in the United States and trained or influenced many notable ethnologists and linguists. He was largely responsible for encouraging women to enter the field of anthropology.

From 1901 to 1905 he was also curator of anthropology 'at the American Museum of Natural History; in that capacity he directed and edited the reports of the Jesup North Pacific expedition, the purpose of which was to investigate relationships between the aborigines of Siberia and North America.

Boas was an indefatigable field worker, collecting voluminous data on the languages, religion and material culture of North American tribes. His work was criticized for lacking integration, but his emphasis on facts rather than interpretation reflected a widespread reaction against the sweeping theories on cultural evolution in vogue during the 19th century. Boas also made important contributions to physical anthropology. After extensive metrical studies made on immigrants and their descendants, he demonstrated that head form is an adaptive trait subject to environmental influences—a conclusion significant for racial studies, and substantiated by later investigators.

Boas established the *International Journal of American Linguistics,* was one of the founders of the American Anthropological association, president (in 1931) of the American Association for the Advancement of Science, and a member of many other scientific societies in the U.S. and abroad. He died in New York city on Dec. 21, 1942.

Boas was a prolific though not always lucid writer. Among his more important books were *Race Language and Culture* (1940), a collection of writings including *Changes in Bodily Form of Descendants of Immigrants; The Mind of Primitive Man* (1938), a series of lectures on culture and race; *Primitive Art* (1928); and *Anthropology and Modern Life* (1929).

For an evaluation of his work and a complete bibliography *see* "Franz Boas, 1858–1942," *American Anthropological Association Memoir* no. 61 (July–Sept. 1943); Melville Herskovits, *Franz Boas* (1953), which includes a selected bibliography.

BOAT, a generic term for small craft propelled by paddles, oars, sail or motor, open or partially decked, and usually less than 45 ft. in length. A vessel larger than this customarily is classed as a ship (*q.v.*), although the word boat is often applied to certain working vessels; *e.g.,* tugboats, that may be of considerable size. This article deals principally with ancient and primitive boats and modern working boats of various types; the equipage of some of these craft is described in RIGGING and SAILS. For a description of modern pleasure boats, *see* the article BOATING. The highly specialized boats and landing craft used in military and naval operations are described in TRANSPORT, MILITARY. (*See* also FISHING VESSELS; LIFEBOAT AND LIFESAVING; YACHT.)

EVOLUTION OF THE BOAT

It is customary to assume that the boat developed from a floating log to a raft to a dugout canoe. Actually, the early forms of the boat were many, and their design and structure depended upon available material. Where suitable timber was at hand, the raft and later the dugout canoe developed. Where suitable timber was not available, reed rafts, skin-covered canoes and skin floats made by inflating the hides of small animals could be found. In some timbered areas bark canoes were used. It may be assumed

that the boat developed from the canoe forms; it is evident that boats did not appear until long after various forms of canoes came into being.

During the evolution of the dugout canoe the sides were raised by means of plank and this led to gradual reduction in size of the dugout portion until it became a mere keel piece, with the rest of the hull built of plank. However, there is reason to doubt that the development of the plank boat was confined to areas where dugout canoes were used. The bark canoe and the skin boat were employed in some timbered areas, and the rigid framing of the skin boat may have been adapted naturally to plank construction once the primitive builder found a way to produce planking. This possibility is supported by the fact that the longitudinal and transverse framing of most planked boats is basically the same as that employed in skin boats.

The development of primitive water craft of each of the basic forms was more rapid in some areas than in others because of varying needs for water transportation. A great many types of primitive craft survived into modern times and some are still in use. Many were of relatively large size and of excellent design for the tasks they had to perform.

Rafts and Dugouts.—The raft, made of timbers lashed or pegged together, was in some cases a mere float, heavy and awkward to propel. However. in a few instances. the raft was developed into an efficient sailing craft with a raised platform that enabled cargo to be carried and protected from water. Rafts made of bundles of reeds lashed together, given a somewhat pointed bow and rudimentary sides, were also used.

Dugouts range from simple, trough-shaped hulls to beautifully formed boats with the sides spread, after shaping, by warping with hot water. In another form, the dugout consists of a number of shaped logs fastened together to form a hull. A more common design einploys a main dugout hull with the sides raised by means of plank secured by pegs or by "sewing," done by passing lashings through holes along the seams of the planking. It is but a short step from the dugout with plank sides to a boat built solely of plank, using sewed fastenings. Seaed construction was extensively used in the South Pacific canoes. The ancient Egyptians built boats of short pieces of plank, laid up like bricks in a wall, but used edge-fastenings instead of serving the seams.

Bark and Skin Craft.—Bark canoes developed in a few areas, ranging in design from craft having only the most elementary framing to the highly developed birch bark canoes of the North American Indians. The birch bark canoes had a thin plank lining held against the inside of the bark cover by an extensive framing of ribs forced under the gunwale. So efficient were the Indian canoes that the white man copied them for wilderness travel.

Skin craft range from inflated skins, used singly or joined together in a raft, to framed hulls of good form and construction. In the latter there is a rigid frame composed of longitudinals and ribs secured by lashings or pegs, and the skins are stretched over the completed framework.

Plank Construction.—The lapstrake type of planking, in which each plank or strake overlaps slightly the one below it, can be seen in an elementary form in some dugouts with plank sides. In the primitive form the lap is sewed its full length. The lapstrake planking method appears to have reached its final form in northern Europe, where iron fastenings were used. As seen in the remains of ancient European craft, the seams were nailed at the laps but the planking was lashed to the ribs or frames. The use of metal fastenings throughout the hull did not become common, apparently. until about the 9th century in northern Europe.

Caravel planking has smooth seams, with the planks placed edge to edge and fastened only to the frames. This originated in the Mediterranean basin; possibly it evolved from the older edge-fastened plank construction of the Egyptians. However, it took its name from a class of ships built in Spain and Italy in the 14th and 15 centuries. Plank construction did not become common in Europe until metal fastenings were procurable, although pegged construction was probably used in an early stage of evolution.

The basic framework of planked boats of the conventional lapstrake or caravel forms is the same: a keel and transverse frames or ribs more or less evenly spaced along the length of the boat. At the gunwale or top edges of the planking there are longitudinals, and sometimes a little below the gunwale there are additional longitudinals to support the rowing seats or thwarts. In the early boats the frames were cut from "knees" or crooked timber, but early in the 19th century steam-bent frames came into use. One marked difference between lapstrake- and caravel-planked boats is that the former usually had ribs put in after the planking was complete uhereas the caravel boat was commonly planked over the ribs. Lapstrake boats do not have the seams caulked except along the keel. Moss was used to caulk the viking boats, while animal hair and textile materials were used in ancient Mediterranean boats. Tar was placed over the caulking to fill the seams. The lapstrake and caravel planking, combined with the basic framework, have been retained as conventional methods of boatbuilding.

Greek and Roman Boats.—Little is known of the boats of Rome and Greece, though more is known about the ships of these eras. No identified remains of Greek or Roman boats have been recovered, and the fragments of contemporary literature and art produce little more than some type names and the impression that some small boats were built with speed particularly in view. It is mere speculation to attempt to describe the individual types; apparently, many types first built as small boats became large, fast, rowing ships in a normal process of evolution. The mode of construction used by the Greeks and Romans appears to have been caravel plank and sawed or hewed frame construction of some kind, but the speed with which boats and ships were reportedly built suggests that some were flat-bottomed and developed from raft forms.

Modern Methods and Materials.—Canvas-covered hulls follow the general plan of birch bark canoe construction in that they have a plank lining supported by ribs. However, canvas boats have rigid framing systems. Canvas or other fabric over battens, following the basic arctic skin-boat construction, is used in small folding boats and in kayaks, which were inspired in design and construction by the Eskimo skin kayak or hunting boat.

Paper boats, made by cementing layers of paper over a hull-mold, have been built successfully, and at one time this construction was popular for small boats and canoes in America. These boats had simple framing and, being made with water-resistant adhesives, were strong and durable.

The use of veneer and plywood to build small craft developed very rapidly after 1920 in the United States. However, the use of plywood panels instead of planking not only required a complete framework but also limited the practical hull forms to V-bottom and flat-bottom types. Molded plywood, in which veneer sheets were laid up over a mold with adhesive between two or more plies or skins, was the next development. This type of construction proved strong and lasting, although the use of a mold and the need for pressure-setting of the adhesives limited the types of molded plywood boat to those that could be mass-produced.

A great many small craft are built wholly or in part of thermosetting plastics. A mold is required and there is usually a special textile employed to give strength to the hull skin. The usual method is to use layers of plastic over textile plies. Both hand-applied and mechanically-applied plastics are widely used, but the latter require a very expensive mold and manufacturing equipment. Metal or wooden stiffeners sometimes are used with the plastic shell, although all-plastic hulls are now quite common. Both molded plywood and plastic construction methods are best suited to mass-production building and therefore to small boats of the open or half-decked types.

EXISTING BOAT TYPES

Primitive Boats.—A number of ancient and primitive boat types have survived into the present century. The rafts still in use include the Brazilian jangada and the catamaran of Ceylon. The Brazilian and other sailing rafts have dagger boards or centreboards fitted between the two centre logs to allow windward sailing; they are fast sailers.

A large number of dugout canoe types have remained in use.

Some of these are merely trough-shaped hulls suitable only for protected waters, but others are well-developed craft. Until late in the 19th century the large single-log dugout canoes of the Northwest Coast Indians of North America were the best developed canoes of that type in existence. Multiple log canoes were used as sailing craft on Chesapeake bay in North America and large craft of a similar form and rig later developed under the type name bugeye. Large dugouts with built-up sides exist in the South Pacific and once were very numerous. The Pacific island canoes are commonly narrow and reqdire double hulls or outrigged floats on one or both sides for stability. One of the most notable of the single-outriggers is the flying proa, one of the fastest sailing boats in the world, first described by Capt. James Cook. The double-hulled craft are made of two canoes of equal size, placed side by side but at a short distance apart. These usually are used as sailing canoes and have come to be known as catamarans. The idea has been adapted by yachtsmen in the sailing catamaran or double-huller, ranked among the fastest sailing types known.

Skin boats have survived in the American arctic in various tribal forms of the kayak or hunting boat and in the larger and open umiak or "woman's boat." Other skin-covered craft, such as the English coracle for river fishing and the Irish curragh for sea fishing and transport, have continued in use for hundreds of years, although the modern versions have outer covers of canvas and tar instead of the original skins and tallow.

The birch bark canoe of the North American Indians could still be found in use into the early 20th century, but in most areas canvas had gradually taken the place of bark long before 1900. Primitive bark canoes are still used by aborigines in South America and Australia. however.

Sewed plank construction in the 20th century was 'mostly confined to some islands in the South Pacific. where basic dugouts were heightened by means of plank sides, and to some very limited areas uhere all-plank boats were built by this method. The basic advantages of sewed plank construction were utilized in a patented process, using copper or bronze wire, that was employed in England early in the 20th century for building high-speed motor boats.

National Boat Types.—The need for craft of the boat class in fisheries. pilotage, salvage and transport resulted in almost innumerable models, each designed for superior performance in a specific task arid to meet geographic and economic needs.

Far East.—In the China seas the sampan is the commonest boat type, although the hull form, rig and fittings vary widely. Some sampans have sharp bows; nearly all have large transom sterns, and the after portion of the gunwale is higher than the forward portion. Sampans are often rigged for sailing with a single battened Chinese lugsail. Usually the boats have only one mast, but there are local types, notably in Hong Kong, equipped with two. The sampan is sculled with a large sweep balanced on the transom stern. It is usually open or partially decked and has a shelter or cabin aft for passengers or freight. In Japanese waters another form of sampan once was common, rigged with a rather primitive lugsail and with a peculiar form: the stem was straight and raking in profile and the forebody long and rather sharp, while the midsection was flat-bottomed. This model later developed into a motor boat and came to be used not only in Japan but in Hawaii and Formosa.

In Malayan waters the proa is the basic boat type. It is a fast, sharp-ended, rowing and sailing boat once popular with the Malay pirates. The proa is open, long and rather narrow, with a "clipper" bow and a sharp stern. The boats are usually rigged with one or two lugsails somewhat like the Chinese lugsail. In early days the type was built more than 60 ft. in length and decked. The name proa is often applied both to this type and to the single-outrigger flying proa mentioned earlier. However, the proa of the Pacific and the Malay boats are entirely different types.

In Indian waters there are a number of boat types, including dugouts nith raised plank sides. sometimes fitted with outriggers, and plank boats with a long, straight, raking stem in profile, a transom stern and a short keel. The latter are usually rigged nith one mast and a settee sail: a lateen sail with the fore corner or tack cut off to form a short luff or fore edge. These boats vary locally in form and rig; one type has greater depth at the bow than at the stern and the keel profile is a hollow curve. This is the pattamar, rigged with two or three masts and considered a fast sailer.

Near East and Mediterranean.—In the Persian gulf and southward along the east African coast the best known boats are usually classed by Europeans as dhows. The two types so named are the bagala and sambuk. These have one or two settee sails, short keels, long and very raking curved stems, square sterns, and a well-formed hull for fast sailing.

The boats of the Mediterranean basin are numerous in type and rig. One is the handsome Turkish *caïque,* a long, narrow rowing boat with graceful ends. designed for speed. These boats sometimes are rigged for sailing with a small spritsail or lugsail and in modern versions are often fitted with an outboard motor in a well at the stern. Small double-ended boats are also used by the Turks; these are called sandals and are often rigged with a single lugsail. A square-stern sailing skiff of distinctive appearance is found on the Turkish Black sea coast; it resembles a coaster of larger size known as the taka. A distinctive double-ended beach boat, known as the cekterme, is also found on the Turkish coast, although this type name came to be more commonly applied to a large auxiliary coaster.

On the Nile may be found the dahabeah, a sailing lighter and houseboat. This boat developed from the Nile gaiassa, a lighter and river freighter with a shallow hull like that of a canal boat, a high, sheer bow and a huge outboard rudder. These boats usually have a large lateen sail forward and a small one aft, although some are fitted with only a single large sail. Another variation is the naggar, a sailing river lighter rigged with a single lugsail, with the boom along its foot parallel with its head.

The best known of Italian boats is the gondola of Venice, a double-ended craft, with ornamental posts at bow and stern, propelled by an oarsman using a single oar or sweep. A now obsolete Venetian boat was the topo. a double-ended, flat-bottomed craft with a single mast carrying a lugsail; it was the forerunner of the Venetian sandal. which is still in use.

The boomed standing lugsail was for a long time most common in the Adriatic, usually in a two-masted rig, while the lateen sail predominated in boats built in southern Italy, on the French Mediterranean coast and in Spain and Portugal. Among small craft of the Mediterranean, combination rowing and sailing boats were once typical, rather than boats built to sail only, but in modern times engines have almost completely replaced sail.

Many local types in the Mediterranean are loosely classed as feluccas, a term originally applied to two-masted lateen sail craft fitted to row and built for speed; later the name came to be applied also to three-masted craft of the galley type that had once been called xebecs.

Northern *Europe* and Great Britain.—The coast of Northern France was the home of a number of types of square-sterned and sharp-sterned lug-rigged boats, usually two-masters. These boats were commonly of lapstrake construction and were good sailers, many carrying large areas of sail. The three-masted lugger or *chasse-marée* of France and a similar type built in England were fast enough to become the traditional craft of Channel smugglers.

England and Scotland produced many distinctive small boats; the coble, a square-sterned beach boat with deep forefoot, still survives as a motor fishing boat, as does the caravel-built Thames bawley. An extinct beach boat is the Yarmouth beach yawl, a long, narrow, lapstrake double-ender with sharp ends. built for salvage work and rigged with two or three lugsails and a jib.

Another noted English type was the Deal galley punt, a square-sterned, lapstrake open boat rigged with a single dipping lugsail and once used for salvage and rescue work off the beach. The cat was a larger lugger of two or three masts used at Deal; both types were very seaworthy and mere fast sailers. Scotland produced many fine skiffs, the class name for a number of open or partly decked, lapstrake, one-masted, lug-rigged boats. The Lock Fyne skiff, the Fifie skiff, and the Scaffie and Zulu skiffs were fine examples of sailing and rowing fishing boats. The Shetland sexern was particularly fast and seaworthy; this type

was rigged with a single lugsail and its hull was low-sided and sharp-ended.

In the Netherlands and Belgium small boats fitted to sail had distinctive wing-shaped leeboards pivoted on each side at about amidships, to reduce leeway when sailing to windward. The boats were usually shallow in body and strongly built, with full, buoyant ends. Danish boats generally have sharper lines and deeper draft, and the smaller ones, commonly lapstrake built, sail and row well. The praam, a lapstrake boat with square stern and a small transom bow, is a popular Danish type; formerly a sailing and rowing boat, it came to be used extensively as a motor boat. The praam can also be found on the Norwegian coast.

The predominance of the double-ended, lapstrake hull in Scandinavia is very marked and some modern boats strongly resemble those of the vikings. Scandinavian small boats are usually fast rowing and sailing craft with bow and stern sharp and curved in profile.

North America.--Many small boat types developed in North America during the 19th century. In eastern Canada the Labrador whaler, a lapstrake, double-ended rowing and sailing boat used in the Labrador fisheries! became popular, and its design appears to have inspired the design of the Tancook whaler, a schooner-rigged centreboard fishing boat notable for its excellent handling qualities. Another boat developed in the maritime provinces was the Cape Island sloop, a deep draft keel sloop once popular in the shore fisheries. On the Great Lakes the Canadians produced a two-masted, half-decked, square-sterned fishing skiff, the Collingwood skiff. as well as a similar type in double-ended form. Perhaps the best known Canadian types are the lumberman's drive-boat or bateau, a double-ended, flat-bottomed rowing and poling boat used in the lumber drives when timber is floated downstream to the mills; and the York boat, a double-ended sailing and rowing boat used in the fur trade. The large birch bark *maitre canot* of the fur trade, an oversized version of the Indian canoe, used by the fur trade "brigade" or freighting party, also was once of economic importance.

The Cnited States and Canada both produce the dory, the flat-bottomed skiff of the New England and maritime provinces fisheries. Some dories are fitted with centreboards for sailing. Others were equipped with engines. and this led to the design of special types in which rounded side frames replaced the straight frames of the regular fishing dory, producing a hull with an almost round bottom and a wide plank keel. This form of hull was carried to its highest degree of evolution in the New Jersey Seabright skiff or beach skiff, in which the bottom is very narrow and the sides very round. Formerly a rowing and sailing beach boat, the Seabright skiff developed into a high speed, seaworthy motorboat once favoured by liquor smugglers and later used for sport fishing.

There have been more than 200 distinct types of small American sail and rowing boats under 40 ft. in length. Some of the more notable of these are the Hampton boat of New England, first a lapstrake sail and rowing boat like the Labrador whaler but later a square-sterned, two-masted, half-decked boat equipped with a centreboard. This design was found suitable for the installation of engines and was gradually modified into a fishing launch. The Block Island boat and No Man's Land boat were two-masted, double-ended beach boats notable for their seaworthiness. The New Haven sharpie was a large, two-masted, flat-bottomed boat, and its use spread southward to the Carolina sounds following the development of the oyster fisheries. Of a number of small sailing scows that also were employed in the U.S. fisheries, the New Jersey garvey is one of the better known. This type of sailing scow had one leeboard held to the side by a rack or iron bar-and-staple device and was usually rigged with one or two spritsails. It was used in the oyster and other inshore fisheries and in modern versions has been modified into a low-cost but efficient launch.

Another boat that has been adapted for use with engines is the New Orleans lugger. Originally a single-masted, square-sterned boat with a centreboard, the only lugger-rigged boat in the American fisheries, it was a fast sailer. and its good handling qualities made it ideal for use as a power boat. The San Francisco felucca, a single-masted, lateen-rigged fishing boat, also developed into a double-ended power craft now known as the Monterey boat.

The term pirogue is the old West Indies name for a dugout and was later applied to scow ferries having leeboards and to a round-bottomed boat with a sharply raked foremast forward and a mainmast aft. These boats are obsolete, and the name is applied to a dugout or similar crude, shallow-draft boat used for negotiating swamplands and shallow inlets in Louisiana.

Ships' Boats.—The boats carried on shipboard for harbour transportation, rescue work, etc., constitute a special class. Usually they are open boats fitted to row, although some are sailboats and many modern types have engines.

The largest boat on shipboard is the launch or longboat, originally a burdensome sailing and rowing boat. capable of carrying such heavy loads as anchors and cannon. When steam engines became available the launch became a self-propelled boat and, in the present century, a motor boat. The cutter was a long, narrow boat especially designed for speed under either sail or oars; it usually was carried only by naval or revenue vessels. Another naval type was the gig, similar to the cutter but sharper in its lines, and usually reserved for the personal transport of high-ranking officers. Both the gig and cutter were designed with narrow transom sterns and some rocker or curvature in the keels.

The yawl or dinghy, sometimes called a stern-boat when it was slung from davits at the stem of the ship, was a short, square-sterned rowing boat, either lapstrake- or caravel-planked, and sometimes fitted to sail. Modern yawls are powered, and the yawls carried aboard skipjacks, the V-bottomed sloops popular in Chesapeake bay waters, are known as push-boats because they are used to push the mother ship in a calm.

The whaleboat is a light, swift, rowing and sailing boat fitted with a centreboard; usually it is caravel-built, although lapstrake whaleboats predominated at one time. Developed for use by whaling crews, its superior handling characteristics made it popular as a general purpose ship's boat, and it often serves as a cutter or gig.

The lifeboat is a double-ended rowing boat carried aboard ship for rescue purposes. Originally of wooden lapstrake construction, these boats now are almost universally made of steel, and some are equipped with diesel or gasoline engines. They often are built with special air chambers to make them unsinkable, and many are designed to be self-bailing and self-righting in heavy seas. The size and fitting of lifeboats is established by law, as is the number a ship must carry. See also Index references under "Boat" in the Index volume.

BOATING for pleasure has been enjoyed for several centuries, but the sport has increased tremendously in popularity in the 20th century, particularly in North America, western Europe and Australasia. This article deals with the growth of this form of recreation and also with the various kinds of power boats, sailboats and rowboats. Boating is most often carried on as a pleasure for its own sake, but it is also enjoyed as a competitive sport, or in connection with such sports as fishing, hunting (shooting) or water skiing. (For the history of sailboat racing and cruising see YACHTING.)

Growth of Boating.—The growth of boating as a sport increased markedly after World War I and even more rapidly after World War II. Among the factors contributing to this growth was the progressive development of more reliable, lighter and more powerful outboard motors to power speedboats and hydroplanes, utility boats for fishing, camping trips and water skiing, cruisers and houseboats and for use as auxiliaries on sailboats. The development of outboard motors was paralleled by the development of inboard motors, both gasoline and diesel. and by the successful introduction of new materials in boatbuilding, especially plywood, glass fibre and aluminum. The widespread marketing of do-it-yourself plans and instructions and of boat kits consisting of par-

tially precut or prefabricated parts for building boats made it possible for more people to own their own boats. At the same time, the development of lightweight, maneuverable automobile trailers, equipped with small winches for launching and loading boats, enabled more and more people to take small boats along on vacation trips and weekend outings for fishing, water skiing or simply boating on lakes and streams. The spreading network of highways and the establishment of the type of boat harbours known as marinas, boat-launching ramps and docking facilities made more and more waters accessible to boaters. Added to all these factors was the increasing availability of leisure time together with what some psychologists and sociologists identified as a widespread urge to escape urbanization and get, even if momentarily, back to nature, impelling people to seek recreation on the water.

In the early 1960s the marine industry estimated there were 7,800,000 pleasure boats in use on United States waters. It grouped them as follows: 3,940,000 outboards, *i.e.,* boats under 16 ft. in length with transoms designed to accommodate outboard motors; 2,500,000 rowboats, dinghies, prams and other miscellaneous craft (sometimes used with outboard power but not considered speedboats) ; 541.000 motorboats numbered by the U.S. coast guard for use on navigable waters (having a navigable outlet to the sea), this group including all inboard boats, outboards 16 ft. or more in length and some 44,500 auxiliary-poviered sailboats; 496,000 sailboats without inboard po er; 319,000 unnumbered inboard motorboats in use on waters not under federal jurisdiction: and 4,000 of the largest inboard cruisers and auxiliary-powered sailboats documented by the U.S. bureau of customs. In Great Britain trade estimates for the early 1960s showed that there were approximately 100,000 pleasure boats in use, of which 1.000 were the larger type of cruiser, big enough to be registered with the registrar of shipping, although many of these were probably in the Mediterranean. In the U.S., a federal boat-numbering system which came into force in April 1960 was based on horsepower rather than size of the boat. It required that every motorboat of more than 10 h.p. be numbered (registered). either by the state in which it operated or, in the few states that failed to set up their own numbering systems, by the federal government. Most states went beyond the federal code, originally drawn in 1958, and adopted laws requiring all motorboats, regardless of horsepower. to be registered. One effect of the new law was a rapid continuation of the trend toward larger outboard speedboats. Under the old law, outboard speedboats frequently were built just under 16 ft. to escape the inconvenience of registration. (C. R. McC.; S. N. C.)

POWER BOATING

Speedboats. — One of the most popular types of pleasure craft is the speedboat, a small, usually open motorboat, designed for swiftness and mobility in calm water.

The outboard speedboat, which lends itself to mass production, led the so-called boating boom after World War II. The development of more powerful motors broadened the function of the speedboat so that a family runabout with an 80 h.p. motor could go more than 40 m.p.h. or, sacrificing speed for pulling power. tow six water skiers. Water skiing began to rival fishing as a reason for buying a speedboat, either outboard or inboard. In addition, speedboats were used for day cruises, as yacht club launches and, in many cases, for simply "running about" on the water.

Powered either by inboard or outboard motors, speedboats range approximately from 12 to 25 ft. in length; the average outboard speedboat measures just under 15 ft., the average inboard somewhat longer. Passenger capacity ranges from one in the smaller racing craft to half a dozen or so in the conventional pleasure speedboat. Freeboard (distance from top of side to water line) is fairly low. Most speedboats are decked over at the bow and have wrap-around or straight windshields. Some are equipped with removable or fixed coverings that protect part of the cockpit. Speedboat types include: runabouts, utilities, water-ski boats, bass boats and racing motorboats. While speeds of 40 m.p.h. or more are not uncommon for recreational speedboats and one firm has offered a written guarantee of 60 m.p.h. with its 20- and 24-ft. inboard runabouts, racing outboards have exceeded 100 m.p.h. and racing inboards have bettered 200 m.p.h. (See also MOTORBOAT.)

Hull Design. — The primary goal in designing a fast boat is to reduce friction and resistance between hull and water. Speedboats are fast largely because the shape of their hulls succeeds in cutting this resistance. Virtually all speedboats have planing hulls; *i.e.,* hulls which, when properly matched with motor and propeller, rise partially out of the water and skim, or "plane," across the surface. The bottom, normally round or V-shaped near the front, is somewhat flat or shallow near the stern. The stern is cut off square so that displaced water, attempting to flow inward there. breaks abruptly away from the hull. Water flowing faster and faster under the boat exerts a dynamic force that lifts the hull to the surface. In contrast, as the slower displacement hull gains speed, it tries to draw in the water pushed aside by the how and sides — water which, at slow speeds, flows inward of its own accord and comes together at the tapered stem. This creates suction and prevents such a craft from exceeding its relatively slow "hull speed," although only comparatively low power is required to maintain that speed. The ultimate in planing design is the three-point racing hydroplane, which at planing speed rides only on its propeller and two sponsons. The three-point principle, in which the boat is supported by three planing surfaces arranged in a triangle with the apex near the stern, was advanced originally by William Froude in England in the 1870s. Hydrofoils go one step further. First explored before the turn of the 20th century by Alexander Graham Bell. they were developed mainly by the Germans and Italians before and during World War II. The thin foils extending into the water on either side and below the boat lift the hull entirely out of the water, in the same manner as wings lift an airplane.

Motors.—Outboard motors vary from 1- or 2-h.p. midgets to powerful units that weigh more than 200 lb. and generate 100 h.p. They operate on a mixture of gasoline and marine oil. The outboard is steered either by a handle on the motor or by remote controls. In the latter system the throttle, gearshift and electric-starter controls are located near an automobile-type steering wheel in the front of the cockpit. The wheel is connected to the motor either by rope-and-pulley or by steel cables. These turn the motor to right or left. The underwater unit of the motor itself forms the boat's rudder.

The inboard speedboat, with engine or engines inside the hull connected by a shaft to the propeller, normally is somewhat larger and more powerful than its outboard counterpart. Some inboards have engines generating more than 500 h.p.

Inboard-outboard power assemblies, first developed largely in Sweden and introduced commercially in the late 1950s, consist of an inboard engine driving an outboard propeller unit by a shaft through a hole in the transom.

A major development in inboard pleasure boats occurred in 1960 with the introduction of a 16-ft. craft using a jet-propulsion unit developed by C. W. F. Hamilton of New Zealand. The jet unit, powered by a marine engine, included a screened water intake flush with the keel amidships; a three-stage axial-flow turbine pump (equivalent roughly to a series of three propellers in a row, each boosting the next) ; a nozzle at the stern through which water is ejected into the air at a rate of 2,250 gal, per minute; and hydraulically operated deflectors or "gates" on either side of the transom opening to control the steering. The force of the water stream propels the craft according to the equal-and-opposite-reaction law of physics. In reverse, the stream is deflected forward under the hull. Because it has neither a propeller nor a rudder, the jet is capable of running in as little as four inches of water. It is able to make extremely sharp turns, even at full throttle. Another kind of jet, which pushes against water instead of into the air, was developed in Italy ior use in outboard motors. The stream ejected into the air gives considerably more thrust, with consequently higher speeds.

Materials.—Most speedboats are built of wood (smooth planking or overlapping, clinker, or "lapstrake"). aluminum or reinforced plastics such as those made of glass fibres. In the late 1950s, the latter became the most popular material, with aluminum falling somewhat behind. The design and construction of plastic small

craft started in 1876 when George Waters of Troy, N.Y., made the first laminated paper rowing shells, bonded in layers with shellac. The modern glass fibre craft is built on the same principle, the hull consisting of alternate layers of glass fibre cloth and mat, each saturated with liquid polyester resin as it is "laid up" into the wooden mold, which represents the desired hull shape. When the resin sets, the mold is removed, leaving a glass fibre hull with an impact strength greater than wood. The material also is impervious to dry rot, can be molded into any shape that does not have sharp corners and provides a one-piece hull that does not require caulking. Since glass fibre is heavier than water and would sink, boats of this material need built-in flotation tanks. Another molded hull employs a five-ply plastic construction built around a cellular or honeycombed centre. It has great impact strength and will not sink.

Materials greatly influence the design of a speedboat. A round-bottom hull is better suited to glass fibre or molded plywood. Sheet plywood or conventional wood planking go better with V-bottom craft.

Racing.—The major divisions in motorboat competition are stock inboard, stock outboard, inboard hydroplane and outboard hydroplane. Each division has a number of classes, depending mostly on engine displacement. Some of the smaller craft are barely big enough to hold the driver; the biggest, the unlimited hydroplanes, weigh close to four tons. Many hundreds of races and regattas are held each year in the United States under the sanction of the American Power Boat association, governing body for the sport in that country. Most races are held over closed courses. Some, like the Mississippi River marathon, are long-distance endurance events. A separate division was established for pleasure boats, which compete in marathons of from 50 to more than 250 mi. Major trophies for unlimited hydroplanes include the Harmsworth trophy, international, donated in 1903 by Sir Alfred Harmsworth of England, later to become Lord Northcliffe; the American Gold cup, donated in 1904 to the American Power Boat association by the Columbia Yacht club, N.Y.; and the President's cup, first contested in 1926. (See also MOTORBOAT.)

Cabin Cruisers.—A cabin cruiser is a motorboat with an enclosed cabin designed primarily for comfort and shelter and containing most, or all, of the minimum essentials of living. The category covers a variety of craft with a wide range in size, speed, accommodations, function and cost. Cruisers range in length from about 17 to 60 ft. or more and in speed from under 10 to more than 40 m.p.h. Unlike the sailing auxiliary or motor sailer, the cabin cruiser is wholly dependent upon its engine or engines for power. A typical cruiser would have, in its cabin or cabins: sleeping berths for four or more persons, stove, sink, icebox or refrigerator, toilet, storage lockers and water tank. Many large cruisers also are equipped with electronic aids to navigation such as radar and an automatic piloting device; most carry ship-to-shore radio and depth finder, or echo sounder. The more luxuriously appointed craft often have wall-to-wall carpeting, frozen food storage. showers, garbage-disposal unit and air conditioner. A cabin cruiser can be many things: a means of vacation, weekend or overnight travel and for practising seamanship and navigation on inland lakes and streams or coastal waters; a pleasant base for entertaining, picnicking, exploring, swimming, fishing or sunning; a regatta committee boat, towboat or ferryboat; or a pretentious, seldom used status symbol. After World War II, the preference in cruisers appeared to have swung toward smaller craft, while the demand in outboard and inboard runabouts mas for larger boats. Cruisers of more than 60 ft. or so are becoming scarce. Those over that length generally are listed as "motor yachts."

Types.—Outboard cruisers seldom are less than 17 ft. or more than 26 ft. long; however, with more powerful outboard motors they may be more than 30 ft. These craft are powered by either one or two outboard motors attached to the transom. A motor of 35 h.p. is regarded as the minimum requirement; a twin installation will deliver up to 160 h.p. About half the length of the small cruiser is devoted to the cabin, the rest to an open or partly covered cockpit in the rear part of the boat. Some outboard cruisers carry only a fear of the living essentials. They may have a chemical toilet, portable stove and limited sleeping quarters. Such boats are called day cruisers. The outboard cruiser has gained in popularity because of its low initial cost compared to inboards, its maneuverability on the water, where its shallow draft and absence of underwater gear increase mobility, and its light weight, which makes transportation by trailer easy.

The inboard cruiser, in most cases, is larger than its outboard counterpart. It is powered by one or two engines, either gasoline or diesel, located inside the boat. Power, in a twin-screw cruiser, can go to 600 h.p. or more. A diesel engine costs more to install than a gasoline engine, but since it burns nonexplosive fuel oil, the fire hazard is greatly lessened. A diesel also is considered more economical to operate. Despite a trend toward the use of plastics in the construction of smaller boats, including many outboard cruisers, wood is still the preferred material for inboard cruisers. Mahogany and teak, in particular, are thought to provide the sleek look desired in such craft. Many cruisers are designed to the specifications of individual yachtsmen and are custom-built by private boat yards.

Design.—Cabin cruisers, particularly the larger ones, are capable of venturing into the open ocean. But they are not so well suited for long ocean voyages as the sailing yacht or the motor sailer, which are not restricted in cruising range by the amount of fuel that can be carried. The cabin cruiser, with its relatively shallow draft and round or V-shaped bottom, is at its best in protected or semiprotected waters—inland rivers and lakes or coastal waters. For stability, the cabin cruiser relies mostly on its ample beam (width); in heavy seas, it will pitch and roll more than the sailing yacht or motor sailer whose keel, mast and sails act as a steadying force. One of the few types specifically designed for offshore work is the sport fisherman (see *Utility Boats*, below). Another seaworthy type is the inboard-powered sea skiff, of sturdy lapstrake (overlapping) construction, open or having a shelter-cabin and with a high freeboard. A popular form of cruiser in British waters follows the shape of the fishing craft in use round the coast. Since speed is not the main concern, most cruisers have displacement hulls rather than the planing or semi-planing hulls found on speedboats. V-bottom hard-chine hulls with straight planking are easier to construct 'and provide more cabin room because of their depth. They also tend to be faster and drier than round-bottom hulls, since the sharp angles between the bottom and sides of the boat throw bow waves out and away. But the round-bottom hull, usually built with steam-bent ribs, is considered stronger than the V-bottom, and more stable. It also is thought to give a better appearance to the boat. Many power cruisers have a V or round shape forward, tapering out to an almost flat stern. (S. N. C.)

Utility.—A utility boat is a special kind of all-around craft. It is usually an open boat with perhaps a canvas shelter top, from 14 to 30 ft. in length, light and fast. It earns its name by its ability to perform many useful functions. Its spacious cockpit enables it to carry several people or a quantity of camping or other gear and makes it an admirable fishing boat. A utility boat may be powered with an inboard or an outboard motor; when intended primarily for fishing on inland waters a relatively small motor often is used. For water skiing or exploring, a more powerful motor is preferred. The ocean-going sport fisherman, or sport-fishing cruiser, sometimes classed as a utility boat, is seaworthy in construction, hull form and power plant and may have outriggers, fish boxes and other fishing equipment as well as adequate cruising accommodations. Other utility boats may be specially designed for shallow draft fishing over shoals, for transporting sportsmen to camps or cabins accessible only by water, or for other purposes.

Houseboats.—The houseboat is found all over the world. Houseboats, as the name implies, provide first of all a home that floats. Houseboats may be equipped with engines or even powered by sail, but essentially they are broad-beamed flat-bottomed craft that provide a maximum of living space gained at great sacrifice or elimination of seaworthiness, speed and maneuverability. Houseboat types range from the canal and sailing barges of England and continental Europe to the square-ended junks of far east-

ern rivers. At its crudest a houseboat is simply a shanty built on a log raft. Moving is accomplished by tow or drift. At its most refined, a houseboat is a cruiser of broader beam and with more extensive living quarters than a cruiser hull of comparable dimensions would accommodate. Such boats as these can safely cruise sheltered waters under their own power.

A post-World War II innovation was the outboard-powered houseboat cruiser. These employ light%-eight construction and space-saving interiors to give commodious living quarters. Some designs are equipped with wheels that permit them to be towed down a highway like a land trailer; the wheels retract into special wells when the boats are launched. See also HOUSEBOAT.

(C. R. McC.)

SAILING

The sport of sailing has grown with that of power boating. Sailing as a sport in Europe almost certainly started in Holland in about the 16th century and was introduced into England by King Charles II. Yachting was once associated with seagoing vessels. Indeed the early yachts were evolved either from the smaller naval craft or from fishing or other working boats; *e.g.*, "America" was built on the lines of a New York pilot boat. All boats designed primarily for pleasure, including such craft as the 15½-ft. International Snipe and 10½-ft. International Cadet, are yachts; the sport of racing and cruising is dealt with under YACHTING (for the smaller boats see especially the section *United* States: *Smaller* and One-Design Classes). Various types of racing and cruising craft are identified below.

GEORGE O'DAY ASSOC.

FIG. 1.—12-FT. FIREFLY, A PLANING SAILBOAT, WITH SAILS REEFED ON A BROAD REACH

Easy leaders in style and glamour are racing sailboats. The sole purpose of their design is speed. Fastest of all are the catamarans. These are twin-hulled boats, descendants of the outrigger canoes of the south seas. Next in line for speed are the planing sailboats. and here the brilliant British naval architect, Uffa Fox, led the way. Racing boats conceived on his drawing board were designed to rise to the surface and skim on the water at full speed. He achieved great success in the 1530s in the 14-ft. International and International 10 square metre canoe classes and, with Tom Thornycroft and Morgan Giles, he did much to perfect the type of dinghy designed to plane, which has become the popular form of British racing dinghy.

An older design, but equally tricky and for years the fastest water-sailing boats (sailing iceboats are much faster than any water-borne sailing craft) are the so-called inland scows. These are long, extremely flat craft, light for their sail area. with two bilge boards (instead of a centreboard) and double rudders. These, too, are planing boats, the principles of their hull dynamics being essentially the same as those applying to speedboats (see Power Boating: Speedboats: Hull Design, above).

But the heart of the racing class lies in one-design craft. All boats in a one-design class are built to rigid specifications. The boats in the many one-design classes range from 8 ft. prams to the famous 12-meter yachts. The majority are in the 12 to 22 ft. range and are almost always Bermuda, or Marconi, rigged and carry a jib. Most classes have international, national and regional races in which the best boats compete annually.

Ocean racers, larger craft, 40 to 80 ft. in length, annually compete in a variety of races, more often made up of boats from a localized area, but sometimes, as in the Bermuda race or Fastnet, boats from all over the world race internationally. A complicated handicap formula makes these races possible, for the boats are dissimilar as to length, rig and design. Sail area: rig, displacement, water iine length and other factors are all figured to give each boat a relative standing against a norm or "scratch" boat. The boat that does best in relation to this scratch boat wins.

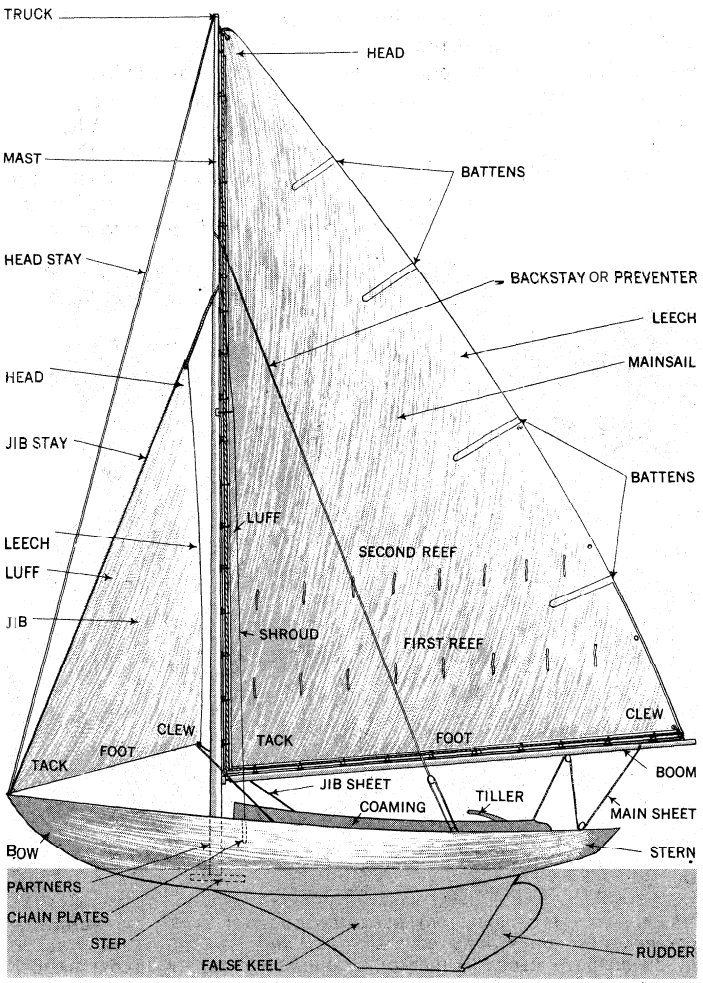
FIG. 2.—OCEAN RACING MARCONI-RIGGED YAWL, WITH SMALL STAYSAIL AND LARGE SPINNAKER

Day sailers take many forms. These boats are not classed, and they are not raced. They are roomy, steady, practical and wholly enjoyable boats on which to spend a morning or afternoon sailing with family or friends. Generally the term applies to any sailboat not a racing boat that lacks accommodations for overnight living aboard.

Probably no type of sailboat is better known than the cruising sailboat which, although small enough to be handled by a crew of one or two, or perhaps half a dozen, is capable of making long ocean voyages and even of circling the globe. Instead of the tall masts of the racer, the masts of the cruising sailboat are lower and stronger, sail area is less, to put less strain on hull and rigging. Hard-to-handle spinnakers and flying jibs are nonexistent. Ports and cockpit are small; canvas, rigging and construction is heavier. The boat is built to weather storms and withstand the weight of crushing waves breaking over it. Rigs are "balanced" so, with the wheel lashed, the boat can sail itself hour after hour, while the crew sleeps, eats or mends. Most renowned of the



FROM H. A. CALAHAN, "YACHTSMAN'S OMNIBUS," THE MACMILLAN COMPANY; 1951

FIG. 3.—PARTS OF A MARCONI-RIGGED DEEP-KEEL BOAT

modern cruising sailors has been Irving Johnson and his "Yankee," a 97-ft. brigantine. With students as crew he has circumnavigated the earth a half-dozen times or more. Most famous of the solitary cruisers was Joshua Slocum who in 1895–98 sailed his sloop, the "Spray," alone around the world and wrote a classic book about it, *Sailing Alone Around the World* (1900).

The motor-sailer is just what the name implies: a sailboat that has a motor larger than an auxiliary (used primarily for getting in and out of harbour) and can be sailed under power. The variations are endless. Generally, the description applies to a type of boat that is bluff of the ends, rugged and slightly slower under sail than a cruising sailboat, yet with smooth design that allows it to maintain a steady eight to ten knots under power. (Z. T.)

How a Boat Is Sailed. — The sails of a boat are airfoils which by their angle of incidence to the air stream (the wind) generate the drive that propels the boat. The trim of the sails is governed mainly by the angle of the desired course to the wind. When sailing to windward (fig. 4[F] and 4[G]) the boat's course is at the smallest practicable angle to the wind. The sails are then trimmed to an angle with the wind that produces their greatest driving force — an angle that is usually about 10° and varies with the efficiency of the sails. The resultant force produced by the sails may be further resolved into a component in the direction of the desired course (drive) and another normal to it (leeway force). Under the conditions of fig. 4(F) and 4(G), the drive force will be about one-third of that producing leeway. The latter has to be resisted by the boat, whose ability in this respect is one determinant of the smallest practicable angle of the course to the wind. Very efficient racing craft may sail at about 40° to the wind; undistinguished performers may not be able to sail closer than 55° uithout suffering from excessive drift to leeward. When the course lies at right angles to the wind (fig. 4[A] and 4[C]) the sails are still trimmed at approximately the same angle of incidence to the air stream. but their angle to the course is bigger and accordingly the driving force is increased and that to leeward reduced. On this point of sailing the drive and leeway forces are approximately equal, and a boat is faster under the condition in fig. 4(A) and 4(C), than those of 4(F) and 4(G). When the course is such as to bring the wind still further aft the sails reach the aerodynamic condition known as stalled, and also the direction of the drive force swings with the sails closer to the direction of motion (fig. 4[H] and 4[J]) until the two coincide when the wind is astern 4(B). When the direction of the wind is abaft the beam and it is no longer possible to trim the sails to a uniform angle of incidence of about 10°. the most efficient sails are those with a full curvature — such as the spinnaker (fig. 4[B]) — which deflects the maximum volume of wind through the biggest possible angle. It will be evident that under the conditions of fig. 4(F) and 4(G), when a boat is said to be "close-hauled" or on a tack, it is necessary to follow a zigzag course (4[D] and 4[E]) in order to reach a point dead to windward. When the bow of a boat is steered through the eye of the wind she is said to be tacking (fig. 4[I]); when the same evolution, of bringing the wind from one side to the other, is performed by steering so that the wind passes round the stern, she is said to be jibing, or gybing (J). *See* also NAVIGATION; OLYMPIC GAMES; RIGGING; SAILS.

Sailing and Yacht Clubs. — With few exceptions, sailboat racing and all organized boating activity is conducted under the auspices of a vast network of chartered yacht clubs found clustered around boating centres all over the world. The oldest is the Royal Cork Yacht club established in Ireland in 1720 as the Cork Water club. Most of these clubs are affiliated with their own national or regional authority; *e.g.*, the Royal Yachting association, for Great Britain, the North American Yacht Racing union, for North America. While the primary purpose of most clubs is social, these clubs make an important contribution to boating as a nhole by establishing competitive standards, promoting competitive events and attending to the endless details of executing these. In addition, most of the larger one-design classes such as Lightnings, Stars, Dragons, Snipes, etc., have their own class associations that supervise and foster the class and sponsor national and, in some cases, international racing events in the class. These are held at yacht clubs, the club varying usually from year to year. Thus the Star international championship may be decided one year in Naples. Italy; the next in Rye, N.Y. Organizations may be worldwide, such as the International Flying Dutchman Class organization, or purely national, such as the British Dragon association. Most yacht clubs supervise a series of races for their own members and host regional races or qualifying races for national and international events. While most small boat races are held on weekends, important regattas may encompass several days with morning and afternoon races. For the more important of these events and for the history of yacht clubs see YACHTING.

Some clubs may have specialized objects such as the Cruising Club of America or its British counterpart, the Royal Ocean Racing club, both organizing offshore racing events and regulating the handicapping of ocean racers. There are also many clubs which cater exclusively for the owners of power boats.

The most highly organized boating force in the world is the U.S. Power squadron. consisting of more than 200 units in 25 districts of the United States, This group, of some 35,000 members, was organized in 1914 as something of a small boat naval reserve. A notable feature is the provision of instructional classes covering all aspects of boating, including pilotage and navigation. There are many clubs in Britain which offer instruction, notably the Little Ship club and the Cruising association, of London, and the Clyde Cruising club with headquarters in Glasgow, although none of these confines its membership to either power boat or sailing men. There are also motorboat racing clubs and water-ski clubs, the former organizing motorboat racing and the latter concerned with the regulation of the comparatively young sport of water skiing.

Many yacht clubs organize competitive power boat events. Called predicted log races, navigational skill rather than speed is the basis for scoring. In these, the skipper of a boat predicts the exact time he will pass specified points around a predetermined course. Not allowed a watch, he must adjust the speed of his boat to such variables as mind, tide and current so that the time requirement is met. The skipper coming closest to his prediction wins.

In addition to races for sailboats and predicted log races for power boats most yacht clubs hold regattas in which events are not limited to boats built for racing and many conduct overnight, or longer, cruises. (2. T.)

OTHER PLEASURE BOATS

Canoes.—The canoe of the general type known as the Canadian canoe among sportsmen and in Olympic games events was developed by the North American Indians as a utilitarian carrier. A versatile craft, it has retained its popularity for fishing, for racing and aquatic events at summer camps, as well as for more formal racing events, and for short and long camping trips and expeditions, both in the wilderness country of the north woods of North America and along the well traveled rivers and canals of the British Isles and continental Europe. The kayak type canoe, evolved from the Eskimo craft, has been especially popular in Great Britain and also is represented in Olympic events. White-water canoeing, negotiating swift rapids, appeals to some enthusiasts. Either the open Canadian canoe or the kayak may be equipped for cruising with mast and sails, leeboards and a paddle or rudder for steering. The sailing canoe for racing is decked and has watertight compartments. uses a centreboard, a rudder for steering, and a sliding outrigger seat for balance. (See also CANOE)

Rowboats.—Any boat that relies on oars alone for propulsion falls in the rather loose category of rowboats, or "pulling" boats as fishermen may call them. Although they are fast disappearing as norkboats, as motors replace oars in every corner of the globe, they are still probably the most numerous of any type found around most water fronts and at most fishing camps and docks on inland waters. Prams and dinghies propelled by oars still ferry many a yachtsman ashore. Both are small light boats capable of being towed behind or taken aboard a yacht.

A true rowboat, or sculling boat. has an easy motion through the water, and, most important, "glides" between power strokes. Thus the boat's forward motion never ceases; each unhurried stroke of the oar keeps the boat under way and a steady tempo of strokes can be maintained hour after hour. A boat that does not glide requires the force of inertia be broken at each pull of the oars, an effort that will quickly tire the strongest man. Boats are roved in one of two ways: either the roner sits facing the stern and pulls with his legs and back, or he faces ahead. letting his weight fall forward on the oars. Sometimes the boat is "sculled" by one oar over the stern. A few outstanding types still survive. The fishing dory of the Grand Banks is a famous example. The chase boats of the whale ships mere roned and sailed and are the prototype of the modern lifeboat.

Mention must be made of the single-, double- and eight-oared racing shell, since it represents the apogee of speed attained by oars. These boats are long, frail craft, specially equipped with seats which enable the rower or rowers to put the maximum power into each sweep of the long scull or oar. These are used solely in competitive racing (see ROWING).

Punts.—The punt is an interesting flat-bottomed square-ended craft designed to be poled rather than rowed. Long popular in England, especially on the Thames, its use is confined to sheltered shallow waters. A specialized form of punt is the duck punt used for duck shooting, mainly in the eastern part of England. This has evolved over the years as a form of flat bottomed canoe, propelled by oars, paddles or poles, mounting a large bore shotgun, which is used for stalking ducks and geese in the shallow estuaries. An extremely fast form of sailing boat, peculiar to Norfolk, has been evolved from these boats.

Miscellaneous.—Easily portable rubber life rafts, sometimes propelled by outboard motors, have been adapted to pleasure boating uses. as tenders for small yachts, for negotiating very shallow or weedy waters, or as pontoons decked with various materials serving essentially as floating platforms from which to fish or swim.

BOATSWAIN (BOSUN). Before the Royal Navy was established the boatswain was the expert seaman in an English merchant vessel. Each ship had a master, who was proficient in navigation, and a boatswain, who was second in command. The boatswain was responsible for the care of the masts, yards, sails, rigging, anchors. boats and cordage; his shrill boatswain's pipe or whistle, which could be heard above the roar of the sea or noise of battle. gave all signals to the crew; he was assisted by boatswain's mates, who were petty officers. When the king hired a ship he issued a warrant to her ouner, and another warrant for the services of the boatswain, thus originating the name warrant officer.

From the beginnings of both the Royal Navy and the U S. navy boatswains have been warrant officers. In modern vessels the boatswain has charge of anchors and anchor gear, cargo-handling gear, rigging, boats and the instruction of the crew in practical seamanship, such as boat handling. (J. B. HN.)

BOBADILLA, FRANCISCO DE (d. 1502), of Aragonese origin, became the confidential agent of Ferdinand and Isabella of Spain and as such imprisoned Columbus in Santo Domingo and returned him to Spain in irons. As knight commander of Calatrava, Bobadilla took part in the reconquest of Spanish territory from the Moors, and upon Moorish evacuation of borderlands he mas made military governor of Jaén (Córdoba) and subsequently participated in the siege of Granada (1492). When Columbus asked the Catholic kings for an agent and judge to investigate the claims against him by rebels in his ranks they sent out Bobadilla with complete powers to investigate and make recommendations. Reaching Santo Domingo on Aug. 23, 1500, when Columbus was in great difficulties, Bobadilla decided to send Columbus and his brother Diego to Spain in irons as prisoners of the crown. He was considered to have exceeded his instructions but was himself recalled in Sept. 1501, to be succeeded as governor by Nicolás de Ovando. The ship which carried Bobadilla and his papers was lost in the hurricane that struck the returning fleet in June 1502. See COLUMBUS, CHRISTOPHER.

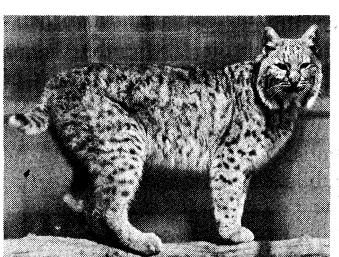
BOBBIO, a town in Piacenza province in the Emilia-Romagna region. Italy, 45 km. (28 mi) S W. of Piacenza city, and the see of a bishopric. Pop. (1957 est.) 6,279 (commune). It is an ancient town (Bobium), with narrow streets and wide squares, in a valley dominated by Monte Penice and natered by the Trebbia river. It contains the monastery and abbey of S. Colombano (11th and 13th centuries, restored in 1600), with the tomb of the saint, whose relics are preserved in the museum. The cathedral, romanesque and baroque, contains the tomb of S. Gianelli. There are also the medieval Ponte Vecchio ("Old Bridge") over the Trebbia, a small palazzo, the Casa di Teodolinda (15th century), the Castello Malaspina (14th century), and the sanctuary of Madonna dell'Aiuto (17th century). The town acquired fame from St. Colombano, an Irish monk (d 615), and was ruled by the Lombard kings and Frankish emperors. The bishopric was created in 1014. In 1176 the town fought against the emperor Barbarossa at Legnano, and in 1748 it became part of Savoy. (MU. T.)



BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

BOBCAT OR NORTH AMERICAN BAY LYNX (LYNX RUFUS)

BOBCAT, the North American bay lynx (*q.v.; Lynx rufus*), found in eastern North America from Canada into Mexico. Other races, or perhaps species, are found in western North America. The name refers to its short stumpy tail. The colour is reddish brown or gray, spotted and streaked with black. Bobcats,

larger than the true wildcat (*Felis sylvestris*) and smaller than the leopard (*q.v.*), vary greatly in size, adults weighing 12 to 39 lb. Two to four young are born in spring, remaining with the mother until autumn.

Larger bobcats prey on deer, in addition to rabbits, small rodents and birds. This species differs from the Canada lynx in having shorter pelage, poorly developed ear tufts and black bands on the tail above the black tip. See also CARNIVORE.

(J. E. HL.; X.)

BOBOLINK (RICEBIRD), *Dolichonyx oryzivorus*, a North American bird allied to the American orioles, grackles and meadoa larks and placed with them in the large family Icteridae. It is remarkable for its buntinglike bill and its rippling song (the name bobolink is derived from its call), which the bird generally sings while fluttering across a meadow. The bobolink is a migrant, breeding in the northern United States and southern Canada in summer and wintering in South America, which it reaches by a route through the West Indies. In the southern part of the United States this bird feeds upon rice and grain and is consequently unpopular with the farmer. Farther north, however, it is an insect eater, and the young, as is nearly always the case with small birds, are fed almost exclusively upon insects. Five mottled eggs are laid in a nest of grasses on the ground. The male in spring is black, with yellow hindneck and pale gray rump, but in fall it becomes a dull, streaked buff and blackish-brown like the female and young.

BOBRUISK (BOBRUYSK), a town of Mogilev *oblast* (province) of the Belorussian Soviet Socialist Republic, U.S.S.R., stands on the right bank of the Berezina river. Pop. (1959) 97,000 First mentioned in 16th-century sources, the town has a much troubled history. It was held by Lithuania, Poland and Russia at various times. was bombarded by Napoleon and was the scene of a major battle during the German retreat in 1944. The fortress of 1769 survives.

Its industries include engineering (pumps and saw-milling machinery), timber working (saw-milling, veneer and furniture), chemicals. food preparation and clothing and shoe manufacture. The main Minsk-Gomel railway crosses the Berezina there and there is a branch line to Oktyabrski The town is the focus of five highways. The Berezina is navigable for small craft, for which there are repair facilities at Bobruisk. (R. A. F)

BOBRZYNSKI, MICHAL (1849–1935), Polish historian whose writings inaugurated a reappraisal of his country's past and who also played some part in its political affairs during the final years of Austrian rule. Born in Cracow on Sept. 30, 1849. he studied at the university there, graduating as doctor of law in 1872 and becoming its professor of the history of law in 1877. His most fruitful work was done in the years 1873–85, on the social history of medieval Poland. His most important book. *Dzieje Polski* ("History of Poland"), first published in 1879, was written in some measure as the foundation of a program for the so-called "Stanczycy," a political group which at first represented the liberal bourgeoisie but later allied itself with the conservative country squires of Austrian Poland. Bobrzynski regarded the weakening of the centrsl government as having been the main cause of the 18th-century partitions of Poland and therefore criticized the structure of the "nobility's republic" severely. He thus became the chief exponent of the "pessimistic" (or Cracow) school of Polish historiograpliy.

Entering active politics in 1885, Bobrzynski was a leader of the Conservative group both in the Galician diet and in the Vienna *Reichsrat*. From April 1908 to May 1913 he was viceroy of Galicia. In Oct. 1917 he served for a short time in Vienna as minister for Galicia but resigned when he saw no hope for an "Austro-Polish" solution of the Polish question. After 1918 he retired from political life, but published *Wskrzeszenie panstwa* polskiego ("The Restoration of the Polish State"), two volumes (1920–25). The fourth edition of his Dzieje *Polski* (1927–31) included a third volume covering the most recent period. Bobrzynski died at Poznan on July 3, 1935. (A. GI.)

BOBSLEDDING, the sport of sliding down an ice-covered natural or artificial incline on a four-runner sled carrying two or four persons. Bobsledding originated in Switzerland around 1890, and is attributed to two U.S. vacationers who endeavoured to increase the thrills of tobogganing by adding runners to increase the toboggan's speed. The sport grew in popularity and in 1898 the first organized competition was held on the Cresta run at St. Moritz, Switz., which had been constructed 13 years earlier for one-man toboggans. The bobsled traveled much faster on the icy run and with improvements in sled construction during the next few years the Cresta, built for slower speeds, became too dangerous for bobsledding.

In 1904 a separate bobrun was built at St. Moritz having a gentler slope and high banked turns. In 1923 bobsledding became an internationally recognized sport with the organization of the Federation Internationale de Bobsleigh et Tobogganing and it was included in the first Winter Olympic games at Chamonix, France, in 1924. In 1931 the first bobrun in the United States was built on Mt. Van Hoevenberg near Lake Placid, N.Y., for the 1932 Olympics.

Runs.—The bobrun used in international competition must be at least 1,500 metres long and have an average slope between 8% and 15%. There are generally from 15 to 20 turns ranging in size up to huge hairpins of more than 180°. Most bobruns have permanent foundations of concrete or stone set into the earth. The foundation is covered with several inches of wet snow which is then saturated with water and allowed to freeze. The straightaways have sidewalls of reinforced ice about 18 in. high. The large turns are banked very steeply and are built up as high as 20 ft to prevent the fast traveling bobsleds from flying out of the turn

European bobruns are quite narrow, only four to five feet wide, leaving less than a foot of clearance on each side of the sled. The American bobrun at Lake Placid. on the other hand, is six to eight feet wide and has about a half inch of snow frozen to the ice, giving the runners a better grip for steering. The major turns have an overhanging lip of ice to prevent the sleds from going over the top.

Sleds.—Early bobsleds were built mostly of wood. Steel runners were adopted within a few years and by the second half of the 20th century steel and aluminum were used throughout. The four runners are generally mounted in pairs on two axles, allowing them to rock freely. Steering is accomplished by turning the front axle either with ropes or by a wheel linked to the axle by cables. The brake is a toothed bar nhich is pressed against the ice between the rear runners Racing bobsleds have a streamlined cowling in front of the driver to reduce wind resistance. The principal manufacturer of bobsleds for many years was the Feierabend family of Engelberg, Switz. The Italian Podar bobsled was introduced during the mid-1950s and soon proved its superiority by winning most of the major races. In addition, many sleds are built and raced by individuals.

Two types of bobsled are used: two-man boblets, as they are called in Europe, and four-man bobsleighs. Rules limit the maximum weights to 363 lb. and 507 lb., the maximum length to 106 in. and 149 in and the minimum runner thickness to .320 in. and .400 in. respectively for the tao types of sleds. Furthermore, the runner surfaces must be half round and separated by $26\frac{3}{8}$ in. The crew is limited in meight to an average of 220 lb. per man.

Racing.—A racing team originally consisted of five persons (four men and a woman). The team of five, which lay prone on the bobsled. was last used in the 1928 Olympics, after which it was reduced to four men. The team must now sit upright. The two-man event was begun in 1929. Since 1931 both two-man and four-man international competition has been held each year except for a seven-year interruption during World War II.

A race consists of four descents by each team, the total time for the four heats determining the winner. Electrical timing equipment measures elapsed time to $\frac{1}{100}$ of a second A running start is used from a fixed position a few feet behind the start line. The heavier four-man sleds attain speeds approaching 100 m.p h. while the smaller and lighter two-man sleds are only a little slower.

The technique which a racing team must master involves pushing the sled at the start to attain maximum starting velocity and balancing their neight to prevent the sled from skidding. Many

early teams had a technique of bobbing their bodies back and forth with a sudden snap (hence the name) which was presumed to increase the speed of the sled. It is doubtful whether bobbing accomplished this result. In any event it was discontinued as higher speeds were attained through improvements in sled design. The driver, who is the captain and most critical team member, must learn to sense the stability of the sled and to react quickly to prevent skids and to maneuver properly on the turns.

BOBWHITE, one of the best-known North American game birds, *Colinus* virginianus, of the subfamily Odontophorinae (new world quail) is about ten inches long, mottled. reddish-brown above, with white on the breast. Common to the region east of the Rocky mountains. north to Minnesota and Ontario and south to the Gulf of Mexico, it has been successfully introduced into Idaho and Oregon.

The bobwhite resembles the (resident or nonmigratory) partridge and (migrant) quail of Europe, and is known by both these names, but is best named from the ringing call. "bobwhite!" which resounds through the fields in the evening twilight when the family group is assembling for the night. These families, or coveys, keep together until the spring following the hatching of the young birds; they trot confidently through the stubble picking up seeds and insects—altogether too confidently, for in many states they were brought close to extinction by the hunter, but are again increasing under protection. Since 15 or 20 eggs are laid, they would increase rapidly if permitted. Heavy snow and ice are severe on these nonmigratory birds; they will come readily to feeding stations in winter.

A few of the subspecies found in the United States are: the smaller, darker *C.* v. *floridianus* of Florida; *C.* v. texanus, grayer above. of Texas; and *C.* v. *ridgwayi* (the masked bobwhite) of southwestern Arizona. Other subspecies and species extend through eastern and southern Mexico to the borders of northern Brazil, including 14 subspecies of *C.* virginianus ranging to Cuba and Guatemala. and various races of the black-throated bobwhite (C. nigrogularis), white-faced bobwhite (C. *leucopogon*) and crested bobwhite (C. *cristatus*). *See* also QUAIL. (G. F. Ss.)

H ARMSTRONG ROBERTS

BOBWHITE (COLINUS VIRGINIANUS) FEMALE (LEFT) AND MALE (RIGHT)

BOCAGE, MANUEL MARIA BARBOSA DU (1765–1805), the most notable Portuguese lyrical poet of the 18th century, was born in Setúbal, the son of a lawyer. He entered the army at the age of 14, transferring to the navy at 16. At the royal naval academy in Lisbon, however, he spent his time in love affairs, writing and declaiming poetry and leading a Bohemian existence. In 1786 he was sent to serve in India where he was promoted lieutenant but deserted and fled to Macao, returning to Lisbon in 1790. He then joined the literary society known as the New Arcadia but was expelled for attacks on his fellow members. In 1797 he was imprisoned. accused of propagating republicanism and atheism. During his imprisonment he undertook translations of Virgil and Ovid. Translation work provided him with a livelihood after his release, by which time he had abandoned his revolutionary and antiecclesiastical sentiments. Bocage employed various verse forms: satires, epistles, idylls, but he is at his best in the sonnet. Despite the neoclassical framework of his poetry, Bocage's intensely personal accent, frequent violence of expression and obsession with fate and death anticipate the Romantic verse of the 19th century.

Bocage's works were published as follows: *Rimas,* vol. i (1791), vol. ii (1799), vol. iii (1804). His complete works were edited by Inocêncio da Silva (1853) and T. Braga (1876).

BIBLIOGRAPHY.—T. Braga, *Bocage, sua vida e época litterária* (1902); Hernâni Cidade, *Bocage* (1936) and *Lições de cultura e literatura portuguesas,* vol. ii (1940); 4. J. Saraiva and O. Lopes, *História da Literatura Portuguesa* (1954).

(N. J. L.)

BOCAGE, a term of widespread application in western districts of France, indicating their well-timbered character in contradistinction to the *campagnes,* hedgeless tracts of arable land characteristic of the old-established areas of open-field agriculture in northeastern France. The bocage country consists of a patchwork of small, irregular, hedge-enclosed fields, with numerous trees. The term is especially applied to districts in western Normandy and Vendée. (AR. E. S.)

BOCAS DEL TORO, a province in northwestern Panamá; also a bay, group of islands and a small town on the island of Colón. Area of the province is 3,332 sq.mi. Population of the province (32,110 in 1960) is concentrated largely in the low plains northwest of Almirante bay, The plantations of the province supplied most of the bananas exported from Panamá between 1900 and the late 1930s, but the banana trees were gradually destroyed by the Panamá disease (*Fusarium* cubense), and cacao, abacá (manila hemp) and rubber were planted on abandoned banana lands. These, the chief products, are exported through the port of Almirante, 140 nautical miles west of Colón, Panamá. (C. F. J.)

BOCCACCIO, GIOVANNI (1313–1375), Italian writer and humanist, one of the greatest figures in European literature, was born in Paris in 1313. His father, Boccaccio di Chellino, called Boccaccino, was a merchant whose family belonged originally to Certaldo in Tuscany. Boccaccino's brother Giovanni, however, had moved to Florence not later than 1297 and Boccaccino had followed him thither. (Boccaccio could thus regularly describe himself as a citizen of Certaldo or of Florence, despite the accident of his Parisian birth.) Boccaccio's mother was probably French, but his contradictory statements about her in his *Filocolo* and in his Ameto—that she was a young girl of royal birth and that she was a widowed gentlewoman—may both be discounted as examples of a sort of autobiographical embellishment to which he was much inclined (particularly when writing of his early years) in conformity with recognized literary patterns of the time. The year of his birth is specified by Petrarch (*Senili,* viii, 1), and Boccaccio's own statement that he was born in Paris of a French mother is supported by documents showing that his father was in Paris in 1310, 1313 and 1314 for business transactions in which the great banking house of the Bardi was engaged.

Youth in Naples.—Boccaccio passed his early childhood rather unhappily in Florence. His father had no sympathy for Boccaccio's literary inclinations and sent him (not later than 1328) to Naples to learn business, probably in an office of the Bardi. Boccaccio claims to have spent six years in this situation and seems also to have spent an equal period studying canon law—likewise on his father's insistence (because of the prospect of emoluments) and against his own inclination. His claim to have been determined on a literary career from birth is probably to be regarded partly as another autobiographical embellishment of his past.

The Bardi, of whose business Boccaccino had become an associate, dominated the court of Naples by means of their loans. Moreover, the king, Robert of Anjou, took pleasure in surrounding himself with men of letters. All doors, then, were open to Boccaccio in Naples, and the years that he spent there were decisive for his education and his tastes. His commercial activity brought him into contact with everyday life in its varied aspects, and his ex-

perience of the aristocracy of the business world was to give his writing the special quality which recommended it to that milieu above all. Contact with the court, on the other hand, showed him all that survived of the splendours of chivalry and feudalism and aroused in him a taste for high and decorous endeavour and for the old nobility's courage, self-control and courtesy, which he was to pass on to his own world, that of the rising *bourgeoisie.* He mixed with the learned men of the court (above all Paolo da Perugia, Xndalb del Negro and perhaps Barlaam) and the friends and admirers of Petrarch (Barbato da Sulmona, Giovanni Barrilli and Dionigi da Borgo San Sepolcro), through whom he came to know the work of Petrarch himself. Petrarch and Boccaccio together were to mark out the paths along which the humanism of the Renaissance was to develop.

These years in Naples, moreover, were the years of Boccaccio's love for Fiammetta, whose person dominates all his literary activity up to the *Decameron* (in which there also appears a Fiammetta whose character somewhat resembles that of the Fiammetta of his earlier works). Boccaccio's accounts of the love affair are certainly romanticized and contradict one another occasionally: in the earliest works Fiammetta is unfaithful, whereas in the *Elegia di Madonna Fiammetta* it is she who is betrayed; and in *Filocolo* she is a king's daughter, whereas in *Ameto* and in *Fiammetta* she is only the daughter of a noblewoman married to a rich bourgeois and courted by the king. Attempts to use passages from Boccaccio's writings in order to identify Fiammetta with a supposedly historical Maria, natural daughter of King Robert and wife of a count of Aquino, are therefore untrustworthy — the more so since there is no documentary proof that this Maria ever existed.

It was probably in 1340 that Boccaccio was recalled to Florence by his father, involved in the bankruptcy of the Bardi. The sheltered period of his life thus came to an end: thenceforward there were to be only difficulties and occasional periods of poverty. From Naples, however, the young Boccaccio brought with him a store of literary work already completed. The *Caccia di Diana,* his earliest work, is a short poem, in terza rima of no great merit, in which a number of beautiful women of Naples are reviewed within the loose framework of a fable. Much more important are two works with themes derived from the medieval romances: *Filocolo* (*c.* 1336), a prose work in five books on the loves and adventures of Florio and Biancofiore (Flore and Blanchefleur); and *Filostrato* (*c.* 1338), a short poem in ottava rima, telling the story of Troilus and the faithless Criseida. The *Teseida* (probably begun in Naples and finished in Florence, 1340–41), is an ambitious epic of 12 cantos in ottava rima, in which the wars of Theseus serve as a background for the love of two friends, Arcita and Palemone, for the same woman, Emilia: Arcita finally wins her in a tournament, but dies immediately.

While all these themes of chivalry and love had long been familiar in courtly circles and were already in favour also with the bourgeois and even with the lower classes, Boccaccio not only enriched them with the fruits of his own acute observation of real life and insight into the human heart but also sought to present them nobly and iilustriously by a display of learning and rhetorical ornament, so as to make his Italian worthy of comparison with the monuments of Latin literature. It was Boccaccio who raised ottava rima, the metre of the popular minstrels, to literary dignity and launched it on its way to becoming the characteristic vehicle for Italian verse. Moreover, these early works had immediate effect outside Italy: Chaucer drew inspiration from *Filostrato* for his *Troilus and Criseyde* (as Shakespeare was later to do for *Troilus and Cressida)* and from *Teseida* for his "Knight's Tale."

The Return to Florence. — The 10 or 12 years following Boccaccio's return to Florence about 1340 are the period of his full maturity, culminating in the writing of the *Decameron.* From 1341 to 1342 he was working on the *Ninfale d'Ameto,* in prose and terza rima, which describes how a rude shepherd is raised to spiritual refinement and worldly honour through love. Next came *L'Amorosa Visione* (1342–43), a mediocre allegorical poem of 50 short cantos in terza rima, in obvious imitation of Dante but revealing also some affinity with Petrarch's *Trionfi,* so that some critics have argued that Petrarch's poem was in fact inspired by Boccaccio's. The *Elegia di Madonna Fiammetta* (1343–44), in prose, shows remarkable psychological penetration, though the style and narrative method are heavy.

The slightly later *Ninfale fiesolano* (perhaps 1344–4j), in ottava rima. on the love of the shepherd Africo for the nymph Mensola, is written with a graceful and studied simplicity foreshadowing 15th-century poetry. To complete the survey of Boccaccio's Italian writings before the *Decameron,* mention must be made of the *Rime,* begun in his youth but continued throughout his life, for the most part in the style established for the love lyric by the Sicilian school, by the exponents of the *dolce stil novo* or by Petrarch.

Boccaccio meanwhile was trying continually to put his financial affairs in order, though he never succeeded in doing so. Little is known. however, of the detail of his life in the period following his return to Florence. He was at Ravenna with Ostasio da Polenta between 1345 and 1346; at Forli in the service of Francesco degli Ordelaffi in 1347; in Florence during the ravages of the Black Death in 1348; and in Florence again in 1349. The Florentines appointed him ambassador to the lords of Romagna in 1350, municipal councilor and also ambassador to Louis, duke of Bavaria, in the Tirol in 1351, ambassador to Pope Innocent VI in 1354 and a member of the Ufficiodella Condotta in 1355.

Petrarch and the Classics. — Of far more lasting importance than official honours was Boccaccio's first meeting with Petrarch, in Florence in 1350, which began a friendship doing honour to both. Boccaccio, who had already written a life of Petrarch in Latin *(De vita et moribus Francisci Petrarchae)* revered the older man as his master (though respect did not preclude frank criticism); Petrarch proved himself a serene and ready counselor and a reliable helper. Together. through the exchange of books, news and ideas and through the stimulus that they afforded one another, they laid the foundations of the humanist reconquest of classical antiquity.

His meeting with Petrarch, which occurred when he was already working on the *Decameron,* helped to bring about a decisive change in Boccaccio's literary activity. After the *Decameron,* of which Petrarch remained in ignorance until the very last years of his life, Boccaccio wrote nothing in Italian except *Corbaccio,* the late Dantesque writings *(see* below) and perhaps an occasional lyric. Turning instead to Latin, he now devoted himself to humanist scholarship rather than to imaginative or poetic creation. His encyclopaedic *Genealogia deorum gentilium,* medieval in structure but humanist in spirit, was probably begun in the very year of his meeting with Petrarch but was continuously corrected and revised until his death. His *Bucolicum carmen* (1351–66), a series of allegorical eclogues on contemporary events, follows classical models on lines already indicated by Dante and Petrarch. His *De claris mulieribus* (1360–74), a collection of biographies of famous women, is the complement of Petrarch's *De viris illustribus,* just as his *De casibus virorum illustrium* (1355–74), on the inevitable catastrophe awaiting all who are too fortunate, reflects Petrarch's *De remediis utriusque fortunae.* Finally, there is his compilation of classical geographic names, *De montibus, silvis, fontibus, lacubus, fluminibus, stagnis seu paludibus, et de nominibus maris* (1355–74).

The meeting with Petrarch, however, was not the only cause of the change in Boccaccio's writing. A premature weakening of his physical powers and disappointments in love may also have contributed to it. Some such occurrence would explain how Boccaccio, having previously written always in praise of women and love, came suddenly to write the bitterly misogynistic *Corbaccio* and then turned his genius elsewhere. Furthermore, there are signs that he may have begun to feel religious scruples. Petrarch describes how the saintly Carthusian monk Pietro Petrone, on his deathbed in 1362, sent another Carthusian, Gioacchino Ciani, to exhort Boccaccio to renounce his worldly studies; and it was Petrarch who then dissuaded Boccaccio from burning his own works and selling his library. As early as 1360, moreover, Boccaccio's way of life had been regarded as austere enough to justify his being entrusted uith a cure of souls in a cathedral (he had taken minor orders many years earlier, perhaps at first only in the hope of being given benefices).

Boccaccio's circle in Florence was of vital importance as a nucleus of early humanism. Leonzio Pilato, whom Boccaccio housed from 1360 to 1362 and whose nomination as reader in Greek at the Studio he procured, made the rough Latin translation through which Petrarch and Boccaccio became acquainted with Homer's poems — the starting-point of Greek studies by the humanists. The recovery of Latin classical texts (Varro, Martial, Apuleius, Seneca, Ovid and, above all, Tacitus) likewise occupied Boccaccio's admiring attention. Even so, he did not neglect Italian poetry, his enthusiasm for his immediate predecessors, especially Dante. being one of the characteristics that distinguish him from Petrarch. His *Vita* or *Trattatello in laude di Dante* and the two abridged editions of it that he made show his devotion to Dante's memory.

Last Years. — All these studies were pursued in poverty, sometimes almost in destitution, and Boccaccio had to earn most of his income by transcribing his own works or those of others. In 1362, on the invitation of Niccolb Acciaiuoli, he went to Naples in some hope. but was disappointed and returned at once to Florence. Then, in 1363, he retired to Certaldo. He was twice sent as ambassador to Pope Urban V, at Avignon in 1365 and in Rome in 1367 In 1370–71, on the invitation of Niccolò di Montefalcone, he paid another visit to Naples, with no better success. In Oct. 1373, he began public readings of Dante's *Divina Commedia* in the church of S. Stefano di Badia in Florence. A revised text of the commentary that he gave with these readings is still extant, but breaks off in the 17th canto of the *Inferno,* at the point that he had reached when, early in 1374, ill-health and the criticisms of those who disapproved of his explaining Dante to the multitude made him lose heart. Petrarch's death (July 1374) was another grief to him. and he retired again to Certaldo.

There Boccaccio died, on Dec. 21, 1375, and was buried in the church of SS. Michele e Jacopo (his bones seem to have been scattered in 1783) Franco Sacchetti expressed the general dismay of men of letters at the death within 18 months of the two great writers when he said that all poetry was now extinct *(mancata ogni poesia).*

The **Decameron.**—In the form in which it is read today, the *Decameron* was probably composed in the years 1349–51.

The *Decameron* begins with the flight of ten young people (seven women and three men) from plague-stricken Florence in 1348. They retire to a rich, well-watered countryside, where, in the course of a fortnight, each member of the party has a turn as king or queen over the others, deciding in detail how their day shall be spent and directing their leisurely walks. their outdoor conversations, their dances and songs, and, above all, their alternate storytelling. This storytelling occupies ten days of the fortnight (the rest being set aside for personal adornment or for religious devotions) ; hence the title of the book itself, *Decameron* or "Ten Days' Work." The stories thus amount to roo in all. Each of the days, moreover, ends with a *canzone* for dancing sung by one of the storytellers, and these *canzoni* include some of Boccaccio's finest lyric poetry.

In choosing a framework of this sort for his stories Boccaccio was following a tradition familiar in oriental and medieval literature. To this tradition, however, he brought a new element. In addition to the roo stories, he has a master theme, namely the way of life of the refined *bourgeoisie,* who combined respect for conventions with an openminded attitude to personal behaviour.

The sombre tones of the opening passages of the book, where the plague and the moral and social chaos that accompanies it are described in the grand manner, are in sharp contrast to the scintillating liveliness of Day I, which is spent almost entirely in witty disputation, and to the playful atmosphere of intrigue that characterizes the tales of adventure or deception related on Days II and III. With Day IV and its stories of unhappy love the gloomy note returns, but Day V brings some relief, though it does not entirely dissipate the echo of solemnity, by giving happy endings to stories of love that does not at first run smoothly. Day VI reintroduces the gaiety of Day I and constitutes the overture to the great comic score, Days VII, VIII and IX, which are given over to laughter, trickery and licence. Finally, in Day X, all the themes of the preceding days are brought to their most exalted pitch, the impure made pure and the common made heroic. Even if it is not always artistically convincing, this conclusion forms a noble testament, ending with the glorification of fidelity, constancy and womanly obedience in the story of Griselda.

The prefaces to the days and to the individual stories and certain passages of especial magnificence based on classical models (on Livy at his most florid or on Apuleius at his richest rather than on Cicero), with their select vocabulary and their elaborate periods, have long held the attention of critics. But there is also another Boccaccio, the master of the spoken word and of the swift, vivid, tense narrative free from the proliferation of ornament. These two aspects of the *Decameron* make it the fountainhead of Italian literary prose for the succeeding centuries.

The romantic view of the *Decameron,* propounded by Francesco De Sanctis, who regarded it as a "Human Comedy" in succession to Dante's *Divine Comedy* and Boccaccio as the pioneer of a new moral order superseding that of the middle ages, is no longer tenable, since the middle ages can no longer be presented as having been wholly ascetic or wholly turned toward God in contrast with a virtually pagan Renaissance concerned only with the human. Medieval literature in general does not ignore man and the flesh and even has passages that exalt the individual; and the men of the Renaissance, far from ignoring God. strove in many ways to reconcile religious truth and Christian doctrine with both ancient philosophy and the new science. Also, in particular, the whole corpus of Boccaccio's work is perforce medieval in subject matter, form and taste, at least in its point of departure. It is the spirit in which Boccaccio treats his subjects and his forms that is new. Boccaccio in the *Decameron* for the first time deliberately shows man striving with fortune and learning to overcome it and even. when possible. to exploit it. This marked dualism of virtue and fortune lies at the root of the feeling and thought of the Renaissance. The *Decameron* exalts essentially what Machiavelli was to call the virtue of man: his intelligence. his eagerness. his sense of proportion, his tireless self-control and his power to bend events to his own designs. To be truly noble. according to the *Decameron,* man must accept life as it is. without bitterness; must accept, above all, the consequences of his own action, however contrary to his expectation or even tragic they may be. To realize his own earthly happiness he must confine his desire to what is humanly possible and renounce the absolute without regret. Thus Boccaccio insists both on man's powers and on their inescapable limitations. A sense of spiritual realities and an affirmation of moral values underlying the frivolity even in the most licentious passages of the *Decameron* are features of Boccaccio's work which modern criticism has brought to light and which make it no longer possible to regard him only as an obscene mocker or sensual cynic.

Boccaccio and the Renaissance. — Boccaccio was also a man of the Renaissance in other senses. His humanism comprised not only classical studies and the attempt to rediscover and reinterpret ancient texts. but also the "humanism of the vernacular" *(umanesimo volgave),* which he and Petrarch consciously initiated. This meant the raising of literature in the modern languages to the level of the classical by setting standards for it and then conforming to those standards. Such an undertaking, however, requires the writer to master his own caprices and impulses, to submit to the restraints of an illustrious and unalterable tradition, to tame his passions by the exercise of his intellect in the interests of formal perfection: poetic originality is to be sought only within the confines of tradition. In the second half of the 15th century and in the 16th century humanism did produce a vernacular literature in conformity with these requirements: indeed the humanist principle that the classical ideal should permeate the whole of modern life had as its natural consequence that the language and literature in which modern life was expressed should receive the stamp of classicism. Boccaccio advanced farther than Petrarch in this direction not only because he sought to dignify prose as well as poetry but also because, in his *Ninfale fiesolano,* in his *Elegia* di *Madonna Fiammetta* and in the *Decameron,* he ennobled everyday experience, tragic and comic alike. While his *Teseida* and his *Ninfale d'Ameto* invite comparison with classical genres (as do Petrarch's *Trionfi),* his *Filocolo* and his *Filostvato*

raise to the level of learned art the literature of chivalry and love that in his day had fallen to the level of the populace. The same attention to popular and medieval themes was to characterize Italian culture in the second half of the 11th century. Without Boccaccio, the culmination of the Renaissance would be historically incomprehensible.

BIBLIOGRAPHY.—*Editions:* Modern editions of Boccaccio's minor works in Italian are as follows: *Il Filocolo,* ed. by S. Battaglia (1938); *Il Filostrato* and *Il Ninfale fiesolano,* ed. by V. Pernicone (1937); *Teseida,* ed. by S. Battaglia (1938) and by A. Roncaglia (1941); *L'Ameto, Lettere, il Corbaccio,* ed. by N. Bruscoli (1940); *L'Amorosa Visione,* ed. by V. Branca (1944); *Elegia di Madonna Fiammetta, con le chiose itzedite,* ed. by V. Pernicone (1939) and by F. Ageno (1954); *Le Rime, l'Amorosa Visione, la Caccia di Diana,* ed. by V. Branca (1939; new ed. of *Le Rime* and *La Caccia di Diana,* 1958); *Il commento alla Divina Commedia e altri scritti intorno a Dante,* ed. by D. Guerri, 4 vol. (1918–26). Selections from the *Filocolo,* the *Ameto* and the *Elegia di Madonna Fiammetta* are included in the edition of selections from the *Decameron* by E. Bianchi. C. Salinari and N. Sapegno. 6th ed. (1952). Of Boccaccio's Latin works *Bucolicum carmen* and some poems and letters, as well as some shorter poems, are printed in *Opere latine minori,* ed. by A. F. Massera (1928); there is an edition of the *Genealogie deorum gentilium libri* by V. Romano, 2 vol. (1951). Eng. trans. of the minor works include: *Filostrato,* trans. by W. M. Rossetti (in *Chaucar's Troylus and Cryseide Compared With Boccaccio's,* 1873), by H. Cummings (in verse, 1924) and by R. K. Gordon (in *The Story of Troilus,* 1934); *The Nymphs of Fiesole,* trans. from the *Ninfale fesolano* Ly John Goubourne (16th century; new ed. 1952); *Amorous Fiammetta,* trans. from the *Elegia* by B. Young (1587; new ed. by E. Hutton, 1926); *The Falle of Princis,* trans. from the *De casibus* by John Lydgate (*c.* 1430; modern ed. by H. Bergen, 1923–27); *Forty-Six Lives front Boccaccio's De Claris Mulieribus,* trans. by Henry Parker, Lord Morley, ed. by H. G. Wright (1943); *Boccaccio on Poetry,* trans. from books XIV and XV of the *Genealogia* by C. G. Osgood (1930); and *Life of Dante,* trans. by P. H. Wicksteed (1904).

There are editions of the *Decanteron* by U. Bosco (1946–1951); by G. Petronio, with full commentary (1950); by V. Branca, with full commentary (1951–52): by C. S. Singleton (1955); and by N. Sapegno (1956). Ens. trans. include a celebrated anonymous version (1620; *see* H. G. Wright, *The First English Translation of the Decameron, 1620,* 1953) and modern versions by J. M. Rigg (new ed. 1948) and by R. Aldington (2 vol., 1956). On the text see M. Barbi, *La Nuova Filologia e l'edizione dei nostri scrittori* (1938); M. Sampoli Simonelli, "Il Decameron: problemi e discussioni di critica testuale," *Ann. Sc. norm. sup. Pisa,* XVIII (1949); V. Branca, "Per il testo del Decameron," *Studi di filologia italiana,* VIII and XI (1950–53); V. Branca, *Tradizione della opere di Giovanni Boccaccio* (1958).

BOCCALINI, TRAIANO (1556–1613), an anti-Spanish Italian theorist of the *ragione di stato* ("reason of state") and an extremely effective satirist, was born at Loreto, the son of an architect. He was educated for the law and passed many years in the papal service (1584–1612). In 1612 he left Rome for Venice where, in contact with the papal nuncio, he was probably engaged in diplomatic activity. Boccalini's most considered work was the *Commentari sopra Cornelio Tacito,* published posthumously with the *Lettere politiche ed historiche* (of doubtful authenticity) under the title La *bilancia politica* ("The Political Scales"). 3 vol. (1678). A slighter though more popular work was his *Ragguagli di Parnaso* (1st "Centuria," 1612; and "Centuria," 1613; critical ed. by G. Rua and L. Firpo, 3 vol., 1910–48), a sequence of 201 ironical newsletters in which the wise men of all centuries discuss politics, literature and art, under the guidance of Apollo. Another series of 31 *ragguagli,* the *Pietra del paragone politico* (1615), contains Boccalini's most vigorous denunciation of the Spanish domination in Europe. It was widely translated, the first English version, by Henry. earl of Monmouth, being called *Advertisements from Parnassus in two centuries with the Politicize Touchstone* (1656). *Religione e Ragione di Stato* (first pub., 1933) is a dialogue concerned with the attitude of Charles V toward the German Protestants.

Boccalini died in Venice, Nov. 29, 1613.

See G Silingardi, *La vita, i tempi, e le opere di Traiano Boccalini* (1883): F. Meinecke, *Machiavellism,* Eng. trans. by D. Scott (1957). (D. M. WE:)

BOCCHERINI, LUIGI (1743–1805). an Italian composer and cellist best known for his chamber music. Born at Lucca, Feb. 19, 1743, he studied under his father and at Rome, and after establishing a local reputation soon made an international one when a concert tour culminated in his appearance at the famous Paris Concert Spirituel in 1768. He was promised a favourable reception at the Spanish court. and on visiting Madrid was appointed chamber music composer to the Infante Don Luis. After Don Luis' death in 1785 Boccherini probably took up a post in Berlin under Friedrich Wilhelm II, but returned to Madrid on the latter's death in 1797 and, despite patronage from Lucien Bonaparte and some old acquaintances, died there in extreme poverty on May 28. 1805.

The types of post Boccherini held determined that he was to be primarily a composer of chamber music. and it certainly seems that his own inclinations and gifts lay in that direction. He produced more than 100 each of quintets and quartets, more than 50 trios and more than 50 chamber works in other forms. His output also includes some sacred music! symphonies and concertos. the last mainly for his own instrun ent, the cello (though it is notable that a Boccherini violin concerto provided the model for Mozart's Violin Concerto in D, K. 218). The Cello Concerto in B flat. Boccherini's best-known complete work. is to some extent spurious. being arranged from two Boccherini concertos by the 19th-century composer and cellist Friedrich Griitzniacher. His well-known Minuet is from his String Quintet in E major, Op. 13 (or 11), no. 5.

Boccherini has often been compared to Haydn, usually to his disadvantage. A contemporary, Giovanni Puppo. characterized him as "Haydn's wife," but it hardly does Boccherini justice to regard him as no more than an emasculated Haydn: their qualities are of different kinds. It is true that his music often lacks Haydn's characteristic forward-drive and virility, qualities which derive from a keen sense of form and symphonic development. Thus whereas Haydn's first movements usually centre upon the closely reasoned argument of their development sections. Boccherini's depend on their thematic material and the way in which it is presented and re-presented, and his development sections often lack a firm sense of direction and purpose. Closely related to this difference between the two composers are their divergent attitudes toward texture. *Concertante* writing has little place in Haydn's schemes but is of fundamental importance to Boccherini's, and he obtains a wide variety of tone-colours by writing high viola or cello parts (he was clearly influenced here by his own instrumental facility). His varied treatment of instrumental texture is one of the most characteristic features of his music. While Haydn. with his emphasis on the dramatic nature of sonata form, is in the mainstream of musical development, Boccherini can be said to represent a backwater. His concern was the production of smooth, elegant music: his favourite expression marks were *soave, con grazia* and *dolcissimo,* and his favourite dynamic msrk was *pianissimo.* Especially toward the end of his Iife his music displayed certain stylistic mannerisms in general mood, phrasing and melodic shapes (the last two possibly because of Spanish influence). But it is in his gentle warmth and superlative elegance — often with a hint of melancholy just below the surface — that we find Boccherini's most characteristic contribution.

See A. Bonaventura, *Boccherini* (1931). (S. J. SA.)

BOCCHUS, the name of two kings of Mauretania in the 2nd and 1st centuries B.C.

BOCCHUS (2nd–1st century B.C.), king of Mauretania from c. 118 B.C. to 91 B.C. In 106 B.C. he gave half-hearted assistance to his son-in-law Jugurtha, king of Kumidia, against the Romans, with whom he had unsuccessfully tried to make a treaty. After suffering some losses he was persuaded in 105 B.C. by L. Cornelius Sulla, a lieutenant of the Roman commander Gaius Marius, to change sides and betray Jugurtha. He was rewarded with some Kumidian territory and became a loyal dependent of Rome. Later, he supported Sulla with gifts and money during the latter's political career at Rome.

BOCCHUS (1st century B.C.), probably a descendant of the former, in 49 B.C. king of Mauretania east of the Mulucha river (Moulouya in northeastern Morocco), his brother Bogud ruling the area to the west. Both supported Julius Caesar against the supporters of Gnaeus Pompeius in Africa (49–46 B.C.), and Bocchus' rule was extended to much of Numidia after Caesar's victory of Thapsus (46 B.C.). After Caesar's death (44 B.C.) Bogud supported Mark Antony while Bocchus supported Octavian. Bocchus seized Bogud's territory when the latter was campaigning in Spain. and forced him to flee to Antony in the east. Bocchus then ruled over all Mauretania until his death in 33 B.C.

See S. Gsell, *Histoire ancienne de l'Afrique du Nord,* vol. vii and viii (1928). (B. H. WA.)

BOCCIE, the chief Italian bowling game, controlled by the Unione Federazioni Italiane Bocce, is especially popular in Piedmont (where the first organization was formed in Turin, 1898) and Liguria. The game is also played in Italian communities throughout the United States and Australia and has a large following in South America. The first world championships were held in Genoa, Italy, in 1951.

The playing area, or alley, is 75 × 8 ft., with a surface of sand or soil, and is enclosed with boarded ends and sides 18 in. and 12 in. high. respectively. Each player (four to a side) in turn rolls or throws a wooden unbiased ball to a smaller wooden ball. or "jack," the object being. as in the game of bowls (*q.v.*), to bring the ball to rest closer to the jack than any ball of the other side, to protect a well-placed ball or to knock aside an opponent's ball. Rebounds from the side walls are allowed. (H. L. EH.)

BOCCIONI, UMBERTO (1882–1916), Italian painter and sculptor and a pioneer of the Futurist movement, was born at Reggio di Calabria on Oct. 19, 1882. He worked in Rome from 1898 to 1902 under the avant-garde painter Giacomo Balla, then a follower of Georges Seurat. In 1902 he went to Paris, then for some months to Russia and back from 1904–06 to Padua and Venice. He then met F. T. Marinetti, founder of the new Futurist literary movement. Boccioni, with Balla, G. Severini, L. Russolo and C. Carra formed an artists' branch of the movement and issued in 1910 two manifestos which, though extravagant, are important documents of modern art. Urging the overthrow of the cult of the past, they exult in speed, violence and pure sensation, praising the subject matter of a mechanized age. Their program is hinted at in the manifesto of Feb. 11, 1910: "Forms in movement are multiplied, deformed, follow one another like vibrations in the space through which they pass."

Boccioni's Futurist work, crowded into the years between 1911 and his death at war on Aug. 16, 1916, takes as its main theme the "development in space" of figures and common objects which are excavated, opened out, rotated and multiplied to give the illusion of dynamic movement. Some of the finest are in the Museum of Modern Art, New York.

BOCHART, SAMUEL (1599–1667), an erudite orientalist and pastor of the French Reformed Church, was born at Rouen on May 30, 1599. After studying theology and oriental languages in France. England and Holland he settled at Caen, where he died on May 16, 1667. He achieved fame by his debate, printed in 1630, with the former Jesuit François Véron, the government-appointed polemicist for the conversion of the Huguenots. Bochart's norks, still quoted, are *Geographia sacra* seu *Phaleg et Chanaan* (1646), dealing with the table of nations in Genesis ix and with the Phoenicians. and *Hierozoicon . . . de animalibus sacrae scripturae* (1663), *a* learned collection of material from classical and oriental sources. Unfortunately an uncritical predilection for Phoenician led him to produce many fanciful etymologies. His complete works were published in 1675 (4th ed., 1712).

See W *R.* Whittingham, *Essay on . . . Samuel Bochart* (1829). (W. D. McH.)

BOCHOLT, a town of Germany which after partition of the nation following World War II was located in the *Land* (state) of North Rhine-Westphalia, Federal Republic of Germany. It lies on the Aa, a stream near the Dutch frontier, 12 mi. N. of Wesel. Pop. (1950) 37,674, (1959 est.) 43,983. The church of St. George (1415–86) is in Gothic style, while the Rathaus (1618–21, restored 1928–34) is in Dutch Renaissance style. Nearby are the castles of Anholt and Gemen. The town is a centre of the cotton industry and there are also iron foundries and machine manufactures.

BOCHUM, an industrial city of Germany which after partition of the nation following World War II was located in the *Lend* (state) of North Rhine-Westphalia, Federal Republic of Germany. In the heart of the Ruhr district. it lies 15 km. (9 mi) E. of Essen and 20 km. (12 mi.) W. of Dortmund. Pop. (1950) 289,804; (1959 est.) 361,537. Bochum serves as a commercial and cultural centre for a densely populated area. There is an adult college giving courses in administration, industry and foreign trade, and during 1946–59, 35 new schools were built. The theatre, rebuilt in 1953, has an annual Shakespeare festival. There are a municipal orchestra and a celebrated junior choir. After World War II only 10,000 of the city's 93,000 houses remained undamaged, and it was rebuilt with broad streets and numerous parks, becoming a conference centre for the Ruhr district. The Propsteikirche or priory church (1599) is the only ancient monument still intact. The southern part of the town is the civic centre and residential area, and the town hall (1926–31) has a carillon cast in Bochum. The suburbs stretch down to the Ruhr river and include the castle of Blankenstein, part of the original settlement, and a 13th-century church at Bochum-Stiepel with wall paintings of the early middle ages There are also a large municipal park, zoological gardens, a geological museum of the Ruhr mines and a world-famous mining museum. The industrial area extends to the west and north. Bochum is served by a network of railway lines connecting it with other Ruhr towns, the chief of which runs from Dortmund to Essen. Bochum owes its importance to the growth of its coal, iron and steel industries, especially mining, in which almost one-half the population is engaged. It also manufactures mining equipment, has a mining college, and is the headquarters of the Miners' Trade union. Miners' Insurance association and Miners' Co-operative, and of other industrial associations. and of a mining research institute. Die casting was developed in Bochum about 1850. and among its products are cast-steel church bells. Manufactures and industries include textiles, chemicals, television sets, tobacco processing and brewing.

Founded in the 11th century as a stronghold by Count Adolf III, Bochum received its town charter from Count Engelbert III in 1321. Until the growth of the coal. iron and steel industries in the mid-19th century, it remained a small agricultural tonn. It became a city in the early 1900s. During World War II Bochum was captured by the Allies in April 1945. (H. M. RG)

BÖCKLIN, ARNOLD (1827–1901), Swiss painter, whose influence on German painting, especially on the Munich school, was very great, was born at Basel, Oct. 16, 1827. He studied at Ddsseldorf, Antwerp, Brussels and Paris, but found his real inspiration in Italy, where he returned from time to time. and nhere the last years of his life nere spent. Bocklin first won a reputation by his "Great Pan," exhibited at Munich in 1856, and bought for the Pinakothek. From 1858 to 1861, he taught at the Weimar academy, but the nostalgia for the Italian landscape pursued him, and after an interval during which he completed his mythological frescoes for the decoration of the gallery at Basel, he returned to

Italy. At Basel, and in almost all the great German galleries, there are many examples of his art. However, he was first and foremost a landscape painter. In his numerous mythological subjects he sought to express the soul of the landscape in the figures to which it gave birth. His "Isle of the Dead" inspired Sergei Rachmaninoff's symphonic poem of the same name. He died at San Domenico, near Florence, Jan. 16, 1901.

BOCSKAY, ISTVÁN (STEPHEN) (1557–1606), prince of Transylvania and a national leader of the Hungarians, was born at Kolozsvár (Cluj) in Transylvania. Brought up at the court of the Báthorys, he won the confidence of Sigismund Báthory (*q.v.*), prince of Transylvania, whom he advised to form an alliance with the Holy Roman emperor, who was also the Habsburg king of Hungary, instead of with the Ottoman sultan. When in 1599 Báthory's successors deprived Bocskay of his estates, he fled to Vienna to seek protection and redress. He was alienated, however, by the emperor Rudolf II's attempts to deprive royal Hungary of its constitution and the Hungarian Protestants of their religious liberties. Bocskay, a devout Protestant, therefore sought Turkish aid and helped the Turkish armies in driving the Habsburg forces out of Transylvania. As a reward the Hungarian diet elected him prince of Transylvania in 1605, and he was recognized as such by the sultan Ahmed I, who sent him a magnificent jeweled crown made in Persia. Although Bocskay refused to assume the title of king, he made skilful use of the Turkish alliance. Rudolf, faced with the possible loss of Hungary and strongly urged by his brother the archduke Matthias, entered into negotiations with Bocskay and ultimately made peace with him by the treaty of Vienna (June 23, 1606). This treaty restored and guaranteed all constitutional and religious rights and privileges of the Hungarians in Transylvania and in royal Hungary. Bocskay was recognized as the prince of Transylvania, and the right of the Transylvanians to elect their own princes was affirmed. Bocskay received the fortress of Tokaj and the counties of Bereg, Szatmár and Ugocsa. Soon afterward he concluded a treaty with the Turks at Zsitvatorok, which confirmed the provisions of the treaty of Vienna. Bocskay's sudden death on Dec. 29, 1606, was attributed to poison given him by his chancellor, Mihály Kátay, who was killed in the market place of Kassa (Kosice in Slovakia) by the enraged followers of Bocskay. (*T. K.*)

BODE, JOHANN ELERT (1747–1826), German astronomer, best known for his statement of "Bode's Law." He was born at Hamburg on Jan. 19, 1747. He founded in 1774 the well-known *Astronomisches Jahrbuch*, 51 yearly volumes of which he compiled and issued. He became director of the Berlin observatory in 1786, withdrew from official life in 1825, and died at Berlin on Nov. 23, 1826. Among his other publications was *Uranographia* (1801) a collection of 20 star maps accompanied by a catalogue of 17,240 stars and nebulae. He propounded, in 1776, a theory of the solar constitution similar to that developed in 1795 by Sir William Herschel. He gave currency to the empirical rule known as "Bode's Law," which was actually announced by Johann Daniel Titius of Wittenberg in 1766. This law expresses the proportionate distances of the several planets from the sun. For a statement of the law see PLANET: Distances of the Planets. The law was an important factor in the discovery of the minor planets most of which are located between Mars and Jupiter. See ASTEROIDS.

BODE, WILHELM VON (1845–1929), German art critic and museum director, whose opinion was especially valued in the field of Dutch and Flemish paintings and Italian sculpture, was born at Kalvorde, Brunswick, on Dec. 10, 1845. At first Bode entered the legal profession but he turned to the study of art and became assistant in the Berlin museum in 1872. Toward the end of a most distinguished career he was made general director of all the royal museums in Prussia (1906). He resigned in 1920. Under his management the status of the Berlin museums rose to world-wide importance. Bode's knowledge extended over a wide field, and he wrote innumerable essays and books on Italian Renaissance sculpture, painting and furniture, oriental rugs, German sculpture and Dutch and Flemish painting of the 17th century, especially on Rembrandt. Bode died on March 1, 1929. His memoirs, *Mein Leben*, were published in 1930. (Hs. *H.*)

BODEL, JEHAN (*c.* 1167–1210), French lyric and epic poet, dramatist and (probably) author of *fabliaux*, was born at Arras and probably held some public office there. He planned to go on the fourth crusade, but was stricken with leprosy and admitted to a lazar house near Arras in 1202, dying there early in 1210. He wrote five pastourelles (one apparently in 1199), probably nine *fabliaux* (*c.* 1190–1200), the Jeu de Saint Nicolas (*c.* 1200), the *Chanson des Saxons* (before 1202) and the *Congés* (1202).

The *Jeu de Saint Nicolas* shows marked dramatic qualities and crusading fervour. It treats a theme first presented at the abbey of Fleury-sur-Loire (Orleans manuscript 201) and then by Hilarius in his Latin *Ludus super iconium Sancti Nicolai*, giving it new form and dimensions by relating it to the crusades. In Bodel's version the image of the saint, to which the sole survivor of a defeated Christian host is found praying, is made the source of a miracle. This image, placed upon the Saracen king's treasure, does not prevent its removal by thieves, who interrupt their drinking, dicing and brawling (presented in tavern scenes in which the everyday life of the people of Arras provides strong local colour) to carry it off, but the saint in person forces them to return it and the king and his people are converted.

The *Chanson des Saxons*, belonging to the period of decadence of the epic, adds roman d'aventures episodes to the story of Charlemagne's Saxon wars. The *Conge's are* Bodel's poignant, but courageous, farewell to his fellow citizens and his plea for admission to a lazar house.

F. J. Warne's edition of *Le Jeu de Saint Nicolas* (1951) contains a bibliography. Editions of other works are: *Chanson des Saxons* by F. Menzel and E. Stengel (1906, 1909) and *Congés* by G. Raynaud in *Romania IX*, pp. 226–27 (1880).

BODENSTEDT, FRIEDRICH MARTIN VON (1819–1892), German writer, whose poetry enjoyed great popularity during his lifetime, was born at Peine, Hanover, on April 22, 1819. As a young man he traveled extensively and obtained an appointment as head of a school in Tiflis, where he made a study of Persian literature. In 1851 he published Die Lieder des Mirza Schaffy (Eng. trans. The Songs of Mirza Schaffy, 1880), a collection of poems written in an oriental style, which was instantly successful. In 1854 he became professor of Slavonic languages at Munich. At this period he made numerous translations from Russian authors, notably Pushkin, Turgenev and Lermontov, and also composed an epic on a Circassian theme. He relinquished his post in 1858 in order to take up a professorship in early English literature, and from that time devoted his attention primarily to the Shakespearean drama. He collaborated with Paul Heyse and others in a new translation of Shakespeare's works (1866–72), and himself translated the sonnets. From 1866 onward Bodenstedt was director of the court theatre at Meiningen. Among his other works are *Tausendundein Tage im Orient* (1850), *Shakespeares Zeitgenossen und ihre Werke* (1858–60) and translations from Hafiz and Omar Khayyam. He died at Wiesbaden on April 18, 1892.

BIBLIOGRAPHY.—Bodenstedt's collected works were published in 12 vol. (1866–69); *Erzählungen und Romane* (1871–72). See also Bodenstedt's *Erinnerung aus meinem Leben* (1888–90); G. Schenk, *Friedrich von Bodenstedt. Ein Dichterleben in seinen Briefen* (1893).

BODHISATTVA (literally, "enlightenment-being") is one on the way to enlightenment; *i.e.*, a Buddha-to-be. In the sutras of primitive Buddhism, Buddha often speaks of himself, "while I mas yet an unenlightened Bodhisattva." In the sutras of Mahayana Buddhism, however, Bodhisattvas were elevated to a more dignified status and sent on specified missions; *e.g.*, Avalokitesvara (Kuan-yin or Kwannon) in the Saddharma Pundarika Sutra, Sudhanasresthi-daraka in the Avatamsaka Sutra, and Maitreya, the future Buddha. The repeated passage was: "Upward to seek the Bodhi, downward to cultivate the people." Naturally, these Bodhisattvas made much of cultivating and sav-

ing the people, this being a new focus of Buddhist faith in Mahayana Buddhism. *See* also MAHAYANA; BUDDHISM. (F. MA.)

BODHIVAMSA (MAHABODHIVAMSA): *see* PALI LITERATURE.

BODICHON, BARBARA LEIGH SMITH (1827–1891), English leader in the movement for the education and political rights of women, was born at Watlington, Norfolk, on April 8, 1827. In 1857 she married an eminent French physician, Eugène Bodichon, continuing, however, to lead the movements she had initiated on behalf of English women. In 1869 she published her *Brief Summary of Laws of England Concerning Women,* which had a useful effect in helping forward the passage of the Married Women's Property act. In 1866, co-operating with Emily Davies, she proposed a scheme for the extension of university education to women. and the first small experiment, a college at Hitchin, developed into Girton college, Cambridge, to which Mme Bodichon gave liberally of her time and money. She studied under the English artist William Henry Hunt, and her water colours showed originality and talent. She died at Robertsbridge, Sussex, on June 11, 1891.

BODIN, JEAN (1529 or 1530–1596), French political philosopher whose exposition of the principles of stable government was widely influential in Europe when medieval systems were giving place to centralized states, was born at Angers, the son of a master tailor. At the age of 15 or 16 he was professed in the Carmelite house at Angers, and three years later he was sent to the house of his order in Paris to complete his education. In 1551, however, he was dispensed from his vows—the circumstances are a matter of conjecture—and went to the University of Toulouse to study civil law. There he remained, as student or teacher, until 1561. That year he abandoned the teaching of law for its practice and returned to Paris as *avocat* du *roi,* just as the civil wars between Catholics and Huguenots were starting. In 1571 he entered the household of the king's brother, François, duke of Alençon, as master of requests and councilor and was there brought into contact with persons in the inner circle of the administration and diplomatic service. He himself only appeared once on the public scene, and that was as deputy of the third estate for Vermandois at the estates-general of Blois in 1576. His disinterested conduct on that occasion lost him royal favour. He opposed the projected resumption of war on the Huguenots in favour of negotiation with them; he also opposed the suggested alienation of royal domains as damaging to the monarchy; and he defended the right of the third estate to dissent from the recommendations of the two privileged orders. When, therefore, the duc d'Alençon died in 1583, Bodin retired to Laon as *procurateur* to the presidial court. He remained there until 1596 when he died of the plague.

Bodin's fame as a writer on law and politics had already spread abroad. The outcome of his academic years was the publication in 1566 of the *Methodus ad facilem historiarum cognitionem,* a scheme for the determination of the universal principles of law by a critical examination of the whole known field of history. But the bitter experience of civil war and its attendant anarchy turned his attention to the problem of authority. Anarchy, he came to think, is the supreme human catastrophe, order the supreme human need, and in the *Six livres de la République* of 1576 he examined the conditions under which order may be secured. He thought the secret lay in the recognition of the sovereignty of the state. His conception was Roman in origin, but removed from its particular historical setting and generalized. Supreme power is the distinctive mark of the state. It is unique, absolute in that no limits of time or competence can be placed upon it, and self-subsisting in that it does not depend for its validity on the consent of the subject. Governments command by divine right because government is instituted by Providence for the well-being of men. It is essentially a power to command, expressed in the making of lams in which are included all such other functions as the authorization of all appointments to office and the conduct of foreign relations. In the well-ordered state, this power is exercised subject to the principles of divine and natural law; in other words, the commands of the decalogue are enforced, and certain fundamental rights, liberty and property, are secured to the subject. But should these conditions be violated, the sovereign still commands with authority as well as power since he may not be resisted. The whole duty of the subject is obedience. He has no right of resistance to the sovereign power that he had no part in instituting, or to the law that he had no part in making, however tyrannical either might be.

There are only three types of commonwealth—monarchy, aristocracy and democracy—according to whether sovereign power lies in the one, in a minority, or in the majority. But each may have a government whose form exhibits the characteristics of one of the other types. In his search for order, the combination that Bodin preferred as the most stable was a monarchy functioning through democratic machinery. Such combined the strength that comes from unity with the strength that comes from popularity, since estates or parliaments are means whereby the king can keep in touch with the grievances and aspirations of his people.

These analyses, to the 16th century so original and so illuminating. won Bodin immediate fame. His book went through ten editions in his own lifetime, and he himself published a Latin version in 1586. It was also translated into Italian, Spanish, German and English. Its influence was marked well into the 17th century—on Thomas Hobbes and the English royalist writers. for instance. But Bodin himself devoted more than half the book to the urgent practical problem of order and examined exhaustively the causes of disruption in the various types of commonwealth and the means to their several preservation. One of his most original themes was the importance of climate. Laws must conform to the temperament of the people, and that is the product of environment—of which the essential constituents are temperature, humidity and configuration; environment determines not only physique but moral and intellectual aptitudes. Laws and institutions therefore are to be judged by relative, not absolute, standards of suitability. Such speculations did not appeal to a century that was essentially doctrinaire, and they attracted little notice. In retirement at Laon he turned his attention away from politics to religion, and composed the *Heptaplomeres,* a colloquy between a Catholic, a Calvinist, a Lutheran, a Muslim, a Jew, a theist and an Epicurean, with the object of finding a universally agreed religion. It is discovered in the decalogue. All else is demonstrated to be a matter of individual predilection. The detachment with which the argument was developed was so remarkable that it had to wait for publication until 1841, though the book circulated in manuscript soon after Bodin's death. Among his other works are *Responsio ad Paradoxa Malestretti* (1588), explaining the 16th-century revolution in prices, and a cosmological work, *Universale Theatrum Naturae* (1594).

BODLEY, SIR THOMAS (1545–1613), English diplomat and man of letters, founder of the library of Oxford university called, after him, the Bodleian, was born at Exeter, March 2, 1545. His father had gone abroad to avoid persecution as a Protestant during Mary's reign, and Thomas was educated in Geneva. The family returned to England on Elizabeth I's accession and he entered Magdalen college, Oxford. In 1563 he became a fellow of Merton college and in 1569 was elected university proctor. He also held office as deputy orator. He had shown considerable aptitude for languages, and in 1576 he went abroad for four years to enlarge his experience, with the expressed intention of devoting the rest of his life to the service of the state.

In 1584 Bodley entered parliament for Portsmouth. and in the following year was sent to Denmark and Germany, in an attempt to form a league to help Henry of Navarre. In 1588 he went on a secret mission to France and soon after his return was made resident minister at The Hague. The difficulties of his position there were complicated by the intrigues of the queen's ministers at home, and he repeatedly asked to be recalled. He was finally allowed to return in 1596, and, although proposals for his becoming secre-

tary of state continued to be made until 1605, he insisted on retiring from public life.

In retirement Bodley's mind turned to Oxford. Being equipped with wealth, learning and leisure, he determined to refound the university library, established in 1327, enlarged by Humphrey, duke of Gloucester, but almost destroyed by the commissioners appointed under Edward VI to inculcate university reform. His offer was accepted in 1598, and the library was opened on Nov. 8, 1602, with 2,000 books. Not surprisingly Bodley was eager to acquire Protestant theology, but all fields of learning then recognized were represented. He solicited help from wealthy and learned friends in England and abroad and in 1610 made an agreement with the Stationers' company for the presentation of a copy of every work registered by them. This hastened the library's rapid growth, and the first extension was begun in the same year.

Bodley had married a rich widow in 1587, but had no children. He was knighted in 1604 and died in London, Jan. 28, 1613, being buried in Merton college chapel. In his will, which left most of his fortune to the library, he made specific provision for its further enlargement *(see* also LIBRARIES).

Sir Thomas wrote his own life to 1609, which was published with the first draft of the statutes drawn up for the library, along with his letters to the librarian, Thomas James, in T. Hearne's *Reliquiae Bodleianae* (1703). His *Letters . . . to Thomas James* (1926) and *Letters . . . to the University of Oxford* (1927) were edited by G. W. Wheeler.

See also *Trecentale Bodleianum,* published for the Bodleian library (1913). (X.; G. M. B.)

BODMER, JOHANN JAKOB (1698–1783), Swiss-German critical writer, who contributed greatly to the development of an original German literature in Switzerland, was born at Greifensee near Ziirich on July 19, 1698. He was professor of Helvetian history in Ziirich from 1725 until 1775 and from 1737 a member of the *Grosser Rat.*

He published (1721–23), in conjunction with J. J. Breitinger (1701–76) and several others, *Die Diskurse der Mahlern,* a weekly journal after the model of the *Spectator.* Through his prose translation of Milton's *Paradise Lost* (1732) and his successful endeavours to make a knowledge of English literature accessible to Germany, he aroused the hostile criticism of J. C. Gottsched (*q.v.*) and his school, and a controversy arose which ended in the complete discomfiture of the latter.

Bodmer's most important writings are the treatises *Von dem Einfluss und Gebrauche der Einbildungskraft* (1727); *Von dem Wunderbaren in der Poesie* (1740); and *Kritische Betrachtungen über die poetischen Gemalde der Dichter* (1741), in which he pleaded for the freedom of the imagination from the restriction imposed upon it by French pseudo-classicism and for descriptive poetry in general. He was also engaged in studies of Shakespeare, Tasso, Dante and Cervantes, translated Homer (in hexameters), rediscovered the importance of medieval German poetry *(Minnesang, Nibelungenlied, Parzival),* espoused the causes of Montesquieu and Rousseau and thus played a part in European literature as a precursor of J. G. von Herder. In his own country he was an influential national educator, J. K. Lavater, H. Fuseli and J. H. Pestalozzi being among his pupils. As a poet he was unsuccessful.

Bodrner died at his farm near Ziirich on Jan. 2, 1783.

BODMIN, a municipal borough and county town in the Bodmin parliamentary division of Cornwall, Eng., 32 mi. W.N.W. of Plymouth by road. Pop. (1961) 6,209. Built of local stone and granite, it lies at the southwestern end of Bodmin moor, a granite mass covered by peaty moorland. The site, on the main Land's End road, is near what seems to have been a transpeninsular route between the Fowey and Camel estuaries. There are traces of Roman mining settlements of the 1st–2nd century A.D.; in the vicinity there are many archaeological remains. Bodmin's history begins with the arrival in the 6th century of St. Petroc, whose 12th-century ivory reliquary is preserved in the church. The rich and powerful Augustinian priory dedicated to him, of which only a few stones remain, held the manor at the time of Domesday Book. The Perpendicular church of St. Petroc, rebuilt in 1469–72 and greatly restored in the 19th century, is the largest in Cornwall. The town, recorded as a borough in 1190, was finally incorporated in 1553. It was a market for tin and wool in the reign of Edward II and a "coinage" town for taxing tin bars.

Three Cornish risings centred in Bodmin: in 1497 Cornish tax rebels were led by two Bodmin men and defeated at Blackheath; Perkin Warbeck had himself crowned Richard IV at Bodmin; and in 1549 a revolt against the new Prayer Book was stamped out there.

Many of the county institutions are at Bodmin, which is the assize and quarter sessions town, while Truro has the county offices and the cathedral. There are no significant industries, but Bodmin is the centre of an agricultural area. The largest employer of labour is St. Lawrence's hospital.

BODO (BÅRÅ), a race of tribes in Assam, India, divided roughly into two groups, the western consisting of the Chutiya, Plains Kachari, Rabha, Garo, Mech, Koch, Dhimal and Haijong tribes, the eastern of the Dimasa or Hill Kachari, Hojai, Lalung, Tippera and Moran tribes. The Bodo race were formerly dominant in Assam, where a Chutiya kingdom was destroyed by Shan invaders *(see* SHAN) who set up the Ahom kingdom in its place in the 13th century. The Chutiyas practised human sacrifice, but the general features of Bodo customs may be inferred from the accounts of Kacharis (*q.v.*), Garos and Tipperas. Most of the Bodo tribes have now become superficially Hinduized, and it has been suggested that the Tantrik beliefs, for which the Hinduism of Assam is conspicuous, are based on Bodo belief and custom which has permeated and coloured the superimposed religion *(see* MAHAYANA: *Doctrine).* The languages belong to the Tibeto-Burmese family.

BODONI, GIAMBATTISTA (1740–1813), Italian printer and type face designer, father of the "modern" style of type introduced into the U.S. in about 1912 and popular in the early 1960s in newspapers and books. Bodoni, the son of a printer, was born Feb. 26, 1740, at Saluzzo in Piedmont. He became a compositor for the press of the Propaganda and later was placed in charge of the printing house of the duke of Parma. Under Bodoni, the Parma printing house became well known throughout Europe.

The intrinsic value of his editions is seldom equal to their outward splendour. His Homer, however, is a truly magnificent work; and his Greek letters are faultless imitations of the best Greek manuscript. His editions of the Greek, Latin. Italian and French classics are all highly prized for their typographical elegance. and some of them are not less remarkable for their accuracy. Bodoni died at Padua on Nov. 30, 1813.

In 1818 a magnificent work appeared in two volumes quarto. entitled *Manuale Tipografico,* containing specimens of the vast collection of types that had belonged to him. The style of type named after Bodoni is classified as "modern" although Bodoni designed it about 1798. The classification refers to the design features, rather than to the age of the type. As shown in the following specimen

This is set in 10 point Bodoni bold

the thick main strokes and thin secondary strokes provide extreme contrast in Bodoni. Other identifying characteristics are the thin, straight serifs and the lengthy ascenders and descenders.

See De Lama, *Vita del Cavaliere Giambattista Bodoni* (1816); Bertieri, *L'Arte di Giambattista Bodoni* (1913).

BODY AND MIND. To human beings reflecting on their own nature, it seems clear that each man has two distinguishable aspects. Certain of his qualities and activities belong to him as a physical body and are observable by others and in an obvious sense spatially localized, but there are also processes within him which are known to himself alone and not obviously connected with any physical organ; *e.g.,* unspoken thoughts, wishes and feelings. Since these processes are not publicly observable and not

easily localized, they are thought of as nonphysical and it is a short step to refer them to some nonphysical entity, which is their subject, as the body is the subject of physical activity. This is called the mind (*nous*) or soul (*psyche*). Anaxagoras (*q.v.*) seems to have been the first in western philosophy to make this dualism of body and mind explicit, although it is doubtless implicit in earlier thinking. Plato states it clearly, especially in the *Phaedo* Mind-body dualism has always been attractive as leaving open the possibility of human survival of death. The body obviously perishes, but the mind or soul may be immortal.

Natural and attractive though it is, dualism presents logical difficulties because of the close and inescapable connection between mental and purely bodily functions. Aristotle was aware of these difficulties and, in his *De Anima,* put forward a theory of the soul as the form (*q.v.*) of the body. This seems to be a sort of behaviourism, according to which the soul is inseparable from the body. An exception is made, however, in favour of the intellect (*nous*), which Aristotle regards as separable from the body.

This somewhat unsatisfactory compromise was in general adopted in the middle ages as being in accordance both with the facts of biology and with the demands of religion. The problem became acute in the 17th century, which first saw the hope of presenting physical nature as a closed system: it is revealed in its sharpest form in the works of Descartes (*see* especially *Meditations* ii and vi). Descartes found himself maintaining three propositions which, taken together, are incompatible: (1) that physical nature is a closed system, or, in other words, that all physical events are completely explicable in terms of physical laws; (2) that the mind is a substance of a different nature and separable from anything physical; and (3) that every mind is in intimate causal connection with some physical body.

Subsequent discussions have been largely determined by a desire to escape from this impasse. Interactionists reject the first proposition; the second is denied, although in different ways, by epiphenomenalists and by behaviourists; and the third is abandoned by parallelists.

Interactionism.— This theory commends itself to unsophisticated common sense and is also the presupposition of much religious thinking. It does not logically require the theory of a mind-substance. All that is logically presupposed is that mental events are distinguishable from physical events; but in order to complete his theory the interactionist must indicate the relation holding between mental events when they belong to the same mind or person. The essential thesis is that mental events can be both caused by, and causative of, physical events: *e.g.,* that in sensation the physical causes the mental and in volition the mental causes the physical event. There is, however, an ambiguity in the word "cause." Many philosophers since Hume have maintained that the word as used in science can mean no more than "invariable antecedent." There is no intelligible or necessary connection between cause and effect. Empirical investigation is the only way to find out causal relations. and, conversely, the empirical evidence of invariable precedence or concomitance is sufficient to establish a causal relation. (*See* **CAUSALITY.**) On this view it seems clear that interactionism is correct, since the evidence for invariable connection between mental and physical in both directions is extremely good. Attacks on interactionism have been made (1) by philosophers using a stronger notion of causation and (2) in the interests of a specific scientific theory.

An example of the first type of objection is to be found in the reasons which led the occasionalists and Spinoza to reject Descartes's theory of interaction. They demanded intelligibility in the causal relation and held that the condition of intelligibility was likeness between cause and effect. Since Descartes had denied any properties in common between mental and physical. it seemed that no causal connection was possible. This consideration led to the parallelism of Spinoza (*see* below) and to occasionalism (*q.v.*).

The second type of objection appeals to some recognized principle of physical science (*e.g.,* the conservation of energy) that is held to be logically incompatible with the proposition that mental events produce physical changes. Such objections have great force when the principle in question is of high generality and is well supported. They are not, however, logically conclusive. It may be pointed out that these principles are not logically necessary truths but rather scientific postulates or conventions and therefore modifiable under sufficient pressure from empirical facts. Alternatively it may be argued that, with a suitable understanding of the terms involved, the principle is not incompatible with interaction; *e.g.,* that mental-physical causation does not involve the transference of energy and so is compatible with the principle of conservation of energy.

Epiphenomenalism.—Epiphenomenalism (*q.v.*) involves the following propositions: (1) that physical nature is a closed system and all physical changes, including those taking place in human and animal bodies, are explicable in terms of physical laws alone; and (2) that the notion of causation involves that of explanatory force, so that only physical processes can properly be regarded as causes of physical changes, and mental events, being superfluous from the explanatory point of view, cannot be accepted as causes of change in the human body. Perhaps the meaning of the theory can best be grasped by consideration of an analogous relation which is sometimes thought to hold between primary and secondary qualities. For example, the chemical changes caused by light may be explained entirely in terms of its primary qualities (*i.e.,* wave length and frequency): its actual colour as perceived, being irrelevant to scientific explanation, is thus a mere epiphenomenon. This may be more than an analogy, as many philosophers hold that the secondary qualities exist only in relation to consciousness.

It may be argued against epiphenomenalism that it involves a logical incoherence. For the notion of explanatory cause on which it relies is that of the determination of events in accordance with laws, and laws of nature are established only by means of empirical correlations. Now empirical correlations are in fact found of the four types. physical-physical, physical-mental, mental-physical and mental-mental. In principle, therefore, laws of any of these types may be used in explanation, and the preference of the epiphenomenalist for the first two types rests partly on considerations of economy and partly on determination to be hard-headed.

It may also be objected that the epiphenomenalist cannot explain the emergence of mental phenomena in the evolutionary process, in which they are inefficacious and therefore useless.

The epiphenomenalist may reply to the second objection that mental phenomena are the inevitable, although otiose. accompaniments of physical developments which themselves have survival value; *e.g.,* the extreme complication of the brain tissues. To the first objection there is no complete logical answer; but it may be said that, while the choice of explanatory laws is to some extent arbitrary, it is both more economical and more fruitful to regard physical correlations as fundamental. This approach has led to the most spectacular advances in physical science in general and in medicine in particular. The force of this reply is somewhat weakened, however, by developments in psychiatry: for instance, in the treatment of mental illness by psychoanalysis.

Behaviourism.—Behaviourism (*q.v.*) in its crude form is the denial of the existence of mental processes. It thus dissolves the problem, but is patently false. A more subtle form has been developed by some philosophers with the help of the technique of linguistic analysis. Their thesis is that the language that we use in referring to "mental processes" in fact refers not to events different in kind from bodily processes but to these same processes in a more complicated way. For example, in attributing understanding to a man we are not ascribing some peculiar inner process to him but referring in a shorthand way to certain capacities, tendencies and dispositions to overt action. Although this thesis has been applied with considerable success to some of the mental concepts, it breaks down in the attempt to explain sensation and mental imagery. The reason is that sensing and imagining involve events which are inescapably "inner" or private, so that a full account of them cannot be given on the behaviouristic view. But it appears that the occurrence of such "inner" events is part of what we mean to assert by attributing a mind to an organism. If this is so, it follows that behaviourism cannot give a complete account of mind.

Parallelism.— This theory was first worked out by Spinoza.

He begins with the thesis that there can be no causal connection between the totally disparate. Therefore, like the epiphenomenalist, he regards physical nature as a closed system; but, unlike the epiphenomenalist, he regards psychical nature also as a closed system. Each complete event occurring in a human being has a mental and a physical side or component, and neither of these is to be regarded as a cause or explanation of the other. Nevertheless, since there is a complete correlation between the mental and the physical, it is possible, once the laws of correlation have been worked out, to infer from the occurrence of a physical to the occurrence of a mental event and vice versa. It appears that parallelism, in order to be consistent, must be universal and so involve panpsychism, the theory that all physical events have a mental side and that all physical objects in some sense have "minds"; for if mental events cannot be caused by physical events, it is impossible that mind which was not present from the beginning should have manifested itself in the course of the evolutionary process. But panpsychism is made possible only by an immense and unplausible extension of the notion of unconscious mind, such as is found in Leibniz. Without this, universal parallelism is inconsistent with the facts. Even in animals and human beings there appear to be many physical events which have no mental correlates. This consideration has led some thinkers to adopt a narrower form of parallelism; that is, a parallelism between mental and cerebroneural events. This, however, is difficult to distinguish from epiphenomenalism.

Supplementary Arguments.—It is now necessary to mention certain empirical discoveries which are or have been thought to be relevant to the problem.

The first is the verification of the evolutionary hypothesis, especially with regard to the descent of man. This renders untenable any theory which, like that of Descartes, makes a sharp division between man and other animals, by attributing to man a peculiar kind of soul substance. If universal parallelism is to be rejected, the evolutionary hypothesis seems at first to favour the interactionist; but if he is to make good his case against the epiphenomenalist, he must be able to point to some respect in which the possession of consciousness is favourable to the survival of the organism. This is more difficult than would at first appear. The capacity to discriminate between distant objects, for example, which is given by sight, is obviously advantageous; but it seems clear that the same advantage would be gained if the organism had a capacity to respond in a discriminating way to different objects such as that which a self-directing machine has. Again, processes akin to ratiocination can be completed by machines. If the facts of evolution are to be cited in support of interactionism, it is consciousness of the process, not simply the possession of certain faculties, that must be shown to favour survival.

Secondly, the construction of self-directing and self-correcting machines *(see* N. Wiener, *Cybernetics,* 1948) has been thought by some to be relevant to the mind-body problem. The relevance of these facts, however, is indirect. The occurrence of "intelligent" or "goal-directed" behaviour in machines does not tell in favour of behaviourism. It rather seems to make clear the distinction between the concept of mentality and that of goal-directed activity, for however successful and complicated the behaviour of machines, we do not attribute minds to them. It does, however, tell indirectly in favour of epiphenomenalism, as showing that consciousness of such behaviour is irrelevant to its efficiency.

Thirdly: arguments for parallelism or epiphenomenalism have been drawn from the discovery of the detailed correlation between brain events of certain types and mental events of certain types. More specifically, neurophysiologists have succeeded in mapping the areas of the brain. stimulation of which is correlated with the different types of sensory experience. By direct stimulation of the brain in the appropriate areas it is possible to produce, for example, visual sensation without the normal stimulus via the eye and the optic nerves. The areas of the brain which are involved in the movement of the various parts of the body have also been located. Logically the facts in question seem to be capable of interpretation on any theory, and some of their discoverers, as C. S. Sherrington. E. D. Adrian and J. C. Eccles, have interpreted them in an interactionist manner. *(See* BRAIN.)

Finally. the empirical data collected in the study of psychical research and parapsychology (*qq.v.*) seem to indicate that mental events are governed by laws independent of the laws of physics and thus to tell in favour of interactionism. It seems clear that the type of fact generally referred to by the terms "telepathy" and "clairvoyance" cannot be explained in terms of physical or physiological laws known at present, but it is by no means certain that they could not be accommodated by an epiphenomenalist theory. Moreover the situation is logically complicated by the fact that the more securely clairvoyance and telepathy are established as natural phenomena, the more difficult it is to produce a near-decisive proof of human survival after death, the one piece of empirical evidence which would tell decisively in favour of interactionism. Phenomena formerly interpreted as communications from the dead can often be explained in terms of paranormal cognition by the living.

It will be seen from the foregoing discussion that the problem is not purely scientific but also metaphysical; it cannot be completely solved on empirical grounds, and a decision in favour of one theory or another must rest partly on the interpretation of the key terms, such as "cause."

BODY-SNATCHING, the secret disinterment of dead bodies in order to sell them for purposes of dissection. Prior to the licensing of medical schools and legal provisions for making cadavers available for anatomical study, "resurrectionists" did a lucrative business, and it mas prudent to protect the graves of the newly buried against violation. Body-snatching was a misdemeanour at common law. *See* CORPSE. (B. CE.)

BODY TEMPERATURE: *see* ANIMAL HEAT.

BOECE (BOYCE), **HECTOR** (*c.* 1465–*c.* 1536), Scottish historian and humanist, author of an important Latin history of Scotland, was born at Dundee about *1465.* He was educated at Dundee and the University of Paris, where he was appointed regent (professor) of philosophy in the college of Montaigu and became a friend of Erasmus, who in two epistles wrote of him in the highest terms. The chief adviser of William Elphinstone, bishop of Aberdeen. in the foundation of Aberdeen university, he was its first principal and was in Aberdeen about *1500* when lectures began in the new buildings. As principal he read lectures on divinity: he received a small pension from the court (*1527–34*), was a canon of Aberdeen, vicar of Tullynessle and then rector of Tyrie.

His first work, *Episcoporum Murthlacensium et Aberdonensium ... Vitae,* was printed at the press of Jodocus Badius (Paris, *1522).* The portion of the book in which he speaks of Bishop Elphinstone is of enduring merit; it includes an account of the foundation and constitution of the college and some notices of its earliest members. But Boece's fame rests on his history of Scotland, *Scotorum Historiae a prima gentis origine* (Paris, *1527;* Scots trans. by John Bellenden, *q.v., Croniklis of Scotland,* ?1536). The *1527* edition contains *17* books: another edition *(1574)* containing the 18th book and a fragment of the 19th, was published by Ferrerius, who added an appendix of *35* pages. Boece's history is no mere chronicle, for he knew and copied Livy. It is a glorification of the Scottish nation, based on legendary sources, and is more interesting as romance than as history. Raphael Holinshed embodied an English version of Bellenden by William Harrison (*q.v.*) in his *Chronicles (1578)* and thus the plot of Shakespeare's *Macbeth* is traceable to it. It had a wide currency abroad through its French translation, by Nicolas d'Arfeville, and coloured French ideas of Scottish history for a long period.

Boece professed to have obtained from the monastery of Icolmkill, through the good offices of the earl of Argyll and his brother John Campbell of Lundy, the treasurer, certain original histories of Scotland, including that of Veremundus, of whose writings nothing is now to be found.

BIBLIOGRAPHY.—Bellenden's Scots trans. was reprinted for the Ban-

natyne Club (1821) and the earlier ms. version first printed for the Scottish Text Society in 2 vol., ed. by R. W. Chambers, E. C. Batho and H. W. Husbands (1938—for 1936—and 1941): William Stewart's verse translation, The *Buik* of the *Croniclis of* Scotland (completed c. 1535) was issued in 3 vol., in the "Rolls Series," ed by W. B. D. Turnbull (1858). Vol. 1 of a 16th-century Scots manuscript version found at Mar Lodge, Braemar, now in the Pierpont Morgan library, New York, was first printed for the Scottish Text Society in 1946 (for 1943). *Episcoporum . . .* Vitae was reprinted for the Bannatyne Club (1825) and trans by J. Moir for the New Spalding Club (1894). A commonplace verse rendering of the Life of Bishop *Elphinstone,* written by Alexander Gardyne in 1619, remains in manuscript. (X.; N. D.)

BOECKH, AUGUST (1785–1867), the German professor who helped more than any other man of his period to enlarge the scope of classical scholarship, was born at Karlsruhe on Nov. 24, 1785. As a student at Halle under F. A. Wolf, and as a young lecturer and (1807) professor at Heidelberg alongside the comparative mythologist F. Creuzer, he learned to value the contribution which knowledge of Greece and Rome makes to the history of culture. In 1811 he became professor of classical literature at the new University of Berlin where he remained until his death on Aug. 3, 1867.

His talents were unusually varied. A good Greek scholar, he had a gift for mathematics and a solid interest in the details of social history. During his formative years at Heidelberg he made his mark with an edition of the pseudo-Platonic dialogues; but he also wrote papers on Plato's Timaeus, showing the impact of astronomical hypotheses on cosmology, and a treatise which discussed the changes introduced by actors into the Greek tragedies. The publication of his Pindar made him famous. The first volume (1811) transformed the appearance of the text, rejecting the traditional division into short lines, and founded the scientific study of Greek metres in their relation to music. The second volume (1821), containing the schoiia, was less revolutionary, and after that Boeckh abandoned textual criticism except for occasional articles and a mediocre edition of Sophocles' *Antigone* (1843). Philosophy likewise claimed less of his attention, though he produced an article on Plato's cosmology (1852). His love of mathematics combined with his interest in antiquities to attract him to new fields. With his Staatshaushaltung der Athener (1817; Eng. trans., The *Public* Economy of Athens, 1828) and treatises on the Laurium silver mines, on the weights, coinage-standards and measures of the ancients and on inscriptions about the Athenian navy (1840), he placed Greek economic history on a firm basis. He continued his study of the astronomers, and a fine series of monographs, of which *Zur* Geschichte der Mondcyclen der Hellene? (1855–56) was the most important, elucidated the obscurities of classical chronology.

These extensive researches were pursued simultaneously with a great public enterprise. In 1815 the Berlin academy decided to publish a Corpus *inscriptionum* Graecarum with Boeckh as editor. The first volume appeared in 1828. It was followed in 1843 by the second, prepared with the help of J. Franz, and in 1853 and 1877 by two others in which Boeckh had little part. The work has been severely criticized, for Boeckh accepted incorrect transcripts and his restorations were often unjustified, so each volume required supplements almost as soon as it was printed. For all that, the Corpus must rank as a great achievement. Its topographical classification was eminently sound. it brought together material previously scattered in a number of inaccessible sources, and subsequent advances in epigraphy could hardly have occurred without its help.

Boeckh also deserves to be remembered for his brilliant attempt to formulate systematically the aims of classical scholarship. His recommendations are embodied in the *Encyklopedie* und *Meth*odologie der *philologischen Wissenschaften* edited from his lectures by E. Bratuscheck (1877). There the classical scholar's task is defined as the reconstitution of the mental world of Greece and Rome, not only from written memorials, but from art, institutions, customs and history. This catholic concept owes a plain debt to Hegel, but it had a value independent of its idealist presuppositions. It provided a much-needed counterweight to the rigidities of G. Hermann (*q.v.*) and his school who took a purist pride in limiting their work to textual criticism and interpretation. Some at least of the credit for the impressive strides made in classical learning outside the purely linguistic field since the early 19th century must go to Boeckh's imaginative teaching and example.

BOEHMITE, alpha alumina monohydrate, is one of two known alumina monohydrates; the beta-form is diaspore (*q.v.*). It is a common constituent of bauxite (*q.v.*), particularly the bauxites of Europe, accompanied chiefly by iron oxide and clay minerals. The pure mineral contains 85% alumina and 15% water, whereas a typical boehmite-bauxite may contain 70% alumina. Western hemisphere bauxites commonly contain only a few per cent of boehmite, gibbsite (*q.v.*) predominating.

Artificial boehmite with properties of the natural mineral can be prepared from gibbsite by dehydration or hydrothermally, or by direct precipitation from solutions.

Boehmite bauxites are treated by the Bayer leaching process, using more drastic conditions than for gibbsite bauxites. Following selective solution of boehmite, alumina is reprecipitated as gibbsite for further treatment for production of aluminum or alumina chemicals. On calcination, boehmite passes through possibly three essentially anhydrous intermediate phases, including gamma alumina, until, at around 1,200° C., alpha alumina (corundum) is formed. The exact nature of the intermediate phases is not known but is of considerable interest to chemical, ceramic and catalyst industries because of certain adsorptive properties. (See also ALUMINUM.)

Boehmite is orthorhombic; refractive indices are uncertain but the mean value approximates 1.64. Cleavage is pinacoidal. Specific gravity is 3.01 to 3.06 (artificial), and hardness is about 4. The formula is $Al_2O_3.H_2O$ or AlOOH. (W. K. GR.)

BBEOTIA (mod. Gr. VOIOTIA), a district of ancient Greece, now comprising most of the modern prefecture (nomos) of the same name, with its administrative centre at Levadhia (Lebadea). The modern district extends farther than the ancient Boeotia in the northwest to include part of ancient Phocis (*q.v.*). Boeotia is bounded by Attica on the southeast, by the Gulf of Corinth on the south, by Phocis (mod. Gr. Fokis) on the west. by Locris (Fthiotis or Phthiotis) on the north and by the Gulf of Euboea on the east. Area 3,174 sq.km. (1.225 sq.mi.). Pop. (1961) 114,474.

Boeotia is entered through the Cephisus (Kifisos) valley. It has two extensive fertile plains separated by a low ridge, an outlier of Mt. Helicon or Elikon (5,735 ft.), on which Thebes (Thivai) stands. The northern plain is a lacustrine basin, now drained, containing Lake Copais (Kopais), which the Cephisus river inundates unless the underground channels (katavothrai) are kept clear. The southern plain is watered by the Asopus (Asopos) river. The plains being shut off from the sea by foothills, the climate is torrid in summer and raw in winter. The soil is rich and suitable for crops (wheat, cotton, tobacco, olives, grapes) and pasture. The main road through Greece enters Boeotia at Parapotamii (Anthokhori or Belesi) between Mt. Parnassus (*q.v.*; 8,061 ft.) and Mt. Cnemis (Knimis; 3,000 ft.), and passes through Thebes and over Mt. Cithaeron (Kithairon; 4,623 ft.) to Attica. It is thus a fertile district of strategic importance historically.

History. — Paleolithic and Neolithic settlements occurred in the northern plain; and Early and Middle Bronze Age peoples (the latter speaking Greek) occupied both plains. Mycenaean Boeotia was second only to the Argolis in the eastern Peloponnese. The Cadmea (the citadel of Thebes), and in northern Boeotia the treasury of Minyas at Orchomenus (*q.v.*) and the castle of Gla or Goulas show the strength of its rulers; and mythology tells of Minyas. Cadmus, Heracles and Oedipus, and of the sack of Thebes (*q.v.*) a generation before the Trojan War (see TROY AND TROAD). A new people appeared before and after the Trojan War, the Boiotoi, who gave their name to the country, Boeotia instead of Cadmeis. This generation may have composed epic poems from which the *Iliad* of Homer (*q.v.*) descended; for they spoke Aeolic, the dialect in which epic originated, and their cities were men-

tioned first in the catalogue of Greek ships in the second book of the *Iliad,* together nith the name Boiotoi. The tradition of epic survived in the work of the Boeotian poet Hesiod (*q.v.*).

In classical times Boeotia was famous for music, lyric poetry such as that of Pindar (*q.v.*) and political experiment. Although the population was partly Aeolic and partly northwestern Greek in origin. many cities combined to form about *550* B.C. the Boeotian league of which the coinage carried a shield as the emblem of unity in defense and religion. While Thebes led the federal movement and Orchomenus led the separatist states, Athens intervened in *519* B.C. to annex Plataea (*q.v.*) as well as Hysiae and Eleutherae, small states on the frontier between Athens and Thebes, and defeated the Boeotians in *506* B C. Enmity between Athens and Thebes influenced Thebes and most of Boeotia, excepting Thespiae (*q.v.*), in siding with Persia during the invasion of Xerxes in *480,* and the victorious Greeks punished Boeotia by disbanding the Boeotian league. A period of weakness ensued during which Sparta restored the league and Athens destroyed it again, setting up democratic governments in the cities (457 B.C.). But in *446* B.C. the cities rebelled, joined the Spartan alliance and reconstituted the Boeotian league, which entered the Peloponnesian War (*q.v.*) on Sparta's side. Their victory over Athens at Delium *(424 B.c.)* established their military reputation and justified an independent policy. The Boeotian league led the rising against Sparta in the Corinthian War *(395–386* B.C.), but Persia's support of Sparta resulted once again in the dissolution of the Boeotian league.

Meanwhile the Boeotian league had developed from the 6th-century alliance of sovereign states into a close-knit confederacy, organized in *11* wards by *431* B.C. Each ward, comprising one or more cities, returned a general *(boeotarclt),* several judges and many councilors to the federal government, which consisted of four councils uith sovereign authority. One council in turn prepared the business for the assembly of all four councils. Later, about *400* B.C., a single council was instituted, its *660* members being returned by the 11 wards. Indirect representative government of this kind was called oligarchical by the Greeks, and the cities in the wards were also oligarchically governed. the franchise being limited to the propertied classes. Thebes held a predominant position in the league. The council met there; and Thebes. having reduced its neighbours to tributary status, controlled four of the wards and supplied the finest contingent to the federal army. But in *382* B.C. Sparta treacherously occupied the Cadmea and held Thebes in bondage.

The revival of Thebes began in *379* B.C. when together with Athens it challenged the supremacy of Sparta *(see GREECE: Ancient History).* Two brilliant Thebans. Pelopidas and Epaminondas *(qq v.)* and the Boeotian hoplites destroyed Spartan power and challenged Athens' supremacy at sea *(371–362* B.C.). The Boeotian league revived on a democratic system. All Boeotians, whatever their property. were members of an assembly convened at Thebes, and their vote decided all matters of policy. Executive officials, elected in the wards which were now reduced to seven (Thebes controlling three), were answerable to the assembly of Boeotians. This experiment of direct rule by an electorate numbering at least *25,000* men was at first eminently successful. Other districts under federal systems contracted alliance with Boeotia: Aetolia, Acarnania, Phocis and Thessaly in central Greece, and Arcadia and Achaea in the Peloponnese. But this great block of military power was soon split by imperialist ambitions. and the Boeotian league itself destroyed Orchomenus *(363)* and intervened in the Achaean league *(366)* and the Arcadian league *(362).*

Decline set in rapidly when Phocis hired mercenary troops and ravaged Boeotia *(354)* in the Sacred War which Philip II of Macedonia ended in *346* B.C. as an ally of Thebes. Although the hfacedonian alliance might have been profitable, Boeotia chose to join Athens in the fight for Greek independence and her finest troops—the sacred band of Thebans—fell to a man in the battle of Chaeronea *(338).* The Boeotian league was again dissolved and a Macedonian garrison controlled Thebes. In *335* B.C. when Thebes rose for the second time against Alexander the Great of Macedonia, it nas destroyed on the order of the Greek league with the connivance of Alexander. Thereafter Boeotia had little history. It passed under the control of the Aetolian league and the Macedonian kings, and suffered from the general decline which Roman government brought to Greece.

BOER, Dutch form of the English word "boor," in its original meaning of husbandman or farmer (Ger. *Bauer*), a name applied to South Africans of Dutch or Huguenot descent, especially to early settlers of Transvaal and the Orange Free State (*qq.v.*) and their descendants. *See* SOUTH AFRICA. UNION OF: *History.*

BOERHAAVE, HERMANN *(1668–1738),* Dutch physician and professor of medicine who was the first great clinical, or "bedside," teacher. was born at Voorhout near Leiden on Dec. *31, 1668,* and died at Leiden on Sept. *23,* 1738. He graduated in philosophy at Leiden and in medicine at Harderwyck. He spent the whole of his professional life at Leiden, being professor of botany and medicine, rector of the university, professor of practical medicine and professor of chemistry. His genius so raised the fame of the University of Leiden, especially as a school of medicine, that students came to it from all parts of Europe. Through his pupils he exerted an influence on later medical teaching at Edinburgh, Vienna and in Germany, and because of this influence he is often credited with founding the modern system of medical instruction. *(See MEDICINE,* HISTORY OF: *Boerhaave.)*

His principal works are *Instztutiones medicae (1708); Aphorismi de cognoscendis et curandis morbis* (1709), on which his pupil and assistant, Gerard van Swieten (1700–72), published a commentary in five volumes; and *Elementa chemiae (1724).*

BOER WAR: *see* SOUTH AFRICAN WAR.

BOETHIUS, ANICPUS MANLIUS SEVERINUS (*c.* 480–524), Roman scholar, philosopher, theologian and statesman, author of the celebrated work *De Consolatione Philosophiae* ("On the Consolation of Philosophy"), belonged to the Christian family of the Anicii, of whom one member, Olybrius, had been emperor in 472. After the early death of his father, who had been consul in *487,* Boethius was brought up in the house of Q. Aurelius Memmius Symmachus. a senator of high intellectual and moral qualities, whose daughter Rusticiana he married. After holding some of the highest offices in Italy under the Ostrogothic king Theodoric (consul in 510, possibly head of the senate and, above all. *magister officiorum* or head of the civil and other services *c.* 520–522) and after greeting in the senate his two young children as joint consuls in 522, he was accused of conspiring against the king in favour of the eastern emperor Justin I. He mas accused of supporting the senator Albinus in his dealings with the emperor, of writing subversive letters and of magic practices. The religious situation at that time made such accusations plausible, and Boethius' position is not completely clear in spite of his self-defense in *De Consolatione Philosophiae.* Imprisoned, probably in Pavia *(in agro Calventiano),* in 522 and perhaps tortured, he was put to death in 524. Two centuries later he was reburied in the church of S. Pietro in Ciel d'Oro in Pavia; and his remains seem to have remained there ever since, except for an interruption between 1799 and 1923 (when they were in the cathedral). Boethius was held as a martyr and a saint; a local cult of him was approved by the ecclesiastical authorities. His contemporaries regarded him as a man of profound learning: the grammarian Priscian speaks of him as having attained the summit of honesty and of all sciences; Cassiodorus, who succeeded Boethius as *magister officiorum,* employs language equally strong; and Ennodius, the bishop of Pavia, knows no bounds for his admiration. During the middle ages, the influence of Boethius was very powerful, because he had preserved much of the culture of later antiquity.

Writings.—Boethius' writings can be grouped under four headings: (1) theological treatises; (2) works on the four "arts" of the *quadrivium,* arithmetic, geometry, music and astronomy; *(3)* logi-

cal norks; and (4) the philosophical and poetical *De Consolatione Philosophiae.*

Five theological treatises have survived: the first, *De Trinitate;* the second, *Utrum Pater et Filius et Spiritus Sanctus de divtnitate substantialiter praedicentur;* the third, *Quomodo substantiae, in eo quod sint, bonae sint, cum non sint substantialia bona;* the fourth, *De Fide catholica,* which would seem to be authentic, thoughdoubts have been expressed about it; and the fifth, *Contra Eutychen et Nestorium.* (A work entitled *Hebdomades* has not been preserved.) The *De Trinitate* and *Contra Eutychen et Nestorium* are the two most important of these five and seem to be connected with the "Scythian" controversy of 519–521 (a sequel to the termination of the Acacian schism; *see* PAPACY). In the *De Trinitate* Boethius tries to explain philosophically the apparent absurdity of the unity-and-trinity of God on the basis of the Aristotelian categories: God is substantially—or rather, supersubstantially—one, while the three Persons are internal relations (these conclusions are confirmed in the second treatise listed above). In the *Contra Eutychen* two opposite doctrines, according to which either the double nature in Christ implies a duplicity of substance or the unity of substance implies a single nature, are tentatively answered by means of subtle distinctions between the concepts of essence, substance. etc., and of the definition of *persona* as *naturae rationabilis individua substantia.*

Of Boethius' writings on the four advanced arts of the medieval curriculum, the *De Institutione arithmetica* and *De Institutione musica,* both of them adaptations and re-elaborations of Nicomachus of Gerasa's Greek handbooks, have survived entire. The *Geometria,* a translation or elaboration of Euclid's *Elements,* is almost completely lost; and nothing remains of Boethius' work on astronomy (based, Cassiodorus says, on Ptolemy).

Boethius' vast production in the field of logic is preserved almost complete: only his translation of Aristotle's *Posterior Analytics* and possibly some commentaries on Aristotelian works seem to have disappeared. This logical corpus includes: translations of Porphyry's *Isagoge* and of Aristotle's *Categories, De Interpretatione, Prior Analytics, Topics* and *Sophistici Elenchi;* two commentaries on Porphyry's work, one on Aristotle's *Categories,* two on the *De Interpretatione* and perhaps parts of a commentary on the *Prior Analytics;* an incomplete commentary on Cicero's *Topica;* an elementary treatise on categorical syllogisms, partly in two recensions *(Prolegomena,* often wrongly called *Introductio ad syllogismos categoricos,* and the actual *Introductio* in two books. wrongly called *De Syllogismo categorico)*; a treatise *De Syllogismo hypothetico;* a short treatise on different kinds of classification, *De Divisione;* and the *De Differentiis topicis,* in which Cicero's and Themistius' systems of *"loci dialectici et rhetorici"* are compared with each other. Most of what is included in the commentaries and treatises probably derives from the teachings of the Porphyrian school.

The *De Consolatione Philosophiae,* which Boethius wrote when he was in prison waiting for the execution of his death sentence, is his best title to fame as a writer and as an independent philosopher. In its five books, poems in various metres—some of them of considerable literary value—alternate with longer sections in prose, often rhetorical and sophisticated, sometimes full of dignity, occasionally moving. Dry philosophical arguments are expounded in florid language. Boethius exhibits there the Neoplatonism and the Stoicism which he had imbibed in Rome (most probably he never was in Athens—as many believed in the past—or in Alexandria—as was later suggested by P. Courcelle). Since the work deals with philosophy and with what might be termed natural theology, Boethius ignores the possibility of finding consolation in any Christian belief; but there is nothing in the work to suggest that Boethius was not a Christian when he was writing it. The first book opens with a few verses, in which Boëthius describes how his sorrows had brought him to a premature old age. As he is thus lamenting. a majestic woman, whom he recognizes as his guardian Philosophy, appears. Resolving to apply the remedy for his grief, she questions him for that purpose. She finds that he believes that God rules the world, but does not know what he himself is; and this absence of self-knowledge is the cause of his neakness. In the second book. Philosophy presents to Boethius Fortune, who enumerates the blessings that he has enjoyed and then proceeds to discuss the unsatisfactory blessings that are bestowed by her. In the third book, Philosophy promises to lead him to true happiness, which is to be found in God alone: since God is the highest good and the highest good is true happiness, God is true happiness. Nor can real evil exist, for God is all-powerful, and since He does not wish evil, evil must be nonexistent. In the fourth book, Boethius raises the question why, if the governor of the universe is good, evils exist and why virtue is often punished and vice re arded. Philosophy proceeds to show that in fact vice is never unpunished, nor virtue unrewarded. From this, Philosophy passes on to a discussion of the nature of providence and fate and shows that every fortune is good. The fifth and last book raises the question of man's free will and God's foreknowledge and, by an exposition of the nature of God, attempts to show that these doctrines are not inconsistent: the conclusion is that God remains a foreknowing spectator of all events and that the ever-present eternity of His vision agrees with the future quality of our actions, dispensing rewards to the good and punishment to the wicked.

BIBLIOGRAPHY.—The collected works of Boëthius were printed by J. P. Migne in *Patrologia latina,* lxiii–lxiv (1847). For special editions of texts see *De Institutione arithmetica* and *De Institutione musica,* ed. by G. Friedlein (1867); *Commentarii in Aristotelis περὶ ἑρμηνείας,* ed. by C. Meiser (1877–80); *In Isagogen Porphyrii conzmenta,* ed. by S. Brandt (1906); *Theological Tractates,* ed. by H. F. Stewart and E. K. Rand, with Eng. trans. (1918; with reprints); and *De Consolatione Philosophiae,* ed. by G. Weinberger (1934) and by A. Fortescue (1925). Notable English translations of the *De Consolatione Philosophiae* were made by King Alfred, by Geoffrey Chaucer and by Queen Elizabeth I; for a modern version *see* that by *H.* R. James (1906).

BOETHUS (fl. 2nd century B.C.), Greek sculptor of the Hellenistic age, was probably a native of Chalcedon. He was noted for his production of metal objects and for his representation of children, especially for a group of a boy and a goose, of which several marble copies survive.

See M. Bieber, *The Sculpture of the Hellenistic Age,* pp. *81* ff. (1955); G. Lippold, *Handbuch der Archaologie,* III, i, p. 328 (1950).

(C. C. V.)

BOG is soft, spongy, water-logged ground, compcsed of vegetation, chiefly mosses (during the early history of the bog) in various stages of decomposition. Though the term hog is widely used to mean almost any wet surface covered with vegetation, plant ecologists and geographers use it in a more restricted meaning. A bog is an area which has no external drainage or almost none. Vegetation begins to accumulate and continues to accumulate indefinitely. As it partially decomposes and becomes compressed by the weight of the overlying material, it forms a layer of organic material called peat (*q.v.*).

In some cases the peat in a bog is almost pure organic material; in other cases it may be mixed with small quantities of mineral matter washed in from the sides of the depression. If there is open water (a pond or small lake) in the depression. the edges will be invaded by a floating mat of vegetation, commonly water lilies and sedges. This floating mat thickens from both the top and the bottom and eventually will become sufficiently solid and thick to support a man. Bushes and branched shrubs gradually invade the area. followed by tamarack. Animal life is usually rather scarce in bogs.

Water movement in a bog is at a minimum, and so, even as the surface rises as a result of accumulations of peat, erosion does not remove the material; consequently organic accumulations in the bottoms of peat bogs can reach considerable thickness.

(W. C. C.)

BOGAZKOY, a Turkish village (pop., 1960, 1,539) about 125 mi. E. of Ankara, near the ruins of ancient Hattushash (Hattusas), capital of the Hittite empire. The remains consist of a large fortified city on a steep slope enclosed by deep ravines and falling northward more than 800 ft. from summit to base. Much of the city wall, its towers, gates and subterranean passages are still visible above ground. Five temples, the largest in the northern and lowest quarter of the city, have been excavated, as well as the acropolis (now Buyuk kale), formerly the residence of the great kings of Hatti. Three royal archives of clay tablets written in cuneiform (in Babylonian, in Hurrian, in Hittite and in some local Anatolian languages) constitute the main source of information on Hittite history and culture. The one was found in 1907 in the above-mentioned large temple, the two others in 1906 and in 1931–33 in the acropolis. A rock face (Nishan Tash) in the higher quarters of the town bears an inscription of the great king Suppiluliumas in nine lines of Hittite hieroglyphs.

Bogazkoy was first inhabited in the later phase of the 3rd millennium B.C.; *i.e.*, in pre-Hittite times. During the 19th century B.C., under the name Khattush, it was a trading centre for Assyrian merchants, who lived side by side with the local inhabitants. Old Assyrian business tablets and storerooms of this period in the northern part of the town were excavated in 1938 and 1953. Shortly after 1800 B.C. Khattush, which was the residence of King Pijushtish, was stormed by Anittas, the Hittite king of Kussara, and laid in ruins. But in the 16th century B.C. the Hittite capital was transferred to Hattushash (the Hittite name of Bogazkoy). The Hittite kings had their residence there for more than three centuries, with the exception of King Muwatallis (1315–1290), who, probably on strategic grounds, preferred Dattassa, a town in southeastern Asia Minor. Hattushash, considerably enlarged and strengthened about 1400 B.C. (at the time when the Hittite empire gained the position of a great power on an equal basis with Egypt and Babylonia), came to an end shortly after 1200 B.C. The so-called "Peoples of the Sea," wandering seafarers of the Aegean, probably in alliance with Anatolian peoples who had formerly been vassals of the Hittites, overthrew the Hittite empire and ruined the capital. Many traces of that event have been found everywhere in the city. Later occupation of the spot in the Phrygian, Hellenistic and Roman periods was unimportant. The former opinion that the Pteria of Herodotus was identical with Bogazkoy was not confirmed by the excavations.

About one mile to the east is a sculptured rock grotto, called Yazilikaya. Between it and the town Hittite burials (and also traces of cremation) were found in 1952, on the site of what was evidently the necropolis of Hattushash. In the grotto are two natural chambers of different sizes adorned with reliefs, 67 in the large gallery, 15 in the small. In front of the rock chambers, excavations in 1938 brought to light architectural constructions, laid out essentially on the same plan as Hittite temples. The reliefs of the rock temple, the most important known specimens of imperial Hittite monumental art (14th and 13th centuries B.C.), show in the big chamber two processions, one of gods and the other of goddesses, arranged according to their rank in the Hittite (or Hurrian ?) pantheon.

The small chamber may have been the mortuary temple of a Hittite king Tudhaliyas. Two reliefs of great kings also are carved in the rock of Yazilikaya. See also HITTITES.

BOGNOR REGIS, a seaside resort and urban district in the Chichester parliamentary division of West Sussex, Eng., 65 mi. S.S.W. of London by road. Pop. (1961) 28,144. Hotham house and Dome house (now a teachers" training college) were built about 1792 by a London merchant who made Bognor fashionable. "Regis" commemorates King George V's convalescence at Craigweil house (now demolished) in 1929. The town, which has long sandy beaches, dates from the 18th century, the mother parish being South Bersted.

BOGOMILS (BOGOMILES), members of a religious sect that flourished in the Balkans between the 10th and 15th centuries. It arose in Bulgaria toward the middle of the 10th century from a fusion between a set of dualistic, neo-Manichaean doctrines imported from the near east, notably from the Paulicians of Armenia and Asia Minor, and a local Slavonic movement whose aim was to reform, in the name of an evangelical Christianity, the recently established Bulgarian Orthodox Church. The Bogomils were so called after their founder, the priest Bogomil, whose name is a Slavonic translation of the Greek Theophilus. Their doctrines and behaviour are described in detail by the Bulgarian priest Cosmas in his "Sermon Against the Heretics," written in Old Church Slavonic, probably soon after 972. Their central teaching, based on a dualistic cosmology, was that the visible, material world was created by the devil. Hence they denied the doctrine of the incarnation and rejected the Christian conception of matter as a vehicle of grace. They rejected baptism and the Eucharist, and spurned the cross, miracles, church buildings, the order of priesthood and the whole organization of the Orthodox Church. The moral teaching of the Bogomils was as consistently dualistic: if the visible world is the creation and the realm of the evil one, all contact with matter and the flesh, which are the devil's best instruments for gaining mastery over men's souls, should be avoided. The Bogomils consequently condemned those functions of man that bring him into close contact with matter, especially marriage, the eating of meat and the drinking of mine. In fact, until the 14th century, the moral austerity of the Bogomils invariably was acknowledged by their fiercest opponents; and they have been called with justification "the greatest puritans of the middle ages." Cosmas describes them as social anarchists and accuses them of spurning manual labour and of preaching civil disobedience.

During the 11th and 12th centuries Bogomilism spread over many European and Asian provinces of the Byzantine empire. The alarming growth of the heresy in Constantinople resulted, about 1100. in the trial and imprisonment of prominent Bogomils in the city and in the public burning of their leader, Basil, vividly described by Anna Comnena. The sect had by then gained many adherents in the aristocratic families of Byzantium. In the *Panoplia dogmatica* of Euthymius Zigabenus, composed about that time, the Bogomils are credited with a complex doctrinal system: a cosmology in which the Judaeo-Christian version of the book of Genesis is interpreted in a dualistic sense, by a sophisticated use of allegory and a strong admixture of unorthodox mythology; a Christology in which the classical docetism (*i.e.*, disbelief in the reality of the incarnation) of the early Bogomils and of the Paulicians is curiously allied with elements of the New Testament and a pseudo-trinitarian theology; a negative attitude to the Old Testament, combined with a readiness to use parts of it for exegetical purposes; and use of the allegorical method in interpreting scriptural texts in accordance with Bogomil doctrine.

In the second half of the 12th century Bogomilism spread westward. The Serbian ruler Stephen Nemanya (c. 1167–96) was obliged to summon a general assembly of his land to check this peril. More important still was its extension to Bosnia, where Bogomilism, modified and known as the Patarene or Bosnian faith, was embraced by the rulers and the nobility and developed, between the late 12th and the 15th centuries, into a national movement. About 1150 the influence of Bogomilism on the dualistic sects of Italy and France became clearly apparent. The Cathar or Albigensian movement was, in all probability, not simply an offshoot of Bogomilism but rather a revival of earlier heterodox trends in western Europe, to which Bogomilism gave a more coherent and

systematic form (see CATHARI). However, from the middle of the 12th century Bogomilism certainly exerted a direct and paramount influence upon the doctrines and the ritual of the Cathars, and by the early 13th century the dualistic communities of southern Europe formed a single network, stretching from the Black sea to the Atlantic.

In the country of its birth Bogomilism remained a powerful force until the late 14th century. The Bulgarian authorities convened several church councils, notably the Council of Trnovo (Turnovo) (1211), to condemn its teachings. But after the Ottoman conquest of southeastern Europe obscurity descended upon the sect. Many Bogomils, especially in Bosnia, were converted to Islam. A vague dualistic tradition that has left traces in the folklore of the Southern Slavs, and some curiously carved funeral monuments scattered in the mountains and forests of Bosnia and Hercegovina, are all that remain today of the most powerful sectarian movement in the history of the Balkans.

BOGOR, a foothill city in western Java, Indon., formerly named Buitenzorg ("without care") by the Dutch, and capital of a regency and residency of the same name. Pop. (1956 est.) 115,585. It lies about 30 mi. S. of Jakarta and 870 ft. above sea level. The climate is healthful with an annual average mean temperature of 77.7° F. The site for the city was chosen in 1745 by Governor General van Imhoff as a residence instead of Jakarta (then Batavia). Its famous botanical gardens were laid out in 1817 by C. G. E. Reinwardt, a former professor of botany at Amsterdam. and have become one of the world's outstanding centres of research, with an extensive scientific library, laboratory and zoological museum. Other scientific institutions at Bogor include the General Agricultural Experimental station, the Forestry Research institute, a laboratory for chemical research and an institute for rubber research. The former residence of the Netherlands Indies' governor general, built in 1856, is now the presidential summer residence and houses part of the president's art collection. Bogor is a residential town, many of its inhabitants working in Jakarta, to which it is connected by road and electric train service.

The residency of Bogor (4,483 sq.mi.) consists of the regencies of Bogor (1,437 sq.mi.), Sukabumi and Tjiandjur. Most of the residency is mountainous, with many volcanoes and fertile plateaus. The chief crops are rice, tea, cinchona (quinine), rubber and coffee.

BOGORAZ, VLADIMIR GERMANOVICH (1865–1936). Russian anthropologist, whose study of the Chukchi ranks among the great works of ethnography, was born in Ovruch, Volhynia, on April 27. 1865, and began his career at the University of St. Petersburg. He joined the revolutionary party, Narodnaya Volya (People's Will), and was arrested in 1886, imprisoned and then exiled to Siberia. While in exile in the Yakutia region he worked with Vladimir Jochelson on the ethnography and linguistics of the area. From his place of exile he also published poems and stories under the name of N. 4. Tan.

From 1895 to 1897 he was a member of the Sibiriakov expedition under the Russian geographical society to northeast Siberia. In 1900–01, when Franz Boas organized the Jesup North Pacific expedition under the program of the American Museum of Natural History, New York, Bogoraz was charged with responsibility for the Anadyr (northeast Siberian) section. At this time he gathered materials on the ethnography of the Chukchi. On his return to St. Petersburg in 1901 he was under police surveillance, and moved to New York, where he produced one of his greatest works, The *Chukchee*. He returned to Russia in 1904 where he helped organize the first peasant congress and the Labour group in the state duma.

In 1918 he was appointed professor of Leningrad university and curator of the Museum of Anthropology and Ethnography. The following year he organized the ethnographic faculty of the university with L. Y. Sternberg. During the 1920s and early 1930s he directed the work of the Arctic Institute of the Institute of the Peoples of the North in Leningrad. He published grammars, a dictionary, textbooks for Chukchi children, collections of folklore, ethnographic studies, historical sketches and a novel about the Chukchi. He also wrote on the folklore of the neighbouring Koryak. Finally, he produced a number of general studies of Siberian ethnography, folklore, and history, remaining outside the Communist party of the Soviet Union.

Bogoraz was a man of wide interests and creative activity in many spheres, both scholarly and political. He died in Leningrad on May 12, 1936. (L. K.)

BOGOTA (SANTA FE DE BOGOTÁ), the capital of the Republic of Colombia and of the interior department of Cundinamarca. Pop. (1961 est.) 1,256,640. The city is on the eastern margin of a large elevated plateau 8,563 ft. above sea level. Several streams, one of which, the San Francisco, passes through the city, unite near the southwestern extremity of the plateau and form the Rio Funza, or Bogota, which finally plunges over the edge at Tequendama, 20 mi. from Bogotá, in a perpendicular fall of about 475 ft. The city is built upon a sloping plain at the base of two mountains, Guadalupe and Monserrate, upon whose crests stand two imposing churches. From a broad avenue on the upper side, downward to the west, slope the streets, through which run streams of cool, fresh water from the mountains above. The north and south streets cross these at right angles, and the blocks thus formed are like great terraces. A number of well laid out plazas, or squares, ornamented with gardens and statuary, have been preserved; on these face the principal public buildings and churches.

Bogotá is the political, financial and social centre of the republic and has some industrial and considerable commercial activity. Railway lines connect the city with the major settlements of the plateau and the upper Magdalena river, and it is located on the Colombian portion of the Simón Bolivar highway which runs from Cucuta to the Ecuador border. Disadvantages resulting from Bogotá's isolated land position were alleviated to some extent by the development of air transport. Good air service is available to all the major cities of the republic and to international points.

Bogotá is an archiepiscopal see, founded in 1561, and is one of the strongholds of medieval clericalism in South America. It has a cathedral and about 30 other churches, some dating from the 16th century. It also has many old conventual buildings now used for secular purposes, their religious communities having been dissolved by Tomás Cipriano de Mosquera and their revenues devoted in great measure to education. The capitol, occupied by the executive and legislative departments, is an elegant and spacious building, erected after 1875.

Bogota has always taken an interest in education. and has been called the "Athens of South America." Its institutions of learning include a university, several colleges and schools, a public library, a national observatory, a natural history museum and a botanic garden. The plain surrounding the city is fertile and intensively cultivated; it pastures cattle and produces cereals, vegetables and fruit in abundance. It was the centre of Chibcha civilization before the Spanish conquest and sustained a large population. The Banco de la República has an outstanding collection of pre-Colombian gold objects.

Bogotá was founded in 1538 by Gonzalo Jiménez de Quesada and was named Santa Fe de Bogotá after his birthplace, Santa Fe, near Granada, Spain. To this was added the name of the locality used by the Chibchas. Bacatá, which in time was written Bogotá. It was made the capital of the viceroyalty of Nueva Granada and soon became one of the centres of Spanish colonial power and civilization on the South American continent. In 1811 its citizens revolted against Spanish rule and set up a government of their own. In 1814 Bolivar captured the city and the capital was transferred to Bogota. Bolivar departed early in 1815, and the following year the city was occupied by the Spanish general Pablo Morillo (1777–1838), who subjected it to a ruthless military gov-

ernment until 1819, when Bolivar's victory at Boyacá compelled its evacustion. On the creation of the republic of Colombia, Bogotá became its capital, and when that republic was dissolved into its three constituent parts Bogota remained the capital of Nueva Granada (which became officially Colombia in 1861).

(A. J.L.; J. W. Mw.; X.)

BOGRA (BAGURA), a town in the Rajshahi division of East Pakistan, the headquarters of Bogra district, is 57 mi. N.E. of Rajshahi, on the west bank of the Karatoya river, a tributary of the Jamuna. Pop. (1961) 33.799. Good communications make it the commercial centre for the southern part of the Barind tract between the Ganges and the Jamuna: it is at a major road junction and is on the metre-gauge railway from Santahar to Kurigram. It has a match factory and oil mills, and there is a nursery for sericultural development. It is the seat of Azizul Haq college, affiliated to Rajshahi university.

BOGRA DISTRICT is a level plain, crossed by many streams: lying west of the Jamuna. Area 1,502 sq.mi. The eastern part, between the Karatoya and the Jamuna, is low-lying and abounds in *khals* or water gullies and *jhils* or marshy meres; the west is higher and above the flood level. Almost all the population (1,574,105 in 1961) depends on agriculture, rice being the staple crop.

Seven miles northwest of Bogra lie the extensive mounds known as Mahasthan, which are identified by inscriptions going back to Mauryan times with the city of the Pundra kingdom, Pundranagara or Pundravardhana. Antiquities found there indicate that the city flourished throughout the subsequent centuries. while excavations revealed also rich remains of the Gupta and Pala periods, including many molded terra-cotta plaques. (K. S. AD.)

BOHEMIA (Czech CECHY, German BÖHMEN), a historic country of central Europe, bounded on the south by Austria, on the west by Bavaria, on the north by Saxony and Lusatia, and on the east by Silesia and Moravia. For centuries a kingdom, it was from 1918 to 1939 and from 1945 to 1949 the westernmost province of Czechoslovakia. On Jan. 1, 1949, however. the provincial organization was dissolved, and Bohemia lost its political identity, being divided among a number of new districts of the Czechoslovak state.

HISTORY

The Latin name of the country is derived from that of a Celtic tribe, the Boii (*q.v.*), who were supplanted by the Germanic Marcomanni in 8 B.C. It is probable that Slav peoples entered the country by the 1st century A.D., but the stages of Slav immigration cannot be reliably established. The most powerful of the Slav tribes were the Cechove (Czechs) who gradually subjugated other peoples in the area After their settlement in Bohemia the Cechove were in turn conquered by the Avars, but they succeeded in overthrowing their oppressors in the early years of the 7th century.

EARLY HISTORY TO 1526

The **Premyslid** Dynasty.—According to early tradition the founder of the first Czech ruling house was Premysl, a plowman, married to Princess Libuse (Libusa). The scanty records concerning Bohemia date from the 9th century, when several attempts made by German-speaking missionaries to introduce Christianity into Bohemia met with little success. The Slav tribes east of Bohemia were organized early in the 9th century into a powerful political unit known as Great Moravia (see MORAVIA). Invited in 863 by its prince, Rostislav, Cyril (Constantine) and Methodius, Greek monks from Salonika, came to preach the gospel there. Using the Slav language in religious instruction and in divine service, they secured a notable success, despite political maneuvers against them supported by the German ecclesiastics, advocates of the Latin rite, who claimed jurisdiction over the territory. From Moravia, Christianity spread rapidly to Bohemia and to other Slav countries. Some legends ascribe the conversion of the Bohemian prince Borivoj and his consort Ludmila to Archbishop Methodius. Some of Methodius' disciples moved to Bohemia and helped to establish the Slav liturgy in that country.

During the 10th century Bohemia was consolidated politically. After the collapse of Great Moravia *c.* 907, the western portion of that empire was attached to Bohemia and continued to exist as a province. The eastern half, inhabited by Slovak tribes, was annexed by Hungary. The rulers of Bohemia successfully defended their lands against their Germanic neighbours west and southwest. In the latter part of the 10th century Bohemia extended its frontiers into Silesia and the lowlands farther east. Of the Bohemian rulers at this period the best known was Borivoj's grandson Vaclav (St. Wenceslas). By his zeal in spreading Christianity he antagonized adherents of heathen concepts. In 929 Vaclav was murdered by his brother Boleslav I (929–967). After his death Vaclav was venerated as the patron saint of Bohemia. Under Boleslav II (967–999) the church in Bohemia was organized and a bishopric was founded in Prague (c. 973). At that time the Latin was replacing the Slav liturgy which by the 11th century had been completely supplanted. The second bishop of Prague, Voytech (Adalbert), tried to improve the standards of church life but found little understanding among his countrymen for his lofty ideals. Disillusioned, he left his diocese to inaugurate missionary activity among the heathen Prussians on the shores of the Baltic and suffered a martyr's death in 997.

The death of Boleslav II was followed by a period of fratricidal warfare between his sons which was terminated in 1012 when the youngest. Oldrich, established himself. By the death of Oldrich in 1037 much of the dynasty's territory had been lost to powerful neighbours, but with the accession of his son Bretislav I (1037–55) the tide turned again in favour of the Premyslid house The boundaries of Bohemia became stabilized and the process of internal regeneration was accelerated.

For about a century and a half, although the Premyslid family had no serious rivals within the country, feuds among its members hindered political development, the chief source of trouble being the absence of any strict law of succession. Whereas at some periods the principle of seniority was observed, the oldest member of the dynasty succeeding to the throne, at other times claims were made on the basis of a right of primogeniture. Dynastic rivalries not only caused domestic distress but also invited foreign intervention.

In the early period of its history Bohemia became dependent on the East Frankish kingdom. Later the German kings as emperors (see HOLY ROMAN EMPIRE) were able to exact tribute from the Bohemian princes, and the struggles over the succession served the emperors as justification for military intervention as well as for attempts to strengthen the ties linking Bohemia with the empire. Some princes co-operated with the emperors in military expeditions and were ultimately compensated for their services. Prince Vratislav II (1061–92) obtained from the emperor Henry IV the title of king of Bohemia (1085) as a personal privilege. Early in the 12th century the princes of Bohemia gained the dignity of a cupbearer to the emperor, one of the highest court offices. For personal participation in a campaign in northern Italy, Prince Vladislav II (1140–73) was awarded the royal crown by the emperor Frederick I Barbarossa (1158). Vladislav's gains were mostly dissipated by his successors under whom the Premyslid state was considerably weakened and temporarily divided. In 1182 Barbarossa, taking advantage of a disputed succession, was able to separate Moravia from Bohemia, but the division had no real or lasting significance.

In 1197 Premysl Otakar (Ottokar) I became undisputed overlord throughout the Premyslid domains, and in 1198 he was able to secure the royal title for his descendants as well as for himself. The imperial charter of 1212 granted by the emperor Frederick II and known as the golden bull of Sicily finally established the relationship between Bohemia and the empire and gained for the Bohemian king the right of investiture of bishops. Premysl Otakar I led his kingdom from depression to political prominence and economic prosperity. Under King Vaclav I (1230–53), colonists from abroad, mostly German-speaking, were invited to settle in royal boroughs and in the border areas. His son Premysl Otakar II (1253–78) was one of the greatest rulers of Bohemia. Through marriage he obtained possession of the Austrian lands, and in 1260 the nobility of Styria also recognized him as their

ruler. Both personal bravery and financial resources facilitated his penetration into other Alpine provinces. Before his opponents made a common front to check his advance Premysl exercised influence in Carinthia as well as in some territories along the Adriatic coast. The extension of his dominions involved Premysl in repeated wars with Hungary. In the battle of Kressenbrunn (Austria) in 1260, Premysl Otakar II decisively defeated Béla IV of Hungary. Another enemy, who appeared on the scene in 1273, proved more dangerous than the Hungarians. In that year Rudolf, count of Habsburg, was elected king of the Romans, and soon after claimed the Austrian lands as vacant fiefs of the empire. A war ended in Premysl's defeat (1276). He was obliged to surrender to Rudolf all territorial acquisitions, retaining only the inherited provinces of Bohemia and Moravia. Humiliated by harsh peace terms, he prepared for a new campaign. In 1278 he invaded Austria and attacked Rudolf's army, allied with the Hungarians, at Diirnkrut on the Marchfeld, but lost both the battle and his life (Aug. 26, 1278).

The years of trouble closed with the coronation of Premysl's son Vaclav (Wenceslas) II. Under him Bohemia quickly recovered from the catastrophe and again played an active part in international affairs. Diplomatic dexterity and enormous wealth, derived chiefly from silver mines. opened to Vaclav II the w y to Poland. After a few initial successes in Little Poland he obtained the Polish crown (1300). In 1301 he was seriously considered as a candidate for the vacant throne in Hungary. After his premature death in 1305, his only son Vaclav (Wenceslas) III inherited Bohemia, but he was assassinated on his way to Poland. Thus in 1306 ended the long rule of the Premyslid dynasty.

The Luxembourg Dynasty.— The Bohemian throne was contested by several candidates and finally, in 1310, the crown was offered to John of Luxembourg, son of Henry VII, king of the Romans. John was married to Eliska (Elizabeth), the second daughter of Vaclav II, and became the founder of the Bohemian branch of the Luxembourg house. His successors ruled in Bohemia for more than a century.

Soon after his succession John's German advisers were a cause of discontent to the Bohemian nobles and in 1318 they were finally dismissed. After this date John devoted little time to domestic affairs, the government of the country being virtually controlled by the Bohemian noble Henry of Lipa. The king was imbued with the spirit of chivalry and spent most of his life abroad, participating in numerous campaigns. John fell at Crécy (1346) fighting for the French. Under John and his successors new territories were acquired, mostly by peaceful means, and incorporated into the kingdom, which was made up of five provinces — Bohemia, Moravia, Silesia, Upper Lusatia and Lower Lusatia — and held a prominent position among central European countries.

To John's son and successor, Charles (see CHARLES IV). Bohemia owed more than to any of its earlier rulers. With John, Charles, who had been appointed administrator of the country in 1341, paved the way for the elevation of the bishops of Prague to the rank of archbishops (1344). Before succeeding to the Bohemian throne as Charles I (1346) he was elected king of the Romans as Charles IV, and in 1355 he was crowned emperor in Rome. He confirmed or revised the earlier documents regulating the relations between Bohemia and the empire, and issued charters stabilizing the position of the incorporated provinces under the Bohemian crown. He kept Bohemia at peace and contributed largely to the welfare of its inhabitants. By circumspect policy Charles re-established the balance between the royal authority and the aspirations of the landowning nobility. His efforts to codify the customary laws and to stabilize the legal system were opposed by the nobility, but he retreated without jeopardizing his prestige. Charles resided in Prague, and under him the city was enlarged by the foundation of a new district (*nove* mesto). Architects, sculptors and painters from other countries were employed by the king, the church and the wealthy noblemen. This gave rise to the flourishing of the late Gothic style in Bohemia and its sister provinces. In 1348 Charles founded at Prague a university which became a centre of intellectual activity. Charles died in 1378.

Under Charles's son Vaclav IV, crowned king of Bohemia already in 1363 and German king as Wenceslas (*q.v.*) from 1378, Bohemia lost much of its power. Internally it suffered from conflicts between the ruler and the lords. There were also struggles between the king and the hierarchy, represented by John of Jenstejn, archbishop of Prague. The movement for church reform that originated under Charles IV acquired under Vaclav IV such force that it dominated the history of Bohemia for several decades. An overwhelming majority of the Czechs espoused the reform program formulated by John Huss (*q.v.;* Czech, Jan Hus), and attempts to settle the conflict between the reform party and the hierarchy made no headway. In 1414 Huss accepted the invitation of Vaclav's brother. Sigismund, king of the Romans, to attend the Council of Constance (*q.v.*). He proceeded there with a letter of safe conduct guaranteeing his return issued by Sigismund, but was imprisoned, declared a heretic and burned on July 6, 1415. The inevitable and immediate result was the outbreak of civil war in Bohemia. Until 1436, when peace was made, Bohemian history is essentially the record of the Hussite wars (see HUSSITES).

KARLSTEIN CASTLE NEAR PRAGUE, ERECTED BY MATTHIAS OF ARRAS FOR CHARLES IV OF BOHEMIA. BUILT IN 1348–67, THE CASTLE WAS FULLY RESTORED IN 1888–97

George **of Podebrady.**—In 1436 Sigismund, who had inherited a claim to Bohemia on his brother Vaclav's death in 1419, proceeded to Prague and was accepted as king. He died in the following year (1437) and was succeeded by his son-in-law, Albert of Austria, whom the estates chose as their king. Albert died after he had reigned over Bohemia less than two years. Though it was known that Albert's widow, Elizabeth, would shortly give birth to a child, the question as to the succession to the throne again arose; for it was not until 1627 that the question whether the Bohemian crown was elective or hereditary was to be finally decided. The nobles formed two parties opposed to each other both in political and in religious matters. The Hussite lords from various parts of the country were organized, under Ptacek of Pirkstejn, to promote national interests. As a fairly large number of moderate Catholics joined them, they could be described as a national party. Many knights and the royal boroughs, both predominantly Hussite, also ranged themselves with this party. The other party represented conservative elements, mostly Catholics, although some moderate Utraquists (partisans of communion in both kinds) joined it. Oldrich of Rozmberk (Rosenberg) was the most powerful of the Catholic lords, but the actual leader of the conservative and pro-Habsburg nobles was Menhart of Hradec.

In 1440 the two parties came to an agreement known as the Letter of Peace, in which they pledged themselves to respect the

compacts of Prague (1433; see HUSSITES) and to work for the confirmation of John of Rokycany as archbishop of Prague, elected in 1433 but not recognized by the pope. In Feb. 1440, Queen Elizabeth gave birth to a son, known in Bohemia as Ladislav (Laszlo V of Hungary. also called Ladislas Posthumus). After protracted negotiations the estates of Bohemia recognized the rights of this infant in principle (1443), putting off a definite agreement on the terms of his admission to the throne of Bohemia. Ladislav remained in Austria under the guardianship of his uncle, the German king Frederick III, and Bohemia continued to be the scene of conflicts between the rival parties of the nobility.

After Ptacek's premature death in Aug. 1444 one of his followers, George of Podebrady (*q.v.*), assumed the leadership of the national party. For almost four years the course of public life in Bohemia was strongly influenced by the contest between Menhart of Hradec and the youthful Hussite leader.

The national party, representing a distinct majority of the population, made several agreements with its opponents to replace the outdated Letter of Peace of 1440. These efforts were hindered by Oldrich of Rozmberk who was in fact not interested in the establishment of a provisional government, fearing that George of Podebrady would play the leading role in it. Of the many provincial diets held at this period the most memorable was the general meeting of the estates of Bohemia, held in Prague during 1446. Delegates from the incorporated provinces of the kingdom (Moravia, Silesia and the Lusatias) joined with the estates of Bohemia. A committee representing three estates (lords, knights and the royal boroughs) prepared resolutions relating to political and religious conditions in the kingdom. Envoys were elected to ask Frederick III's permission for Ladislav to journey to Bohemia in order that he might be brought up among the Czechs. An attempt to elect a regent was frustrated by Rozmberk's intrigues. An attempt to obtain the pope's recognition of John of Rokycany was equally unsuccessful. Although members of the Catholic party agreed that a mission should be sent to Rome, they did not abide by the vote and used their influence to dissuade the papal court from granting concessions to their Utraquist opponents.

The meagre results of congresses and provincial assemblies convinced George of Podebrady that he would only be able to unify and pacify the country by defeating Menhart's party. He spent more than a year in consolidating the national party and, masking his preparations, assembled a considerable army in the second largest city of Bohemia, Kutna Hora (Kuttenberg). Then, instead of marching against unruly elements in the remoter parts of the kingdom, he attacked Prague, Menhart's chief stronghold, and surprised it early in Sept. 1448.

This military victory, which was soon followed by the death of Menhart, confirmed George's power and prestige. With his large following he was able to keep in check Rozmberk's partisans, who were to persist in opposition until Rozmberk's death in 1462. Although Rozinberk's faction tried to prevent an agreement between George and Ladislav's guardian, Frederick III, the latter was so impressed by George's power and political dexterity that he preferred to negotiate with him rather than with Rozmberk. In 1451 Frederick, as emperor, appointed George governor of Bohemia. Two years later Frederick III released Ladislav from his custody.

After his coronation on Oct. 28, 1453, Ladislav ruled in Bohemia with George's advice and effective help. As Ladislav could claim to be the rightful king and was known as a fervent Catholic, he was quickly recognized in the incorporated provinces and tightened their links with Bohemia. His reign, however, was cut short by his sudden death on Nov. 23, 1457. George was accused of having poisoned the adolescent king, but research has proved this accusation to be entirely unfounded. The throne was again vacant. Several foreign candidates, including Ladislav's brothers-in-law, William, duke of Saxony, and Casimir IV of Poland, presented themselves as candidates. The estates of Bohemia reaffirmed the elective character of the crown of Bohemia and on March 2, 1458 elected George of Podebrady king. As not only the Utraquists but also the Catholics voted for him, the election represented a considerable achievement.

In the early part of his reign King George was allied with Matthias I Corvinus (Mátyás Hunyadi), king of Hungary. Matthias sent to Bohemia two Hungarian bishops who crowned George king according to the rites prescribed by Charles IV. Thereafter. George's principal concern was to have his title recognized by the estates of the incorporated provinces. On the whole he succeeded, except with the Catholic and predominantly German city of Breslau (Wroclaw), capital of Silesia, though a provisional agreement with the municipality was reached late in 1459 with the help of papal envoys. In his home and foreign policy George was loyally supported by the Utraquists, especially the lesser nobility and the royal boroughs. For their benefit he attempted in 1452 to get the compacts of Prague solemnly sanctioned by Pope Pius II. When his petition was rejected, George assembled the estates at Prague in Aug. 1462 and declared his devotion to the Utraquist principle of communion in both kinds and his readiness to risk his life and crown in the defense of his faith.

In the ensuing conflict with the papacy George's following was considerably reduced. The city of Breslau repudiated the interim agreement and placed itself under papal protection. In 1465 a group of Catholic noblemen, headed by Zdenek of Sternberk, formed a hostile league at Zelena Hora (Griinberg) and entered into negotiations with Breslau and other Catholic centres. In the following year Pope Paul II granted his moral support to the confederates by excommunicating George and by releasing all Roman Catholic Bohemians from their oath of allegiance to him. It was also through papal influence that, in 1468, Matthias of Hungary deserted his former ally and gave his support to the league of Zelena Hora. Desultory warfare broke out between the two parties, in which George was at first successful; but fortune changed when the king of Hungary invaded Moravia and obtained possession of Brno, the capital. At a meeting of the Catholic nobles of Bohemia and Moravia at Olomouc (Olmiitz) in Moravia, Matthias was proclaimed king of Bohemia (May 3, 1469). In 1470 George obtained some successes over his rival, but he died on March 22, 1471. George of Podebrady, the only Hussite king of Bohemia, and Charles IV were the rulers of Bohemia who most endeared themselves to their countrymen.

Vladislav 11.—After protracted negotiations Prince Wladyslaw, son of Casimir IV of Poland, was elected king of Bohemia as Vladislav II at Kutna Hora, on May 27, 1471. This election was a victory for the national party, and may be considered as evidence of the strong anticlerical feeling in Bohemia. Matthias was an unconditional adherent of Rome, while the Polish envoys who represented Vladislav promised that he would maintain the compacts. The new king was involved in a struggle with Matthias of Hungary until 1478, when a treaty concluded at Olomouc secured Bohemia for Vladislav, Matthias retaining Moravia, Silesia and Lusatia during his lifetime, although they were to be restored to Bohemia after his death.

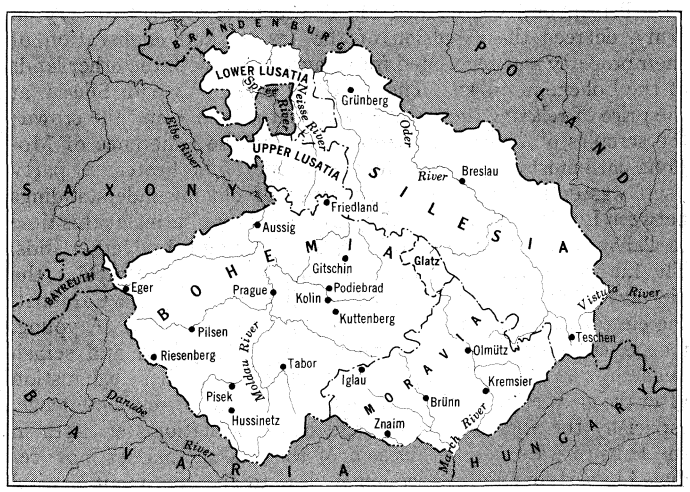
The reign of Vladislav was marked by a decrease of the royal prerogative, while the nobility attained an unprecedented power at the expense not only of the royal authority but also of the rights of the townsmen and peasants. Decrees of 1487 and 1497 practically established serfdom in Bohemia, where it had hitherto been almost unknown. It is impossible to exaggerate the importance of these measures for the future of Bohemia. The rulers of the country were thenceforth unable to rely on that numerous sturdy and independent peasantry of which earlier Bohemian armies mainly consisted. Various enactments also curtailed the rights of the Bohemian townsmen. It was tacitly assumed that the townsmen had no inherent rights, but only such privileges as might be granted them by their sovereign with the consent of the lords and knights. Civil discord was the inevitable consequence. Several meetings of the diet took place at which the towns were not represented. The latter in 1513 formed a confederacy to defend their rights. and chose Prince Bartholomew of Munsterberg—a grandson of King George—as their leader.

The Diet of St. **Wenceslas.**—Vladislav was elected king of Hungary (as Ulaszlo II) in 1490, and many of the events of his later life belong to the history of Hungary, where he died in 1516. His successor was his son Louis, who had already been crowned as king of Bohemia at the age of three. According to the instructions

of Vladislav, Sigismund, king of Poland, and the emperor Maximilian I were to act as guardians of the young king. The Bohemian estates recognized this decision, but they refused to allow the guardians any right of interference in the affairs of Bohemia. The great Bohemian nobles, and in particular the supreme burgrave, Zdenek Leo, lord of Rozmital, ruled the country almost without control. The beginning of the nominal reign of King Louis was marked by an event which had great importance for the constitutional development of Bohemia. At a meeting of the estates in 1517 knoan as the diet of St. Wenceslas they settled the questions that had been the causes of discord. The townsmen renounced certain privileges which they had hitherto claimed, while the two other estates recognized their municipal autonomy and tacitly sanctioned their presence at the meetings of the diet, to which they had already been informally reddmitted in 1508 At the first sitting of this diet, on Oct. 24, it was declared that the three estates agreed thenceforth "to live together in friendly intercourse, as became men belonging to the same country and race." In 1522 Louis arrived in Bohemia from Hungary, of which country he had also been elected king. He soon became involved in bitter conflicts with magnates competing for high offices in the kingdom. About the same time religious controversies flared up, echoing Martin Luther's activities. Some clerics in hitherto entirely Catholic German-speaking areas joined the Reformation, and some of Luther's ideas were also received sympathetically by resolute Utraquists. In 1525 King Louis returned to Hungary and opened his campaign against the Turks. He requested aid from his Bohemian subjects but only one faction of the nobility, headed by the lords of Rozmberk. granted the required subsidies, while their rivals, led by Leo of Rozmital, purposely delayed sending any forces to Hungary. There mere, therefore, but few Bohemian troops at the battle of Mohács (Aug. 29, 1526), at which Louis was decisively defeated and shortly after was drowned while retreating.

HABSBURG RULE, 1526–1918

Ferdinand I.—The crown left vacant by the death of King Louis was claimed by the archduke Ferdinand of Austria, by virtue of the hereditary rights invested in his wife Anna, Louis's sister, by the succession pacts concluded by Ferdinand's grandfather Maximilian. The Bohemian estates, however, denied these rights and claimed the exercise of their prerogative to fill the vacant throne by election. Ferdinand acquiesced, then outmaneuvered and defeated his most dangerous rivals, the dukes of Bavaria, and was unanimously elected on Oct. 23, 1526. The incorporated provinces (Moravia, Silesia and the Lusatias) of the Bohemian crown, however, which the Bohemian magnates had neglected to convoke for the electoral diet, revenged themselves by recognizing Anna and Ferdinand as their sovereigns by hereditary right. This national division enabled Ferdinand to refuse to sign the severest clauses of the electoral capitulation presented to him by the diet. In 1541, a fire having destroyed the state archives. Ferdinand. with the forced consent of the diet, substituted an act recognizing his wife's hereditary right instead of the act registering his election, and in 1547 he exacted from the diet a fresh confirmation of this recognition.



KINGDOM OF BOHEMIA FROM THE 14TH TO THE 17TH CENTURY

In consolidating and strengthening his position in Bohemia, Ferdinand first set about restoring the power of the monarch. The country had suffered so severely from anarchical conditions that it was in general grateful to a prince who could restore public order and security. Even the establishment of central authorities to direct the affairs common to all the sovereign's dominions (foreign relations, military organization, finance) encountered little opposition, as the measures decided by these authorities were executed in Bohemia only by the constitutional national authorities Where the king and the nation clashed was on the religious question, and the defeat of the nation resulted from its divisions.

Conditions in those parts of the kingdom of Bohemia which had been solidly Catholic had been changing rapidly since the appearance of Martin Luther. Among the German-speaking inhabitants of Silesia and of the Lusatias Lutheranism made rapid progress, and even the Hussite Church with its Czech membership was split under the impact of Luther's activities. The majority, usually designated as Neo-Utraquists. favoured close co-operation with the Reformed churches outside Bohemia. but the conservative minority clung to the hope of reunion with the Roman Catholic Church on the basis of the compacts. The Unity of the Czech Brethren constituted yet another religious body: founded about 1457, it had broken away in 1467 from both the Catholics and the Utraquists and had established its own clergy. The Unity was originally a tiny group, but it attracted new members, including some noble families, by its discipline and striving for the pure Christian life. Also must be mentioned radical groups like the Anabaptists, which had found refuge in Moravia after 1526 and were sheltered by wealthy lords. Ferdinand was fully occupied by the wars against the Turks and by urgent affairs in his other dominions and for 20 years he exercised little influence on religious developments in Bohemia but as a firm Catholic he was bound, when the time came, to favour his coreligionists. In 1546 Bohemia mas drawn into the great duel between the house of Austria and German Protestantism.

The Bohemian estates long wavered between resistance and obedience to the king, who summoned them to assist the cause of his house; finally (1547) the diet met unconvoked by the king, despite his express prohibition (which made its action revolutionary), drew up a list of demands which would have given it supreme power and reduced the king to a figurehead, and nominated a provisional directory. The defeat of the German Protestants at Miihlberg suddenly reversed the situation; it was now Ferdinand who dictated. His rigour was directed chiefly against the towns, which he had long considered the chief hotbeds of rebellion and heresy, particularly Prague. Their administrative autonomy was replaced by the authority of royal judges and, in Prague, of royal captains also, and their judiciary autonomy by a new royal court of appeal; and under pretext of revising old privileges, they were deprived of most of their domains. which passed to the king (who, however, later restored many of them). These measures impoverished the burgesses and rendered them politically impotent; thereafter, administratively and in the diet, the towns were puppets of the king. The nobles and knights most compromised also had their estates confiscated or reduced to fiefs. There were few death sentences; only two nobles and two burgesses were executed on the eve of the opening of the "bloody diet" (Aug. 22, 1547) which recorded Ferdinand's measures and again recognized that the crown was hereditary. The lords and knights had viewed without displeasure the humiliation of their old rivals, the towns, but this naturally increased their own dependence on the king. The latter was able partially and temporarily to repair his disorganized finances, out of the yield of the confiscated estates. Believing that he would easily master heresy in the Czech countries, Ferdinand proceeded with much rigour against the Czech Brethren whom he regarded as the ringleaders (together with the towns) in the revolt. Persecution, however, only enhanced the Brethren's courage and determination, and the diet of Moravia, where tolerance was general. opposed the king's demands. While Lutheranism increasingly

penetrated the Utraquist Church, Ferdinand thought to recover heretics by persuading the pope to concede communion in both kinds to lay persons (1564). He also introduced the Jesuits into Bohemia (1561), and their work prepared the generation which after the battle of the White Mountain realized Ferdinand's plans much more fully and boldly than he himself had conceived.

Maximilian II.—To ensure respect for the hereditary principle, Ferdinand had made the estates recognize his eldest son, Maximiiian, in 1549. This custom of recognition of the heir presumptive during the king's lifetime was again follow-ed in the cases of Maximilian's own three successors, his sons Rudolf and Matthias and the latter's nephew Ferdinand. As a young man, Maximilian had appeared favourably inclined toward the Protestants; but after his election as emperor (1564) he adopted his father's policy in a milder form. He readily accorded the diet the abrogation of the compacts, which, originally a guarantee of religious liberty, had become under Ferdinand an obstacle to the free development of Protestantism in its various forms, including the Unity; but he refused tc authorize the Neo-Utraquists to adopt the Augsburg Confession. In 1575 the Lutheran and Calvinist tendencies agreed on the text of a new confession, the Bohemian Confession. Maximilian managed to dissuade the estates from giving this legal sanction, and he persuaded them to content themselves with his word of honour to respect religious liberty and with the right of electing 15 "defenders" to watch over the liberty of the Protestant faith; promises which Rudolf repeated on his recognition as king. Maximilian died on Oct. 12, 1576. disappointed in his far-reaching international ambitions. He left the royal authority ueaker and less respected than he found it.

Rudolf II.—In the middle of the 16th century more than two-thirds of the population of Bohemia was Protestant (Neo-Utraquist or Lutheran) and one-tenth the Unity of the Czech Brethren. Rather more had remained Catholic, especially in southern Bohemia and Moravia; among the nobles, however, the proportion of Catholics was much higher (about one-fourth). As soon as the Counter-Reformation began, this Catholic minority gained in numbers and vigour; various nobles, including some great families, reverted to the old faith; the Catholic magnates began to impose their religion throughout their domains. While the old Utraquist Church, not adhering to the Bohemian Confession, fell into final collapse. the Czech Neo-Utraquists and the German-speaking Luthe-ans improved their organization and overcame their former doct-inal confusion The Unity of the Czech Brethren co-operated with he Neo-Utraquists in practical matters but worked out its oun system of doctrine, more of the Calvinist than the Lutheran type A selected group of scholars, inspired by the initiative of John Blahoslav, one of the most remarkable leaders of the Unity of the Czech Brethren, translated the Bible into Czech. It was published in six volumes in 1579–94 at Kralice at the expense of Lord John of Zerotin. It was re-issued several times and came to be known as the Kralice Bible. Though they were scholarly men, the Czech Brethren, with but few exceptions, were not experienced in worldly affairs and were numerically too weak to help the nation greatly in the impending struggle.

The religious divisions were partly the manifestation of social and national conflict. The economic evolution of the 16th century tended to enrich the magnates, who extended their great properties at the expense of the knights, while the cities decayed in consequence of the shifting of the great trade routes. The economic condition of the peasants improved slightly, but their legal status grew worse, the greater need of labour inducing the magnates to restrict increasingly their liberty of movement. The spread of Protestantism in Bohemia had attracted German immigrants, who advanced the linguistic frontier and forced the estates, first of Moravia, then of Bohemia, to issue laws in the early 17th century protecting the use of the Czech language in public life.

Rudolf II, with his unstable, suspicious and melancholy character and narrow Spanish upbringing. was not the man to pilot the kingdom through a formidable crisis. His arbitrary attempt to exterminate Protestantism in Hungary evoked István Bocskay's formidable rebellion, which forced Matthias, the king's lieutenant in Hungary, to sign the peace of Vienna with the rebels and that of Zsitvatorok with the Turks (1606). On Rudolf's refusing ratification. Matthias, supported by the Hungarian and Austrian magnates, rose against him; Moravia followed him, whereupon Bohemia remained faithful to Rudolf. The peace of Liben (1608) left Matthias in possession of Moravia and Austria, and recognized him as future king of Bohemia. The fratricidal struggle naturally profited the nobles; Matthias was curbed by a confederation of his new subjects, and Rudolf had to sign a series of articles designed to exclude all foreign influence from Bohemia and vest all real power in the diet. He demurred only to the religious demands; but, Matthias having yielded on this point, the diet of 1609 finally forced Rudolf to grant confessional liberty for the nobles and royal towns, liberty of conscience for all, a constitutional guarantee for the Bohemian Confession, appointment of the consistory by the estates and control of the university by defenders chosen by them. This famous charter, known as the *Majestat* (or "Letter of Majesty"; July 9, 1609), was accompanied by an agreement between Catholics and Protestants, indubitably sincere but so obscurely drafted that it afterward provoked disputes which developed into the rebellion of 1618. While the last remnants of the traditionalist Utraquist Church reverted to Catholicism. the new consistory was composed of Neo-Utraquists and the Czech Brethren. Because of the wisdom of Vaclav Budovec, the moral leader of the Unity, the new regime opened smoothly. Rudolf, whose sole thought was now revenge against Matthias, encouraged his cousin Leopold, bishop of Passau, whom he hoped to make his successor, to conspire with the Catholic magnates to cancel the *Majestat* and release his mercenaries upon Bohemia, which they invaded as far as Prague. The country rose against the invaders; Matthias came to the estates' assistance, who in turn elected him king of Bohemia on May 23, 1611, and Rudolf, who had betrayed all parties, had to abdicate (Aug. 11, 1611), dying soon after (Jan. 1612).

The Revolt.—Under Rudolf, Prague had been the capital of the Habsburg domains. Matthias moved the capital to Vienna, thereby confirming the estates in their suspicions and opposition. Nevertheless the diet of 1617 dared not refuse to recognize as their future king the archduke Ferdinand of Styria, Matthias' nephew, a pupil and docile instrument of the Jesuits. For several years, however, the leaders of the Protestant party had been in communication abroad to prepare a revolt; Bohemia was also affected by the situation in Germany, where conflict between the Catholic league and the Protestant union was growing acute. Violation of the promises contained in the *Majestat* regarding the royal and church domains and Matthias' action in entrusting the government to a council composed of fanatical Catholics brought the outbreak nearer. Rejection of the claims presented in March 1618 by the Protestant assembly legally convoked by the defenders in virtue of the *Majestat* led in May to the famous Defenestration of Prague, when the two most ardent Catholics of the council, Jaroslav of Martinic and William of Slavata, were hurled into the moat of the castle (being, incidentally, only slightly injured). The diet appointed a council of 30 directors, decided to levy an army, decreed the expulsion of the Jesuits and confiscation of their property and negotiated for an agreement with the other lands of the Bohemian crown. They reached agreement with Silesia, at the price of relaxing the ties between that province and the crown; the scruples of Charles of Zerotin delayed the adherence of Moravia until most of its importance was gone. The Protestant party itself was divided by the reappearance of old misunderstandings between Lutherans and the Czech Brethren, gravitating at this time to Calvinist centres in Switzerland, Germany and the Netherlands. The Lutherans were estranged when, on the death of Matthias, the diet again proclaimed the throne elective and invited a Calvinist, the elector palatine. Frederick V, to fill it (Aug. 1619). A young, inexperienced and weak sovereign; an undisciplined and selfish oligarchy; an inferior army and lack of foreign allies; exhaustion after the great effort of the 15th century; decline of self-confidence, especially the absence of what had been the nation's strength in the Hussite wars, the enthusiasm of the peasant masses, now reduced to serfdom and consequently deaf to any sentiment beyond that of their misery and social hatred—these causes explain the

defeat of the insurgents at the battle of White Mountain, at the gates of Prague (Nov. 8, 1620). Frederick, the "winter king," fled, followed by many of the magnates, abandoning the country to Ferdinand, who had become emperor in Aug. 1619, and to the Jesuits.

The Reaction, 1620–27.—Prince Charles of Liechtenstein, the new governor, presided over the political reaction, the papal nuncio, Giovanni Carafa, over the ecclesiastical. The execution in June 1621 of 27 real or alleged leaders of the revolt (3 lords, 7 knights, 17 burgesses) preluded the general confiscation of the rebels' properties, whereby three-quarters of the estates (excluding those of king and church) changed hands; this gigantic expropriation, which was attended by scandalous corruption, substituted for the old aristocracy new families, Spaniards, Walloons and Germans, who had furnished the emperor's mercenary officers. One of the most greedy and best favoured of them was the celebrated Wallenstein (*q.v.*). The concession of communion in both kinds was revoked, all pastors were expelled, and all Protestant schools were closed, and the ancient and glorious university, the entire conduct of public instruction and the censorship were all delivered to the Jesuits (1622). In 1625 the re-Catholicization of the towns by fines, prison and bailiffs began; by 1626 it was complete, at least outnardly. In 1627 all nobles refusing to adopt Roman Catholicism, nhich the new constitution proclaimed as the sole recognized religion, were expelled. Revolts of the peasants against conversion were fairly easily repressed. The serfs had not the last resort of nobles and burgesses who refused conversion--emigration. Thirty-six thousand families emigrated, comprising nearly a quarter of the nobility and urban population of Bohemia, the moral and intellectual flower of the nation. In 1627 Ferdinand enacted a new constitution. Absolute heredity was established, the practice of securing recognition for the future king disappearing; the estates were forbidden any legislative initiative on any important point; Roman Catholicism was proclaimed the sole religion; the clergy were constituted as the leading estate in country and diet; and German was admitted beside Czech as the official language. Legally, the Bohemian lands preserved their independent identity; actually, they were absorbed in the Habsburg monarchy, keeping their own administrative forms so long as they remained patrimonial, losing them increasingly as Bohemia was transformed into a modern state.

National Decline.—In 1648 the peace of Westphalia sanctioned internationally the policy practised by the Habsburgs in Bohemia since 1621. Its articles pertaining to Bohemia were a heavy blow for the Czech exiles who thereby lost the last hope of a restitution of ancient liberties to their homeland. Few of them returned, as the terms imposed by the ruler included recantation. The exiles were scattered throughout the Protestant world and a handful of them reached the shores of the "new world." The Neo-Utraquists and the Lutherans preferred Saxony to the more distant countries. Members of the Unity of the Czech Brethren moved either to Hungary or to Poland. Several prominent exiles settled in the Polish city of Leszno (Lissa). among them J. A Komensky (Comenius. q *v.*) who lived there from 1628. From Leszno, Komensky visited England, Sweden and Transylvania to advocate his schemes for educational reform. From 1656 to his death Komensky lived in Amsterdam, using his talents to advance learning and to edify the scattered members of the Unity. His death on Nov. 15, 1670. and his burial at Naarden marked the end of organized activities of the Czech emigration, and indeed of Czech intellectual life. Bohemia, exhausted by the wars and depopulation, was falling rapidly into misery and torpor. The peasant class, now sole representatives of the nation. were crushed under the yoke of greedy and brutal foreign adventurers. their new masters. The large landed properties, which formerly covered one-third of the country. now occupied two-thirds, while the estates of the knights and the towns had become insignificant. The population nas reduced by 50% or more. The peasant, with three days of corve'e (compulsory labour on the manorial estates) a week under the lam of 1680, rising to six at busy periods under that of 1738, his dues multiplied fivefold between 1660 and 1730, could hardly live, fell into debt and degenerated physically; frequent risings were brutally repressed. Czech fell to be a peasant tongue, German monopolizing polite society and public life. The old ties with Moravia, which gravitated increasingly toward Vienna, were reiaxed. In Slovakia. Czech gained a little ground, because of the Bohemian immigrants; and the Slovak peasants, with the Ruthenians, formed the bulk of the forces raised by the Hungarian rebel chiefs against the Habsburgs; but they were led in the name of Hungarian liberty, for the benefit of Magyar nobles. The reconquest of Hungary from the Turks, the peace of Szatmár, and the adoption of the pragmatic sanction (1720 in Bohemia), guaranteeing the succession of Maria Theresa, further strengthened the position of the dynasty and consolidated the unity of the Habsburg monarchy.

(O. O.)

Period of Enlightened Despotism, 1740–90.—In the early years of Maria Theresa's reign, by the treaties of Breslau (1742) and Dresden (1745), the Bohemian crown lost to Frederick the Great of Prussia the rich province of Silesia, except for the three duchies of Troppau, Teschen and Jagerndorf *(see* AUSTRIAN SUCCESSION, WAR OF THE). At the same time the last fragments of Bohemian independence were diminished by various reforms which inaugurated the administrative centralization of the Habsburg lands. In 1749 the Bohemian chancellery was merged with that of Austria in Vienna, and in 1751 local administration, such as it was, nas reorganized, being removed from the control of the nobles represented in the Bohemian and Moravian diets and placed within that of a bureaucracy based on Vienna. The fact that, when Charles Albert of Bavaria had temporarily occupied Prague in 1741 with the intention of establishing his claim to the empire, many members of the Bohemian nobility had done homage to him was something that Maria Theresa did not forget. Centralization was carried through with all the more zeal in Bohemia.

The misery of the Bohemian peasantry was only intensified by the long years of fighting with Prussia and its allies, often on Bohemian territory, between the accession of Maria Theresa and the end of the Seven Years' War in 1763. In the last years of her reign there occurred two events of major importance. In 1773 the Jesuit order was dissolved, leaving its uealth and power in Bohemia to be taken over by the government; in particular the Jesuit university of Prague and many Jesuit schools were inherited by the state. In 1775. after the desperation of the serfs had broken out in revolt in various districts of Bohemia, the so-called Robotpatent (from the Czech robota, "work") was issued, which restricted the corve'e and other forced labour and encouraged landlords to convert serf dues into money payments. Thus the door had been opened to great changes at the time of Maria Theresa's death in 1780.

Her son, the emperor Joseph II, who had in fact shared the government with her since 1765, believed in a more sweeping transformation. He was an enlightened despot par excellence and desired to bring about a more humane and efficient system of government. His Edict of Toleration (Oct. 13, 1781) completed the process which began with the fall of the Jesuits and abolished the draconic dispositions which had throttled religious life in Bohemia since Ferdinand II's day; Protestants were now free to practise their religion. At about the same time, on Nov. 1, 1781, Joseph issued another of his most important decrees which is sometimes rather hastily described as having abolished serfdom; in effect it restored to the peasants the personal liberty that they had lost in the 15th century, the rights to marry, to move or to undertake work without seigneurial permission. but they were left with heavy economic obligations to the nobility. By an edict of Feb. 10, 1789, the emperor hoped to abolish most of these too: henceforth the peasants were to pay maximum dues of 30% of the total yield of their land, 12% to the state and 18% to landlord and priest. Personal services, such as the corve'e, were to be abolished.

In the interests of efficiency Joseph II believed in standardization, and he therefore, in 1784, introduced German as the language of administration in Bohemia, as in nearly all the other provinces under his rule. At the same time German replaced Latin in the University of Prague. Already in 1770 German had replaced Latin in the Bohemian grammar schools, and in 1774 German had been established as the language to be used in the increasing number of elementary schools except in the lowest classes. Thus by

the time of Joseph II's death in 1790 Bohemia seemed superficially to have lost any separate character. Nevertheless better social conditions, greater educational facilities and the feeling of release which the Edict of Toleration and the relaxation of the censorship had brought about helped to kindle a new interest in the history of the Czechs and their language.

Joseph was succeeded by his brother, Leopold II, amidst a great outburst of protest from the church and nobility against the dead emperor's reforms. In Bohemia, however, in spite of its exaggeratedly feudal tradition, an instinctive adaptation to the spirit of the age of the French Revolution caused many nobles to adopt liberal formulas; some of them, too, began to interest themselves in the Czech language as a weapon with which to resist the centralist German-speaking authorities. Although less fierce than in Hungary, Bohemian opposition to Vienna proved sufficiently obstinate. The emperor Leopold made peace with the nobility by sacrificing to it the edict of 1789 which had abolished forced services and limited the taxes on land, while many of Joseph's other innovations were frequently ignored in practice. Leopold, however, made a notable concession to the new interest in Czech among the educated classes in Bohemia by founding a Czech language professorship in the Charles university in Prague. Almost simultaneously the idea of Czech solidarity with the Serbs, indeed of Pan-Slav solidarity, began to be voiced in Bohemia: it was positively expressed. for example, by the scholar and patriot, Josef Dobrovsky —a young man at the time—who delivered a public address in Leopold's honour on the occasion of the emperor's coronation as king of Bohemia in Prague in 1791. After Joseph II had refused any such concession to what he condemned as Bohemian particularism it was characteristic of Leopold that he made the conciliatory gesture of being crowned with St. Wenceslas' crown. Unfortunately for Bohemia and for Austria, Leopold II died in 1792.

The Revival of National Sentiment, 1792–1848.—The French Revolutionary and the Napoleonic Wars (1792–1815) suspended the political life of the shaken Habsburg monarchy and reduced it to financial extremity. In the Bohemian provinces events in France awoke some faint echo in the peasant masses, while the passage of Russian troops in transit further stimulated nascent Slav sentiment among the Czechs. The first generation of "awakeners," with Dobrovsky and Josef Jungmann in command, introduced the scientific study of the Czech language. After the final overthrow of Napoleon in 1815 the Czech national movement, hitherto inspired mainly by 18th-century rationalism, came under the influence of German romanticism. The study of history now supplanted that of philology, and the historian Frantisek Palacky (1798–1876) became the leading figure. Palacky was a Protestant Moravian who had been educated at the Lutheran *lycée* of Bratislava (Pressburg) in Slovakia. He was supported by a small group of aristocrats, and notably by Count Kaspar Sternberg, who had founded the Bohemian museum in 1818. These people were evidently more concerned with the protection of the territorial integrity of Bohemia—upon which their power depended—against Viennese centralism, than with the emergence of the Czech nation. Provincial patriotism again, although of a very different trend for it was antifeudal, inspired the new German literature of Bohemia at this time. After the European revolutions of 1830 had revealed the instability of the restoration settlement of 1815 and the Polish insurrection of 1831–32 had aroused feelings of Slav solidarity toward the Poles among the Czechs, their national renaissance became more of a political and a liberal movement. Karel Havlicek, a liberal democrat and the disciple of French thinkers and writers, joined Palacky, a liberal conservative, as a leader of Czech opinion. It was in 1836 that Palacky's History *of Bohemia* began to appear: after five years it began to encounter difficulties with the censorship because it justified Huss and his Czech compatriots.

The Revolution of 1848.—During the 1840s the Bohemian diet increasingly demanded the decentralization that the nobles desired. But with the revolution of 1848 the leadership of Bohemia temporarily passed from the aristocracy to the newly emerging German and Czech middle classes. The Czechs' program comprised an autonomous Bohemia constitutionally governed and recognized as having the same status as Hungary. This Bohemia was still to form part of an Austrian empire, which was mainly Slav in population; it was on no account to be drawn, as the Bohemian Germans wished, into a united Germany where all but the German inhabitants were sure to be ignored. For this reason Palacky refused an invitation in April 1848 to join the revolutionary German parliament at Frankfurt. Indeed the Slav reply to the large claims of the German patriots and to the growing intransigence of the Magyars of Hungary (to whom the Slovaks were subject) was to call a Pan-Slav congress which assembled in Prague on June 2, 1848. Ten days later young Czech radicals staged a revolutionary demonstration there which was very soon suppressed by the Austrian army under Alfred von Windischgratz (the first prince of the name). The imperial government proceeded to ignore the constitutional concession it had made to the Czechs on April 8 in accordance with the demands of their program. Nevertheless when Josip Jelacic, the *ban*, or governor, of Croatia, brought a Croat army to the rescue of the emperor against the Magyars and the left-wing Germans of Austria, the Czechs and the other Slavs were bound to side with the archduke Francis Joseph and the Croats. A constituent assembly met in Vienna in July but was dispersed when Windischgratz occupied the imperial capital in October. In Nov. 1848, shortly before Francis Joseph became emperor, an assembly was convened at the small Moravian town of Kremsier (Kromeriz), where a promising draft constitution aimed at the autonomy of the nationalities within the empire was prepared. On March 7, 1849, however, the Kremsier parliament was dissolved (as a result of the imperial manifesto published on March 4 proclaiming a unitary constitution for the whole empire), and the imperial government soon after returned to a rigid absolutism for another decade.

Czech and German Rivalry, From 1848.—The only clear gain from the revolution of 1848 was the final liberation of the peasants. None of the national groups which made up the Austrian empire profited more than the Czechs from the Act of Emancipation of Sept. 7, 1848, which abolished the feudal system of land tenure. As Joseph II had wished, all forced services came to an end and the peasants became the owners of a part of the land that they tilled or they paid a free money-rent for all of it. It has been seen that after the Thirty Years' War the Czechs had survived only as a nation of serfs and that until the beginning of the 19th century any middle class that there was had consisted of a handful of intellectuals. It is also true that until 1919 Bohemia and Moravia remained the home of huge estates owned by a German-speaking aristocracy. The establishment of peasant ownership nevertheless enabled the Czechs to begin to build up a certain modest national wealth in land while the recognition of personal liberty fortified their claim to education in their own language. In 1859 Francis Joseph announced that in secondary schools in predominantly non-German districts education need not be completed in German provided that the pupils had a thorough knowledge of the German language: from about the same time elementary schools in the Czech villages were conducted only in Czech.

Up to the middle of the 19th century Bohemia, roughly speaking, had been divided into a Czech central region which was agricultural and an important German fringe which was predominantly industrial. In July 1851 the abolition of tariffs between the Austrian lands and Hungary helped to induce a period of economic expansion and change, stimulated also by the construction of railways. Soon independent Czech-owned small industries began to develop, and Czech labour, which was cheaper, began to penetrate into the German industrial areas, especially into the lignite mines in northern Bohemia. The new national awareness after 1848 caused one of the most bitter racial conflicts of the 19th, and indeed of the 20th, centuries. Until 1848 and indeed much later, the Germans of Bohemia took it for granted that theirs was the ruling race in the whole Habsburg monarchy. They felt outraged by the emergence within their own provincial frontiers of a Slav community with a higher birth rate than their own which seemed prepared to challenge their supremacy and which even claimed historic priority over the Germans, as the true Bohemians.

The Czech challenge was increasingly made in economic and educational terms. In 1868 the first major Czech bank, the Zivno-

stenska Banka, was established. This helped the Czechs to acquire more land and industrial property and thus the property qualifications which had become necessary in 1861 for political enfranchisement *(see* beloa).

A law of 1868 provided for elementary state education throughout Austria, and according to article 19 of the Austrian constitution of Dec. 1867 it was claimed that if 40 children speaking a minority language lived within a radius of about one-half mile they should become entitled to a school of their own. This claim, even when it was recognized, often led to violent disputes, the provision of a school perhaps depending upon the arrival of a Czech family in a German-speaking district or vice versa. From 1880 onward each side had a school union of its own to sponsor private schools: each side also had a national gymnastic society, the *Sokol*, acquiring an almost mystical significance for the Czechs. Because of their educational zeal and their natural thrift and industriousness the Czechs developed a flourishing middle class, often peasant-born. in the second half of the century. They were able to establish themselves in the liberal professions and later crowded into the public services, not only in Bohemia but throughout Austria. Thus in the end the imperial bureaucracy acquired a disproportionately large number of Czech officials. This nas not unimportant in preparing the way for the future Czechoslovak state.

Politically the first decade after the revolution of 1848 was one of centralist absolutism with as severe a censorship as before. The concordat of 1855 re-established a clericalism which was distasteful to much German, as well as to much Czech. opinion in Bohemia. After various fruitless experiments. on Feb. 26, 1861, a new constitution was inaugurated by the February, or Schmerling, patent drafted by the minister of the interior, Anton von Schmerling. A main function of the provincial diets became the election of the imperial parliament, or *Reichsrat*. The diets themselves were thenceforward to be elected by a series of electoral colleges which greatly favoured the Germans and the wealthier classes, mostly German in any case, at the expense of the Slavs and the poorer populations of the Habsburg empire. Since the Czechs constituted the most powerful Slav group, it was in Bohemia that opposition to the Schmerling franchise system was most intense. Many middle-class Germans of Bohemia and Moravia, on the other hand, mere now drawn into the government in Vienna; these were people who believed far more dogmatically than the aristocracy in the necessity for a German ruling race. Thus the Schmerling constitution accentuated the growing conflict between the tao races of Bohemia. It should be added that many Czechs continued to accept germanization because of its practical advantages: the Czechs who resisted German pressure were all the more pugnacious.

The two most prominent Czech leaders, Palacky and his son-in-law, F. L Rieger, aware of the pressure exerted in Vienna by the Hungarian aristocracy in favour of Magyar nationalist claims, had already in Jan. 1861 allied themselves with a group of the Bohemian nobility in the hope of exerting similar pressure in the name of the Czechs. This alliance with the so-called "historic" party of the Bohemian aristocracy was based upon the conception of the territorial integrity of Bohemia and Moravia (what the Germans called *Böhmisches Staatsrecht)*; by insisting upon this Palacky and Rieger hoped to safeguard the Bohemian inheritance as effectively as the Hungarians were stressing the integrity of the Magyar inheritance. the lands once ruled by St. Stephen. Both Czechs and Hungarians resisted the Schmerling constitution as best they could, the Czechs boycotting the *Rrichsrat* from 1863 onward, and indeed for the following 15 years.

A new government in 1865 headed by Richard Belcredi, a member of the "historic" party. brought a *détente* together with the suspension of the February patent. But in the following year the Austrian armies were humiliatingly defeated by the Prussians in the Seven Weeks' War and a new Germany was at once projected to which Austria was not to belong. This aroused Slav hopes of a still more Slavonic Austria. hopes which were dashed in 1867 when the emperor felt it necessary to yield to the Hungarians' demands and sign the *Ausgleich*, or Compromise, with them According to this his domains were divided into two virtually sovereign states linked nith one another for diplomatic and military puraoses; the Slavs were subjected to the Germans in Austria and to the Magyars in Hungary. the Czechs and Slovaks being cut off from one another by the frontier newly recognized between Austria and Hungary within the Habsburg empire. which thus became the Dual Monarchy. From the Czech point of view, as Palacky said, this was twice as bad as centralism since it meant centralism twice over. Four years later Francis Joseph seemed to be willing to give to the Czechs what he had given to the Magyars, but he suddenly changed his mind and left them with nothing but a feeling of having been betrayed by the dynasty. When in 1873 the diets ceased to elect the *Reichsrat*, the electoral colleges remained to give both diets and *Reichsrat* their old bias as before. The policy of Palacky and Rieger had failed. Yet. disappointed though they were, the Czechs were unable to devise a policy other than that of passive resistance which they continued until 1878. In that year the German Liberals of the monarchy opposed the occupation of Bosnia-Hercegovina by Austria-Hungary because they objected to a further increase of the Slav population. The emperor Francis Joseph and his generals disliked this criticism of imperial foreign policy and the Liberal ministry was dismissed in favour of a more clerical and. in many ways. a more conservative government headed by an old friend of the emperor's, Eduard Taaife. Taaffe, who took office in 1879, expressly set out to take more account of the Slavs in the monarchy and annoyed the Germans by appointing a prominent Czech called Prazak to be a minister in the central government in Vienna By this time the Czechs had returned to the *Reichsrat*.

The Czechs gained appreciable advantages from the new regime. By a language decree of 1880 the Czech language mas placed upon the same footing as German in the Bohemian administration and courts of law. In 1882 a Czech university separate from the German one was established in Prague, thus at last providing the Czechs nith higher education in their own language. At about the same time a Czech national theatre. paid for by private subscription, was opened in Prague. But the Czech national leaders were embarrassed by the need. as one of them said. of thus "picking up crumbs." and of depending so much on the government in Vienna and the "historic" nobility, which was growing more intransigent in its clerical conservatism. By reaction the influence of the Young Czechs. a more advanced fraction, grew. A compromise concluded by the more conservative Old Czechs with leaders of the Germans of Bohemia in 1890, although offering real gains to the cause of the Czechs, was denounced by the others because it left the German language in a slightly privileged position. At the elections the next year the Old Czechs were roundly beaten by the Young Czechs. Taaffe's resignation in 1893 put an end to this phase.

On both sides in Bohemia, and in Moravia too, racial feeling was becoming exacerbated by extremists, the most notorious of them all being the Pan-German group led by Georg von Schonerer which won keen support among some of the German Bohemians. In 1897 a decree issued by the minister-president Rasimir Badeni put the Czech language on the same footing as German for all administrative purposes; this uould have compelled German officials in Bohemia to learn Czech. It was greeted nith an uproar and was subsequently nithdramn. With tumults in both the *Reichsrat* and the Bohemian diet the quarrel between the Germans and the Czechs began to threaten the stability of the Habsburg monarchy. As minister-president (1906–08), Max von Beck tried to arrive at a solution by reforming the franchise for the *Reichsrat*. In 1907 he put through a lam that reorganized the constituencies along racial lines and gave a vote to every male over 24; the old system of privileged voting remaining valid for the diets of the provinces or cronnlands only Although Beck's reform introduced a far more equitable method of voting. German votes for the *Reichsrat* were still appreciably weighted as against those of the Slavs.

In more tranquil Moravia another compromise had been achieved in Nov. 1905 which went far to safeguard the rights of the Czech population — comprising 70% of all Moravia's inhabitants — while retaining a slight German predominance. This arrangement worked reasonably well for the remaining years of the Habsburg period. In Bohemia, honever, the problem of racial conflict was insoluble. The elections to the *Reichsrat* in 1907 greatly increased the Czech representation in Vienna, particularly that of the Czech

Agrarian party and of the Social Democrats. Even in the diet in Prague the Czechs, as they grew richer, gained more and more seats. All the more obstinately did the Bohemian Germans block any reform of the franchise for the Bohemian diet. By 1913 the negative attitude of both nationalities had indeed paralyzed the diet, and an imperial commission was substituted for its executive committee.

Since the Russian revolution of 1905 the Pan-Slavism of the Czechs had grown, and when in 1908 Austria-Hungary proclaimed the definite annexation of Bosnia-Hercegovina they were angered that these territories should be kept from the Southern Slavs or Yugoslavs. From this time onward their hostility to Austrian foreign policy became pronounced: they condemned it as anti-Slav, subordinate to Germany and increasingly dominated by the Magyars, whose power in the monarchy grew as the German-Slav division of Austria became more apparent. The Czechs moreover felt concerned by the increased persecution of the Slovaks—whom they increasingly regarded as a part of their own race—in Hungary (see SLOVAKIA).

Masaryk.—Below the surface of all the political turbulence and the racial pettiness which was common to both Germans and Czechs, a new spirit, modern, critical and scientific. had been growing among the Czechs since the division of Prague university. It found political expression in the numerically small "Realist" party led by the Slovak professor T. G. Masaryk (*q.v.*) who lecturcd in philosophy at the Czech University of Prague. Masaryk gathered around him a group of young intellectuals who tried to introduce a more balanced and humane approach among the Czechs and to substitute among the Slovaks the idea of self-help in the place of their natural fatalism and Russophile mysticism. Masaryk's courage and energy in the Zagreb and Friedjung trials won him a unique authority among all the Slavs of Europe: for Czechs and Slovaks he embodied the spirit of the Bohemian Brethren applied to modern society.

During World War I Masaryk and other Czech leaders directed their energies toward achieving Czech independence, and the last few years of Bohemia's history as a province of the Habsburg monarchy are better regarded as the prelude to the proclamation. on Oct. 28, 1918, of the republic of Czechoslovakia (*q.v.*) with the history of which that of Bohemia is thereafter inseparable.

BOHEMIAN FOREST, the covering term for the southwestern highlands of the Bohemian massif largely on the German-Czechoslovak frontier, which extend from the upper valley of the Ohre in the northwest to a section of the Danube valley in Austrian territory (between Melk and Krems) in the southeast.

The terminology of the ranges which compose the highlands is intricate and confused. The main group, the Sumava (Forest mountains), average 3,500 ft. in height and rise to the summits of Arber (Javor), 4,780 ft., on the Bavarian side of the frontier and Plechy (Plockenstein). 4,521 ft., on the Czechoslovak side. They are mainly composed of granite and give the impression of mass rather than height, with a fault-line scarp to the southeast and a gradual slope on the inner side. The forest cover, both coniferous and deciduous, is thick and the population is scanty.

To the northwest, the much lower range of the Cesky Les (Oberpfalzer Wald) is separated from the main group by the Domazlice (Taus) pass at 1,404 ft. The gradients are gentler and the hills largely cleared for upland farming. To the southeast the Vyssi Brod pass (2.339 ft.) separates the Sumava highlands from the Novohradskehory and the Greinerwald, mainly in Austrian territory. On the inner side of the Sumava. the upper valley of the Vltava (Moldau) forms a broad longitudinal trough with considerable groups of foothills beyond it. To the southeast, the parallel and lower ranges of the Bavarian forest lie close but wholly within German territory. All belong to this southwestern rim of the Hercynian massif, composed of Archean rocks and raised to their present elevation through the pressures of the much later Alpine mountain building to the south.

BOHEMIAN-MORAVIAN HIGHLANDS (Czech CESKO-MORAVSKA VRCHOVINA), the southeastern bounding ranges to the Bohemian massif that divide the two former provinces of Bohemia and Moravia, now in Czechoslovakia. They extend approximately from the basin of the Dyje (tributary to the Morava) in the south, to the upper basin of the Morava river in the north. The average height of this hill country is 2,000 to 2.500 ft., although the Jihlava heights in the south rise to 2,746 ft. (the Javorice summit) and the Zdar group in the north to 2,743 ft. (Devet Skal). There is a considerable variety of rock type and structure. Much of the highland is composed of ancient gneiss and granite rocks common to a great part of the Bohemian massif. but a substantial belt of Permian sandstone crosses it from north to south; on the Moravian side. the Drahanska Planina group of hills are of Devonian limestone and contain the famous Moravian karst (the Macocha abyss and caverns).

The highlands are bleak, sparsely populated country from which there has been a steady exodus to the more promising lowland on either side. The ancient town of Jihlava (Iglau), with its silver mining traditions. lies at 2.350 ft. on the southern route across the hills. Ceska Trebova at 1,400 ft. is near the summit of the northern route.

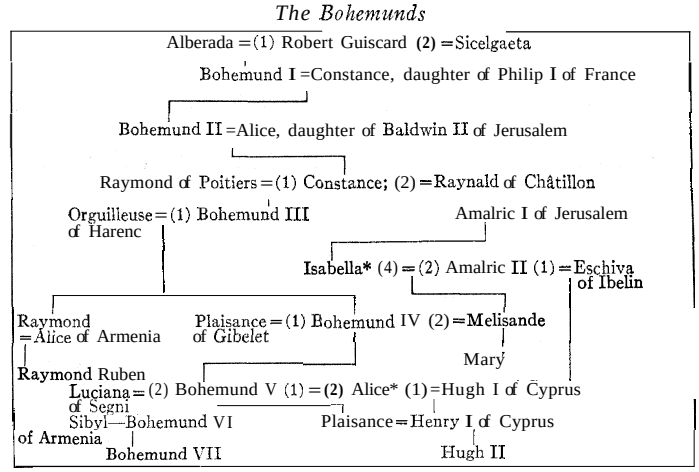
BOHEMUND, the name of a series of Frankish princes of Antioch, afterward counts of Tripoli. Their connection is shown in the table.

BOHEMUND I (c. A.D. 1057–1111), prince of Antioch, was the eldest son of Robert Guiscard, by an early marriage contracted before 1058. He served under his father in 1081 in the attack launched by the Normans of southern Italy on the Byzantine empire and commanded during Guiscard's absence (1082–84). penetrating into Thessaly but being repulsed by the emperor Alexius I Comnenus. This early hostility to Alexius had a great influence in determining the course of his future career and thereby helped determine the history of the first crusade. On the death of Guiscard in 1085, his younger son Roger succeeded to the duchy of

The Bohemunds



*Alice was Isabella's daughter by her third husband, Henry II of Champagne.

Apulia and Calabria, and the landless Bohemund rebelled against him. The war was finally composed by the mediation of Pope Urban II and the award of Taranto and other possessions to Bohemund. In 1096 crusaders began to pass on their way through Italy to Constantinople, and Bohemund joined the crusade. He gathered a fine Norman army, at the head of which he crossed the Adriatic and penetrated to Constantinople along the route he had tried to follow in the 1080s. At Constantinople he did homage to the emperor. From Constantinople to Antioch, Bohemund was on important occasions the real leader of the first crusade. His high military ability enabled him to devise measures to counter the unfamiliar tactics of the Turks. The capture of Antioch was in fact a result of his connection with Firuz, one of the commanders in the city; but it seems probable that Bohemund persuaded the leading crusaders against an immediate assault in Oct. 1097 and did not bring matters to an issue until it seemed certain that the other commanders would allow his claims to dispose of the city. By the early summer of 1098 their assent could no longer be withheld in the face of the approach of a great Turkish army of relief under Kerbogha. Antioch fell on June 2, 1098, and Bohemund claimed it by right of conquest, with a reservation in favour of the emperor if he should fulfill his promise to aid the crusaders. But Bohemund was not secure even after the city's surrender and the defeat of Kerbogha; he had to make good his claims against Raymond IV of Toulouse, nhom he had alienated and who soon became the ally of Alexius. He obtained full possession in Jan. 1099. Bohemund went to Jerusalem at Christmas 1099 and had Daimbert of Pisa elected as patriarch It might seem in 1100 that Bohemund was destined to found a great principality in Antioch, which would dwarf Jerusalem; he had a fine territory, a good strategical position and a strong army. But he had to face two great forces—the Byzantine empire, which claimed the uhole of his territories and was supported in its claim by Raymond of Toulouse, and the strong Muslim principalities in the northeast of Syria. Between these two forces he failed. In 1100 he was captured by the Danishmend amir of Sivas, and he languished in prison until 1103. His nephew Tancred took his place; but meanwhile Raymond established himself with the aid of Alexius in Tripoli and was able to check the zxpansicn of Antioch to the south Ransomed in 1103 by the generosity of an Armenian prince, Bohemund resumed his offensive against his Muslim neighbours. In May 1104, however, he was severely defeated near Rakka on the Euphrates and, despairing of his own resources, returned to Europe for reinforcements. He was enthusiastically received and won the hand of Constance, daughter of Philip I of France. Re exerted himself to organize a crusade against Byzantium and collected an army with which he besieged Durazzo. But Alexius proved too strong. and Bohemund had to submit to a humiliating peace at the Devoll river (1108), by which he became the vassal of Alexius with the title of *Sebnstos* and promised to admit a Greek patriarch into Anticch. Bohemund never returned to Syria, and was buried at Canosa di Puglia, in Apulia, Italy, in 1111.

BOHEMUND IT (1108–1131), son of Bohemund I and Constance of France, went in 1126 from Apulia to Antioch, which, since the fall of Roger, the successor of Tancred, in 1119, had been under the regency of Baldwin II; and soon after his arrival he married Alice. the younger daughter of Baldwin. After joining with Baldwin in an attack on Damascus (1129), he was slain on the northern frontier by a Muslim army (1131).

BOHEMUND III (d. 1201) was the son of Constance, daughter of Bohemund II, by her first husband. Raymond of Poitiers. and succeeded his mother in the principality of Antioch in 1163. In the following year he suffered defeat and capture by Nureddin at Harenc (Harim) in northern Syria. Thereafter the principality of Antioch was never again a power in the Levant. Until about 1180 it was a Byzantine protectorste, and it was the influence of Manuel I Comnenus that secured Bohemund's early release from captivity. In 1177 he made an unsuccessful atrempt to recapture Harenc. In 1180 he deserted his second wife Irene, or Theodora Comnena, for a certain Sibyl, and he was in consequence excommunicated. By his first wife. the princess Orguilleuse, he had had two sons, Raymond and Bohemund (the future Bohemund IV). Raymond married Alice, a daughter of the Armenian prince Ruben (Rhupen), brother of Leo of Armenia. and died in 1197. leaving a son, Raymond Ruben: and the problem that occupied the last years of Bohernund III was to determine whether his grandson. Raymond Ruben, or his younger son. Bohemund, should succeed him in Antioch. Leo of Armenia championed his great-nephew, Raymond Ruben. Bohemund the younger, however, prosecuted his claim with vigour and even evicted his father from Antioch about 1199; but he was ousted through the efforts of Leo (then king of Armenia by the grace of the emperor Henry VI), and Bohemund III died in possession of his principality (1201).

BOHEMUND IV (d. 1233), younger son of Bohemund III and Orguilleuse, became count of Tripoli in 1187 and succeeded his father in the principality of Antioch, to the exclusion of Raymond Ruben, in 1201. After Raymond Ruben's death in 1221, Bohemund reigned in Antioch and Tripoli until his own death.

BOHEMUND V (d. Jan. 1252). son of Bohemund IV by his wife Plaisance (daughter of Hugh of Gibelet), succeeded his father in 1233, and carried on the struggle with Armenia until 1251. when the marriage of the future Bohemund VI to the sister of the Armenian king finally brought peace. By his first marriage (1225) with Alice, the widow of Hugh I of Cyprus. Bohemund V connected the history of Antioch for a time with that of Cyprus. He had resided chiefly at Tripoli, and under him Antioch was left to be governed by its bailiff and commune.

BOHEMUND VI (1237–1275) was the son of Rohemund V by Luciana, a daughter of the count of Segni (nephew of Innocent III), and succeeded his father in 1252. His sister Plaisance had married in 1250 Henry I of Cyprus, the son of Hugh I; and the Cypriot connection of Antioch was thus maintained. In 1252 Bohemund VI established himself in Antioch, leaving Tripoli to itself, and in Feb. 1258 he procured the recognition of his nephew, Hugh II of Cyprus, as king of Jerusalem In 1268 he lost Antioch to the Mamelukes under Baybars. Thus fell the richest and oldest of the Frankish middle eastern principalities Bohemund died in 1275.

BOHEMUND VII (d. 1287), son of Bohemund VI by Sibyl. sister of Leo III of Armenia, succeeded to the county of Tripoli in 1275, with his mother as regent. He had trouble with the Templars who were established in Tripoli, and in the very year of his death he lost Laodicea to the sultan of Egypt. He died without issue, and within two years Tripoli was captured by the Egyptians (1289).

Yewdale, *Bohemund* I, *Prince oj Antioch* (1923); C. Cahen, *La Syrie du fiord à l'époque der croisades* (1940); R Grousset, *Histoire des croisades,* 3 vol. (1934–36); S. Runciman, *A History* of *Crusades,* 3 vol (1951–54).

BÖHM, GEORG (1661–1733), German composer known for his keyboard music. He was born at Hohenkirchen, near Ohrdruf, Thuringia, Sept. 2, 1661. the son oi an organist-schoolmaster. After an early education at Goldbach and Gotha. he nent to Jena university in 1684, and left probably in 1690. In 1698 he became organist of St. Johannis, Luneburg, where he remained until his death on May 18, 1733.

Bach may possibly have studied with Bohm, and was certainly influenced by his work. Though Bohm wrote many cantatas and sacred songs, he is chiefly remembered for his keyboard norks, in which he deploys differing styles for harpsichord and organ. The harpsichord suites are in the manner of J. J. Froberger. Böhm is at his most original, honever, in his impressive toccatas, preludes, fugues and postludes for organ, and above all in his organ partitas on chorale melodies. where he shows an independence and freedom oning much to the spirit, though not to the technique, of earlier harpsichord suites. His collected works were edited by J. Wolgast, two volumes (1927–33). (C. P. Co.)

BÖHM-BAWERK (BÖHM VON BAWERK), **EUGEN** (1851–1914), Austrian economist. was born at Brunn on Feb. 12. 1851. He mas professor of economics at Vienna and several times Aus-

trian minister of finance. Böhm-Bawerk's theory of interest, based on a combination of the time preference and marginal productivity principles and derived from the marginal utility theory of value—of which he also gave the most comprehensive presentation—marks a major step forward in the understanding of why capital yields profit. Even critics of his theory recognize his merits as a historian of interest theories; his critical analysis of the Marxian theorem of the declining rate of profit is widely regarded as a classic. Having shown earlier that interest must appear in all rational economic calculation, even in that of a noncapitalist society, he developed, toward the end of his life, a general concept of laws of economic rationality, valid regardless of the social order and limiting the effectiveness of power in economic affairs. His work, like that of other opponents of socialism, contributed substantially to the development of non-Marxist socialist theory after *1918*.

Böhm-Bawerk's most influential writings were *Capital and Interest* (1884–89), trans. by William Smart (1890); *Positive Theory of Capital* (1889), trans. by Smart (1891); *Karl Marx and the Close of His System* (1896), translated and published together with related essays by other authors (1949); and *Control or Economic Law?* (1914), trans. by John R. Mez (1931). His collected essays were edited by F. X. Weiss (1924–26). (C. L.)

BÖHME (BÖHM, BOEHME, BOEHM, BEHMEN), **JAKOB** (1575–1624), German mystic and philosophical theologian, early proponent of life philosophy (*Lebensphilosophie*), was born on or before April 24, 1575, in Altseidenberg, near Gorlitz. After brief schooling he became a shoemaker. In *1600*, under the influence of his Lutheran pastor, Martin Möller, he had a remarkable religious experience wherein he was given to know that "in Yes and S o all things consist." This, the dialectical principle, became the germinating core of his thought, growing as he matured, leading him to write *29* books and tracts wherein he sought to reconcile the speculative thought of his time with a more traditional mysticism.

Bohme's first book, *Avrora, oder Morgenröthe im Aufgang* (1612), which he himself called "my childlike beginning," brought condemnation from ecclesiastical and civil authorities. After seven years of enforced silence he again took up his pen in 1619 to expound his views, and during the next six years he wrote some astonishing philosophical, theological and devotional works. Growing rapidly in his speculative powers, his mind broadened by contact with contemporary thought, he gained maturity in two works written in *1623: Von der Gnadenwahl* ("On the Election of Grace") and *Erklärung über das Erste Buch Mosis,* better known as *Mysterium Magnum*. His devotional works were gathered by his admirers in a collection known as *Der Weg zu Christo* (*The Way to Christ;* 1623), and they have been reprinted often. He died on Nov. 17, *1624,* leaving uncompleted several works that showed promise of even greater achievement.

Bohme's greatest speculative problem mas to try to show how the Yes and So, good and evil, dark and light, came from the living heart of reality. His chief religious problem was to show how the duality of life, including the stubborn presence of evil in the world, was to be overcome through the reconciliation of these contrasts in spiritual unity. His speculations then tried to show how a dual and even threefold world emerged from a single source, how a threefold God emerged from one primitive power and how a threefold human nature came from the original creative act. These speculations, however, were a prelude to his chief interest: how this divided world is to be made one again, how the wrathful principle in nature and the stubborn recalcitrance of human sin are to be overcome. Bohme's thought took some bizarre turns, chiefly verbal, in his earlier works, and his reputation has suffered because of it.

Yet in spite of the Faustian mood sometimes associated with his work, his ideas have had far-reaching effect on western thought, both philosophical and religious. He was a main influence on the romantic age as well as on Schelling, Hegel, Schopenhauer, Nietzsche, Hartmann, Bergson, Heidegger and other philosophers. His religious thought was influential on George Fox and the early Quakers as well as on a host of German Pietists. Furthermore his influence continued to be reflected in modern theologians such as Nicolas Berdyaev and Paul Tillich.

Böhme's works were edited in collected editions by Gichtel (1682), Glusing (1715) and Ueberfeld *(1730)*, the last being reprinted as the authoritative text by Peuckert (1955 *et seq.)*. Early English translations by J. Ellistone, J. Sparrow and Blunden were reprinted by Watkins, and later translations of some tracts mere made by Earle and Stoudt.

BIBLIOGRAPHY.—Prime biographical materials were translated by F. Okeley, *Memoirs of Jacob Behmen* (1780), and other, later discovered materials by Peuckert, *Das Leben Jakob Böhmes* (1924), and R. Jecht, *Jakob Böhme, Gedenkgabe . . . , Görlitz* (1924). The best modern interpretation is A. Koyré, *La Philosophie de Jacob Boehme* (1929); the most profound is E. Benz, *Der Vollkommene Mensch nach Jakob Böhme* (1937). A modern work in English using all sources, older and modern, is J. Stoudt, *Sunrise to Eternity* (1957). (J. J. ST.)

BOHOL, an island and province north of the Mindanao sea in the Republic of the Philippines. Pop. *(1960) 602.497*. The province includes numerous small coral islands off the north and west coasts. The main island is composed of a volcanic core, in most places covered with coralline limestone, and has a land area of *1,575* sq.mi. It is generally flatter on the north and west coasts than on the east and south, where hills oftentimes rise abruptly almost from the water's edge. In the west central portion of the island and extending onto the Loon peninsula to the west are the spectacular "chocolate drop" or "haycock" hills. They are roughly symmetrical, conical limestone remnants of an earlier erosion cycle, a phenomenon known to be present in only two or three other places in the world.

Bohol is primarily an agricultural island and has about 25% of its land surface under cultivation. Rice, corn and coconuts are the principal crops, but tobacco, abaci, maguey and some fruit and vegetables are also grown. A secondary livestock industry, on the rougher terrain near the east coast, is centred at Ubay. Tagbilaran is the capital and commercial centre. Pop. *(1060) 20.353*. Loon *(30,415)* and Ubay *(34,358)* are the most populous municipalities. (AN. C.)

BOHR, HARALD AUGUST (1887–1951), Danish mathematician, brother of the physicist Niels Bohr, was born in Copenhagen, April 22, *1887*. He won early fame as a soccer player. He received his Ph.D. in 1910, became professor at the Polytechnic institute in Copenhagen in 1915, and at the university in 1930. His early mathematical research was mainly concerned with Dirichlet series and their application to analytic number theory through the Riemann zeta function. His most notable contribution to mathematics was the creation of the theory of the almost periodic functions. Bohr died in Copenhagen Jan. 22, 1951. (O. OE.)

BOHR, NIELS HENRIK DAVID *(1885–*), Danish physicist, one of the most ingenious interpreters of his generation of the problems in modern theoretical physics. Born at Copenhagen on Oct. 7, 1885, Bohr received his doctorate at the University of Copenhagen in 1911, and proceeded immediately to the Cavendish laboratory at Cambridge, Eng., for further study under Sir J. J. Thompson. The following year he worked under Sir Ernest Rutherford at Manchester, Eng. Experiments by the latter in *1911* on the scattering of alpha-rays *(see* RADIOACTIVITY) had led Rutherford to propose a new "nuclear'! theory of atomic structure.

Only ten years before, Max Planck, in Germany, had proposed a novel idea with respect to radiation—that it came forth from or was absorbed by atoms only in restricted amounts, or "quanta," of energy. Young Bohr, on his return to Copenhagen in 1913, following his year with Rutherford, applied the Planck quantum hypothesis to the Rutherford nuclear atom model, in an attempt to account for the known facts of radiation emitted by atomic structures. Hitherto these phenomena were completely obscure in terms of any classical theory. Bohr proceeded first by making two exceedingly bold assumptions: (1) that the electron cloud of any atom was a stable, nonradiating system when and only when its component electrons were each in certain "stationary states" of energy appropriate to each electron; (2) that radiation, when absorbed or emitted by an isolated atomic system, must he strictly monochromatic (*i.e.*, of a single frequency!, and that this occurred when and only when the total energy of the atom was changed by

the transition of some one of its electrons from one of its many possible stationary states to another. At once Bohr was able to calculate very closely the frequencies of the entire spectrum of atomic hydrogen, and this did much to gain serious attention for his radical approach. His two assumptions remained a fundamental for modern theories of atomic structure. Second, and supplementary to Bohr's two postulates. was a statement of a "correspondence principle" to the effect that in certain limiting cases the laws of quantum theory converge toward and become identical with the laws of classical mechanics. Modern wave-mechanical theories *(see* QUANTUM MECHASICS: *The Bohr Atom)* confirmed Bohr's stationary states by criteria for stationary "electron waves"; and later the additional attribute of spin and the consequent possession of a magnetic moment by atomic electrons was all that was needed to make the restrictions on annular momenta of atomic electrons. that were imnlicit in Bohr's hypotheses. ,conform with highest precision to the many refinements of measurement of atomic spectra of later years.

Bohr's great achievement mas recognized internationally by the Nobel prize award to him in 1922 and by many other honours. which included the Atoms for Peace award in 1957. In Jan. 1939 Bohr attended the Fifth Washington Conference on Theoretical Physics. He was then head of the Copenhagen Institute for Theoretical Physics, which had been established through his influence in 1920 and had become one of the leading intellectual centres of Europe. He brought to this conference the interpretation by Lise Meitner and Otto R. Frisch of his institute, that in the fission of uranium a crude analogy between an unstable heavy atomic nucleus and a rupturing water drop might be hazarded. Within a two-week period, a three-column letter to the editor of the *Physical Review* appeared in that journal in which he laid the broad foundations of a "liquid droplet" theory of nuclear phenomena. There followed extensive publications by Bohr and others showing provisional verification by observations of this second bold approach, this time toward understanding the innermost central character of atomic systems.

(H. B. LM.)

BOHTLINGK, OTTO VON (1815–1904), German Sanskrit scholar whose works are of great value in Indian and comparative philology, was born on June 11. 1813, at St. Petersburg, Russia. In 1868 he settled at Jena, and died at Leipzig on April 1, 1904. His first great work mas an edition of Panini's *Acht Bücher grammatischer Regeln* (1839–40), which was in reality a criticism of Franz Ropp's philological methods. This book Bohtlingk again took up 47 years later, when he republished it with a complete translation under the title *Paninis Grammatik mit Übersetzung* (1887). 'The earlier edition was followed by *Vopadevas Grammatik* (1847); *Über die Sprache der Jakuten* (1851); *Indische Sprüche* (2nd ed.. 1870–73. to which an index was published by Blau, 1893); and other works. But his magnum opus is his great Sanskrit dictionary. *Sanskrit-Wörterbuch* (1853–i5: new ed., 1879–89), which. with the assistance of his two friends, Rudolf Roth (1821–95) and Xlbrecht Weber (1825–1901), was completed in 23 years.

BOHUN, the name of an English family of Marcher lords prominent in the 13th and 14th centuries. Of Norman origin, the Bohuns came to England in or soon after 1066, but were not at first of much importance, and their early genealogy is somewhat uncertain. HUMPHREY DE BOHUN (d. 1129) acquired Trowbridge and lands in Wiltshire by marriage, but the true founder of the family fortunes was his son. HUMPHREY (d. *c.* 1166), whose marriage to Margaret. elder daughter of Miles, earl of Hereford (d. 1143), later brought the Bohuns the lion's share of his vast inheritance in the Welsh border counties. together with the office of constable of England. It was probably this Humphrey's son HUMPHREY (d. c. 1183) who, as constable, commanded the royal forces that routed the English rebels of 1173 at Fornham in Suffolk. and helped to defeat the Scottish invasion in 1174. He later married Margaret, sister of the captured King William of Scotland.

His son HENRY (d. 1220), who was created earl of Hereford by King john in April 1200, was one of the 25 lords elected to maintain the Magna Carta. and in the subsequent civil war he fought for the baronial party and was captured at the battle of Lincoln in 1217. His marriage to Matilda, sister and heiress of William, the last Mandeville earl of Essex, brought their son HUMPHREY (d. 1275), 2nd earl of Hereford. the title of earl of Essex (1236) and great estates in that county. Humphrey took part in the baronial movement (1258–65) against Henry III, but by 1263 he rejoined the royalists and was captured by Simon de Montfort at the battle of Lewes in 1264. His son HUMPHREY (d. 1265). however. was steadfast in his support of De Montfort, and died of wounds received fighting with him at the battle of Evesham (1265). This Humphrey made another of the judicious marriages which enriched the family fortunes: his wife. Eleanor, daughter of William de Braose, inherited the Welsh lordships of Brecon, Hay and Haverfordwest. Humphrey, 2nd earl of Hereford. was succeeded by his grandson, HUMPHREY (*c.* 1249–98), 3rd earl, who served Edward I loyally in his Welsh wars. Despite the unjust treatment he received when Edward I gave judgment in his disputes with John Giffard (1284) and the earl of Gloucester (1291–92), it is doubtful whether personal disaffection inspired his opposition to the king in 1297. With the marshal. Roger Bigod. earl of Norfolk, he refused to serve abroad unless the king were present in person, and the two earls led the movement which forced Edward I to confirm the charters.

HUMPHREY (*c.* 1276–1322), 4th earl, joined the lords ordainer against Edward II and helped to overthrow Piers Gaveston in 1312. He was taken prisoner at the battle of Bannockburn (1314), but was exchanged for the wife of King Robert I. He later supported the "middle party" until the rise of the Despensers drove the Marcher lords into rebellion: he was killed in the civil war that followed. at the battle of Boroughbridge on March 16, 1322. His sons and successors in the earldom. JOHN (1306–36) and HUMPHREY (*c.* 1309–61), led retired lives: neither was able to perform his duties as constable, and probably both suffered from a lifelong infirmity. The most active member of the family during this period was their younger brother WILLIAM DE BOHUN (d. 1360). He fought at the battles of Sluys (1340) and Crécy (1346), was the king's lieutenant in Brittany in the 1340s, and served against Scotland as admiral. Edward III rewarded his efforts with grants of land and the title of earl of Northampton (1337). William's son HUMPHREY (1342–73), succeeding both his father and his childless uncle, Humphrey, temporarily united the three Bohun earldoms of Hereford, Essex and Northampton in his own person. but his death without issue ended the male line of the family. His estates were partitioned between his daughters. ELEANOR (1366–99). wife of Thomas of Woodstock (afterward duke of Gloucester), whose share passed to the Staffords, and MARY (*c.* 1370–94), wife of Henry, earl of Derby (afterward Henry IV), who carried her portion to the house of Lancaster.

(C. D. R.)

BOIARDO, MATTEO MARIA, CONTE (1441?–1494), Italian poet whose *Orlando Innammorato* was the first poem to combine the Xrthurian and Carolingian traditions of romance. was born at Scandiano, near Reggio Emilia. in May 1441. He spent much of his life after 1476 at Ferrara. under the patronage of the dukes of Este. He was captain of the ducal forces at Modena from 1480 to 1482. and at Reggio from 1487 until his death there. Dec. 19, 1494. Apart from his duties. his time was taken up by controversies with his relatives arising from a hereditary feud and, after his marriage (1479), with the care of his family.

His chief pleasure was in study and poetry and he wrote numerous works, both in Latin and Italian. Of the Italian the *canzoniere, Amorum libri tres* (published 1499), tells of his love for Antonia Caprara and. despite the strong Petrarchan influence, remains the most personal and spontaneous collection of lyrics in the 15th century. *Orlando Innammorato,* begun about 1476.

was intended to consist of three parts. but only the first two (published 1483) and nine cantos of the third were completed at the poet's death. The great importance of Orlando *Innammorato* (to which Ariosto's *Orlando* Furioso was conceived as a sequel) is that it combines the Arthurian cycle of chivalrous love adventures with the Carolingian cycle glorifying military honour, patriotism and religion. The poem was not popular during the Renaissance. partly because of its dialectical and erudite language, partly because of the careless construction of the episodes and characters. but chiefly because of its delineation of strong and primitive passions, which, a true expression of Boiardo's poetic genius, was not in tone with the tendencies of the time.

Boiardo's complete works in two volumes were edited by A. Zottoli (1936–37).

BIBLIOGRAPHY.—C. Altucci, "Boiardo lirico," *Giornale* storico *della letteratura italiana,* cvi, pp. 39–80 (1935); G. Reichenbach. *L'Orlando Innammorato* di *Matteo Maria Boiardo* (1936); V. Kossi, *Il Quat*trocento, pp. 441–463, 3th ed. (1953). (G. P. G.)

BOIE, HEINRICH CHRISTIAN (1744–1806). German writer and journalist. founder and editor of some influential literary periodicals. was born in Meldorf. Holstein (then part of Denmark). July 19. 1744. After studying theology and law at Jena he went to Gottingen in 1769. There, in 1770, he founded with Friedrich Gotter the *Musenalmanach,* which he edited until 1775 and then. with Christian von Dohm, produced Das *deutsche Museum* (1776–91; from 1789 *Neues deutsches Museum*). These periodicals—Dus *deutsche Museum* was one of the best of its day—provided both an outlet and a stimulus for the Gottingen *Dichterbund* or *Hain,* the younger poets in revolt against the French influence of the Enlightenment. Boie became secretary to the commander in chief at Hanover (1776) and administrator of Siiderditmarschen, a province of Holstein (1781). He died at Meldorf, March 3, 1806.

See K. Weinhold, H. C. Boie (1868); W. M. C. Hofstatter, Das Deutsche Museum und das *Neue* Deutsche *Museum* (1908).

BOIELDIEU, FRANÇOIS ADRIEN (1775–1834), French composer who developed the comic opera into an early form of romantic opera. Born at Rouen on Dec. 16. 1775, he studied with the cathedral organist, Charles Broche. His first operas were produced in 1793 and 1795. At Rouen he also composed and performed numerous piano sonatas, remarkable for their form, which constitute the first important body of works written for the piano by a French composer. In 1796 he settled in Paris where he met Joseph Méhul and Luigi Cherubini, and in the following year produced three one-act comic operas. La *Famille Suisse, L'Heureuse Nouvelle* and Le Pari, which established his reputation. Appointed professor of the piano at the conservatory in 1798. he continued to write for the theatre, his main successes being Le *Calife* de Bagdad (1800) and Ma tante *Aurore* (1803). From 1804 to 1810 he was chapelmaster and director of the opera at St. Petersburg where he wrote a score of choral music for Jean Racine's *Athalie.* Appointed director of music to Louis XVIII in 1816, he was elected a member of the French institute in 1817 and professor of composition at the conservatory in 1820. His main operas of this period were Jean de Paris (1812), Le Petit Chaperon Rouge (1818) and La Dame blanche (1825), on a libretto of Eugène Scribe derived from Scott's The Lady of the Lake, The Monastery and *Guy Mannering.* Proclaimed his masterpiece, it remained a standard work in the repertory of French opera. His last opera. *Les* Deux *nuits* (1829), contains some fine music but has a poor libretto. Ruined by the revolution of 1830, he died at Jarcy on Oct. 8, 1834.

Boieldieu's work illustrates the evolution of French operatic and instrumental music in the generation following the French Revolution. His operatic style in its lighter aspects was compared to that of Rossini. In scenes of mystery and romance that suggest Weber, particularly in La Dame blanche, he brought the comic opera to the borders of romantic grand opera. Besides operas and piano works he wrote numerous romances for voice accompanied by harp or piano. some showing his original melodic gifts.

See G Favre. *Boieldieu: sa vie, son oeuvre,* 2 vol. (1944–45) and La *Musique française* dc *piano avant* 1830 (1953). (E. LR.)

BOII, a Celtic tribe, one section of which settled in Cisalpine Gaul and another in nhat was later Bohemia to which it gave its name The history of both sections is puzzling and the relationship between them impossible to establish confidently. Liw. writing in the late 1st century B C, stated that the Boii came over the Great St Bernard pass about 600 B C. But their lands in Italy were later concentrated around Bononia (Bologna). where archaeology shows that the Etruscans still held Felsina (the city's earlier name) well after 400 B.C. So even if Livy's date for the first Celtic invasions of Italy is correct. it would be doubtful whether the Boii in particular crossed so early: and the route he gives them seems impossible. In 283 the Boii were defeated by the Romans at Lake Vadimo (south of Orvieto). and in 225 at Telamon (Talamone) in Etruria. They gave valuable help to Hannibal in 218, and continued to resist Rome between 201 and 151; but they were then completely subdued and lost half their lands, Bononia being made a Latin colony in 189.

Archaeological evidence proves the existence of Celtic occupation in Bohemia by, at latest. 400 B.C. The first writer to mention Boii in this district is Julius Caesar, according to whom they crossed the Danube in 60 B.C. and attacked Noreia (Neumarkt in Styria in Austria). The Helvetii (*q.v.*) were joined by 32,000 Boii in invading Gaul, and Julius Caesar after his victory near Bibracte (Mt. Beuvray) in 58 allowed their survivors to settle in the territory of the Aedui between the Liger (Loire) and Elaver (Xllier) rivers. The remaining Boii south of the Danube were exterminated by Burebista of Dacia about 50 B C, and those in Bohemia were expelled by the Marcomanni (*q.v.*) in 8 B C.

Strabo stated that many Boii were expelled from northern Italy in 191 B C. and settled near the Danube; this is possible, but may simply be an attempt to explain the Bohemian Boii, nho probably arrived much earlier. Most modern scholars suppose two roughly simultaneous migrations from Gaul, one eastward, the other across the Alps. If, however. the Boii entered Italy not by the St. Bernard but by the Brenner pass. they may have been an offshoot from a slightly earlier settlement near the Danube, coming to join other Celts already established in the Po valley.

BOIL AND CARBUNCLE. A boil (or furuncle) is an acute local inflammation of the skin and underlying tissues resulting from an infection by the bacterium Staphylococcus *aureus* that begins around the hair follicle and its associated sebaceous gland From the time inflammation becomes noticeable, the boil increases variably in size with swelling, redness and pain. It ordinarily drains spontaneously through the follicle opening. with discharge of pus and tissue debris. There may be little resultant scarring, or it may be quite marked.

Groups of boils in which many hair follicles are infected are called carbuncles.

Boils are known to have afflicted mankind since the time of Job. Until recent years they have been regarded only as an annoying, painful and partially disabling type of infection that may be chronic and recurrent. Since 1955–56 boils have been found to be caused in an increasing percentage of cases by staphylococci that are not affected by penicillin and various "broad spectrum" antibiotics. Such infections were seen initially in the patients and attending personnel of hospitals but are now encountered frequently in the general population of areas in which antibiotic agents have been widely used. Treatment has thereby become less effective, and boils may sometimes be the starting point for serious systemic infections. particularly in young infants, persons debilitated by other diseases or the aged.

The term boil has also been applied to a variety of tropical infections of the skin but is properly used only with staphylococcal infections. (D. M. P.)

BOILEAU-DESPRÉAUX, NICOLAS (1636–1711). French poet and literary critic. celebrated as the most influential exponent of classical standards for poetry. was born in Paris on Nov. 1, 1636, the son of a registrar of the grande chambre in the

parlement who had originally been a mere clerk in the registry (the poet's claim to be descended from a noble 14th-century family was based on forged documents). His mother died when he was 18 months old: and his childhood was not too happy. After studies at the Collège d'Harcourt and then at the Collège de Beauvais, which he left in 1652, he read law and was admitted as an advocate on Dec. 4, 1656. Early in 1657, however. his father died. and Nicolas promptly abandoned his legal career. He turned to the church and had himself tonsured, only to become a layman again.

Following the example of his brother Gilles Boileau. who was already well known as a man of letters. Nicolas tried his hand at poetry. At first he wrote satires. seeing himself as a rival to Juvenal. Next. from 1663 on, he wrote verse epistles in the manner of Horace. Then, in 1674. he published *L'Art poétique* and a translation of the pseudo-Longinus On *the Sublime,* as well as the first four cantos of Le *Lutrin* (the remaining two were not published until 1683). At this time he enjoyed the patronage of Madame de Montespan to a high degree, and in 1677 she secured his appointment as historiographer royal. For the next 15 years he refrained from expressing too forcefully his low opinion of contemporary poets. He was elected to the French academy in 1684.

In 1692 Boileau returned to controversy, angered by the success of the "moderns" against the "ancients." Regarding women as the most active supporters of the moderns, he wrote his satire *Contre les femmes* (published as *Satire x,* 1694). Thencefornard he found himself drawn into writing several more satires and epistles. When current controversy took an increasingly religious turn, he published his epistle *Sur l'amour de Dieu* (*Épître xii,* 1698) and began another satire, *L'Équivoque,* against the Jesuits and the moderns. This last piece occupied his life from 1703 on and from 1707 to 1711 he tried in vain to get permission to publish it.

Boileau's last years were spent at Auteuil. where in 1685 he had bought a house in a handsome garden. There he was pleased to act as the grand old man of French literature, the last survivor of the age of greatness. He died in Paris on March 13. 1711.

Satires.—Boileau's satires must be considered in two groups: the first nine. written 1660–67; and the last three, written from 1692 on. The first nine, originally composed to be read in manuscript to a circle of iriends, treat established reputations very disrespectfully, so that when an unauthorized edition of six of them appeared (166j), Boileau was seriously frightened and hurriedly issued an authorized edition (1666) with the most daring passages suppressed and the names of the victims altered. These early satires are lively and powerful. but it is clear that when he wrote them Boileau was not thinking of setting himself up as the legislator of Parnassus. For the later satires *see* above.

Epistles.—Boileau's *épîtres* were intended to give him a more respectable air. Between 1669 and 1677 he published nine. Much more reserved in rone than the satires, the epistles have nevertheless certain merits. but noticeably less than those of Horace. In his old age he added three more to the series.

Le **Lutrin.**—This poem deals with a dispute among the canons of the Sainte-Chapelle in Paris which had caused some amusement in 166;. Boileau was well qualified to judge what had been going on and gives an amusing account of it. *Le Lutrin* is a burlesque poem on the lines of Alessandro Tassoni's *Secchia rapita* (1624). parodying epic style by applying it to a trivial topic.

L'Art Poetique and Traite du Sublime.— Long regarded as the voice of "everlasting reason." *L'Art poétique,* a didactic treatise in verse, has been of the greatest importance in the history of French and English classical poetry. hlodern criticism, however, recognizes its intrinsic value to consist in the light that it sheds on literary controversy in the classical period.

The original mistake was the belief that Boileau had himself determined the rules that he defined. It is now accepted that, on odes, Boileau only says what Charles Cotin had said better before him: that Boileau's rules for tragedy were expounded quite satisfactorily by Jean Chapelain in 1630 and by the abbé d'Aubignac (François Hedelin') about 1640; that Boileau did nothing to destroy the vogue for burlesque, since burlesque died about 1656, before he had published a single line; and that the abbé Claude Fleury. with whom he was well acquainted. said ten years previously n-hat Boileau had to say about eclogues. *L'Art poétique* is interesting. however, as a statement on behalf of the ancient party against the moderns. Boileau defines the literary forms used by the ancients because they, by implication, exclude these used by the moderns. He defines tragedy in order to set it up against the love-dramas that the moderns were producing and he attacks the Christian epic because the moderns had ill-advisedly raised the subject in the course of the controversy.

The same motivation was behind Boileau's *Traité du sublime.* The treatise *On the Sublime* attributed to Longinus had attacked meretricious ornaments of style, clever subtleties and turgidity—the very faults that Boileau discerned in the moderns. Also, the Greek treatise had hailed as "sublime" that same greatness of thought and imagery that Boileau recognized in the ancients and could not see in the moderns.

Good editions of Koileau's works are by Jacques Berriat Saint-Prix, 4 vol. (1830–37) and by Charles Boudhors (1932 et *seq.*j

See, ior the original text of satires i–ix, A. Adam. *Les Premières Satires* de *Boileau* (1942) and ior an assessment of Boileau's real position in the literary world of his time, Adam's *Histoire de* la *littérature française au XVII^e siècle,* vol. iii and v (1952–56). (AE. A.)

BOILER. In engineering, a boiler is a device for making steam from water. This operation requires a supply of heat at elevated temperature. The usual boiler has a furnace in which a fossil fuel (coal. oil or gas) is burned, and the heat released by combustion is subsequently transferred through metal walls to generate steam at a positive pressure within the boiler vessel. Some boilers utilize waste fuels and waste heat, as in certain industrial processes. or the heat from nuclear reactions. as in some atomic power plants

The customary boiler. however, is direct-fired by a conventional fuel. and because of the two requirements — heat generation and heat absorption — the unit is more properly called a steam generator to indicate the inclusion of the many necessary components and accessories which reach beyond the simple implication of evaporation, or boiling from the liquid to the vapour state.

HISTORY

Introduction.- he origin of the steam boiler is contemporaneous with the invention of the steam engine. Its development has been a vital element in the successful generation of power by steam. In its earliest stages: during the 18th century, the pressure vessel or boiler was constructed of materials and in forms that were subsequently demonstrated to be entirely inadequate. Cast iron, lead. wood and brickwork—often in the form of flat surfaces—were prevalent. The tremendous potential hazards of such materials and designs were soon recognized. James Watt's "waggon" boiler (*see* below), built of wrought iron, marked a striking improvement in practice. Flat suriaces were stayed by the use of iron rods, and brickwork was reduced to a minimum by the incorporation of internal wrought-iron flues. These boilers operated at pressures of 5 to 25 lb. per square inch (p.s.i.) without undue hazards. With the development of the art of steam generation. pressures of approximately 100 p.s.i. were demanded in the latter half of the 19th century to serve compound steam engines. During the 20th century the introduction of steam turbines imposed tremendous burdens on the boiler designer. By the early 1960s boilers were being designed capable of generating steam at pressures as high as 5.000 p.s.i. with steam temperatures up to 1,200° F. Units, were also being designed in sizes large enough to supply approximately 3.000,000 lb. of steam per hour.

The impact of this progress led to the exclusive use of steel for the pressure parts of the boiler and steel alloys, such as stainless steel, for the high-temperature parts of the superheaters. For economy in the use of metal and for maximum safety in the structure, boiler parts ideally should be of a spherical shape but for practical reasons are usually cylindrical. The pressure parts of modern boilers are essentially an assembly of steel cylinders. drums and tubes.

Safety. — The paramount need for safety in both the construction and operation of boilers was learned through bitter experience. No boiler can be built or run without full compliance with the

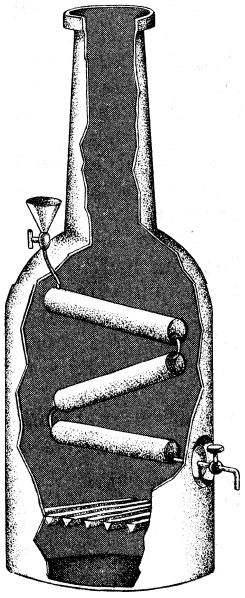

FIG. 1.—FIRST WATER-TUBE BOILER, BUILT BY WILLIAM BLAKEY IN 1766

most stringent boiler codes and laws, the enforcement of which rests within the police power of the state supplemented by the authority of the insurance underwriters. The design and construction of a boiler calls for most exact knowledge in the fields of machine design, metallurgy, heat transmission and fluid mechanics, coupled with experience of shop fabrication, welding and field erection techniques.

Early Boilers. — The earliest boilers recorded in history, such as those of Hero of Alexandria (c. 130 B.C.), were little more than playthings. During the Renaissance there were many attempts to picture or to devise ways in which the expansive power of steam might be utilized. Treatises by Matthesius in 1571, Ramelli in 1588, Branca in 1629 and Edward Somerset, marquis of Worcester, in 1663 all explored this fascinating subject. In 1679 Denis Papin devised a boiler that included what might be called the first safety valve. There followed more realistic efforts by Thomas Savery. 1698; Thomas Newcomen, 1690–1720; Haycock. 1720; John Allen. 1730; and others.

Watt's "Waggon" Boiler and Later Designs. — These early developments culminated in 1769 in James Watt's "waggon" boiler, the first truly successful boiler. It operated at 5 p.s i. steam pressure. Just prior to Watt's invention William Blakey patented the first water-tube boiler in 1766 (fig. 1). In this same period the great improvements made by Watt and others in the steam engine resulted naturally in rapid development of boilers to provide the necessary steam. Richard Trevithick, about 1800. constructed a boiler for high pressure with an internal flue that gave much improved fuel economy. John Stevens, in 1803, invented a water-tube boiler of small tubes connected at one end to a reservoir About 1820 the Cornish boiler appeared on the market and by successive steps was modified during the next 50 years, with many internal flues, ultimately leading to the fire-tube construction that was so popular toward the end of the 19th century. During this same period the water-tube boiler was being developed with the patent of Joseph Eve, 1825 (fig. 2), covering the first sectional design with well-defined circulation. In 1826 Goldsworthy Gurney employed small U-shaped tubes and in 1856 Stephen Wilcox was the first to use inclined water tubes connecting water spaces at the front and rear with a steam space above (fig. 3). There were many further steps in the development of the water-tube boiler using, for example. box headers or sectional headers. vertical or inclined header$ longitudinal or cross drums, curved tubes or straight tubes.

MODERN COMMERCIAL BOILERS

Introduction.– –By the early 1960s the art of boiler design and manufacture had reached a degree of perfection that would have been considered unattainable only a short time previously. Before discussing the many aspects of modern boiler design, however. it would be aell to illustrate the principle of operation of a typical steam generator so that the reader may become acquainted nith the principal components involved and thereby be in a better position to understand the material that follows

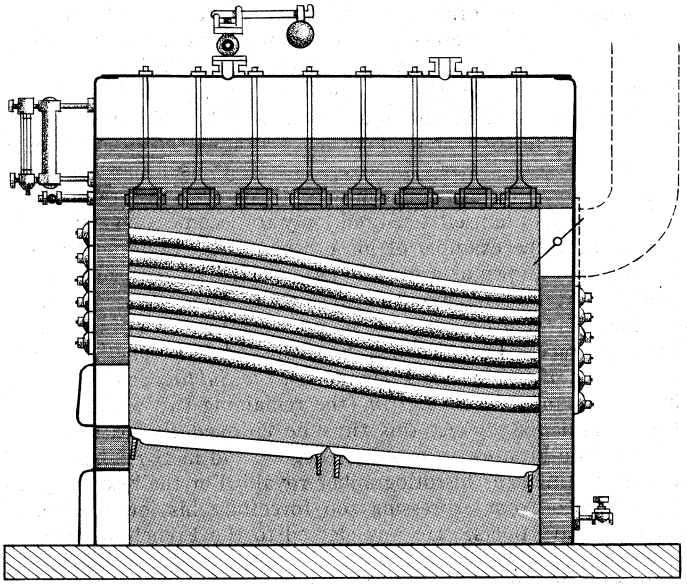

FIG. 3.— STEPHENWILCOX BOILER OF 1856. INCLINED WATER TUBES CONNECTED WATER SPACES AT FRONT AND REAR WITH STEAM SPACE ABOVE

In a typical modern water-tube boiler the coal in lump form is stored in the coal bunker at a sufficient elevation to permit gravity feed through an automatic coal weighing device into the pulverizer. In the pulverizer the coal is ground into a fine dust. after which it is picked up by a stream of air coming from the air preheater and blown through tubes into the burners In the burners the mixture of coal and air is joined by more air, called secondary air, from the air preheater, forming a combustible mixture that burns freely and creates a hot luminous flame that fills the furnace cavity Heat from this flame is transferred to water circulating in tubes located around the walls and across the top of the furnace; when sufficient heat is transferred. steam is generated inside the tubes. This steam is released into the drum near the top and from there is delivered to the superheater tubes extending down into the furnace. The superheater tubes are arranged evenly across the furnace so that hot gases will pass over the tubes and transfer heat to the steam inside the tubes by convection In this manner the steam is heated to a very high temperature before being delivered to the outlet header

After passing over the superheater tubes the hot furnace gases are directed by baffles, passing first over tubes carrying relatively cold water from the large upper drum down to the centrally located drum; these tubes form a part of the natural water circulation system of the boiler. From here the gases flow over the economizer tubes and surrender additional heat. The economizer is a device for preheating boiler feed water before it enters the main boiler drum. From the economizer the flue gases pass down over the tubes of the air preheater, giving up additional heat to air needed for combustion. In this manner air coming from the forced-draft fan is preheated before joining the fuel in the pulverizer and burners. This increases combustion efficiency and also extracts valuable heat from the exhaust gases before they are discharged through the fly-ash separator, induced-draft fan and stack to the atmosphere.

The foregoing describes only one particular design and is presented to give the reader a general idea of the arrangement of drums, tubes and other components in a modern boiler. There are very many other designs and no one design or type is superior to all others, but each is good for some specific service conditions. The attempt to meet different kinds of service conditions leads to the wide diversity of designs found in modern usage.

Fire-Tube and **Water-Tube** Types.—Boilers are usually classified according to whether they are of (1) the fire-tube or (2) the water-tube type. In the former the hot gases from the furnace flow inside steel tubes, approximately four inches in diameter, with water on the outside of the tubes. In the latter the situation is reversed and the boiling water is inside tubes, from one to four inches in diameter, with the hot gases circulating over the outside of the tubes. Fire-tube boilers use straight tubes while water-tube boilers use either straight or curved tubes.

Each type requires a drum that is partially filled with water. The drum serves the important purpose of allowing the steam bubbles to be separated from the mass of boiling liquid, thus assisting in the delivery of dry or nearly dry (99% moisture-free) steam. In fire-tube boilers the drum surrounds the nest of tubes that are rolled into flat tube sheets. The tubes serve to stay or brace the tube sheets and are limited to a length of from 20 to 25 ft. so that boilers for pressure of more than 200–300 p.s.i. and capacities of more than 25,000 lb. per hour cannot be built without excessive drum thickness. Water-tube boilers, on the other hand, do not have these limitations because the tubes are outside the drum and a unit for 2.500 p.s.i. pressure, delivering 1,000,000 lb. of steam per hour, might have a 60-in. diameter drum, 6 to 8 in. thick and 45 ft. long. Drum thicknesses for lower pressures would be proportionately less.

The respective advantages of the two types of boilers are: for fire-tube boilers, simple, inexpensive construction for low-capacity and/or low-pressure service; for water-tube boilers, suitability for high pressures and temperatures, with maximum efficiency, flexibility in design and arrangements. quick steaming and maximum safety. Prior to 1900, this last advantage was so clearly recognized that the water-tube boiler was often called the safety boiler. The divided structure, together with the small quantity of water in the pressure vessel, serves to reduce the potential severity of explosion.

Service Criteria.— The wide variety of acceptable designs of commercial boilers is the consequence of attempting to meet the service conditions with the most satisfactory arrangements. The following service criteria are significant in dictating features of design acceptability:

Safety.—There is no substitute for a safe structure. The risks of potential damage by the expansive energy of hot water under pressure are so great that it is often necessary to sacrifice otherwise desirable features in order to comply with the requirements of codes and regulations for the design, construction and operation of boilers and other pressure vessels. The absolute requirement of safety is most clearly recognized when one considers the installation of a boiler in a hospital, theatre or ship.

Shape.—The physical shape is determined by the service application. For example, a locomotive boiler must conform to the limitations of the right of way as to headroom, width and radius of curvature of the track. The limitations on a marine boiler are entirely different. Those on a central station boiler are again different. If real estate is expensive, ground area occupied should be at a minimum and skyscraper construction prevails, with the boiler possibly 150 ft. high. If the stationary boiler is to be installed on inexpensive real estate, the structure can spread out laterally.

Bulk.—In transportation service, for example on a ship, it is desirable to use a design and details that restrict the amount of space occupied and thus improve the pay-load capacity of the vessel

Weight.—Weight reduction is an obiective in all commercial applications in order to keep the price of the boiler at a minimum. In transportation services, moreover, a reduction in weight, as well as in space occupied, increases equivalently the cargo-carrying capacity of the vessel or vehicle. Perhaps the most striking examples of both weight and bulk reduction are found in naval service. Such reduction leads to increased armament, cruising radius and speed—paramount objectives in naval-vessel effectiveness.

Setting.—A setting is necessary to confine the furnace operations and hot gases and to provide structural strength. Steel. brickwork and moldable refractories are the common materials employed. In transportation applications the attendant vibrations and pounding dictate the minimum use of brick, and the self-contained designs are preferred. For stationary service. the improved performance and maintenance obtained with brickwork can be utilized, if desired.

Character of Labour.—Highly skilled labour permits design details that could never be tolerated in regions where labour is unskilled.

Cleanability.—Impurities in furnace operations and in water lead to: (1) the fouling of surfaces by soot, slag and scale with attendant loss of capacity and efficiency; and (2) contamination of steam delivered by foaming, priming and ineffectiveness of separation with consequent fouling of equipment beyond the boiler. Provision must be made to facilitate removal of these impurities. The extent of the respective fouling sources will dictate design arrangement and details.

Life.—Some constructions are justified by long life, *e.g.*, public-utility plants, while others, as for contractors, need only short life.

Efficiency.—High efficiency can be built into a boiler by increased investment, if so desired. All applications, however, because of adverse fuel prices, load factors and the like, cannot support the same high investment. Efficiencies of boilers consequently show wide diversity.

Cost.—In any commercial application of a boiler the ultimate criterion of suitability rests in the total cost of the steam produced. This must reflect the carrying charges on the investment, together with the costs for fuel, labour, maintenance and supplies. In certain noncommercial applications, such as naval service, the cost criterion is subordinate to other needs, in this case, military efficiency.

General.—The preceding factors result in the wide diversity of boiler designs. The market requirements determine the propriety of alternative designs. The state of the art in the early 1960s is illustrated, in part, in the table. This material gives representative data and demonstrates the progress achieved through nearly two centuries of experience with boilers for power purposes. The limits of size, pressure, temperature and efficiency are all indicated in the table.

PRINCIPLES OF BOILER DESIGN

There are two important aspects of boiler design—structural and thermal. The scientific dictates of these phenomena must be combined with fabricating and operating techniques to give a suc-

Comparative Size and Capacity Data for Representative Modern Boilers

Application	Locomotive boiler	Marine boiler (large ocean liners)	Industrial boilers				Large utility boiler
			Horizontal return tubular boiler	Package unit	Small unit	Large unit

cessful design. The rules of safety dominate, but the designer has great latitude within those rules to demonstrate his skill in the economic use of metal.

Structural Aspects. — A sphere, as noted previously. is the ideal form for a pressure vessel, but the difficulties of building spheres and the inadequacy of the spherical form for good heat transmission preclude its use and lead to the use of cylindrical parts — drums and tubes. The basic law of bursting strength states that the required thickness of a cylinder wall is directly proportional to the diameter of the cylinder and also to the internal pressure. Small diameters are therefore preferred to large diameters, and especially so with the higher steam pressures. The ends of cylinders must be covered and, since flat surfaces are the least desirable structural members, these ends are curved (bumped or dished) in order to avoid the use of stays and braces. Since water-tube boilers take the best advantage of these precepts, all large boilers (more than 25.000 lb. of steam per hour) and all high-pressure boilers (more than 200 or 300 p.s.i.) are of that type. Riveted construction was formerly used for drums, but welding superseded this technique. Boiler tubes are either seamless drawn or welded. Manholes and handholes are generally provided for access to internal parts. Tubes are arranged in bundles or banks together with drums and/or connectors by the use of expanding, rolling and welding techniques.

Provision must be made for supporting the dead weight of the boiler (perhaps as much as 2,000 or 3,000 tons). The difference between assembly and operating temperatures requires provision for unequal expansion of the parts without damage to the structure or associated equipment. Generally the boiler is so mounted that the drum is carried in slings or saddles and other parts are consequently free to move as needed. In marine applications the boiler is bottom-supported.

Thermal Aspects. — In the transfer of heat from hot gases to water in a boiler there are two objectives: (1) to transmit the most heat through a square foot of surface; and (2) to effect the transmission of the maximum quantity of heat generated in the combustion of the fuel. The first objective seeks to produce the maximum amount of steam per square foot of boiler surface. The second objective seeks to use the fuel or heat source nith maximum efficiency. These objectives conflict because maximum steam-making capacity per square foot of surface calls for maximum temperature difference between gases and water, whereas maximum efficiency in the use of fuel calls for the maximum cooling of the gases and consequent lowest possible temperature for the gases leaving the surface. The latter means low temperature difference between gases and water, which is in opposition to the first objective.

Metals, it should be noted, lose their strength rapidly with increasing temperature. The problem, consequently, is to keep the metal safely below a predetermined maximum limit of temperature; *e.g.*, 950° F. with carbon steel, 1,200" F. with stainless steel. This requires a recognition of the fact that the flow of heat from furnace gases to boiling water is through a complicated path in which the hot gases offer a high thermal resistance while the metal and boiling water film offer thermal resistances that are only a small fraction of the gas film resistance. The metal temperature is accordingly fixed by keeping the metal wet. High heat-transfer rates, and therefore high steam-making rates per square foot of surface, are obtained by vigorous scrubbing action and gas flow velocity. If the metal is not kept wet, as when steam bubbles are allowed to accumulate, the metal temperature rises rapidly to a point where its structural strength is impaired; the metal then overheats, burns and ruptures. The metal temperature is controlled by ample circulation of water so that a scrubbing action removes the steam bubbles as soon as they are formed and replaces them with water to keep the surface wet. Circulation is usually accomplished by thermal convection effects. The boiler drum is placed at a sufficient height above the tube bundle so as to create a flowing current of liquid or steam-free water in the downcomers and a current of steam and water in the risers. The difference in density of these two columns establishes the convection circulation. Some large high-pressure boilers use pumps to control the circulation of the water. This results in greater latitude in the height and arrangement of surfaces but places dependence upon the reliability of the pump. Other designs, which can be adapted to operation at pressures above the critical (3.200 p.s.i.), use the once-through, or forced-circulation, principle.

With the provision- of adequate circulation on the water side. it is then possible to improve heat transfer by reducing the thermal resistance of the gas side, which is essentially an insulating layer or film. This reduction is accomplished through suitable subdivision of the gas streams to give highly turbulent gas streams at high velocity. High temperatures, of course, are of great assistance in promoting heat transfer.

The surface that is exposed to direct radiation from the fire will generate the most steam per square foot not only because of temperature level but also because the gas film that clings to the surface does not retard radiant rays. High gas temperatures increase the steam-making capacity per square foot of boiler surface, but boiler efficiency cannot be high unless the furnace gases are cooled to the lowest practical value before discharge to the atmosphere.

High capacity per unit of surface and high efficiency are thus in opposition, and the designer must exercise his ingenuity and skill to get the most effective combination. In the ultilization of these skills, the water-tube boiler offers greater latitude of choice than does the fire-tube boiler, and therefore a greater diversity of designs of that type prevails. Curved tubes, in turn. give more freedom for choice in design than do straight tubes. The hot gases can be given flow direction over the surfaces by the judicious use of baffles.

Superheaters. — A superheater is a bundle of tubes arranged to take the steam from the boiler drum and raise its temperature a predetermined amount above the saturation value (perhaps as much as 300° or 400° F.). This assures the supply of superheated steam to, and the improved operating efficiency of, associated engines and turbines. Superheater tubes are of steel or steel alloys, usually 1 to 2.5 in. in diameter, and arranged in a general hairpin and continuous loop shape between inlet and outlet headers. Variations in arrangement and location in the boiler setting will change the performance characteristics. Resuperheaters, or reheaters, are incorporated in many large boilers to raise the temperature of the steam after it has been partially expanded in turbines operating on the reheat cycle.

Furnace Walls. — Refractory brick walls are satisfactory in small units but with high rates of firing in the furnace it is necessary to use water-cooled walls that are connected into the main circulatory system. Refractory cannot generally withstand the slagging and fusing action of the ash constituents of the fuel at high furnace temperatures. The extent and manner of water cooling is varied by the use of plain steel tubes, finned tubes and studded tubes, all with or without different thicknesses of plastic refractory. Outside the water tubes is an insulating jacket and casing that serves to keep the furnace gastight and to reduce heat loss to the surroundings.

Economizers and Air Heaters. — Economizers and air heaters are two important heat traps used in many boilers to improve efficiency by lowering the flue gas temperature below the value that could be obtained with boiler heating surface alone.

Economizers recover heat from the flue gases by transferring it to the feed water when the water is on its way to the boiler. This serves to raise the temperature of the water, usually without evaporation, and the water must be under boiler pressure. Economizers were formerly constructed of cast-iron tubes in the interests of corrosion reduction and cost, but cast iron proved unsuitable for pressures of more than 200 p.s.i. Steel-tube construttion superseded cast iron. This necessitated the introduction of degasification of feed water to eliminate corrosion.

Air preheaters recover the heat from the flue gases by transferring it to the air supplied for combustion. This serves to raise the temperature of the furnace and to improve combustion rates and efficiency, as well as to lower the stack gas temperature and thus improve the over-all economy of steam making. Air heaters are of the recuperative or the regenerative type. The former generally

employs a bank of straight steel tubes, one to three inches in diameter, usually with the flue gases inside the tubes and air outside the tubes. The regenerative type, on the other hand. transfers the heat by the use of a slowly revolving drum of corrugated metal that moves alternately through the hot flue gas and cold air streams.

Economizers are more expensive than air heaters because of the pressure loading. but heat transfer rates are several times higher, so that there may be an economic advantage in their use. Flue gases, in any event, should not be cooled below the dew point (200° to 300° F.) or corrosion troubles will follow. Combustion air temperatures must not be raised too high (500° to 700° F.). Economic considerations ultimately determine the extent to which economizers and/or air heaters can be used.

Fuels, Furnaces and Firing. — The furnace is that part of the boiler into which the fuel—solid, liquid or gas—is fed, together with air, the resultant chemical reaction (combustion) releasing heat. Many stationary boiler installations are built to operate with either of two alternative fuels. and sometimes three, for most effective economics. Chemically there are only two elements of importance in this combustion reaction of fuel and air. They are carbon, which has a heating value of 14,100 B.T.L. per pound, and hydrogen. which has a heating value of 61,000 B.T.L. per pound. The basic chemistry of combustion is simple. Fuels, however. as presented by nature, contain many impurities such as water, sulfur and ash. Some of the carbon and hydrogen appears as hydrocarbon (volatile) compounds. It is in the burning of these fuels that many serious. and often unresolved, problems arise. In fact it is necessary to use a highly skilled fireman as well as to select a skilfully designed furnace. The release of heat is accomplished in the furnace, and the boiler surface will accept and transfer to water the heat that is so released. With a good furnace design it is possible to (1) reduce investment by generating the maximum amount of heat in a given furnace volume; and (2) reduce operating costs by high furnace efficiency. The latter requires the minimum of unburned combustibles in the furnace gases and in the refuse and the minimum of excess air to avoid dilution of the heat released and the louering of the furnace temperature.

The problems encountered in attaining these objectives are concerned (1) with the feeding of fuel and air; and (2) with the mixing of the fuel and air. so that each molecule of carbon and hydrogen finds the necessary molecules of oxygen to produce carbon dioxide, water vapour and heat. The feeding is the easier problem and the mixing is the difficult, elusive problem with the goal a molecular mixture of chemical correctness.

Gaseous Fuels. — In the firing of gaseous fuels there can be varying degrees of mixing external to the furnace, thus changing the flame length and furnace volume.

Liquid Fuels.—In the firing of liquid fuels (oil burning) there can be no premixing of fuel and air. Fuel oil (Bunker C) for boiler firing is the heavy residue of refinery distillation. It is highly viscous, of good heating value (18,500–19,000 B.T.U. per pound; 145,000–150,000 B.T.U. per gallon), available in many markets at favourable prices and especially acceptable for marine applications regardless of price. As a substitute for the gaseous state, a spray-making device must be used when burning oil. Steam at 100 to 400 p.s.i. pressure can be used to atomize the fuel, or a mechanical atomizer may be employed in which the liquid fuel is put under pressure (irom 100 to 1,000 p.s.i.) by a pump and delivered through a sprayer nozzle or tip into the furnace.

The alternatives in the choice of steam v. mechanical atomizers are based upon the operating range of capacity. the value of the water lost with steam atomizing and the over-all cost. Fuel is delivered by tanker, tank car or truck to large outdoor storage tanks or directly to the ship's hold for marine service. It is recovered from storage, as needed, with a system of pumps. strainers and heaters, to deliver clean fluid oil to the burners. Surrounding the burners are air louvers and registers to control and direct the requisite quantity of air and to contribute the necessary mixing and turbulence in the furnace.

Caul. — Because of prevalence and cost, coal is the common fuel for boiler firing. It is burned either in solid form, as on a grate, or, when pulverized, in suspension. The solid form of the fuel and its high ash content create problems not present in gas and oil firing. In installations burning less than half a ton of coal an hour, a fixed, shaking or dumping grate, with hand firing, may be used. Hand firing results in maximum labour costs and poorest efficiency because of poor control over combustion conditions. Stokers are used for mechanical capacities beyond the limit of hand firing and burn at rates as high as 10 or 20 tons of coal per hour. The stoker is more than a mechanical coal feeder. It is constructed to permit the feeding and proportioning of air, the removal of ash and the distillation, gasification, mixing and burning of the combustible.

One stoker type is the chain grate, in which a layer of coal three to six inches thick is fed in at the front end. with the grate traveling at a speed of about one foot per minute and refuse being discharged at the back end. This type is suitable for burning anthracite and noncaking bituminous coals.

Spreader stokers have a feeder mechanism that projects the coal onto a dumping or moving grate. These stokers carry thin fire beds (one to two inches thick), are built in sizes up to 15 tons per hour and are suitable for burning almost any coal but anthracite.

Underfeed stokers are used with coals that cake. Green coal is introduced from below into troughs fed by rams that serve not only to feed coal but also to break up the cake by agitation of the bed. On the inclined sides of the troughs are tuyères for the introduction of air. The coal gradually works to the upper surface of the fuel bed as it becomes incandescent. The entire mass moves slowly to the ashpit at the rear. The fuel bed is about two feet thick and is a good device for distillation, gasification. mixing and combustion.

Pulverized coal requires a mill where the coal is ground to the fineness of a pomder (approximately 70% through a 200-mesh screen). Coals differ in grindability and require from 10 to 25 kw hr. per ton for pulverizing. The system must have drying devices to avoid packing. The powdered coal may be delivered directly to the burners (unit system) or to a bin (storage system) from which it is in turn delivered to the burners. Pulverizing is analogous to spraying in oil burning. Primary air is used to blow the pulverized coal into the furnace. Mixing and turbulence shorten the flame, reduce the furnace volume and promote combustion.

Ash removal is a serious problem and, depending upon the fusion temperature of the ash, the furnace must be designed to operate with ash in the dry state or in the molten state. A furnace cannot work alternately wet and dry. It can be built to handle the ash one way or the other but not both.

Cyclone *Furnace.*—This furnace, one of the most modern developments. burns low-grade fuels of high ash content and low ash fusion temperature. Crushed coal in sizes less than one-quarter inch is fed into the cyclone. It swirls around the periphery of the cylindrical chamber like a cyclone and burns with high heat intensity. The hot gases escape through the opening at the back into the boiler furnace and the molten ash flows to the ashpit below. The cyclone furnace results in a steam-generator plant that occupies less volume for the same capacity than other accepted methods of firing coal in large installations.

Coal- *and Ash-Handling Systems.*—Coal is generally stored outdoors and in amounts suitable for supplying the plant over a period of one to six months to avoid problems of uncertain delivery caused by bad weather or strikes and to take advantage of favourable buyers' markets. Coal must be compacted to avoid deterioration, loss by wind and rain and spontaneous combustion. Various types of mechanical unloading and reclaiming equipment are used. Bunkers are included in the power plant. They are proportioned to assure adequate fuel supply with single shift operation of the coal-handling equipment. Coal is fed from the bunkers through hoppers to cyclones, pulverizers or stokers.

Ash-handling systems are diverse, ranging from the wheelbarrow to the mechanical systems using bucket, pneumatic or hydraulic conveyors. The ash must ultimately be deposited in some location where it will not prove a burden.

Waste Fuels and Waste Heat. — Waste fuels and heat from many industries, such as woodworking, pulp and paper, sugar refining, steelmaking and chemical producing, can be used for steam generation. Each waste fuel has its own peculiarities, such as high moisture content, low heating value and contaminants; thus diversity of furnace design prevails. In the case of waste heat from industrial furnaces, it is possible generally to make steam economically if the waste gases have temperatures of more than 800' or 1,000" F., depending upon fuel price and load factor.

Draft Systems. — The purposes of the draft system are: (1) to provide the air needed for the combustion of the fuel; and (2) to deliver the hot gases from the furnace to the boiler surfaces, and when sufficient heat has been absorbed to eject the spent gases to the atmosphere. The draft system regulates the flow of air to the furnace and thus controls the rate of combustion and the output of the boiler. The air that is supplied is always in excess of the amount repuired. Good practice is represented by 10% to 25% excess air with natural gas; 10% to 15% with cyclones; 15% to 30% with fuel oil and pulverized coal; 20% to 40% with large stokers; 30% to 60% with small stokers; and as much as 150% with hand firing. The maximum air requirements determine the capacity to be installed in the draft system with dampers, or their equivalent, for control at lighter loads.

Natural Draft. — Like circulation in a boiler, natural draft is a thermal effect caused by the difference in density of a vertical column of warm gas inside a stack and the column of cold air outside the stack. The taller the stack and the higher the stack gas temperature, for a given atmospheric temperature, the greater will be the draft. This theoretical draft is measured by the difference in pressure that exists at the base of the stack. When an opening is made at the base, air will flow in by virtue of the pressure difference. Stacks are built of brickwork, concrete or steel plate (lined or unlined) as determined by the service and the economics. They must be structurally sound to withstand the external wind pressures that will prevail.

Mechanical Draft. — This is used for heavy fires and high rates of combustion when stacks for natural draft would become prohibitively tall. This is especially significant when low stack temperatures (300' F.) are used in order to reduce the thermal loss to the atmosphere and thus improve the efficiency of steam making. Fans and blowers are employed to develop the requisite pressures, and a stack of minimum height is provided to discharge the gases at a reasonable distance above ground level for effective dissemination. The fan or blower may be placed ahead of the furnace to deliver air for combustion under positive pressure — consequently called forced draft; or the fan or blower may be placed at the flue outlet from the boiler setting, exhausting the products of combustion under negative pressure and delivering them to the base of the stack. This latter application is called induced draft, and equipment for this service must handle hot gases (up to 700° F.) contaminated with varying amounts of soot, cinders and dirt. The physical size of the fan or blower for induced draft is much larger than the equivalent forced-draft unit for the same service because the latter handles only air at atmospheric, not stack, temperature.

Jet blowers using steam as the actuating fluid can be installed for forced- or induced-draft service to entrain air or flue gas. These units are inefficient but simple, foolproof and low in first cost. They are commonly found on steam locomotives utilizing engine exhaust to create the induced draft at the base of the short stack, thus creating the characteristic pulsating noise and puff of the "iron horse."

Fans are driver! directly by motors or turbines or indirectly through gears or variable-speed couplings. Some small installations use propeller-type fans in the interest of low initial cost and some marine installations use them because of their compactness. The general preference is for centrifugal types in which there is a rotor, similar to a paddle wheel. The rotor turns within a spiral or scroll case. Gas enters at the eye of the rotor and is discharged at the outer periphery to the scroll. Fans with variable speed, or its equivalent, are advantageous because of their high efficiency in service. Excellent control of draft is accomplished with this arrangement, with dampers as a supplement.

Balanced Draft. — This is a combination of forced and induced draft that maintains substantially atmospheric pressure in the furnace. It is employed on many large installations but there is an increasing tendency to use an airtight boiler casing and to put the entire boiler setting under positive pressure, thereby eliminating the induced-draft fans. This results in (1) the minimum of auxiliary power for draft creation; and (2) elimination of the air leakage into the boiler setting that causes dilution, chilling of gases and loss of efficiency.

Flues and *Breeching*.—Sheet metal platework, with or without cement or brick lining, constitutes the flue or breeching which connects the boiler to the stack.

Dust Catchers and Cinder Traps. — Pollution of the atmosphere by the discharge of cinders, fly ash, smoke and noxious gases is no longer tolerated as a necessary evil in enlightened communities. Proper control of combustion will reduce the smoke nuisance. The use of fuels that are low in sulfur content will reduce the toxic effects of sulfur dioxide and trioxide. Fly ash and cinders accompany coal firing. Some methods of firing are less troublesome on this score than others; *e.g.*, underfeed stokers and cyclone furnaces. In other cases most of the ash (as much as 90%) may appear in the flue gases. This ash is in the form of fine dust particles, many not visible to the naked eye but some as large as one-eighth of an inch across. Numerous varieties of dust separators and cinder traps are used for the separation of these particles. Mechanical separators, operating on inertia principles, are good with larger size particles and heavy dust loadings. Electrostatic precipitators that charge the dust particles and attract them to electrodes are especially helpful in the separation of the finer particles (less than 40μ). Good fly-ash elimination systems are large, bulky and costly but they often operate with sustained separation efficiencies in excess of 90%. Such performance generally results in a discharge (gas dust) loading of less than 0.85 lb. per 1,000 pounds of gas, which is acceptable under many air pollution control codes and laws. The demand for effective law enforcement is steadily increasing.

Boiler Accessories. — There is a wide assortment of supplementary apparatus and instruments that are needed to make a steam-generator installation operate satisfactorily. Some are required by law; others are chosen because they improve efficiency, maintenance or operating labour costs.

Pressure gauges are of the flexible (Bourdon) tube type. A flattened tube is formed into the arc of a circle and sealed at the free end; when subjected to internal pressure it tends to straighten out, thus moving a pointer across a dial on which appears a pressure scale.

Water columns give, in a gauge glass, a direct indication of the water level in the boiler drum. Low-water level will lead to burning of the boiler surface and high-water level will allow liquid water to pass into the steam line and damage running machinery. 'Remote level indicators and alarms for high and low water may be employed.

Try cocks are used to determine the water level when the water column is out of service. They operate on the principle that steam escaping from an orifice into the atmosphere is colourless for many feet, but water gives the characteristic white plume right up to the orifice.

Safety valves are required to relieve any excess pressure that might develop as a consequence of a drop in the steam take-off rate from the boiler without an accompanying reduction in the firing rate. They are of the spring loaded, poppet type, tamperproof, and are set at a pressure greater than the operating pressure. Their number, adjustment and setting are rigidly supervised by government and insurance inspectors with the responsibility for change resting in the licensed operator.

Feed *System*.—Continuity of feed water supply is an absolute essential for safety. The water must be available at a pressure sufficiently above the boiler pressure so that water will flow into the boiler when the feed valve is opened. Pumps are an essential auxiliary to all boilers and for assurance of service continuity they are installed in duplicate and with alternative drives. Steam drive usually gives greatest reliability but electric drive is more efficient.

Pumps may be of the reciprocating. centrifugal or injector types The water is delivered through the piping system. with a level control \-alve and check valve to the boiler drum

Steam Take-off System.—Boiler drums serve to disengage steam from nater. but assurance of dry steam is secured by a dry pipe in the boiler drum for small sizes Highly developed scrubbers and separators are used in the larger designs. Clean (less than 3 parts per 1,000 000 of solids). dry steam is then assured for the superheater Beyond the superheater there must be a stop valve fol isolating the boiler from the rest of the plant when the boiler is shut donn. It should have a nonreturn feature to protect the plant. nhen a tube failure occurs. by preventing the flow of steam into the damaged boiler from other sources.

Blowdown Systems—Under efficient operation, any impurities that are present in the feed water are not carried over into the evaporated steam. so that they become concentrated in the water contained in the boiler. When the solids in solution approach values such as 1,000 to 2.000 parts per 1.000 000 it is necessary to have a blowdown arrangement. This allows impurities to be removed from the circulatory system with the minimum of water and heat loss.

Boiler *Cleaning.*—Despite all precautions that can be taken it becomes necessary to clean periodically the water-side surfaces of accumulated deposits and scale. This can be done with a mechanical tube cleaner that chips the scale loose or it can be done chemically with an acid solution. The chemical method must be carried out with skill to avoid damage to the metal of the boiler structure.

The gas-side surfaces must be cleaned regularly, perhaps once or tnice a shift. to remove accumulations of ash, soot and slag. Soot blowers. using compressed air or steam, direct high-velocity jets at the surfaces to be cleaned. Gas-side cleanliness is essential to maintain the output and efficiency of the plant. Water-side cleanliness is necessary to prevent overheating of metal parts and accompanying burning and rupture.

Feed *Water* Treatment.—Boilers should be fed with chemically pure water. This means freedom from all scale-forming compounds, from acid, from floating contaminants such as oils and fats and from dissolved gases such as oxygen and carbon dioxide In industrial process plants the make-up may run to 100%. This make-up nater requires treatment for the removal of impurities; the steam exhausted from the steam power plant is condensed and returned to the boiler since this condensate is pure distilled water. Because of steam and uater losses in the engine room. the boiler may require make-up feed water amounting to 1% or 2% of the steam supply rate. Various kinds of treating plants are employed, depending for their selection on the nature of the impurities to be removed the operating pressure and temperature and the costs. Treating plants may include many of the following elements: sedimentation chambers, filters. chemical treatment with soda ash or zeolites, demineralization equipment, evaporators and degasifiers.

Instruments and Controls.—Skilful operation and supervision are necessary for the most economical performance of a steam-generating plant. For intelligent operation it is essential to provide the operator with the tools needed for effective performance. Boilers are accordingly equipped with varying degrees of instrumentation and control depending upon costs Instruments are of the indicating, recording and integrating types and typically show pertinent temperatures, pressures, air and steam flows, fuel burned, draft pressure and flue-gas analyses.

Supplementary laboratory facilities give heating value of the fuel, refuse analysis, water and steam purity. A typical large modern steam-boiler plant has an elaborate instrument panel showing all of the readings needed for the skilful manipulation of the plant, which is remotely controlled from the instrument board. Television cameras transmit continuous pictures of firing conditions nithin the furnace and of the boiler water level. The entire operation can be turned from manual to automatic at the will of the operator. The automatic combustion-control system is remarkable in its supervision and leads to performance uhich could never be matched by simple manual operation.

MERCURY VAPOUR BOILER

Another type of boiler, one that received considerable attention prior to World War II was the mercury boiler, used in the binary mercury-steam cycle. In this cycle mercury vapour generated in a mercury boiler is directed through a mercury turbine and then exhausted into a special condenser-boiler. In the condenser-boiler the latent heat of the mercury is transferred to water. which is thereby converted into steam. After being superheated in the furnace of the mercury boiler. the steam is employed for generating power using a conventional steam cycle. Thus, power is generated by both the mercury turbine and the steam turbine, but heat is rejected to the surroundings only in the steam portion of the cycle. This results in higher thermal efficiency than obtainable with the steam cycle alone because of the more favourable thermal characteristics of mercury vapour at high temperatures.

Because of practical difficulties, as well as economic and safety considerations, work on the binary mercury-steam cycle has been neglected in favour of the more modern high-pressure, high-temperature multiple reheat steam cycles.

In the early 1960s there were four mercury boilers in operation in the United States. All generated mercury vapour at pressures close to 145 p.s.i., corresponding to a saturation temperature of 964° F. The largest of these units was located at Kearney, N.J., and generated 2,200,000 lb. of dry saturated mercury vapour per hour at 155 p.s.i. absolute and 975° F.

NUCLEAR STEAM GENERATORS

Another type of steam generator that is entirely different in design from the fossil fuel boilers previously described. is the nuclear steam generator. In this type unit, heat is generated in a vessel by the fissioning of uranium-235 (U^{235}). The fission process takes place in the core of the reactor. which consists of suitably shaped elements of natural uranium (U^{238}) or some other uranium compound enriched with U^{235}. The elements are usually encased in a noncorrosive can or jacket. The core is supported in the vessel in such a way that a coolant can be directed around the elements of the core in the most effective manner for absorbing the heat released during the fission process. The rate of fission is governed by means of control rods. which reduce the rate of fission when inserted into the core and increase the rate when withdrawn.

In one type of reactor the coolant consists of ordinary water. When fission takes place the heat released is transferred to the water, causing it to boil and thus generating steam. The steam can be directed to a turbine for the generation of power just as in a conventional steam power plant.

Steam can also be generated indirectly with other types of nuclear reactors. In these a fluid other than water circulates through the reactor core and absorbs heat. This fluid is in turn circulated through heat exchangers and the heat is eventually transferred to water for the formation of steam. Among the fluids that can be employed are liquid sodium, various organic compounds and gases such as carbon dioxide.

For further information concerning nuclear reactors see NUCLEAR ENGIKEERING: Boiling *Water* Reactors.

(T. BR.; RD. A. BR.)

BOILING POINT, the temperature, for any given liquid, at which the application of heat ceases to raise the temperature of the liquid and instead converts the liquid into its vapour. The boiling point of water under normal pressure (760 mm. mercury) is 100° C. or 212° F.

The effect of increasing the pressure is to raise the boiling point; the presence of dissolved impurities also raises the boiling point but to a much less marked extent.

See BAROMETER *Hypsometer;* LIQUID STATE, THE; SOLUTIONS: *Elevation of the Boiling Point.*

BOISE, the capital and largest city of Idaho, U.S., and the seat of Ada county; in the southwest part of the state. (For comparative population figures *see* table in IDAHO: *Population*) Sheltered by a mile-high ridge on the north and east, Boise has a mild, four-seasonal climate; most winters have little snow, and hot summer days are balanced by cool summer nights. Low humidity and an annual rainfall of slightly over 12 in. make irrigation essential. Three important dams (Arrowrock, 350 ft. high; Anderson Ranch. 456 ft.; Lucky peak, 340 ft.) provide the region with water storage and recreational facilities.

Named by French Canadian settlers for the tree-lined river (Fr., *boisé,* "wooded") which provided relief for travelers across the desolate wastes of the Snake river plains, Boise became a welcome oasis on the Oregon trail. However, the town was not founded until the 1862 gold rush to Boise basin. Ft. Boise was established on what is now Government Island, July 4, 1863, and a community developed providing services for the nearby mines. Boise's position at the crossroads of the Oregon trail and a primary mining route (Boise basin to Owyhee) ensured the city's early gron th.

In 1864 Boise was incorporated as a city and became the capital of Idaho, as well as seat of the newly created Ada county. The *Idaho Daily Statesman,* established there in the same year, is the state's oldest nenspaper.

Mementos of Boise's early history survive in contemporary cabins, Urquides Village established in 1863 for packers to the mines. some early Ft. Boise structures and the assay office building completed in 1872. Hot water (172° F.) from artesian wells still supplies heating for residences and public buildings.

Agricultural expansion and the growth of a commercial lumber industry contributed to the city's rapid growth in the early part of the 20th century. Left off the main line of the Union Pacific until 1925, Boise made early use of commercial aviation (1926). One of the world's largest construction companies grew up there; smaller diversified industries and extensive wholesale trade and trucking also developed Federal and state agencies provide much local employment, and Boise is the Columbia basin headquarters for the U.S bureau of reclamation.

Boise junior college, with an annual enrollment of more than 1,000 students, mas established in 1932. (M. D. B)

BOISGUILLEBERT, PIERRE LE PESANT, SIEUR DE (1646–1714). French economist and precursor of the physiocrats (*see* PHYSIOCRATIC SCHOOL). was an important advocate of economic and fiscal reforms for France, which was approaching economic collapse late in the reign of Louis XIV. He was strongly opposed to Colbert's economic policy of attempting to increase the manufacturing potential of France by keeping agricultural prices at a low level in the hope that low-wage goods would be an incentive to industry. Like his physiocratic successors, Boisguillebert felt that the wealth of the nation was dependent on the prosperity of the agricultural sector. He was an agricultural protectionist, but his belief in the natural order and his opposition to the medieval economic restrictions which had proliferated during this period brought him close to a *laissez faire* position. In matters of fiscal reform he advocated direct rather than indirect taxes, the reform of the taille, and an income tax consisting of a 10% levy (*dime*). For his views on these matters and his support of the disgraced Sebastien de Vauban (*q.v.*) he was for a time exiled.

See E Daire, *Economistes financiers* du *XVIII^e siècle,* 2nd ed. (1831); Hazel van Dyke Roberts, *Boisguilbert, Economist of the Reign of Louis XIV* (1935). (L. N.)

BOISROBERT, FRANÇOIS LE METEL, SEIGNEUR DE (1589–1662), French poet, dramatist and wit, was born in Caen of a Huguenot family. Abandoning a legal career in Rouen, he went to Paris in 1616 and attached himself first to Cardinal du Perron, then to the queen mother, Marie de Médicis (who in 1618 engaged him to translate Guarini's *Pastor fido*), and finally to Richelieu. Having abjured his Protestantism, he took orders in the Roman Catholic Church in 1623 and subsequently received a canonry of Rouen and other benefices. With a reputation for repartee and practical jokes, he was kept as a jester by Richelieu (though the latter is said to have disliked him personally) and so acquired great influence over the fortunes of men of letters, both before and after his inclusion in the Académie Française (1634). His parody of Corneille's Le *Cid* was highly gratifying to Richelieu. Most of his 18 plays are tragicomedies, several of them adaptations from Spanish works: *La Folle Gageure* (1653), *L'Amant ridicule* (1655) and *La Belle Plaideuse* (1655), a source for Molière's *L'Avare,* deserve mention. His *Epîtres en vers* (1647; ed. by M. Cauchie, 2 vol., 1921–27) serve as an index of the literary quarrels of his time.

BOISSIER, MARIE LOUIS ANTOINE GASTON (1823–1908), French scholar and historian of Roman civilization, was born at Nimes on Aug. 1 j, 1823. After 10 years as a lecturer at Nimes, Boissier mas appointed professor at the Lycée Charlemagne in Paris. and in 1862 succeeded Sainte-Beuve as professor of Latin poetry at the Collège de France. He was elected to the French academy in 1876, and appointed permanent secretary in 1895 He was long associated with the *Revue des deux mondes* in which his scholarly but by no means forbidding historical works appeared. He died at Viroflay on June 11, 1908. His works include studies of Roman Africa, the decline of paganism, the opposition to the Caesars and biographies of Latin poets. Between 1896 and 1906 several of his books were translated into English.

See P Thoulouze, *Gaston Boissier* (1923).

BOISSY D'ANGLAS, FRANÇOIS ANTOINE DE (1756–1826). French statesman, a defender of moderate policies during the Revolutionary period, was born at Saint Jean-la-Chambre, near Annonay, on Dec. 8. 1756. Elected in 1789 by the third estate of the *sénéchaussée* of Annonay as deputy to the estates-general. he was *procureur général syndic* for the directory of Ardèche during the Legislative Assembly (*see* FRANCE. *History;* FRENCH REVOLUTION). Elected to the Convention in 1792, he sat in the centre, voting in the trial of Louis XVI for his detention until deportation should be judged expedient. A supporter of the Thermidorian reaction against Robespierre, he was in Jan. 1795 elected to the Committee of Public Safety. During the rising of 1 Prairial year III (May 20. 1795), he presided over the Convention and remained unmoved by the menaces of the insurgents. When the head of the deputy Jean Féraud was presented to him on the end of a pike, he saluted it impassively. His report on behalf of the committee that drew up the constitution of the year III showed keen apprehension of a return of the Reign of Terror, and his proposal to lessen the severity of the revolutionary laws led to his being suspected of disloyalty to the republic. As a member of the Council of the Five Hundred he became still more suspect. Proscribed after the coup of 18 Fructidor year V (Sept. 1797), he retired to England. Returning to France under the consulate, he was made a member of the tribunate in 1801 and a senator in 1805. Having voted for Napoleon's abdication in 1814 he was admitted to the chamber of peers on the first Restoration, but during the Hundred Days he rallied to Napoleon. Readmitted eventually to the chamber of peers under the second Restoration, he worked to secure the freedom of the press. Boissy d'Anglas died in Paris on Oct. 20, 1826.

BOITO, ARRIGO (originally ENRICO) (1842–1918), Italian poet and composer, whose fame rests upon his opera *Mefistofele* and the librettos based on Shakespeare's *Othello* and *The Merry Wives of Windsor,* which he wrote for Verdi. The son of an Italian miniature painter and a Polish countess, Boito was born at Padua. Feb 24,1842. and from 1853 to 1861 received his musical education at the Milan conservatory, where he also studied Italian literature. A traveling scholarship took him to Paris, where he met Verdi, for whom he wrote the text of the "Hymn of the Nations" in 1862. When war broke out in 1866, he joined Garibaldi's

volunteers. While working on *Mefistofele,* for which he derived his text from Goethe's *Faust,* he occupied himself with musical journalism, championing German. and attacking Italian. music and musicians with more vigour than discretion. Verdi was deeply offended by one of Boito's remarks, which seemed to reflect on his artistic integrity. By 1868, when *Mefistofele* was produced at Milan. Boito's polemics had provoked such hostility that the opera mas withdrawn after two performances. A much-revised version was successfully produced at Bologna in 1875 and has remained in the Italian repertory. Boito's second opera. *Nerone,* occupied him for nearly 50 years and was still not quite finished when he died, at Milan, June 10. 1918. Completed by V. Tommasini and Arturo Toscanini. it mas produced at La Scala, Milan. in 1924. but despite its grand design and spectacle, was found to be lacking in the musical character that distinguished *Mefistofele.*

A reconciliation between Boito and Verdi was effected in 1873 and Boito undertook the revision of the libretto of Verdi's *Simone Boccanegva.* His masterly versions of *Othello* and of *The Merry Wives* (the libretto for *Falstaff*) stimulated the imagination of the aged composer to its greatest feats. Besides the librettos for Verdi and for himself, Boito wrote texts for several other composers, the only survivor in the modern repertory being Ponchielli's La *Gioconda.*

BOJER, JOHAN (1872–), Norwegian novelist known chiefly for his vivid and realistic studies of peasant life in his native province, was born at Orkesdalsøren, Trondelag. on March 6, 1872. His first novel to command attention was *Et folketog* (1896). It was inspired by social fervour, and so were *Den evige krig* (1899) and *Moder Lea* (1900).

En pilgrimsgang 11902) and *Troens magt* (1903) show a more subtle portrayal of character and a surer grasp of plot. and there is further growth in *Fangen som sang* (1913) and *Den stove hunger* (1916). *Den sidste viking* (1921). Bojer's most popular book, about fishermen in the Lofoten, is epic in conception and contains remarkable descriptive passages and dramatic situations. In *Vor egen stamme* (1924), about Norwegian emigrants to the Cnited States; his sympathy, sense of adventure and achievement and understanding of the process of uprooting and readjustment, form a more complex pattern. In *Folk ved sjoen* (1929), probably his finest work, the simple, realistic framework of the story is transformed by his symbolical vision. Later publications were *Gdvd og grend* (1933), short stories; *Læregutt* (1942) and *Svenn* (1946), memoirs; and *Skyld* (1948), a novel. A number of his works have been translated into English.

See Carl Gad, *Johan Bojer, the Man and His Works* (1920); *P.* G. La Chesnais, *Johan Bojer* (1930). (G. RN.)

BOK, EDWARD WILLIAM (1863–1930). U.S. editor and author, born at Helder. Neth.. Oct. 9, 1863. n-as taken at the age of six to Brooklyn. N.Y., where he entered public school without knowing English. The family's poverty caused him to go to work as an office boy for the Western Union Telegraph company. A youthful hobby of autograph collecting led. him to meet outstanding political and literary personages with the result that he was encouraged to improve himself. Attending night school. he worked for Henry Holt & Company. book publishers. for two years. beginning in 1882. and then transferred to Charles Scribner's Sons, where. at the age of 24. he became advertising manager of *Scribner's Magazine.* In 1886 he established the Bok Syndicate Press for which he developed. as a regular newspaper feature. a full page of reading material for women. The striking success of the "Bok page" as a cultivator of feminine interests led Cyrus H. K. Curtis to invite the editorial innovator to the editorship of the *Ladies' Home Journal.*

Against the advice of his associates. Bok left New York city and went to Philadelphia, Pa.. where he became one of the most original editors in the history of periodical journalism. He devised departments to inform and advise women on almost everything. He campaigned for woman suffrage. sleeping-car improvement. wildlife conservation and clean cities and towns. He opposed roadside billboards. public drinking cups and power company encroachment at Niagara falls, New York. His announcement in 1892 that he would accept no more patent medicine advertising opened the way for a crusade that enlisted other editors and culminated in the enactment of the Pure Food and Drug act of 1906. His boldest venture was to break the taboo against printed mention of venereal disease. By 1917 readers n-ere sending him nearly 1.000.000 queries annually for public reply.

After editing the *Ladies' Home Journal* for 30 years. Bok retired in 1919 to write one of the most noted autobiographies, *The Americanization of Edward Hok,* published in 1920 and awarded a Pulitzer prize the next year. He devoted the rest of his life to benefactions. including the creation of the Philadelphia award to a citizen who performed a notable community service—an idea adopted in many other cities. In 1923, to mitigate the horrors of war which he had seen first hand at the battle fronts in 1918, he created the American Peace award of $100,000 for the best practicable plan through which the United States might co-operate with other nations in achieving and preserving world peace. Many plans were submitted and that of Charles H. Levermore was declared the winner. Bok established the Harvard advertising awards in 1923 and endowed the Woodrow Wilson chair of government at Williams college (Williamstown. Mass.). His last years went into developing the Mountain Lake bird sanctuary and building the "singing tower." both near Lake Wales, Fla. The tower, with its 71-bell carillon, was dedicated in 1929. Bok died in Florida on Jan. 9, 1930.

In addition to his autobiography, Bok published *Successward* (1895), *The Young Man in Business* (1900), *Two Pevsons* (1922), *A Man From Maine* (1923). *Twice Thivty* (1925), *America Give Me a Clzance!* (1926), *Dollars Only* (1926) and *Perhaps* I *Am* (1928). (I. DD.)

BOKENAM, OSBERN (1392?–1447?), English author of a book of legends of women saints, was born on Oct. 6, 1392, if the statement in his "Life of St. Margaret" that he had lived "ful yerys fyfty" is to be taken strictly. His birthplace is unknown, but may have been Old Buckenham, Norfolk. In a concluding note to his *Legends of Holy Women* he is described as "a Suffolke man, frere Austyn of the convent of Stokclare." He traveled in Italy and in 1445 was a pilgrim to Santiago de Compostela. He wrote a series of 13 legends of women saints! over 10,000 lines in all, mainly in seven- or eight-lined stanzas. Bokenam, a follower of Chaucer and John Lydgate, doubtless had in mind Chaucer's *Legend of Good Women,* but his writing is crude and unskilful. There is more interest in the prologues than in the legends themselves, which are closely translated from the Latin. His chief but by no means only source was the *Golden Legend (Legenda Aurea)* of Jacobus de Voragine (*q.v.*), archbishop of Genoa, whom he cites as "Januence." The first of the legends. of St. Margaret, was written for his friend Thomas Burgh. a Cambridge friar; others are dedicated to pious ladies who desired the histories of their name saints. The manuscript Arundel 327 (British museum, London) is the only copy of Bokenam's work; it was finished in 1447 and presented by the scribe. Thomas Burgh. to a convent unnamed "that [the nuns] shulde have mynd on hym and of hys systyr Dame Betrice Burgh."

See the edition by M. S. Serjeantson, *Legendys of Hooly Wummen,* Early English Text Society, no. 206 (1938). Earlier editions were for the Roxburghe club (1835) and by C. Horstmann (1883). (N. D.)

BOKSBURG, a town of the Transvaal province of the Republic of South Africa, lies 15 mi. E. of Johannesburg. Pop. (1960) 70,933, of whom 27,806 mere Europeans. Established in 1887 as the administrative centre of the East Rand, it is now the most important gold-producing town on the Witwatersrand. Buildings include the first post office, bank, hotel, school, public library, railway station and municipal offices on the East Rand. It is a rapidly expanding industrial and educational centre, with residential suburbs and good recreational facilities. Boksburg lake and Cinderella yachting lake are main pleasure resorts. The town adjoins Jan Smuts international airport and the important Germiston railway junction, and is on the main line to the port of Lourenço Marques, Mozambique; it is also the focal point of 11 main roads.

There is a wide variety of heavy and light industry including the manufacture of freight cars, rail points and crossings; transformers, switchgear, high tension insulators and electric motors; structural steelwork and fencing; soap, edible oils, ceramics. enamelware, plywood, stainless steelware, telephones, electronics, nuts and bolts, and the canning of fruits. In addition to gold. a main export is refractory fire clay products.

(W. C.D. S.; P.R.N.)

BOLANGIR, a town and district in Orissa, India. The town, headquarters of the district, is 155 mi. W. of Cuttack. Pop. (1961 census) 18,670. It contains Rajendra college (1943), affiliated to Utkal university, and Sailasri palace, the residence of the former ruler of Patna state.

BOLANGIR DISTRICT was formed from the former principalities of Patna and Sonepur after their merger with Orissa in 1948. Pop. (1961) 1,070,016. Area 3,440 sq.mi. It is comparatively open country bounded northeast by the Gandhamardan hills (over 3,000 ft.); west by a narrow forest belt; and southeast by the Tel, a tributary of the Mahanadi (*q.v.*). To the northeast is a tract of forest and scrub jungle. Four-fifths of the population depends on agriculture, the main crop being rice, with some raggee millet and gram. Sonepur, at the Mahanadi-Tel confluence, is a weaving centre. Titlagarth, served by the Vizianagram-Nagpur metre-gauge railway, has ancient cave temples; Vaidyanath, on the Tel, has ancient sculptured monuments; and at Ranipur-Jharial is the temple of the 64 yoginis. (MA. M.; N. K. S.)

BOLAN PASS, an important gateway through the Central Brahui mountains in Kalat, Pakistan, connecting Sibi with Quetta. The pass extends for 60 mi. from Rindli in the south to Darwaza near Kolpur in the north. For centuries it has been the route for traders, invaders and nomadic tribes between India and high Asia. By the treaty of Gandamak (1879) the Bolan route was brought under British control. The Sind-Pishin railway, linking plains and plateau, originally followed the Bolan river from Sibi; destructive floods in 1890, however, led to its abandonment, and the line now follows the Mashkaf valley (which debouches into the plains near Sibi) to its junction with the Bolan at the coal-mining town of Mach. The road still follows the old route via Rindli. The passage between the limestone rocks is in places extremely narrow; south of Mach it gradually widens out into Laleji plain.

The pass is subject to extremes of temperatures, the icy winter wind often being destructive of life. The climate is arid, and brown, yellow and gray unmodified by verdure are the predominant colours of the rocks. (K. S. AD.)

BOLAS (Span. boleadoras) are South American Indian weapons made of stone balls, usually grooved and well polished, sometimes encased in animal hide, and attached to long, thin ropes which, when twirled and thrown, are designed to strike an animal so as to entwine its legs, rendering it immobile. They are classified into single-, double-, and triple-ball types, the last being the most commonly encountered archaeologically, historically and in modern times.

This weapon was characteristically used in hunting rhea, guanaco, puma (as a single-ball mace) and other animals found in open country. It was also employed against horses and cattle in post-Conquest times in the Gran Chaco, the Pampas and Patagonia. Although principally a hunting weapon, bolas were used effectively in combating Spanish cavalry and in intertribal skirmishes, once Indians had acquired horses and tribal segments had begun to expand beyond ancestral territories as a consequence of frequent predatory raids.

Bolas were widely distributed in South America. According to many Spanish chroniclers of the 16th, 17th and 18th centuries, they were used in highland Peru and Bolivia by the Quechua and Aymara, in Chile and Argentina by the Araucanians, and in the Argentine Pampas and Patagonia were the favourite weapon of the Charrúa, Querandi, Puelche, Tehuelche, and other peoples. In the Gran Chaco bolas were employed by the Abipón, Mocovi and, well into the 19th century, by the Lengua.

Bolas are used by the Uruguayan and Argentine-gauchos. The single-ball type, called bola perdida, is used by the contemporary Uru who employ a bola de paja ("straw ball") in duck hunting in the marshlands along the southern border of Lake Titicaca. See also WEAPONS, PRIMITIVE.

See J. H. Steward (ed.), Handbook of South American Indians, Smithsonian Institution, Bureau of American Ethnology, Bulletin 143, vol. 5, pp. 253–54 with bibliography (1949); J. H. Steward and L. C. Faron, Native Peoples of South America (1959). (L. C. FA.)

BOLE, in mineralogy, a yellowish, brownish or reddish clay allied to bauxite and laterite (*qq.v.*), is a hydrous aluminum silicate containing iron oxide. It occurs as partings or layers between successive ancient lava flows, as for example in Antrim, N.Ire., the west of Scotland and in the Deccan, India, probably representing the soils formed by weathering during intervals between eruptions.

BOLERO, a lively Spanish dance in $\frac{3}{4}$ time with a strongly marked rhythm. Not of folk origin, its creation, about 1780, is attributed to Sebastián Cerezo, celebrated dancer of Cádiz. In the bolero (probably from *volar* "to fly") the dancers, either singly or by couples, display virtuosic skill in many brilliant and intricately difficult steps to a constant rattle of their castanets. Distinctive features are the paseo ("walk"), bien prado ("sudden stop"), cuatra (entrechats-quatre), and various beating steps (battements). Outstanding among musical examples is Ravel's sensational *Bolero* (1928) for large orchestra. (L. HT.)

BOLESLAV, the name of three Premyslid princes of Bohemia.

BOLESLAV I (d. 967), prince of Bohemia 929 to 967, was the second son of Prince Vratislav. He became ruler of Bohemia, by the murder of his elder brother Vaclav (St. Wenceslas), in 929. Boleslav was the real creator of the medieval Czech state in that he made Prague its effective administrative centre, fostered Christianity in western and central Bohemia and established royal castellanies to control tribal areas. The emperor Otto I invaded Bohemia in 950 and forced Boleslav to recognize his suzerainty, but this did not affect Bohemia's autonomy. Boleslav seems to have imposed his authority also on Silesia and Moravia.

BOLESLAV II (d. 999), prince of Bohemia 967 to 999, son and successor of Boleslav I, successfully continued his father's work by further consolidating the supremacy of the Czechs over the other Bohemian tribes and by the foundation of monasteries, nunneries and capitular churches. He secured the establishment of the bishopric of Prague in 973 or 974, under the metropolitan authority of the archbishops of Mainz. He treacherously but completely destroyed the Slavnikovci, the only princely rivals of the Premyslid dynasty in Bohemia, in 995. He was usually loyal to his suzerains, the emperors Otto I, II and III, whom he helped in their conflicts with the Polish princes, though his support of the rebellious duke of Bavaria, Henry the Wrangler, caused Otto II to lead punitive expeditions against him in 975 and 977–978.

BOLESLAV III the Red (d. 1037), prince of Bohemia 999 to 1002 and again in 1003, was the eldest son and successor of Boleslav II. Troubles in Bohemia drove him to flee in 1002 first to Germany and then to Poland. He made a brief return in 1003 with Polish help, murdered his enemies and was again expelled. Falling into the hands of Boleslaw I (*q.v.*) of Poland, he was blinded and kept in prison until his death in 1037.

(R. R. Bs.)

BOLESLAVSKY (BOLESLAWSKI), **RICHARD** (1889–1937), motion-picture and stage director, was born in Warsaw, Pol., on Feb. 4, 1889. From 1906 until 1915 he appeared with the Moscow Art theatre, and in 1920 he went to New York city, becoming stage director for the American Laboratory theatre (1924–29). In 1929 he began a film career that included the direction of *Rasputin* and the Empress (1933), Clive of India (1935) and Les *Misérables* (1935). He died in Los Angeles, Calif., Jan. 17, 1937.

Boleslavsky described his experiences in World War I in his two autobiographical books, Way of the Lancer and Lances Down (both 1932). In 1933 he published an important book on acting, Acting: the First Six Lessons. (M. S. BY.)

BOLESLAW I THE BRAVE OR THE GREAT (966 or 967–1025), the first king of Poland, was the son of Mieszko, the first Christian prince of Poland, and the Czech princess Dobrawa. After his

father's death in 992 he expelled his stepmother and brothers from the country and began, by energetic political and military action, to develop and to expand the Polish state. He gave a magnificent entertainment to the Holy Roman emperor Otto III at Gniezno, the capital of Poland, at the grave of St. Wojciech (Adalbert), in March 1000 and considerably strengthened his position in relation to the empire, throwing off a tribute that had been paid since his father's time for part of the Polish state's territory. He obtained from the emperor and from Pope Silvester II the erection of Gniezno into an archbishopric and reorganized the church in Poland, directing its missionary activity toward Prussia and the land of the Pechenegs. On Otto's death he seized Lusatia and Misnia (Meissen) and took the opportunity of intervening in Bohemia on behalf of Boleslav the Red, though afterward he had him blinded and took the throne in Prague for himself (1003). He refused, to accept Bohemia as a fief of the empire and began war against the German king Henry II. In 1005 he lost all his western conquests, but in a second war (1010–13) he regained Lusatia and Misnia, and a third war ended in Jan. 1018 by the peace of Budysin (Bautzen), whereby he retained the conquered lands. Boleslaw then warred against Yaroslav, grand prince of Kiev, defeated him on the banks of the Bug river, placed his son-in-law Svyatopolk on the Kiev throne and occupied the disputed territory on the upper Bug (Czerwien and other castles) —also in 1018. His exertions to win recognition as king ended successfully with his coronation at Gniezno in 1025, but in the same year he died.

Boleslaw left Poland one of the mightiest states of Europe with a good administration and an independent church. His dominions comprised the basins of the Vistula and the Oder rivers, Lusatia, Misnia and also Moravia. Contemporaries appreciated his diplomatic abilities and his military talents.

BOLESLAW II THE GENEROUS OR THE BOLD (1039–1081), king of Poland from 1058 to 1079, the eldest son of Casimir I and the Russian princess Dobronega Maria, began his rule in 1058, after his father's death. The contemporary struggle between the German kings and the papacy enabled him to pursue a relatively free foreign policy and to restore the international position of Poland. He helped Bela I to obtain the Hungarian crown (1060) against the Germans and their protégé and refused to pay the tribute for Silesia that his father had paid to the Czechs. Intervening on behalf of Izyaslav in Kiev, he occupied that city in 1069 and recovered Czerwien and other castles. He and Pope Gregory VII had common interests both in Hungary and against the German king Henry IV, and it was because of these interests that Boleslaw was crowned in the presence of papal legates in 1076. A second intervention in Kiev (1077), again in order to help Izyaslav, was followed by catastrophe: Polish nobles. supported by the Germans and the Czechs, began a rebellion in the name of Boleslaw's brother, Wladyslaw Herman. Among the rebels was the bishop of Cracow, Stanislaw (St. Stanislas), whom Boleslaw put to death in 1079. General rebellion compelled the king to leave Poland, taking his son with him. They fled first to Hungary, but the place of Boleslaw's death in exile is unknown; tradition says that it was Ossiach in Carinthia or Wilten in Tirol.

See POLAND: *The Piast Kingdom.*

See T. Grudziński, *Boleslaw Szczodry* (1953 *et seq.*). **(A. GI.)**

BOLESLAW III THE WRY-MOUTHED (1086–1138), prince of Poland, was the son of Boleslaw II's brother Wladyslaw Herman and Judith of Bohemia. During his father's lifetime he and his elder half-brother Zbigniew were both given provinces of their own, and both mere used by the nobles in their struggle against the old prince and his palatine, Sieciech. Wladyslaw Herman died in 1102, and Boleslaw in 1104 began to fight for the restoration of Polish sovereignty over western Pomorze (Pomerania). This secured him the support of the Polish knights against Zbigniew, who in 1106 acknowledged Boleslaw's suzerainty. In 1107, however, Zbigniew was banished; and after his return in 1112 he was blinded. In 1109 Boleslaw repelled the armed intervention of the emperor Henry V and the Czechs in Silesia, whose invasion was broken by the successful Polish defense of Glogow and in battle near Wroclaw. Boleslaw's many expeditions to Pomorze, which extended over ten years, secured for Poland the Baltic coast from the mouth of the Vistula to the mouth of the Oder. The local prince Warcislaw, who ruled western Pomorze from his seat at Szczecin, became Boleslaw's vassal; and the union of the country with Poland was to be strengthened by converting the inhabitants to Christianity. This was begun by the Spanish hermit Bernard and continued by Otto, bishop of Bamberg. In 1135 Boleslaw paid homage to the emperor Lothair II for Pomorze and the island of Rügen (though Rügen was never conquered by Poland). Boleslaw died in 1138, leaving a statute governing the inheritance of the throne. This statute was an attempt at a compromise with the growing centrifugal tendencies manifested by the Polish nobles. Poland was divided between Boleslaw's four sons, the eldest son being accorded the overlordship of the whole.

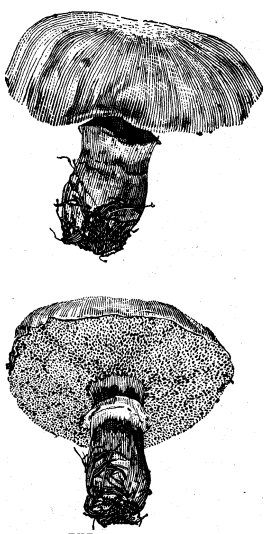
BOLETUS, a very common genus of mushrooms. Nearly all the species grow on the ground, in woods or under trees in the early autumn. They are brown, red or yellow in colour; the pores also vary in colour from pure white to brown, red, yellow or green and are from a fraction of an inch to nearly an inch long. A few are poisonous; several are good for eating. One of the greatest favourites for the table is *Boletus edulis,* recognized by its brown cap and white pores, which become green when old. *See* also MUSHROOM.



COURTESY OF THE DOMINION BOTANIST, DEPARTMENT OF AGRICULTURE, OTTAWA

BOLETUS ELEGANS

BOLEYN, ANNE: *see* ANNE (Anne Boleyn or Bullen).

BOLINGBROKE, HENRY ST. JOHN, 1ST VISCOUNT (1678–1751), English politician, who, endowed with the talent but not the strength of character requisite in a great political leader, exercised considerable influence in British politics during the first half of the 18th century, was born in London on Oct. 1, 1678, the son of Sir Henry St. John, Bart. (afterward 1st Viscount St. John). He was educated at Eton and perhaps at Christ Church, Oxford. He traveled abroad in 1698 and 1699 and in 1700 married Frances Winchcombe.

Notorious already for his libertinism, St. John won early renown as an orator when he entered parliament for the family seat of Wootton Bassett in 1701. St. John associated himself with the aggressive forces of high Toryism, and was given charge of the Bill of Settlement (1701) which gave statutory sanction to the Hanoverian succession. With the prospect of Anne's reign ahead, the high Tories were never less Jacobite, and St. John considered promoting his fortunes by paying court at Hanover in person. That he opposed the oath of abjuration of James, the Old Pretender, in 1702 indicated that he was already becoming attached to the moderate Robert Harley *(see* OXFORD, ROBERT HARLEY), with whom he had been hitherto politically unconnected. In 1702 he was elected to the commission on the public accounts, and after Anne's accession he assisted William Bromley to introduce bills against occasional conformity (the practice of receiving communion according to the rites of the Church of England, in order to qualify for public office, and then attending dissenting meetings for worship); but being connected with Harley, he voted against the motion to tack the Occasional Conformity bill to the Land-tax bill (1704). Through Harley he became secretary at war (1704); through him he began already to de-

velop his idea that party was obsolescent; and through him he was put in direct touch with the duke of Marlborough, the most important influence in his life thereafter. And it was this connection with Harley, not an alleged conspiracy to secure ministerial defeat in the commons, which compelled his resignation in 1708. He then urged Harley strongly to ally himself with the Tories.

On Harley's return to power in 1710, St. John, who insisted on high office, became northern secretary of state and privy councilor and soon began to lead the high church party and the October club of extremist high Tories against his chief, intending to establish a Tory monopoly of office fatal to Harley's hopes of non-partisan government. In 1711 friction between them increased as St. John promoted an unsuccessful expedition to take Quebec, partly to exemplify the high Tory doctrine that England should direct its mar effort in the maritime and colonial sphere, partly to win the queen's favourite Abigail Masham by providing a command for her incompetent brother "Jack" Hill and partly, according to Harley, to relieve his distressed private finances by illicit commissions on war contracts. This expedition failed, but St. John maintained his prominence by negotiating peace in Europe.

Between Aug. 1710 and April 1711 peace terms had been secretly discussed in outline between Harley, the earl of Jersey and the duke of Shrewsbury, and the French minister, the marquis de Torcy; agreements on the Spanish and commercial questions and the disposal of the barrier fortresses had been substantially settled before St. John was admitted to the secret. He accepted the proposals, however, and from April 1711 took charge of the negotiations. By October he had secretly arranged with France the precise advantages which England was to obtain and left the allied gains to be settled in detail at a general conference of the powers in 1712; then England and France could enforce the agreements they had concluded. Viscount Bolingbroke (as he became in 1712) fought for peace at home by priming Jonathan Swift with anti-Whig propaganda, by introducing the stamp duty to restrict the press campaigns of his enemies and by accusing Sir Robert Walpole and Marlborough of receiving illicit commissions, but he laboured chiefly to impose his terms upon the angry allies without allowing France to exploit their discords. He secured a peace with France by further private bargaining but incensed the allies both by withdrawing British military effort before an agreement had been concluded and by accepting terms which openly contravened previous British undertakings, especially to the Dutch and Catalans. The treaty of Utrecht, however, was a cardinal settlement and was Bolingbroke's one great political achievement.

For the government, however, the peace created a further problem, for among the disillusioned allies was George, the Hanoverian heir to the British crown, who naturally turned to the English Whigs, the avowed war party. Bolingbroke's negotiations with France were redolent of undertakings to restore the Old Pretender; the failure of the ministers to remove the Old Pretender from France only thickened the atmosphere of suspicion. The struggle between Harley, now earl of Oxford, and Bolingbroke was intensified by the knowledge of George's hostility, and in its turn exacerbated fears of the ministers' promises to the Old Pretender. Bolingbroke had been chagrined that he had received only a viscountcy when Oxford had become an earl; he won over Lady Masham through whom Oxford had pulled wires with the queen and removed his fellow secretary, Lord Dartmouth, Oxford's friend; still worse, the Schism act (1714) that forbade any nonconformist to keep a school both infringed the revolution settlement and aroused exaggerated fears that its promoters contemplated open treason.

In truth Oxford had maintained contacts with the Jacobites since the autumn of 1710, but merely ensured against a restoration he would not promote; Bolingbroke entered the correspondence much later. Until the peace was signed neither would risk the treaty by taking positive steps. When in March 1714 the conspiracy foundered on the Old Pretender's refusal to change or dissemble his religion, Bolingbroke still occupied second place in the ministry, and a very subordinate place in Jacobite hopes. Neither minister committed himself, and just before Oxford's fall, Bolingbroke was convinced that a Stuart restoration could not succeed on a purely Catholic basis, nor by Scottish and Irish support alone. Bolingbroke did not shrink from civil war but in the summer of 1714 was too clear-sighted to risk his party by disputing the succession on which he knew them to be irremediably divided.

The issue between Oxford, now physically and mentally degenerate, and Bolingbroke culminated in a dreadful scene in the queen's presence, and in Oxford's dismissal on July 27, 1714; on Aug. 1, Anne died and Bolingbroke's pomer was broken. A negotiation with the Whigs proved futile, and he was dismissed from office. The Tories' hopes that George I might employ them in a mixed ministry were wrecked upon the Hanoverians' exclusive association with the Whigs and Oxford's determination to seek his own security at Bolingbroke's expense. For himself Bolingbroke expected nothing, and even in autumn 1714 was planning, after parliament adjourned, to go abroad for treatment for a neglected disease. By March 1715 the ministry, perhaps under Dutch and imperial pressure, clearly intended Bolingbroke's execution, and on the advice of Marlborough he fled to France. He did not at first join the Old Pretender, and his claim may be true that he did so only when urged by his friends in England who had become exasperated with the new government. By July 1715, however, the Old Pretender had appointed him secretary of state, and in the following month an act of attainder was passed against him in England.

Bolingbroke urged James to be cautious, especially after the impeachment and flight of the duke of Ormonde (q *v.*), of whose influence in England much had been hoped, and the death of Louis XIV who had helped the Jacobites. But without Bolingbroke's knowledge, the Old Pretender ordered the earl of Mar to anticipate his arrival by rising in Scotland.

Already irritated by clerical influence at James's court, Bolingbroke had to draft him a declaration for presentation to the English people and was incensed when his guarantees to the Church of England were removed by the Old Pretender's priests. Early in 1716, soon after the failure of the rising, he was dismissed as the result of petty intrigues and jealousies.

At once Bolingbroke sought to ingratiate himself with the English government. In March 1716 he was in touch with Earl Stanhope; in September his father was created Viscount St. John, and Bolingbroke later declared that the king promised to restore him. In April 1717 he began his *Letter* to *Sir William Wyndham* (which was published only in 1753) narrating his relations with the Old Pretender and urging his old associates to abandon the Jacobites. In 1717 Bolingbroke, who had always neglected his wife, formed a liaison with the widow of the marquis de Villette, and on his wife's death in Nov. 1718 he resolved to marry her. In this marriage (1722) Bolingbroke proved happy, though perhaps not completely faithful. At the same time he bought La Source, a small estate near Orléans, and began biblical, philosophical and mathematical studies. In 1722 he complained to Lord Polwarth that his pardon was still delayed and was encouraged to apply to the English ministers. In May 1723 he received his pardon, but the restoration to his peerage and estates still required the intervention of parliament. He now worked secretly for the government in both domestic and foreign affairs, but to the end Walpole resisted any concessions to him. Finally, on a private mission to London, Lady Bolingbroke secured the king's approval by a gift of £11,000 to his mistress the duchess of Kendal, and in 1725 an act was passed to enable Bolingbroke to hold real estate but leaving him excluded from the house of lords.

Owing nothing to Walpole, Bolingbroke resumed his feud against him, and from his new residence at Dawley. near Uxbridge, with Pope, Swift and William Pulteney, he organized literary and parliamentary attacks on the government and launched the *Craftsman*, the most celebrated political journal of the day. Just before the king's death, aided by the duchess of Kendal, and with Walpole's knowledge, he secured a royal audience but altogether failed to shake Walpole's pomer. Under George II Bolingbrokelaboured to unite the opposition Whigs under William Pulteney, and his old Tory friends under Wyndham, on the basis of the old "country"

platform. Their attacks culminated in the defeat of Walpole's Excise bill in 1733, but failing to exploit his advantage and discouraged by Walpole's success in the elections of 1734, Bolingbroke retired to France.

There he resumed his studies in history and politics but returned to England in 1738 and joined the Leicester house opposition, for whom he wrote the *Patriot King*. Early in 1739 Bolingbroke returned to France. and the death of Wyndham in 1740 completed his isolation from English politics; though in close touch with the earl of Marchmont, he secured no political advancement upon Walpole's dismissal in 1742. In 1744 he settled in England again. He had already clashed with William Warburton about the comments Pope had invited him to make on some of Bolingbroke's manuscripts. After Pope's death, Bolingbroke found that Pope had secretly printed 1.500 copies of the *Patriot King;* Bolingbroke produced a corrected edition and, attacking Pope's breach of faith. became involved in further controversy with Warburton. Though intimate with the earls of Chesterfield and Marchmont, Bolingbroke was no longer of political consequence; his distress at his wife's death on March 18, 1750, undermined his own failing health, and he died of a cancer in the face on Dec. 12, 1751 and was buried at Battersea.

Bolingbroke's supreme talent was in oratory; his rhetorical prose came soon to be neglected, though complete editions of his works were published in 1754, 1778 and 1809. Bolingbroke's most important political writings were the "Remarks on the History of England" (1730–31), and "A Dissertation Upon Parties" (1733–34) in the *Craftsman*. Bolingbroke had earlier aspired to political power through party but preached the doctrines he had learned from Harley. He claimed that since the union of parties in the revolution of 1688, party was obsolescent, and that each party had so far abandoned its original standpoint that the only significant political division lay between court and country. Here Bolingbroke gave the best contemporary analysis of the evolution of party. His opposition standpoint, however, blinded him to the truth that because party ties had so far dissolved, the government could not but seek the support essential for its parliamentary business by the ties of corruption and influence. Unable to foretell the development of the cabinet and prepossessed by his animosity against Walpole, Bolingbroke concluded that the system of influence must enslave parliament even more surely than the methods of Charles II.

BOLÍVAR, SIMÓN (1783–1830), soldier-statesman to whom six Latin-American republics owe their freedom from Spanish rule, is regarded by many as the greatest genius the Hispanic-American world has produced. A man of international renown in his own day, his reputation has steadily increased since his death. There are few figures in European history and none in the history of the United States that display the rare combination of strength and weakness, character and temperament, prophetic vision and poetic power that distinguish Simón Bolivar. His life and his work have grown to mythical dimensions among the people of his continent, but no myth is required to sustain an admiration for this extraordinary man.

Bolivar, the son of a Creole aristocrat. was born to wealth and position on July 24, 1783, in Caracas, Venez. His father died when the boy was three and his mother died six years later. His uncle, Esteban Palacios, cared for his properties and provided him with tutors. He was an unruly child, and only one of his teachers had a lasting influence on him. This was Simón Carreño Rodriguez, an eccentric disciple of Rousseau. He introduced Bolivar to the fascinating world of 18th-century thought, which produced on him a deep and lasting effect.

At the age of 16. Bolivar was sent to Europe to complete his education. For three years he lived in Spain, and in 1802 married the daughter of a Spanish nobleman, Maria Teresa Rodriguez del Toro, with whom he returned to Caracas. The young bride lived less than a year after her marriage, being stricken with yellow fever. Bolivar often pondered on the effect her tragic death may have had on him and believed that it was the reason for his taking up a political career while still a very young man. In 1804, when Napoleon's star was approaching its zenith, Bolivar returned to Europe. France and Italy attracted him particularly. In Paris he met his friend and tutor and under Simón Rodriguez' renewed guidance steeped himself in the writings of the European rationalists. In addition to Locke. Hobbes. Buffon. D'Alembert and Helvetius. he plunged into Voltaire, Montesquieu and Rousseau Montesquieu and Rousseau had the deepest influence on his political thinking, but Voltaire coloured his philosophy of life. In Paris he also met the German scientist, .Alexander Humboldt, who had just returned from his voyage through Hispanic America, and who confessed to Bolivar that he believed the Spanish colonies to be ripe for independence. This idea took root in Bolivar's imagination and on a trip to Rome, standing on the heights of the Monte Sacro, he made a vow to liberate his country.

One other experience enriched his intellect at this time: he watched the extraordinary performance that culminated in Napoleon's coronation in 1804 as emperor of the French. Bolivar's reaction to the coronation wavered between admiration and revulsion. Napoleon had betrayed the ideas of the Revolution, but he had also shown what a single individual could achieve when driven by the desire for power and glory. The desire for glory was one of the permanent traits in Bolivar's character, and there can be little doubt that it was stimulated by Napoleon. The example of the Corsican was, nevertheless, a warning that Bolivar heeded. In his later days he always insisted that the title of Liberator was higher than any other and that he would not exchange it for that of king or emperor. In 1807 he returned to Venezuela by way of the United States, visiting the eastern cities and meeting many Americans.

Independence Movement.— The Latin-American independence movement got its start a year after Bolivar's return *(see* LATIN AMERICA: *The Independence Movement)*. It was touched off by Napoleon's invasion of the Iberian peninsula. In 1808 the Bourbon family had been forced to abdicate and Napoleon's brother, Joseph, had been proclaimed king. The Spanish people, however, had resisted the intruder, and a junta assumed governmental powers during the absence of the legitimate king. Napoleon failed completely in his attempt to gain the support of the Spanish colonies, who claimed the right to nominate their own officials. Following the example of the mother country, they wished to establish juntas which would rule in the name of the king. Many of the Spanish settlers, however, discerned in these events an opportunity to sever the ties that bound them to Spain. Bolivar participated in many conspiratorial meetings. and when the governor, Vicente de Emparán, reprimanded him, he answered boldly that he had declared war on Spain and could not withdraw. On April 19, 1810, Emparán was officially deprived of his powers and expelled from Venezuela. and a junta took over. To obtain help, Bolivar was sent on a mission to London, where he arrived in July. His assignment was to explain to England the plight of the revolutionary colony, to gain recognition for it and to obtain arms and support for future eventualities. Some blunder in his negotiations caused him to fail on all counts, but in spite of this, his English sojourn was a fruitful one. It gave him an opportunity to study the institutions of the United Kingdom, which remained for him models of political wisdom and stability. He fostered the cause of the revolution by getting in touch with Francisco Miranda (*q.v.*), who in 1806 had attempted to liberate Venezuela singlehanded. Bolivar persuaded Miranda to return to Caracas and to assume command of the independence movement.

Venezuela was in ferment. In March 1811, a national congress met in Caracas to draft a constitution. Bolivar, though not a delegate, threw himself into the debate that agitated the country. In the first public speech of his career he spoke out courageously: "Let us lay the cornerstone of American freedom without fear. To hesitate is to perish." After long deliberation the national assembly declared Venezuela's independence on July 5. 1811. Bolivar now actively entered the army of the young republic, whose commander in chief was Miranda. But in the short time since their

London meeting the two men had drifted apart, Miranda called Bolivar a "dangerous youth," and Bolivar had misgivings about the ability of the aging general. When the Spaniards rallied to retain control of the colony, Bolivar was placed in charge of Puerto Cabello, a port vital to the existence of Venezuela. Treasonable action by one of Bolivar's officers opened the fortress to the Spanish forces, and Miranda, believing the loss of Puerto Cabello fatal to any future military action, entered into negotiations with the Spanish commander in chief, Juan Domingo de Monteverde. An armistice was signed which left the entire country to the mercy of Spain (July 1812). Miranda was turned over to the Spaniards—some authorities say at Bolivar's instigation—and spent the rest of his life in Spanish dungeons.

Cartagena Manifesto.—Determined to continue the struggle, Bolivar obtained a passport to leave the country and went to Cartagena in New Granada (now Colombia). There he published the first of his great political memoranda: *El manifiesto de Cartagena*. In this document we encounter a new Bolivar. "As a son of unhappy Caracas," he begins, "I have miraculously escaped from its political and material destruction, and am here to serve the banner of freedom." His reference to miraculous escape refers to the catastrophic earthquake of March 26, 1812, which took a tremendous toll of lives in Caracas and other towns. He did not hesitate to point out the underlying causes for Venezuela's downfall: "Not the Spaniards, but our own disunity had led us back into slavery. A strong government could have changed everything." Bolivar had now emerged as the champion of strong government for the nascent republics of Hispanic America.

His plea was answered by the people of Kew Granada, and he was named commander of an expeditionary force whose task was to liberate Venezuela. In a sweeping hard-fought campaign he vanquished the Spaniards in six pitched battles and regained control of the capital. On Aug. 6, 1813, he entered Caracas, was given the title of Liberator and assumed political dictatorship.

But the war of independence was just beginning. The majority of the people of Venezuela were hostile to the forces of independence and weary of the sacrifices imposed. Civil war broke out, cruel, anarchic, murderous, without respect for law, either human or divine. Bolivar himself resorted to extreme measures, such as the '(war to extinction" and the shooting of prisoners. But his severity failed in its object. In 1814 he was once more defeated by the Spanish. Spain now drew into the war the *llaneros*, the cowboys of the Orinoco valley, led by José Tomás Boves; and converted them into an undisciplined but savagely effective cavalry that Bolivar was unable to repulse. Boves captured Caracas in 1814 and subjected the city to terrible atrocities. Thus ended the second Venezuelan republic. Bolivar narrowly escaped Miranda's fate. He managed to reach Cartagena, where he was commissioned to oust the Spaniards from Bogotá and succeeded in doing so. He then laid siege to Santa Marta but when royal replacements arrived he fled to Jamaica.

Letter From Jamaica.—In exile he turned his mind toward gaining support from Great Britain, and in an effort to convince the British people of their stake in the freedom of the Spanish colonies, he wrote the greatest document of his career: *La Carta de Jamaica* ("The Letter From Jamaica"). "The bonds," wrote Bolivar, "that united us to Spain have been severed." He was not dismayed that the Spaniards had in certain instances won the upper hand. "A people that love freedom will in the end be free." Bolivar outlined a grandiose panorama from Chile and Argentina to Mexico. "We are," he said proudly, "a microcosm of the human race. We are a world apart, confined within two oceans, young in arts and sciences, but old as a human society. We are neither Indians nor Europeans, yet we are a part of each." What kind of government should emerge from the cataclysm of the independence movement? "The American states need the efforts of paternal governments to heal the wounds and scars made by despotism and war." He proposed constitutional republics, modeled on the government of Great Britain, with a hereditary upper house, an elected lower house and a president chosen for life. The last provision, to which Bolivar clung throughout his career, constituted the most dubious feature of his political thinking.

In the *Letter From Jamaica* Bolivar showed himself as a great internationalist. Looking forward to the day when the representatives of all Hispanic-American nations would gather in a central location such as Panamá, he wrote, "How ineffable it would be if the Isthmus of Panamá should become for America what the Straits of Corinth were for the Greeks. May God grant that we can some day enjoy the good fortune of opening a congress of representatives of the republics, kingdoms, and empires that would discuss peace and war with the rest of the nations of the world."

But Great Britain did not respond to his overtures. By 1815 Spain had sent to its seditious colonies the strongest expeditionary force that had ever crossed the Atlantic. Its commander was Pablo Morillo. Since neither Great Britain nor the United States would promise aid, Bolivar turned to Haiti, a small republic that had freed itself from French rule. Pres. Alexandre Pétion gave Bolivar a friendly reception, and granted him money and weapons.

Campaign Against New Granada.—Three years of indecisive defeats and victories followed. Bolivar landed on the mainland, came to grief and took refuge in Haiti for the second time. In 1817 he decided to set up headquarters in the Orinoco region, which had not been devastated by war and from which the Spaniards could not easily oust him. He engaged the services of several thousand foreign soldiers and officers, mostly British and Irish, established his capital at Angostura (Ciudad Bolivar), began to publish a newspaper and established liaison with the revolutionary forces of the plains. Their leader, José Antonio Páez, recognized Bolivar's authority, and by 1819 the latter was firmly in command. In the spring of that year he conceived his master plan of attacking the Spanish position on its western flank. He had previously centred his hopes on the liberation of Caracas, but he now concentrated on the bolder project of an attack on the Spanish viceroyalty of New Granada. In the plains of Casanare a force of patriots had withstood all Spanish attempts to destroy them. Their leader, Francisco de Paula Santander, made contact with Bolivar, who operated in the eastern part of the plains, and on June 11, 1819, the armies of Bolivar and Santander met and merged.

Bolivar's attack on New Granada will always be considered one of the most daring in military history. The route of the small army (about 2,500 men including the British legion) led through the plains, but it was the rainy season and the rivers had become lakes. For seven days, said one of Bolivar's aides, they marched in water up to their waists. Ten navigable rivers were crossed, most of them in cowhide boats. But the journey through the plains seemed child's play in comparison with their ascent of the Andean mountains that stood between Bolivar and the city of Bogotá. Bolivar had chosen to cross the pass of Pisba, which the Spanish considered an inconceivable approach. An icy wind blew across the heights of the pass, and many of the scantily clad troops died of cold and exposure. But fatigue and loss were more than outweighed by the advahtage gained in descending unopposed into New Granada. When the Spaniards recovered from their surprise, it was too late to throw Bolivar back. A series of skirmishes followed, culminating in the crucial battle of Boyacá on Aug. 7, 1819, when the bulk of the royalist army surrendered to Bolivar. Three days later he entered Bogotá. It was the turning point in the history of northern South America.

Independence Gained.—Indefatigably Bolivar set out to complete his task. He appointed Santander vice-president in charge of the administration, and in Dec. 1819 made his appearance before the congress that had assembled in Angostura. Bolivar was made president and military dictator. As he said, the union of New Granada and Venezuela had been his determined goal since his earliest fighting days. He urged the legislators to proclaim the creation of a new state: the republic of Great Colombia, and three days later *La República de Colombia* was established. It was a federation and, since two of its three departments, Venezuela and Quito (Ecuador), were still under royalist control, it was only a paper achievement. Bolivar knew, however, that victory was finally within his reach, and for the first time in his long struggle fortune did not retract its smile. A revolution had forced the Spanish king to recognize the ideals of liberalism on the home front and his action quite naturally discouraged the Spanish forces in

South America. Bolivar persuaded Morillo to open armistice negotiations, and the two warriors met in a memorable encounter at Santa Ana, signing in Nov. 1820, a treaty that ended hostilities for a six months period. When fighting mas resumed, Bolivar found it easy, with his superior manpower, to defeat the Spanish forces in Venezuela. The battle of Carabobo, June 1821, opened the gates of Caracas, and Bolivar's homeland was at last free. In the autumn of the same year a congress convened in Cúcuta to draft a constitution for Colombia. Its provisions disappointed Bolivar. Although he had been elected president, he thought the constitution too liberal in character to guarantee the survival of his creation. However, as long as more urgent assignments claimed his attention, he mas willing to put up with its weak structure. Leaving the administration to Santander, he asked permission to continue his military campaign.

At the end of a year, Ecuador was liberated. In this campaign Bolivar was assisted by the most brilliant of his officers, Antonio José de Sucre. While Bolivar engaged the Spaniards in the mountains that defended the northern access to Quito, capital of modern Ecuador, Sucre marched from the Pacific coast to the interior. At Pichincha on May 24, 1822, he won a victory which freed Ecuador from the Spanish yoke. On the following day the capital fell and Bolivar joined forces with Sucre on June 16.

It was in Quito that the Liberator met the great passion of his life. the vivacious and beautiful Manuela Sáenz (*q.v.*). Manuela was the ideal woman for a gallant soldier like Bolivar, the perfect mixture of Amazon and hetaera. An ardent revolutionary, she freely admitted her passion for the Liberator and followed him from camp to battlefield and even to the presidential palace.

Bolivar and San Martin. — The territory of Colombia had now been completely recovered from Spain and its new government recognized by the United States. Only Peru remained in the hands of the foreign masters. It was the Peruvian problem that brought Bolivar and San Martin together. San Martin had done for the southern part of the continent what Bolivar had accomplished for the north. On July 22, 1822, the two men met in Guayaquil, and their conference has been a source of controversy ever since. From Bolivar's side there are ample, though not unbiased, reports about the conversations that took place. From San Martin only fragmentary information is obtainable. It has been said that San Martín came to request military aid from Bolivar, and that in addition he wanted to reach an understanding on problems of boundaries and the political future of Latin America. There was scant sympathy between the two. Bolivar, brilliant, amhitious, self-centred, was convinced that he was the "chosen son," singled out by providence to complete the independence of his people. San Martin was stoic, taciturn, self-effacing and moderate. His failure to influence Bolivar was almost a foregone conclusion. On his return from Guayaquil he resigned his office in Lima and went into exile (Sept. 1822).

Peru. — The avenue leading to Bolivar's ultimate ambition was now open. In Sept. 1823 he arrived in Lima. The Spanish army occupied the Sierra east of Lima and its position was considered unassailable. But for Bolivar, after the trials he had successfully passed, this was no deterrent. Men, horses, mules, and ammunition were systematically assembled to form an army, and in the southern winter of 1824 he moved out of the temporary capital in Trujillo and ascended into the high cordillera country. Once more, as chief of staff, Sucre was his able assistant. The first major battle, at Junin, was easily won by Bolivar, who then left the successful termination of the campaign to Sucre. On Dec. 5. 1824, the Spanish viceroy, La Serna, lost the battle of Ayacucho and surrendered with his entire army.

Bolivia. — Bolivar was now president of Colombia and Peru. Only a small section of the continent — Upper Peru — was still defended by royalist forces. The liberation of this region fell to Sucre, and in April of 1825 he reported that the task had been terminated. The new nation selected Aug. 6, the anniversary of the battle of Junin, as its birthday and chose to be called Bolivia after the name of the Liberator. For this child of his genius. Bolivar drafted a constitution which showed once more his authoritarian inclinations: a lifetime president, a legislative body without power, and a highly restricted suffrage. Bolivar was devoted to his own creation, but as the instrument of social reform which he had envisaged, it was a failure.

Treaties of Alliance. — Bolivar was now at the high point of his life. His power extended from the Caribbean to the Argentine-Bolivian border. He had conquered severe illness, which during his sojourn in Peru had made him practically an invalid for months at a time. Another of his favourite projects, a league of Hispanic-American states, came to fruition in 1826. He had long advocated treaties of alliance between the American republics, whose weakness he correctly apprehended. By 1824 such treaties had been signed and ratified by Colombia, Peru. Mexico. Central America. and the united Provinces of Rio de la Plata. In 1826 a general American congress convened in Panamá. Compared with Bolivar's original proposals, it was a fragmentary affair, since only Colombia, Peru, Central America, and Mexico sent representatives. The delegation from the United States never reached Panamá. These four nations signed a treaty of alliance and invited all other nations to adhere to it. A common army and navy were planned, and a biannual assembly representing the federated states was projected. All controversies among the states were to be solved by arbitration. Despite its meagre results, the congress of Panamá laid the cornerstone for future hemispheric solidarity and understanding. The Organization of the American States and the United Nations can look to Bolivar as one of the first statesmen in the world sincerely interested in advocating and implementing international co-operation. (See PAN-AMERICAN CONFERENCES.)

But Bolivar was aware that his plans for hemispheric organization had met with only a limited degree of acceptance. His contemporaries thought in terms of individual nation-states; Bolivar in continents. In the field of domestic policy he continued to he an authoritarian republican. Many of his followers offered him the crown. but the Liberator preferred his old title to that of "Simon the First." He thought of himself as a rallying point, and anticipated civil war as soon as his words should no longer be heeded. Such a prophecy, made in 1824. was fulfilled in 1826.

Civil War. — Venezuela and New Granada began to chafe at the bonds of their union. The protagonists in each country, Páez and Santander. opposed each other. and at length civil war broke out. Bolivar left Lima in haste and most authorities agree that Peru was glad to see the end of his three-year reign and its liberation from Colombian influence. In Bogotá, Bolivsr found Santander advocating the constitution of Cúcuta and arguing that Páez be punished as a rebel. But Bolivar was determined to preserve the unity of Colombia and was therefore milling to appease Páez, with whom he became reconciled early in 1827. Páez bowed to the supreme authority of the Liberator, and in turn Bolivar promised a new constitution which would do justice to Venezuela's desire for regional independence. He took over the presidency and called for a national convention that met at Ocaña on April 2. 1828. Bolivar refused to influence the elections with the result that the liberals under the leadership of Santander gained the majority. Bolivar had hoped that the constitution of Cúcuta would be revised and presidential authority strengthened. but the liberals blocked any such attempts. A stalemate developed. Arguing that the old constitution was no longer valid and that no new one had taken its place, Bolivar assumed dictatorial powers. He flattered himself when he said that "the whole nation recognizes my authority," but he soon learned the bitter truth. A group of liberal conspirators invaded the presidential palace on the night of Sept. 25, and Bolivar was saved from the daggers of the assassins only by the quick-wittedness of Manuela Sáenz. But though this attempt on his life had failed, the storm signals increased. Bolivar's precarious health began to fail. Peru invaded Colombia with the intention of annexing Guayaquil. Once more Sucre saved Colombia and defeated the Peruvians at Tarqui (1829). A few months later one of Bolivar's most honoured generals. José Maria Córdoba. staged a revolt. It was crushed, but Bolivar was disheartened by the continued ingratitude France, England, even the United States, tried to intervene in the domestic affairs of the country. In the fall of 1829, Venezuela seceded from Colombia. Reluctantly

Bolivar realized that his very existence presented a danger to the internal and external peace of the nations that owed their independence to him, and on May 8, 1830, he left Bogotá planning to take refuge in Europe.

But Bolivar was a broken man and his health became worse en route. Reaching the Atlantic coast. he learned that Sucre, whom he had trained as his successor, had been assassinated. Bolivar's grief was boundless: "They have slain Abel." It was the final blow. In vain a military uprising in Bogotá called him back. "Believe me," he wrote, "I have never looked upon uprisings with friendly eyes, and during these last days I have even repented of those we undertook against the Spaniards." Even more disillusioned was his comment on his own lifework: "We have ploughed the sea." The projected trip to Europe was canceled. and at the invitation of a Spanish admirer, Bolivar journeyed to the estate of San Pedro Alejandrino, near Santa Marta in the delta of the Magdalena. It seemed ironical that his life should end in the house of a Spaniard. On Dec. 17, 1830. he died of tuberculosis. One of his last proclamations, dated Dec. 10, 1830, said: "My last wishes are for the happiness of my country. If my death can contribute anything toward the reconciliation of the parties or the unification of the country, I shall go to my grave in peace."

Bolivar remains the towering genius of the Hispanic-American world. His deeds as warrior, his acumen as political thinker and sociologist, his brilliance as writer and prophet are unsurpassed among his people. As a human being, he had, like most heroes, certain frailties. but they are more than balanced by his "passion for friendship," his generosity, and his complete disregard of monetary considerations. His international outlook is as fresh as it was in 1824 when he wrote before the battle of Junin: "The freedom of America is the hope of the universe." *See* also Index references under "Bolivar, Simón" in the Index volume.

BOLÍVAR, a department of Colombia whose limits are the Caribbean sea on the north and west, the department of Atlántico and the Magdalena river on the east, and the departments of Antioquia on the south and Córdoba on the southwest. Pop. (1961 est.) 782,750. It has an area of 13.386 sq mi., the department of Córdoba having been carved from it in 1951. Bolivar is mostly a low. hot, humid, forested region. Livestock, sugar cane, tobacco, cotton, cereals, coffee and forest products are included in its rural produce, and its mineral resources include gold. coal and oil. Its main industries (textiles, petroleum refining and beverages) and foreign commerce are centred in or operate from the capital, Cartagena (*q.v.*). Communications mere once very inadequate, depending principally on the Magdalena river, but roads now link Bolivar with its neighbouring departments and other areas to the south, and by air it is in contact with all parts of Colombia and the world. (T. E. N.)

BOLÍVAR, a province in highland Ecuador, bounded west by Los Rios, north by Cotopaxi and east by Chimborazo. Its triangular-shaped area is 1,242 sq.mi., and its population (1960 est.) 147,400. The capital city is Guaranda. The province lies between the Cordillera de Guaranda on the west and Mt. Chimborazo on the east. It is drained by the Rio Chimbo. From its forests come valuable timber and cinchona. Its crops include barley, potatoes, wheat, maize, sugar cane, bananas, tobacco, oranges, coffee and vegetables. Much land is used for beef cattle, and, at higher altitudes, for the grazing of sheep. There is very little mining. In 1884 this province was separated from Los Rios to which it had belonged previously. (P. E. J.)

BOLIVAR, a state of Venezuela, is its largest (area 91,892 sq.mi., pop. [1961] 212.028) and potentially one of its richest. Most of it is drained by the Orinoco river. The northern part consists of savanna or llanos (*q.v.*), which to the south gives way gradually to rising ground intersected by forest-covered hills. The southern portion of the state is mountainous; in the southeastern corner of Bolivar, arising steeply out of the forest, is the Gran Sabana, a high plateau. The climate is generally tropical with a rainy season from May to October. Life in the northern part of the state was quickened by discovery and development of high-grade iron ores on either side of the Rio Caroni near its confluence with the Orinoco.

There are millions of tons of iron ore shipped annually from Puerto Ordaz and Palua (at the mouth of the Rio Caroni) to the United States. A national steel plant for processing domestic ore was constructed near Puerto Ordaz. a city which holds great industrial promise because it has excellent transport facilities, with many raw materials nearby and cheap power (generated at falls on the lower Caroni). New mineral deposits are discovered annually. In addition to iron ore, the state has some of the world's richest bauxite and manganese deposits located east of El Pao and near Upata. Gold is mined at El Callao, 112 mi. S. by road from the Orinoco port of San Félix; diamonds along the Caroni, the Rio Paragua and at Icabarú (town). Some farming is done in the more populous northern part, where about one-third of the population is agricultural.

Ciudad Bolivar (*q.v.*), the capital, is the agricultural, cattle and mineral centre of the state and the hub of the river transport system. (L. WE.)

BOLIVAR, the unit of currency of Venezuela, named after the liberator, Simón Bolivar. The bolivar is subdivided into 100 centimos.

The silver bolivar was introduced into Venezuela in 1879 to remedy a chaotic monetary situation resulting from the fact that, after 1848, various foreign coins had appeared in the country. They circulated freely and by 1879 Spanish pesetas, pesos of other Latin-American countries, U.S. and British silver coins, and French five-franc pieces were all in circulation. With the introduction of the bolivar, however, a national currency came into being. It was defined as equal in value to one franc of the Latin Monetary union formed in 1865 ***(see*** MONETARY AGREEMENT). Spanish and French silver coins. which continued to circulate in Venezuela, were gradually replaced by bolivares until in 1886 all foreign currencies were declared commodities and only the national currency was permitted to circulate as money.

In 1918 Venezuela changed from a silver to a gold standard. By a law of June 24. 1918, the monetary unit of the country was declared to be the gold bolivar with a content of .290323 g. of fine gold. or .32258 g. of gold .900 fine. This established a gold parity with the U.S. dollar of 5.18 bolivares per dollar which in 1934. as a result of the depreciation of the dollar, was changed to 3.06 bolivares per dollar. Exchange control was introduced in 1936 and official buying and selling rates for the bolivar were established. From 1935 to 1937 the official rate undervalued the bolivar considerably and stood at 3.93 bolivares per dollar. In 193i the official rate was changed to 3 19 bolivares per dollar, whereas the free rate fluctuated between 3.21 and 3.74 in the period up to 1942.

In 1943 a new official rate of 3.35 bolivares per dollar was established. In addition to this general rate, special buying and selling rates were set. The International Monetary Fund par value in Sept. 1961 was 3.35 bolivares per dollar. For petroleum exports the rate was 3.09, and other exports 3.33: whereas the rate for imports was 3.35. (B. F. H.; Jo. M. L.)

BOLIVIA, an inland republic of South America, once a part of the Inca empire and later of the Spanish viceroyalty of Peru and known as the province of Charcas, or Upper Peru. Its legal capital is Sucre, but the actual seat of government is La Paz. It is the fifth largest political division of the continent and extends approximately from 9° 44' to 23° S., and from 58° to 70° W. It is bounded north and east by Brazil, southeast by Paraguay, south by Argentina, and west by Chile and Peru. The area is 424,162 sq.mi. Pop. (1959 est) 3,416,000. The article is organized according to the following outline:

I. Physical Geography
   1. Geology and Structure
   2. Physiography

I. PHYSICAL GEOGRAPHY

1. Geology and Structure.—Knowledge of the geological structure of Bolivia is incomplete, for few qualified geologists have worked there for an extended period of time. In fact, vast areas are still virtually unexplored, particularly the northeastern part of the Oriente, the monadnocks along the Paraguayan border and the northern subandean zone in the Andes.

Bolivia shows a simple geological structure. From east to west one distinguishes old crystalline rocks of the Brazilian shield (largely covered by alluvium of the lowlands of the Beni and the northern Chaco rivers); the subandean zone, adjacent to the Andean system on the east; the Eastern and Central Cordilleras, forming a uniform Paleozoic block; the Altiplano depression, which is covered along its western border by the Quaternary volcanic Cordillera Occidental.

Rocks of the basement complex crop out over long stretches of the Oriente, separating the alluvial troughs of the Beni and the Chaco rivers. Because of recent uplift the area is dissected into blocks that descend like steps toward the Paraguay river. The Cordillera Oriental is a group of massifs of shales or slates, sandstones or quartzites of the Paleozoic Age which rest on a granitic core. Little is known as yet regarding these much-folded complex structures. The Altiplano is essentially a long structural depression—a broken synclinal structure—occupied in its deepest hollow by Lake Titicaca. The Altiplano lies between the border of the western plateau (the Cordillera Occidental) and the Putina Synclinorium. The rocks of the Altiplano have been much deformed and modified by compression. The Cordillera Occidental is really the western plateau covered largely by somewhat dissected volcanoes. The rocks consist of vast accumulations of lavas of rhyolitic, trachytic and andesitic composition. The peaks are those of dormant and extinct volcanoes.

2. Physiography.—Although three-fifths of Bolivia's area consists of vast low plains, the western part is one of the highest inhabited areas in the world and constitutes the real Bolivia. The Andes there attain the greatest breadth and are divided into two great parallel ranges enclosing a plateau whose surface lies but a few thousand feet below the summits of the mountains themselves. Between these ranges lies the monotonous. bleak Altiplano. This is a relatively flat-floored depression 500 mi. long and 80 mi. wide, with an elevation of from 12,000 to 13,000 ft. The floor of this great depression, mostly composed of water-laid deposits from the bordering mountains, and appearing quite level, slopes gently southward. Its evenness is broken by occasional hills and ridges. The margins of the basin are marked by numerous interlocking alluvial fans that have built up an almost continuous piedmont plain of fairly gentle grade. The northern and eastern sections, the Oriente, comprise fully three-fifths of Bolivia. They are composed of low alluvial plains, great swamps, flooded bottom lands and gently undulating forest regions. In the extreme south is the Bolivian Chaco, a fairly level and low area that varies strikingly with the seasons of rain. It is a veritable swamp during the three or four months of the rainy season and a hot semidesert during the remaining eight or nine months of the year.

Northward from the Chaco, but still comprising a portion of the Oriente. is the Santa Cruz area. It is generally level, with a downward slope to the north. Drainage is not the problem there that it is in the Chaco, as there are several small north-flowing streams that interlace the area.

The northernmost segment of the Oriente is the upper Beni, a low, wet plain covered in large part by heavy tropical rain forest. Much of it is subject to severe inundation during the rainy season—Nov. to May inclusive.

To the northwest, where the plains blend into the lower slopes of the Andes, are heavy forests. Better drained than the lowlands, this area, the Yungas, is more healthful and constitutes one of the most attractive parts of Bolivia. Though still quite difficult of access, it is densely populated.

Hydrography.—The rivers fall into three distinct systems: Amazon, Rio de la Plata and Lake Titicaca. The eastern lowlands of Bolivia have many lakes, most of them little known. The great swampy plains along the Beni and Mamoré rivers contain several lakes and lagoons, some of them large, such as Lake Rogoaguado. Along the Paraguay river there are several lakes, partly produced by obstructed outlets, such as Bahía Negra, Caceres. Mandioré, Gaiba and Uberaba. some of them navigable by small craft. Above these are the great Zarayes swamps. This region, like that of the north, is subject to inundations during the summer (Nov. to May). Traffic is then possible only by boat.

The third drainage system is that of the great central plateau. One of the most elevated of all inland basins, it comprises Lake Titicaca near the north end; the Desaguadero, its outlet; Lake

Poop6 into which the Desaguadero river flows; the Lake or salt Marsh (Salar) of Coipasa (connected with Poop6 by the Lacajahuira, the small outlet of the latter); and the great Salar de Uyuni, independent of the rest of the system but receiving the waters of an extensive, though very arid area at the south end. Into this system enter many short streams from the neighbouring heights, chiefly the Cordillera Real, with its immense snow fields. Having no outlet to the sea the water of this extensive basin is wholly absorbed by the dry soil and by excessive evaporation. Lake Titicaca, at an elevation of 12,497 ft., is the highest large navigable lake in the world. It lies on the Bolivia-Peru border and is about 110 mi. long and 46 mi. wide, with a total area of 3,141 sq.mi. The indented shore offers much topographic variety, sometimes rising abruptly, sometimes running back in low gentle slopes. The water level fluctuates seasonally, summer rains and melting snows accounting for a rise of five or six feet. Many islands dot the surface of the lake. The largest, the Isla de Titicaca, is generally considered to have been the refuge of survivors from the earlier civilization that apparently centred about the ancient metropolis of Tiahuanaco, just east of the lake, where there are extensive ruins of admirable stone constructions. On the smaller Isla de la Luna impressive ruins also exist. Having an outlet and a fairly constant inflow, largely of melted snow, the water of Lake Titicaca is fresh, except in the shallower parts where rapid evaporation leaves it slightly brackish. The temperature of the water is low, being little above freezing during much of the year, but never low enough to form ice. Strong winds are often encountered and squalls are frequent during the summer thunderstorms. Where the margins of the lake are shallow the shore is fringed with a border of bulrush (totora) that supplies material for building reed boats known as balsas. Lake Titicaca belongs partly to Bolivia and partly to Peru, the boundary crossing near the middle from the northeast to southwest.

Lake Poop6 is quite different in character from Lake Titicaca It occupies a very shallow depression in the plateau only a few feet belo the general level of the surrounding land and is nowhere more than 10 ft. deep at normal stage. However, it covers 977 sq.mi. at low stage, and the surrounding land is so flat that the lake reaches sometimes almost to Oruro, fully 30 mi. from the low-water shore. The Lacajahuira, the only visible outlet of Lake Poopó, moves underneath the sand and empties into the Salar de Coipasa which, at high water, covers about the same area as Lake Poop6 at low water, but usually consists only of wide, marshy, salt-encrusted wastes, with a small permanent body of water in the lowest part. There is no outlet. The Salar de Uyuni is of a similar character but much larger than Coipasa. It covers about 3,500 sq.mi. and consists wholly of salt-encrusted swamp, except for pools of water that form at times in the lower places. Like Coipasa, it has no outlet. The Rio Grande de Lípez is its most important affluent.

3. Climate. — Bolivia lies wholly within the tropics but it possesses every gradation of temperature from that of equatorial lowlands to arctic cold. The Yungas climatic zone comprises all the lowlands and the mountain valleys up to an elevation of approximately 6,000 ft. The atmosphere is humid. The mean temperature is about 77" F., with no great departures from this figure, and the rainfall, occurring throughout the year, is heavy (30–50 in. at least). The valley zone, which includes the deep valleys from 6,000 to 9,500 ft., has a warm climate with moderate variations in temperature and no cold weather, and is semitropical in character and products. The zone which includes the heads of the deep valleys above the valley zone, with elevations ranging from 9,500 to 11,000 ft., is temperate, though subject to an occasional frost in winter, and is favourable to the production of hardy cereals and vegetables. Both in the valley and the heads of the deep valleys zones there is likely to be a scarcity of rain but in most cases there is an abundant supply of water for irrigation. The Puna (or Altiplano), which lies mostly between 11.000 and 14,000 ft.. includes the great central plateau. Always cool, it varies little from summer to winter, except in the matter of rainfall; the former season brings only rain while occasional snow falls in winter. The air is too cold for growing crops other than potatoes, barley and quinoa. The mean temperature is estimated at 50.4" F. (La Paz). The Puna Brava extends from 13.000 ft. up to the snow limit (about 18.000 ft.) and covers a bleak, inhospitable territory. inhabited only by shepherds and miners. Above this is an arctic zone within the tropics.

In general, the tropical and temperate regions are healthful and agreeable, and have varied and abundant products. It is in these two zones that most of the white people live, as well as many of the Indians. On the Puna, however, particularly around the borders of Lake Titicaca, there are districts of dense Indian population, of which some have more than 125 persons per square mile. Most of the distinctly Indian settlements are now found above 11.000 ft. It was at such elevations that the great cities of the Inca and pre-Inca period, such as Cuzco and Tiahuanaco, were situated. The high rate of mortality among the natives of this region (life expectancy is estimated at 35 years) is due in large part to unsanitary living conditions and diet rather than to climate. Nevertheless, doctors believe that the high altitude is an important contributing factor in the contraction of respiratory diseases.

Precipitation is as varied as the temperature. East of the Cordillera Oriental rains fall throughout the year. On the west side of this Cordillera, the elevated plateaus have a limited rainfall in the north (21 in. at La Paz), which comes only during the summer months and diminishes toward the south until the surface becomes absolutely barren. Brief and furious thunderstorms sometimes sweep the northern plateau and Lake Titicaca in summer. (G. M. McB.; L. We.)

4. Vegetation. — Because of diversities in altitude the flora of Bolivia represent every climatic zone, from the scanty arctic vegetation of the lofty Cordilleras to the luxuriant tropical forests of the Amazon basin. Between these extremes the diversity in vegetation is as great as that of climate and soil. The plateau is primarily a grassland. Above 10,000 ft. few trees are found, but where there is even a light rainfall the hillsides and the high plains support a scant growth of coarse bunch grass (*Stipa ichu*), which is the principal pasture of domestic stock. This grass grows up to the snow line. Two other plants are the *tola* and the yareta; the former is a low shrub, the latter a highly resinous mosslike bush that grows in a compact fibrous mass. Both of these are used extensively for fuel. Vegetation in the Altiplano changes little in summer and winter. The vegetation of the valley is varied. Below the grass meadows at the top of the Cordillera Real is the dense Ceja de la Montaña forest. It cloaks most of the steep ridges and valleys in the belt of clouds and is composed of trees of many varieties. A major tree in this zone is the cinchona, whose bark is the source of quinine. The coca shrub, from whose leaves cocaine is obtained, also is native to this area, and orchids, mosses and lichens are common. Below, on the lowest slopes and flat valley bottoms, is the Montaña (tropical lowland) forest. It separates from the Ceja at about the 4,000-ft. contour. The forest of the foothills in this area is true tropical rain forest, the crowns of the trees forming a canopy beneath which there is but thin undergrowth. Many of the trees are huge with high trunks often buttressed at the base. The flora of the Oriente varies according to subregion. The Beni subregion is characterized by some of the heaviest forest in the Amazon basin. This forest lacks pure stands of trees and hence has been little exploited, but the rubber tree (Hevea brasiliensis), mahogany, cedar and others are important to man. The Santa Cruz area to the south is transitional (40% grass and 60% forest) between the forest area to the north and the scrub forest and grass of the Chaco to the south. Trees and palms are scattered through the dense growing grass. In the northern and western parts of the area many trees grow to great height and size. Among the principal useful trees are the Cuchi, a hard, durable wood used for construction; the *Almendrillo*, a hardwood tree, and the *Mara*, a mahogany that is easy to work and is widely used for doors and furniture. The Chaco subregion, south of the Santa Cruz area, is a plain. During the rainy season part of it is converted into swamps, but during the dry season it literally burns up. It is covered with tropical scrub forest interspersed with patches of grassy savanna, the grass apparently de-

veloping under conditions of flooding. There are areas where the thorny deciduous trees, mimosas and acacias. grow close together in veritable thickets; there are other places, particularly along rivers, where taller trees form bands of dense semideciduous forest; there are places where scrub trees dot the grass cover like apple trees in an orchard; and there are extensive areas of savanna. It is not unusual for trees to grow in salt-impregnated soils and in swampy associations.

5. Animal Life.—The native animal life closely resembles that of the neighbouring areas of Argentina, Brazil and Peru. In the rain forest of the north, the fauna is distinguished by a wide range of species none of which becomes very numerous, however, because competition is too great to permit it. Among the more important snakes are the anaconda. or nater boa, and the bushmaster. Crocodiles, technically known as caymans, are common, as are lizards. The forest, nith its constantly saturated narm air, provides a favourable habitat for salamanders, frogs and toads. Birds are present in large numbers. Among the birds that seldom descend to the ground are the fruit pigeons, parakeets, many toucans, hornbills and touracos. Seen high in the sky gliding in search of carrion are king and black vultures. Conspicuous among the mammals are the sloth. monkey, jaguar (largest of the American cats), ocelot, opossum, tapir, capybara (so-called water pig, largest of the rodents), peccary, armadillo and anteater. Insects are particularly abundant since there is no ninter and they can breed throughout the year. Among those of greatest concern to man are mosquitoes, flies, leaf-cutting ants and termites.

Southward of the rain forest are the grasslands, scrub steppe and scrub forest. The fauna there include the jaguar, puma and deer (among the mammals), the cayman and some snakes; e.g , the bushmaster and the fer-de-lance. Conspicuous among the birds are the rhea (a large flightless South American ostrich). a species of large stork and the common vulture. Waterfowl are abundant. There are myriad forms of insect life. Since much of the country is swampy for an extended period mosquitoes of all kinds are present in enormous numbers. Flies, gnats and ants are also abundant Insects are a major source of discomfort to human beings in the Chaco.

In the Montaña the fauna differs from that of the Altiplano and occurs in zones. ,Mammals are more abundant on the lower slopes and in the valleys than higher up. There are to be found two kinds of deer, the armadillo, various opossums, the spectacled bear, peccary, jaguar, capybara and the tayra—a huge weasel, described as ugly and vicious.

Particularly interesting and certainly most distinctive are the animals of the highlands, for the climate and fauna of the far south (Patagonia) are extended northward along the western fringe of the continent by the height of the Andes and the presence of the cold Humboldt current. Accordingly, the fauna differ notably from that of the adjacent rain forest. The most striking animals of the Puna are the guanaco and the vicuña—American representative of the Camelidae. Their altitudinal limits are from about 8,200 to 18,000 ft. The guanaco, ahich is regarded as the wild progenitor of the llama, is found there at about its northern limit. The vicuña, which is particularly inured to extreme cold, thin air and little water, grazes on small alpine shrubs and plants. Rodents are well represented in the highlands, the most specialized and best known being the large chinchilla. viscacha, mara and cavy. The cavy occupies the more deserted parts of the Altiplano.

Bird life is abundant, particularly on Lakes Poop6 and Titicaca, and includes geese, ducks, grebes, coots, cormorants and gulls. In the swamps there are curlews. plovers and snipes. In this region dwells the condor, which in Peru roosts and breeds from heights of 10,000 to 16,000 ft. In Bolivia the condor descends to sea level in search of food on the nest side of the Andes but not to low altitudes on the east side of the mountains. Insect life, though abundant and varied at lower levels. is largely absent above 10.000 ft.

Of the five animals definitely domesticated in the western hemisphere, four were tamed in Bolivia and Peru—the llama, alpaca, guinea pig and muscovy duck. The llama is the beast of burden in the bleak, barren uastes of the Puna but is seldom observed at elevations below 7,500 ft. It is not only a beast of burden but also supplies meat, wool, leather, tallow, hair and fuel (dung). The alpaca is best adapted to high altitudes and does well in the wet, marshy ground of high elevations. It is not a pack animal but is reared for wool. The cavy, or guinea pig, a small tailless rodent, is raised by almost every Indian family in the highlands as a source of meat and as a pet, from 5 to 15 being kept in the average house. The muscovy duck is raised for food and is the only bird that has been domesticated in the Central Andes.

II. GEOGRAPHICAL REGIONS

To understand Bolivia one must divide it into regions, for there are profound differences among the various parts of the country. For example, agriculture, the dominant economic activity. is sharply differentiated by topographic and climatic variations. The almost impenetrable mountain ranges have made Bolivia, from the standpoint of terrain. a nation divided against itself. The term region as employed here refers to large areas that are uniform in certain respects and distinct from adjacent areas.

Bolivia is divisible into three major regions: (1) the highlands or Altiplano; (2) the Valles or Montañas; and (3) the Oriente. The Valles region in turn is divisible into two subregions and Oriente into three. The agriculture in each major region differs so markedly from that in the others that one might suppose the country would have a varied and balanced output. This is regarded as the potential agricultural strength of Bolivia and the goal to be achieved. Such, however, is not yet the case. Both volume of production and interchange of products that would make this potential strength an actuality are lacking because of a combination of circumstances but dominantly because of transport deficiencies.

The major bases for regional division are the great differences that exist in altitude. terrain and soils. In Bolivia variations in climate are closely related to differences in altitude, and differences in natural vegetation are closely related to differences in climate and soil.

1. The Highlands or **Altiplano.**—This highland region is composed of three distinct parts—the Cordillera Occidental, the Altiplano. and the Cordillera Real. It comprises about one-seventh of the total land area of Bolivia. It is a high. bleak, windswept, cold and barren region. From season to season it changes very little but experiences sharp daily variations in temperature. The days may be warm and agreeable but the nights are invariably cold and uncomfortable. The northern part receives so little precipitation—about 21 in.—that it can scarcely support agriculture. The southern portion receives even less and is virtually a desert. Rising above the Altiplano are volcanic peaks some of which exceed 21.000 ft. with passes exceeding 13,000 ft. Drought, frost and hail are hazards even during summer.

Strangely enough, this hostile region is not only one of the highest inhabited areas on earth but is also Bolivia's most densely populated region: about 60% of the total population dwells there. Most of the important cities such as La Paz and Oruro, many small tonns, and most of the mines are in the Altiplano. This concentration results from continuity of historical tradition, presence of large mineral deposits and relative proximity to Chilean and Peruvian ports. It was there that the Inca (*q.v.*) and pre-Inca institutions had their beginnings. Despite almost continued cold, a paucity of rainfall, a short growing season and strong winds throughout the area, these early Indians developed one of the world's most important independent scientific agricultures. It was in the Altiplano. too, that the Spaniards became eatablished in the early colonial period. They came seeking precious metals but many soon abandoned the quest and settled down on large agricultural estates.

Altiplano agriculture is limited to the production of potatoes, barley and quinoa. a variety of lamb's-quarter. These crops are rotated in a three-year cycle after which the plot of land is not cultivated for a period of from 12 to 14 years. though pastured by llamas and alpacas, by some sheep. and in favoured spots even by cattle. Unfortunately, the Altiplano does not produce adequate food for its own population: more than 50% of the country's food

is imported; such food obviously is costly. Nearly all the farm work is performed by Indians. Until 1952 most of the land was held by hacendados in very large estates of from 1,000 to more than 10,000 ac., most of which dated back to the days of the Spanish conquistadors when large grants of land (encomiendas), together with the Indians who worked them, were given to loyal followers of the crown. Out of this practice grew the feudalistic systems that prevailed down to the 20th century. The rest of the land was held communally by the Indians.

This semifeudal system of land tenure prevailed until 1952 when Victor Paz Estenssoro broke up the large estates and gave plots of land to the Indians—the land to be paid for within 25 years. Thus by 1956 Bolivian landowners totaled 800,000 as compared with only 50.000 three years earlier. It was believed that Indian landownership would ultimately be good for the country, but at the start of the 1960s there was much confusion and the once productive large estates were little more than kitchen gardens for the new owners. The dense population requires a relatively high intensity of land use and there is little potentially productive land in the Altiplano under 14,000-ft. altitude that is not in use.

The Altiplano is the mining region of Bolivia. In fact a mining complex has put its stamp on the nation. In the eyes of the outside world mining is regarded as the principal activity of the country, for minerals furnish most of the foreign exchange needed to pay for the large imports of food and manufactured products required for domestic consumption. Actually only about 2% of, the population is employed by the mining industry.

Mining is most important in the eastern portion of the Altiplano. While gold, silver, copper, antimony, bismuth, tungsten, lead and zinc all are mined. it is tin that is most important. Bolivia is the only nation in the western hemisphere that mines tin commercially. However, the ores are complex and occur in veins difficult to locate. Some of the deposits are nearly mined out; there is almost no fuel for smelting within the country; and the mines lie at such great elevations that only Indians can perform sustained physical labour in them. Moreover, transportation is unsatisfactory, though it is better than elsewhere in the country. This combination of adverse factors makes Bolivia a high cost producer of tin. The leading tin mining area is the Cordillera Real from north of La Paz to the southern portion of the department of Potosi, with the principal fields in the Cordillera de las Cruces in the department of La Paz: in the triangle formed by Oruro, Avicaya and Uncia: in the Potosi area; and in the province of Sud Chichas. The two outstanding mines are Llallagua and Huanuni.

Everywhere in the Altiplano the life of the miner is hard but as elsewhere in the world, it is much worse in some mines than in others. In one area the ore-bearing rock is so hot that the Indian miners wear only a breechcloth and rubber boots; the temperatures vary from 120° to 125° F. and the humidity ranges from 90% to 95%. Rock dust fills the air getting into the lungs of the miners (60% of whom are reported to have tuberculosis). At the end of the working day, the miners leave the sweltering mine shafts, entering the cold air of the Altiplano and of their unheated homes.

Population in the Altiplano does not increase much because of the appalling infant mortality rate—one of the highest in the world. This results from exposure to cold, malnutrition and lack of hygienic child care. Life expectancy in the region is about 35 years. The Altiplano is a hard land—hard for man to grow crops and to raise most livestock, hard to find fuel to cook with or to keep warm by. The clothing and blankets are made from the wool of sheep and llamas. Most Indians chew coca and a major reason is that it numbs their senses to the cold. A cud of dried coca leaves bulges from the cheek of almost every Altiplano Indian. Life there is an endless struggle to wrest from a stubborn nature enough food, fuel and wool to live by.

The Altiplano has been Indian for centuries and promises to remain so. Most Indians there are illiterate, though some progress has been made in education. The Indians follow time-honoured customs. Centuries of bitter experience with the white population have taught the Indians to have as little as possible to do with white men if they are to protect their tiny plots of land or what remains of the previous year's harvest.

2. The Valles **(Montaña).**—Eastward of the highland region lies a complex area of deep valleys and high mountain spurs. The most important part of this region is a subregion known as the Yungas. Actually the term Yungas is not clearly defined by geographers and economists. Some apply the term to the entire eastern slope of the Cordillera Real. while others restrict it to the narrow subtropical valleys in the Andes east of the Cordillera Real. There the Yungas is considered to be those river valleys on the eastern slope of the Andes where the elevation is 6,000 ft. or less—essentially the area northeast of La Paz but extending southward almost to Cochabamba. With its softer, milder temperatures, the Spaniards found that not only they but also their livestock and crops became more easily acclimated.

Because of poor transport facilities, the area must produce such subsistence crops as alfalfa, barley, cacao, coffee, corn. rice, yuca, wheat and fruits (avocados, bananas, grapefruit, oranges and tangerines). Where climatic conditions are favourable but transport difficult, such cash crops as coca, sugar cane and coffee are produced. These have high value per unit of weight or bulk and thus can pay the costly transportation to the Altiplano. However, only by exploiting the Indian has it been possible to make a profit on these crops. Most important of the three is coca, which is restricted to the lower Yungas, north and east of La Paz, where it is gronn by Indians on terraces of steep slopes of valley walls at grades up to 30° or more from the horizontal. Since the chewing of coca is almost universal among the highland Indians and its purchase constitutes one of the principal items of family expenditure, coca production provides the principal source of cash income for the entire populace and the Yungas has become Bolivia's richest subregion. Only within the past two decades have roads into the Yungas been sufficiently improved to enable trucks to enter and leave safely. It should be noted that the Yungas is one of the most densely populated areas of Bolivia and with the Altiplano is reported to have 80% of the total population of the country.

3. The **Oriente.**—This region, the largest, least productive, most sparsely populated, and possibly the least known. comprises the vast semicircular territory to the north and east of the Valles. Despite the many physical and cultural characteristics making for identity, there is sufficient diversity to justify division into subregions: the northern rain forest: the humid subtropical central zone (comprising the northern and southern parts respectively of the departments of Santa Cruz and Beni); and the semiarid Chaco. Through the centuries this region has been effectively separated from the Yungas and the Altiplano by poor communications.

The Northern Rain Forest or *Upper* Beni *Subregion.*—This subregion begins at Bolivia's northern border and extends southward through the department of Pando and includes about half the department of Beni. Isolated from the effective national territory by the lofty Andes, the Beni subregion is economically closer to Brazil than to Bolivia. The land is for the most part covered by heavy, tropical rain forest like that of the Amazon basin of which it is a part. There grows the *Hevea* brasiliensis, the best source of natural rubber. The precipitation is heavy, some rain falling throughout the year. The wet season extends from November to April and the dry season from May to October. It is hot throughout the year. So flat and low is much of this subregion that serious floods often inundate thousands of square miles. In the southern portion are some small clearings where cattle are raised. Some wild rubber is still collected and though the subregion is Bolivia's leading cattle raising area, there are no all-weather roads connecting it with the Altiplano. Accordingly, beef is flown to La Paz. However, cattle from Beni show a high incidence of internal parasites and mature slowly. Even the hides bring a discounted price because of scars from cattle ticks. Native wild grasses comprise most of the pastures through plantings of Pará grass (*Panicum purpurascens*) made in low-lying areas and guinea and elephant grass have been planted in some fenced pastures.

Humid *Subtropical Central Subregion.* This subregion comprises roughly the northern two-thirds of the department of Santa

Cruz. Its geographic centre lies approximately 75 mi. N. of the city of Santa Cruz but its heart is the city and its immediate tributary area. The area is semitropical in climate—a transition between the wet Beni and the semiarid Chaco—and is reasonably free from both disease and parasites. For centuries this area was almost unknown and it still is among the most isolated areas in South America. Topographically, it varies from flat to rolling and lacks the heavy floods of the Beni to the north and of the Chaco to the south. The vegetation includes ribbons of tropical forests and strips of chaco., Low, scrubby thornbush dominates the drier sandy ridges.

This subregion was not important in the past. Its big disadvantage over the centuries nas remoteness: it was worlds away from the Altiplano and, though potentially productive, its lands produced only for subsistence and for the single market of Santa Cruz. The Cochabamba-Santa Cruz highway completed in 1953 reaches into the Yungas and Altiplano from Santa Cruz and for the first time in Bolivian history the potentially productive surplus agricultural lands in the lowlands were connected nith the population centres in the Altiplano by year-round motor traffic.

United States missions sent to help Bolivia produce more food have operated in all regions. but they have been most successful in the Santa Cruz area where the production of rice, corn and sugar cane has been increased. US technicians introduced mechanized farming. However, it must be realized that most Bolivians are highlanders and it is not yet known nhether mountain people can be brought donn safely into the lowlands Generally, when transferred to the Oriente, with its extremely hot weather, insects and stagnant water, they become ill and must return to the Altiplano to recuperate. A number of these people have migrated into an area 25 mi. E. of Santa Cruz and near the railway connecting this city with Corumbá and São Paulo. However, mountain folk prefer to remain in the Altiplano. Many experts believe that the area can contribute nhat is expected of it only if settlers are brought in from other countries. Italians, Okinawans and others have been introduced. While most colonies have failed. several, including that of Okinawans, showed some progress after difficult starts. The principal reason for failure has been lack of markets.

Chaco.—The Chaco is a huge area shared by Bolivia, Argentina and Paraguay. Much of it has not yet been explored. It is a low. level plain that slopes almost imperceptibly toward the east. The subsoil is impermeable. The streams that cross it are sluggish, as is indicated by such names as Rio Salado ("salty river"), Rio Confuso ("confused river") and Rio Perdido ("lost river"). The waters are generally brackish. In fact, the acquisition of a potable water supply is a major problem. The Chaco is an area of striking contrast between seasons, being one of the hottest parts of South America during the rainy period when temperatures of 100° F. are common. The vegetation consists of great stretches of savanna interspersed with frequent islands of forest. Most wooded tracts consist of jungle, though large clumps of palm trees are common. The grasslands, which are often covered with water during the rainy season, become withered and nearly valueless for grazing during the dry season.

The Chaco has practically no roads other than the few that penetrate into the petroleum section. Bolivia's potential petroleum zone is a 150-mile band paralleling the Cordillera Real. Actual production is restricted to the Chaco. The most active field, the Camiri in southeastern Bolivia, produces light-grade oils and is connected with Sucre. Cochabamba and La Paz by the world's highest pipeline. For heavy oil, Bolivia depends upon the Bermejo field near the Argentine border. There are several additional fields. Bolivia not only meets its own requirements (except for lubricants and high octane aviation gasoline) but has large quantities of oil for export.

Population is sparse in the Chaco. There are a few villages and a negligible amount of farming. The population consists mostly of small tribes of nomadic Indians. The raising of cattle is the chief activity and, in spite of floods and droughts, large herds, usually unattended, roam the territory. Most of these cattle are marketed in Argentina.

The Oriente is thus an enormous region, the central portion of which is believed to have promising possibilities for crops and cattle. It is handicapped by transport deficiencies, though it is better off in this respect than ever before because of the Cochabamba-Santa Cruz highway. By 1956 arteries connecting with this highway had been completed. Cut off by the mountain barrier, except for the new highway, the low-lying Oriente has had little to do with the rest of the country, and its few agricultural and livestock products have trickled into Brazil and Argentina rather than into the Altiplano. (L. WE.)

III. THE PEOPLE

The people of Bolivia, unevenly distributed over its area. are concentrated mainly in the numerous valleys and plateaus of the Andean mountains. Fear of the many pests and diseases common to tropical lowlands drove first the Indians and then the Spanish immigrants to live at the higher altitudes. The result has been serious overcrowding in certain areas of the highlands while the lowlands have remained unoccupied, with the exception of a few settlements founded by the Spanish during colonial days and many small groups of Indians widely dispersed over the forested northeast.

1. Racial Types.—The term race, as commonly used in Bolivia, is exceedingly ill-defined. Sometimes it applies to a set of physical characteristics but most often it is used to include not only these elements but others such as language, type of dress, place of residence and occupation. An Indian, for example, might be classified as of mixed race, or even white, providing he had achieved a certain level of educational refinement and economic status.

In general, the population of Bolivia is classified into three major racial divisions: white, cholo (mixed) and Indian. The term white generally refers to people of European extraction and to all those born locally whose parentage, history, education or achievements have resulted in an upper-class placement. The cholo group includes the Indian-white mixture plus the more or less racially pure Indians who, as the result of their own efforts to change their speech or indigenous dress, have been classified as cholo. The Indians are dark-skinned natives. They are illiterate, or nearly so, speak little or no Spanish, and provide the unskilled labour in the economy. The more numerous Indian groupings include the Xymaras of the highlands, who constitute about 25%, and the Quechuas of the valleys, who form about 37% of the total population. The remaining Indians constitute a variety of linguistic groups totaling about 2% of the total population.

2. Languages.—Bolivia is a country of many languages. According to the 1950 census only 36% of the population spoke Spanish while about 64% spoke some Indian dialect. As a result of a colonial policy designed to prevent Indians from learning Spanish, the white group was obliged to learn the local Indian dialects (usually Aymara or Quechua) with the result that most of the whites speak one or both of these languages.

3. Religion.—Despite the comparative freedom that Protestant churches have enjoyed in Bolivia since independence, the population has remained predominantly Roman Catholic. No religious census of the country has been taken in more than half a century but records available for La Paz for 1942, where most of the non-Catholics are concentrated, showed 95% of the city's population to be Roman Catholic. In the rural areas the percentage would probably be much less.

4. Customs and Culture.—Contemporary Bolivian culture has evolved from a mixture of imported European customs and those of the indigenous people of the area. The contribution of the latter is still evident in dress, types of houses, agricultural methods and food. It is largely the influence of the Indian that makes Bolivian culture different from that of many other Latin-American countries.

The Bolivian family is an extensive organization that includes, in addition to parents and children, a wide range of relatives bound together by ties of visiting, mutual aid and kinship. Concerning all economic and social problems, at either the local or the national level, the rural family of Bolivia has always presented

a solid front. Individual roles within the family are rigidly defined. In the middle-class and upper-class families the activities of the women and girls are largely limited to the home. In lower-class families, and especially in rural families, the women are expected not only to perform many duties as homemakers but also to participate in certain field activities and in the marketing of farm products.

Marriage usually takes place at an early age. Although many unions are not formally legitimized the family is a stable unit seldom broken by desertion or separation. When marriage does take place there is often a dual ceremony since neither the state nor the church recognizes marriages performed by the other.

Native clothing of the indigenous population is generally colourful with many combinations of the brighter shades. Men wear tight-fitting wool trousers, large blanketlike garments called ponchos. and hats of many sizes, shapes and colours. Native female dress generally consists of bright blouses, a multitude of skirts of contrasting colours, and many shapes and hues of hats, including the derby.

The diet of the rural people is simple, consisting mostly of potatoes, a cereal called quinoa, or pigweed, and a little meat of llama or sheep. Both potatoes and meat are preserved by being dried in the sun.

Most forms of commercial recreation and amusement are available to the residents of the cities but the major diversions of the rural people are the frequent religious festivals at which people dance, visit, sell and exchange their wares, and consume enormous quantities of alcohol and *chicha,* a fermented corn beer. Weddings, birthdays, christenings and the numerous saints' days are also celebrated by dancing and drinking. (O. E. L.)

IV. HISTORY

1. Spanish Era. — After the defeat of the Incas by the Spaniards in the 16th century the natives were reduced to virtual serfdom and their territory was reorganized as a dependency of the viceroyalty of Peru and known as Alto Peru or, politically, the *audiencia* of Charcas. The seat of government was Chuquisaca, alternatively known as La Plata or Charcas and now called Sucre. Then as later the primary economic interest of the country was in mining. The city of Potosi was founded in 1545 by Diego Centeno after the discovery of the fabulously rich silver mines there. Half a century later Potosi had a population of 120,000; there were 160,000 inhabitants in 1650; and—as the mines declined—8,000 in 1825. With the switch to the production of tin in the 20th century, the population again increased to 45,758 in 1950. Until the 18th century, when Mexico City surpassed it, it was the largest city in the new world. Its mines were long the principal source of Spain's mineral wealth from America, and its extravagant display and fabulous wealth far eclipsed that attending the famed California gold rush and the oil strikes of Oklahoma and elsewhere, so that its very name became synonymous with great wealth. In 1776 the entire region of Charcas was detached from the viceroyalty of Peru and made a part of the newly created viceroyalty of Buenos Aires. In 1780–82 occurred the uprising of the Indians, led by an Indian who took the name of Tupac Amaru, in an attempt (one of many) to drive out or exterminate the Europeans. The movement was conducted with great cruelty on both sides and resulted in the complete defeat of the Indians and the execution of their leader.

The inhabitants of Alto Peru joined with the other Spanish-American colonies in an effort to secure political independence from Spain and to break the dominance of the European-born group. When the patriots of Buenos Aires had succeeded in liberating the interior provinces of the Rio de la Plata they turned their arms against their enemies in Upper Peru. From July 1809 until Aug. 1825 almost uninterrupted warfare was waged in the Argentine provinces of Salta and Jujuy and around Titicaca. Upper Peru was invaded by the army of Buenos Aires, which, after twice defeating the Spanish troops, was able to celebrate the first anniversary of independence near Lake Titicaca in May 1811. Soon, however, the patriot army, because of the dissolute conduct and negligence of its leaders, was defeated in July 1811 by the Spanish and driven back into Jujuy. Four years of warfare were ended in 1815 by the total rout of the patriots in a battle that took place between Potosi and Oruro. Then came a revolt of the Indians of the southern provinces of Peru and, the object being the independence of the whole country, it was joined by numerous Creoles. This insurrection was speedily put down by the royalists. In 1816 the Spanish general José de la Serna, having been appointed commander in chief of Upper Peru, attempted to invade the Argentine provinces in a march on Buenos Aires, but he was forced to retire by the irregular gaucho troops of Salta and Jujuy. For six years there was guerrilla warfare between the patriots of Upper Peru, who had taken refuge in the mountains, chiefly of the province of Yungas, and the royalist troops. In June 1823 the expedition of Gen. Andrés Santa Cruz, prepared with great zeal and activity at Lima, marched in two divisions upon Upper Peru, and in the following months of July and August the whole country between La Paz and Oruro was occupied by his forces. He later permitted a retreat to be made before a smaller royalist army, and a severe storm converted this movement into a precipitate flight, only a remnant of the expedition again reaching Lima. In 1824, after the victory of Ayacucho, Gen. Antonio de Sucre, whose valour had contributed so much to it, marched with a part of the army into Upper Peru. On the news of the victory a universal rising of the patriots took place, and before Sucre had reached Puno and Oruro, in Feb. 1825, La Paz was already in their possession and the royalist garrisons of several towns had gone over to their side. The Spanish general, Antonio de Olañeta, with a diminished army of 2,000 men, was confined to the province of Potosi. He held out until March 1825, when he was mortally wounded in an action with some of his own rebellious troops. General Sucre was now invested with the supreme command in Upper Peru, until the requisite measures could be taken to establish in that country a regular and constitutional government. Fifty-four provincial deputies assembled at Chuquisaca, the capital, to decide, upon the invitation of the government of the Argentine provinces. whether they would or would not remain separate from that country. In Aug. 1825 they decided that Upper Peru should in the future constitute a distinct nation, for which they chose the name Bolivia in honour of Simón Bolivar (*q.v.*), and issued at the same time a formal declaration of independence.

2. Independence and Instability. — The first general assembly of deputies dissolved on Oct. 6, 1825, and a new congress was installed at Chuquisaca on May 25, 1826, to take into consideration the constitution prepared by Bolivar for the new republic. After a favourable committee report was made, it was approved by the congress as the constitution of the republic. Bolivar then returned to Venezuela. General Sucre mas chosen president for life, according to the constitution, but accepted the appointment for the space of only two years and on the express condition that 2,000 Colombian troops should be permitted to remain with him.

Independence did not secure a peaceful future. Repeated uprisings occurred and at the end of 1827 General Sucre and his Colombian troops were driven from La Paz. A new congress, which was formed at Chuquisaca in April 1828, modified the constitution given by Bolivar and chose Marshal Santa Cruz for president; hut only a year later a revolution, led by Gen. Pedro Blanco, for a time overturned the government. Quiet being again restored in 1831, Santa Cruz promulgated the code of laws which bore his name. and brought financial affairs into some order; he also concluded a treaty of commerce with Peru. In 1835, when a struggle for the chief power had made two factions in the neighbouring republic of Peru, Santa Cruz was induced to take a part in the contest. He marched into that country, and after defeating Gen. Agustin Gamarra, the leader of one of the opposing parties, completed the pacification of Peru in the spring of 1836, named himself its protector and had in view a confederation of the two countries. At this juncture the government of Chile interfered actively and, espousing the cause of Gamarra, sent troops into Peru. Three years of fighting ensued until in a battle at Yungay in June 1839 Santa Cruz was defeated and exiled, Gamarra became president of Peru and Gen. José Velasco provisional chief in Bolivia. The Santa Cruz party, however, remained strong in Bolivia and

soon revolted successfully against the new head of the government, ultimately installing Gen. José Ballivián in his place. Taking advantage of the disturbed condition of Bolivia. Gamarra attempted to annex the rich province of La Paz, invading it in Aug. 1841 and besieging the capital; but in a battle with Ballivián his army was totally routed and Gamarra himself was killed. The Bolivian general was now in turn to invade Peru, when Chile again interfered to prevent him.

Ballivián remained in the presidency until 1848, when he retired to Valparaíso. At the end of that year Gen. Manuel Belzu, after leading a successful military revolution, took the chief power and during his presidency endeavoured to promote agriculture, industry and trade. Gen. Jorge Córdova succeeded him. but had not been long in office when a new revolt in Sept. 1857, originating with the garrison of Oruro, compelled him to leave the country. His place was taken by José María Linares, the originator of the revolution, who, taking into his own hands all the powers of government and acting with the greatest severity, caused himself to be proclaimed dictator in March 1858. Fresh disturbances led to the deposition of Linares in 1561. José M. de Achá was chosen president.

New causes of disagreement with Chile had arisen meanwhile in the discovery of rich beds of nitrate and guano on the coastland of the desert of Atacama. The threats of open warfare were set at rest by the treaty of Aug. 1866, in which the 24th parallel of latitude nas adopted as the boundary between the two republics. A new military revolution, led by José Mariano Melgarejo, broke out in 1865 and in February of that year the troops of President Achá were defeated near Potosí, when Melgarejo took the dominion of the country. After defeating two revolutions, in 1865 and 1866. the new president declared a political amnesty, and in 1869, after imposing a revised constitution on the country, he became its dictator.

3. Relations With Chile and Peru.—In Jan. 1871 President Melgarejo was in his turn expelled by a revolution headed by Col. Agustín Rforales. The latter, becoming president, was himself murdered in Nov. 1872 and was succeeded by Col Adolfo Ballivián, son of the former president, who died in 1874. Under this president Bolivia entered upon a secret agreement with Peru which was destined to have grave consequences for both countries. By the treaty of 1866 between Bolivia and Chile, Bolivia. besides conceding the 24th parallel as the boundary of Chilean territory, agreed that Chile should have a half share of the customs and full facilities for trading on the coast that lay between the 23rd and 24th parallels, Chile at that time being largely interested in the trade of that region. It mas also agreed that Chile should be allowed to mine and export the products of this district without tax or hindrance on the part of Bolivia. In 1870, in further consideration of the sum of $10.000, Bolivia granted to an Anglo-Chilean company the right of working certain nitrate deposits north of the 24th parallel. The great wealth which was passing into Chilean hands as a result of these compacts created no little discontent in Bolivia, nor was Peru any better pleased with the hold that Chilean capital was establishing in the rich district of Tarapacá. On Feb. 6, 1873, Bolivia entered upon a secret agreement with Peru, the ostensible object of which was the preservation of their territorial integrity and their mutual defense against exterior aggression. There can be no doubt that the aggression contemplated as possible by both countries was a further encroachment on the part of Chile.

Upon the death of Adolfo Ballivián, immediately after the conclusion of this treaty with Peru. Tomás Frías became president. He signed yet another treaty with Chile, by which Chile agreed to withdraw its claim to half the duties levied in Bolivian ports on condition that all Chilean industries established in Bolivian territory should be free from duty for 25 years. This treaty was never ratified, and four years later Gen. Hilarión Daza, who had succeeded Frias in 1876, demanded as the price of Bolivia's consent that a tax of ten cents per quintal should be paid on all nitrates exported from the country, further declaring that. unless this levy was paid, nitrates in the hands of the exporters would be seized by the Bolivian government. As an answer to these demands, and in order to protect the property of Chilean subjects, the Chilean fleet was sent to blockade the ports of Antofagasta, Cobija and Tocopilla. On Feb. 14, 1879, the Chilean colonel Emilio Sotomayor Baeza occupied Antofagasta. and on March 1 the Bolivian government declared war. (*See* PACIFIC, WAR OF THE.)

4. Outbreak of War.—An offer on the part of Peru to act as mediator met nith no favour from Chile. The existence of the secret treaty. well known to the Chilean government, rendered the intervention of Peru more than questionable. and the law passed by the latter in 1875, which practically created a monopoly of the Tarapacá nitrate beds to the serious prejudice of Chilean enterprise. offered no guarantee of its good faith. Chile replied by curtly demanding the annulment of the secret treaty and an assurance of Peruvian neutrality. Both demands being refused, Chile declared war upon Peru. The superiority of the Chileans at sea, though checked for some time by the heroic gallantry of the Peruvians, soon enabled them to land a sufficient number of troops to meet the allied forces which had concentrated at Arica and other points in the south. The Bolivian ports were already in Chilean hands, and a sea attack upon Pisagua surprised and routed the troops under the Peruvian general Juan Buendia and opened the way into the southern territory of Peru. Gen. Hilarión Daza, who should have co-operated with Buendia, turned back on receiving news of the Peruvian defeat, and led the Bolivian troops to Tacna in a hasty and somewhat disorderly retreat. The fall of San Francisco followed, and Iquique, which was evacuated by the allies without a struggle, was occupied. Severe fighting took place before Tarapacá surrendered, but the end of 1879 saw the Chileans in complete possession of the province.

Meanwhile a double revolution took place in Peru and Bolivia. In the former country Gen. Mariano Prado was deposed and Col. Nicolás de Piérola proclaimed dictator. The Bolivians followed the example of their allies. The troops at Tacna, indignant at the inglorious part they had been condemned to play by the incompetence or cowardice of their president. deprived him of their command and elected Col. Heliodoro Camacho to lead them. At the same time a revolution in La Paz proclaimed Gen. Sarciso Campero president, and he nas elected to that post in the following June by the ordinary procedure of the constitution. During 1880 the war was chiefly maintained at sea between Chile and Peru. Bolivia taking little or no part in the struggle. In Jan. 1881 the battles of Chorillos and Miraflores were fought, attended by heavy slaughter and savage excesses on the part of the Chilean troops. They were followed almost immediately by the surrender of Lima and Callao, which left the Chileans practically masters of Peru. In the interior, however, where the Peruvian admiral Lisardo Montero had formed a provisional government, the war still lingered, and in Sept. 1882 a conference took place between the latter and President Campero, at which it was decided that they should hold out for better terms. But the Peruvians soon wearied of the useless struggle. On Oct. 20, 1883, they concluded a treaty of peace with Chile (the treaty of Ancón); the troops at Arequipa, under Admiral Montero, surrendered that town. and Montero himself, coldly received in Bolivia, where he had fled for refuge, withdrew from the country to Europe. On Nov. 9 the Chilean army of occupation was concentrated at Arequipa, while what remained of the Bolivian army lay at Oruro. Negotiations were opened and on Dec. 11 a truce was signed between Chile and Bolivia. By this treaty Bolivia agreed to the occupation by Chile of the whole of its seacoast, including the port of Cobija.

5. Treaties of Peace and Commerce.—On May 18, 1895, a treaty was signed at Santiago between Chile and Bolivia "with a view to strengthening the bonds of friendship which unite the two countries" and "in accord with the higher necessity that the future development and commercial prosperity of Bolivia require her free access to the sea." By this treaty Chile declared that if, in consequence of the plebiscite (to take place under the treaty of Ancón nith Peru) or by virtue of direct arrangement, it should "acquire dominion and permanent sovereignty over the territories of Tacna and Arica, she undertakes to transfer them to Bolivia in the same form and to the same extent as she may acquire them"; the republic of Bolivia paying as an indemnity for that transfer

$5,000,000 silver. If this cession should be effected, Chile should advance its own frontier north of Camerones to Vitor, from the sea up to the frontier which actually separates that district from Bolivia. Chile also pledged itself to use its utmost endeavour; either separately or jointly with Bolivia, to obtain possession of Tacna and Arica. If it failed. it bound itself to cede to Bolivia the roadstead *(caleta)* of Vitor, or another analogous one, and $5,000,000 silver. Supplementary protocols to this treaty stipulated that the port to be ceded must "fully satisfy the present and future requirements" of the commerce of Bolivia.

On May 23, 1895, further treaties of peace and commerce were signed with Chile. During those ten years of Bolivia's recovery from the war, the presidency was held by Gregorio Pacheco, who succeeded Campero and held office for the full term; by Aniceto Arce. who held it until 1892, and by Mariano Baptista, his successor. In 1896 Severo Alonso became president, and during his tenure of office diplomatic relations were resumed with Great Britain, Carlos Aramayo being sent to London as minister plenipotentiary in July 1897. As an outcome of his mission an extradition treaty was concluded with Great Britain in March 1898.

In December an attempt was made to pass a law creating Sucre the perpetual capital. Until this time Sucre had taken its turn with La Paz, Cochabamba and Oruro. La Paz rose in open revolt. On Jan. 17 of the following year a battle was fought about 40 mi. from La Paz between the insurgents and the government forces in which the latter were defeated with the loss of a colonel and 43 men. Col. José Pando. the insurgent leader, having gained a strong following, marched upon Oruro and entered that town on April 11, 1899, after completely defeating the government troops. Severo Alonso took refuge in Chilean territory; and Colonel Pando formed a provisional government. He had no difficulty in obtaining his election to the presidency without opposition. He entered upon office on Oct. 26 and proved himself strong and capable. He had to deal with two difficult settlements as to boundaries with Chile and Brazil and to improve communication in order to revive mining and other industries. The dispute with Brazil over the rich Acre rubber-producing territory was accentuated because the majority of those engaged in the rubber industry were Brazilians who resented the attempts of Bolivian officials to exercise authority in the district. This led to a declaration of independence on the part of the state of Acre and the dispatch of a body of Bolivian troops in 1900 to restore order. There was no desire, however, on the part of President Pando to involve himself in hostilities with Brazil, and in a spirit of concession the dispute was settled amicably by diplomatic means and a treaty signed in Nov. 1903. A new boundary line mas drawn, and a portion of the Acre province ceded to Brazil in consideration of a cash indemnity of $10,000,000.

The long-standing dispute with Chile with regard to its occupation of the former Bolivian province of Antofagasta under the Pacto de Tregua ("Pact of Truce") of April 4, 1884, was more difficult to arrange satisfactorily. In 1895 there had been some prospect of Chile's conceding an outlet on the sea in exchange for a recognition of the Chilean ownership of Tacna and Arica. The discovery, however, of secret negotiations between Bolivia and Argentina caused Chile to change its conciliatory attitude. Bolivia was in no position to venture upon hostilities or to compel the Chileans to make concessions, and the final settlement of the boundary dispute between Argentina and Chile deprived the Bolivians of the hope of obtaining the support of the Argentines. President Pando and his successor, Ismael Montes, who became president in 1904, saw that it was necessary to yield and to make the best terms they could. A treaty was accordingly ratified in 1904. which was in many ways advantageous to Bolivia, though the republic was compelled definitely to cede to Chile the maritime provinces occupied by the latter power after the war and to do without a seaport.

The government of Chile undertook to construct a railway at its own cost from Arica to the Bolivian capital, La Paz, and to give the Bolivians free transit through Chilean territory to certain towns on the coast. Chile further agreed to pay Bolivia a cash indemnity and lend certain pecuniary assistance to the construction of other necessary railways.

6. Era of Stability. — On Aug. 6, 1909, President Montes was succeeded by Eliodoro Villazon. During their administrations the progress of Bolivia mas marked and to the end of 1927 conditions in the republic were much more stable, both economically and politically, than ever before. General Montes assumed office for a second term on Aug. 6, 1913. and remained president until 1917. World War I had a considerable influence upon the trade of Bolivia: imports decreased, while exports, mainly minerals, increased very considerably in value. The country proclaimed its neutrality in 1914 but departed from this attitude in consequence of Germany's submarine policy. Diplomatic relations with Germany were severed on April 13, 1917, the reason for this action being that a German submarine had torpedoed in neutral waters a ship nith the Bolivian minister to Berlin on board. The republic took no direct part in the war on the side of the Allies, but all its resources in metals nere at their disposal.

Montes relinquished office on Aug. 6. 1917, and was succeeded by his former minister of finance, José Gutiérrez Guerra. Soon afterward agitation for an outlet to the Pacific reached an acute stage. Apparently. President Gutiérrez Guerra's policy was aimed at a *rapprochement* with Chile over the long-standing grievance resulting from the loss of Bolivia's coastal territories Popular indignation against this attitude led to demonstrations: Guerra was forced to resign. and was escorted out of the country to Arica. Meannhile World War I had ended.

Bolivia was represented at the Versailles conference, signed the peace treaty of 1919 and became an original member of the League of Nations. Following the deposition in July 1920 of President Gutiérrez Guerra, the provisional government of Bolivia prosecuted the popular demand for a revision of the situation in regard to its lost territory.

7. After World War I.—The presidency of Bautista Saavedra (elected 1920) was productive of marked economic progress. Nevertheless some measure of political unrest mas experienced both in 1924 and 1925. A revolutionary movement took place in July 1924 but nas promptly suppressed by the government. Ostensibly the object was to promote the secession of the province of Santa Cruz to the neighbouring republic of Brazil. but active opposition to the policy of the Saavedra government was really the purpose of the disturbance. On Jan. 1925 José C. Villanueva, a physician nho had been serving as minister of public instruction and agriculture, and Abdón Saavedra, a brother of the president, were nominated as Republican candidates for president and vice-president. The Liberal party nominated Daniel Salamanca for the presidency. After a vigorous electoral campaign the Republican candidates were elected on May 2 by an overnhelming majority. On Sept. 1 congress declared the election of May 2 null and void. President Saavedra transferred his office to Felipe Guzmán, president of the senate, to administer the government provisionally pending a new election. In December the new election was held and Hernando Siles, a Republican, was elected.

8. Gran Chaco Dispute. — In 1927 Bolivia and Paraguay reopened negotiations in an attempt to settle their boundary dispute in the Gran Chaco, but these ultimately broke down. Armed clashes commencing in 1928 developed by 1932 into a full-fledged war, continuing through 1933, 1934 and part of 1935. generally favourable to Paraguay in a military sense and exhausting economically to both. A truce was finally arranged in June 1935, and negotiations were undertaken through the mediation of Argentina, Chile, Peru, the U S. and Uruguay. Not until July 1938, however, was a definite settlement made. Under the arbitral award which followed, Bolivia renounced title to nearly 100.000 sq.mi. which it had claimed. The new boundary between the two countries nas drawn so that Bolivia retained the territory in which petroleum was being exploited. Paraguay, on the other hand, was permitted to retain control of the rivers down which the oil might have been transported to foreign markets. The entire disputed area was subjected to intensive petroleum exploration. (See CHACO and PARAGUAY.)

(G. M. McB.; L. W. BE.; F. L. KR.)

9. Emergence of **M.N.R.**—Throughout the war, Bolivia con-

tinued politically unstable. In 1930 the Siles government was overturned, and early in the following year Daniel Salamanca was elected president. Extreme economic difficulties and military reverses brought about his overthrow by a *coup* d'etat headed by his vice-president, Luis Tejada Sorzano (Nov. 28, 1934). He in turn was forced from office on May 17, 1936, by Col. David Toro, who undertook a program looking to eventual state socialism. On July 13, 1937, a bloodless coup brought in Lt. Col. Germán Busch, a 33-year-old army officer: as provisional president. Busch became constitutional president under a new constitution in 1938. He followed a vigorous and repressive policy, interning his enemies in a concentration camp. In Aug. 1939 his rule came to an end when he died under mysterious circumstances. It was officially declared that he had committed suicide, but his partisans believed that he had been murdered. His followers subsequently organized a political party called the Movimiento Nacionalista Revolucionario (M.N.R.), which developed a program calling for: (1) avenging the alleged murder of Busch; (2) nationalizing the tin mines; (3) enrolling the miners in politically oriented unions; and (4j following a pro-axis policy in World War II. In the years after Busch's death the M.N.R. played a major and violent role in Bolivian politics resulting in increased governmental instability in the country.

Busch was succeeded in the presidency by Carlos Quintanilla. He remained in office until April 1940 when he was replaced by Gen. Enrique Peiiaranda. Both Quintanilla and Peiiaranda faced strong unrest and repeated revolutionary threats, principally from the M.N.R. Tension was heightened on Dec. 20, 1942, when government troops fired on a group of striking tin miners at the Patiño mine at Catavi. The long-brewing crisis reached its climax exactly a year later when the Peiiaranda government was overthrown in a well-planned revolution engineered by the M.N.R.

Maj. Gualberto Villarroel was named president, but the real head of the regime was M.N.R. leader Victor Paz Estenssoro, who became finance minister. Argentina recognized the new regime on Jan. 3, 1944, but the United States and the other American republics withheld recognition until June 23 on the ground that the M.N.R. was pro-axis and that Argentina had aided the revolution. The Villarroel government declared war on the axis powers in April 1943, and enacted new laws to improve working and housing conditions. It came into sharp conflict with the wealthy tin interests headed by the Patiños, Aramayos and Hochschilds.

The M.N.R. was deposed in a rebellion that took place on July 21, 1946. Villarroel was hanged from a lamppost in La Paz, but Paz Estenssoro and other M.N.R. leaders escaped to safety. Supreme court president Tomás Monje Gutiérrez became provisional president on Aug. 16. Enrique Hertzog was elected constitutional president in March 1947. He endeavoured to restore order but was frustrated by repeated attempts by the M.N.R. to depose his administration. He resigned on May 7, 1949, ostensibly because of ill-health, and was succeeded by Vice-Pres. Mamerto Urriolagoitia, who also had to cope with trouble fostered by the M.N.R., including a major civil war in August and September of that year. In the presidential election held in May 1951 Paz Estenssoro, although an exile in Argentina, was a legal candidate and received more votes than any of his rivals. Rather than risk a resumption of M.N.R. rule! President Urriolagoitia annulled the election and on May 16, 1951, turned over the government to Gen. Hugo Ballivián. The efforts of the M.N.R. to regain power were finally successful in April 1952 when the government was overthrown by popular revolt and Paz Estenssoro returned to take over the presidency. The United States recognized his government on June 2. The new government acted quickly to nationalize the mining properties belonging to wealthy interests in Oct. 1952, and the next year expropriated large estates to distribute the land to peasants. Paz Estenssoro served out his full term, the only president to do so since Bautista Saavedra (1925). In the elections of May 1956 the M.N.R. candidate, Hernán Siles Zuazo, vice-president under Paz Estenssoro, won easily. He took office the following month.

During the 1955–60 period Bolivia was plagued by economic depression, strikes and political unrest. Exports of both tin and petroleum dropped sharply in 1958 and 1959; inflation continued; and the government faced grave budgetary problems in spite of substantial aid from the United States and from the International Monetary fund. Under the leadership of President Siles Zuazo the government followed a left-of-centre policy. It was reported that over 500 strikes occurred in Bolivian industry in 1958. A series of measures to improve the nation's economic position failed to prevent widespread unrest. In June 1960 President Siles Zuazo was succeeded by the former president and M.N.R. leader, Victor Paz Estenssoro, who was elected president by a large majority. (X.)

V. POPULATION

The population of Bolivia, according to the 1950 census, was 3,019,031; (1959 est.) 3,416,000. The population density is only eight persons per square mile and the areas of settlement are unevenly distributed over the territory. Heavy concentrations are in the high Andean plateau and in the many valleys that stretch down the eastern slope of the Andes. Heaviest densities are in the valleys of Cochabamba, Sucre, Tarija and the Yungas. The largest cities (1959 est.) were: La Paz (409,500); Cochabamba (99,099); Oruro (77,874); Potosi (52,278); Santa Cruz (49,305); and Sucre (44,913). With the exception of Santa Cruz these cities are located at relatively high altitudes; La Paz, Oruro and Potosi are all above 12,000 ft.

The population of Bolivia is predominately rural. Almost two-thirds of those counted in the 1950 census were classified as rural even though all persons living in villages of 1,000 and over were considered as urban.

According to the 1950 census returns. approximately 63% of the population is Indian. The non-Indian portion includes whites, cholos (a mixture of white and Indian) and a few thousand Japanese and Okinawans. Actually the racial classification is a subjective one in many cases. Cholo, for example, is more of a class than a racial classification and refers in the main to Indians who have abandoned the colourful, homespun native clothing for European dress. Since the men renounce their indigenous dress more readily and more generally than do the women the result is a disproportionate number of cholo men married to Indian women.

The population of Bolivia is relatively young; about 40% of all persons are under 15 years of age. This is largely the result of excessively high birth rates although some of it seems to be due to the hazards of life in high altitudes.

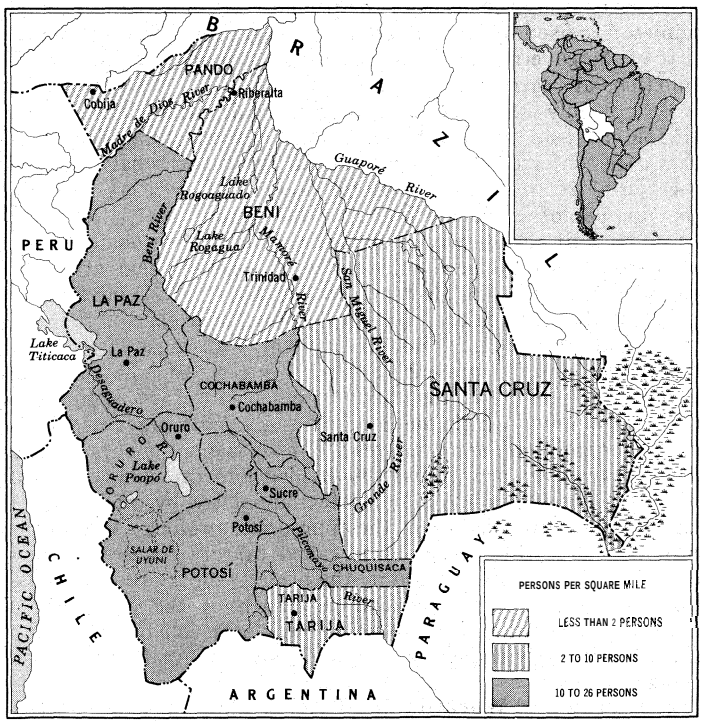

FIG. 2.—POPULATION DENSITY OF BOLIVIA

Because of their harsh climate the highlands have not attracted numerous immigrants to Bolivia. The most numerous European groups in 1950 were Germans (3,207), Spanish (1,256) and Polish (1,223). Most of these Europeans were concentrated in the cities of La Paz and Cochabamba. Immigration from neighbouring countries has been slightly greater but is still negligible in comparison with emigration to countries in lower altitudes.

As a result of limited immigration and high death rates, especially among young children, the growth of the population of Bolivia has been relatively slow. In certain areas of the highlands the number of children who die under one year of age still equals the number born. Marked improvements in health conditions were made during the 1950s, however, and infant mortality was drastically reduced.

As a general rule, the whites are concentrated in the cities and the cholos and Indians in the country. Most of the businesses, professions and better paid government jobs are in the hands of the whites. The cholos are concentrated in the skilled and semi-skilled jobs and services and the Indians in the unskilled or menial occupations. Land reform legislation aims at redistribution of land to enable the Indian and cholo to move from their traditional positions as farm labourers to positions of management and even ownership. (O. E. L.)

VI. ADMINISTRATION AND SOCIAL CONDITIONS

1. Government. — Under the constitution of Nov. 23, 1945, the governmental structure is arranged with executive, legislative and judicial branches, each theoretically independent of the others. The national government is centralized on the general model of France, with the national territory divided into nine regional departments.

Legislative authority is in the hands of a congress, which consists of a senate and a chamber of deputies, and meets annually at La Paz for a session of 90 days. The senate has three members from each department, or 27 in all, elected by popular vote and serving terms of six years. One-third of the senate is elected every two years. The number of deputies is determined by law. They are elected by popular vote and serve terms of four years. one-half of the membership being renewed biennially.

Executive authority is in the hands of a president and a cabinet. The president and vice-president serve four years and are ineligible for immediate re-election. The president is required to make a tour of the country at least once during his term of office in order to study the needs of the people. The number of cabinet ministers is fixed by law. Sucre is the legal capital, but the actual seat of the government is La Paz, where legislative and executive functions are carried on.

Before July 21, 1952, only literate adult male citizens were eligible to vote in national elections. An electoral decree of that date conferred the franchise on all citizens who have reached the age of 20, regardless of either literacy or sex. As a result, the number of eligible voters rose to approximately 1,600,000, or about half the national population. In the national election of June 17, 1956, the first presidential election held after the electoral decree of 1952, ballots were cast by 955,412 Bolivians.

The pattern of regional and local government reflects the centralized character of the Bolivian system, with most of the governmental units representing the interests of the national authorities rather than the local communities. Each of the nine departments into which the country is divided is governed by a prefect, appointed for a four-year term by the national president. The departments are themselves divided into provinces, each of which is administered by a subprefect appointed by the president upon the recommendation of the appropriate prefect. Within the provinces are still smaller units called cantons; these are governed by *corregidores*, chosen by the prefects on the recommendation of the subprefects concerned. Each of the cities has a popularly elected municipal council which, in collaboration with the presidentially appointed mayor, deals with matters of local concern.

2. Living and Working Conditions. — Approximately 1,000,000 Bolivians were gainfully employed in the early 1960s. Of this figure, about 67% were occupied in agriculture, hunting and fishing; the rest were employed in mining and quarrying, manufacturing, construction, electrical, water supply and sanitary services, and in miscellaneous occupations. Working conditions, including the length of the working day, wage rates and the practice of many employers of making a portion of the wage payments in coca (a habit-forming drug) and other nonmonetary forms, have long been major and bitter economic and political issues in Bolivian national life, with the tin miners among the leading seekers of labour reforms. Labour unions were illegal in the country before 1943, but have since then become major interest groups. Like similar organizations in a number of other Latin-American countries, Bolivian unions tend to place about as much emphasis upon political as upon economic objectives.

3. Welfare Services. — Bolivia has a social security program providing for health and maternity benefits, compensation for workmen injured during the course of their employment, and family allowances for persons unable to find work. In fhe 1950s, the government expanded its response to the growing recognition of the need for new public services in the fields of health and sanitation. In 1956. for example, the infant mortality rate was 106.1 per 1,000 births; there were 4,000 persons per physician, and 11,194 persons per dentist, in the country; 1.8 hospital beds existed for every 1,000 Bolivians; and the daily per capita calorie consumption stood at 1,612. A significant part of the government's steps to cope with these problems has taken the form of participation in the technical assistance programs offered by the United Nations and the United States.

4. Justice. — Judicial authority in Bolivia is vested in the supreme court, superior district courts and minor tribunals. The supreme court, with headquarters at Sucre, is divided into two sections of four justices each, with the chief justice presiding over both. Justices are elected by the chamber of deputies for ten-year terms on the basis of nominations of the senate. District court judges are elected by the senate on the basis of nominations of the supreme court. In conformity with the centralized nature of the country's constitutional system, the police force is a national rather than a regional or local agency. The police are administered through the national ministry of interior, headed by a cabinet minister appointed by and responsible to the president.

5. Education. — Education is, by law, vested in three administrative bodies: the ministry of education, fine arts and Indian affairs; the national council of education; and the supreme university council. The country is divided into nine school districts, corresponding to the departments. Each school district maintains primary, secondary and technical schools.

The country's seven universities are located in seven of the nine departments. The bureau of Indian and rural education, established in 1934, maintains regional schools stressing the trades and crafts. Illiteracy is estimated at 68.9%.

6. Defense. — All males between 19 and 55 years of age are subject to military service. A permanent force of 15,000 men is authorized by law, but the actual standing army numbers closer to 10,000 men. There is a small air force which was reorganized by a U.S. mission. (G. I. B.)

VII. THE ECONOMY

Bolivia is a classic example of the vulnerability of an unbalanced economy. Few countries in the world have been endowed by nature with a greater diversity of raw materials. Bolivia has within its own boundaries all the resources necessary to provide a sound economic foundation for its national life. But these potentialities have been neglected and it is the contrast between the actual poverty of the country and the richness of its undeveloped resources that has given currency to the picturesque description of Bolivia, originated by Alcides D'Orbigny in the middle of the 19th century, as "A beggar sitting on a chair of gold."

Exploitation of the natural wealth of the country is impeded by geographical, demographical and historical factors, all discussed above. Communications and surface transport, both within the country and with world markets outside, are lamentably inadequate for healthy economic development, and the natural difficul-

ties of the terrain render them excessively expensive to construct and maintain. Apart from the developing petroleum industry the country is without resources of fuel and power, while the cost of exploiting the large latent possibilities of hydroelectric power has been prohibitive. The meagre population, centred mainly on the high western plateau, is not economically adaptable. The Aymara and Quechua Indians, who constitute 70% of the population, still live at a bare subsistence level practically outside the monetary economy and are wedded to primitive methods of agriculture and ancient ways of life. They have not proved adaptable for development schemes in the richer lowland areas.

The nation's economy has become reliant on mineral production, and successive governments have built up a system for subsidizing the importation of foodstuffs, raw materials and essential consumer goods by indirect taxation of the mining industry. During the 1930s and 1940s mineral exports supplied the government with more than half its tax receipts, the necessary reserve for its banking and monetary system and the means of importation. This reliance on one industry encouraged progressive neglect of other domestic resources and by the mid-20th century, although there had been a small growth of light manufactures, the country was even more dependent on imported agricultural products and raw materials than in earlier years. The Bolivian economy has for these reasons been peculiarly sensitive to fluctuations in the world markets for nonferrous metals, particularly tin. An excessive dependence on the mining industry led to a catastrophic collapse of the whole economy when this industry failed in 1953.

1. Mining Industry.— Bolivia is estimated to contain 8% of the world reserves of tin and its output of tin is about 17% of production outside Communist countries. It also contains large reserves of zinc, copper. lead, wolfram, antimony, residual silver and some gold. Bolivia is a high-cost producer, particularly of tin, because of its difficult terrain, heavy transportation costs, high taxation and exacting labour legislation. After 1940 the grade of the ores in the larger mines deteriorated and the industry was until 1952 kept on a profitable basis only by strict attention to exploration and development and by the use of up-to-date extractive machinery.

In 1952 the government expropriated the assets of the three large mining firms uhich, in addition to other minerals, were together producing about 75% of the national output of tin. Management of the tin mines was then delegated to a semiautonomous government agency, Corporación Minera de Bolivia, created for that purpose. Nationalization coincided with a drop in the world prices of tin and a significant decline in demand because of world overproduction and the cessation of stockpiling by the United States. Bolivian production became uneconomic and the industry continued to operate at a loss. Some of the smaller mines were forced to close, while the government's financing of the deficits of the nationalized industry was a main cause of the unprecedented inflation that followed 1952. The industry was crippled by burdensome labour legislation, strikes, absenteeism, lack of discipline and an excessive labour force, which it was not allowed to diminish. Exploration and development of the mines were sacrificed to immediate needs, and funds were not available for the essential renewal of worn-out equipment. By 1956 production was lower by a third than in 1949, and the decline continued. In 1957 the quota system established by the International Tin council reduced Bolivia's permitted production by a further 31%, but actual production fell below this amount. In the autumn of 1960 restrictions on exports were removed. In 1956 United Kingdom smelters contracted to buy the surplus Bolivian ores which would be released by the closing of the Texas smelter set up by the United States with the needs of the last war in view. A combine of United Kingdom smelters also arranged in 1957 for a loan of £2,800,000 to meet the Bolivian government's contribution to the buffer stock under the International Tin agreement. The Gnited Kingdom thus became again, as traditionally it was, Bolivia's main customer.

2. Petroleum Industry.— In 1960 the output of Bolivia's small petroleum industry stood at 568,000,000 1. equaling the previous peak year of 1957. The industry supplies the greater part of the country's domestic requirements and exports small quantities under agreement to Brazil, Argentina, Paraguay, Chile and Peru. An oil pipeline from the principal oil field at Camiri in southeastern Bolivia to the Argentine frontier came into operation in 1955. By a petroleum law of 1955 (ratified in Nov. 1956) the government sought to interest foreign capital in the exploitation of the country's oil resources. At first little interest was shown, but, perhaps as an indirect consequence of uncertainty in the middle east, concessions were granted to several oil companies.

3. Economic Diversification.— In 1953 the government announced a program of economic diversification by which it planned to raise domestic living standards and remedy the chronic deficit in the balance of payments by stimulating home production of foodstuffs and raw materials so as to reduce the demands on importation. The program envisaged reclamation of arable land by large irrigation schemes on the western plateau, increased sowing of grain, revival of sugar and cotton production in the eastern territories, stimulation of the rubber and timber industries, better exploitation of the domestic cattle reserves by improvement of stock. installation of cold storage plants and the construction of surface communications from the eastern plains to the uplands. The cost of the program was far too great. An appeal was made to the United Nations technical assistance board and a team of experts advised on the problems involved. Nothing of any account was achieved and the situation of the country became more precarious than when it was initiated. In 1953 a politically motivated law for breaking up the large estates and giving the small Indian farmers title to the land resulted in a decline even of those products which had until then survived the general decay of agriculture.

4. Inflation and U.S. Aid.—In 1953 it became clear that the economy had collapsed. At the end of 1952 Bolivia's net balance of payments deficit had reached $32,600,000. Early in 1953 a 90-day loan was negotiated with the New York Federal Reserve bank against gold deposited to the amount of $9,500,000 in order to maintain the flow of essential imports and this was followed by a withdrawal of $2,500.000 from the International Monetary fund. In the autumn of 1953 the United States, fearing either internal anarchy with Communist infiltration or alternatively the partition of Bolivia among neighbouring states, initiated a program of emergency economic aid.

The five years that followed the reforms of 1952 were characterized by violent inflation. The main and constant inflationary cause was the monetary expansion by which the government financed the deficits of the nationalized mining industry and adjusted the resultant disequilibrium of the balance of payments position. The high cost of ambitious social legislation put an added strain on an economy already bankrupt of resources, and continual forced increases of wages, despite theoretical freezing of wages during much of the period, resulted in an acute wage-price spiral. The money in circulation stood at 9,500,000,000 bolivianos in 1952 and at the time of stabilization in 1956 had reached 165,-300.000.000 without any corresponding commodity increase. The rate of exchange on the free market in 1953 stood at about 600 bolivianos to the U.S. dollar, increasing to about 10,000 within three years.

Although U.S. aid was projected in 1953 as an emergency salvage operation, it had become apparent by 1956 that Bolivia was settling into the position of a permanent dependent. It was realized that the mechanism of aid had been defective and that the receipt of U.S. goods inhibited home production because neither Bolivian farmers nor industrialists could compete with the prices of counterpart goods. Moreover, smuggling across the borders had become rife. Under pressure from Washington, therefore, drastic measures were taken to stabilize the currency.

5. Currency Stabilization.— In Dec. 1956 measures were taken to stem inflation and to stabilize the currency. Arbitrary rates of exchange, whose chief value had been to enable the government to subsidize imports by imposing an indirect tax on the mineral industry, were abolished and the boliviano was allowed to find its own level, being made freely convertible for all purposes at an initial rate of 7,500 to the U.S. dollar. At the same time restric-

tions on imports were removed along with subsidies and price controls. In order to give the experiment a chance, wages were frozen for one year and the people were warned that still further increases in the cost of living would have to be met by austerity. The U.S. government and the International Monetary fund together subscribed a loan of $25,000.000 to cushion possible weakening of the boliviano on the free exchange.

The arrangement survived initial disruption. In 1957 there was a depreciation of approximately 11% in the boliviano rate. In Oct. 1958 it stood at 26.300 to the pound sterling and in the early 1960s it fluctuated around 33.300. American aid continued at a rate of U.S. $20,000.000 to $25,000,000 a year, or about 32% of the Bolivian budget.

6. Communications. — Bolivia has approximately 1,800 mi. of railway, concentrated mainly on the western plateau. Three lines run from La Paz to Pacific ports, the Arica-La Paz line, the Antofagasta-La Paz line, which has a branch running to the Argentine frontier at Villazón, and the La Paz-Guaqui line, which connects with steamers across Lake Titicaca to the Peruvian port of Mollendo. This network connects the main towns of the western plateau and there are several branches running to mining areas. There is no railway connection between the western plateau and the eastern lowlands. Later-constructed lines connect the town of Santa Cruz with Corumbá on the Brazilian frontier and with Yacuiba on the Argentine frontier.

Bolivia is said to have about 12,000 mi. of motor roads, but a high proportion of these are serviceable only in the dry season. The only surfaced roads are those connecting La Paz with the Yungas, the highway between Cochabamba and Santa Cruz and about 40 mi. of the Bolivian section of the Pan-American highway. There is no road connection between the western plateau and the northern section of the lowlands.

Because of the inadequacy of surface communications, air transport is exceptionally important to Bolivia. Various international lines link La Paz with neighbouring capitals and connect La Paz, Oruro, Cochabamba and Santa Cruz with the main world air routes. The national air line Lloyd Aereo Boliviano (LAB) maintains an internal passenger and freight service and is still the only link between many parts of the country and the major towns of the Altiplano.

BOLLANDISTS, the small group of Belgian Jesuits who edit and publish the *Acta Sanctorum,* the great collection of biographies and legends of the saints, with allied documents, edited in the original languages and arranged according to their feast days in order of the calendar. The original idea was conceived by a Jesuit father, Heribert Rosweyde *(see* HAGIOLOGY). His intention was to publish in 18 volumes the lives of the saints in their authentic Latin text, from the manuscripts, adding notes. After his death (1629) another Jesuit, Jean Bolland, continued to amass material and, on the advice of Henschenius (Godefroid Henskens), who was his associate after 1635, extended the scope of the work. Publication began at Antwerp in 1643, with the two January volumes. February appeared in 1658, March in 1668, April in 1675 and so on. From 1659. Papebroch (Daniel van Papenbroeck) collaborated. This was the most brilliant period in the history of the *Acta Sanctorum.*

The freedom of Papebroch's criticism made him many enemies, and he had often to defend himself against their attacks. After the suppression of the Society of Jesus in 1773 the work was continued, with some inequalities but always in the same spirit, first at Antwerp until 1778, then at Brussels in the abbey of Caudenberg, and finally in the Premonstratensian abbey of Tongerloo, north of Louvain. Thus, vol. iv (1780) and vol. v (1786) of October bear the imprint of Brussels, vol. vi of the same month (1794) that of Tongerloo. In the last named year, the French revolutionary armies invaded Belgium for the second time, and the work had to stop. Eventually the former library and archives were partly recovered. Much of them was acquired by the Bibliothèque royale of Brussels.

After the re-establishment of the Society of Jesus in Belgium the work was taken up in 1837, with the support of the Belgian government, and the Bollandists mere installed at the Collège St. Michel in Brussels. In 1845 appeared vol. vii of October. the first of the new series, which reached vol. xiii (the last) of October in 1883. A Russian Jesuit, J. Martinov, edited the *Annus ecclesiasticus Graeco-Slavicus,* at the beginning of vol. xi of October (1864).

In 1882 the activities of the Bollandists were brought more into line with the progress of historical methods. A quarterly review was established under the title of *Analecta Bollandiana* by C. De Smedt. It includes studies in preparation for the continuation and remolding of the *Acta Sanctorum,* unedited texts, dissertations and, after 1892, a *Bulletin des publications hagiographiques,* containing criticisms of recent works. In addition to this journal, the Bollandists undertook the analysis of the hagiological manuscripts in the principal libraries. Besides numerous library catalogues published in the *Analecta (e.g.,* those of Chartres, Namur, Ghent, Messina, Venice, Dublin, Edinburgh, etc.), separate volumes in the series *Subsidia hagiographica* were devoted to the Latin manuscripts in the Bibliothèque royale at Brussels, two volumes (1886–89), to the Latin and Greek manuscripts in the Bibliothèque nationale at Paris, five volumes (1889–96), to the Greek and Latin manuscripts in the Vatican (1899 and 1910), to the Latin manuscripts in other libraries of Rome (1909) and to the Greek manuscripts in Great Britain, Germany and neighbouring countries (1913).

The Bollandists also prepared inventories of the hagiological texts hitherto published, and of these appeared the *Bibliotheca hagiographica Graeca* (1895; 3rd ed. rev., 1957), the *Bibliotheca hagiographica Latina* (1898–1901, with later supplements), the *Bibliotheca hagiographica orientalis* (1910) and the *Miscellanea hagiographica Hibernica* of Charles Plummer (1925; in English, with a catalogue of Irish hagiography). These indispensable works delayed the publication of the principal collection, but gave it a more solid basis and a scientific stamp, besides extending the field toward east and west. The *Martyrologiurn Hieronymianum* occupies vol. ii of November, published in two parts: first a diplomatic edition (1894), then a critical text (1931). The *Synaxarium* of Constantinople, by H. Delehaye, forms an introductory volume to the month of November (1902), and the *Martyrologiurn Romanum,* with a complete commentary, an introductory volume to the month of December (1940). Vol. iii of November appeared in 1910, vol. iv (up to Nov. 10) in 1925. These publications are produced by a small group of specialists (there were six Bollandists in 1962) working in common without a superior.

The *Acta Sanctorum* in the original edition (Antwerp, 1643–1770; Brussels, 1780–86; Tongerloo, 1794; and again Brussels, 1845–) form 67 folio volumes. They should be quoted, as in the present article, by month and volume, not as a continuous series, and preferably in the original edition. There are two reprints, unrevised, to be used with caution: one at Venice (1734–70) up to vol. v for September; and one at Paris (1863–70) up to vol. xii of October, with general indexes (1875).

BOLL WEEVIL, a beetle *(Anthonomus grandis)* of the family Curculionidae, and the most serious pest of cotton in the United States. The estimated average annual loss of cotton and cottonseed caused by this insect is $203.000.000. Much of this loss could be economically prevented by the proper use of control measures.

The first home of the boll weevil was undoubtedly in southern

ADULT BOLL WEEVIL (ANTHONOMUS GRANDIS) ON BLOSSOM. OR SQUARE. OF A COTTON PLANT

Mexico or Central America. Before 1892 it had spread throughout much of Mexico. It occurs southward to Guatemala. Costa Rica, Cuba and Haiti. About 1892 it entered the United States near Brownsville, Tex. By 1894 it had spread to half a dozen counties in southern Texas, and extended its range annually until, in 1922, almost all of the cotton-producing sections had become infested. Since 1922 the spread of the weevil has been more or less held to this area. Practically the only cotton-growing territory remaining uninfested is the semiarid zone including California, Arizona, New Mexico and western Texas.

The adult boll weevil is about one-fourth inch long, varying from one-eighth to one-third inch, with a breadth about one-third of its length. This measurement includes the snout, which is approximately one-half the length of the body. Variation in size is dependent upon the amount of food the insect has obtained in the larval stage. Individuals from bolls (unripe pods containing lint and seed) are therefore nearly always larger than those from squares (fruit buds). Newly emerged individuals are light yellowish in colour, but this changes to a gray or nearly black shade in a few weeks. In the field the most conspicuous indication of the presence of the boll aeevil is the flaring and falling of numbers of squares or buds. Unfavourable climatic conditions and careless cultivation, however, frequently cause great shedding of the fruit, which is often mistaken for weevil damage. If excessive shedding is noted and the squares upon being cut open show a white, curved grub that has fed upon the contents, there is little doubt that the boll weevil has caused the damage.

The boll weevil passes the winter as an adult beetle. With the advent of autumn weather the adult boll weevils in cotton fields begin to seek protection against the winter. They fly in every direction, although their movements are governed partially by the prevailing winds. They may fly into hedges, woods, cornfields, haystacks, farm buildings or other places. A number of weevils also obtain hibernating quarters without leaving the cotton fields. These may crawl into cracks in the ground, under grass, weeds or other trash, and into the burrs from which the cotton has been picked. During the winter the weevils take no food, and remain practically dormant; on warm days they may move about to a certain extent. Emergence from hibernation depends primarily upon temperature and rainfall in the spring. In the southern portions of the cotton belt emergence usually begins from the first to the middle of March, but farther north it is somewhat later. Emergence has been prolonged from the middle of February to about Aug. 1. Fortunately about 95% of hibernating adults die during the winter, and others die before cotton plants produce the squares in which the eggs are laid.

In the spring and throughout the fruiting season of cotton, the eggs are deposited by the female weevils in cavities formed by eating into the buds and fruit of the plant. An egg hatches under normal conditions in about three days and the grub immediately begins to feed. In from 7 to 12 days the larva or grub passes into its pupal stage. This stage lasts from three to five days. Then the adult emerges and in about five days begins to breed. Climatic conditions cause considerable variation in the duration of the stages, but on an average it requires from two to three weeks for the weevil to develop from the egg to the adult. There may be seven or more generations per year depending on latitude.

The adult weevils feed upon the squares and bolls. The females refrain, throughout most of the season, from depositing eggs in squares visited by other females. but when most of the fruit has become infested, several eggs may be placed in a single square or boll. As many as 15 larvae have been found in a boll. The squares are preferred as food and as places for depositing eggs. As long as a large supply of squares is present the bolls are not generally damaged to any serious extent. The weevil is not known to breed in plants other than cotton except under abnormal conditions.

Although much progress has been made in developing direct control measures against the boll weevil, recommendations differ in various sections of the cotton belt. Detailed recommendations as to insecticides, etc.. can be obtained from local agricultural authorities or experiment stations. and these should be followed carefully. A combination of different indirect methods is vital to a successful control program. These include: early destruction of cotton stalks; cleanup of favourable hibernating areas; frequent shallow cultivation; soil improvement and fertilization; seed treatments; early planting; etc. The development of early-maturing, rapid-fruiting, high-yielding varieties of cotton has helped greatly in enabling the farmers to produce satisfactory crops in spite of the boll weevil. BOLOGNA, GIOVANNI DA (JEAN BOULOGNE) (1529–1608), Flemish sculptor, a most powerful and inventive artist of the time, was born at Douai in 1529. About 1555 he traveled to Italy, settling (1557) in Florence, where he spent the rest of his life. He attracted the notice of Francesco de' Medici, for whom many of his most important works were made. Among his earliest works in Florence were a bronze Bacchus, later placed on a fountain in the Borgo San Jacopo; two children fishing (now in the Museo Nazionale, Florence), cast for a fountain in the Casino Mediceo; and a bronze Venus. made for the villa of Castello and now at Petraia. The "Fountain of Neptune" at Bologna (1563–66) established his reputation. This was recognized by the commission in 1565 of a group. "Florence Triumphant Over Pisa," designed as a counterpart to Michelangelo's "Victory." The full-scale plaster model of this work (Accademia, Florence) was initially set up with the "Vic-

BY COURTESY OF VICTORIA AND ALBERT MUSEUM

"SAMSON AND A PHILISTINE," A MARBLE STATUE BY GIOVANNI DA BOLOGNA. IN THE VICTORIA AND ALBERT MUSEUM, LONDON

tory" in the Palazzo Vecchio and was later (1570) replaced by the marble version now in the Museo Nazionale. The masterpieces a-hich followed it include the marble groups of "Samson and a Philistine" (1567; Victoria and Albert museum. London); "The Rape of the Sabines" (1579–83) and "Hercules and Nessus" (1594; both in the Loggia dei Lanzi. Florence); a famous bronze figure of Mercury (1574; Museo Nazionale, Florence); and a bronze equestrian statue of Cosimo I in the Piazza della Signoria (1587–94)

Bologna also enjoyed great popularity as a maker of garden sculpture for the Boboli gardens, Florence ("Fountain of Oceanus." 1571–76, "Venus of the Grotticella," 1573), and for the Medici villas at Pratolino (the colossal "Apennine," 1581), Petraia and Castello. The bronze birds which he cast for a grotto in the Castello garden are now in the Museo Nazionale, Florence. He was also a prolific manufacturer of bronze statuettes; the most notable collection of these is in the Kunsthistorisches Museum, Vienna. In addition to his secular commissions. Bologna was responsible for a large number of religious sculptures, which include (in marble) the fine "Altare della Libertà" in Lucca cathedral (1577'79) and (in bronze) reliefs of Passion scenes in the chapel of the University of Genoa (1579–85) and the SS. Annunziata, Florence. reliefs in the Salviati chapel in S. Marco, Florence (1579–88), and the "St. Luke" of Or San Michele (1597–1602).

He died in Florence on Aug. 13, 1608.

An Italian sculptor in all but birth, Bologna transformed the Florentine mannerism of the mid-16th century into a style of European significance. For three centuries his work was more generally admired than that of any sculptor, except Michelangelo.

(J. W. P.-H.)

BOLOGNA (Etruscan FELSINA; Roman BONONIA), the capital of the province of that name and of the Emilia-Romagna region, Italy, lies between the Reno and Savena rivers at the foot of the Apennines, 180 ft. above sea level, about 214 km. (133 mi.) S E. of Milan and 106 km. 166 mi.) N. of Florence by road. Pop. (1957 est.) commune 399,739.

Description.- he central part of the city is built on the old, perfectly rectangular Roman city with narrow, right-angled streets, around nhich the town grew during the middle ages. By 1200 it had its first brick walls of which only a few gates are left. Most of the larger walls built in the 13th century were destroyed after 1903, but seven gates remain. The centre of Bologna still preserves a medieval atmosphere and the presence of arcades in most streets gives the town a particular aspect of its own. Many columns have artistically cut stone capitals. Of the many towers erected in the 12th–13th centuries only a few remain, among which the Asinelli (about 300 ft. high with a lean of 4 ft.) and the Garisenda (150 ft. high, about 10 ft. out of perpendicular) are typical; these were both built in 1109–19 and are two of the buildings characteristic of Bologna. In the centre of the city is a big open square formed by the Piazza Maggiore and the Piazza del Nettuno. Around it are: the Palazzo d'Accursio or Palazzo Comunale. now the town hall, begun in the 13th century and continued in different styles, with a beautiful Madonna sculptured by Niccolò dell' Arca and the statue of Pope Gregory XIII, the reformer of the calendar; the Palazzo del Podestà of the 13th century (the front is 15th century); and the Palazzo di Re Enzo, where King Enzio (*q.v.*) nas kept prisoner for 23 years until his death (1249–72). Nearby there is the Fontana del Nettuno (1564) by Giovanni da Bologna (Jean Boulogne).

The Isolani, Serracchioli, and Grassi houses, and a few others, are typical examples of 13th-century dwellings a-ith wooden columns. Other remarkable buildings are the Palazzo della Mercanzia, the old chamber of commerce (probably by Antonio di Vincenzo, the architect of San Petronio cathedral); the *palazzi* Pépoli, Bevilacqua (begun in 1477. one of the finest in Bologna), Albergati. Drappieri, Davia-Bargellini, Fantuzzi.

To St. Petronio, the city's patron saint, who in the 5th century was its first bishop, was dedicated one of the greatest churches of Christianity, begun in 1390. The base and the doors have fine marble decorations: the front is unfinished. The interior in Gothic style is admirable for its harmony and form. The emperor Charles V was crowned there by Pope Clement VII (1530). Santo Stefano is the name given to a group of four romanesque churches of the 11th to 13th centuries, erected on the ruins of a pagan temple. The so-called Cortile di Pilato and the cloister are the most impressive. San Francesco is a magnificent example of French-Gothic architecture (1236); it has two towers and a characteristic apse. It was damaged during World War II but has since been restored. Nearby are the beautiful Glossatori tombs. San Domenico contains the famous altar-tomb of St. Dominic who died in Bologna in 1221. San Pietro is a baroque cathedral built on the remains of a romanesque church. Other churches distinguished for their architecture include Santa Maria dei Servi, San Martino, l'Annunziata, San Giovanni in Monte. The beautiful brick front of the Spirito Santo (1478) ,may be particularly noticed.

The university, one of the oldest and most famous in Europe, attained its greatest splendour in the 12th–13th centuries. Thousands of students, Dante among them. came to Bologna to study Roman law under celebrated scholars. The university had no fixed residence — the lectures were mostly held in the great halls of convents — until the Archiginnasio was erected under Pius IV (1563); then it moved (1803) to the Palazzo Poggi, which for about a century had been the seat of the famous Istituto delle Scienze, founded by Gen. L. F. Marsili to give a more modern impulse to scientific studies. During World War II the Archiginnasio palace was damaged and the well-known Anatomy room completely destroyed; it has since been restored. Its most eminent teachers included: Irnerius and Francesco Xccursio (Accursius), noted jurists; the great naturalist Ulisse Aldrovandi (*q.v.*); Marcello Malpighi and Luigi Galvani (*qq.v.*); and Giosue Carducci (*q.v.*) who taught and lived in Bologna for nearly 50 years until

THE PALAZZO COMUNALE AND THE FOUNTAIN OF NEPTUNE, BOLOGNA

his death (1907). A famous son of Bologna was Guglielmo Marconi (q v.; 1874–1937) There are two great libraries the Biblioteca Comunale dell' Archiginnasio and the Biblioteca Universitaria and also others with special collections. The library of the Conservatorio Musicale is especially noted for its precious works. (Bologna has a great musical tradition. Wagner's operas were performed there for the first time in Italy.) The Museo Civico contains important remains of past civilizations; the material is displayed in 18 large rooms in chronological order from prehistory onward. The collections from the Umbrian (Villanova) civilization and the Etruscan necropolis in the neighbourhood of Bologna are remarkable. The art gallery (Pinacoteca Nazionale) houses a notable collection of paintings of the Bolognese school (the Carracci. Francesco Albani, Guido Reni. Domenichino, Guercino, Francia [qq v.], Pellegrino Tibaldi), and possesses numerous works, including portraits, by Titian, Tintoretto and Paolo Veronese The most famous is Raphael's "St. Cecilia." There is also a remarkable collection of drawings and engravings. The Teatro Comunale. one of the finest in the peninsula, was designed by Antonio Galli Bibiena (completed 1763).

History.—Bologna was of Etruscan origin (*see* FELSINA); it was later occupied by the Gallic Boii, and in 192 B.C. became a Roman municipium (Bononia) Little was known of it in the periods which followed. It nas subject to the Greek exarchate of Ravenna (6th century) and then passed, because of Pepin III's donation of the exarchate, to the papacy. It was occupied by barbarians. Huns, Goths and Visigoths; after a feudal period it became a free commune when the emperor recognized its rights (1183). Bologna later knew the tyranny of a few Signori (the Pepoli, Visconti, Bentivogli) and protracted struggles between rival families. Cnder Giovanni II Bentivoglio (1462–1506) fine buildings were erected. Pope Julius II incorporated it with the papal states and for more than three centuries Bologna enjoyed a peace unknown to other states. During the Napoleonic period it was annexed to the Cispadane republic. and in 1860 it became part of the kingdom of Italy. During World War II it was occupied by German troops from Sept 1943 until it was recaptured by U.S.. Italian and Polish troops (Allied 5th and 8th armies) on April 21, 1945.

Communications and Industry.—From its geographical position Bologna is important as a road and railway centre. Most traffic between northern Italy (Milan, Verona, Venice, Trieste) and the central and southern parts of the country (Florence. Rome, Naples. Bari, Sicily) passes through it. After World War II the airfield was used only by private airplanes. Bologna had several local industries (silk, veils, ropes, etc.), and the principal resource until World War I was agriculture based on the surrounding fertile plain where large quantities of wheat. grapes, rice, hemp, sugar beet and fruit nere produced. There was a considerable foodstuff industry (sausage, macaroni. sugar. rice-hulling'). Mechanical industries including the manufacture of electric motors, railway materials, motorcycles and agricultural machines had developed by mid-20th century. *See* also Index references under "Bologna" in the Index volume. (LU. M.)

BOLOMETER, an instrument for measuring radiation by means of the rise in temperature of a blackened metal strip in one of the arms of a resistance bridge. In the first bolometer, invented by Samuel P. Langley. a Wheatstone bridge was used in conjunction with a galvanometer which showed a deflection proportional to the intensity of radiation (when the deflection was not great). O. Lummer and F. Rurlbaum's bolometer consists of four platinum gratings (each of which is made of a series of strips) inserted in the arms of a Callendar-Griffiths bridge; two of these gratings, in opposite arms of the bridge. are placed one behind another, so that the openings of one are opposite the strips of the other, and are exposed to the radiation, the other opposite pair being shielded; this arrangement doubles the effect on the galvanometer. and also compensates for any extraneous temperature changes. The spectrum bolometer consists of a single strip set on edge. in an arm of a bridge; it is used for exploring the distribution of intensity of radiation in a spectrum. *See* BLACK BODY; HEAT; LANGLEY, SAMUEL PIERPONT; **SUN.**

BOLSENA (anc. VOLSINII), a town in the province of Viterbo. Lazio region, Italy, 18 km. (about 11 mi.) W.S.W. of Orvieto by road, stands on the northeast bank of Bolsena lake (ancient Lacus Volsiniensis) which is 1,000 ft. above sea level. Pop. (1957 est.) commune '4,330. After the Etruscan town was razed to the ground by the Romans in 280 B C., the inhabitants migrated to the new site which they named after their former town. The castle dates from the 10th century. There is a small museum of Etruscan and Roman remains in the Palazzo Comunale. The 11th-century church of Santa Cristina. with its elegant Renaissance façade, was slightly damaged during World War II; it contains reliefs by the Della Robbia family of artists. In the adjoining catacombs is the Cappella del Mirácolo, with a 10th-century tabernacle and "St. Christina" by Andrea della Robbia. The town is famous for the miracle of 1263 nhen a Bohemian priest, skeptical about the doctrine of transubstantiation, was convinced of its truth by the miraculous appearance of drops of blood on the Host he was consecrating on an altar in the crypt of this church. In commemoration of this Pope Urban IV instituted the feast of Corpus Christi and built the cathedral at Orvieto. To the north of the town are the remains of a Roman amphitheatre. The inhabitants are chiefly engaged in market gardening and in the production of wine and oil; fishing is also practised.

For the Etruscan Volsinii (modern Orvieto) *see* VOLSINII.

BOLSHEVIKS, the name assumed by adherents of the radical left wing of the Russian Social Democratic Labour party in 1903 and maintained as a part of the official title of the Communist party of the U.S.S R. until 1952.

The name, a misnomer. originated in the Russian word for majority and was adopted by adherents of Nikolai Lenin (Vladimir Ilyich Ulyanov) when they won a temporary majority of places on the party's executive committee and nenspaper editorial board in 1903. Subsequent shifts in loyalties passed control to their opponents. called the Mensheviks (members of the minority) because of their temporary minority status in the party councils But the Bolsheviks, the real minority faction insofar as actual adherents among the total Social Democratic membership were concerned, retained their politically advantageous name In 1912 they created in effect a political party independent of the Mensheviks for the elections to the fourth Russian state *duma* Through a "military revolutionary committee" the Bolsheviks provided skilled leadership to the masses in November 1917, and although they were only a part of the left-wing revolutionary forces, they attained such notoriety that the second Russian revolution of 1917 became known in history as the "Bolshevik Revolution." When their party changed its name in March 1918 to Communist party, the factional title "Bolsheviks" mas retained in parentheses to indicate continuity.

Bolshevik principles of political party organization were characterized by strongly held attitudes toward qualifications for membership and discipline. Lenin demanded that members not only accept the party program but personally participate in a party organization. which he interpreted as limiting admission to candidates willing to become active revolutionaries and not to remain mere sympathizers willing to support candidates and contribute funds. He exacted strict discipline, expecting members to accept orders from the party's executive and not to attempt to influence formulation of policy by the centre. Thus he created a foundation for what became a monolithic totalitarian organization quite different from the usual political party.

Bolshevik participation in the *duma* was dictated by a desire to propagandize revolution rather than to legislate social reform. Bolsheviks accepted Marxism as their creed and dogmatized it, arguing that parliamentary activity could never create the requisite economic base for socialism. Their attitude led to boycott of the first *duma* elections in 1906 so long as revolution seemed possible following the riots and strikes of 1905; but as calm returned the boycott was abandoned, too late for elections in industrial areas friendly to Bolsheviks. The second *duma* elections in Jan.–Feb. 1907 returned 18 Social Democrats of the Bolshevik faction, but these were a minority in the party caucus of 65. The faction was reduced to 6 of the 14 Social Democrats by the electoral reform preceding the third *duma* elections in Nov. 1907 and

held the same position in the fourth *duma* elections of 1912. Bolshevik deputies in the *duma* were selected solely from bench workmen to heighten propaganda effects on the industrial masses, but party intellectuals directed them from the background and wrote their speeches to demand a democratic republic. an eight-hour working day and confiscation of large landed estates. This program was designed to appeal to intellectuals, workmen and peasants. National minority groups were wooed by declarations in favour of self-determination, but not to the extent of upsetting party centralism by federation of national groups within the party.

Bolshevik influence grew slowly even after the March 1917 revolution, as measured by representation in the newly emerging bodies claiming to represent the interests of workers, peasants and soldiers under the name of soviets (councils) *(see* SOVIET). In the first national congress of representatives from local soviets the Bolsheviks had only 105 representatives against 248 Mensheviks and 285 Socialist Revolutionaries, the latter of whom favoured agrarian interests. At the second congress of soviets on the eve of the November revolution Bolsheviks had become a majority, but they had no control of the executive until the main body of Mensheviks and Socialist Revolutionaries withdrew in protest against the Bolshevik-led *coup d'état.* Thereafter Bolshevik supremacy was unshakable and the new government was molded in subordination to Bolshevik direction.

See COMMUNISM; MARXISM; *see* also Index references under "Bolsheviks" in the Index volume.

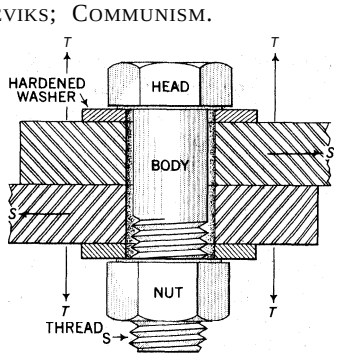
BOLSHEVISM: *see* BOLSHEVIKS; COMMUNISM.

BOLT, an old English word for a crossbow shaft or the pin that fastened a door. From the swift flight of an arrow comes the verb "to bolt," as applied to a horse. to bolting food, etc.. and such expressions as "bolt upright"; also the use in the United States of "bolt" for refusing to support a candidate nominated by one's own party.



BOLTED CONNECTION SHOWING THE TENSILE LOAD *T* AND THE SHEAR LOAD *S*

From the sense of "fastening together" is derived the use of the word as a definite length (in a roll) of a fabric (40 yd. of canvas) or wallpaper (16 yd.). From crossbow terminology comes the usage that describes the part of a rifle or machine gun that is used to load a cartridge and obturate the breech of the barrel. Thus, the bolt of a rifle is used to ram or insert the round into the breech end of the barrel, to support the rear of the cartridge against the explosive forces and to extract the cartridge case after firing. *(See* MACHINE GUN: *Systems of Operation;* SMALL ARMS, MILITARY.)

Bolt as a Connector. — In construction and manufacturing, bolt describes a mechanical fastener used for connecting two or more parts. A riveted or nailed joint is a permanent connection, but a bolted joint can be readily disassembled and reassembled; for this reason bolts, or screw fasteners, are used to a greater extent than any other type of mechanical fastener and have played an important part in the development of mass production methods.

The bolt, which forms part of the connection shown in the figure, consists of a head and a cylindrical body having cut or rolled screw threads along a portion of its length. The nut is the female member of the pair. having internal threads to match those of the bolt. Hardened washers are often used to prevent crushing under the head and nut and to distribute the preload into the members. As shown in the figure, tensile loads elongate the bolt and shear loads tend to cut it apart.

Many bolted connections carry only small or nominal loads and for these the fasteners can be of any suitable material, including mood. aluminum. brass, iron and alloy steels. But certain joints in bridges, aircraft. pressure vessels and the like carry important loads, and failure of these could be dangerous to human life. For important joints the bolt should be a tough, high-strength steel and the nut a soft or ductile steel. Yielding of the relatively soft nut during wrenching distributes the load more uniformly over the threads and avoids thread stripping. The bolt should be preloaded by tightening the nut so as to utilize most of the elastic strength of the bolt. Then a tensile load on the members will reduce the compressive force between them but will have little effect on the bolt tension. This is very important because it is the variation in bolt tension that causes the nut to loosen. An additional advantage of a high bolt preload is that the high compressive forces between the members create more friction and enable the members to carry larger shear loads. A tight joint is much less likely to fail than a loose one, and there is much evidence to indicate that if a joint is made tight enough and if good material is used, then, if it did not fail during tightening, it never will fail.

Production and Classification. — Threads on bolts and screws are usually produced by cold rolling between flat dies, but they may also be cut on a lathe or with a round die. Nut, or internal. threads are cut by a rotating tool called a tap. Thus, a tapped hole in a member is a threaded hole that serves as a nut. In 1918 standardization committees from Canada, the United Kingdom and the United States agreed to use the same thread proportions, called the Unified Thread Standards. The thread shape and the number of threads per inch. called the pitch, compose the major area of agreement Standard threads are always cut right hand, which means that a nut will advance along a fastener when turned in a clocknise direction.

The word bolt refers to a fastener that is intended to be paired with a nut. but the word screw, or screw fastener, refers to any threaded connector. Bolts and screws are classified according to the type of head, the intended use and the thread form. Square, hexagon and socket heads are examples of head types available for use when a wrench is to be used in tightening. For use with a screw driver, round, flat, fillister and oval heads are common. Carriage bolts, anchor bolts, stove bolts, etc., are so named because of their application. Screws are also manufactured with special thread shapes so as to be self-tapping; for example, wood, lag and sheet metal screws produce threads in the female member when they are driven. The drivescrew and threaded nail are other examples of self-tapping fasteners; they are driven with a hammer.

Most nuts have a square or a hexagon shape so they can be tightened with a nrench. But wing nuts and knurled nuts, for example, are designed for tightening by hand. Among the many special-purpose nuts is the castellated nut, which is slotted to permit locking by insertion of a wire or cotter pin through the bolt.

Self-Locking Nuts. — Nuts are made self-locking by employing wedging action, spring action or frictional material; many varieties are available. The Columbia nut, for example, is made in two halves, the outer one being split so that it wedges against the bolt thread as it is tightened into the inner tapered half. The Dardelet rivet-bolt has nonstandard threads that are tapered; when the nut is tightened, the surfaces wedge together to form a tight locking action. Self-locking by spring action is obtained by permitting the nut to elastically distort itself during tightening, or by distorting the threads in some manner prior to assembly. Interference nuts incorporate an unthreaded plastic or fibrous material to bear tightly against the bolt after assembly to achieve self-locking. (J. E. SH.)

BOLTON, DUKES OF, were members of the Paulet *(q.v.)* family and held the title between 1689 and 1794. CHARLES PAULET (c. 1625–993, 1st duke. who became 6th marquess of Winchester on his father's death in 1675 had, from 1661, been member of parliament for Winchester and then for Hampshire. He was an ardent Whig in Charles II's reign, supported William of Orange in 1688 and was made duke of Bolton on April 9. 1689. He was an eccentric, famed for grotesque extravagances. He died at Amport,

Hampshire, on Feb. 27, 1699. His elder son, CHARLES (1661–1722), 2nd duke, who had also supported William of Orange, was lord lieutenant of Hampshire and Dorset, a commissioner (1706) to arrange the union of England and Scotland. and lord lieutenant of Ireland (1717–22). His third wife, Henrietta (d. 1730). nas an illegitimate daughter of James, duke of Monmouth. According to Swift. the second duke was "a great booby"; he died on Jan. 21. 1722. His eldest son. CHARLES (1685–1754), 3rd duke, born on Sept. 3, 1685. held many public offices and attained high rank in the army. He mas an early opponent of Sir Robert Walpole but nas not deprived of any of his offices until 1733 because, said Lord Hervey of Ickworth. he was "such a fool ·· Several minor places were restored to him in 1740. He was a famous gallant and on the death of his first wife in 1751 married the actress Lavinia Fenton, his mistress since 1728. He died at Tunbridge Wells on Aug. 26, 1754, and was succeeded by his brother HARRY (1691–1759). 4th duke. Harry was succeeded by his sons CHARLES (*c.* 1718–65), 5th duke, and HARRY (1719–94), 6th duke. The latter was on three occasions (1744, 1752 and 1755) court-martialed and acquitted. and held the rank of admiral He was governor of the Isle of Wight from 1766 to 1780. On his death at Hackwood, Hampshire, on Dec. 25, 1794, without male heirs, the dukedom became extinct.

BOLTON (BOULTON), **EDMUND** (1575?–1633?), English historian, antiquarian and poet whose lyrics are among the best in the miscellany *England's Helicon* (1600) was educated at Trinity hall, Cambridge, and the Inner Temple, London. A "poor kinsman" of the duke of Buckingham, he obtained a minor position at court but was debarred from public office because of his Catholicism and tried to support himself by writing. A friend of Camden and other scholars, he petitioned James I to form a royal academy, but the king died before giving formal sanction. Plans for official histories of England and London also failed and Bolton, after imprisonment for recusancy, seems to have died in poverty. His most considerable works are *Nero Caesar* (1624) a history of Nero's reign, and *Hypercritica,* a treatise on the writing of history in which he reviews contemporary authors It is reprinted in J. E. Spingarn's *Critical Essays of the 17th Century,* vol. i (1908).

BOLTON, HERBERT EUGENE (1870–1953), U S. historian, was born near Tomah in Wilton township. Wis., July 20. 1870. He graduated from the Tomah high school in 1889. Milwaukee Normal school in 1891, and the University of Wisconsin in 1895. He went on to do graduate work at the University of Pennsylvania as Harrison fellow. 1897–99. earning a Ph D. in history in 1899. The next two years he taught at the Milwaukee State Normal school and then mas named instructor in history at the University of Texas. Bolton saw a great opportunity in the study of the southwest's complex of cultures. For several summers. 1902–06, he did research in various Mexican archives, then in 1907–11 he undertook extensive explorations in the Archives of Mexico, sponsored by the Carnegie Institution of Washington. Thus he familiarized himself with Spain's northward advance into the "Spanish borderlands," as he later called this area. Stimulated by the discovery of new materials, he began the publication of articles and books on this region. Bolton's major works numbered a score. and his total bibliography of books and articles more than a hundred His *Guide to Materials for the History of the United States in the Principal Archives of Mexico* (1913) was a landmark. He was professor of history at Stanford, 1909–11. and at the University of California. 1911–40; concurrently, 1916–40. he was director of the Bancroft library. Bolton died Jan. 30, 1953, at Berkeley, Calif.

See Mary Ross, *The Writings and Cartography of Herbert Eugene Bolton* (1932), *Greater America: Essays in Honor of Herbert Eugene Bolton (1945).* (*G. P.* HD.)

BOLTON (BOLTON-LE-MOORS). municipal and county borough, divided into Bolton East and Bolton West parliamentary divisions, Lancashire, Eng., 11 mi. N.W. of Manchester. Pop. (1961) 160.887. Area 23.9 sq.mi. The town is surrounded by high moorland and is divided by the Croal. a small tributary of the Irwell, into Great and Little Bolton. It is the centre of the fine-cotton spinning area of Lancashire's textile industry; it makes textile and other machinery and has engineering, chemical, leather and other works. The town is mostly of 18th–19th century growth, the most notable public buildings being the town hall and the civic centre (1939) which includes an art gallery and museum. Hall-i'-th'-Wood, a half-timbered house dating in part from 1483, is a folk museum; there Samuel Crompton (*q.v.*) invented the spinning mule (1779). Richard Arkwright (*q.v.*) was also living in Bolton when he invented his spinning machinery (about 1768). Much of the history of the textile industry is illustrated in the Chadwick museum.

The manor was granted by William I to Roger de Poictou and passed to the Harringtons of Hornby castle, who lost it with their other estates for their adherence to Richard III. In 1485 Henry VII granted it to the 1st earl of Derby. The manor of Little Bolton seems to have been, at least from Henry III's reign, distinct from that of Great Bolton and was held until the 17th century by the Botheltons or Boltons. The site of the church of St. Peter (1870) has long been occupied by a parish church (one was there in the 12th century). In 1251 William de Ferrers obtained a charter for a weekly market and a yearly fair, but gradually this annual fair was replaced by four others chiefly for horses and cattle. The New Year and midsummer show fairs arose during the 19th century. In the Civil War Bolton sided with the parliament, and in 1643 and 1644 the royalist forces assaulted the town. Bolton was incorporated in 1838 and became a county borough in 1888. From early days it was famous for its woolen manufactures; cotton goods were not made in Lancashire until 1641, when Bolton was named as the chief seat of the manufacture of fustians, vermilions and dimities. Velvets were first made there about 1756 by Jeremiah Clarke and muslins and cotton quiltings in 1763 The first spinning factory was erected about 1780.· Bleaching has been carried on since the early 18th century, and large ironworks grew up in the late 19th century. In 1791 a canal was built from Manchester to Bolton and by an act of parliament (1792) Bolton moor was enclosed. The borough owns more than 500 ac. of parks and grounds, besides the 15th-century Smithills hall and estate of more than 2,000 ac. of parkland and moorland bought in 1938. Bolton school dates from 1524.

BOLTON ABBEY, village in the West Riding administrative division of Yorkshire, Eng., is about 19 mi. N.W. of Leeds and 6 mi. from Ilkley by road. Its name was taken inexactly from the great Augustinian foundation of Bolton priory, the ruins of which are beautifully set near the right bank of the river Wharfe in a wooded valley enclosed by hills. The nave. used as the parish church since the 12th century, is Early English and Decorated. The transepts and choir are in ruins. and remains of domestic buildings are slight. With the rest of the district of Craven, the manor was granted by William the Conqueror to Robert de Romili, whose heiress, Cicely, and her husband, William de Meschines, founded and endowed a priory at Embsay. near Skipton, in 1120. In 1151 it was moved to a new establishment at Bolton Abbey which was erected by their: daughter Alice, wife of William Fitz-Duncan. whose son (according to legend) was drowned in the river nearby. The manor, also called Bolton abbey, was sold in 1542 to Henry Clifford. 2nd earl of Cumberland, and descended to the dukes of Devonshire.

BOLTRAFFIO, GIOVANNI ANTONIO: *see* BELTRAFFIO. GIOVANNI ANTONIO

BOLTZMANN, LUDWIG (1844–1906), Austrian physicist, made important contributions to many branches of physics; his greatest achievements were the development of statistical mechanics and the statistical explanation of the second law of thermodynamics.

Boltzmann was born in Vienna on Feb. 20, 1844, and studied at the university there, receiving his doctorate in 1866. He held professorships in mathematics (Vienna. 1873–76). experimental physics (Graz, 1876–89) and theoretical physics (Graz, 1869–73; Munich, 1889–93; Vienna, 1894–1900; Leipzig, 1900–02; Vienna,

1902–06), but theoretical physics was his real vocation.

When Boltzmann began his scientific work, he attacked the problem, until then unconsidered, of explaining the second law of thermodynamics on the basis of the atomic theory of matter. In a series of papers published during the 1870s Boltzmann showed that the second law could be understood by combining the laws of mechanics, applied to the motions of the atoms, with the theory of probability. In this way he made clear that the second law is an essentially statistical law and that a system will approach a state of thermodynamic equilibrium because the equilibrium state is overwhelmingly the most probable state. The entropy function of thermodynamics, whose behaviour shows the trend to equilibrium and whose maximum value characterizes the equilibrium state, is itself a measure of the probability of the macroscopic state. (The equation relating entropy and probability is engraved on the monument at Boltzmann's grave in Vienna.) In the course of these investigations Boltzmann worked out the general law for the distribution of energy among the various constituents of a system at a definite temperature, derived the theorem of equipartition of energy, derived the integro-differential equation for the change of the distribution of atoms due to collisions, and in general laid the foundations and built much of the structure of statistical mechanics, a structure later elaborated by J. W. Gibbs.

Apart from his work on statistical mechanics Boltzmann made extensive calculations in the kinetic theory of gases. He was also one of the first Europeans to recognize and to expound the importance of J. C. Maxwell's theory of electromagnetism, a subject on which he published a two-volume treatise in his own characteristic style. One must also mention Boltzmann's thermodynamic derivation of Stefan's law for black body radiation, a derivation which H. A. Lorentz called "a true pearl of theoretical physics."

Boltzmann's work in statistical mechanics was strongly attacked by W. Ostwald and the energeticists who did not believe in atoms and wanted to base all of physical science on energy considerations only. He also suffered from misunderstandings of his ideas on the nature of irreversibility on the part of others who did not fully grasp the statistical nature of his reasoning. Boltzmann was fully justified against both sets of opponents by the discoveries in atomic physics which began shortly before 1900 and by the fluctuation phenomena. such as Brownian motion, which could be understood only by statistical mechanics.

Ill and depressed. Boltzmann took his own life on Sept. 5, 1906, at Duino, near Trieste.

See STATISTICAL MECHANICS; HEAT: Radiation: Relation Between *Radiation* and *Temperature;* KINETIC THEORY OF MATTER: The *Equipartition* of *Energy;* CHEMISTRY: Physical *Chemistry:* The Kinetic Theory of Gases.

BIBLIOGRAPHY.—Engelbert Broda, *Ludwig Boltzmann* (1955); René Dugas, La *théorie physique au sens de Boltzmann* (1959). In addition to his scientific books and collected scientific papers, Boltzmann published a collection of *Populare Schriften* (1905) which reveal much of his wit, artistic sympathy and humour. (M. J. K.)

BOLU, the chief town of an *il* of the same name in northwestern Turkey. lies 2.500 ft. above sea level in a rich plain watered by the Bolu Su, a tributary of the Filyos (*Billaeus*). Pop. (1960) 13.743. Its industries include timber, cotton and leather manufacture. Three miles east of the town, at Eskihisar, are the ruins of Bithynium, the birthplace of Antinous (*q.v.*); it was also called Antinoopolis and in Byzantine times Claudiopolis. In and around Bolu are numerous marbles with Greek inscriptions, chiefly sepulchral, and architectural fragments. At Ilica, south of the town, are warm springs well-known for their medicinal properties.

The *il* of Bolu (pop. [1960] 353,769; area 2.681 sq.mi.) includes the plain of Bolu and the mountains bordering it to north and south. The plain is fertile and its chief products are cereals, tobacco and maize (corn). In the neighbourhood are large forests of oak, beech, elm, chestnut and pine, from which some of the timber is shipped to Istanbul. The plain is one of the east-west chain of important plains in northwestern Turkey, which includes the Izmit and Adapazari plains. The other principal towns of the *il* are Akcakoca. Diizce. Gerede and Mudurnu.

BOLYAI, WOLFGANG (FARKAS) (1775–1856), Hungarian mathematician. poet and dramatist. was born at Szekler-Land. and died at Maros-Vásárhely, n-here he was a professor in the Reformed college. and where his son Johann was born. Bolyai studied for a few months at Jena, before proceeding in 1796 to Göttingen n-here he became a close friend of C. F. Gauss. a 19-year-old student at the time. The tn-o young men discussed the foundations of mathematics. particularly those of Euclidean geometry: and on his return home in 1799, Bolyai attempted to prove Euclid's postulate of parallels. Gauss detected the error in Bolyai's attempt, but Bolyai persisted in his efforts, although he admitted that he was probably wasting his time.

BOLYAI, JOHANN (JÁNOS) (1802–1860), famous mathematician son of Wolfgang. was one of the founders of non-Euclidean geometry. Up to the age of 10. Johann knew no mathematics. By 13, under his father's teaching, he had mastered the calculus and analytic mechanics. At 1 j he entered the Royal Engineering college at Vienna. to prepare for service in the army engineering corps. which he joined at the age of 20. In the army, young Bolyai divided his 'time between his duties. dueling, violin playing and mathematics. In 1823, in his 22nd year, he sent his father the draft of his *Absolute* Science of *Space,* a complete and consistent system of geometry constructed without assumption of Euclid's parallel postulate. That such a non-Euclidean geometry should be logically possible showed that the postulate of parallels is independent of Euclid's other postulates. and that attempts to prove the postulate by Euclidean geometry are necessarily futile. The new geometry was printed as an appendix to an elementary work on the foundations of mathematics (*Tentamen,* etc.) by W. Bolyai, and published in 1831. Johann's pleasure in his epochal achievement was spoiled by the discovery that he had been largely anticipated by Gauss', who. however. made no public claim to the new geometry. As early as 1826. N. I. Lobachevsky also had anticipated Johann. Bolyai and Lobachevsky were unaware of each other's existence while both were working toward the same end. The creation of non-Euclidean geometry has been compared with the Copernican revolution in astronomy for its profound influence on philosophy and science. *See* also GEOMETRY: *Non-Euclidean Geometry.*

(E. T. B.)

BOLZANO (Ger. BOZEN), the capital of Bolzano province, a noted tourist area in the Trentino-Alto Adige region of Italy, lies at 869 ft. on the Brenner railway, 58 mi. S. of the Brenner pass and 35 mi. N. of Trento. It lies at the confluence of the Talvera and Isarco rivers, which flow united into the Adige, about 2 mi. S.W. Pop. (1957 est.) commune 81.562, mostly German-speaking. Nothing is known of a settlement there before the dark ages. In the 7th and 8th centuries Bolzano was held by the counts of Bavaria. It was given with the rest of the diocese to the bishop of Trent by Conrad II in 1027, and was a bone of contention between the bishops of Trent and the counts of Tirol (which fell to the Habsburgs in 1363) until 1531, when it was ceded to the counts. It was ceded to Bavaria with the rest of the Tirol in 1805, but the rebellion of Andreas Hofer (*q.v.*) united it to Austria in 1809. Bolzano was part of the Napoleonic kingdom of Italy from 1510 to 1813, and from then until 1919 was under the Austrian empire. The old town, with its low-pitched Tirolean arcades, is surrounded by modern quarters, which were developed under Italian rule. In the central Piazza Walther is a statue of Drusus, which recalls his campaign against the Germanic tribes in 38 B.C., and the Duomo, a Gothic church of the 14th–15th centuries (restored in 1945). To the west is the former Dominican monastery, which has a frescoed cloister and chapels, but the church was damaged during World War II. To the north and east is the Via dei Portici, with its heavy, low arcades, and the 14th-century Franciscan church (rebuilt). There are scenic promenades along the rivers. and below the Lungotalvera Sant' Antonio is the 13th-century Castello Mareccio (with five later towers) which houses the municipal archives. There is a musical conservatory, a civic museum (of fine arts) and the Castelroncolo (Runkelstein) which contains murals of chivalric subjects of about 1400. Manufactures include steel, textiles, canned fruits and wines.

BOMA, a port of the Republic of the Congo and capital of the district of Bas-Congo, on the Congo river estuary 60 mi. from the

Atlantic coast and 175 mi. S.W. of Léopoldville. Pop. (1958 est.) 31.598 of whom 1.306 were nonindigenous. It was the second port of the former Belgian Congo and an important commercial centre. Boma is an outlet for the produce of Mayumbe (palm oil, bananas, timber especially limba), and is linked with that district by road and a narrow-gauge railway which terminates at Tshela. Industries include edible oil extraction, soapmaking and refrigeration, and there is a small naval shipyard. Boma, one of the oldest towns of the Congo, was where Capt. J. K. Tuckey landed in 1816, and where Henry Morton Stanley ended his crossing of central Africa. Formerly known as Lombi, later Embomma, it was a slave market before the middle of the 19th century. At that time, as a European trading post, it possessed factories of French, British, Dutch and Portuguese companies. In 1886 Boma became the capital of the Congo Free State and was the capital of the Belgian Congo until 1926. (HE. NI.)

BOMB, an explosive-containing device that is not hurled by either a gun, as is an artillery shell, or a self-contained propellant, as is a rocket, but is usually dropped by planes and sometimes placed by hand. The word formerly referred to an explosive shell fired by cannon.

Air bombs became important weapons with the extensive use of aircraft (dirigibles and airplanes) in World War I. At first hasty adaptations of artillery shells, they rapidly took on a streamlined, finned design of their own. By the beginning of World War II, aerial bombs had been improved to a high degree of ballistic efficiency, planes had been especially designed to carry them and drop them in successive groupings, and considerable effort had been put into the development of intricate bombsights.

The commonest type of bomb dropped in World War II was the high explosive, demolition type for use against enemy strong points, transport, ships and cities. This bomb often had a fairly thin casing. Sometimes, however, its casing was heavy and the nose section thick so that it would penetrate such cover as 24-ft.-thick concrete over submarine pens before exploding. Demolition bombs used by the British during World War II weighed as much as 22,000 lb. each, while the maximum size used by the United States was 4,000 lb. The U.S. army developed for the air force a monster 21-ton bomb, but it was not even test dropped until 1947. Another type commonly used was the fragmentation bomb, which had a casing designed to break into fragments that flew in all directions at high velocity. This type of bomb was most effective against personnel.

A third commonly used bomb is the incendiary. As its name implies, it is used against inflammable installations or buildings. On hitting the target, it spreads flaming chemicals or thermit (*q.v.*), a mixture of powdered metals creating such intense heat that its fire is very difficult to quench. Chemicals that cause severe burns to personnel and other chemicals to poison, to signal, or otherwise to harass and incapacitate an enemy may be used in chemical bombs. Most common is napalm, a mixture forming a sort of jelly of naphtha or gasoline and a petroleum wax. Napalm was widely used by United Nations forces in Korea, but other chemical bombs, especially those containing poison gas, were held in reserve. Psychological warfare has its own bombs that carry great numbers of propaganda leaflets over the enemy territory.

Lightning-like expansion of gases resulting from the simple reaction of chemicals, or oxidation, bursts conventional bombs apart violently and causes damage by both the concussion or blast effect and by flying fragments. Late in World War II a revolutionary new type—the atomic bomb—was completed and used for the first time. One A-bomb, as it was called, destroyed most of the city of Hiroshima. Japan, in Aug. 1945. This bomb derived its power—the equivalent of 20,000 tons of T.N.T.—from disintegration of the nucleus of a radioactive atom. In the early 1950s the first hydrogen or H-bomb (fusion or thermonuclear bomb) was tested. The power of the H-bomb—many times that of the A-bomb—prompted efforts to outlaw its use in war (*see* DISARMAMENT), while its lethal after-effects, especially radioactive fallout, caused world-wide concern. Meanwhile, the development of long-range missiles tended to reduce the importance of aerial bombs.

See AIR WARFARE; AMMUNITION, ARTILLERY; ATOMIC ENERGY.

For the products of volcanic activity called bombs, *see* VOLCANO; VOLCANISM. (F. D. McH.)

BOMBACACEAE, the bombax or kapok family, dicotyledonous plants, all trees, and often deciduous. It is allied to the mallow family (Malvaceae), to which the cotton plant belongs, and is characteristic of the tropics. The flowers are often large and showy. Included in the family are: *Adansonia,* the African baobab (*q.v.*); *Bombax* with about 30 species in tropical America; and the closely allied *Gossampinus* with 12 species in southeast Asia.

Ceiba, with 10 or more species, is largely American, and its fruits produce the kapok (*q.v.*) of commerce. *Ochroma lagopus* is the South American balsa (*q.v.*), noted for its very light wood, while the Malayan *Durio zibethinus* bears the noted durian (*q.v.*), a fruit remarkable for its distinctive odour.

BOMBARDE, a wind instrument, the name derived from a piece of artillery in the 14th century to denote a tenor shawm (*q.v.*), with German forms *Pumhart* and *Pommer.* The name survives in Brittany to denote a small shawm played in duet with a bagpipe. (A. C. BA.)

BOMBARDON, an old name for the contrabass brass instrument used in military and brass bands, now called simply "bass." It is a tuba (*q.v.*) built in two sizes: E flat bass, and BB flat (double B flat) bass, the latter pitched a fourth below the first. The term *bombardone* had occasionally, in Italy up to the 18th century, denoted a bass shawm or bombarde. In the 1820s the Viennese maker K. Riedl reintroduced the name, first for a kind of ophicleide, next for a large valved trombone. The connotation "tuba" in Germany and England dates from the mid-19th century. (A. C. BA.)

BOMBAY, until May 1, 1960, a state of the Republic of India, was on that date split into two separate states: Gujarat and Maharashtra. The history of the Bombay state and of the Bombay presidency which preceded it forms the subject of the greater part of this article. For the geography and the earlier history of the area *see* GUJARAT and MAHARASHTRA. *See* also the article on the city of Bombay.

The first Europeans in modern times to appear on the western coast of India were the Portuguese. Vasco da Gama arrived at Calicut (now Kozhikode) in 1498, and the Portuguese made their capital at Goa in 1510 and established trading stations along the coast at Bombay, Bassein, Diu and Damão. In 1613 the English East India company obtained permission from the emperor Jahangir to establish a factory at Surat. The company's headquarters were transferred from Surat to Bombay in 1672.

The territory of the British presidency was confined at first to the narrow limits of the island of Bombay. In 1775, hoping to acquire Salsette and Bassein, the British championed the cause of Raghoba, a pretender to the peshwaship of the Maratha confederacy. The Bombay forces proved no match for the more mobile Marathas and were forced to capitulate. The situation was retrieved by Warren Hastings who dispatched reinforcements across the peninsula from Bengal. The treaty of Salbai (1782) secured peace with the Marathas for 20 years. Lord Wellesley (1797–1805) was the first governor-general to realize that the time had come for the British to stand forth as the paramount power in India. By the treaty of Bassein (1802) the peshwa, Baji Rao II, who had been attacked by Holkar, was reinstated at Poona as a British puppet in return for which he agreed to receive a British subsidiary force and to accept British arbitration in all disputes with his neighbours. This led to war with the Maratha chiefs. Wellesley was recalled before he was able completely to crush their power. Their final defeat and the establishment of British paramountcy was the work of the marquess of Hastings (1818–23).

The first lieutenant governor of the enlarged Bombay presidency was Mountstuart Elphinstone (1819–27), whose aims were to pacify the country, avoiding violent changes, to establish law courts, to codify the law and to encourage vernacular education. Aden was added to the presidency's jurisdiction in 1839; and after its conquest by a Bombay army under Sir Charles Napier in 1843 Sind became a subordinate province under a commissioner, with its capital at Karachi. Interspersed with British territory were a

number of Indian states, the debris of the Maratha empire, the chief being Baroda, Kolhapur and the short-lived kingdom of Satara. A land revenue system for the whole presidency was laid down in 1847, and a commission to investigate awards, instituted by Lord Elphinstone (governor 1853–60), disclosed the fact that many estates were being held rent-free without titles. In spite of this and the annexation of Satara by Lord Dalhousie, the mutiny of 1857 produced few repercussions in Bombay and the Deccan. In 1858, together with the other provinces of British India, the Bombay presidency came under the control of the crown.

Of the later governors of Bombay in the Victorian period, the most distinguished was Sir Bartle Frere (1862–67). The period up to World War I was one of regular progress, with occasional setbacks such as the outbreak of plague in 1898 and the disastrous famine in Gujarat, 1899–1902. Serious efforts to prevent a recurrence of this catastrophe were made by Sir George (afterward Lord) Lloyd (1918–23) who undertook the construction of a series of tanks designed to irrigate parts of the presidency most exposed to a failure of the monsoon. His crowning achievement was the great Sukkur barrage on the Indus, opened after his retirement in 1932. During the early decades of the 20th century Bombay's advance toward political independence followed the same pattern as in the other provinces of India (*q.v.*). Sind became a separate province and Aden was placed under the British colonial office in 1937. On Aug. 15, 1947, British rule came to an end. The first Indian governor was Raja Maharaj Singh. On Nov. 1, 1956, when the reorganization of the states took place. the boundaries of Bombay were altered, the state gaining eight predominantly Marathi-speaking districts from Madhya Pradesh and losing the greater part of four Kanarese-speaking districts to Mysore.

The dissolution of the Bombay state on May 1, 1960, and its replacement by the states of Gujarat and Maharashtra was the result of separatist agitation by the Gujarati-speaking peoples in the northern part of the state and by the Marathi-speaking peoples in the south. Bombay city fell to the share of Maharashtra.

(C. C. D.; X.)

BOMBAY, capital of the former Bombay presidency and Bombay state and-since May 1, 1960, capital of the new state of Maharashtra, Republic of India, is the principal seaport of western India. Bombay Island, on which the older part of the city lies, consists of a low-lying flat plain, one-fourth of which is actually below sea level. This plain is flanked by two parallel ridges of low hills which intersect beyond the southern extremity of the island where they form a dangerous reef, on which the Prongs lighthouse stands. The western line of low hills stands out in bold relief, with Malabar hill, 180 ft. above sea level, as its highest point. The eastern hills have an irregular outline with knolls and low hills about 100 ft. high: Mazagon hill, Sewri hill, Parel hill and others. The island is about 11½ mi. long by 3 to 4 mi. broad and covers an area of about 25 sq.mi. From north to south it is more or less a rectangle, toward the southern end of which extend two wide-open crablike claws of unequal length, with a broad expanse of water, the Back bay, between them.

The city was commonly called Bombay Island long after the name had become a misnomer; before 1810 the construction of causeways and breakwaters across a tidal creek had united the island with the longer island of Salsette on the north and so continuously with the mainland. Neither did the name entirely drop out of use after the rise of Greater Bombay, a term in official use since 1950, when the city expanded northward by the inclusion of Salsette. Between 1950 and 1957 a number of old municipal boroughs, including Bandra, Kurla, Parle-Andheri, Juhu, Ghatkopar-Kirol, Malad and Mulund, were incorporated in Greater Bombay. The city extends to the southern outskirts of Thana, on the Central railway, 21 mi. N. of the Victoria terminus.

The creation of Greater Bombay was a much belated measure, for by 1940 the island city was dangerously overcrowded, and people continued to flock there in thousands, mostly in search of employment. The old industries were all located in the island, and new industries sprang up within the same confined area. The only solution was to establish factories and workshops outside the city; this required roads, transport facilities and essential amenities, all

W. SUSCHITZKY

GATEWAY OF INDIA, BOMBAY. ON THE WATER FRONT OF THE ARABIAN SEA

of which was achieved successfully and on a vast scale. The area of Greater Bombay in 1961 was 186 sq.mi. Pop. (1961) 4,146,491.

Bombay owes most of its prosperity to the great waterway constituting the harbour, 7 mi. wide at the opening and narrowing as it runs north to the creek. There are few more scenic and impressive sights than the approach up this waterway studded with hilly islands, with a view of the stately buildings of the city, and to the right the palm-fringed shore of the mainland rising gradually to the peaks of the Western Ghats in the distance. Bombay's position as the gateway of India, its fine natural harbour and the enterprise of its inhabitants, made it one of the first cities of the world. Public and commercial buildings especially notable are the municipal corporation building, the Victoria railway terminus, the general post office, the museum, the Institute of Science, the Reserve bank, the head offices of the Western railway, the town hall, the Gateway of India (a large arch in 16th-century Gujarat style built to commemorate the visit of King George V and Queen Mary in 1911), and the clock tower of the university.

The climate of Bombay is hot and humid, the mean temperature ranging from 91° F. in May to 67° F. in January. Annual rainfall is 88.7 in.

History. — It is now generally admitted that the Norwegian orientalist Christian Lassen (1800–76) was right in identifying the Heptanesia of Ptolemy (A.D. 150) with the seven islands which in course of time made up Bombay Island: Bombay (the central island) and, clockwise from west to east, Worli, Mahim, Parel-Sewri-Sion, Mazagon, Old Woman's Island and Colaba; the seven were separated by creeks often broad and deep. The name Bombay is probably derived from Mumba Bai or Mumba Devi, a Hindu goddess; from the 9th century A.D. until 1348 Bombay was under Hindu rule. It then changed hands and became part of the sultanate of Gujarat. Sultan Bahadur Shah of Gujarat ceded it to the Portuguese in 1534; and in 1661 the Portuguese gave it to Charles II of England as part of the dowry of Catherine of Braganza, sister of the king of Portugal. On April 6, 1662, an expeditionary force with Sir Abraham Shipman in command sailed for Bombay in a squadron of the Royal Navy under the earl of Marlborough. They were not allowed to land. Viceroy Antonio de Mello de Castro would not give up Bombay and persisted in his refusal for two years and four months. Finally, Humphrey Cooke, who had succeeded Shipman, took possession of Bombay in the king's name. During the years of waiting Shipman and over 300 men had perished on the island of Angediva, about 51 mi. S.E. of Goa. The articles of surrender, drawn up by de Castro and signed by Cooke, stipulated that only Bombay, and no other island, was to be ceded. On March 27, 1668, Bombay was leased to the East India company by the crown for the nominal rental of £10 a year, In 1672 Gerald Aungier, the president of Surat, transferred his seat of government to Bombay and became the city's real founder.

Bombay was then one of the most unhealthy places in the east.

The islands were covered with palm trees manured with rotting fish, and the creeks at low tide became putrid swamps. It was a common proverb that "two monsoons were the age of a man." Aungier started work on filling in the creeks, opened a hospital and established a high court. Above all, he proclaimed complete religious toleration. and this brought in the Parsee merchants from Gujarat, who were destined to play a prominent part in the development of the city (see PARSEES). He fortified the town so effectively that it was able to repel raids by the Sidis of Janjira and a formidable attack by the Dutch fleet in 1673. When he died in 1677 the city had a population of 60,000 and was already able to claim the proud title of "Urbs prima in Indis." There was friction, however, between the king's officers and the company's government, and in 1683 an abortive rebellion was raised by Richard Keigwin, a naval officer. The 18th century was a period of constant expansion. The city, whose growing prosperity made it a tempting prize, was surrounded by elaborate fortifications. Work went on steadily at the reclamation of the breaches between the islands, particularly that between Rorli and Mahim which was finally closed by William Hornby, governor from 1771 to 84, who constructed the great causeway known as the Hornby Vellard.

Among the many who have contributed to Bombay's rise to eminence from the 18th century none are deserving of greater praise than members of the Parsee community. Among the first was Lavji Naserwanji Wadia, a shipbuilder or *wadia,* who added the name of his craft to the family name. A native of Surat, he came to Bombay in 1736, superintended the extension of the docks and started a shipyard which turned out many fine vessels, including ships of the line for the Royal Navy. His enterprise also called for men skilled in many trades and thus were so n the seeds of an extensive industry. The trade of the island increased steadily with the elimination of foreign competition: the Maratha pirates' nest at Gheria or Vijayadurg, 170 mi. down the coast, was destroyed by Robert Clive and Charles Watson in 1756, and Portuguese power was waning. French rivalry ceased with the capture of their settlements. Most important of all, the island of Salsette and the port of Bassein were ceded to Bombay by the Marathas under the treaty of Salbai in 1782.

With the fall of the Maratha empire, Bombay, as the capital of the new presidency, entered into a fresh era of prosperity and importance under its first lieutenant governor, Mountstuart Elphinstone (1819–27). In 1838 regular monthly communication between Bombay and England by way of Suez and Alexandria, Egy., was established, the duration of the journey being 45 days. This was shortened to 30 days with the opening of the Suez canal in. 1869. Meanwhile, railways were being built and were bringing into the city the raw cotton destined to provide its staple industry. The first section of the Great Indian Peninsular line from Bombay to Thana was opened in 1853, and the Bombay, Baroda and Central India railway reached the city in 1864. Two years later the Victoria terminus was built on reclaimed land. During the governorship of Sir Bartle Frere (1862–67), the walls surrounding the fort, now obsolete, were demolished and Bombay cathedral was rebuilt. Between 1861 and 1865 occurred the famous trade boom when, because of the American Civil War, Bombay held practically a monopoly of the world's cotton trade. Fortunes were made and lost in a day, but with the collapse of the Confederate states came a disastrous slump which shook the city to its foundations. Nevertheless, its financial stability was soon recovered.

Cowasji Nanabhoy Davar, another Parsee, made a notable contribution to Bombay's growing prosperity in 1884, when he started the city's first successful cotton mill. During the next five years 50 more mills were established, benefiting not only Bombay but also other states or provinces. Another notable Parsee was Jamshetji Nasarwanji Tata (1839–1904), who discovered the Gurumaishini iron deposit and was the real founder of the steel and iron industry in India; the great Tata Iron and Steel company was established by him and his sons (see TATA family). Jamshetji Tata was the first to think of harnessing the monsoon rains that ran to waste down the slopes of the Western Ghats; the great project was carried out by his son, Sir Dorabji Tata, and by 1915 the city had at its disposal an enormous supply of cheap hydroelectric power, on which were based many industrial enterprises. Among them are mills for paper, flour, rice, oil and timber; rope, leather, stone, cement and metal works; sugar, tobacco, tea, tile and brick factories; printing presses and many kinds of workshops. There are also electric streetcars and trains.

During the last decades of the 19th century the city changed greatly. Along the Esplanade (now Mahatma Gandhi road) arose an imposing row of buildings: the vast secretariat. high court, university library, senate house, clock tower, and public works and post offices, all designed in the florid Gothic style then popular. The Cranford market was built in 1871. The Bombay port trust was constituted in 1873. The first waterworks at Vihar and Tular, and later at Tansa, brought a supply of fresh water to replace the unsanitary wells, and a drainage system was installed in 1879.

The great increase of trade brought a corresponding rise in population, which in 1891 reached 821,000. To cope with the resulting overcrowding and squalor, the City Improvement trust was set up for the purpose of making new streets, clearing away slums, reclaiming more land from the sea and constructing on it sanitary dwellings for the millworkers. This led to the Back bay development scheme sponsored by Sir George (afterward Lord) Lloyd in 1918, an ambitious project for building a sea wall from Colaba point to Marine Lines enclosing an area of 1,300 ac. which would be reclaimed and added to the city. The scheme miscarried for technical reasons and was the subject of an inquiry in 1926. As a result it was decided to proceed for the time being only with the two end sections. Work was resumed after World War II, when the Marine drive, extending from Chowpatty Sea Face road up to the junction with Harvey road, was constructed. This was the first dual highway of its kind in India. At the same time projects for suburban development were steadily pushed on. Salsette Island was developed. and residential quarters were constructed along the railway and arterial roads at Mahim. The cotton, grain and oil depots were removed from Colaba to Sewri.

Population. — In 1901 the population of Bombay city and suburbs was 847,497; 40 years later it had doubled (1,695,168). In 1951, with a population of 2,329,020, Bombay was the second largest city in India, next only to Calcutta, and its growth has continued. The cosmopolitan character of the population is brought out as much by the presence of nearly 25,000 persons belonging to 49 countries other than India as by the variety of religious beliefs among the nationals themselves. While by far the largest part of the population in 1951 was Hindu (2,039,244), Muslims (412,266) and Christians (206,191) were by no means unimportant. Besides these, in 1951 there were 80,110 Jains, 68,660 Parsees, 16,265 Jews and 13,984 Sikhs. Among the nonnationals British (4,846 in 1951), Americans (494), Chinese (1,360), Portuguese (11,759), Iranians (1,626), Pakistanis (1,677), Afghans (242) and Arabs (256) are the chief. The principal languages spoken are Marathi (by 1,236,874 persons in 1951), Gujarati (523,127), Urdu (181,975), Hindi (211,313), Konkani (129,943), Telugu (78,000), Sindhi (66,714), Tamil (59,295) and Kanarese (52,011). Besides these, more than 50 other languages are spoken.

Cultural Facilities. — The city has become an important intellectual centre. The beginning of its scholarly growth dates from 1804 and the foundation of the Literary Society of Bombay, formed "for the purpose of promoting useful knowledge, particularly such as is immediately connected with India." Foremost among its founders was Jonathan Duncan, governor of Bombay. In 1830 it moved into the town hall, where it has ever since been housed, and in 1827 a union was effected with the Royal Asiatic Society of Great Britain and Ireland, established in London in 1823. Thenceforward the Literary society was known as the Bombay branch of that society. It adopted an open-door policy. In 1804 there were 17 members, all Europeans; by 1864 there mere 204, of whom 160 were European and 44 Indian. In 1893 Justice K. T. Telang became the first Indian president, and many other Indians have since held this office. In 1954 membership stood at 1,036. The society has made a name for itself throughout the world by its Quarterly Journal, the publication of which was first resolved upon in 1841; one of its greatest local assets is its library, started in 1805, a storehouse of knowledge perhaps without equal in the east.

The University of Bombay, established in 1857 as an affiliating body for the whole presidency, gradually added to its teaching functions and after the establishment of regional universities in the state in 1948–50 its jurisdiction was confined to Greater Bombay. In 1957 there were 32 constituent colleges imparting higher education, and 9 other recognized scholarly institutions. The university maintains three postgraduate institutions, a school of economics, sociology and politics, a department of chemical technology and a department of statistics. The colleges are coeducational except for one college exclusively for women, Sophia college, founded in 1940. The number of students rose from 29,361 in 1954 to 42,396 in 1958.

The Prince of Wales Museum of Western India was founded in 1904, though only in 1921 did it begin to function as a museum. (Bombay had possessed a museum since 1840.) It has three sections, art, archaeology and natural history, and the establishment of an industrial section was being considered in 1960. In its grounds is the Jehangir Art gallery, completed in 1952.

The Bharatiya Vidya Bhavan (Palace of Indian Learning) was founded in 1938 for research and the study of Sanskrit and ancient and modern Indian languages, history and religion. The Tata Institute of Fundamental Research was founded in 1945 by the Sir Dorabji Tata trust and the government of Bombay to carry out fundamental research in physics, mathematics and allied sciences, and is the biggest centre for cosmic ray and nuclear research in India. Its school of mathematics is perhaps the largest and most active in India. The Tata Institute of Social Sciences was founded in 1936 and offers training in professional social work. The Haffkine institute was founded in 1896 and was in 1960 the largest antibacterial vaccine manufacturing concern in Asia with a potential capacity of more than 5,000,000 to 6,000,000 ml. of vaccine per month.

Primary education in the city is free and compulsory, and is the responsibility of the municipal corporation.

Local Government. — The municipal corporation of Bombay is one of the oldest and most influential local authorities in India. Besides its standing committee and improvements and education committees, the electric supply and transport committee is its important feature. The corporation consists of members elected in the several wards of the city under adult franchise. Bombay and environs developed considerably as a result of the activities of the development directorate, set up in 1920, and of the corporation improvements committee which later took over the task of development. The public health department is in charge of sanitation, registration of births and deaths, prevention and control of communicable diseases, etc. There are also inspectors controlling food sanitation in all its aspects. Bombay has an abundant supply of drinking water and a city-wide drainage system.

Hospitals. — The Bombay municipality provides medical care for its citizens in three major general hospitals and a number of other institutions including a group of hospitals for tuberculosis, free dispensaries, maternity homes, maternity and child welfare clinics, an eye hospital, a quasi-municipal institution for the treatment of leprosy, etc. The largest is the K.E.M. (King Edward VII Memorial) hospital, which is reputed one of the best in India. It can accommodate 550 in-patients and has over 1,000 outpatients daily.

Economy. — Bombay is the principal port for imports into India. Import and export trade in tons rose to 5,807,000 and 3,333,000 respectively in 1958–59. Among imports wheat (1,355,000 tons) and machinery were predominant, and among exports manganese (295,000 tons) and other ores, oil cakes and cotton. Bombay is the centre of the cotton and textile industry of India and, after Calcutta, is the largest financial centre in the country. Wool, leather, chemicals, oil and engineering are other important industries.

The Tata electric system, originating in 1915 with three catchment lakes in Lonavla and a hydroelectric plant in Khopoli, became the principal source of power for the city and for a total area of more than 1,000 sq.mi. It is the largest power system in southeast Asia. A new thermal station has been under construction near two new oil refineries on Trombay Island. The new station was designed to burn by-product gases from the refineries as well as liquid and solid fuels.

Communications. — Bombay possesses a natural deepwater harbour about 70 sq.mi. in area. The dockyard, established in 1735, has a sea face of nearly 700 yd. and an area of about 200 ac. There are three enclosed docks with a water frontage of more than 3,000 yd. and a combined water area of 104.5 ac. Alexandra dock, completed in 1914, is entered through a lock 100 ft. wide, while the Prince's dock and the Victoria dock, completed in 1880 and 1888 respectively, have tidal working. There are two dry docks measuring 1,000 ft. by 100 ft. and 525 ft. by 65 ft. 6 in., built in 1914 and 1891 respectively. The docks are fully equipped for the rapid landing of cargo with ample accommodation for storage. Extensive works of port development and modernization, begun under the first five-year plan, have continued.

Ballard pier, the ocean passenger terminal, a few minutes from the centre of the city, is 1,500 ft. long; ships up to 750 ft. long can be brought alongside. Special trains of the Central and Western railways leave for all parts of India from the railway station adjoining the main building. Coastal passengers also embark and disembark at Ferry wharf on the Alexandra dock harbour wall.

Bulk white oils are handled at the deepwater pier at Pier Pao, about five miles from the docks, and the oils are pumped to the installations a few miles away. Black oil is discharged to the installations from the Alexandra dock harbour wall. The new marine oil terminal near Butcher Island was designed to berth large tankers carrying crude oil at any state of the tide.

The port is administered by a board of 25 trustees, some nominated by the government and others elected by various interests. The port trust has its own railway connecting with the trunk lines and with a network of sidings more than 130 mi. in total length serving the docks, the bunders (quays) and the many large depots such as those for cotton, manganese ore and grain. The land area of the estate and docks owned and administered by the board is about 2,000 ac. Bombay is the headquarters of both the Central and the Western railways. The completely electrified suburban railway system is a model of efficient, though still inadequate, communication in a highly industrialized area. The line between Bombay and Poona, passing through many tunnels in the Bhor Ghat, is also electrified. Local transport includes a fleet of over 600 buses and 250 streetcars.

Bombay (Santa Cruz) airport is one of the important international air traffic centres, connecting directly with the west and through Calcutta with the east. Daily air services are maintained to and from almost all important cities within the country.

(J. H. GE.)

BOMBAY DUCK, the dried and salted flesh of a small fish (*Harpodon* nekereus) that inhabits the western coastal waters of India. Esteemed as a relish in curried dishes, it is sold as a gourmet item in the western world.

BOMBAZINE (BOMBASINE), a textile, usually black in colour, with a silk warp and worsted weft woven in either plain or twill weave. Cheaper grades of bombazine are woven with a rayon warp and worsted or cotton weft.

The word bombazine is derived from the Greek *bombycid,* meaning a moth of the silkworm genus Bombyx. Bombazine was originally made exclusively of silk and in a variety of colours in addition to black. But as it came to be used more and more for mourning and in the garb of religious orders, its colour became standardized as black. It was woven with silk warps and worsted wefts. Bombazine was woven in ancient China and Japan, 16th-century Elizabethan England and in Italy, France, Spain and England during the 18th and 19th centuries. In Spain and South America, women often attire themselves in black bombazine when attending church or making visits of condolence. Mantillas for winter wear in those countries also are frequently made of black bombazine.

(J. K. T.)

BOMBING AND BOMBARDMENT, the discharge of missiles, usually in large numbers, from heavy weapons—land artillery, naval guns, mortars and rocket launchers—and also the discharge of bombs from aircraft. (Up to about 1916 the term bombing indicated the employment of hand and rifle grenades by

infantry soldiers.) In land warfare it is usually employed as a prelude to an assault, to incapacitate or lower the morale of the defenders. Naval bombardments are frequently employed to cover an assault from the sea or by troops already established ashore. Aerial bombing is sometimes used in direct support of troops, but more often against rear military establishments. centres of industry and communications. Bombardment by land-based artillery reached its peak in World War I, when at the battle of Messines in May and June 1917, 3.500.000 shells were fired from British guns alone. The naval bombardments against the Dardanelles forts and other defensive works during the Gallipoli campaign of 1915 were the heaviest of their kind up to that time. In World War II many landings were supported by heavy naval bombardments. including those on Japanese-held Pacific islands and the Normandy coast in June 1944. (See also AIR WARFARE; ARTILLERY: BOMB.)

Since 1945 the development of nuclear weapons has vastly increased the destruction which a bombardment can cause. Missiles of obliteration with ranges of hundreds or even thousands of miles can now be fired from rocket launchers on land or sea. One such missile can cause more destruction than thousands of conventional shells or bombs. (See also MISSILES; ROCKETS.)

International law prohibits the bombing of undefended towns. Efforts mere made at the Hague Conferences (*q.v.*) to prohibit all bombing from the air or at least to limit aerial bombing to military targets. Prolonged efforts during the 1950s to prohibit bombing by nuclear weapons were fruitless. See also DISARMAMENT; LAWS OF WAR. (C. N. B.)

BOMB SHELTER, a structure designed to offer protection to military or civilian personnel against aerial bombing attacks. Bomb shelters appeared during the first half of the 20th century as a means of passive defense against high-explosive bombs dropped from manned aircraft. During the 1950s, as long-range missiles armed aith nuclear narheads approached operational use the term was loosely applied to a wide variety of protective structures

World War I shelters, offering protection against bombs neighing up to 100 lb., were largely improvised in home basements, stronger buildings subways, tunnels and caves World War II, nith large-scale attacks on cities by aircraft carrying bombs such as the 4 000-lb "blockbusters," made special shelters necessary for homefront defense. Public shelters in heavily-bombed cities of Europe, such as London. Coventry, Berlin. Hamburg, were of many types: long, covered trenches in public parks, reinforced basements of larger buildings, subway stations, church vaults, tunnels, caves and earth-covered or concrete blockhouse structures above ground. Family shelters took the form of reinforced basements, steel-section backyard and indoor structures, and sandbagged groundfloor rooms.

The use of the first nuclear bombs on the Japanese cities of Hiroshima and Nagasaki during World War II emphasized the need for peacetime civilian shelter programs against future conflicts. During 1950–54 U.S. studies considered both the adaptation of existing buildings and the construction of blast-resistant shelters in principal cities. European and Scandinavian countries nearer the threat of nuclear attack constructed heavy shelters, some in solid rock, to protect up to 20,000 persons per shelter. Home shelters were required by law in Sweden, Norway and Denmark.

In 1954 the successful test of a thermonuclear bomb with force measured in millions of tons of TNT clearly showed that providing shelters close to such explosions would be impractical if not impossible. Up to that time U.S. civil defense authorities had tested, by means of actual atomic explosions, several family. public and industrial shelter types designed to protect their occupants against thermal, blast and radiological effects near the focal point of such explosions. The L.S. government also called for study of plans to evacuate large cities, such plans to be combined with provision of shelters outside the potential heavy damage areas of target cities.

In planning for the future. estimates of warning time available for evacuation were reduced in the light of new developments in rockets and missiles, particularly the intercontinental ballistic missile. With these weapons looming on the horizon. U.S. civil defense planning turned more to limited evacuation and the provision of blast-resistant shelters for metropolitan areas and lighter shelters in suburban areas. Shelters were regarded as being particularly valuable as protection against radiological fallout from distant nuclear explosions. Shelters tested by the U.S. during the 1957 atomic test series in Nevada included reinforced concrete dome shelters, an underground concrete garage-personnel shelter and earth-mounded. underground concrete family shelters.

See also CIVIL DEFEKSE. (R. S. B.)

BOMBYCILLIDAE, a small family of beautiful perching birds called waxwings. The family name means "small silky ones." See WAXWING.

BON (BÖN): see TIBETAK BUDDHISM.

BONACOLSI, an Italian family that held despotic power in Mantua from 1276 to 1328 and also for a time in Modena (1312–26) and Carpi (1317–26). They first appear in the later 12th century among the consular families of Mantua, over whom and all other contenders for poner they came in time to prevail by their dexterity in exploiting urban faction. Their effective lordship began in 1276. when Pinamonte di Martino Bonacolsi was created *capitano del popolo*. He was followed by Bardellone (captain general and perpetual rector. 1291–99), Guido (1299–1309) and Rinaldo, commonly called Passerino (1309–28), who in 1311 obtained imperial recognition and the office of imperial vicar. It was Passerino who won Modena and Carpi. The Bonacolsi were deposed and exterminated during a rising on Aug. 16. 1328, organized by the Gonzaga (*q.v.*), who seized power in their place.

See C. D'Arco, *Studi intorno al municipio di Mantova,* vol. ii and iii (1871–72) ; P. Torelli, article in *Atti Accad. Virgil. (1923).* (*P.* J. J.)

BONA DEA, the "good goddess," an old Roman deity of fruitfulness, both in the earth and in \\-omen. She was identified with Fauna, and by later syncretism also with Ops and Maia—the latter no doubt because the dedication day of her temple on the Aventine was on May 1. This temple was cared for, and the cult attended. by women only. and the same was the case at a second celebration, at the beginning of December. in the house of a magistrate with imperium. which became famous because of the profanation of the mysteries by Publius Clodius (*q.v.*) in 62 B.C., and the political consequences of his act. Wine and myrtle were tabooed in the cult of this deity, and myths grew up to explain these features of the cult. Herbs with healing properties were kept in her temple, and also snakes. the usual symbol of the medicinal art. Her victim was a sow (*porca*), as in the cults of other deities of fertility, and was called *damium,* and it is understood that the goddess herself was known as Damia and her priestess as damiatrix. These names are almost certainly Greek; Damia is found worshiped at several places in Greece, and also at Tarentum. where there was a festival called Dameia. It is thus highly probable that on the cult of the original Roman goddess was engrafted the Greek one of Damia, perhaps after the conquest of Tarentum (272 B.C.).

BONALD, LOUIS GABRIEL AMBROISE, VICOMTE DE (1754–1840), French philosopher and politician. standing with Joseph de Maistre as a leading apologist of "legitimism." was born at Le Monna. near Millau in Rouergue. on Oct. 2, 1754. Mayor of Millau from 1785 to 1789, he became president of the administration of the new *département* of Aveyron in 1790 but resigned in 1791 in protest against the Civil Constitution of the Clergy. Emigrating. he served for a time in the prince de Condé's army and then settled in Heidelberg. His extremely royalist *Théorie* du *pouvoir politique* et *religieux* (1796) was condemned by the Directory. He returned to France in 1797. To the ensuing years belong his *Essai analytique sur les lois* naturelles de *l'ordre* social (1800), *Du* divorce (1801j and *Législation* primitive *considérée . . . par les seules lumières* de la raison, 3 vol. (1802). He showed great reluctance to accept official positions under Napoleon; but after the restoration of the Bourbons, he became a member of the council of public instruction (1814), deputy for Aveyron (1815–22). minister of state (1822) and president of the censorship commission (1827), being moreover nominated to the Académie

Française (1816) and created vicomte (1821) and peer (1823). His books of this period were: *Réflexions sur l'intérêt général de l'Europe* (1815); *Pensées sur divers sujets et discours politiques,* 2 vol. (1817); *Recherches philosophiques sur les premiers objets des connaissances morales,* 2 vol. (1818); *Mélanges,* 2 vol. (1819); and *Dkmonstration philosophique du principe constitutif de la société* (1830). On the July Revolution of 1830 he resigned his peerage and retired to Le Monna, where he died on Nov. 23, 1840.

Bonald was a fervent legitimist, against the principles of the Enlightenment and of the French Revolution: his philosophy and his political activity went hand in hand. Arguing that man could not have invented language because language is the prerequisite of thought (*"l'homme pense sa parole avant de parler sa pensée"*), he contends that language must have come to man by divine revelation. From this metaphysical basis he proceeds to demonstrate the natural rightness of the traditional monarchy in church and state (the pope and, in France, the Most Christian king) as the structure of society: the elemental family group, father, mother and child, is paralleled in politics by the group sovereign, ministers and subjects (or king, nobility and third estate), in science by the group cause, means and effect, in revealed religion by the group God, Mediator and man.

His *Oeuvres complètes* was edited by J. P. Migne (3 vol., 1859) and the selection was edited by Paul Bourget and Michel Salomon (1905).

See H. Moulinié, *De Bonald* (1916); M. *H.* Quinlan, ***The*** *Historical Thought of the Vicomte* ***de*** *Bonald* (1953).

BONAPARTE, the name of a family made famous by Napoleon I (*q.v.*), emperor of the French. The French form Bonaparte was not commonly used, even by Napoleon, until after the spring of 1796. The original name was Buonaparte, which was borne in the early middle ages by several distinct families in Italy. One of these, which settled at Florence before the year 1100, was divided in the 13th century into the two branches of San Miniato and Sarzana. A member of this latter, Francesco Buonaparte, emigrated in the middle of the 16th century to Corsica, where his descendants continued to occupy themselves with the affairs of law and the magistracy.

CARLO MARIA BUONAPARTE (1746–1785), the father of Napoleon I, took his degree in law at the University of Pisa and, after the French conquest of Corsica, became assessor to the royal court for Ajaccio and the neighbouring districts. In 1764 he married LETIZIA RAMOLINO (1750–1836), a beautiful and high-spirited girl descended from an old Corsican family. Joseph, her third child and the first to survive, was born in 1768, Napoleon in 1769, and nine other children, six of whom survived, subsequently *(see* table). Simple and frugal in her tastes and devout in thought, Letizia helped to bind her children to the life of Corsica while her husband, who died at Montpellier in 1785, a schemer by nature and a Voltairian by conviction, pointed the way to careers in France.

Though endowed with immense wealth and distinguished by the title of *Madame Mkre* during Napoleon's years of power, Letizia continued to live mainly in retirement and always in the exercise of a strict domestic economy. After the events of 1814 she joined Napoleon in the island of Elba. In 1815 she returned with him to Paris during the Hundred Days. After Waterloo she took up her residence at Rome, under the protection of Pope Pius VII, who treated her with great kindness. In 1818 she addressed a pathetic letter to the powers at the congress of Aix-la-Chapelle, petitioning for Napoleon's release on the ground that his mortal illness had removed any possibility of his ever again threatening the world's peace. The letter remained unanswered, the powers having reason to believe that its terms had been previously concerted with Napoleon. Afterward, saddened by the death of Napoleon, of her daughters Pauline and Élisa, and of several grandchildren, she lived a life of mournful seclusion. She died in 1836.

BROTHERS AND SISTERS OF NAPOLEON I

JOSEPH (1768–1844), Napoleon's eldest surviving brother, was born at Corte in Corsica on Jan. 7, 1768. He was educated at the college at Autun in France, returned to Corsica in 1784, went to study law at Pisa (1787–88), then returned again to Corsica. Like his brothers, he embraced the French republican side, and on the victory of Pasquale Paoli's supporters he sought refuge in France. He settled at Marseilles and married Julie Clary, daughter of a rich merchant there. Joseph went on a mission to Genoa in 1795 in connection with plans for the recovery of Corsica. In 1796 he accompanied Napoleon in the early part of the Italian campaign and had some part in the negotiations with Sardinia which led to the armistice of Cherasco. He took part in the French expedition for the recovery of Corsica and helped the commissioner of the French republic, A. F. Miot de Melito, in the reorganization of the island. He was appointed by the Directory minister to the court of Parma in March 1797 and then to Rome. Discords arose between the Vatican and the French republic, and it is clear that Napoleon and the Directory ordered Joseph to encourage revolutionary movements in Rome. On Dec. 28, 1797, a disturbance took place opposite the French embassy which led to the death of the French general Léonard Duphot. Joseph returned to Paris and became one of the members for Corsica in the council of five hundred.

Before the *coup d'dtat* of 18 Brumaire, Joseph helped Napoleon in making overtures to E. J. Sieyès and J. V. Moreau, but otherwise did little. He was a member of the council of state and of the *corps législatif*. He concluded at Mortfontaine a convention with the United States (1800). He also presided over the negotiations which led to the treaty of Lunéville with Austria (1801); and he and H. B. Maret represented France in discussions with the British envoy, Lord Cornwallis, which led to the treaty of Amiens (1802). On the question of the consolidation of Napoleon's po er as first consul for life (Aug. 1, 1802) with the chief voice in the selection of his successor, the brothers disagreed. As neither Joseph nor Napoleon had a male heir, Joseph as eldest brother claimed to be recognized as heir, while Napoleon wished to recognize the son of Louis Bonaparte. On the proclamation of the French empire (May 1804) the friction became acute. Joseph refused Napoleon's offer to make him king of Lombardy if he would waive all claim of succession to the French throne.

Meanwhile Joseph had striven in vain to avert a rupture with England, which came about in May 1803. In 1805 he acted as chief of the French government while Napoleon was in Germany. Early in 1806 he was sent to Naples to expel the Bourbon dynasty. By the decree of March 30, 1806, Napoleon proclaimed Joseph king of Naples, but allowed him to keep intact his claims to the throne of France. During his brief reign at Naples, Joseph abolished the relics of feudalism, reformed the monastic orders, reorganized the judicial, financial and educational systems and initiated several public works.

Joseph was suddenly called away by Napoleon to take the crown of Spain (May 1808). There his difficulties were far greater *(see* SPAIN: *History;* PENINSULAR WAR), and his sovereignty was little more than titular. Compelled to leave Madrid hastily in Aug. 1808 after the Spanish success at Baylen, he was reinstated by Napoleon at the close of the year. Thereafter he was kept in a subordinate position which led him on four occasions to offer to abdicate. After Joseph's flight from Spain in 1813 the emperor wrote to the minister of war (July 11, 1813): "His behaviour has never ceased bringing misfortune upon my army; it is time to make an end of it."

Napoleon was equally dissatisfied with Joseph's conduct as lieutenant general of France, while he himself was conducting the campaign of 1814. On March 30, Joseph empowered Marmont to make a truce with the assailants of Paris if they should be in overpowering strength. On the surrender of the capital Joseph at once retired. The part which he played during the Hundred Days (1815) was also insignificant. After Napoleon's surrender to the captain of H.M.S. "Bellerophon" at Rochefort, Joseph went to the United States. In 1830 he pleaded for the recognition of the claims of Napoleon's son, the duke of Reichstadt, to the French throne. He afterward visited England and for a time resided in Genoa and then in Florence, where he died on July 28, 1844. In person he somewhat resembled Napoleon, but utterly lacked his energy. He was too supine and luxurious for the tasks thrust on him by

his brother. His writings, however, prove that he retained for Napoleon warm feelings of affection.

LUCIEN (1775–1840), Napoleon's second surviving brother, was born at Ajaccio on May 21, 1775. He followed his elder brothers to the schools of Autun and Brienne but, being debarred by defective sight from the army, went to the seminary at Aix-en-Provence (1786). His excitable and volatile disposition agreed ill with the discipline of the place, and on the outbreak of the Revolution in 1789 he returned to Corsica and became the leading speaker in the Jacobin club at Ajaccio. Lucien urged his brothers to break with Paoli and headed a Corsican deputation which went to France to denounce Paoli and to solicit aid against him. In the south of France he worked hard for the Jacobin cause. In May 1794, he married Christine Boyer (1773–1800), by whom he had two daughters, Charlotte (1795–1865) and Christine Égypta (1798–1847). The *coup d'e'tat* of Thermidor (July 1794) compelled him to accept a small post at St. Chamans. There he was arrested and imprisoned for a time until Napoleon procured his release and found him a post as commissioner in the French army in Germany. Lucien disliked the army and was sent to Corsica. In 1798 he entered the council of five hundred at Paris as deputy for Corsica. He was president of that body on 19 Brumaire (Nov. 10) 1799, when Napoleon overthrew the national councils at the palace of St. Cloud. By refusing to put the vote of outlawry, for which the majority of the council clamoured, by his opportune closing of the sitting and by appealing to the soldiers outside to disperse "the representatives of the dagger" Lucien turned the scale in favour of his brother.

This event, the chief event of Lucien's life, was fatal to the cause of democracy of which he had been the most eager exponent. In one of his earlier letters to his brother Joseph, Lucien stated that he had detected in Napoleon "an ambition not altogether egotistic but which surpassed his love for the general weal; . . . in case of a counter-revolution he would try to ride the crest of events." This suspicion became a dominant feeling, and the relations between Lucien and Napoleon became strained during the period of the consulate (1799–1804). Lucien accepted office as minister of the interior, but was soon deprived of it because of political and personal differences with the first consul. Napoleon then appointed him ambassador to the court of Madrid (Nov. 1800), where he again fell into disfavour. He returned to Paris and again opposed Napoleon's schemes. Lucien's next proceeding completed the breach. After his first wife's death he became enamoured of a Mme Jouberthou (Alexandrine de Bleschamps; 1778–1855), and despite the express prohibition of the first consul secretly married her at his residence of Plessis-Chamant on Oct. 26, 1803. At that time Napoleon was pressing Lucien to marry the Spanish infanta Luisa, the widow of Louis, king of Etruria, and he now ordered him to leave French territory. Lucien departed for Italy with his wife and infant son, after annoying Napoleon by bestowing on her publicly the name of Bonaparte.

For some years Lucien lived in Italy, chiefly in Rome. In Dec. 1807 Napoleon sought to come to an arrangement by which Lucien would be made a French prince, provided that he would annul his marriage. Lucien refused this and. after residing for some time at his estate of Canino. from which he took the papal title of principe di Canino, he left for the United States. Captured by a British ship, he was taken to Malta and thence to England. where he lived under some measure of surveillance up to the peace of 1814. Returning to Rome, he offered Napoleon his help during the Hundred Days (1815), stood by his side at the "Champ de Mai" in Paris and was the last to defend his prerogatives at the time of his second abdication. He spent the rest of his life in Italy and died at Viterbo on June 29, 1840. His publications include an epic, *Charlemagne ou l'Église délivrée,* two volumes (1814), *La Vérité sur les Cent-Jours* (1835) and *Mémoires,* of which only the first volume appeared (1836).

ÉLISA (1777–1820), Napoleon's eldest sister to survive infancy, born at Ajaccio on Jan. 3, 1777, was married on May 5, 1797, to Félix Baciocchi, a member of a Corsican noble family. Napoleon gave her the principality of Piombino in March 1805, Lucca in the following June and finally, in March 1809, made her grand duchess of Tuscany. Her pride and ability had great influence on the administration and on Italian affairs in general. Her relations with Napoleon were frequently strained; in 1813–14 she abetted Joachim Murat in his enterprises. After her brother's fall she retired, with the title of contessa di Compignano, first to Bologna and afterward to Sant'Andrea near Trieste, where she died on **Aug.** 7, 1820.

LOUIS (1778–1846), Napoleon's third surviving brother, was born at Ajaccio on Sept. 2, 1778. Napoleon supervised his education and in 1795 procured for him admission to the military school at Châlons. Louis went through the Italian campaign of 1796–97 with Napoleon and acted as his aide-de-camp in Egypt in 1798–99. In 1802 Napoleon as first consul married him to Hortense de Beauharnais *(see* HORTENSE), a forced union that led to deplorable results. In 1804 Louis was raised to the rank of general and entered the council of state. In 1805 he became governor of Paris and undertook various military and administrative duties.

Napoleon proclaimed Louis king of Holland on June 5, 1806. From the first the emperor reproached him with being too easy with his subjects. Their relations were embittered by a violent jealousy which Louis conceived against his wife. In 1808 the emperor offered Louis the throne of Spain, but when Louis refused it the honour went to Joseph. In 1809 Napoleon was thinking of annexing Holland in order to stop the trade which the Dutch secretly carried on with England. At the close of the year Louis went to Paris, partly to procure a divorce and partly to gain better terms for Holland. He failed in both respects. After the collapse of negotiations with Great Britain in the spring of 1810, the emperor again pressed Louis hard and finally sent French troops against the Dutch capital. On July 1, 1810, Louis abdicated and fled from his kingdom, which on July 9 Napoleon annexed to France.

Louis then took the style of comte de St. Leu. After some time in Bohemia, Austria and Switzerland, he spent his later life chiefly in Italy (in Rome or in Florence), largely occupied with literary pursuits. As well as the *Documens historiques et réflexions sur le gouvernement de la Hollande,* three volumes (1820; Eng. trans., 6 pt., 1820), he published *Marie, ou Les Peines de l'amour,* two volumes (1812), *Mémoire sur la versification,* two volumes (1819–20) and *Le Retour* (1846). He was much gratified by the devotion of his two surviving sons to Italian nationalism and was grieved by the death of the elder son, Napoléon Louis, during the Romagna rising of 1831 and by the failure of the other, Charles Louis Napoléon, in the Strasbourg and Boulogne conspiracies (1836 and 1840; *see* NAPOLEON III). Louis died at Livorno on July 25, 1846.

PAULINE (1780–1825), the second to survive, the gayest and the most beautiful of Napoleon's sisters, was born at Ajaccio on Oct. 20, 1780. She married Gen. C. V. E. Leclerc (1772–1802), a staff officer of Napoleon, in 1797 and accompanied him to San Domingo. When Leclerc died of yellow fever she returned to Paris. She then married Prince Camillo Borghese (Nov. 6, 1803) and went with him to Rome, but soon tired of him, returned to Paris, and gratified her whims in ways that caused some scandal. In 1806 she received the title of duchess of Guastalla. Her offhand treatment of Napoleon's new empress, Marie Louise, led to her removal from court in 1810. Nevertheless she went with her mother to Elba in 1814 and is said to have expressed a wish to share Napoleon's exile in St. Helena. She died of cancer in Florence on June 9, 1825. Canova's statue of her as Venus reclining on a couch is well-known.

JÉRÔME (1784–1860), Napoleon's youngest brother, was born at Ajaccio on Nov. 15, 1784; he shared the fortunes of the family in the early years of the French Revolution, was educated at Juilly, and was called to the side of his brother, then first consul, in 1800. While in the consular guard he fought a duel with the younger brother of Gen. L. N. Davout and was wounded. Soon afterward he was transferred to the navy and cruised in the West Indies, where he left his ship and went to the United States. At Baltimore on Dec. 24, 1803, he married Elizabeth Patterson (1785–1879), daughter of William Patterson, a merchant there.

When in 1805 Jérôme brought his wife to Europe, the emperor ordered her to be excluded from his states. Jérôme vainly sought to bend his brother's will in an interview at Alessandria. In May 1805 he received command of a small squadron in the Mediter-

ranean, while his wife proceeded to Camberwell, Eng., where she gave birth to a son. In November Jérôme returned to service in the navy. Napoleon made him a prince of France and gave him command of a division of South Germans in the campaign of 1806. After the battle of Jena, Jérôme received the surrender of several Prussian towns. An imperial decree having annulled the Patterson marriage, the emperor married Jérôme to the princess Catherine of Wurttemberg and, in pursuance of the terms of the treaty of Tilsit (1807), made him king of Westphalia. In the Russian campaign of 1812 Jérôme was entrusted with a movement which might have brought the southern Russian army into grave danger; on his failure (probably due to his lack of energy) the emperor promptly subjected him to the control of Marshal Davout, and Jérôme returned to Kassel.

In 1813, on the fall of the Napoleonic regime in Germany, Jérôme retired to France. In 1814 he spent some time in Switzerland and at Trieste. Returning to France in 1815, he commanded a division on the French left wing at Waterloo and attacked Hougoumont with great pertinacity. On Napoleon's second abdication Jérôme proceeded to Wurttemberg, where he lived for a time with the style of prince de Montfort. Finally he was allowed to proceed to Augsburg. Thereafter he resided at Trieste, or in Italy or Switzerland. His consort died in 1835, and in 1840 he made a morganatic marriage with Giustina Pecori, widow of the marchese L. Baldelli-Bartolini. He returned to France in 1847, and after the rise of his nephew Louis Napoléon to power, became successively governor of the Invalides, marshal of France and president of the senate. He died at Villegenis (Seine-et-Oise), on June 24, 1860.

.CAROLINE (1782–1839), Napoleon's youngest sister, was born at Ajaccio on March 25, 1782. Early in 1800 she married Joachim Murat (*q.v.*), whose interests she afterward advanced with all the power of her ambitious and intriguing nature. He became governor of Paris, marshal of France (1804), grand duke of Berg and of Cleves (1806), lieutenant of the emperor in Spain (1808) and, early in the summer of 1808, king of Naples. The distance of this capital from Paris displeased Caroline; her relations with Napoleon became strained, and she associated herself with the equivocal movements of her husband in 1814–15. Before his tragic end at Pizzo on Oct. 13, 1815, she had retired to Austrian territory. She died in Florence on May 18, 1839.

DESCENDANTS

Of Lucien **Bonaparte.**—The male line of descent from Lucien Bonaparte is shown in the accompanying table. Three members of this line, however, deserve separate notice here.

CHARLES. LUCIEN (1803–1857), principe di Canino and di Musignano, Lucien's eldest son, was born in Paris on May 24, 1803. He was a scientist rather than a politician and was a correspondent of many learned societies. He married his cousin Zénaïde, daughter of Joseph, in 1822. At the age of 22 he began the publication of *American Ornithology,* four volumes (1825–33), which established his scientific reputation. A series of other works in zoology followed. He took part in the political agitation in Italy, and he declared himself at Venice in favour of the independence of Italy and the expulsion of the Austrians. He entered the junto of Rome in 1848 and was elected deputy by Viterbo to the national assembly. The failure of the revolution forced him to leave Italy in July 1849. He went to Holland, then to France, where he turned again to science. He died in Paris on July 29, 1857. His principal works were *Conspectus systematis ornithologiae, mastozologiae, erpetologiae et amphibologiae, ichthyologiae* (1850), *Tableau des oiseaux-mouches* (1854) and *Ornithologie fossile* (1858). Of his 12 children *(see* Table), 3 sons and 5 daughters survived him.

LOUIS LUCIEN (1813–1891), fourth son of Lucien Bonaparte, was born at Thorngrove, Grimley, Worcestershire, Eng., on Jan. 4, 1813. He passed his youth in Italy, not going to France until 1848, when, after the revolution, he was elected deputy for Corsica (Nov. 28, 1848); his election having been invalidated, he was returned as deputy for the Seine in June 1849. He sat in the right of the legislative assembly, but had no direct part in the *coup d'état* of Dec. 2, 1851. Napoleon III named him senator and prince, but he took hardly any part in politics. Instead he spent much of his time in England, where he devoted himself to philology, in particular to the study of English dialects. He also published some notable works on the Basque language. He died at Fano, Italy, on Nov. 3, 1891, leaving no children.

PIERRE NAPOLÉON (1815–1881), fifth son of Lucien Bonaparte, was born in Rome on Oct. 11, 1815. He joined the rebels in the Romagna (1830–31), and was then in the United States, where he went to join his uncle Joseph, and in Colombia with Gen. Francisco Santander (1832). Returning to Rome, he was taken prisoner by order of the pope (1835–36). He finally took refuge in England. At the revolution of 1848 he returned to France and was elected deputy for Corsica to the constituent assembly. He declared himself an out-and-out republican and voted with the Socialists. His attitude contributed greatly to give popular confidence to his cousin Louis Napoléon (Napoleon 111), of whose *coup d'dtat* on Dec. 2, 1851, he disapproved; but he was reconciled to the emperor and accepted the title of prince. The republicans at once abandoned him. From that time on he led a debauched life and lost all political importance. In Jan. 1870 a violent incident brought him again into prominence. As the result of a controversy with Paschal Grousset, the latter sent two journalists to provoke him to a duel. Pierre Bonaparte took them personally to account, and during a violent discussion he drew his revolver and killed one of them, Victor Noir (Yvan Salmon). The high court acquitted him of murder, and criticism then fell upon the government. Pierre Bonaparte died in obscurity at Versailles on April 7, 1881. He had married the daughter of a Paris working-man, Justine Eléonore Ruffin, after the birth of her two children by him. His *Souvenirs, traditions et révélations* appeared in 1876.

Of Louis **Bonaparte.**—Louis Bonaparte's two elder sons predeceased him. His third became emperor of the French as Napoleon III (*q.v.*). Napoleon III's only son by the empress Eugénie, NAPOLÉON EUGÈNE LOUIS (1856–1879), prince imperial, was born in Paris on March 16, 1856. He was a delicate boy, but when the Franco-German War of 1870 broke out his mother sent him to the army. After the first defeats he had to flee from France with the empress and settled in England at Chislehurst, completing his military education at Woolwich. On his father's death (Jan. 9, 1873) the Bonapartists proclaimed him Napoleon IV, and he became the official pretender. The Bonapartist leaders thought that he should win his crown by military prestige and he was persuaded to attach himself as a volunteer to the British expedition to Zululand in Feb. 1879. While out on reconnaissance with a few troopers he was surprised by Zulus and killed at Ulundi (June 1, 1879). His body was brought back to England and buried at Chislehurst.

Of Jérôme Bonaparte.—As shown in the table, Jérôme Bonaparte had children by both his ma-riages.

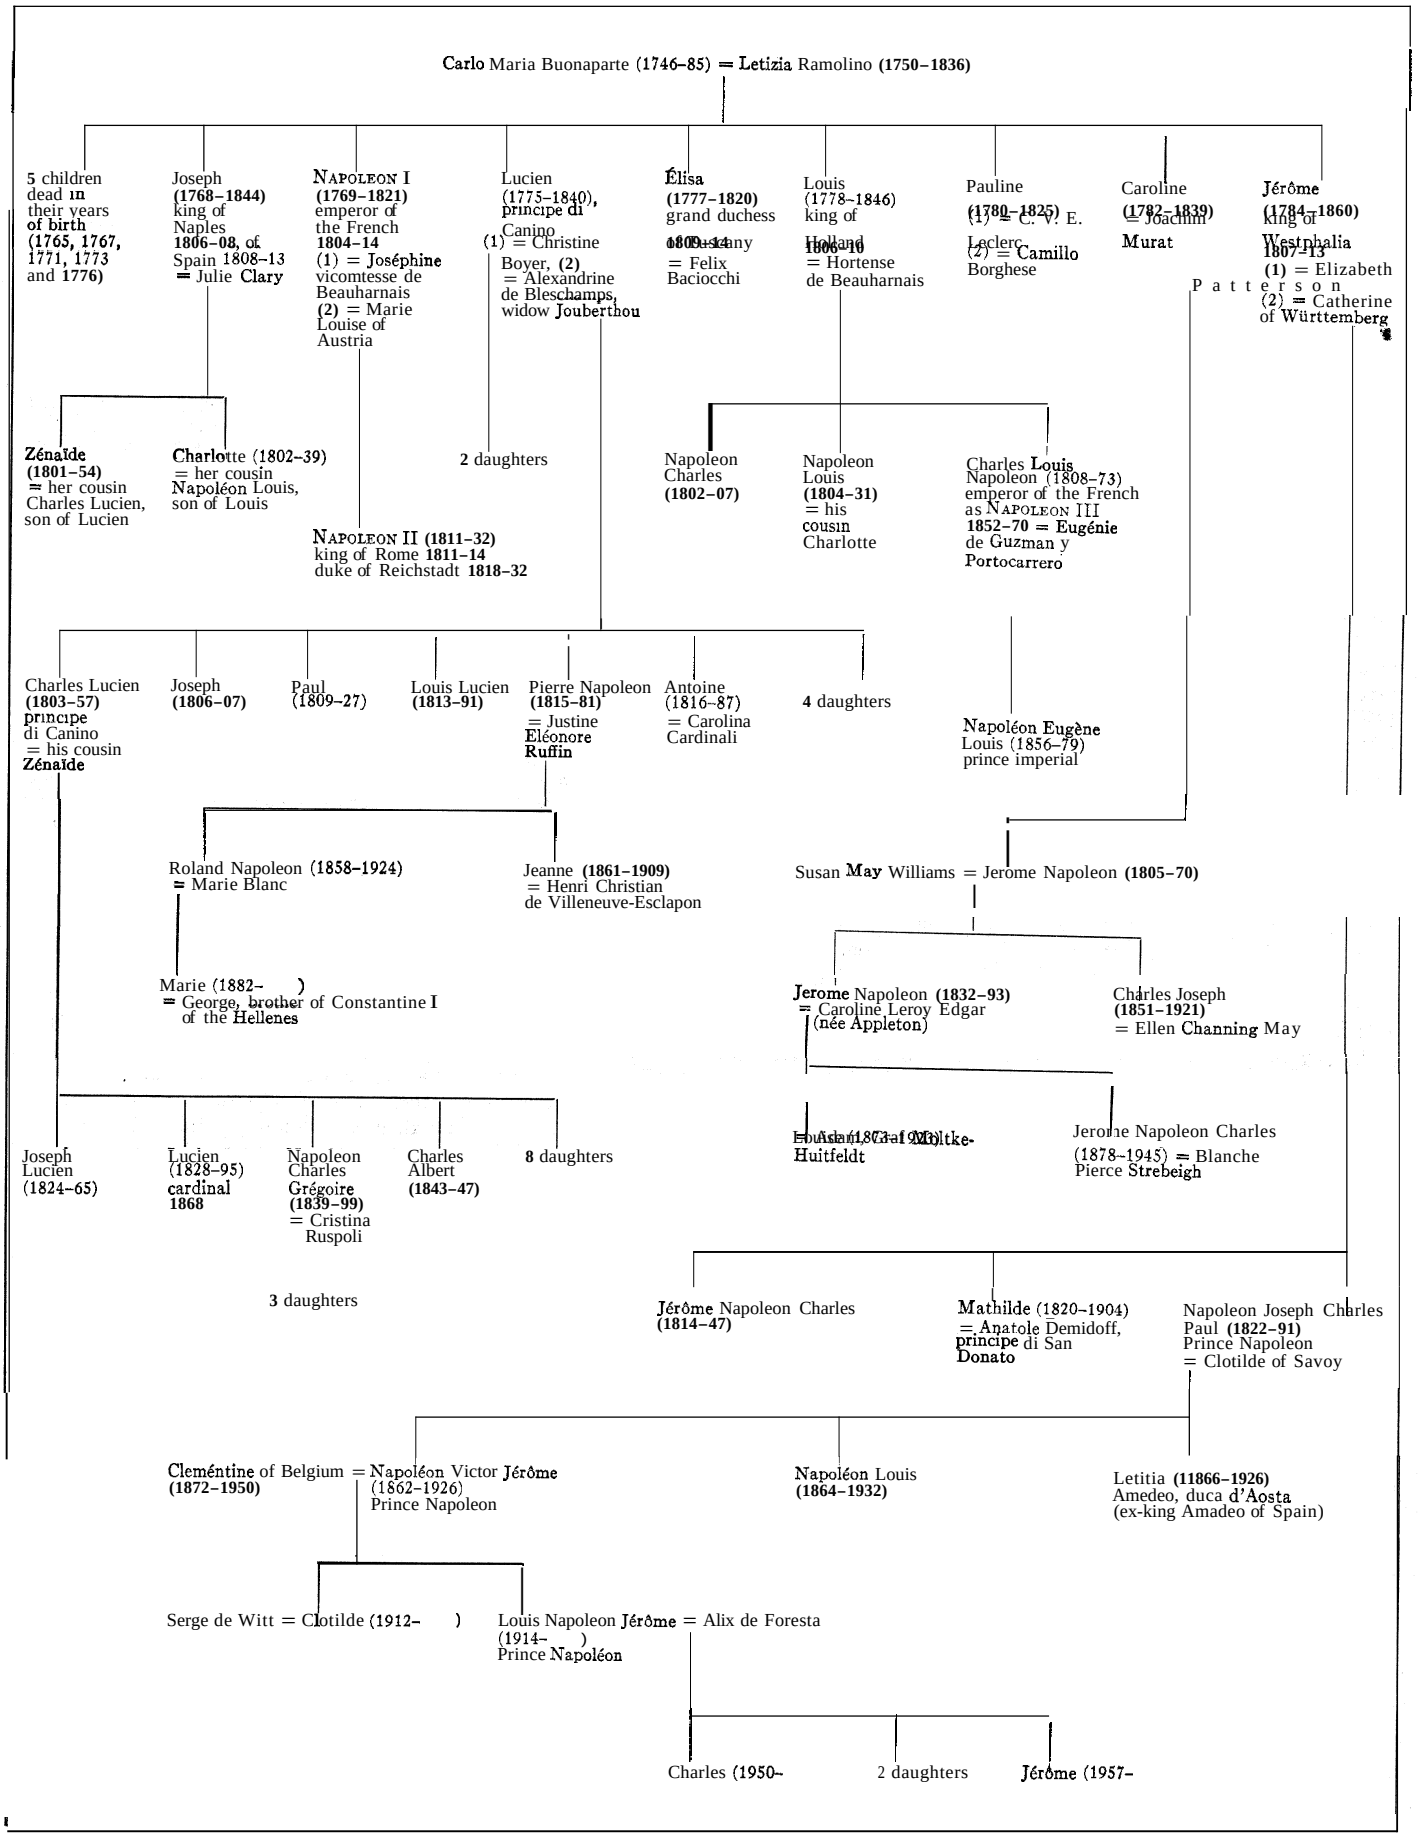
The BONAPARTES OF BALTIMORE were descended from Jérôme's marriage with Elizabeth Patterson (*see* above). Although this marriage was valid according to U S. law and Pope Pius VII refused to declare it void, Jérôme was forced to separate from his wife, and after a stay in England she returned to Baltimore. The only child of this marriage was JEROME NAPOLEON BONAPARTE (1805–70), who was born in England but resided chiefly in Baltimore. He was on good terms with his father, who for some time made him a large allowance, and father and son occasionally met. His elder son, also called JEROME NAPOLEON (1832–93), whose children are shown in the accompanying table, entered the French army, with which he served in the Crimea and in Italy.

CHARLES JOSEPH BONAPARTE (1851–1921), brother of the last-named, attained a distinguished place in U.S. politics. Born in Baltimore on June 9, 1851, and educated at Harvard university, he became a lawyer in 1874, was elected president of the National Municipal league, and occupied other public positions. He was secretary of the navy in Pres. Theodore Roosevelt's cabinet from July 1905 to Dec. 1906, and then attorney general of the United States until March 1909. He died in Baltimore on June 28, 1921.

Of Jérôme's three children by Catherine of Württemberg/two deserve special mention:

MATHILDE (1820–1904), Jérôme's only daughter, was born at

THE HOUSE OF BONAPARTE



Trieste on May 27, 1820. After being almost betrothed to her cousin Louis Napoleon she was married in 1840 to Anatoli Demidov (Anatole Demidoff, principe di San Donato), whose conduct led to a separation within five years. After the election of Louis Napoleon to the presidency of the republic she did the honours of the Élysée until his marriage. She continued to live in Paris, having great influence as a friend and patron of men of art and letters, until her death in Paris on Jan. 2, 1904.

NAPOLÉON JOSEPH CHARLES PAUL (1822–1891), Prince Napoléon, sometimes known as "Plon Plon" (supposedly because soldiers in the Crimean War nicknamed him "Plomb-plomb" or "Craint-plomb" (Fear-lead), was the only son of Jérôme's second marriage to survive him. He was born at Trieste on Sept. 9. 1822. After the French Revolution of 1848 he was elected to the national assembly as a representative of Corsica, and (his elder brother, Jérôme Napoléon Charles, having died in 1847) assumed the name of Jérôme. Notwithstanding his ostensible opposition to the *coup d'état* of 1851, he was designated. on the establishment of the empire, as successor to the throne if Napoleon III should die childless. Privately he professed himself the representative of the Napoleonic tradition in its democratic aspect and associated mainly with men of progressive ideas. At court he represented liberal opinion against the empress Eugénie. In 1854 he took part in the Crimean campaign as general of division. Returning to France, he undertook the chief direction of the national exhibition of 1855. In 1858 he was appointed minister for the colonies and Algeria, but his activity was diverted into a different channel by his sudden marriage in Jan. 1859 with the princess Clotilde of Savoy, daughter of Victor Emmanuel II. Thus, when the war for the liberation of Italy broke out, Prince Napoléon commanded the French corps that occupied Tuscany, and it was expected that he would become ruler of the principality.

In the last years of the second empire Prince Napoléon chiefly distinguished himself by remarkable speeches. His indiscretion equalled his eloquence: one speech (1861) sent him to America to avoid a duel with the duc d'Aumale; another (1865), in which he protested against the Mexican expedition, cost him all his official dignities. The fatal war of 1870 mas resolved upon during his absence in Norway and was strongly condemned by him.

After the fall of the empire he lived in comparative retirement until in 1879 the death of Napoleon III's son made him direct heir to the Napoleonic succession. His part as Bonapartist pretender was unfortunate and inglorious, and before his death he was virtually deposed in favour of his elder son. He died in Rome on March 17, 1891. In the character of his intellect, as in personal appearance, he bore an extraordinary resemblance to the first Napoleon.

Napoleon Joseph's elder son, NAPOLÉON VICTOR JÉRÔME (1862–1926), became the recognized Bonapartist pretender on his father's death. His brother, NAPOLÉON LOUIS (1864–1932), took service in the Russian army and was appointed governor of the Caucasus in 1906. Napoléon Victor's son LOUIS NAPOLÉON JÉRÔME (1914–) succeeded to his father's pretensions.

(P. F. DE L.)

BONAR, HORATIUS (1808–1889), Scottish Presbyterian minister and hymn writer, was born in Edinburgh, Dec. 19, 1808. He was licensed to preach at St. John's church, Leith (1833), and was ordained minister of North Parish church, Kelso (1837), remaining there until appointed minister of the Chalmers Memorial church in Edinburgh (1866). At the disruption of 1843 Bonar joined the Free Church; he was moderator of its assembly in 1883. He published three series of *Hymns of Faith and Hope* between 1857 and 1866; but with a few notable exceptions his hymns fail to inspire, perhaps from their lack of scriptural imagery and of doctrinal content. Bonar died at Edinburgh. July 31, 1889.

BONAVENTURA (BONAVENTURE), **SAINT** (GIOVANNI DI FIDANZA) (1221–1274), Italian theologian, doctor of the church, known as *doctor seraphicus*, was born at Bagnorea near Viterbo. He became a Franciscan about 1243, studied in Paris under Alexander of Hales and John of La Rochelle, taught there from 1248 onward and succeeded to the teaching chair reserved for the Franciscans (which both his masters had occupied) in 1253. He was appointed general of the Franciscan order in Feb. 1257 and in the following October he became a doctor of theology. The latter occurred only after Pope Alexander IV's intervention had helped him to overcome the opposition of the masters of the university, led by William of St. Amour, who for some time had been trying to prevent the Franciscans and Dominicans from teaching. Bonaventura tried to reconcile the two extreme groups within his order, the *Spirituales* and the *Relaxati;* the general chapter of his order at Narbonne (1260) promulgated the Franciscan constitutions as revised by him. He declined the archbishopric of York in 1265; renewed his fight against the secular masters of the university, who were now led by Gerard of Abbeville; and as a cardinal and bishop of Albano (from June 1273) prepared and attended the great council of Lyons (1274). In the course of this council he died, on July 14 or 15, 1274. He was canonized by Sixtus IV in 1482 and made a doctor of the church by Sixtus V in 1588. His feast day is July 14.

Bonaventura's works include a vast commentary on Peter Lombard's *Sentences*, the *Quaestiones disputatae*, the *Breviloquium* (all three written while he was a professor in Paris), the *Itinerarium*

mentis in Deum, the various *Collationes (De decern praeceptis, De septem donis Spiritus Sancti, In Hexaemeron)*, the *De reductione artium ad theologiam*, the *De triplici via* and the *Soliloquium*.

Bonaventura was at the same time a man of action and a philosopher, theologian and mystic. In philosophy he strongly adhered to the Augustinian tradition with its Platonic elements. While accepting Aristotle insofar as his teaching was clearly compatible with revelation. he did not try to adapt most of his doctrines to a Christian point of view.

Following his Franciscan predecessors, he ascribed to primary matter some kind of actuality: its *rationes seminales* are positive aptitudes which will develop into the several forms in the process of becoming; the principle of individuation is to be found in the union of matter and form. Every being has a plurality of forms; unity is preserved in each of them by the subordination of lower to higher forms (in man, to the rational soul). The most important of the lower forms of man is the "corporeal form." identified with light: by giving actuality to the body. it preserves the independence of the soul and ensures its spirituality and immortality. But the soul itself is a compound of some kind of matter and form. The soul's knowledge of the corporeal world is produced by interaction betn-een the intellect (both active and passive) and objects as perceived by the senses. Divine illumination helps this knowledge to conform to the *rationes aeternae* or ideas in God's mind, which contain the fullness of sense objects. Spiritual beings are known through innate species; the soul can thus know itself and, indirectly, God, whose image it is. The existence of God can also be proved by a posteriori arguments. by the analysis of the concept of God (Anselm's argument) and from the nature of truth (Augustine's argument).

In order to complete philosophical speculation which. in its concern for all things. leads to God, we need the imperfect but certain knowledge of God given in faith; for the soul's faculties of knowing and loving. though of divine origin. have been contaminated by its union with the body. Faith is also the foundation of the mystical contemplation of God. which Bonaventura regards as the end of man and discusses at great length in the tradition of the Pseudo-Dionysius and the Victorines.

This contemplation has its origin in the discovery of God's imprint in the corporeal world and is developed through the recognition of His image in the soul and the apprehension of His being and infinite goodness. It requires prayer, meditation and the theological virtues, especially charity. The whole process is accompanied by divine grace. But contemplation itself can only be perfected in the next life.

Among the first printed editions of Bonaventura's writings may be mentioned those of the *Itinerarium* (1472), of the *Breviloquium* (1472), of the *Soliloquium* (1474), of the commentary on book i of the *Sentences* (1474–77?) and of the commentary on book ii of the same (1477). Collected editions of Bonaventura's works are: (1) the edition commissioned by Pope Sixtus V and executed by C. Boccafuoco *et al.*, seven volumes (1588–96; reissues, 1609 and 1751); (2) the edition of A. C. Peltier, 15 volumes (1864–71); and (3) the definitive edition by the Fathers of the Collegio di San Bonaventura, under Fr. I. Jeiler, O.F.M., ten volumes (1882–1902). There are English translations of the *Itinerarium* by J. *E.* Mahony, under the title *The Franciscan Vision* (1937); of the *De Reductione* by E. T. Healy (1939); of his life of St. Francis (1904); and of *The Mirror of the Blessed Life of Jesus Christ* (1926).

(L. M.-Po.)

BONCOMPAGNO DA SIGNA (*c.* 1165–c. 1240), one of the most influential teachers of the art of letter writing in 13th-century Italy, was born at Signa near Florence. He taught mainly at Bologna and published numerous treatises on rhetoric and on letter writing (the *ars dictandi*), the most important of which are the *Boncompagnus* or *Rhetorica antiqua* (completed by 1215) and the *Rhetorica novissima*. He also wrote a historical work on the siege of Ancona *(Liber de obsidione Anconae)* and a treatise on the afflictions of old age *(Libellus de malo senectutis et senii)*. His works are not only outstanding documents of the revival of rhetoric, but also important sources for contemporary life and manners. Boncompagno died in Florence *c.* 1240. There are editions of the *Rhetorica novissima* by *A.* Gaudenzi in *Bibliotheca iuridica medii aevi*, vol. ii (1892); of the *Liber de obsidione* by G. *C.* Zimolo in *Rerum Italicarum scriptores*, vol vi (1937); and of the *Libellus* by F. Novati in *Rendiconti dell' Accademia dei Lincei (classe di scienze morali)*, series 5, vol. i (1892).

(N. R.)

BOND, SIR EDWARD AUGUSTUS (1815–1898), English librarian who was among the first to make classical paleography into a scientific discipline, was born on Dec. 31, 1815, at Hanwell, Middlesex, and educated at the Merchant Taylors' school. He entered the Public Record office in 1833, under T. D. Hardy at the Tower of London, and five years later went to the manuscript department of the British museum. In 1850 he was appointed Egerton librarian and in 1866 succeeded Sir F. Madden as keeper of manuscripts. His work in reorganizing the manuscript department was of lasting value; the classified catalogues of manuscripts are a result of his efforts. He was principal librarian and secretary from 1878 to 1888 and was created knight commander of the order of the Bath shortly before he died, Jan. 2, 1898; in London. Under Bond's supervision the White wing was built to provide accommodation for prints, manuscripts and newspapers and, in conjunction with E. Maunde Thompson, he founded the Palaeographical society. Bond edited four volumes of *Facsimiles of Ancient Charters in the British Museum* (1873–78), *Speeches of the Managers and Counsel in the Trial of Warren Hastings* (1859–61) and other interesting documents. (J. M. WI.)

BOND, SIR ROBERT (1857–1927), leader of the Liberal party in Newfoundland, was born Feb. 25, 1857, at St. John's. He was educated at Queen's college, Taunton, Eng., and then returned to Newfoundland and entered politics. His term as prime minister (1900–09) is memorable for the concessions made to outside capital in an attempt to develop the natural resources of the colony. Most notable was the arrangement with the proprietors of the London *Daily Mail* which led to the opening in 1905 of a paper mill at Grand Falls, thus inaugurating a logging industry which was destined to replace the fishery as the chief contributor to Newfoundland's income.

Bond was repeatedly overruled by the United Kingdom in his attempts to legislate with regard to historic fishing privileges granted by Britain to French fishermen in 1783 and to U.S. fishermen in 1818. France gave up the right to use Newfoundland shores in 1904, but Bond continued to denounce Britain's continued interference with his attempts to restrict American activities.

In 1909 Bond resigned because the British governor refused his advice that the assembly should be dissolved again, the general election of 1908 having resulted in a tie. A former supporter, Sir Edward Morris, became prime minister as leader of a new People's party. Bond formed an alliance with a radical Fishermen's union but his influence continued to decline and in 1914 he went into retirement. He died at Whitbourne, Nfd., March 16, 1927, and was buried in the Anglican churchyard there. (G. O. R.)

BOND, WILLIAM CRANCH (1789–1859), U.S. astronomer who, with his son, George Phillips Bond, discovered a new ring system and a new satellite (Hyperion) of Saturn and constructed an improved type of recording chronograph, was born at Portland, Me., on Sept. 9, 1789. Largely self-educated, Bond was attracted to astronomy by the solar eclipse of 1806. He independently discovered many comets, beginning with that of 1811, and was appointed the first astronomical observer by the corporation of Harvard college in 1840, an unsalaried position held concurrently with that of astronomical observer for the federal government. He became director of the Harvard college observatory upon its com-

pletion in 1847. He was elected associate of the Royal Astronomical society ,in 1849, the first American so honoured. The application of photography to astronomy was greatly advanced under his administration at the Harvard observatory. He died at Cambridge, Mass., on Jan. 29, 1859.

See E. S. Holden, *Memorials of* W. *C. and G. P. Bond* (1897).

(O. J. E.)

BOND: *see* BAIL; FIDELITY AND SURETY BONDS; GUARANTEE; INVESTMENT PAPER; REAL PROPERTY AND CONVEYANCING, LAWS OF.

BOND (IN FINANCE), a type of promissory note issued by governments and by private corporations specifying an obligation to return borrowed funds. Bonds are usually issued in more formal fashion than promissory notes and ordinarily are under seal. This process involves a printing of some formality, including numbering and lithographing or engraving, to minimize fraud. Bonds are printed on paper that is somewhat larger than letter-size, plus coupons. Usually the debt indicated by the bonds is of substantial size and is advanced by a relatively large number of creditors known as bondholders, although it is not uncommon for all or most of the bonds represented by a debt to be held by one lender, such as an insurance company or a pension fund, under an arrangement known as a private or direct placement.

Bonds may be issued in any denomination, but in the United States they are commonly issued in denominations of $1,000. In essence, the borrower promises to pay interest when due, usually semiannually, at a stipulated percentage of the face value of the bond, and to redeem the face value of the bond at maturity in legal tender. Interest on bonds is most often collectible through the presentation of numbered coupons which the holder clips from the bond. A coupon is usually printed and attached for every interest date throughout the life of the bond.

When bonds are sold, accrued interest is added to the sales price. The purchaser advances to the seller a percentage of the next interest coupon payable computed by dividing the whole time period between interest due dates by the actual time elapsed since the previous interest due date. The money is paid in advance to obtain the partly earned coupon.

Most bonds are payable to the bearer and are thus easily negotiable, but it is usually possible to have the bond registered and thus made payable only to the named holder. The great majority of bonds are callable, meaning that the issuer can redeem them at his option, upon appropriate notice, well before maturity. Maturity or due dates for bonds are usually at least more than one year from issuance, and normally run from 10 to 30 years, although much longer periods have been used.

The four major classifications of bonds by borrowers in the United States are: (1) government bonds, issued by the United States and foreign governments; (2) municipal bonds, issued by states, cities and other such governmental bodies, usually backed by some element of taxing power; (3) revenue bonds, issued by quasi-governmental corporations to finance public conveniences such as toll roads, exhibition halls, airports, or water works, and secured only by the revenue from the projects involved; and (4) corporate bonds, issued by private, profit-seeking corporations such as those in the railroad, utility and industrial fields, or by nonprofit corporations. Technically, bonds may also be issued by proprietorships and partnerships.

Contract terms are very important to both parties and are normally found in the indenture, an agreement between the borrower and a trustee acting on behalf of the bondholders. In the United States, the minimum duties and responsibilities of the trustee, if the bonds are publicly offered, are specified in the Trust Indenture act of 1940, but not in the case of government and municipal bonds. Bonds are often referred to by a term having reference to the most distinctive feature of the loan contract. Most prevalent among these types are the following:

1. Mortgage bond, a general obligation of the borrower that is also secured by a lien against real estate or other property such as equipment owned by the borrower. The type of lien is usually indicated by additional words such as first, second, or general.

2. Debenture bond, a general obligation of the borrower with no prior lien on specified property. In Great Britain the term debenture stock is equivalent to the U.S. debenture bond. A bond of this type can be subordinated, meaning that the holder agrees to accept a junior creditor position relative to other creditor obligations such as bank loans.

3. Convertible bond, a general obligation of the borrower, plus an additional covenant to exchange ownership securities (stock) at a fixed price to the bondholder, at the holder's option, good for a specified time. The value of the bond may subsequently increase should the market value of the stock exceed the option price.

4. Special district bond, usually an issue of a subdivision of a municipality such as a board of education or park district. It is a general obligation backed by the taxing power of the district.

5. Collateral trust bond, a general obligation plus the security of a specified lien on securities or other personal property of the borrower.

6. Equipment trust certificate, a security commonly thought of as a bond having a specific lien against equipment such as railroad cars, trucks, airplanes or buses. Technically, it is an ownership and not creditor security since the equipment is commonly leased to the user.

7. Income bond, a general obligation of the borrower with a contingent promise to pay interest only if earned.

8. Sinking-fund bond, a bond containing a covenant to set aside certain amounts at specified periods to build up a redemption fund or to retire outstanding bonds.

9. Tax-exempt bond, in the United States, a bond that is not subject to the federal income tax, and may also have state tax-exemption features. Bonds issued by states, municipalities and their subdivisions fall into this category.

There are many other descriptive terms attached to bonds to denote some special feature in the indenture that the borrower thinks will be of special interest to the lender. The indenture also includes many protective provisions, promises made by the borrower that are thought to assure greater safety to the lender, such as closed-end mortgage clauses, acceleration, after-acquired property clauses, etc.

All bonds are, as we have seen, general creditor obligations of the borrower. In addition, they may contain additional covenants offering an inducement to the lender to favour the borrower with his funds such as a lien on specified property or the others mentioned above. Fundamentally, however, the source of repayment lies in the income or cash-generating power of the assets to which the funds are committed or in the income-raising ability of the governmental body.

BONDE, GUSTAF, COUNT (1620–1667), lord treasurer in the regency council appointed in 1660 to govern Sweden during the minority of Charles XI, was born at Esplunda on Feb. 4, 1620. In 1645 he became a member of the inland revenue board, in 1648 governor of Sodermanland and in 1653 a privy councilor. In 1660 he became lord treasurer and a member of the regency council, where he advocated a policy of retrenchment at home and withdrawal abroad in opposition to the overambitious financial and foreign policy of the chancellor Magnus Gabriel de la Gardie.

From 1660 to 1662 Bonde was successful in forcing through reductions of expenditure and a careful examination of crown contracts and pensions, and stood inflexibly opposed to any renewal of a policy of donating crown lands. These policies made him bitter enemies who helped the chancellor to sabotage Bonde's reforms. His economic system was broken before the final blow of the wasteful Bremen War (1665).

Bonde withdrew from further political disputes, but his ideas were defended by a group of his treasury subordinates and by his successor Sten Bielke (d. 1684). Embodied in the report of the *Blue Book* (1668) they became the basis of much of the financial system of Charles XI. Bonde died at Hamburg on May 25, 1667.

See G. Wittrock, *Karl XI:s Formyndares Finanspolitik 1661–1667* (1914).

BONDFIELD, MARGARET GRACE (1873–1953), British trade union leader and the first woman to attain cabinet rank in Great Britain, was born on March 17, 1873, at Chard, Somerset. At the age of 14 she became an assistant in a draper's shop at Brighton, but soon afterward moved to London. She became assistant secretary of the Shop Assistants' union in 1898 and secretary of the National Federation of Women Workers in 1921.

She was made chairman of the Trades Union congress in 1923, being the first woman to hold that position, and in Nov. 1923 was elected Labour M.P. for Northampton. In the Labour government of 1924 she was parliamentary secretary to the ministry of labour. She was British government delegate on the governing body of the International Labour office, and at the sixth session of the International Labour conference (Geneva, 1924) she was particularly concerned with the project to develop by international agreement facilities for the utilization of workers' leisure. She was defeated at the general election of Oct. 1924 but she returned to parliament in 1926 as member for Wallsend. She became minister of labour in 1929 and gained her seat in the cabinet. She was generally judged to be well worth her place, for she was a competent administrator as well as a clear and forceful speaker. Defeat in the general election of 1931 terminated her parliamentary career, but she was chairman of Women's Group on Public Welfare (1939-49) and from 1941-43 lectured in the United States for the British Information services. She died on June 16, 1953, at Sanderstead, Surrey.

Margaret Bondfield possessed both practical ability and an immense warmth and idealism. She had inherited a fine tradition of religious dissent and political radicalism, and her life fully illustrated her conviction that the strength of British socialism derived from its religious foundations.

See M. Bondfield, *Life's* Work (1949); M. Hamilton, Margaret *Bondfield* (1925). (R. J.)

BONE, HENRY (1755–1834), English painter, whose miniature portraits in enamel were outstanding. was born at Truro on Feb. 6, 1755. He was employed by London jewelers for small designs in enamel, and in 1800 the beauty of his pieces attracted the notice of the Royal Academy, and he was admitted an associate in 1801; in 1811 he was made an academician. Up to 1831 he executed many beautiful miniature pieces of much larger size than had been attempted before in England; among these are 85 portraits of the time of Queen Elizabeth I, of different sizes, from 5 by 4 in. to 13 by 8 in.. now at Kingston Lacey. Wimborne, Dorsetshire. These: and pieces in the Wallace collection, London, were his greatest works. He died in London on Dec. 17, 1834.

BONE, SIR MUIRHEAD (1876–1953), British artist. best known as an etcher and dry-point engraver, was born at Glasgow, Scot.. on March 23, 1876, son of David Drummond Bone, a journalist. He first studied architecture and then art in the evening classes of the Glasgow School of Art. Being attracted by the picturesque aspect of buildings. he executed drawings of views in his native town. His method was generally that of dry point; as a draftsman he used pencil, charcoal and sepia. In 1899 he issued a Portfolio with etchings of Glasgow. He moved to London in 1901 where the exhibition of his works in 1903 established his fame. In 1904 ten of his dry points were published by Obach. His work displays a devotion for every form of intricate scaffolding: thus his famous etching "The Great Gantry" (1906) is a study of Charing Cross railway station after the accident to the roof in 1905, with a network of scaffolding set up for reconstruction. This, his "Xyr Prison" and "Liberty's Clock" are among the finest works in dry point.

During World Wars I and II he served as official artist with the British forces. He was knighted in 1937. Bone died at Ferry Hinksey, Oxford, on Oct. 21, 1953.

BÔNE, the capital of the *département* of Bône, Algeria, and a port on the gulf of Bône near the mouth of the Seybouse river, lies 260 mi. E. of Algiers near the Tunisian border. Area of commune about 42 sq.mi. Pap. (1960) 144,000 (metropolitan) comprising 100,000 Algerians (Muslim), 44,000 European French subjects. The town rises from the shore up the cork-covered slopes of the Edough foothills. The old town with its narrow streets dominates the centre of the city and is grouped round the Place d'Armes where are the earliest French houses and the mosque of Salah Bey (1787). In the 11th-century mosque of Sidi-bou-Merouan the prayer room is divided into seven naves and seven bays, with columns taken from the ruined forum of Hippo. The synagogue, close by, was built in 1852.

West of the old town is the new town, built since 1870 along both sides of the Cours Bertagna. Its straight roads cross at right angles and the chief public buildings include the town hall (1888), the municipal theatre (1954), the prefecture (1958), the cathedral of St. Augustine (1850), the basilica of St. Augustine (1881), the Protestant church (1882), the hospital (1958), schools, technical colleges and the Hippo museum near the excavations of the Roman city. There are public gardens round the town hall and others are the Randon gardens and the Jean Coggia park.

Bône, the chief exporter of minerals on the Mediterranean (iron ore and phosphates)! is also a passenger. trading and fishing port and a port of call. Main roads connect Bône with Philippeville, Constantine, Guelma and Souk-Ahras. There are railways to Algiers and on to Morocco via Constantine, to Tunis via Souk-Ahras and to Biskra and Touggourt via Constantine. There is an airport at Bône-Les Salines, 6¾ mi. S.E., with service facilities to France and other towns of north Africa.

In the surrounding countryside are arable and stock-raising farms, forests and mines. The important mine of Karezas produces arsenic and tungsten. The effort to industrialize Algeria after World War II has given Bône several major industries including motor and railway workshops, aluminum and chemical works.

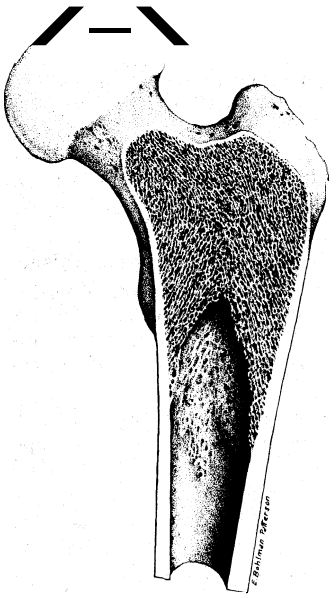
Bône's exceptional situation on a coast poorly supplied with natural harbours, on a large bay between Cape Garde and Cape Rosa and protected from the west and northwest winds, attracted the earliest sailors. It seems certain that in the 12th century the Phoenecians founded a trading port there which later became Hippo Regius, the chosen residence of the kings of Numidia. At the end of the Punic Wars the inhabitants received their independence from Rome and Hippo became a flourishing town. St. Augustine (*q.v.*), bishop of Hippo from 396 to 430, made it the centre of Christian thought. Much of the town was destroyed by the vandals in 431 but was delivered by the emperor Justinian in 533. Two centuries later it was overcome by the Arabs and the beneficial effects of Roman rule and Christianity soon disappeared. The remaining citizens, driven on to high ground nearby, built a new town, Bouna el Hadida, invisible from the sea. Surrounded by walls, it later became the headquarters of pirates and fugitives. For many centuries Bône was one of the small cities of north Africa under the domination of successive rulers. In 1535 it was occupied by the soldiers of the emperor Charles V but was retaken by the Turks in 1540 and remained in their possession until 1832 when the French captured it with a small force. In 1848 Louis Philippe made it a commune administered from Paris, and by the end of the century it had become the important Mediterranean port and city that it now is. (P. A. SE.)

BONE, a dense, highly specialized form of connective tissue, composed of branching cells in an intercellular substance, has certain characteristics which differentiate it from other forms of supporting tissue, the most striking one being that it is hard. This hardness results from the deposition, within a soft organic matrix, of a complex mineral, composed chiefly of calcium, phosphate and carbonate; this process represents one form of calcification. Bone tissue has cells peculiar to it, while for the most part the cells common to loose connective tissue are lacking. Bone, as a tissue, has important functions, largely concerned with storage and metabolism of calcium and phosphate. The individual bones are organs, characterized by the bone tissue of which they are formed; together with the joints they form the skeleton or framework of the body of most vertebrates. They serve to house a blood-forming tissue—the bone marrow (*q.v.*)—and to protect vital organs of the body, notably the brain and spinal cord.

Structure.—Most bones, and especially the long bones, are made up of two types of structure (*see* fig. 1). The shafts, or diaphyses, are formed of compact bone; the expanded ends, or epiphpses, usually include a vaulted structure of spongy or cancellous bone, with a thin cortex, or outer layer, of compact bone; this arrangement serves to transfer weight and stress from the shafts of the bones to the joints. The internal structure of compact and of spongy bone is identical.

The haversian system, or osteone, is the unit of structure of bone. This is irregularly cylindrical and branching, of microscopic

size with thick walls and a narrow canal, carrying one or more small blood vessels, and is usually oriented in the long axis of the bone (*see* fig 2) The walls of the osteones are made up of concentric layers or lamellae, the form and structure of the unit being given to it by the fibrous protein, collagen; this substance makes up more than 90% of the dry fat-free weight of the organic matter of bone and yields glue or gelatin when boiled The haversian system in addition to being arranged around a central canal, Includes large numbers of lacunae, or small spaces housing cells and being interconnected by a network of canaliculi or minute canals; these are the channels by means of which the fluids derived from the blood reach and nourish the bone tissue



DRAWN BY E BOHLMAN PATTERSON

FIG. 1 — DRAWING OF A LONGITUDINAL SECTION THROUGH THE NECK AND SHAFT OF A HUMAN FEMUR SHOWING THE STRUCTURE OF SPONGY AND OF COMPACT BONE. REDUCED ½

Cells.—The cellular components of bone are associated with specific functions osteoblasts, located on bone surfaces with the formation of bone; osteocytes, located in the lacunae, with the maintenance of bone as a living tissue; and osteoclasts on the surfaces of bone with its destruction or resorption These cells, having common ancestors are closely interrelated. The bones are surrounded by a membrane, the periosteum; their marrow cavities, which serve also to provide the bones with maximum strength at minimum weight, are lined with a similar membrane. the endosteum. The cells of these membranes have bone-forming capabilities, which are called into play during the normal gronth of the skeleton and during the healing of fractures; when these cells are engaged in the formation of bone they assume the appearance, as well as the functions of osteoblasts.

Interstitial Substance. — The intercellular or interstitial portion of bone is a calcified collagenous substance that makes up its great mass The interstitial substance includes the organic framework or matrix, the inorganic part or mineral. and water. The organic matrix has two chief components, collagenous fibres and a ground substance. Even under the highest power of an ordinary light microscope the interstitial substance of bone appears to be homogeneous, but when viewed with the electron microscope. at much higher magnifications, the collagen fibres become visible, and are seen to be characterized by double cross-banding at regular intervals, averaging 640 angstrom units (one angstrom unit equals one ten-millionth of a millimetre) (*see* fig. 3a). The space between the fibres is filled with crystals of bone mineral. and a semifluid ground substance, also called cement substance.

The bone mineral, commonly called the bone salt, is mainly in the form of extremely minute and difficultly soluble crystals, averaging about 500 angstrom units in length. These are thin, hexagonal tablets (*see* fig. 4), and are arranged in a periodic pattern in bands around the collagen fibres, with the long axes of the crystals oriented in the direction of the fibres. The location of the bands of crystals corresponds to the

cross-banding of the fibres which they surround (*see* fig. 3b) ; this arrangement in space suggests that certain characteristics of the collagen fibres are instrumental in determining the location, formation and growth of the crystals.

The crystal structure and chemical composition of the bone salt are approximated by the formula:

$$3Ca_3(PO_4)_2 \cdot Ca(OH)_2 \quad \text{(hydroxyapatite)}$$

The lattice of the crystal is identical in structure with that of others of the apatite series of minerals. widely distributed in nature; this structure is responsible for the characteristic pattern revealed by X-ray spectroscopy. Between the crystals, and on their surfaces. are ions not included within the lattice structure. It is as though the bone is built up of bricks and mortar! rather than as a monolith of a homogeneous substance. The bricks are the crystals of hydroxyapatite, the mortar consists chiefly of citrnte and carbonate. with an admixture of other ions. The collagen fibres, also between the crystals, serve as reinforcing strands.

Osteogenesis.—Bone always arises. both in fetal and postfetal life, by a transformation of connective tissue. Formation of bone may be preceded by the laying-down of a cartilage model, or it may occur by direct transformation of fibrous tissue. When bone is formed in such a manner as to replace cartilage, itself a connective tissue, the process is intracartilaginous ossification; when the transformation is direct, without the presence of cartilage. it is intramembranous ossification. Both forms of ossification take place during growth and in the healing of fractures.

In bones which have been preformed in cartilage (*q.v.*) a portion of the cartilage persists throughout the period of growth, as a cartilage plate, the epiphyseal cartilage. This cartilage continues to grow, and is constantly replaced by bone, resulting in the growth in length of the bones. The cartilage with its surrounding tissues, also contributing to growth, has been called the growth apparatus. Increase in the diameter of the bone occurs by another process, involving continual erosion or resorption from within the marrow cavity, and formation of new bone, by apposition, on the outer or periosteal surface.

Calcification of bone tissue is effected by the deposition of bone mineral in the organic bone matrix, and ordinarily occurs simultaneously with the formation of the collagenous fibres of the matrix. For calcification to occur, certain conditions must be present, some humoral and others local. The humoral conditions embrace the supply and transport of the necessary minerals and their delivery to the locus of calcification in the concentrations required. The local conditions include whatever it is that differentiates a calcifiable from a noncalcifiable tissue. Since several interrelated factors, not well understood. appear to be involved. it is convenient to refer to a local mechanism. Calcification is best described as crystal formation and growth.

Physiology. — The fact that the bone salt is difficultly soluble is of far-reaching physiologic significance. This property not only

determines the deposition of the bone mineral; it also preserves the structure and rigidity of the bones. Moreover, it is of first importance in maintaining the balance of minerals between the skeleton and the fluids of the body. The adult organism as a whole is normally in a state of approximate calcium balance; *i.e.*, the output of calcium is equal to the intake. There is a constant turnover of the bone mineral, and since the bones account for by far the greater part of the body's store of calcium, an over-all calcium balance means that the rates of deposition and of solution of the bone mineral are also in balance.

The regulation of the transfer of calcium ions between the blood and the bones. in both directions, is the essential feature in the homeostatic regulation of the calcium ion concentration in the blood plasma. The maintenance of this concentration at an approximately constant level is necessary for proper functioning of the heart and of the neuromuscular system. and for the clotting of blood, and thus for life itself. This regulation is mediated by the parathyroid glands (*q.v.*), four tiny bodies embedded in the posterior surface of the thyroid gland.

Remodeling of the haversian systems, which continues throughout the life of the animal, is closely related to the regulation of the exchange of calcium between the blood and the bones. This consists in the formation of tunnels through compact bone, to be subsequently filled in by new haversian systems, by deposition of concentric lamellae on the walls of the tunnel. continuing until only the usual small haversian canal remains. During this remodeling the new bone under formation remains reactive and readily accessible to the circulation over periods of months or more. Except for this process compact bone would become fully mineralized and inert or nonreactive. Even in elderly people remodeling provides a continuous supply of new and reactive bone, able to transfer calcium to the hlood as needed by the organism.

Resorption of hone is, in essence, the putting into solution of a complicated structure, in such a fashion that it disappears. its end products entering the blood stream. It always progresses inward from the surfaces of bone; it never arises within the deeper layers; there is no interstitial resorption of bone. Formation of new bone and resorption are complementary processes; they ordinarily occur in close relation to one another, and both are essential to the growth of bone and to its constant remodeling. Resorption of bone is partially under the control of the parathyroid glands. which mediate the return of calcium from the bone to the blood by destruction of mineral-containing bone tissue. The resorption of bone serves also a second function; *i.e.*, of growth and reconstruction of bone, including haversian remodeling; the resorption taking part in this function, in contrast to that responsible for the regulation of the calcium content of the blood, does not appear to be dependent upon parathyroid activity.

Radioactive Elements and Bone.—Accidental poisoning by radium had been recognized by the 1920s. Later. the introduction of artificially produced radioactive elements. including the fission products of the atom bomb. materially increased the hazards from radioactivity. The situation is made worse by the fact that many

of the radioactive elements, especially radium and strontium, have an affinity for the skeletal system, nhere they may remain fixed for long periods of time (*see* fig. 5), during which they cause damage to the bone marrow and to the bone tissue itself. One of the unfavourable results of long continued internal radiation from radium deposited in the bones has been the occurrence of bone sarcoma, a form of malignant tumour. See BONE, DISEASES AND INJURIES OF; BONE MARROW; CONNECTIVE AND SUPPORTING TISSUES; SKELETON, VERTEBRATE; see also references under "Bone" in the Index volume.

See F C. McLean and M. R. Urist, *Bone: an Introduction to the Physiology of Skeletal Tissue* (1955); *A.* A. Maximow and W. Bloom, *Textbook of Histology,* 7th ed. (1957). **(F.** C. McL.)

BONE, DISEASES AND INJURIES OF. Diseases and injuries of bone may conveniently be discussed under five headings: congenital defects, metabolic disturbances, infections, tumours and fractures.

Congenital Defects.—Of unknown cause, congenital defects range from absence, reduplication, misplacement or deformity of a part to permanent inability to form good skeletal tissues. When the development of cartilage is affected, longitudinal growth of long bones is always abnormal and deformities, if not present at birth, appear in time. The most familiar example of this sort of disturbance is the circus dwarf with his large head, long trunk and short extremities. Defects of bone formation are seen in osteogenesis imperfecta (brittle bones), with its multitudinous fractures, in osteopetrosis (marble bones), in which bone grows dense at the expense of the blood-forming marrow, and in fibrous dysplasia, in which bone becomes replaced by soft fibrous tissue.

The osteochondroses are little-understood disorders of growth in which the bony centre of one or another epiphysis (see BONE: *Structure)* appears to die. This is most commonly seen in the upper femoral epiphysis (hip joint) where the condition is known as Legg-Perthe's disease. If these areas of dead bone are sufficiently protected from stress they are eventually replaced by new

living bone and good function can be expected.

Another growth disturbance, common among adolescent boys, also affects the hip joint. Sometimes the entire epiphysis migrates slowly upon the neck of the femur in the region of the epiphyseal cartilage. This condition of epiphyseolysis (slipped epiphysis) can be treated rather simply if it is seen early. If a marked deformity has already been produced, major surgical reconstruction is necessary. (See also ORTHOPEDIC SURGERY: Methods and Procedures.)

Metabolic Disturbances. — Bones are living, active organs that are constantly being destroyed and rebuilt at the same time. Under normal conditions these two processes are in equilibrium. Bones faithfully reflect the general condition of the tissues they support, and therefore anything that interferes with a person's metabolism has an effect on his skeleton. Deficiencies of vitamin C or D are followed by scurvy and rickets respectively. Dysfunction of the parathyroid gland, the kidney, the gastrointestinal tract, the adrenal glands—in fact of almost any organ or system—may produce changes in the bones. In these cases, treatment is directed toward the underlying disease and healing of the bone follows. Unless there are such specific constitutional disturbances, however, the normal physiologic processes of the skeleton are unaffected by diet. Neither are they affected by age except that the ratio of rebuilding to destruction is slowly altered so that the absolute mass of bone is eventually less. Thus, although the chemical composition of the bone remains the same, the total skeleton becomes less heavy and more delicate. This is one of the reasons why the bones of elderly persons tend to break easily but still repair themselves adequately.

Infections of bone may be caused by any infectious agent but most commonly they result from pyogenic (pus-forming) organisms or tubercle bacilli. Pyogenic osteomyelitis was one of the major orthopedic problems before the introduction about 1940 of the chemotherapeutic and antibiotic drugs (sulfonamides. penicillin, aureomycin, etc.). Thereafter acute osteomyelitis, which results from spread of organisms via the blood stream from another site (abscess, infected ear, etc.), became a relatively rare disease. Furthermore, when it does occur. it is not often a serious threat to life or limb and it is much easier to manage. Judicious surgical treatment combined with drug therapy can in most instances effect a cure while avoiding the distressing complications that once were commonplace.

The antibiotic drugs (streptomycin, etc.) also helped in the treatment of tuberculous osteomyelitis. Since this disease is always secondary to a focus elsewhere in the body, treatment of the skeletal focus must be correlated with treatment of the patient's general condition. It is imperative also to investigate the pulmonary status of both the patient and his contacts.

While solitary tuberculous abscesses of bone are seen occasionally (and often cured by surgical excision), tuberculous osteomyelitis is usually associated with infection in a neighbouring joint. Most commonly involved are spine, hip and knee. but no site is immune Sanatorium treatment of tuberculosis of bone and joints (by diet, rest, fresh air and sunlight) used to be standard and remained popular in Europe.

About 1920 surgical removal of tuberculous lesions began to be recognized as a more certain means of arresting the disease and of hastening rehabilitation of the patient. Most authorities in the United States came to believe that the treatment of choice is definitive surgical intervention as soon as the patient's general condition permits. This may involve excision of diseased tissue together with fusion (stiffening) of the affected joint. (See also TUBERCULOSIS: Non-Pulmonary Tuberculosis.)

Tumours of bones are not common. The relatively few benign ones are amenable to surgical removal. Carcinoma (cancer) never develops originally in bone but often spreads to bone from other sites. Patients with such a spread to the bones usually have pain and disability. There is no known treatment that will effect a cure but much can be done to prolong life and make the patient comfortable. The malignancies that do arise in bone are knonn as sarcomas. Although any of the component tissues may give rise to a malignancy, the three main types are those that form fibrous tissue, bony tissue or cartilaginous tissue, In the treatment of these tumours, the only hope of cure is eradication of the whole process by adequate early surgical excision. This may necessitate amputation but often a limb can be saved by cutting out the involved tissues and substituting a graft from a healthy bone. Irradiation, chemotherapy, isotopes, etc., are useful for palliation or in the treatment of inaccessible lesions, but they had not proved curative by the early 1960s. (See also CANCER: *Symptoms* and *Course* of Certain *Common* Cancers; TUMOUR: Clinical Manifestations.)

Fractures (breaks) are the commonest type of injury to bone. Ordinarily they result from considerable violence, but when a bone is abnormal (softened by disease or grown fragile with age) fractures may follow trivial accidents or even occur spontaneously (pathologic fractures). If the soft tissues are damaged so that the fracture communicates with the external air, the fracture is said to be open (compound); otherwise, it is a closed (simple) fracture. The presence of a fracture is not difficult to suspect and indeed is often evident, but only the roentgenogram (X-ray) will reveal details. (See also FRACTURES AND DISLOCATIONS.)

The principles of treatment of any fracture are to bring the fragments back as nearly as possible to their anatomic position and to hold them in that position until bony union has occurred. Whether or not implementing these principles is easy or even possible depends upon a number of factors, such as the age and general condition of the patient, the site of the fracture, et~.

It is true that fractures heal more easily in children than in adults and, in addition, that the subsequent growth of a child tends to remodel and erase any deformity from a fracture. Therefore, in general, a less accurate reduction is acceptable in a child than in an adult and a shorter period of immobilization usually is required. Moreover, in children stiffness does not tend to develop in joints that are immobilized, so that convalescence is short. On the other hand, if the epiphyseal plate has been injured, subsequent growth in length may be unequal or even completely arrested Occasionally, stimulation of an epiphysis near to, but not involved by. a fracture will result in overgrowth of an extremity. Such uneven growth may be corrected through appropriate surgical measures. It is seldom necessary to resort to operation to treat children's fractures.

Fracture of a major bone in an adult is another matter. Many breaks, such as the common ones of the wrist, are usually treated by simple manipulation and immobilization in plaster. When this is impossible traction may be helpful but often the quickest, safest and most economical way to handle the matter is to operate upon the patient, fix the pieces of bone together and fasten them with metal appliances. If the fracture has involved a joint surface open reduction is imperative, because a perfect fit must be obtained This is specialized surgery, and the decision as to what to do and how to do it must be made individually for each patient. While one fracture demands a cast, another will need traction and a third will need exercises and special treatment to restore function. If, as sometimes happens under the most favourable of circumstances, the bone unites slowly or refuses to unite at all, the surgeon will probably operate again and employ some bone-grafting procedure to stimulate healing.

If there is no interference by unwise treatment, infection or other complications, fractures tend to heal in an orderly fashion. The break is at once surrounded by a hematoma (collection of blood) that is rapidly replaced by the ingrowth of organized scar tissue. Although some of the cells in the bone immediately adjacent to the fracture site will have died, many surface cells survive and proliferate. New bone, therefore, grows from all surfaces, replaces the dead bone and unites the two fragments. The calcium in the new bone, like that of all other bones. is derived from the calcium circulating in the blood. Therefore, unless there is some constitutional disturbance that interferes with the general metabolism, the process of bone healing is not altered by diet or by advancing years.

There are certain fractures that by their very nature are especially difficult. In general, fractures through compact bone heal more slowly and less satisfactorily than fractures through spongy

bone. Also, fractures that have entered joints always give more trouble, because although the bone heals with perfect bone, the cartilaginous surfaces cannot repair themselves so efficiently Bones such as the astragalus (ankle). carpal navicular (small bone in the wrist) and neck of the femur (hip) often break in such a fashion as to interfere with the blood supply. When this occurs, the portion of bone so deprived dies, no matter how well the fracture has been reduced and fixed.

Under these circumstances union of the fracture is difficult to obtain and, even if it occurs, the dead bone must be protected for a long time in order for complete replacement by living bone to result In the absence of such protection, complications such as painful degenerative arthritis can be expected. In such cases various surgical procedures can be performed to improve function, but the final outcome is usually less than perfect

Fractures about the hip. which usually occur in elderly persons, are often difficult to handle even under the best circumstances A high percentage of these breaks will heal uith the ordinary methods of fixation, but for those that do not special methods of handling have been devised Among the most commonly employed are various osteotomies (surgically cutting or removing a piece of bone) designed to change the position of the fragments, certain bone-grafting procedures and the use of metal or synthetics to replace damaged joint surfaces. None of these methods is without its onn complications and none is applicable to every fractured hip. It must be emphasized again that treatment must always be individualized.

BONE BED, a rock stratum or deposit which contains bones. The term is applied not only to those layers occurring at definite geological horizons, but also to the brecciated and stalngmitic deposits found on the floors of caves. The stratified deposits are frequently associated with stream bedding and probably indicate a sorting out and segregation of the heavier bony material accompanying partial or complete removal of the finer sediment by the action of currents.

A well-known hed is the Agate Springs bone bed, composed of disarticulated bones and teeth of extinct mammals, especially rhinoceroses, of Lower Miocene age, in western Nebraska.

BONE MARROW, or myeloid tissue: is located in the cavities of the bones. It produces the blood platelets and all the cells of the peripheral blood (circulating outside the marrow cavities), with the exception of the lymphocytes which are normally produced by the lymphatic tissue. (See BLOOD: Cells of *the* Blood.) In man, at birth, the bone marrow or myeloid tissue has a volume averaging 67 c.c. or 2.3% of the total body weight. In the adult human being, bone marrow volume varies between 1,600 c.c. and 3,700 c.c., or 2.1%–4.9% of the total body weight. In general, its volume is larger in the male than in the female.

Bone marrow is of two types, red and yellow. The difference in colour is based on the preponderance of either fat tissue (yellow) or blood-forming tissue (red). In man, at birth and until about the age of seven. bone marrow is red in colour. Gradually the fat content increases at the expense of the red bone marrow. In the adult the red bone marrow is present only in the bones of the skull, breastbone, ribs, collarbone, spinal column and in the proximal portion of the thighbone and upper arm bone. Under certain conditions, as after serious blood loss or increase in 'temperature, yellow bone marrow may change into red bone marrow. A similar change may occur in diseases that are accompanied by an increase in the blood-forming activity of the bone marrow.

Microscopically the bone marrow consists of a three-dimensional network of special connective tissue fibres, the reticular fibres; to which adhere outstretched reticular cells. These two components constitute the stroma of the bone marrow. Two types of reticular cells are distinguished: fixed macrophages and primitive reticular cells. The fixed macrophages have the ability to phagocytose or take up particulate materials from the blood stream. The primitive reticular cells can change into macrophages or can develop into blood cells. In the stroma of the bone marrow are the fat cells which, as mentioned above, give the bone marrow a yellow colour when present in Iarge numbers. Mature red blood cells. called erythrocytes. and granulated white blood cells, the granulocytes or granular leukocytes, as well as the immature precursors of all these cells, are present in the meshes of the network of cells and fibres. Both cell series of erythrocytes and granulocytes are derived from a common stem cell called by some a myeloblast and by others a lymphoblast. According to the dualistic theory of blood formation, the stem cell of the myeloid elements (myeloblast) of the blood is essentially different from the stem cell of the lymphocytes (lymphoblast). Since no constant morphologic or physiologic differences between the stem cell of the bone marrow and the lymphocytes have been demonstrated and since the so-called lymphoblast is not essentially different from a lymphocyte, the proponents of the unitarian or monophyletic theory of blood formation reject the names myeloblast and lymphoblast for stem cells and call the bone marrow stem cell hemocytoblast.

As the bone marrow stem cell develops into the red blood cell, hemoglobin accumulates in the cytoplasm. The erythrocyte precursors ahich contain hemoglobin as well as nucleic acid in the cytoplasm stain in ordinary blood preparations with a colour which is a mixture of the pink-staining hemoglobin and the blue-staining nucleic acid and are consequently called polychromatophilic erythroblasts. In them the amount of hemoglobin increases gradually at the expense of the nucleic acid. At the same time the nucleus becomes very dark and round and the resulting cell is called normoblast. From this cell the mature nonnucleated erythrocyte arises by either extrusion or dissolution of the nucleus

The granulocytes are formed from the bone marrow stem cell by the elaboration'of granules in the cytoplasm and characteristic changes in the nucleus. Depending on the properties of the cell ultimately produced, the granules become heterophile (neutrophile; staining indifferently with acidic or basic dyes), eosinophile (staining with acidic dyes; *e* g., eosin) or baiophile (staining with basic dyes; *e.g.*, methylene blue) in their reaction to dyes. These immature forms of the granular leukocytes are called myelocytes.

Dispersed between the blood cells and fat cells are the megakaryocytes. It is generally believed that these giant cells produce the blood platelets by the process of pinching off small fractions of their protoplasm.

The peripheral blood is fed new cells via the arteries into the bone marrow and then into large thin-walled vessels, the sinusoids, which drain into the veins. (See BONE.) The cells which form the walls of the sinusoids are different from the ordinary endothelial lining of the blood vessels but they are similar to the macrophagic reticulum cells in that they have the ability to phagocytose. These lining cells. which are named littoral cells, can free themselves from the wall, round off and become free macrophages in the lumen of the sinusoid.

In man, after early embryonic stages, blood formation takes place extravascularly, or outside the blood stream. In birds and in reptiles erythropoiesis. or formation of red blood cells, takes place intravascularly, uhile the granulocytes are formed extravascularly. In the evolutionary series, bone marrow appears first in the tailless group of amphibians, familiar members of which are frogs and toads. In lower vertebrates, blood-cell formation occurs in a great variety of organs such as the spleen, kidney, liver, heart, mucous membranes of the intestine, sexual glands, etc.

The maturation of the erythrocytes is determined in part by the antianemic factor present in the liver. If this antianemic factor is absent, the production of erythrocytes is inhibited and the disease pernicious anemia results. Administration of the antianemic factor restores the maturation process. (See ANEMIA.) The production of erythrocytes is enhanced when the amount of oxygen in the environment is reduced, such as occurs at high altitudes. Certain chemical substances, such as cobalt, have a similar effect. Under pathologic conditions, large changes may occur in the bone

marrow. (*See* BLOOD, DISORDERS OF.) For diagnostic purposes, samples of the bone marrow can be removed by puncture of the breastbone and aspiration of the bone marrow by means of a syringe, a technique called sternal puncture.

All forms of ionizing radiation (X-rays, etc.) have a deleterious effect on the bone marrow with a consequent reduction of the number of cells in the peripheral blood. In animal experiments, it was found that administration of bone marrow cells, and also of other organs such as the spleen, after irradiation enhances the regeneration of the blood-forming organs, including the bone marrow, and in addition has a protective effect on the individual as a whole. *See* also BLOOD; LYMPH AND LYMPHATIC SYSTEM; CONNECTIVE AND SUPPORTING TISSUES; BONE, DISEASES AND INJURIES OF.

BONER (BONERIUS), **ULRICH** (fl. 1324–1349), Swiss writer and Dominican monk, whose collection of 100 fables in verse was very popular in the middle ages and was the first book to be printed in German (Bamberg, 1461). Boner is mentioned in records between 1324 and 1349 and is known to have been of Bernese family. His fables, referred to as *bischaft* or *bispel* ("examples"), were written in Middle High German and probably completed about 1350. They were entitled *Der Edelstein* ("The Precious Stone"), since their effect was intended to resemble that of the spell cast by precious stones. Although Boner names only two of his sources—Aesop's *Fables* and Avianus—it is clear that he also drew on other material.

The form of the *Edelstein* is of particular interest. It begins with a prologue and ends with an epilogue, the one including an opening and the other a closing prayer. The themes of the first four fables are closely linked with the ideas expressed in the prologue on the duties of youth; and the gloomy, *respice finem* mood of the epilogue is anticipated in the last nine fables. Within this framework are two groups of stories: an Aesop group (fables 5–62) and an Avianus group (fables 63–91). In the Aesop group the moral, which embodies the author's own practical wisdom. is generally loosely attached to the story. whereas in the Avianus group the moral is directly derived from the story and inculcates general moral precepts.

Der Edelstein was edited by G. F. Benecke (1816), and also by F. Pfeiffer, in *Dichtungen des deutschen Mittelalters*, vol. iv (1844). Selected fables have been translated into modern German by M. Oberbreyer (1881) and K. Pannier (1895).

See R. H. Blaser, *Ulrich Boner, un fabuliste suisse du XIVe siècle* (1949). (R. H. BL.)

BONESET (*Eupatorium perfoliatum*), a North American plant of the Compositae (*q.v.*) family. It is also called thoroughwort, agueweed and Indian sage, and is common in wet places from Nova Scotia to Manitoba and southward to Florida and Texas. It is a coarse, rough, hairy perennial, two to six feet high, with lance-shaped, toothed and wrinkled leaves, four to eight inches long, which are joined together at their bases around the stem. In August the plants bear small, tubular, white flowers in numerous heads which are arranged in a flattish much-branched cluster four to seven inches wide.

BONESET (EUPATORIUM PERFOLIATUM)

See also EUPATORIUM.

BO'NESS (BORROWSTOUNNESS), a small burgh and seaport of West Lothian, Scot., lies on the southern shore of the Firth of Forth, 18 mi. by road N.W. of Edinburgh opposite Culross. Pop. (1961) 10,194. It has an extensive harbour exporting coal and importing pit props, phosphates, etc., but its trade has been limited by the development of the port of Grangemouth. The chief industry is coal mining, some of the pits extending a long distance below the firth. Fertilizers and earthenware are manufactured. Traces of the Roman Antonine wall (*q.v.*) known as Graham's or Grime's dike lie south of the town. The estate of Kinneil house is now a public park and the house (where the mural paintings have been restored) is an "ancient monument." James Watt developed his invention of the steam engine in the park.

BONFILS, FREDERICK GILMER (1860–1933), U.S. publisher, was born in Troy, Mo., Dec. 21, 1860. He entered the U.S. military academy in 1878 but resigned in 1881. With Harry H. Tammen (1856–1924) he purchased the *Denver Post*, a daily newspaper, in 1895. They dedicated the paper to "the service of the people" and conducted spirited crusades against crime and corruption which brought them into national prominence. Their activities often involved them in lawsuits and in 1900 in an attempt upon their lives by an irate lawyer. The *Post*, above whose building door they inscribed "O Justice, when expelled from other habitations, make this thy dwelling place," became an influential and widely circulated newspaper under their direction. Bonfils died on Feb. 2, 1933, in Denver. (H. J. SG.)

BONFILS, HENRY (JOSEPH FRANÇOIS XAVIER) (1835–1897), French jurist born at Montpellier on July 31, 1835, became professor and eventually dean (1879–88) of the faculty of law at the University of Toulouse. His early work was concerned with the teaching of private law. The first edition of his book on international law, *Manuel de droit international public*, appeared in 1894. As Bonfils states in his preface, this book is not a dogmatic treatise: it is rather an investigation of precedents in the light of history, discovering the origin and the development of the customary rules from their first hesitant application to their ultimate consolidation, examining the divergent opinions of lawyers about them and determining their true significance. Written at a time when international law was regarded as being the sum of the rules governing the relations between sovereign and independent states, Bonfils' book became progressively out-of-date as the concept of interdependence grew stronger. The work of making the necessary changes in it fell to Paul Fauchille (*q.v.*). Bonfils died at Toulouse in 1897.

(ML. ST.)

BONFIRE, a large fire lit in the open air. The earliest known instance of the derivation of the word occurred as *ban fyre ignis ossium* in the *Catholicon Anglicum* (1483). Other derivations have been sought for the word. Thus some have thought it *Baal fire*, passing through *Bael*, *Baen* to *Bane*. Others have declared it to be *boon* fire, a "contribution" fire. everyone in the neighbourhood contributing a portion of the material.

Whatever its origin, the word has long had several meanings: (1) a fire of bones; (2) a fire of corpses, a funeral pyre; (3) a fire for immolation, such as that in which heretics and proscribed books were burned; (4) a large fire lit in the open air on occasions of national rejoicing or as a signal of alarm, such as the bonfires which warned England of the approach of the Armada. Throughout Europe the peasants from time immemorial have lighted bonfires on certain days of the year, and danced around or leaped over them. The earliest proof of the observance of these bonfire ceremonies in Europe is afforded by the attempts made by Christian synods in the 7th and 8th centuries to suppress them as pagan. Thus the third council of Constantinople (680), by its 65th canon. orders: "Those fires that are kindled by certaine people on new moones before their shops and houses. over which also they use ridiculously and foolishly to leape, by a certaine antient custome, we command them from henceforth to cease." Leaping over the fires is mentioned among the superstitious rites used at the Palilia (the feast of Pales, the shepherds' goddess) in Ovid's *Fasti* (*q.v.*). The lighting of the bonfires in Christian festivals was significant of the compromise made with the heathen by the early church. In Cornwall bonfires are lighted on the eve of St. John the Baptist and St. Peter's day; sometimes effigies are burned in these fires, and there are grounds for believing that in ancient times human sacrifices were actually made in the bonfires. Spring and midsummer are the usual times at which these bonfires are lighted, hut in some countries they are made at Halloween (Oct. 31) and at Christmas.

BONGARS, JACQUES, SIEUR DE LA COUDRIÈRE (1554–1612), French diplomat who was also a classical scholar and the compiler of a celebrated history of the crusades, mas born at Orléans in 1554. A Huguenot, he studied in Germany before going to Italy and Constantinople in pursuit of learning. From 1586 the king of Navarre (the future Henry IV of France) sent him on missions to obtain men and money from the German princes and from Elizabeth I of England. When Fabian von Dohna blamed the Huguenots for the defeat of the German troops that he led into France in 1587, Bongars composed a violent pamphlet against him As French minister in Germany (1593–1610), he tried to unite the Protestant princes in a league with James I of England at its head. He died in Paris on July 29, 1612.

Bongars published an edition of Justin's works in 1581 and a French translation of Aristaenetus in 1597 and prepared an edition of Quintus-Curtius (not published until 1696). He was interested, however, not only in classical writings but also in medieval chronicles. His collection of historical works on Hungary (1600) was followed, in 1611, by the far more important *Gesta Dei per Francos* ("God's Work Through the Franks"), a collection of the contemporary accounts of the crusades together with Marino Sanuto's *Secreta Fidelium Crucis*. An edition of his letters, in Latin, appeared in 1647. a French translation of them in 1668–70. His diary of his journey to Constantinople and the pamphlet against Dohna were printed in 1874.

See H. Hagen, *Jacobus Bongarsius* (1874); Roman d'Amat, article in *Dictionnaire de biographie française,* vol. vi (1954). (J. B. R.)

BONGO, a Negro people once extensive in southwestern Republic of the Sudan, now found in small, scattered settlements south and east of Wau. Lack of co-operation among sections, living separated by miles of bush, was decisive in their decimation by waves of invaders since the 18th century. Chiefs had little authority although they were consulted in important legal and social matters.

The Bongo now live along roads, subsist largely on the cultivation oi sorghum, eleusine, sesame and tobacco; they domesticate dogs, chickens, and a few sheep and goats. Famed as hunters, they spend each dry season hunting and fishing. They use poisoned arrows and spears, in addition to nets, traps and snares. Wild fruits, roots and fungi are eaten. Noted for their metalwork, the Bongo supplied neighboring peoples with iron tools until imported iron stopped smelting of local ores. They are fond of music played with flutes, drums, horns and large wooden trumpets.

See P. T. W. Baxter and Audrey Butt, *The Azande and Related Peoples of the Anglo-Egyptian Sudan and Belgian Congo,* pp. 130–135 (1954). (C. C. R.)

BONGO *(Taurotragus* [subgenus *Boocercus] eurycerus),* a large African antelope *(q.v.).* Both sexes bear large horns that spiral in one complete twist; the rich chestnut body is marked with narrow vertical white stripes, the chest with a white crescent. The bongo. one of Africa's wariest animals, is related to the bushbuck and lives in dense forests.

BONHEUR, ROSA (MARIE ROSALIE) (1822–1899). French painter of animal subjects, was born at Bordeaux on March 16, 1822, the daughter of an art teacher, Raymond Bonheur. She was taught by her father and studied in Paris under Léon Cogniet. Her animal paintings are notable for the firm handling of the subjects and the remarkable accuracy of the drawing. Toward the end of her career she developed a more highly polished surface finish reminiscent of Paul Potter. A regular *salon* exhibitor from 1841 onward, she won a first class medal for "Ploughing in the Nivernais" (Luxembourg gallery, Paris) in 1848. Her "Horse Fair," exhibited in 1853. was acquired for a record sum in 1887 by C. Vanderbilt, who presented it to the Metropolitan museum, New York (replica in National gallery, London). Rosa Bonheur was a strong, unconventional personality, and when at home used to wear trousers and smock, and smoke cigarettes. At one time she kept a lioness, and in the period immediately after the Franco-German War she would paint only wild animals such as lions, tigers and wolves. In 1894 she became the first woman to receive the Grand Cross of the Légion d Honneur. She died at By, near Fontainbleau, on May 25, 1899.

BONHOEFFER, DIETRICH (1906–1945), German Lutheran pastor who taught a controversial theology, was born in Breslau on Feb. 4, 1906. He studied under Adolf von Harnack in Berlin, and was influenced by Karl Barth *(q.v.).* Protesting against the anti-Jewish legislation forced upon his church in 1933, he left Germany to minister to German congregations in London but returned to become head of a theological college. Shortly before World War II he was lecturing in the United States, but returned to Germany. He became involved in the German resistance movement and in 1942 met in Stockholm his friend Bishop G. K. A. Bell *(q.v.),* to whom he revealed plans for Hitler's overthrow. He was arrested on April 5, 1943, and hanged in the concentration camp at Flossenbiirg on April 9, 1945.

In his early writings Bonhoeffer is concerned with the theological and sociological implications of the church (*Sanctorum Communio,* 1930) and of Christian obedience (*Nachfolge,* 1937; Eng. trans. *The Cost of Discipleship,* 1948). In his *Ethik* (1949; Eng. trans. 1955) and his *Widerstand und Ergebung* (1951; Eng. trans. *Letters and Papers From Prison,* 1953; U.S. ed. *Prisoner for God,* 1954), he outlines a highly individual interpretation of biblical concepts in a world that has come of age, in which neither metaphysical nor psychological categories are adequate. These works show the way to a revolution in the-understanding of Christian belief, not in a separate "religious" realm but in a dialectical identity with this world and with Christ as one who is, in suffering, absolutely for this world.

BONIFACE (WYNFRITH), **SAINT** *(c.* 672/673–754), the apostle of Germany and organizer of the Frankish church, was born of a good family near Exeter in Devonshire. At the age of seven he became a monk and studied first near Exeter, then at Nursling, near Winchester, under the abbot Winberht. He soon distinguished himself both as scholar and preacher. In 716 he followed the example of other Saxon monks and set out as missionary to Frisia. He was soon obliged to return, however, probably because of the hostility of Radbod, king of the Frisians, then at war with Charles Martel. At the end of 717 he went to Rome, where in 719 Pope Gregory II commissioned him to evangelize Germany. Crossing the Alps, Boniface visited Bavaria and Thuringia; but upon hearing of the death of Radbod he hurried again to Frisia where, under the direction of his countryman Willibrord (d. 738), the first bishop of Utrecht, he preached successfully for three years. About 722 he visited Hesse and Thuringia, won over some chieftains, and converted and baptized great numbers of the heathen. Having sent special word to Gregory of his success, he was summoned to Rome and consecrated bishop on Nov. 30. 722, after taking an oath of obedience to the pope. Then his mission was enlarged. He returned with letters of recommendation to Charles Martel, as a regionary bishop, with a general jurisdiction over Germany.

Charles's protection, as Boniface himself confessed, made possible his great career. Armed with it he passed safely into heathen Germany and began a systematic mission baptizing, overturning idols, founding churches and monasteries, and calling from England monks and nuns, some of whom have become famous: St. Lull, his successor in the see at Mainz; St. Burchard, bishop of Würzburg; Willibald, Boniface's own biographer; St. Lioba. St. Walburga, St. Thecla. In 732 Boniface was created by Gregory III metropolitan of Germany beyond the Rhine, with authority to found bishoprics wherever he thought fit. Several years later, for the third time, he went to Rome. On his return he organized the church in Bavaria into the four bishoprics of Regensburg, Freising. Salzburg and Passau. Then his power was extended still further. In 741 Pope Zacharias made him legate, and charged him with the reformation of the whole Frankish church. With the support of Carloman and Pepin, who had just succeeded Charles Martel as mayors of the palace, Boniface set to work. As he had done in Bavaria, he organized the east Frankish church

into four bishoprics. Erfurt, Würzburg, Buraburg and later Eichstadt, and set over them some of his own monks In 743 he presided at what is generally counted as the first German council At the same period he founded the abbey of Fulda. as a centre for German monastic culture, placing it under the Bavarian Sturmi, whose biography gives many picturesque glimpses of the time. Then came a disciplinary controversy with Fergal (latinized Virgilius), the Irish abbot of Salzburg who ruled the diocese through an Irish bishop under his authority in the Celtic fashion Fergal, a good mathematician and interested in cosmography, was reported to Pope Zacharias by Boniface as believing "that there are another world and other men under the earth, and another sun and moon"—clearly a misrepresentation of the doctrine about the antipodes held a few years before by Bede. This matter was quietly dropped by the pope, who gave judgment for Fergal against Boniface on a few minor points. Boniface took it ill, but Fergal had the last word: under the assumed name of Aethicus Ister ("the Danube Philosopher") he produced a *Cosmographia* purporting to derive from St. Jerome, in fact an elaborate fake, which had a wide circulation in the middle ages and was not unmasked until 1951. Fergal was consecrated bishop of Salzburg after Boniface's death, and canonized in 1233.

Boniface was more successful in France. There a certain Adelbert, a Frankish bishop of Neustria. had caused great disturbance. He had been performing miracles and claimed to have received his relics not from Rome, like those of Boniface, but directly from the angels. Planting crosses in the open fields he drew the people to desert the churches, and had won a great following throughout all Neustria. At the instance of Pepin, Boniface secured Adelbert's condemnation at the synod of Soissons in 744; but he and Clement, an Irish missionary associated with him who held heretical views on predestination, continued in spite of legate, council and pope, to find followers for three or four years more.

Between 746 and 748 Boniface settled at Mainz, as metropolitan over the Rhine bishoprics and over those he had established in Germany—thus ensuring the pre-eminence of the see of Mainz. In 747 a synod of the Frankish bishops sent to Rome a formal confession of faith. Boniface dees not seem to have taken part in the anointing of Pepin as king of the Franks in 751. In 754 he resigned his archbishopric in favour of Lull, and took up again his earliest plan of a mission to Frisia; but on June 5 of the same year he and his companions were massacred by heathens near Dokkum. His remains were afterward taken to Fulda. His feast day is June 5.

St. Boniface has well been called the proconsul of the papacy. His organizing genius, even more than his missionary zeal, left its mark upon the German and French churches throughout all the middle ages. The missionary movement, which until his day had been largely carried on by independent Irish monks, was brought under the direction of Rome. In so welding together the scattered centres and binding them to the papacy, Boniface was actuated by simple zeal for unity of the faith and not by a conscious political motive.

Though pre-eminently a man of action, Boniface left several literary remains, the chief being his letters, which are extremely important from the standpoint of history, dogma and literature. His other works include a grammar, some poems, the fragment of a penitential, and some sermons of doubtful authenticity.

BONIFACE (Lat. BONIFATIUS), the name of nine popes.

SAINT BONIFACE I (d. 422) was pope from Dec. 28/29, 418 to Sept. 4, 422. Born at Rome, date unknown, he was a priest when elected pope by a majority of the Roman electors. Eulalius, a deacon simultaneously chosen by a clerical faction, contested the office until April 419, when he lost the support of Emperor Honorius for violating an agreement that the two claimants leave Rome pending a council's decision. His feast day is Sept. 4.

BONIFACE II (d. 532), pope from Sept. 22, 530 to Oct. 17, 532, was born at Rome, date unknown, of Gothic descent. the first Germanic pontiff. Felix IV designated him, while Boniface was still archdeacon, as his successor. When the majority of the Roman clergy elected Dioscorus, discord followed, settled within a few weeks by Dioscorus' death. (JN. F. B.)

BONIFACE III (d. 607), pope from Feb. 19 to Nov. 12, 607, is principally known for an edict he obtained from the emperor Phocas recognizing the see of Rome as the head of all the churches, which doubtless was intended as a limitation on the claims of Cyriacus, patriarch of Constantinople.

SAINT BOKIFACE IV (d. 615) was pope from Aug. or Sept. 608 to May 615. He converted the Pantheon into the Church of Our Lady of the Rotunda and presided over the council of Rome in 610 attended by Mellitus, the first bishop of London, by whom Boniface sent letters and instructions to Lawrence, archbishop of Canterbury, and to King Aethelbert. Boniface was later venerated as a saint. his feast day being May 2j.

BONIFACE V (d. 625), pope from Dec. 619 to Oct. 625, did much to assist the spread of Christianity in England. especially in Northumbria. According to Bede (in his *Ecclesiastical* History) he wrote encouraging letters to Mellitus, third archbishop of Canterbury; to Justus, bishop of Rochester; to Edwin, king of Northumbria; and to his wife, Aethelberga, thus assisting the work of Paulinus for the conversion of Northumbria.

BONIFACE VI (d. 896) was elected pope in April 896 but died 15 days later.

BOKIFACE VII (d. 985) reigned in June and July 974 and again from Aug. 984 to July 985. Many historians dispute the legitimacy of his claim as pope and implicate him in the deaths of Benedict VI and John XIV. In 974 he was substituted by Crescentius for Benedict VI, who was strangled in prison. Exiled by Count Sicco, the envoy of Otto II, Boniface returned in 984 to throw Pope John XIV into prison and take his place. (C. P. L.)

BONIFACE VIII (Benedict Caetani) (*c.* 1235–1303) was pope from Dec. 24, 1294 to Oct. 11, 1303, when he died in Rome a little more than a month after the attempt against his person perpetrated by Guillaume de Nogaret, the emissary of King Philip IV of France, at Anagni, where, to use the words of Dante (not a friend of Boniface's), "Christ was made captive in his vicar" (*Divine* Comedy Purg. xx, 86).

The catastrophe of Boniface VIII marks the first open rejection of papal spiritual hegemony by the rising national monarchies of the west, and above all by France. Boniface's assertions of papal plenitude of power did not go beyond those of his predecessors in the 13th century. They were in fact more moderate than, for instance, those of Innocent IV (*q.v.*) and were in any case well within the range of the opinions gradually elaborated in the schools of theology and canon law in the period between the age of Gregory VII and that of Boniface. Boniface's failure was due not to any novelty of his views or claims but to changed circumstances, to his inability or unwillingness to gauge their significance adequately and last but not least to his own character: conscious of his superior intellect and at the same time tormented by illness, he was impulsive to the point of imprudence and short-tempered to the point of uncharitableness. It was his exaggerated harshness against the Colonna (*q.v.*)—whose hatred for the Caetani pope was largely due to conflicting interests of the two families in the Koman Campagna—as well as his shortsighted underestimation of the ruthlessness of Philip IV of France and his helpers that led to the coalition of these two disparate forces and to the pope's downfall. Boniface VIII's personal failings, however, can in no way exculpate Philip IV the Fair (*q.v.*) and his ministers, who used against the pope the same means of forgery, defamation, intimidation and violence (practices apparently inseparable from radical nationalism since its beginnings) which they were again to employ a few years later against the Templars.

Benedict Caetani was born in Anagni, probably between 1235 and 1240. He studied law in Bologna and then for many years held increasingly important functions in the administration of the Roman *curia*. Martin IV made him cardinal-deacon of St, Nicholas in Carcere Tulliano in 1281; under Nicholas IV he became cardinal-priest of St. Martin in Montibus in 1291. On his legation to France from 1290 to 1291 he succeeded in delaying the outbreak of renewed war between France and England and in bringing about peace between France and Aragon. It was Cardinal Benedict Caetani who confirmed the unhappy Pope Celestine V (*q.v.*) in his wish to resign and after he had succeeded him found it advisable to intern the old man in the castle of Fumone; there Celestine soon died, and though it was a death by natural causes it was open to suspicion and incriminating aspersions by Boniface's enemies. Among those who carried on the propaganda and opposition against Boniface were not a few of the Franciscan "Spirituals," for instance, the famous Jacopone da Todi (*q.v.*) some of whose poems were written during his imprisonment by Boniface from which he was released only after the pope's death.

The two principal international conflicts which existed from the onset of Boniface's pontificate were that between France and England concerning Guienne and Flanders and that between the kingdoms of Naples and Aragon concerning the island of Sicily, which had broken away from the Neapolitan Anjous after much provocation, disregarding, however, papal feudal overlordship. While Boniface finally, though unwillingly, accepted the independence of the island kingdom under Frederick of Aragon (peace of Caltabellotta, 1302), his attempts to stop hostilities between Edward I of England and Philip IV of France became enmeshed with another important problem, the increasing tendency of these warring monarchs to tax the clergy without obtaining papal consent. While the desire of the late-medieval rulers to tax the wealth of their clergy has been defended and can perhaps be understood, the practice was unquestionably contrary to the canon law of the time. That Boniface refused to look on inactively while the struggle between France and England, which he was trying to terminate, was being financed at the cost and to the prejudice of the church and the papacy is not surprising. In 1296 he issued the bull *Clericis Laicos* which forbade under the sanction of automatic excommunication any imposition of taxes on the clergy without express licence by the pope. This bull had some effect in England, owing chiefly to the steadfastness of the archbishop of Canterbury Robert de Winchelsea, but in France there was no strong defender of papal prerogative against the concerted action of the king and his civil lawyers. Philip IV countered or even forestalled the publication of *Clericis Laicos* by an order forbidding all export of money and valuables from France and by the expulsion of foreign merchants.

While this measure was a very serious threat to papal revenues, it alone probably would not have forced Boniface to those far-reaching concessions which he had to grant the French king within the year, concessions which almost amounted to revocation of *Clericis Laicos*. The necessity to come to terms was caused above all by the insurrection against Boniface of a powerful section of the Colonna family, including two cardinals, culminating in the armed robbery of a large amount of papal treasure in May 1297. A year of military action against the Colonna followed, which ended with their unconditional surrender. They were absolved from excommunication but not reinstated in their offices and possessions; they therefore rebelled again and fled; some of them went to Philip, with whom they had conspired perhaps even before the issue of *Clericis Laicos*.

Boniface's first conflict with the French king was followed by an apparent reconciliation, which was emphasized by the pope's canonization of Philip's holy ancestor Louis IX. A second conflict, which broke out in 1301 around the trumped-up charges against a southern French bishop' Bernard Saisset of Pamiers and his summary trial and imprisonment, proved to be irreconcilable, because now the king threatened and meant to destroy one of the most fundamental gains which the papacy had made and maintained in the great struggles of the last two centuries: the substitution of the pope for the ruler in the control of the clergy. The pope could not compromise here, and in the bull *Ausculta Fili* he sharply rebuked Philip and demanded amends, especially the release of the bishop, who had appealed to Rome. Instead, the king's chancellor Pierre Flotte was allowed to circulate a distorted extract of that bull and thus to prepare public opinion for the great assembly of the estates-general of France in April 1302, in which nobles and burghers enthusiastically and the clergy reluctantly supported the king.

Nevertheless the pope seemed to have good reason to hope for a' favourable termination of the conflict, since Philip's army was shortly afterward disastrously defeated by the Flemish townspeople and since the German king and prospective emperor Albert I of Habsburg was ready to give up his French alliance if the pope would recognize the contested legitimacy of his rule. This recognition was granted early in 1303 in terms which exalted the ideal and traditional, though none too often realized, harmonious relationship between the papacy and the Holy Roman empire. This empire now was said by the pope to possess under ultimate papal supremacy an overlordship over all other kingdoms including France. Already in Nov. 1302 Boniface had issued an even more fundamental declaration concerning the position of the papacy in the Christian world, the famous bull *Unam Sanctum*, which of all papal documents of the middle ages has become the most widely known because of its allegedly radical and extreme formulation of the content of the papal office. The bull as a whole is indeed a very strong but not a novel invocation of the supremacy of the spiritual over the temporal power. At the same time the old Gelasian doctrine that both powers are from God is clearly stated, and in the final dogmatic sentence the pope speaks no longer of the temporal power but of the human creature as the object of papal plenitude of power, submission to which in this sense only is said to be necessary to salvation.

Meanwhile in France, Guillaume de Nogaret had taken Flotte's place as the leader of a violently antipapal royal policy in which Philip was confirmed by other enemies of the pope. One of these was the legate whom Boniface had dispatched to France in these critical months and who betrayed his master, the French cardinal Jean Lemoine (Johannes Monachus). Many unjustified accusations against Boniface, ranging from unlawful entry into the papal office to heresy, were raised against him at a secret meeting of the king and his advisers held in the Louvre at Paris; these accusations were to be taken up and elaborated upon later during the posthumous trial against the pope pursued by Philip IV. Shortly after the Louvre meeting, at which Nogaret had demanded the pope's condemnation by a general council of the church, Nogaret went to Italy to stir up, if possible, rebellion against the pope. Unsuccessful in this respect and attempting to forestall publication of a new papal bull announcing Philip's excommunication, h'ogaret, with the assistance of Sciarra Colonna and the connivance of some of the cardinals, decided to capture the pope at Anagni. In this he succeeded through the momentary complicity of the local leaders of the city of Anagni, who, however, changed their minds after two days, rescued the pope and thus frustrated whatever further plans Nogaret may have had. During these two days Boniface. whom Sciarra Colonna would have killed but for h'ogaret's wish to drag the pope before a council, was probably physically ill-treated. He bore everything with great courage and with the patience and resignation of Job, whose pertinent words (Job i, 21) he quoted. Boniface returned to Rome physically and mentally broken and died soon thereafter. (See also NOGARET, GUILLAUME DE)

Among the lasting achievements of his turbulent pontificate were the publication of the third part of the *Corpus Juris Canonici*, the so-called *Liber Sextus* (see CANON LAW), and the institution of the Jubilee of 1300, which was the first Holy Year. The event was commemorated in a painting by Giotto in the Lateran, a fragment of which still survives in the Basilica of San Giovanni in Laterano. Boniface VIII was a figure of some importance in the revival of the arts in the age of Dante and Giotto. His sepulchre came from the workshop of Arnolfo di Cambio; the tumba with his reclining statue in the Vatican grottoes and a bust in the Museo Petriano may still be seen. Of the numerous

memorial statues erected by himself or others in his honour, and later used by his enemies to brand him as an idolater, several still survive. They are visual evidence for the fact, known also from other sources. that Boniface VIII, who extended the height of the papal tiara (*q.v.*) to one ell, the scriptural unit-measure of the ark of Noah, symbol of the unity of the church, also increased the number of crowns which circle the tiara from one at least to two and perhaps to three, which is their number in modern times.

BONIFACE IX (Pietro Tomacelli) (1355–1404), pope from Nov. 2. 1389 to Oct. 1, 1404, was born at Naples. He viewed the schism of 1378 as a political problem and resorted to all possible means to raise money in order to win allies against the Avignon popes but failed to end the breach.

See P. Hughes, *History of the Popes,* vol. iii (1947). (J. A. CT.)

BONIFACE OF SAVOY (d. 1270), archbishop of Canterbury, sixth son of Thomas I, count of Savoy, was one of several Savoyards who reached high office in England through the influence of Boniface's niece, Eleanor of Provence, queen of Henry III. Elected archbishop of Canterbury in 1241 while still a subdeacon, he went to England only in April 1244. After seven months he returned to the papal court at Lyons, took priest's orders and was consecrated archbishop by Innocent IV (Jan. 15, 1245), remaining at Lyons until 1249. Soldier, diplomat and administrator, but neither canonist nor theologian, this alien prince-bishop, though usually considered a mere royal creature, proved an exceptionally powerful archbishop. He tamed the aggressive independence of the Canterbury chapter; he reformed archiepiscopal finance and cleared his see of debt; he reduced the dependent see of Rochester to complete subordination; he fully enforced his metropolitan rights over all suffragan dioceses. Though he united the entire English clergy to resist Henry's demands for money and to defend ecclesiastical jurisdiction from royal encroachment (1256–59), he also used his great influence at Rome unwaveringly to support Henry III in his disputes with the barons (1258–65). He died in Savoy on July 18, 1270. (R. F. T.)

BONIFACIO, a town in Corsica, an island *département* of France, lies 2 mi. W. of Cape Pertusato, the southernmost point of the island, and gives its name to the strait between Corsica and Sardinia. It is situated high above the sea on a narrow limestone peninsula about 1 mi. long, which parallels the coast and forms a natural harbour. Pop. (1954) 1,895. Said to have been founded about A.D. 828 as a defense against pirates, the town was seized from Pisa by the Genoese near the end of the 12th century, and in 1420 repelled a siege by Alphonso V of Aragon. Captured by the French and Turks in 1554 it was restored to Genoa by the treaty of Cateau-Cambrésis (1559). The customs of the inhabitants differed from those of the other Corsicans, the vendetta being unknown, and a Genoese dialect still is spoken. The churches of St. Dominique (built by the Templars in the 13th century) and Ste. Marie Majeure (12th century) are the most interesting buildings. There is no railway, but a main road runs northwest to Ajaccio and another up the east coast to Bastia. Trade is chiefly with Sardinia, in cereals, wine and cork. There are olive groves nearby and oil and cork works in the town.

BONIFACIUS (d. A.D. 432), Roman general and governor of the province of Africa (425–431), first became famous for his defense of Marseilles against the Goths led by Ataulphus (*q.v.*) in A.D. 413. He commanded troops illegally in Africa from 422 to 425; his position was then legalized but when recalled to court in 427 he refused to leave Africa. He was widely believed to have invited the Vandals to Africa in 429 in order to repel the attacks of the imperial forces. Unable to withstand their advance under Gaiseric (*q.v.*), he became reconciled to the empress Placidia. Appointed *magister militum* (master of the soldiers) to suppress Aetius (*q.v.*), he defeated him at Rimini in 432, but received a wound from which he died three months later. He was a correspondent of St. Augustine of Hippo. (E. A. T.)

BONIFAZIO VERONESE (BONIFAZIO VENEZIANO, BONIFAZIO DE' PITATI) (1487–1553), Venetian painter, a secondary artist working under the shadow of his great Venetian contemporaries, was born in Verona in 1487 and migrated to Venice, where he worked until his death on Oct. 19, 1553. He appears to have been a pupil of Palma Vecchio, and Palma's influence is the dominant factor in his only signed and dated work, a "Virgin and Child With SS. Omobono, Barbara and John the Baptist" (1533), in the Palazzo Reale, Venice. Bonifazio's most celebrated uorks are a series executed for the Palazzo Camerlenghi, now in the Accademia at Venice, of which the earliest, a "Christ Enthroned With SS. Mark, Justina and Three Donors," dates from 1530, and the latest, an "Annunciation," from about 1544. Bonifazio is distinguished by a certain coloristic opulence, which lends interest to his loose-knit compositions and static, rather flaccid forms. Jacopo Bassano was his pupil.

See D. Westphal, *Bonifazio Veronese* (1931). (J. W. P-H)

BONINGTON, RICHARD PARKES (1802–1828), English romantic painter of bright landscapes and history pieces, was born at Arnold near Nottingham, on Oct. 25, 1802. He was the son of a financially unreliable drawing master and a schoolmistress. who implanted in the boy a sense of history and a love for its décor that later dominated his art.

He exercised an influence out of all proportion to his brief life, of which the principal events corresponded with the rapid development and variation of his style. In Calais. France, where the father hoped to set up in the lace trade (c. 1817), Louis Francia taught the boy the Girtin tradition of water colour, which he himself had learned when a refugee in England. Against the father's wishes, he gave Bonington letters to friends, uhich took him to Paris with an introduction to young Eugène Delacroix. The two met accidentally in the Louvre, where, contrary to contemporary practice, Bonington was copying Dutch and Flemish rather than Italian masters. The two became friends and, encouraged by Théodore Géricault, undertook the study of Rubens, thus preparing themselves for John Constable's influence and laying the foundation of the new French school.

Bonington entered the École des Beaux-Arts (1819) and joined the atelier of Baron Gros. who had departed from David's rigid classicism (1820). His bright water colours, a novelty in Paris, financed sketching tours in Normandy. Picardy and Flanders (1821–23). He showed at the Salon in 1822 and at the famous Salon of 1824 with Constable, Sir Thomas Lawrence and others, where he won a gold medal. With Delacroix he studied Constable at dealers' exhibitions in Paris, and together they went to England (1825), where Bonington learned something of Turner's skill. More important, both were affected by the English fashion for painting scenes from history.

This new interest engrossed Bonington; he took immense pains to achieve accuracy, drawing details of armour, costume and furniture. although he did not abandon landscape, as the results of his journey to Venice (1826) show. In his subsequent historical pictures, he evolved in oil a new synthesis of Flemish and Venetian techniques. He strengthened his water colours by adding gum according to the new English practice. He showed in London (British institution, 1826, and Royal Academy, 1828), winning immediate popularity. He visited Lawrence in London in 1827 and died on a third visit to England on Sept. 23, 1828, from tuberculosis, death being hastened by heatstroke.

As a master of the romantic movement, as a technical innovator in oil and water colour, Bonington's influence was marked in England and France; he had many imitators, being the natural interpreter of romance in painting to both nations. His gifts as a draftsman were very high; as a colourist. good. He also showed his talent in the new medium of lithography, inevitably illustrating Sir Walter Scott.

Among his most familiar works are the "Coast Scene, Picardy" and "Henri IV and the Spanish Ambassador" (Wallace collection,

London); "Francis I and the Duchesse d'etampes" and "View of Venice" (Louvre). He may be best studied at the Wallace collection and the Louvre; good examples are in the national galleries of England. Scotland and Canada; in the Castle museum. Nottingham; and (for drawings) in the print room of the British museum.

BONIN ISLANDS (OGASAWARA-GUNTŌ) comprise four major island groups, roughly 40 sq.mi. in land surface area, lying about 500 mi. S.E. of the Japanese mainland. Pop. (1940) 7,361; in 1958 only one island was inhabited, pop. 190. The group includes Parry, Beechey, Bailey, Volcano and Marcus islands. The first three are part of Bonin Islands proper (area 28 sq.mi.), but Volcano Islands (*q.v.*) and Marcus Island are placed within the group for administrative purposes. The whole group is termed Bonin Volcano Islands. The principal island is Peel Island (Chichi-shima) with good deep-water anchorage at Futami-byōchi, but the most famous is Iwo Jima (*q.v.*).

The Bonin Islands form part of an outer festoon which stretches from the central volcanic zone of Japan through the Volcano, Mariana, Mackenzie, Yap and Palau islands to the Moluccas and which, originating in the latter stages of the "alpine" fold movements, is still unstable. The northern end of the arc passes into central Honshū, that part of Japan where earthquakes are most frequent, and in the Bonin group tiny islands appear and disappear. The arc has an important strategic position with regard to the Pacific approaches of the far east.

Although known to several explorers, each of whom gave the group a different name, these islands, conventionally called Bonin, were not permanently settled until 1830. The term "Bonin" is a corruption of the Japanese *Munin* meaning "empty of men," but the Japanese themselves term them "Ogasawara-guntō" after Ogasawara, who allegedly discovered them in 1593. Vague claims by Great Britain and the United States were not pursued, and Japan formally annexed them in 1876. Only about 11% of the total area is good arable land, the remainder being hilly and forest covered. The valuable timber includes cedar, rosewood, ironwood, boxnood, sandal and white oak. Whaling by small factory ships is conducted offshore.

After World War II the Bonin Islands were placed under U.S. military administration along with the Volcano Islands (Kazan-rettō).

BONITO, a name applied to three fishes of the mackerel family (Scombridae). The Atlantic bonito (Sarda sarda) is abundant in the Mediterranean and the warmer parts of the Atlantic ocean. The Pacific bonito (Sarda *chiliensis*) lives in the Indo-Pacific area. The striped bonito (Sarda *orientalis*) is world-wide in warm oceanic waters. Bonitos are found in nontropical waters during the summer. They are similar in form to the bluefin tuna (see TUNNY), but are a smaller fish, not exceeding 30 in. in length. The color is steel blue above, silvery below, with numerous narrow dark stripes. Bonito congregate in large schools. They will readily take bait trolled from a moving boat and are good sport. Bonito are very good eating and of considerable economic importance in tropical areas. (C. Hu.)

BONIVARD, FRANÇOIS (1496?–1570), Genevan patriot, the hero of Lord Byron's poem "The Prisoner of Chillon," was born at Seyssel in Savoy, the son of Louis Bonivard, seigneur de Lompnes. His real character and history are widely different from the legendary account that Byron popularized. Having succeeded his uncle as prior of the Cluniac priory of St. Victor, close to Geneva, he began to oppose the encroachments that Charles III, duke of Savoy, and his kinsman the bishop of Geneva were making against that city's liberties. He was imprisoned by the duke at Gex from 1519 to 1521, lost his priory and became more and more anti-Savoyard. In 1528, supported by the city of Geneva, he took up arms against those who had seized his ecclesiastical revenues, but in 1530 he was again seized by the duke and imprisoned in the castle of Chillon, where he was kept underground from 1532 until the Bernese released him in 1536. Becoming a Protestant, he obtained a pension from Geneva and was married four times In 1542 he began compiling his *Chroniques* de *Genève,* a history of Geneva from the earliest times. His manuscript was submitted to Calvin for correction in 1551 but was not published until 1831 (ed. by D. Dunant). The best edition is that of 1867. Bonivard also wrote De l'ancienne et nouvelle *police* de *Genève* (1555).

BONN, a city of Germany which after partition of the nation following World War II became the capital of the Federal Republic of Germany. A university city and Beethoven's birthplace, Bonn lies on the left bank of the Rhine. 24 km. (15 mi.) S. of Cologne, in North Rhine-Westphalia. Pop. (1959) 146,216. The river is crossed by the bridge to Beuel, built in 1949, and is flanked by an embankment 4 km. (23 mi.) long, on the south side of which is the Parliament house. In the Koblenzerstrasse — parallel to the embankment — there are the buildings of several ministries, schools and hotels, the seats of the federal president and chancellor, and the well-known Alexander Koenig Zoological museum.

The central part of the city, with its narrow streets, contains the Münster (cathedral), built of gray stone in romanesque and Transitional styles (12th and 13th centuries). It is surmounted by five towers of which the central (315 ft. high) is a landmark in the Rhine valley. The Remigius church dates from 1295–1317 and the town hall on the market square from 1737. There Kinkel and his pupil Carl Schurz began the liberal revolt in the 1848 revolutions. The finest building is the university, founded in 1786 by the archbishops of Cologne; originally the electoral palace, it was built about 1717 out of the materials of the old fortifications. The university. suppressed in 1794, was refounded in 1818 as the Rheinische Friedrich Wilhelms university. The botanic garden surrounds the Poppelsdorf palace (1715–30) used by the university. The observatory, long under the charge of Friedrich Wilhelm August Argelander (*q.v.*), stands on the south side of the avenue. A new observatory with a radio telescope has been built on the Stockert near Euskirchen (18 mi.). The Rheinische Landesmuseum contains a valuable collection of Roman and Frankish relics as well as the cranium of the Neanderthal man. On the Kreuzberg, above the suburb of Poppelsdorf, is a 17th-century church and Franciscan monastery, approached by a flight of "holy steps." in imitation of those at Rome. A tower, the Alte Zoll, commanding a magnificent view of the Siebengebirge, is all that remains of the old fortifications and customhouses. A statue of Beethoven was erected in the Miinsterplatz in 1845 and in 1889 a Beethoven museum was opened in the house where he was born. This was badly damaged in 1960 after it had been set on fire by a lunatic.

During World War II the old part of the town was severely damaged; the university, which had been remodeled early in the 19th century, was damaged by fire in 1944 and rebuilt after the war, and the old bridge was blown up in 1945. Notable features of the postwar town are the modern university clinics on the Venusberg, the theatre and the municipal concerts, including an annual Beethoven festival. The original Beethoven hall was destroyed, but a new one was completed in Sept. 1959. Other places of interest are the Arndt Memorial room and folklore exhibition in the Arndt house; the town hall gallery, where modern west German paintings and graphic arts are shown and where alternately there are exhibitions of old and modern masters; and the old cemetery near the centre of the town which contains the graves of many famous men and women.

Bonn is on the main line from the Ruhr and Cologne to Mainz and Basel. The railway along the right bank of the Rhine, from the Ruhr to Frankfurt, passes Beuel opposite Bonn. International trains to many parts of Europe call at Bonn. Long-distance buses connect Bonn with the tourist areas of western Germany as well as with Brussels and Amsterdam. Wahn airport (7 mi. N.) is shared by Bonn and Cologne. Rhine steamers ply between Bonn, Cologne and Mainz.

As the federal capital Bonn is the headquarters of many industrial, professional and economic associations and of the German Industrial and Commercial association. The chief manufactures are stationery, office furniture, light metal goods, stoneware, ciga-

rettes, adhesive plasters and flags; there are also important printing works, publishing houses and insurance companies.

Bonn (Bonna or Castra Bonnensia), a Roman military settlement, was the scene, in AD. 70, of a defeat of the Romans by the Batavi. Greatly reduced by successive barbarian invasions, it was restored about 359 by the emperor Julian. In the centuries that followed the breakup of the Roman empire it again suffered. and was finally devastated in 889 by bands of Norman raiders. Fortified again in the 13th century, from 1267 to 1794 it was the residence of the electors of Cologne. During the various wars of the 16th, 17th and 18th centuries, the town was frequently besieged. Occupied by the French after 1794, it was given to Prussia in 1815 by the congress of Vienna. In World War II it was captured by Allied forces in March 1945. Bonn was made capital of the Federal Republic of Germany in 1949.

BONNARD, PIERRE (1867–1947), French painter, book illustrator, lithographer and etcher, and a leader of the modern French Intimiste school of painting, was born on Oct. 3, 1867, at Fontenayaux-Roses, near Paris. He began law studies about 1885, but spent much of his time at the Académie Julian, where he met Jean Édouard Vuillard (a lifelong friend), Maurice Denis, Paul Ranson and Paul Sérusier, all of whom formed the "Nabis" group (Hebrew *Nebiim*, "prophets"). He worked for a year at the Paris Bcole des Beaux-Arts (1888), and in 1889, after he had sold a champagne poster design, his father allowed him to begin serious training. Japanese art and the precepts of Paul Gauguin then preoccupied him; his work was characterized by flat, black-outlined areas of warm, decorative colour and simplified forms. Humour, allied with keen observation of Parisian life, distinguished his exhibits at the Salon des Indépendants and his illustrations to *La Revue blanche* from 1891. He designed décor for the Théâtre d'Art, and in 1896 Durand-Ruel gave him his first one-man show. In 1895 Ambroise Vollard published the first of many volumes of lithographs, for which Bonnard did *Quelques Aspects de la vie de Paris,* and Bernheim-Jeune became the artist's chief dealer in 1898–99. By 1900, Bonnard's style changed; his palette became gayer, his brushwork looser and more transparent. He turned oftener to landscapes and spent long summers in the Seine valley and southern France. Bonnard liked to paint warm, sunlit domestic interiors, simple, yet radiating a sense of serene well-being. His compositions, often apparently so casually constructed, were always done from memory aided by the scantiest colour notes. Essentially modest and retiring, his death at Le Cannet, on Jan. 23, 1947, passed almost unnoticed.

See John Rewald, *Pierre Bonnard* (1948); Musée National d'Art Moderne, *Bonnard, Vuillard et les Nabis, 1888–1903* (1955).

(D. L. FR.)

BONNAT, LÉON JOSEPH FLORENTIN (1833–1922), French painter best known as a portrait painter and teacher in the French academic tradition, was born at Bayonne on June 20, 1833. He studied under Federico Madrazo at Madrid, and under Léon Cogniet in Paris. His earlier works were genre and historical paintings in which his study of old Spanish art was evident. The long series of characteristic portraits began in 1875. In these he drew inspiration from Velázquez and the Spanish realists. He painted Thiers, Victor Hugo, Carnot, Taine, Pasteur and other contemporaries, about 200 in all, the finest of these being perhaps the portrait of Cogniet in the Luxembourg. In 1888 he became professor of painting at the École des Beaux-Arts, and in 1905 director. He died on Sept. 8, 1922.

BONNER (BOXER), **EDMUND** (c. 1500–1569), bishop of London, has commonly been regarded as a notorious example of a persecuting Catholic bishop in the reign of Mary Tudor. Violent abuse, however, had been directed against the bishop before there was any Marian persecution of Protestants, by the virulent pen of John Bale, bishop of Ossory. Another contemporary, the Protestant martyrologist John Foxe, continued this vituperation of Bonner, so effectively indeed that Bale's denunciation of him as "bloody bishop Bonner" has persisted through the centuries and prejudiced most historians against him.

Bonner was an outstanding Oxford lawyer who served Henry VIII on various foreign embassies. He accepted from Henry first the bishopric of Hereford and later that of London, and promoted Henry's ecclesiastical adventures. He opposed, however, the advancing Protestantism of Edward VI's reign and spent most of this period in prison, being deprived of his London bishopric. Restored to his see on Mary's accession, he devoted himself to the affairs of his diocese, the importance of which made him an outstanding figure in that persecution of Protestants which marked Mary's reign. Bonner's reluctance to intensify the persecution in London, however, brought him a rebuke from Mary's government. Again deprived of his bishopric on his refusal to take the oath of supremacy at the beginning of the reign of Elizabeth I, he spent the last ten years of his life a prisoner in the Marshalsea and died there or Sept. 5, 1569.

BONNET, CHARLES (1720–1793), Swiss naturalist and philosophical writer, famous for his discovery of parthenogenesis in aphids, was born at Geneva on March 13, 1720, of a wealthy French family. He made law his profession, but his favourite pursuit was the study of natural science. In 1740 his paper to the Académie des Sciences containing a series of experiments establishing what is now termed parthenogenesis in aphids or plant lice obtained for him the honour of being admitted a corresponding member of the academy.

He began in 1741 to study reproduction by fusion and the regeneration of lost parts in the fresh-water hydra and other animals; and in the following year he discovered that the respiration of caterpillars and butterflies is performed by pores, to which the name of stigmata has since been given. Bonnet was admitted a fellow of the Royal society in 1743, the same year in which he became a doctor of laws.

In 1745 appeared his *Traitk d'insectologie,* and nine years later his *Recherches sur l'usage des feuilles dans les plantes,* in which he suggests that plants possess powers of sensation and discernment. Bonnet considered that the most important function of leaves is to absorb, by their undersurface, dew that arises from the soil.

He was for many years regarded as an authority on the nutrition of plants. but his experiments and the conclusions he drew from them are more interesting historically than important scientifically.

The threatened failure of Bonnet's eyesight caused him to turn to philosophy. His *Essai de psychologie* was published (1754) anonymously in London and was followed by the *Essai analytique sur les facultés de l'âme* (1760), in which he develops his views regarding the physiological conditions of mental activity. He returned to physical science, but to the speculative side of it. in his *Considérations sur les corps organists* (1762), designed to refute the theory of epigenesis, and to defend the doctrine of pre-existent germs (particles created by the Divine Being and having an inherent power of self-development). In his *Contemplation de la nature* (1764–65) he sets forth the hierarchy of all creatures, and in his *Palingénésie philosophique* (1769–70) he treats of the past and future of living beings, and supports the idea of the immortality of all forms of existence.

Bonnet's life was yneventful, and he seems never to have left Switzerland. Between 1752 and 1768 he was a member of the Great council in Geneva. He died at Genthod, near Geneva, on May 20, 1793.

BONNET, GEORGES ETIENNE (1889–), French statesman nho played a leading part in the appeasement of Nazi Germany, was born at Bassillac, Dordogne, on July 23. 1889, and graduated in the faculty of law, Paris, and from the École Libre des Sciences Politiques. He was a Radical deputy for Dordogne from 1924 to 1928 and from 1929 to 1940. In the more progressive of the cabinets of 1925–26 and 1930–36 he held ministries responsible for financial, economic or social affairs. Increasing association with important banking and industrial interests caused him to move to the right, and he was regarded as another Raymond Poincaré who might save the franc. Under Léon Blum he was

ambassador to the United States for six months in 1937, but British influence thwarted hopes that he might negotiate a separate settlement of the French war debts. After serving Camille Chautemps as a critical finance minister, he was prevented by Radical and Socialist hostility from forming a government.

Bonnet became foreign minister under Édouard Daladier in 1938 and vigorously practised the appeasement of Germany. He was so hostile to the declaration of war in 1939 that he almost caused a breakdown in Anglo-French relations. Instead of resigning he went to the ministry of justice. He worked in favour of the French armistice of 1940, supported the Vichy regime, associated with extreme collaborators and was appointed to the national council. Yet he refused other office and left France before the Allied invasion. This ambiguous attitude saved him after the iiberation, when proceedings were started against him but dropped. Expelled from the Radical party in 1944, he yet retained the support of his local federation and was readmitted in 1352, but was expelled again in 1955 for his opposition to Pierre Mendès-France. Bonnet's postwar influence was small, although he was elected a deputy in 1956 and 1958. He published books on jurisprudence, public finance and politics. (P. W. C.)

BONNET, a cap or covering for the head; usually one kept in place by ribbons or a string tied under the chin.

The name is from the coarse medieval cloth called bonnet derived from the Hindu *banat,* from which hats or hoods were made in the 14th century. From that time the bonnet was worn with many variations in style. It reached its greatest size during the last half of the 18th century, when it was worn over the elaborately dressed wigs then fashionable for women. It was the most popular type of head dress of the 19th century, when it assumed varying shapes with descriptive names such as the cabriolet bonnet, the coat scuitle bonnet, the poke bonnet, the cottage bonnet and the scoop bonnet.

In Scotland the term applies to a brimless cap worn by men and boys. The bonnet of a ship is a supplementary sail laced to the foot of the jib in light winds. The term bonnet is applied to certain protective devices having a form or use similar to the head covering, as in a steam engine or safety lamp, or to a gambler's or auctioneer's decoy. A common British use of the word is for the metal covering over the engine of an automobile.

(M. B. K.)

BONNEVILLE, BENJAMIN LOUIS EULALIE DE (1796–1878), American military engineer and frontiersman, who increased the knowledge of the Rocky mountains, was born in or near Paris on April 14, 1796. His father was the friend of La Fayette, Condorcet and Thomas Paine, and in 1803 Mme Bonneville and the children followed Paine to the United States. Their father, detained for political reasons, joined them later. He graduated from. the U.S. Military academy at West Point, N.Y., in 1815 and his lifelong association with the frontier began with his assigninent to Fort Smith, Ark., in 1821. In 1832 he obtained leave of absence from the army for purposes of exploration and spent four years based on the Green river in Wyoming, establishing himself as a fur trader. Washington Irving edited his journals published in 1837 *(The Adventures of Captain Bonneville, U.S.A., in the Rocky Mountains and the Far West).* Dismissed from the army for overstaying his leave, he was reinstated and served in the Mexican War, was brevetted brigadier-general in 1865, retired in 1866, and died at Fort Smith on June 12, 1878. He was acclaimed at one time as a notable explorer, but later estimates do not credit Bonneville with important discoveries; H. M. Chittenden *(American Fur Trade of the Far West,* 1902) differs from Washington Irving and regards Bonneville as more interested in trade than in discovery. He was, however, a skilful commander and treated the Indians he encountered humanely. (D. MN.)

BONOMI, IVANOE (1873–1951), Italian statesman, premier (1921–22 and 1944–45) and leading anti-Fascist in World War II, was born in Mantua on Oct. 18, 1873. He entered parliament in 1909 as the Socialist deputy for Mantua but was expelled from the party in 1912 with Bissolati-Bergamaschi and joined the Reformist Socialist group. He served as a volunteer during World War I, and in 1920 as war minister in the government of Giolitti, he was a negotiator of the treaty of Rapallo between Italy and Yugoslavia. Bonomi was made prime minister in 1921 but was unable to control Fascist and Socialist excesses and resigned in Feb. 1922. He retired from politics until 1940 when he joined the anti-Fascist movement, becoming its leader in 1942. After Mussolini's fall on July 25, 1943, he headed the national committee of anti-Fascist groups and on the liberation of Rome on June 9, 1944, he was designated premier by the national committee of liberation of which he had also been president. The committee, however, began to press for a more vigorous policy and Bonomi resigned on Nov. 26, 1944, only to be reinstated through the intervention of the British government.

Bonomi laid the foundations of Italy's economic and administrative reconstruction and began the reorganization of the army. On June 12, 1445, he resigned in favour of Ferruccio Parri, but as chairman of the constituent assembly's committee for treaties he took part in the council of foreign ministers at Paris in 1946. He was president of the senate from 1948 until his death, in Rome, on April 20, 1951. (N. S. J.)

BONONCINI (BUONONCINI), **GIOVANNI BATTISTA** (1670– *c.* 1750). Italian composer, chiefly remembered as Handel's rival in England, was born at Modena, July 18, 1670, and studied with his father, the composer and theoretician Giovanni Maria Bononcini, and later under Giovanni Paolo Colonna at Bologna. He showed precocious musical gifts, obtaining his first appointment (as a cellistj in 1687, and soon becoming *maestro di cappella* of San Giovanni in Monte. By 1691 he had published eight sets of works, mainly instrumental music. But it was chiefly as an operatic composer that he was to be known. He moved to Rome about 1692 and in 1699, after a brief period in Venice, settled in Vienna with his brother, the composer Antonio Maria. He was appointed court composer the next year and remained at Vienna until 1711, when he probably returned to Italy.

In 1720 he was invited to London by the new operatic organization, the Royal Academy of Music. The stories of his rivalry with Handel, and their backing by opposed political and social factions, are well known. Eight of his operas were produced in London, the most successful being *Astarto, Crispo* and *Griselda.* Other compositions oi this period include an anthem on the death (1722) of the duke of Marlborough (whose family favoured Bononcini) as well as harpsichord and chamber music. Re left England in disgrace in the early 1730s and went to Paris after submitting, to the Academy of Ancient Music, as his own composition, a madrigal actually written by Antonio Lotti. His last known work, a *Te Deum,* was written in Vienna in the 1740s, and it is likely that he died in obscurity there or in Italy about 1750.

Though he was a prolific and gifted composer, Bononcini's abilities are naturally dwarfed by comparison with Handel's. Only in opera, where both used the same, highly conventionalized idiom, are the two men comparable; Bononcini may not have possessed Handel's orchestral or contrapuntal techniques nor his gifts of musical characterization, but his simple and fluent melodic style and his ability to write well for his singers at least partly compensated. In other fields, Bononcini is a competent and typical Italian composer of the period of Vivaldi and Albinoni.

(S. J. SA.)

BONONIA: *see* BOLOGNA.

BONPORTI, FRANCESCO ANTONIO (1672–1749), Italian composer, notable for his *Invenzioni,* short instrumental suites from which Bach took the title for his keyboard *Inventions.* Born at Trento and baptized there on June 11, 1672, in 1691 he went to Rome, where he studied theology and also composition. After ordination, in 1695 he returned to Trento, where for more than 40 years he held a minor position at the cathedral, meanwhile composing instrumental works that became widely known. His numerous trio-sonatas (Venice, 1696–1706), violin sonatas and concertos, and the ten *Invenzioni* (1712) show novel use of the recitative style and an unconventional handling of melody and rhythm. He hoped always for ecclesiastical preferment but was constantly disappointed, and in 1740 retired to Padua, where he died, Dec. 19, 1749.

See G. Barblan, *Un musicista trentino, F. A. Bonporti (1940).*

BON-SAI (BONSAI, BONZAI), a Japanese term that, strictly speaking, applies only to dwarf trees planted in shallow vessels. those in deeper pots being called *hachi-uye* ("pot-planted"). But both are known as bon-sai, irrespective of the vessels they grow in. The growth of the plants is controlled by pruning, fertilization, etc., so that the trees are trained into the stately shapes of ancient big trees, the vacant space in the pot suggesting plains or distant mountains. The trunk of the tree, the spread of the roots. the distribution of branches, all of which may be used to give an aged appearance to the tree, are especially important. Without showing any trace of artificiality, each tree should develop its own characteristics. The deciduous should have the dignity of age either with or without the leaves, as in nature, though in some the leaves, while in others the flowers or fruits, may constitute the main attraction, according to the season.

The bon-sai may consist of a single tree (*ippon-dachi*) either in an upright or leaning attitude; two trunks (ai-oi) growing out of a single stump or planted closely together to appear as such; groups (*yose-uye*) of similar or different kinds of trees to suggest a forest or wooded mountain side. It may also have high exposed roots (ne-agari); trees or vines drooping down (*ken-gai*) as if overhanging from a cliff; or roots growing out of and embracing a rock (*ishi-zuki*)

The pot in which the trees are planted plays an important part in the scheme, shapes and sizes being determined by the kinds of plants contained. The pots are generally plain, but some have considerable decoration in relief or in painting. They are of earthenware. with a hole in the bottom for drainage lest the roots rot, in shape round, oval, rectangular, octagonal or lobed, etc., of varying depths, and chosen to be in harmony with and in right proportion to the tree.

For centuries the Japanese have cultivated the art of dwarfing trees, using them as ornaments for rooms, and bon-sai still remains a hobby among the aristocrats as well as among the working people of Japan. See also MINIATURE LANDSCAPE.

BIBLIOGRAPHY.—C. Chidamian, *Bonsai-Miniature Trees* (1955); K. Yashiroda, *Bonsai: Japanese Miniature Trees* (1960); Y. Yoshimura and Giovanna M. Halford, *Japanese Art of Miniature Trees and Landscapes* (1958).

BONSTETTEN, KARL VIKTOR VON (1745–1832), Swiss writer in both French and German, of wide cosmopolitan interests and outlook, was born at Bern on Sept. 3, 1745. Of a conservative and patrician family, he had to resist for 12 years being forced into the traditional career of municipal magistrate. Instead he studied Horace and Rousseau, traveled abroad and cultivated friendships in the liberal intellectual circles of Geneva (1763–67. Charles Bonnet), Leiden, England (1769: Thomas Gray), France, Germany (Friedrich von Matthisson) and Italy (cf. his Voyage *sur* la *scène* des six derniers *livres* de *l'Enéide* (1805). After his return to Bern and his father's death (1773), he at last entered provincial politics. He became the enlightened administrator. first of Saanen (1779; cf. Briefe uber ein *schweizerisches* Hirtenland, 1781), then of Nyon (1787), and finally, a judge in the canton of Ticino (1795–97; cf. "Briefe über die ennetbirgischen Vogteien," in Neue Schriften, 4 vol., 1799–1801). After the French invasion and the collapse of the *ancien régime* in 1798, he became a happy emigrant, spending three years with Friederike Brun and her friends in Denmark (cf. La Scandinavie et les *Alpes,* 1826) before settling in Geneva. His charm and cosmopolitan temperament made him an outstanding member of the international elite there and are revealed in his wide correspondence (Briefe an *Matthisson,* ed. by H. H. Fiissli, 1827; Briefe an F. Brun, ed. by F. von Matthisson, 1829; H. Zschokke, Briefwechsel *mit* Bonstetten, 1832), and in various books, forerunners of modern comparative studies of national characteristics. The best is his excellent *L'Homme* du midi et *l'homme* du nord, ou *l'influence* des climats (1824; Eng. trans. 1864). These surpass his philosophical works (*Pensées sur* divers *objets* de bien public, 1815; *Études* de l'homme, 1821; etc.). He also wrote autobiographical sketches, *Erinnerungen* an *mein Jugendleben* (1821) and Souvenirs (1832). He died at Geneva, Feb. 3, 1832.

See W. Klinke (ed.), *Karl von Bonstetten, Briefe, Jugenderinnerungen* (1945); M. *L.* Herking, *Charles Victor de Bonstetten* (1921).

(A. Bx.)

BONTEBOK, an African antelope, *Damaliscus* dorcas dorcas, of the southern districts of Cape Province, standing about 3 ft. 4 in. high at the shoulder, the hindquarters lower, and extending 4 ft. 6 in. from nose to tail, the latter being about 10 in. long. The colour is rich brown, white below, with a lighter "saddle mark" over the back; a narrow white patch extends from between the horns and widens over the face below the eyes and there is a large white patch on the rump. The horns, up to 16 in. long, are curved and lyre-shaped. It is extinct as a wild animal and about 100 are preserved in Bontebok national park, Bredasdorp, and on some nearby farms. See ANTELOPE. (L. H. M.)

BONTOK (BONTOC IGOROT), an ethnic division of the Igorot (*q.v.*) or mountain peoples of north Luzon, Philippines. Occupying 32 villages in the Chico river headwaters area, they numbered about 40.000 in the 1950s. Once feared headhunters, they are now pacified. Rice, the staple food, is grown in terraces; social structure emphasizes bilateral kin groups and village sections (ato); trial mating in girls' houses (olag) precedes marriage; and religion focuses on animal sacrifice (pigs, chickens, dogs) for omen reading.

Trade from the lowlands, Christian missions, schools and other government activities, and influences from the provincial capital at Bontoc in the centre of the area, are gradually changing old ways of life.

BONUS, a term used in business to describe payments in addition to those ordinarily received or due. The original implication was that an exceptional or gratuitous payment is involved. While many uses of the term continued to carry this implication, bonuses came to be employed most widely as an integral part of wage and commission contracts. In these contexts, bonus is used to describe a subsidiary payment contingent upon certain performance by the recipient, as opposed to the basic or regular payment rate. Because the motive underlying a bonus payment system is to provide an incentive for performance, an attempt is usually made to relate the size of the bonus to individual performance. Industrial workers may be given attendance bonuses, production bonuses, efficiency bonuses or safety bonuses. Special bonuses for salesmen and agents. payable in addition to a basic commission rate for sales over and above a certain quota, are used commonly in the field of marketing. Such selling bonuses provide not only an incentive for greater sales efforts but also serve to reduce the turnover of salesmen if the bonus is payable at less frequent intervals than the basic commission rate, and if the bonus rate itself is scaled to length of service.

The problem of achieving an equitable and easily understood system to reward individual effort and also provide sufficient inducement to the individual concerned presents the principal difficulty in establishing the bonus form of payment. When the problem cannot be solved because it is not possible to establish clearly the contribution which a single individual makes to the results of the group, the device of a group bonus is used. The total payment is linked to over-all results obtained and is divided among individuals according to a predetermined arrangement, often based on the employee's salary and length of service. Such group bonus plans are employed most widely in compensating executives, managers and office workers. A less formal use of the bonus concept, which is designed to reward workers for a successful business year, is the annual or Christmas bonus. Bonuses granted to returning war veterans provide yet another example of the use of the bonus idea to express appreciation to members of a large group.

In the world of finance, the generic term bonus has been supplanted to a great extent by more specific terms, especially in the United States. It has become common practice for corporations to pay a regular conservatively computed quarterly dividend to holders of stock and to supplement these payments with a bonus payment, called an extra dividend, at the end of the fiscal year. This

practice enables a corporation to adjust total dividends to a possible decline in earnings by discontinuing the bonus payment while maintaining the regular rate. Mutual life insurance companies likenise establish their premium computations on a conservative basis and, at the end of the accounting period, refund the overpayments of premiums to policyholders as a bonus or dividend payment. Use is also made of bonuses to facilitate the sale of bonds, debentures and preferred stock. These bonuses can take the form of shares of common stock given to purchasers of the senior security which is being marketed; or, as is more usual today, such purchasers are given an option to purchase common stock at a set favourable price within a certain time, in the form of stock purchase warrants. BOOK. Any discussion of books must, because of the complexity of the subject, be many sided to include the major facets that embrace origins, preparation and production as well as the multitude of associated interests that comprise the over-all picture. Books have content, and a study of the character and purpose of content is one obvious approach to them. Much social and historical analysis. broad literary criticism and systematic bibliography have dealt with the content of books. Books also have physical form. Interest in this aspect of books focuses on the materials from which they are made. their format, their script or typography and their illustration and decoration. The form of the book is the field of study of such specialized scholars as papyrologists, paleographers. art historians and analytical bibliographers. Finally. books are made and distributed to people. The investigation of this process is the province of the history of printing and publishing, the history of libraries, enumerative bibliography and textual criticism. In recent years surveys of reading and reading interests extended this study to the ultimate destination of the book in the hands of the reader. Thus there are many fields of specialization which are concerned with the subject of books. They are treated elsenhere in this encyclopaedia, but no one of them alone presents a discussion of the ways in which the contents, the form, the making. distribution and use of books are related to each other in the society which they serve — the subject discussed here.

After a brief introduction, which defines "book," this article is divided into the following sections and divisions:

For other specialized aspects of books see PUBLISHING; PAPYROLOGY; CALLIGRAPHY; PALAEOGRAPHY; WRITING; ILLUMINATED MANUSCRIPTS; LIBRARIES; PRINTING; PRINTING TYPE; TYPOGRAPHY; WOODCUT AND WOOD ENGRAVING; ENGRAVING, LINE; BOOKBINDING; BOOKSELLING; BOOK COLLECTING; LITHOGRAPH; BIBLIOGRAPHY; READING; TEXTUAL CRITICISM; CRITICISM.

The form, content and provisions for making and distributing books have varied so widely during their long history that it is necessary to look for some constant characteristics of the book in order to arrive at a definition of it. The most obvious characteristic is that a book is designed to serve as an instrument of communication. This has been the purpose of such diverse forms as the Babylonian clay tablet, the Egyptian papyrus roll, the medieval vellum codex, the printed paper codex (most familiar in modern times), the microfilm and various other combinations. The same holds true for equally great variations in content. Both Shakespeare's collected plays, first published in 1623. and the most ill-conceived and trivial tract published in that or any other year were designed as instruments of communication.

A second characteristic of the book is its use of writing or some other system of visual symbols (such as pictures or musical notation) to convey a meaning. A sophisticated medium of communication. it requires mastery of the hard-won skills of reading and writing. A third distinguishing feature is publication for tangible circulation. A temple column with a message carved on it is not a book. On the other hand, signs and placards which are easy enough to transport are made to attract the eye of the passer-by from a fixed location and are not usually considered books. Nor are private documents so considered.

A book, for the purpose of this discussion. is a written (or printed) message of considerable length. meant for public circulation and recorded on materials that are light yet durable enough to afford comparatively easy portability. Its primary purpose is to carry a message between people. depending on the twin faculties of portability and permanence. As such. the book transcends time and space to announce, to expound, and to preserve and transmit knowledge. Books have attended the preservation and dissemination of knonledge in every literate society. The following account, keeping mainly nithin the scope of civilization as it developed in western Europe and North America considers the physical book as it appeared at different times in history. the characteristic content and survivals of copies and texts, the means of production and distribution, and the society which has been served.

I. THE ORIGINS OF BOOKS

How soon men began to make books after the invention of writing is hard to ascertain because of the problem of survival of the materials on which books were made. The oldest examples of writing are on stone. The more fragile materials which at various times have been used for writing are less indestructible. The earliest known books mere the clay tablets of Mesopotamia and the papyrus rolls of Egypt. Examples of both date from the early 3rd millennium B.C.

1. Books on **Clay** Tablets. — The ancient Sumerians. Babylonians. Assyrians and Hittites wrote on tablets made from water-cleaned clay. Although these writing bricks varied in shape and dimensions. a common form was a tetrahedron about five inches long. While the clay was still wet. the writer used a stylus to inscribe it with cuneiform characters. By writing on every surface in small characters. he could copy a substantial text on a single tablet. For longer texts he used several tablets. linking them together by numbers and catchwords as is done in modern books.

Either dried in the sun or glazed in a kiln when finished. clay tablets were almost indestructible. Buried for thousands of years in the mounds of forgotten cities, they have been recovered intact in the archaeological excavations which began in the 19th century. One estimate placed the number of clay tablets recovered at 750,000. but new finds continually add to the total of survivals that

represent this book production of 2,000 years. The largest share of the survivals are private commercial documents and government archives. Of the remainder, there are many duplications in texts.

The nature and volume of the surviving records from Mesopotamia and Asia Minor indicate a heavy emphasis on the preservative function of writing and the book. A royal library was discovered in the ruins of the palace of Ashurbanipal, an Assyrian ruler of the 7th century B.C. Bricks containing texts of special value, legal codes, royal annals and epics were usually baked in a kiln for greater preservation. Reading and writing were taught in schools connected with temples, but considering the complex system of writing employed, it is doubtful whether more than a small specialized class learned to read and write.

Clay tablets and cuneiform writing went hand in hand. The script takes its modern name from the \!,edge-shaped marks made by the stylus in clay *(see* CUNEIFORM). When the Aramaic language and alphabet (*q.v.*) arose in the 6th century B.C., the clay tablet book declined because clay was not so adaptable to the Aramaic characters as papyrus was. .Although survivals date as late as 6 B.C., such late examples were the symbols of reaction rather than the products of a thriving scholarship.

2. The Egyptian Papyrus Roll. — The papyrus roll of ancient Egypt is more nearly the direct ancestor of the modern book than is the clay tablet, and it is of about equal antiquity. Papyrus (*q.v.*) as a writing material resembles paper. It was made from a reedy plant of the same name which flourished in the Nile valley. Strips of papyrus pith laid at right angles on top of each other and pasted together made cream-coloured papery sheets. Although the sheets varied in size. ordinary ones measured about five to six inches wide. The sheets were pasted together at alternate edges to make a long roll. To make a book, the scribe copied a text on the side of the sheets where the strips of pith ran horizontally (recto). and the finished product was rolled up with the text inside.

Papyrus affected the style of writing just as clay tablets had done. Scribes wrote on it with a reed pen and inks of different colours. The result could be very decorative, especially when done in the monumental hieroglyphic style of writing. a style best adapted to stone inscriptions *(see* HIEROGLYPHS). The Egyptians created two cursive hands. the hieratic (priestly) and the demotic (commercial), which were better adapted to papyrus.

Compared to bricks. papyrus is fragile. yet an example is extant from 2500 B.C.; and older stone inscriptions portray scribes with rolls. This amazing survival is partly the result of the dry climate of Egypt. in which some rolls survived unprotected for centuries while buried in the desert sands. Another reason for the preservation of Egyptian books was the Egyptians' funerary customs. Obsessed by a concern with life after death, they wrote magical formulas on coffins and on the walls of tombs to guide the dead safely to the gates of the Egyptian underworld. When the space thus provided became insufficient. they entombed papyrus rolls containing the texts. These mortuary texts are now described collectively as the *Book of the Dead,* although the Egyptians never standardized a uniform collection. Such books. when overlooked by grave robbers, survived in good condition in the tomb.

Besides mortuary texts. Egyptian survivals include scientific writings and a large number of myths. stories and tales. The train of native Egyptian scholarship was broken, however, by Alexander's conquest of Egypt in the 4th century B.C.; and the Hellenization program undertaken by the Ptolemaic kings. who ruled from the 4th to the 1st century B.C. The *Book of the Dead* was known in the early Christian era, but not long afterward the books of Egypt were closed and remained a secret until, in the 19th century, Jean François Champollion and Thomas Young deciphered the writing of the Rosetta stone.

Quotations from ancient writings show that scribes were highly regarded in ancient Egypt. They were the priests and government officials employed in the temples. pyramid complexes and the courts of the Pharaohs. Herodotus reported that Egyptian embalmers did a thriving business in copies of the *Book of the Dead.*

3. The Earliest Chinese Books. — The Chinese. though not so early in their development as the Sumerians and the Egyptians, were the third people to create an extensive bookish scholarship independently. Although few survivals antedate the Christian era, literary and archaeological evidence indicates that the Chinese had writing and probably books at least as early as 1300 B.C. Those primitive books were made of wood or bamboo 'strips bound together with cords. Many such books were burned by the Ch'in emperor Shih Huang Ti in 213 B.C. The fragility of materials and the damp climate resulted in the loss of other ancient copies.

The Chinese developed an important literature early and maintained it through an unbroken tradition of scholarship. It was the strength of the tradition which Shih Huang Ti feared when he burned the books. However, enough scholars and books escaped the edict so that a Chinese national bibliography appeared in the 1st century B.C., prepared by a corps of specialists in medicine; military science! philosophy, poetry, divination and astronomy. A classified list of works on tablets and on silk. it mentioned 677 books. With such a tradition, the survival of Chinese texts was assured by continuous copying and was not dependent on the capacity of a lone example to withstand the wear of the centuries.

II. GREEK AND ROMAN BOOKS

1. Greek Books. — The Greeks adopted the papyrus roll and passed it on to the Romans. Although both Greeks and Romans used other writing materials (waxed wooden tablets. for example) the Greek and Roman words for book show identification with the Egyptian model. Greek *biblion* ("book") can be compared with *byblos* ("papyrus"). while the Latin *volumen* ("book") signified a roll. David Diringer reached the conclusion that papyrus was continuously in use in Greece from the 6th century B.C., and cited evidence to indicate its use as early as 900 B.C. Frederic G. Kenyon argued that Homer had books in the 9th century B.C. Plato, Xenophon and Aristophanes mentioned books and their use in the 5th century B.C. The oldest extant Greek rolls, however, date from the 4th century B.C.

The 30,000 extant Greek papyri permit a generalized description of the Greek book. Rolled up. it stood about nine or ten inches high and was an inch or an inch and a half in diameter. When the book was unrolled it displayed a text written in the Greek alphabet in columns about three inches wide separated by inch-wide margins. In spite of the Greek proficiency in decorative arts, few surviving books are illustrated. Such illustrations as have survived were of the practical sort in later scientific books.

Practicality was a mark of the Greek book. The alphabet, although not invented by the Greeks. was adapted and stabilized by them as an instrument of verbal communication with little decorative purpose. Unlike the monumental Egyptian survivals in a decorative hand which sometimes exceeded 100 ft. in length. Greek rolls seldom exceeded 35 ft. in length and featured little embellishment. Such a roll was about as large as could be conveniently held in the hands to read, and it was big enough to hold a book of Thucydides (or one of the longer New Testament Gospels). The average Greek book was shorter. Two books of Homer written in a later small hand fitted a 35-ft. roll.

During the golden age of Athens in the 5th century B.C., books were known and used but were lightly regarded as avenues of learning. Grecian scholarship of the time of Socrates was concerried with that which could be observed by living witnesses; and the interest was focused in the narrow geographical sphere of the city-state. It was an age of brilliant talk based on personal observation and experience. In literature this interest brought forth great tragedies and comedies, speeches. poems, histories and lectures which stand at the beginning of occidental literary traditions; but all evidence indicates that the preferred method of publication at that time was oral. The actor, the orator, the rhapsodist and the lecturer were supreme.

Given the interests and the scope of inquiry of Periclean Greeks, it is noteworthy that they had books and read them at all. The Greek readers were general readers. Though it should not be assumed that all who lived in Athens could read, those who could included more than the narrow circle of scribes and scholars who were trained from youth to reverence books and to make a career of the difficult arts of reading and writing. The Greek alphabet reduced the difficulty, and the Greek books with their nonspe-

cialized content were practical, instruments of communication to a general public.

With the coming of Alexander the Great, the narrow peninsular outlook of the Greeks was broadened into 'a universal attitude which was reflected in their use of books. The Alexandrian kingdoms spread over the east and embraced ancient foreign cultures. The Greeks were forced to extend their interest to these alien peoples and into the records of the past. Consequently, the range of important things became too extensive for oral transmission and for the solitary speaker. In the important Hellenistic cities, most notably at Pergamum and Alexandria, centres of learning aiming at a world synthesis of knowledge grew up. (A noteworthy example of this synthesizing work was the Septuagint, which was a translation of the Hebrew Scriptures into Greek.) Libraries were a distinguishing feature of these centres. The Museum and the Serapeum at Alexandria were reputed at various times to have from 200,000 to 700,000 rolls. The Ptolemies at Alexandria pursued a vigorous collecting policy in an atlempt to acquire good copies of all important texts; and scholars were constantly at work on textual scholarship and the writing of new books, including much detail from the broadened scope of knowledge. As a result, the Alexandrian literature was characterized by the many allusions to things and events outside the popular ken. For this scholarship the book superseded the oral presentation as a primary means of publication. Greek writers referred to the market in books and to prices paid for them. The discovery of surviving papyri in the rubbish heaps of provincial towns indicates that the trade was widely diffused. The record shows that the large libraries of the Hellenistic period maintained scriptoria in which extensive copying was done. However, survivals are scanty and there is no group of extant examples which bear such close resemblance to each other as to indicate that they were the product of the same scribe or *scriptorium*. Some surviving rolls bear the mark of professional work; others are amateurish. The volume of surviving Greek texts is so slender that it arouses speculation about the nature of the large book collections of Alexandria. There are various explanations. First. the Alexandrians were doing textual criticism and required many copies of the same text to carry on the work. Second. the record indicates that the volume of Greek literature was much larger than the survivals, a majority of the texts having been lost. Literary and bibliographical references made by ancient writers and bibliographers indicate, for example, that the dramatists Aeschylus, Sophocles. Euripides and Aristophanes wrote among them about 330 plays. The survivals number 43. Nearly all of Greek lyric poetry has been lost. Many of the texts died a lingering death. Only one-fourth of those cited by Stobaeus, an anthologist of the 5th century A.D.. survived to modern times.

The survival of Greek texts depended on copying by succeeding generations. No manuscript is extant in the hand of either a Greek or Roman author, and the earliest extant copies of most works date from centuries after the composition. In such circumstances. the greatest factor in survival was the widespread and continuing popularity of a work. The centres of textual criticism fostered the preservation of some texts by establishing a canon of writings to be taught in the schools. This practice was more important than their own great librarics, because these collections were destroyed; while the widespread copying rendered books less vulnerable to local disasters. Finally, the universal interest and application of thc content was an important factor which led to the survival of some nonliterary texts through translation into Arabic, Latin and other foreign languages.

2. Roman Books.—Rome was the channel through which the Greek book, both in its original garb and in its Latin dress. was introduced to the alien peoples of western Europe. When the Romans conquered Greece they carried home Greek libraries as a foundation for similar libraries in Rome. Roman libraries had separate collections of Greek and Latin books: but except for the substitution of the Latin alphabet. a Roman papyrus roll closely resembled a Greek one in content: there was much imitation.

The Romans developed a book trade on a fairly large scale. From the time of Cicero there is evidence of large scriptoria turning out copies of books for sale. On several occasions Cicero referred to book shops; Martial complained about professional copyists who became careless in their speed; Pliny described the extensive trade in papyrus. The trade decrees of Diocletian set a price for the copying of books.

Book ownership was widespread among Romans of the upper class. Private libraries were common. and were considered the necessary badge of distinction for anyone mho aspired to high position or social importance. On the other hand, books were also within reach of less prosperous people because the use of slave labour to multiply copies kept prices relatively low. As many as 30 copies of a work might be made simultaneously by a reader dictating to slave copyists. From a comparative study of prices, Felix Reichman concluded that books were cheap enough for people with only moderate incomes to buy them.

The Roman emperors promoted public libraries, but the development in Rome differed from that in Alexandria where succeeding Ptolemies added to the ancestral establishment. There was a tendency for each of the Roman rulers to establish his own library. The Ulpian, established by Trajan, was renowned in antiquity for its scholarly collection. The Antonines appointed a procurator of libraries. Constantine made a survey which reported 28 public libraries in Rome in A.D. 300. All these public libraries in Rome and the provinces, as well as nearly all private collections, disappeared in the dissolution of the western Roman empire. With classical Latin texts. as with Greek texts, survival was dependent on an unbroken tradition of copying.

III. VELLUM AND THE CODEX

The substitution of the codex for the roll was a revolutionary change in the form of the book. The codex is the modern form of the book. Instead of having leaves fastened together on alternate edges to extend in a long strip, the codex was constructed from folded leaves bound together on one side—either the right or the left. depending on the direction of writing. (Some variant forms were bound at the top of the leaves.) The codex enjoyed several advantages over the roll. A compact pile of pages could be opened instantly to any point in the text. eliminating the cumbersome unrolling and rerolling, and facilitating the binding of many more leaves in a single book. In addition. the codex made feasible writing on both sides of the leaf; this was not practical for the roll. Because of its compactness, its ease of opening and its use of both sides of the leaf, the codex could conveniently contain longer texts. The difference can be illustrated with copies of the Bible. While the Gospel of Matthew about reached the practical limit of the roll, a common codex included the four Gospels and Acts bound together; and complete Bibles were not unknown.

The folded note tablets used by the Greeks and the Romans may have suggested the codex form, but its development to eventual supremacy was related to changes in the world of learning and in the materials for making books. The change in the scholarly outlook came from the rise of Christianity; the new material was vellum or parchment (*q.v.*). The codex is often called a Christian book in contrast to the pagan roll. It is also quite customarily called the vellum codex.

1. Vellum **and** Parchment.—Vellum and parchment are materials prepared from the skins of animals. Strictly speaking, vellum is a finer quality of parchment prepared from calf skins, but the terms have been used interchangeably since the middle ages. The forerunner of parchment as a uriting material mas leather. Egyptians referred to documents on leather as early as 2450 B.C., and a fragmentary Egyptian leather roll has been preserved from the 24th century B C.; but leather was rarely used because papyrus was plentiful. Another early people nho used leather for books were the Hebre s. The spectacular discovery of the Dead sea scrolls in the 1940s turned up collections of leather rolls stored in earthen jars in caves along the Dead sea. These liturgical and biblical books, produced by a Jewish ascetic sect, were thought by scholars to have been written near the time of Christ.

Parchment is greatly refined from leather. The skins of various animals—cattle, sheep and goats being most common—are washed and divested of hair or wool. Then the skin is stretched tight on a frame, scraped thin to remove further traces of hair and flesh,

whitened with chalk and smoothed with pumice. Tradition narrates that it was invented as the result of book-collecting rivalry between Ptolemy V of Egypt and Eumenes II of Pergamum about 190 B.C. Fearing the library at Pergamum might outstrip the collections at Alexandria, Ptolemy placed an embargo on papyrus to prevent his rival from making any more books, whereupon Eumenes made parchment. In some support of the tradition stands the fact that both Greek and Latin words for parchment mean "stuff from Pergamum."

Although parchment was used to produce book rolls, and although many early codices were on papyrus, the new writing material facilitated the success of the codex. A sheet of parchment could be cut in a size larger than a sheet of papyrus; it was flexible and durable; and it could receive writing on both sides. These qualities were important. In making a parchment or vellum codex, a large sheet was folded to form a folio of two leaves, a quaternion (quarto) of four or even an octavo of eight. Gatherings made from these foldings were then stitched together to form a book. Because papyrus was more brittle and could not be made in large enough sheets, the folio collected in quires (*i.e.*, loose sheets) was the limit of its usefulness. At the same time, because of the vertical alignment of the fibres on one side, papyrus was not well adapted for writing on both sides.

During 400 years the roll and the codex existed side by side. There were contemporary references to the codex book in the 1st century B.C.; actual survivals date from the and century A.D. In the 4th century A.D. vellum or parchment as a material and the codex as a form became dominant; although there are later examples of rolls. and papyrus was occasionally used for official documents until the 10th century. Some influence of the roll on the codex can be seen in the use of multiple columns on the pages of early codices, much like the columnar writing on the rolls.

2. Christianity and the Book.— It is a marked characteristic of book survivals from the first four centuries A.D. that codices more often contained Christian writings, while pagan works were usually written on rolls. It was after Christianity had swept the Roman empire that the codex achieved its supremacy. There were several points in the Christian use of books that contributed to a preference for vellum and the codex. First, Christianity was rooted in Judaism. which for centuries had revered sacred writings. The Christians retained the Jewish Scriptures and added some writings of their own, a New Testament which they considered even more sacred. There was strong motivation for preserving these unchanging words on the most durable materials, and vellum was more durable than papyrus. Second, in referring to their sacred writings the Christians made comparative studies of sources. The writings were related, and students liked to refer from one source to another. This reference entailed having a comparatively large volume of writings available and increased the attractiveness of the easy turning of pages possible with a codex. In this respect it is noteworthy that Roman legal scholarship, which also required a comparison of sources, likewise shoned an early preference for the codex. A third point was the expressed intention of early Christians to alienate themselves from pagan literature. The use of an entirely different form of book contributed to a sense of proper removal. At the same time the clinging of the pagan authors to an outmoded form may be ascribed in part to a conservative resistance to the Christian ideas.

Aside from the development of the codex, the Christian emphasis on books illustrates the role that the book has to play in society. In contrast with most of the many pagan religions, which were local and confined to a city or a province. the Christian religion aimed at universality. The process of Christianizing the Roman empire pursuant to this goal extended over three centuries, covered thousands of miles and embraced peoples of the most various backgrounds and individuals of the greatest differences of rank. In this process Christian scholarship produced a prolific stream of books, while the literary remains of the local pagan religions are exceedingly scarce. This difference reinforces the point made in contrasting the localized scholarship of the Periclean period with the bookishness of Alexandria. A world-wide outlook led to a greater dependence on books. Biblical texts and translations; commentaries, polemical tracts and pamphlets were important in the circumstances, not only to record belief but also to disseminate and explain it.

It has been noted that the vellum codex superseded the papyrus roll by A.D. 400. The truth is, that by the 4th century the Christian book had superseded the pagan book in every form. Little of importance was written in the classical tradition after A.D. 100. The greatest writers of the following three centuries were such Christian scholars as Origen, Pamphilus of Caesarea. Tertullian, St. Augustine and St. Jerome. Of all Christian books, however, the most numerous survivals are New Testament codices and apocryphal New Testament writings.

IV. THE MEDIEVAL BOOK

1. The Monasteries.— The dissolution of the western Roman empire during the 5th century, and the consequent dominance of marauding barbarians, threatened the existence of books. Fortunately the church withstood the assaults and remained as a stable agency which could provide the security and interest in tradition required by a bookish scholarship. Books found refuge in monasteries. The 6th-century Rule of St. Benedict enjoined monks to read books at certain times. The surrounding social chaos placed upon monasteries the responsibility for making books and creating libraries in order to implement the injunction. A more specific model was set by Cassiodorus Senator. After serving the Ostrogothic kings in high positions. Cassiodorus retired from public life in about 540 to found a monastery and establish a scriptorium at Vivarium. The scriptorium was the centre of his interest there. He supervised the copying of books and wrote guides to learning. the *Institutions* of *Divine and Human Readings*. These set forth references to laudable writers, discussed rules for editing. and suggested procedures for establishing a scriptorium and a library.

Following the early examples, monastic houses throughout the middle ages characteristically had libraries and scriptoria where they copied books to add to their collections. Arrangements for this activity varied from place to place. Occasionally the scriptorium was a single large room. Sometimes the copying was done in carrels, individual cells built in the cloister or library. Fittings for the scriptoria were spare; they lacked heat and artificial light. The labour (if contemporary complaints can be believed) was hard, for it was often said, "Two fingers hold the pen, but the whole body toils." The scribe sat at a desk copying in silence a text that was spread before him. The monks did not follow the practice of the Roman commercial scriptorium where a reader dictated a book while several scribes made simultaneous copies of it. Book production was slowed to a trickle, and the monastic library with as many as 600 volumes was considered to be quite large. Nevertheless, although the fruit was sparse, the bush was tough; and the monastic scriptoria kept the tradition of bookish scholarship alive from southern Italy to the coasts of Ireland during some trying centuries.

The medieval book was a codex written on vellum or parchment. although by the 15th century paper manuscripts were normal *(see* PAPER). Many medieval manuscripts attained a high perfection of colour and form and are renowned for their beauty. Such examples as the Book of Kells from Ireland, the Lindisfarne Gospels from England and the many brilliant "books of hours" made in France, to cite a few instances, are world-renowned as examples of art. However, the customary book was less splendid. Written in a neat book hand that developed into the models from which printing types were drawn, the manuscript books of the middle ages, in all essential points, resembled very closely the printed books of the modern period.

Because the monastic book trade was largely internal: the contents of books are evident from the monastic library catalogues. Generally the catalogues grouped the books in three divisions. First came the Bible *(see* BIBLE, TRANSLATIONS OF) and commentaries. Writings of the church fathers and contemporary theologians followed. Finally there was a smaller section of worldly books— including at various places some classics, mathematics, medicine, astronomy, law and historical and philosophical writings. Books were written in Latin. Only with the onset of humanistic

scholarship in the 14th century, and the rise of important vernacular writers at about the same time. did books in the Greek language and in the various vernacular languages assume any prominence in these catalogues. Most monks had specialized duties, and this was pertinent to the use of books in monasteries. While some monks were noted scholars and writers, many could not even read. However, the custom of reading aloud in the refectory exposed even illiterate monks to the cultural heritage in books.

2. The Revival of **the** Secular Book **Trade.**—For six centuries after Cassiodorus, references to book production outside monasteries are few and hard to interpret. An expansion in book production was notable with the rise of the universities in the 12th century. Much of the impetus of the universities came from a revived interest in the writings of the Greeks of antiquity, which were studied mainly in Latin translation. Around the universities, which were located in the cities, grew up a demand for books. University stationers supplied the demand. The stationers were controlled by the universities. which framed regulations about the content and size of books and set prices for sale and for rental. The University of Vercelli in Piedmont, Italy, framed such a regulation in 1228, and many similar acts are recorded for other universities. A characteristic of the work of the university stationer which had not been so apparent in the work of the monastic scriptoria was his manifolding of copies.

There can be no doubt that books were readily exposed for sale in the 14th century. This is evident in *Philobiblon,* a book finished in 1345 describing the book-collecting activities of Richard de Bury. bishop of Durham. The book relates how the bishop established good relations with stationers and booksellers in England. France. Germany and Italy by sending advance payments. This practice indicates a widespread market. Evidence from the same century indicates that the stationers mere organized in craft guilds in the same way that other trades were organized. A London record of 1357 granted exemption from jury service to writers of text hand. In 1403 the Stationers' Company of London appealed to the city for the right or having their own ordinances.

3. Humanistic and Vernacular Books.—The manuscript books of the 14th and 15th centuries were affected by the rise of humanism and the growth of the vernacular languages (see RENAISSANCE: The ***Revival*** *of Learning in Italy*). Humanism has long stood as a notable example of the capacity of the book to preserve knowledge through centuries of disinterest and neglect. Petrarch was one of the most notable men early connected with the movement; in the first half of the 14th century he began to search for texts of classical Roman authors. He found neglected copies in the dust heaps of monastery libraries, the product of the monastic scriptorium; but he and others generated an enthusiasm for the style of writing and pagan contents that was not medieval. They searched library collections throughout western Europe with the aim of recovering and purifying the classical texts. The restored texts. with the humanistic commentaries and original works in Ciceronian rhetoric. became the prized books collected by lay and ecclesiastical princes. The Laurentian library in Florence, the Ambrosian in Milan. the modern Vatican library and important collections in the Bibliotheque Nationale date from this movement. In England, remote from the influence of Italy, Humphrey, duke of Gloucester, donated humanistic books to Oxford university. By 1450 most of the Latin classics had been recovered and the humanists had turned their attention to Greece, even before the fall of Constantinople in 1453 caused the exodus of so many books and scholars from the eastern capital.

Concurrently with the revived interest in classical literature and language came the production of vernacular books. A vernacular literature had long been growing; and anonymous medieval authors had composed poems and stories of first importance before the 14th century, but the publication had been largely oral. In the 14th and 15th centuries vernacular books appeared. The anonymous classics were put in writing; and such creative geniuses as Dante. Petrarch. Boccaccio. Chaucer and Villon led a great number of lesser writers in producing vernacular books.

The expanded literary production found an expanded society capable of participating in the use and enjoyment of books. Lay princes as well as churchmen promoted learning and were among the patrons of humanism, although the practising humanists themselves were for the most part ecclesiastics. As for books in the vernacular, there is evidence that tradesmen and artisans in the cities were learning to read and write. John Wycliffe directed his English translation of the Bible to them in part. When the vernacular Bible. along with Wycliffe's other works. was proscribed. some of those prosecuted for reading them were artisans. Surviving letters and bills from tradesmen to the great families with whom they dealt are extant from the 15th century. The cities had begun to collect guildhall libraries.

The 1 jth century brought the manuscript book to a point where it merged naturally, if perceptibly, into a world of print. In the wake of the humanists, the content of books was enlarged to embrace as large a sphere of human activity as had interested the classical models. New- writers emerged to put books in the language of the people. More groups of people enjoyed the advantage of literacy. Books were recognized as objects in trade and were handled by guilds as were other articles of commerce. Paper was replacing vellum as the material for books. Creation of the printing press wanted only ingenuity and patience.

V. THE INVENTION OF PRINTING

1. Early Printing.— Printing books on a printing press with movable metal types is traditionally credited as the invention of Johann Gutenberg (*q.v.*) of Mainz, Ger., who was experimenting with the process as early as 1439. There is. however, no extant piece of printing which satisfies the majority of critics that it was done by Gutenberg. The 42-line Bible known as Gutenberg's, of which the Mazarin library copy bears the rubricator's date of 1456, is thought by a preponderance of bibliographers to have been printed by Johann Fust (*q.v.*) and Peter Schoffer. Later investigations, dramatized by the action of the Pierpont Morgan library in trading a copy of the Bible for a missal, indicated that perhaps the Constance missal antedated the Bible as the first substantial printed book. The first dated European book was the Mainz psalter printed by Fust and Schoffer in 1457. So rapid was the spread of printing that by 1500 a press was at work in every major European country except Russia; and about 40.000 issues and editions averaging perhaps 200 copies each had come from the presses. Thus in a period of a scant 50 years follo ing the invention of printing, more copies of books were made than had been copied throughout several preceding centuries.

The process of printing itself is much older than the 15th-century European development. The Babylonians used seals to print their signatures on wet clay tablets. The Chinese printed with wood blocks and passed the art on to the Japanese. who in A.D. 770 supposedly printed 1.000.000 copies of a prayer charm. The oldest extant block book is the Diamond Sutra, a book of Buddhist aphorisms printed in China in AD. 868 The far eastern peoples even experimented with movable types made of wood, clay, tin and other metals, but the ideograms and syllabaries they employed made block books more practical for them.

The extent to which China influenced the development of printing in Europe is questionable. Some Chinese contributions were notable. Paper. so necessary for the exploitation of the printing press, reached Europe from China by way of Islam. Block books and the block printing of pictures preceded printing with movable types in Europe. Since trade routes to the far east were open, this may have been a direct influence. In the European process, there were inventive refinements. The German printers solved the problem of casting metal types of true dimensions and of devising a form in which separate types could be locked in order for printing. They developed an oil-based ink to meet the requirements of metal type. They constructed the printing press, a refined and precise instrument often regarded too lightly.

In Europe little of the motivation which prompted the huge printing of the Japanese charms was present. Although the earliest printed books in Europe were religious in content, they were not produced with the idea that there was a special religious virtue in their mechanical repetition. Instead they were produced to inform through reading. Books had secured a place where reading

was regarded as an important avenue for human learning without regard for supernatural rewards. The trade in books had grown on this basis, and the quick development and spread of printing were a commercial .exploitation of the growing market in books. As evidence of the commercial nature of the development. the list of the foremost early printers includes more names of the ingenious masters of trades and crafts — Gutenberg; Fust, the banker; Nicolas Jenson, the die cutter; William Caxton (*q.v.*), the merchant— than of priests and scholars.

2. Incunabula. — Fifteenth-century printed books, known as incunabula (*q.v.*), featured both traditional and new characteristics. In appearance, the printed books very closely resembled manuscripts. Type faces copied the design of local book hands. From chapter headings, headlines, initial letters and rubrication (often added by hand in a style imitative of the manuscript from which the book was printed) down to the justified right-hand margin, the printed book imitated the manuscript. Title pages giving the name of the printer and the place of publication were usually lacking, such information appearing, if at all, in a concluding paragraph called the colophon (*q.v.*). If there was no attempt to hide the fact from conservative purchasers that the book was printed, there was at the same time little effort to advertise the fact. Some people still preferred manuscript books for one reason or another; and as late as 1486 Johann Tritheim was still conducting a busy scriptorium at the monastery of Sponheim. In content as well as appearance, incunabula were strongly influenced by tradition. The most frequently printed books, in order, were the *Ars minor* of Aelius Donatus, the *Doctrinale puerorum* of Alexander de Villa Dei, Jacobus de Voragine's *Golden Legend* and the Vulgate Bible. By far the largest number of books printed were in Latin.

Along with the traditional, there was much that was new. Nearly three-fourths of the authors listed in the first seven volumes of the *Gesamtkatalog der Wiegendrucke* (as far as it goes, the most comprehensive author list of incunabula) were 15th-century authors. In spite of the preponderance of Latin books a large percentage were in the vernacular, the proportion increasing with distance from Italy. In England. Caxton with his *Dictes and Sayenges of the Phylosophers* (1477) set the pattern for vernacular publishing; and nearly two-thirds of English incunabula were in English. The distribution of subjects treated by 15th-century printed books was as follows: religion 45%, literature 30%, law 10%, science 10% and miscellaneous 5%. As compared with medieval books, incunabula had a high proportion of literature, illustrating the influence of the humanist and the vernacular writer.

3. Printed Illustrations. — Although 15th-century printers characteristically exploited the existing book without attempting to reform learning with the new device of the printing press, their use of printed illustrations actually produced a new means of expression. Printers used woodcuts to print illustrations with the relief process, and experimented with intaglio in copper engravings. Woodcut pictures preceded metal types. It was a simple development to make woodcuts type-high and lock them in the forms with type to print illustrated books. Albrecht Pfister of Bamberg was printing books illustrated with woodcuts about 1461. Copper engravings were also tried. With their adaptability for fine lines, engravings were especially suitable for the reproduction of maps; among the few incunabula illustrated with engravings is a Ptolemy *Geographia* printed at Rome by Arnoldus Buckinck in 1478. However, because engravings required a different press and introduced a separate process into printing. and because experiments with woodcuts were so satisfying, there was no extensive use of engravings before 1550.

The printing of illustrations greatly improved the possibilities for combining pictures with texts in books. Once a picture was prepared for printing, it could be repeated an indefinite number of times with little loss in detail, accuracy. form or original vigour. When great artists such as Albrecht Durer designed woodcuts the result was books of high aesthetic value which could be produced in great numbers. *Hypnerotomachia Poliphili,* printed by Aldus Manutius in 1499, is a monument to the early perfection of the woodcut and to book illustration in general. Equally as important as the reproduction of great art was the opportunity that printed illustrations offered iur the faithful reproduction of pictures and diagrams in scientific books. Although early herbals fell far short of modern standards in their depiction of poisonous plants (often following the custom of using the same picture to illustrate different things symbolically), the process had great potential which was expertly exploited in the anatomical books of Andreas Vesalius in the 16th century. The dawning scientific scholarship profited from the development of printed illustrations; it is significant that both anatomy, with its need for precise illustration of the human body. and cartography. with maps, greatly expanded after development of printed illustrations.

4. Demand and Prices. — The most that can be said about the public demand for books in the 15th century is that the printing press was eagerly accepted and that it developed rapidly. Printers were eagerly sought for. When the English parliament in 1483 passed a law excluding foreign artisans from settling in England, printers mere specifically exempted lest restrictions against foreign printers delay the progress of so useful an art. Hooks were cheaper, especially the small and useful books for which the existing demand justified the printing of large editions from a single setting of type. The general reduction in prices of books was described in 1467 by the bishop of Xleria. Writing to Pope Paul II, he said that books were one-fifth their former price. That books were selling well is indicated by the invasion of the book market by men from other fields. The records of the port of London show that grocers were importing books for sale along with their more usual merchandise.

VI. THE 16TH-CENTURY BOOK

1. Technical Advances. — In the 16th century came the culmination of early printing experiments. Typography was standardized in three major styles — black letter, roman and italic. Except for the cutting of Greek. Hebrew, Anglo-Saxon and other exotic letters. radical experimentation in type design practically ceased. The roman letter gained the most ground; in England by 1600 it had displaced the original black-letter fonts for nearly everything but Bibles. The title page bearing the title, the names of the author, publisher, printer and bookseller, the place of publication and the date was standard by 1520. Pagination. foliation and the printing of signatures, innovations made by Arnold ther Hoernen and Johann Koelhoff of Cologne in the 1470s, were uniformly used. The printing press was so perfected that there were no major changes in its construction until the Stanhope iron press in about 1800.

As a result of the early maturity of printing. some 16th-century books are noted for their perfection of form. Geoffroy Tory of Paris added to the possibilities of decoration with his printed borders and ornaments, 15th-century innovations perfected by him. Hans Holbein the younger followed the precedent of Durer in devoting his high talents to the illustration of books, his *Totentanz* of 1538 being the most famous. Books printed by the Aldine press in Venice, the Estiennes in Paris, Christophe Plantin in Antwerp and the Elzevirs in Leiden set high standards of impression, typography and design.

2. Division of Labour. — With the end of experimentation came standardization. This was reflected by a division of labour in the printing trade. While the early printers had designed their own types, the 16th-century printer bought his types from a noted designer like Claude Garamond of Paris. Although the incunahula printer may have set type and pulled the bar of his own press. the so-called master printers of the 16th-century were more notable for their publishing activities. They had employees to perform the hard physical labour. Anton Koberger of Nürnberg had 24 presses and hired more than 100 workmen; Plantin had 25 presses and 150 workmen. Aldus Manutius, Johann Froben (Basel, Switz.), Plantin, and Robert and Henri Estienne (Paris and Geneva) are often referred to as scholar-printers, but they are famous for their corps of scholarly editors. Froben employed Erasmus as an editor. The building-up of an editorial office belongs to the activities of the publisher rather than the printer.

3. Economics. — The publishers exploited the genius of the printing press to print many hooks cheaply. As compared to 40,-

LA NAISSANCE DU ROY.

SOUS le Règne de Loüis XIII. la France se voyoit triomphante de toutes parts. Les Hérétiques domptez, la Maison d'Autriche humiliée, & l'autorité Royale restablie, rendoient le Royaume aussi heureux que florissant. Mais il manquoit au Roy un Fils, qui pust luy succéder, & vingt-trois ans de mariage sans enfans, luy avoient presque osté l'espérance d'en avoir jamais. Enfin, Dieu touché des vœux ardents d'un Roy pieux, & d'une vertueuse Reyne, leur donna un Fils, dont la naissance, si peu attendue, combla de joye tous les François. Ce visible présent du Ciel fut un gage certain de la Protection divine; & parut dés ce moment asseurer à la France la gloire, où elle est parvenue, & la félicité dont elle jouït.

C'est le sujet de cette Médaille. La France à genoux tend les bras à un Enfant, qu'un Ange descendant du Ciel luy présente. Les mots de la Légende, COELI MUNUS, signifient, *Présent du Ciel*. Ceux de l'Exergue, LUDOVICUS DELPHINUS V. SEPTEMB. M.DC.XXXVIII. *Loüis Dauphin né le 5 de Septembre 1638.*

Engraved frontispiece of the *Médailles sur les Événements du Régne de Louis le Grand*, 1702, from the Imprimerie Royale, established by Cardinal Richelieu

(2655) Numb. 312

A Perfect Diurnall

OF SOME PASSAGES IN PARLIAMENT

And the daily proceedings of the Army under his Excellency the Lord Fairfax.

From Munday July 16. to Munday July 23 1649

Collected for the satisfaction of such as desire to be truly informed.

Printed by E. G. and F. L. for Francis Coles and Lawrence Blaicklocke: And are to be sold at their shops in the Old-Baily, and at Temple-Bar.

Beginning July 16.

His day according to former order, the House meet early upon debate of the Act for sale of the Crowne-Lands &c, the severall provisoes committed Saterday last were then agreed on with some amendments and the Act fully past.

The Case of the E. of *Northampton* who desires to be admitted to his Composition upon the Articles of *Oxford* was reported with a Letter from the Lord Governour of *Ireland* in his behalf upon debate of the whole, the house ordered to refer it to the Committee of Goldsmiths Hall where he is to compound according to the former Rules given the said Committee.

Report was made to the house from the Committee appointed to consider of the losses sustained by *John Brown* Esq; Clerk of the late Lords house given in to amount unto about 4000 l. the house upon debate thereof ordered, That he should be allowed 3000 l. and referred it to a Committee to consider how it may be raised.

Letters were read from the Committee of *York*, and other Letters of some disorders there, of a force put upon them by 500 reduced souldiers that designed to secure the Commissioners And they surprized Sir *Edward Rodes*, and Mr. *Rymer*, who had much adoe to get liberty, the rest got away. The House referred it to the Councel of State; to examine the business, and punish the promoters of the mutinies, as they shall finde cause.

19TH- AND 20TH-CENTURY PRINTING AND BOOKMAKING

000 incunabula, they published 520,000 issues and editions. Disregarding some notable exceptions, the student of the 16th-century book finds a trend to small, cheap formats, In place of expensive folios, Wynkyn de Worde, Caxton's successor. published about 800 low-priced quartos, generally undistinguished in appearance and content but of proven salability. More highly regarded, but illustrative of the same development, were the cheap classics in octavo with which Aldus Manutius earned his greatest fame. In the second quarter of the 16th century, the printers of Paris and Lyons halved the size of the Aldine octavos with their 16mos. only to be outdone at Antwerp and Leiden with still smaller volumes. Printed on thinner paper, these small formats were made still less bulky with the substitution of pasteboard for wooden sides in binding.

With the dominance of publishing and the increase in numbers of journeymen printers. there arose a struggle over markets and printing rights. Printers and publishers tried to take the risk out of publishing by acquiring patents of privilege for the exclusive publication of books known to be in demand. These included laws, service books, school books and (as the Reformation progressed) Bibles. Printers also soon discovered that any risk publication that succeeded required some protection to prevent other printers from copying the profitable book. Consequently, the struggle for printing privileges was a notable feature of publishing in the 16th century. It was characterized by the appointment of official printers. by the granting of protection to single books, by the parceling out of important classes of books and by the self-regulation of the book trade.

The development of printing privileges may be traced in the English book trade. In 1504 Richard Pynson and William Faques were the first to print statutes with royal authority. Pynson kept the title of royal printer until his death in 1530, and the post grew to be a valuable privilege. In 1518 a two-year privilege was granted for Richard Pace's sermon on the recent peace. Anthony Marler in 1542 was granted a privilege for printing all Bibles in English. This practice led the way to granting privileges for schoolbooks, books on common law, primers and all standard works of steady sale. The Stationers' Company of London was chartered in 1557, partly to supervise the administration of commercial privileges and partly to restrict the content of publications. In carrying out the first aim the company established a register of copies where a publisher might enter the title of a book he was publishing and thus secure protection from copying. The publication of unprivileged works was not generally profitable, however; and in 1583 the unprivileged printers of London complained that the printing of ballads, plays and such other things as were not privileged did not provide enough work to keep a man alive. In desperation. a group of rebel printers in 1585 pirated to the extent of 20,000 copies the *ABC and Little Catechism,* privileged to Richard Day.

4. The Contents of Books. — The printing press was the instrument of the Reformation. and controversial religious books and pamphlets hulked large among 16th-century books. Beginning with Martin Luther's challenge to oral debate in 1517, the course of the Reformation can be traced by the debate in print. Attacks brought animadversions, and animadversions evoked refutations. Although religious controversy in books was not new, the use of books in the Reformation had new features. The scope of the controversy was enlarged by the publication in large numbers of books in the vernacular, calculated to appeal to the general public. The reformers emphasized the vernacular Bible as a book for everyone to read. John Huss and John Wycliffe had also promoted vernacular reading, but they were unable to copy books fast enough to prevent their suppression. The printing press outran the censor. William Tyndale's controversial rendering of the New Testament in English with its even more controversial prologues was published in an edition of 3,000 copies. Though banned in England. this edition was circulated because of the possibility of publishing it in a friendlier foreign country. The smuggling of banned books from one country to another was another characteristic of Reformation printing.

Aside from its use in pure controversy. the printing press was instrumental in putting new religious programs into effect. By 1517, religion in Europe depended strongly on a widespread distribution of books. Radical changes in religion required the quick publication of vernacular Bibles or the substitution of new service books for those in use in all the churches. For example. Richard Grafton and Edward Whitchurch received royal writs of assistance in 1548 allowing them to seize presses and supplies and to impress workmen to print the *Book of Common Prayer* to have it ready for use in all the churches in 1549.

As important as the Reformation books (and Counter-Reformation books) were in the 16th century, the percentage of religious books among all those published did not increase. A study of all the books printed in England or books printed abroad for use in England showed that only about 40% were religious and 20% were literary. Religious controversy was as strong in England as anywhere, but the humanists and the authors of plays, poems and tales made their influence felt.

The expansion of intellectual interests as reflected in books is illustrated by the beginnings of modern bibliography. In 1545, Konrad von Gesner published his *Bibliotheca universalis,* an "author list of books in Latin. Greek and Hebrew; he followed it up with the publication of subsidiary lists classified by subject. John Bale compiled a list of writings by all the authors of England. Scotland and Wales. Florian Trefler. an Augsburg monk, complained of the difficulty of locating books in libraries, and recommended the construction of a classified catalogue. The Frankfurt fair catalogues were used as records of current publications; and Andrew Maunsell, a London bookseller, compiled in 1595 a *Catalogue* of *English Printed Books* in which he established rules for distinguishing between authors in his entries. The significant points about these developments are the serious interest taken by scholars in all kinds of books and the beginnings of a systematic approach to bibliography. The day of the man of one book had ended.

5. Reading. — The extent of reading in the 16th century may be inferred from accounts of reading motivations, the growth of schools, studies of book ownership, studies of censorship. and the generalized content of publications (as described above). The Reformation provided motivation for reading. The reformers emphasized the importance of Bible reading by all communicants. Vernacular Bibles were published in large and frequent editions. Luther wrote a pamphlet on education. setting forth a school program. English clergymen were ordered to teach their parishioners to read the Creed. Pater Noster and Ten Commandments, and to show them where they might purchase copies of these. Village petty schools and grammar schools were established in England.

Records of book ownership are comparatively rare. and yield information mainly about scholars who left accounts of their books or whose books were inventoried on their deaths. An inventory (published in the late 1950s) of private library catalogues in England irom 1500 to 1640 showed that. apart from the clergy. only university scholars and physicians owned books in any numbers.

Records of attempts to ban books have been used as evidence of popular reading. Mostly connected with the religious controversy, book proscriptions betrayed a great fear of a popular audience and were most violent against vernacular books. Sixteenth-century proscriptions began with a papal bull (1520) which iorbade anybody to read any of Luther's writings. This was followed by a stream of proclamations. statutes and injunctions issued by kings. parliaments and bishops against the works of other reformers and counterreformers. Prosecutions resulting from disobedience to these measures often found tradesmen in the toils of the law. Thomas More, who was commissioned to refute William Tyndale's argument in favour of an English Bible. wrote in 1528 that more than 40% of the population "could never read English yet." a statement which permits the inference that almost 60% were literate.

VII. THE EARLY MODERN BOOK

1. Authors and Content. — Generally undistinguished in appearance, the 1,250,000 issues and editions published in the 17th century included a high number of unsurpassed brilliance in content. The list of authors whose works were being published for the first time includes Shakespeare. Cervantes. Bacon. Descartes,

Galileo, Molière, Milton, Newton and others scarcely less important This flowering of literary and scientific genius mas at the top of a generally expanded publication. The content of books was marked by a serious consideration of events and experiences which had not been reported in earlier books. History recovered some critical spirit and interest in common details. Biographers recounted the lives of mortals far below the degree of saints. popes, emperors and kings. Antiquarians and excursionists explored local fields and alleys. describing them in books illustrated with engraved maps and pictures. News books appeared to report a limited but immediate account of daily events. Scientists and inventors reported their experiments in scientific periodicals invented for the purpose. Taking a cue from science, literary magazines appeared for the first time. Nearly every literary form reached a high peak of artistry. The vernacular made strong inroads into Latin (even as the language of scholarship) when Descartes published his *Discours de lu méthode* in French. The book became common; and John Bunyan. a little-schooled tinker. wrote a literary classic. *Pilgrim's Progress,* which was widely read by unschooled artisans.

The enlarged content of books reflected a changed approach to knowledge, best described as the birth of the modern scientific outlook. This view continued the shift away from medieval otherworldliness which had begun with humanism and mas carried on through the Reformation and the age of discovery. It emphasized the reality of sensual experience in contrast with the medieval assertion of its unreality. This revised attitude was not bookish, because it derided book learning while ascribing greatest importance to observation and experience as avenues of learning. Since, however, the whole field of experience far exceeded the capacity of any individual. the new approach to knowledge was reflected in books; not only in the published reports of scientific experiments, but in the whole range of life and thought reported in print.

2. Librarians and Book Collectors. — These developments were accompanied by a rise in the esteem accorded to current publication by serious students and scholars: illustrated by the activities of librarians and book collectors. Gal,riel Naudé, advising Cardinal Mazarin on the establishment of a lihrary in a treatise published in 1627, urged the acquisition of contemporary books, even those considered on some accounts to he trivial or erroneous, in order to illustrate the different aspects of human thought. A few years earlier Sir Thomas Bodley had reluctantly accepted deposit copies from the Stationers' company ior his Oxford university library. The same spirit of comprehensive collecting affected their purchases of old books. Naudé built a collection of 40,000 volumes in a few years and found it necessary to provide a subject catalogue to the contents of the Mazarin lihrary. as Bodley had provided a classified catalogue for the Bodleian. An outstanding example of the comprehensive current collector was George Thomason, a London bookseller, who collected nearly 23,-000 tracts and pamphlets published in England during the troubled years of civil conflict from 1640 to 1661 in order to preserve them for posterity. The amount of reading required of a scholar was so greatly expanded that there is speculation that the 17th century finally ended the medieval custom of reading everything aloud; only by reading silently could a man read fast enough to absorb it all.

3. Censorship. — The increased diversity inherent in the new approach to knowledge. and the magnified importance of individual writers were reflected in a changed attitude toward censorship (*q.v.*). Throughout the Reformation period. censorship was normal. Any book assaulting the accepted social order was banned. Few objected to the principle. although banned writers worked for a changed system in which their own hooks would be promoted while those of their adversaries were proscribed. John Milton's *Areopagitica,* published in 1644. was a pamphlet which developed a principle of freedom. Milton argued that if freedom were allowed for the publication of a variety of opinions. truth would triumph over falsehood in a free encounter: but if restrictions on publication continued, an ignorant censor might slay truth before it ever became known. Freedom of puhlication was slow in making headway. Milton himself turned censor for the Commonwealth, and the Restoration licensing act of 1662 was stringently enforced. Yet a spirit favouring a variation of opinion in print was growing. In 1695 the English licensing law was allowed to lapse. An immediate effect of the lapse of the licensing act was the legalization of printing in English towns and cities outside of London.

The lapse of licensing removed the support from the Stationers' Company of London and the authority of its register in protecting printers' copies. Agitation for a law to protect printing rights resulted in the passage of the copyright law of 1709, which vested the rights for publication in the author. The shift from printer's privilege to copyright was another outgrowth of expanded publication and the emphasis on individuals. By the end of the 17th century some authors had acquired large personal followings. Consequently publishers were eager to print their books and could afford to pay them for the privilege. Jacob Tonson paid John Dryden £1,200 for his translation of Virgil. The changed circumstances which made the works of an author commercially valuable, coupled with the agitation for a law to protect printing property, led to modern copyright legislation.

4. The Book in America. — American colonists wasted few years in establishing the printing press. The Spanish began printing in Mexico in the 1530s. Puritans settled at Massachusetts Bay in 1630 and set up a printing press at Cambridge in 1638. The earliest surviving imprint of the Cambridge press. the *Bay Psalm Book,* was printed by Stephen Day in 1640. Four English colonies in America had presses before 1700; Georgia, the last colony established, was also the 13th colony to have a press (1762). The *American Bibliography* of Charles Evans records 18,300 different publications during the colonial period. An analysis of the account books of Franklin and Hall in Philadelphia indicates that probably 70,000 more unrecorded imprints issued from the colonial press. The largest printing centres were Boston, New York and Philadelphia. Most books and papers were in English, but Pennsylvania had a noteworthy German press. and there was some printing in Dutch, French and the Indian languages.

The three largest classes of colonial printing were theology (37%), law (19.5%) and literature (19.5%). Regional variations made theology most important in New England (46%), literature in the middle colonies (27%), and law in the south (52%). Southern printing was the scantiest; the high percentage of legal printing there represented the work of the official printers.

The place of the hook in colonial America cannot be judged by colonial printing alone. The colonists brought books with them, and they imported hooks from Europe. William Brewster brought a lihrary to Plymouth. and on his death in 1644 left a collection of nearly 400 hooks. John Harvard in 1638 willed his collection of books to Massachusetts Bay for the college authorized in 1636. Cotton Mather in 1700 had 2,000 to 3,000 books in his library and cited over 300 authors. William Byrd of Virginia and James Logan of Philadelphia built large private collections, mostly from importations. The Philadelphia Library company, on its organization in 1731, immediately ordered books from a London bookseller. The Reverend Thomas Bray promoted a scheme of parish libraries with books and funds supplied from England. Much colonial writing, perhaps the most important part, was printed abroad.

The colonial book, made in America, played a definite role in fabricating a colonial mentality from various European backgrounds. Many colonial books expressed the dissidence existing in the colonies. The first book published, the Bay *Psalm Book,* was expressive of the Puritan discontent with the ecclesiastical settlement at home. Many other religious books were of a similar nature. Newspapers, legal publishing and almanacs were fitted to the local situation. The jealousy with which the colonists regarded their rights to free political discussion in print came to the fore in 1735 in the Zenger case. John Peter Zenger, a New York printer. was arrested and brought to trial fdr his printed criticisms of the conduct of the English governor of the colony. Disregarding the instructions of the trial judge after the brilliant defense conducted by Andrew Hamilton, rhe colonial jury acquitted Zenger on the ground that his charges were based on fact, a key consideration in libel cases after that time.

5. The Growth of Reading. — A great expansion in the reading public during the 17th and 18th centuries came from the increasing literacy of women. Girls had attended the vernacular schools during the 16th century, and by the 17th century a woman such as Aphra Behn (*q.v.*) could attain fame as a writer. Much of the prose fiction which became popular in the 18th century was addressed to women, and circulating libraries catered to their tastes. Sermons castigating women for wasting their time reading light novels were common.

The general expansion in reading must be viewed historically to seem impressive. Literacy was not universal. Most serious and sustained reading took place in large cities. and cultured travelers often complained of the stark book poverty of provincial towns. However, newspapers circulated widely, even in provincial towns; and it was no great novelty for an artisan or farmer to become a man of letters. The invasion of the world of letters and learning by such men as Benjamin Franklin and Robert Burns is as significant as is the iact that most poor plowmen had neither the skill nor the opportunity to read much if at all. In the 18th century there was great faith in the ability of the common man to educate himself by reading. Concrete expressions of that faith were the encyclopaedias. expensive publishing gambles that were successful. Diderot and the French Encyclopaedists were most famous, but the Encyclopedia Britannica, the German Brockhaus and other national encyclopaedias date from the late 18th century. The many subscription libraries which grew up in England and America were another demonstration of the force of the idea of self-education through the use of books.

6. Prices. — Books were neither more nor less difficult to buy than they are today. The prices, when a ratio of currency values is considered, were approximately the equivalent of modern prices for books. In America a book of poems sold for 1*s.* 3*d.*; and the huge Mennonite martyr book. a folio of 1,512 pages, sold for £1. English prices were higher. but money was not so scarce. Single poems by Pope sold at 1*s.* 6d. Novels sold for 1*s.* 6d. around 1750 but then increased to 2s. 6d. a volume. Subscription books such as Dryden's Virgil at £5 5*s.* and Johnson's Dictionary at 54 15s. (bound) were expensive. The first edition of the Encyclopedia *Britannica* published complete in 1771 cost £12 for the three volumes, but it had been issued serially beginning in 1768 at 6d. an issue. This sort of installment selling put it in reach of more people.

7. The Art of the Book. — Although 17th-century books were generally inferior in appearance to the best examples of the 16th century, type design did not languish perpetually. Cardinal Richelieu established the Imprimerie Royale from which at the end of the century came the *romains du* roi ("king's types") of Philippe Grandjean. In the 18th century William Caslon cut his old-style roman letters; John Baskerville his transitional; and Giambatista Bodoni and Pierre and Firmin Didot developed the modern face. A perfectionist, Baskerville introduced wove paper to set off his types.

The techniques of illustration developed rapidly. Etching, dry point, mezzotint and aquatint were intaglio processes that were widely used. Thomas Bewick's nood engravings changed the technique of the woodcut and became popular in cheaper books. Printed by the relief process, wood engravings became the medium oi the 19th-century illustrated weeklies. Aloys Senefelder's discovery of the lithographic process of printing illustrations (about 1798) was the most significant because lithography is the basis for offset printing.

VIII. THE 19TH-CENTURY BOOK

Spurred on by industrialization, democracy and urbanization, book production multiplied in the 19th century. The number of issues and editions quadrupled, reaching 8,000,000 as compared to 2,000,000 for the 18th century. The sizes of editions also increased. By 1900, best-selling novels sold more than 600.000 copies. The penny newspapers and the popular magazines with aggregate circulations running into the millions created the phenomenon of mass coinmunication.

1. Industrialization. — The mechanization of printing (*q.v.*) provided the means for producing books in vastly larger quantities, but mechanization cannot explain the increased demand for books which it was created to meet. Industrialization in the larger sense had a relation to that demand. The handicraft shops became factories, and around iactories grew cities. In every industrial country the percentage of rural as compared to urban population dwindled steadily. Urbanization meant enlarged communities. Once again in the history of man and the book, man's field of interest was stretched beyond the circle of his personal experience. It was extended even farther because. along with the other inventions that accompanied industrialization, there were developments in rapid transportation and in long-distance communication — the railroad, the steamship and the telegraph — that comparatively laid the world at every man's doorstep. People used many means to enlarge their information. Lecture courses and lyceums flourished. The book also, with its ability to carry a message across time and space, satisfied the desire for experience in a world too large for a man to encompass in his daily rounds. In this respect the industrial cities of the 19th century were akin to Ptolemy's Alexandria.

2. Democracy. — Literacy increased in the 19th century, as shown by statistical reports available for the first time during this period. The growth of democracy, with its emphasis on the widespread public discussion of political issues and on popular education, fostered free schools. Public libraries, a product of the cities, made books available to all. Reading matter was cheap. Advertising in newspapers and magazines paid for the cost of production so that copies of them sold below cost. The famous Tauchnitz editions of separate books, founded in Leipzig in 1837, by 1935 listed more than 5,000 English-language titles at 50 cents. Philipp Reclam's Universal-Bibliothek, another German series (started in 1867), published ten titles a month, growing in 50 years to a list of 6.000 for 20 pfennig (about 10 cents) a copy. Reclam sold more than 18.000.000 copies of German classics. The Boston Society for the Diffusion of Knowledge began publishing cheap paperbound books in 1831, but the development was stifled by an adverse postal ruling in 1843. A more vigorous paperback publishing program flourished in the United States from 1870 to 1890. In 1885 one-third of the titles published in the United States were paperbound books. It was the era of the dime novel, but many cheap books in the United States were pirated from foreign publishers; and the program did not survive the copyright act of 1891, which enabled foreign authors to obtain American copyright on books printed in the U.S.

One development in content during the 19th century was the increased emphasis on children's books. The effect of popular education was seen in the heavy publication of schoolbooks, but children's books as generally defined escaped the confines of the classroom. Children's magazines appeared, and books written especially for children attracted the efforts of many authors, some of whom wrote classics.

3. Mechanization and the Art of the Book. — With the mechanization of printing, the investments in publishing greatly increased, and only large and strong houses could flourish. They established editorial offices in the largest cities, and publishing and manuiacturing of books were separated farther than ever. The spirit of craftsmanship which had motivated many of the small printers with their hand presses declined. Principles of book design were ignored. Machine-made pulp paper deteriorated rapidly. The sewing machine did not duplicate the sturdy work of the hand binder. Late in the century Theodore De Vinne, an American typographer, tried to revive an interest in style. The most influential man, however, was William Morris (*q.v.*), who started the private press movement in 1891 with his Kelmscott press (Hammersmith. Eng.).

In trying to bring art back to the printing of books, Morris made a fetish of handnork. He set type by hand, printed with a hand press on handmade paper and had his books bound by hand. With the aid of Emery Walker he designed new types; and his Chaucer is reputed to be the most beautiful book ever printed in England. His preference for heavy black-letter type, however, made his books more ornamental than readable Characteristically, his

Kelmscott editions, and the editions from the other private presses which followed its lead, were small and expensive. Their chief contribution to bookmaking mas the dramatic way in which they called attention to the artistic possibilities of the book. The publishers of large popular editions were later inspired by the private presses to breathe some art into the machine.

IX. THE BOOK IN THE 20TH CENTURY

1. The Book and Other Media. — The 20th-century book has been affected by the growth of motion pictures, radio and television. These mediums can reach large audiences who have only to look and listen to receive messages presented with all the warmth of the human voice and the vividness of action. Each medium as it was introduced quickly won a wide following. Scientific studies of listening, viewing and reading habits have revealed that more people in the United States watch television or listen to the radio than read newspapers; as many view the movies as read magazines; and that the smallest number of people read books as separately published literary products. Yet the new mediums have not replaced books. More books are being published and the circulation of magazines and newspapers is higher today than before.

The book has survived in face of this competition because of its peculiar capacities as an instrument of communication. First, it is a storehouse of knowledge. While the voice and image of the new media are fleeting, the printed word endures, and the reader can look at it again at his own convenience. Thus it is uniquely valuable for the serious student who needs to refresh his memory while labouring through a difficult passage, as well as for transmitting the cultural heritage from one generation to another. Second, the book is an individual instrument of communication. Silent reading is a solitary act; the reader may go as fast or as slowly as he pleases, while viewing and listening are group activities. Third, the book is cheaper to produce than radio. television and motion picture programs and can afford to cater to smaller audiences. This characteristic promotes individuality because programs aimed at large audiences must seek common ground. Fourth, the book is a compact instrument of communication. A good reader can cover more in an hour than a listener could hear in four hours.

2. Photographic Processes. — Economical photographic processes used in printing have made it possible for publishers to exploit the individuality of the book by printing small editions for limited audiences. One important device is the photo-offset press built in 1904. The photo-offset press may be used to print large editions, but its economy also permits the publication of very small editions. The pages of a previously printed book or a typescript are photographed to make printing plates, eliminating the expense of type composition. This advantage makes an edition of 500 copies feasible as compared to a much higher number for letterpress. The process is used to reissue out-of-print books and to print original typescripts cheaply. Chiefly for scholarly publishing, photo-offset from typescripts is exploited by university presses and specialized private publishers such as the Scarecrow press. One advantage of the photographic technique for scholarly materials is the ease with which complex drawings, diagrams, other illustrative materials and exotic alphabets may be reproduced. Other methods of publishing small editions (called near-print along with photo-offset typescript) make use of office duplicating machines. Scholars in some very specialized and advanced fields find nearly all their reading materials in near-print.

The ease with which photographic reproductions of texts can be reduced in size led to the development of microtexts. With a microtext the page of a book may be reduced to as little as $\frac{1}{200}$ of its original size, so that it must be read with aid of a magnifying reader. An obvious advantage of microtext, important when the flood of print is crowding library shelves intolerably, is reduction in bulk. Libraries generally reduce bulky historical records, such as old newspapers, to microtext for preservation.

A microtext may be a translucent film or an opaque card or sheet. Microfilm, the former, may be a negative or a positive print. Its use makes practicable the reproduction of a single copy of a book. The microfilm is always in print as long as the negative lasts. Libraries in many cases thus make microfilms instead of lending books on interlibrary loan. Opaque cards and sheets are printed both photographically and with the offset press. Opaque microtexts can be issued economically in as few as 50 copies. All the methods of microreproduction are used to reprint rare and unobtainable books and to print such original materials as doctoral dissertations. specialized monographs and anthropological field notes. The invention in the 1950s of photographic type-composing machines opened the possibility for original composition in microtext.

3. Marketing Developments. — In contrast to the experimentation with small and specialized editions, book clubs were a marketing innovation to distribute huge editions by mail. Although German publishers in 1919 began distributing special editions of the classics by mail. the book club which systematically distributed new books by mail order subscription was an American invention. The earliest clubs were the Book-of-the-Month club (1926) and the Literary guild (1927). By the 1960s about 90 book clubs served the United States. By advertising judicious selections heavily, offering book premiums, and reducing prices in accord with their high sales. the large general clubs could sell editions of several hundred thousand copies. In Great Britain, where their development was more gradual, there were between 20 and 30 book clubs in existence in the 1960s.

A revival of paper-bound publishing was the other innovation. The Albatross Modern Continental library, a German venture begun in 1932, published about 400 titles and then took over Tauchnitz. Penguin Books, organized in England in 1935, adopted the Albatross format. Penguin quickly became the largest and most prominent publisher in a domestic language, penetrating the market wherever English was spoken. Pocket Books began the 20th-century U.S. era of paper-bound publishing in 1939, to be followed quickly by Avon and New American Library of World Literature, originally a Penguin subsidiary. By the 1960s over 14,000 titles were available from more than 200 U.S. paper-bound publishers. Annual sales of 30 of these publishers exceeded 250,000,000. In Great Britain about 50 firms published paper-bound books.

The U.S. paper-bound publishers owed their success Io the inexpensive format and to the exploitation of new sales outlets. In the 1960s cheap paper-bound books sold for prices ranging from 25 to 75 cents. They were sold on newsstands, in drugstores and in grocery stores as well as in bookstores, making use of more than 100,000 outlets in the United States and Canada. Sales of 200.000 copies were required to show a profit. Another development was the production of more limited editions of scholarly paper-bound books at prices ranging from 85 cents up. Many university presses adopted this format.

4. Comic Books. — Another mass publishing development was the comic book. Ostensibly for children, comic books are picture stories told through the depicted conversation of the illustrated characters. The technique is at least as old as the *Biblia Pauperum* ("Poor Bible") of the 15th century, but the immediate predecessor of the comic book is the comic strip *(see* CARICATURE AND CARTOON) of the newspapers. The first comic book published was *Famous Funnies* in 1934. They were so popular that in 15 years comic book publishers in the United States were selling at least 35,000,000 copies a month, and over 400 titles were on newsstands. "Comic" is a misnomer, for the books are general in content, ranging from funny animal stories to lurid accounts of crime written in the tradition of the chapbook (*q.v.*) and the dime novel. Scholars interested in the reading of children have had mixed reactions to the comic book. Some denounced the content as harmful and contributing to juvenile delinquency. (Canada banned the sale of crime comics and some cities in the U.S. adopted restrictive ordinances against them. Great Britain introduced legislation in 1956 to ban the sale of horror comics.) Other scholars defended the comic book technique and praised it for introducing children to reading. Surveys indicated that about 90% of the children from the ages of 7 to 17 who had comic books available read them. Some publishers abridged literary classics and issued other "educational" comic books.

5. Children's Books.—Another development in children's books excited general praise. There has been a notable increase

in the number of good books published for children, and the author specializing in juvenile stories has come to occupy a very respectable niche in the world of letters. Educational developments deemphasizing the textbook in favour of more extensive reading promoted this. The growth of children's libraries and the interest of the American Library association also furnished some impetus to the development. Some attention has been focused on good publishing for children in the U.S. by two awards given by Frederick G. Melcher, the Newbery medal since 1922 for the most outstanding juvenile book published during the year and the Caldecott medal since 1938 for the best picture book. Similar annual awards in Great Britain are the Carnegie medal, first awarded in 1937, for the children's book most distinguished in content and printing, and the Kate Greenaway medal, first awarded in 1956, for the best illustrations by a British artist. An important development was the publication of well-designed and illustrated 25-cent books for children. Simon and Schuster pioneered in this field with their Little Golden Books, which have international distribution and are translated in many languages. *(See* CHILDREN'S LITERATURE.)

6. Modern Book Arts.—The 20th century has united art with the machine to produce beautiful books. The happy union shows some influence of the experimenters with private presses. It also reflects the influence of printing historians such as Daniel Berkeley Updike, printer of the Merrymount press; Stanley Morison, adviser to the *Times* (London); Douglas C. McMurtrie; and others who called attention to the art of printing. A number of periodicals. among them *The Fleuron, Dolphin, Alphabet and Image, Imprimatur, Monotype Recorder* and *Signature* in the U.S., and the *Book Collector* in *Great Britain,* though exposed to a high rate of early mortality, fostered interest in beautiful books. The American Institute of Graphic Arts conducts trade book clinics and after 1923 sponsored an exhibition of the best 50 books of the year. In England the Xational Book league performed a similar function.

The union of art with the machine in book production has paralleled other 20th-century developments in industrial design and merchandising. Publishers strive to present an attractive package to the customer. Large presses hire experts in typography and design. An outstanding example of an adviser to a press was Bruce Rogers, long connected with Riverside press, whose beautiful books became collectors' items.

7. Reading in the **20th** Century.—Modern statistical reporting yields a fairly clear picture of ability to read. In such countries as Norway and the Netherlands, illiteracy is negligible. In most modern industrial countries well over 90% of the population can read. Functional literacy alone, however, does not make habitual book readers. The American Institute of Public Opinion reported surveys of adult book reading in highly literate countries (1950–57). In Great Britain over one-half those interviewed were reading a book when they were questioned. In Scandinavia, western Germany, Canada, and Australia. book readers ranged from 30% to 45%. In the U.S. less than 20% were book readers However. surveys made over a period of 20 years showed that 60% of the adults in the U.S. read at least one magazine regularly and 85% read one or more newspapers daily.

Some efforts to extend reading led to a study of the factors which make a book readable. Investigators tried to discover the relationship of literary style. vocabulary and syntax to speed and comprehension of reading. Pioneered by educators interested in teaching reading in schools, readability studies have developed findings applicable to the reading of adults. Some investigstors derived formulas for readability. Perhaps the most widely publicized formula was that of Rudolf Flesch, which is based on sentence length and word length.

After the founding of the United Nations, the United Nations Educational, Scientific and Cultural Organization (USESCO), through its Fundamental Education program, tried to promote reading in the underdeveloped areas of the world. There is a double barrier: (1) illiteracy is high; reports from India and Egypt revealed that no more than 15% of the inhabitants could read at mid-20th century; (2) publishing has languished in those countries, and there is a lack of vernacular books for people to read. The governments and the Fundamental Education program had the twin objectives of increasing literacy and publishing vernacular books for general reading.

For countries possessing ancient and complex cultures but with few vernacular books questions have been raised about the importance of the book in society. Some students regard publishing programs and campaigns to promote literacy as too slow to be helpful in a rapidly changing world. They recommend a greater use of radio, television and motion pictures to educate the citizens of such countries in technological aspects and cultural relations of a shrinking planet, *e.g.,* the stories and themes of the folk culture of India were cast directly into motion pictures without the mediation of books. However, the experience of the countries which are literate, have strong publishing activities and also have the new media, indicates the essential role of the book, which derives from its characteristics of relative permanence and portability. The message of the book lasts longer, and caters to the individual as opposed to the mass.

BOOKBINDING, the joining together of a number of leaves (most frequently of paper, parchment or vellum) within covers to form a codex or book (*q.v.*) as opposed to a roll.

HISTORY

Bookbinding began when the codex started to replace the roll. The parchment notebook first appeared as a rival to wax tablets shortly before the beginning of the Christian era. Classical texts existed in codex form before the end of the 1st century A.D. but at first the codex was normally reserved for Christian books and did not become common for pagan literature before the 4th century.

Coptic and Islamic Bindings.—The earliest elaborately decorated bookbindings were those produced for use on church altars and those that survive are often magnificent examples of the jeweler's, goldsmith's, ivory carver's or embroiderer's arts. But the typical artistic bookbinding is of decorated leather, an art first practised in the monasteries of the Coptic Church in Egypt. Surviving examples, mostly of red or brown goatskin from the 8th

and 9th centuries, show a maturity of design and a wide variety of techniques that indicate the craft had been practised several centuries earlier. In contrast with later European bindings they appear to have been produced by specialists in all forms of decorative leather work and show a variety of techniques — tooling, piercing of the leather and decoration with a stylus.

The earliest-known Islamic bindings were influenced by Coptic designs and methods. At first the horizontal axis of the book was usually longer than its height and the covers were blind-tooled (*i.e.*, ungilt) with formal decoration. By the 11th century the characteristic Islamic design of an oval centre ornament with triangular cornerpieces was in use in Egypt. Two centuries later bindings of first-class workmanship were being produced in Morocco The vertical axis had now become the longer one and the use of gold, both in the form of paint and as gold leaf impressed with a hot metal tool, had become established. Moroccan bindings of the highest class — the majority covering Korans — continued to be produced throughout the 14th and 15th centuries, but even finer craftsmanship was practised in Persia during the 15th century. Floral designs began to replace geometric patterns and some pictorial bindings were produced by embossing with molds. Vivid colouring and delicate filigree work were used with great effect on the insides (or *doublures*) of the covers and flaps that are a feature of these oriental bindings. Similar work was produced in Turkey.

Lacquered bindings appeared first in Persia in the second quarter of the 16th century. the design being painted on specially prepared leather or pasteboard. This style was particularly popular in India as well as Persia and is still practised in the east. But hardly any new ideas have been introduced into oriental bookbinding since the 16th century and the work has become more and more repetitive and the quality has steadily deteriorated.

European Binding and Decoration. — Beginnings. — The earliest known European decorated leather binding, that of the Stonyhurst Gospels from the tomb of St. Cuthbert, is probably English work of the late 7th century. In technique this and one of the three bindings at Fulda that belonged to St. Boniface, the English apostle to the Germans who died in 754, show affinities with Coptic and Islamic work. But by the 10th century European bindings had developed a totally different construction from those of north Africa and Asia, being sewn on cords securely laced into the boards of the binding. Their decoration also developed on different lines, consisting almost invariably of tooling in blind with individual engraved tools. The earliest Carolingian and Ottonian bindings were probably produced in German and French monasteries. They are of blind-tooled deerskin; many of their tools are circular and resemble coin designs.

A more interesting romanesque group dates from the 11th to the 13th centuries. Most of these were produced by lay craftsmen for university students in Paris. Only a few were bound in England, where the technique of blind tooling died out completely by the 14th century. In France, however, it was never wholly abandoned and in all countries, when the invention of printing led to a great extension of binding activity, there was a strong revival of blind tooling. These Gothic bindings of the second half of the 15th century were again mainly decorated mith blind lines and single engraved tools, but the period also saw the spread of two labour-saving devices, the roll (first used in Germany), which produced an engraved strip of decoration, and the block or panel stamp (found in the Netherlands as early as the 13th century), which printed a complete design on the covers of a book with the aid of a simple press. In German-speaking countries there was also practised the so-called *cuir ciselé* or "cut-leather" technique, which usually involved freehand designs on the leather with a stylus or folder rather than a knife. Bindings in the Gothic style continued to be produced in Germany and eastern Europe all through the 16th century and for some time later. By 1459, however, gold-tooled bindings were being produced in north Italy (probably at Venice), the influence of the Levant being shown in the designs of the covers, the patterns of individual tools and a greater delicacy of workmanship. The introduction of gold tooling into southern Italy may have been via Spain, where it had appeared through the influence of Moorish craftsmen From Naples (where they had worked for the Aragonese royal family) came the craftsmen who bound at Buda in the last decade of the 15th century for King Matthias Corvinus of Hungary.

16th-Century Developments. — Until after 1530 Italian gold-tooled bindings were supreme in Europe, the early French gilt bindings from the Blois bindery being imitative of Italian work. In 1538, however, morocco leather (made from good-quality goatskin) became available in France and from that time on the Paris binders have enjoyed a supremacy that has seldom been challenged. The earliest great French collector was Jean Grolier, who used the well-known device Jo. *Grolierii* et *Amicorum*—for Jean Grolier and his friends. An even greater collection than that of Grolier or his friend "Maiolus" (Thomas Mahieu) was formed by Henry II of France, whose binder was probably Claude de Picques. The tools used in this great period of French bookbinding were derived via pattern books for embroidery or metalwork from oriental or arabesque models and most of the designs incorporated interlacing strapwork. Further elaboration of this strapmork to outline small compartments of various shapes and sizes with a ribbon bounded by a double line on one side and a single line on the other produced the characteristic fanfare design of the last quarter of the 16th century, some of the best of which came from the workshop of Nicolas Ève.

Italian binding, notably the fine series of Roman medallion bindings probably executed for Pierluigi Farnese (not, as was at one time thought, for Demetrio Canevari) and his tutor, Apollonio Filareto, kept pace with the best Paris binding up to the middle of the 16th century. The leading German binder of the period was Jakob Krause, court bookbinder to the elector of Saxony.

The most characteristic early 16th-century English bindings were those blocked in blind uith panel stamps of the royal arms, used as decoration and not to denote royal ownership. The earliest English gilt binding dates from 1519, but gold tooling was not regularly practised before 1530, when a craftsman called King Henry's binder was working in the Italian style. Thomas Berthelet, the king's printer, was paid for supplying Henry VIII with "gorgeously gilt" bindings, but it is not known whether he had his own bindery, and several different shops were copying French designs in London in the 1540s and 1550s. One notable English collector, Thomas Wotton, acquired nearly all his finest bindings in France. The English gold-tooled bindings from the libraries of Robert Dudley, earl of Leicester, and Queen Elizabeth I show strong French influence; some were probably the work of Huguenot refugees from Paris and Lyons.

17th Century — The Lyonese bindings mith large blocked centre- and cornerpieces of oriental derivation, which had been produced in almost every European country during the second half of the 16th century, continued in fashion at the start of the 17th. The better-class Paris bindings, however, were either still in the fanfare style or had rectangular panel designs mith spiral and floral tools having solid outlines. It was probably in this style that Le Gascon worked. The bindings erroneously associated with his name date from shortly before 1640 until about 1660 and have designs based on the fanfare patterns and tools with dotted (pointillk) outlines. Some of them are the work of Florimond Badier. The last 40 years of the century showed little innovation in French binding although one or two examples of great distinction were produced in the 1660s for the royal family. In Germany the political situation was not conducive to luxury trades such as fine binding. The characteristic Italian bindings of the century — nearly all the best examples come from Rome — very frequently incorporate a fan in their decoration. The same design appears in France and also in England, nhere during the first half of the 17th century most of the leather bindings were rather coarse and clumsy imitations of French work.

In the Commonwealth period variegated colour and more delicate tooling were introduced and with the Restoration came the golden age of English binding. It is now possible to recognize the work of some of the binders of this period, such as Stephen and Thomas Lewis, Henry Evans, Samuel Mearne, Fletcher, Roger

Decorated leather Coptic binding on an 8th-century manuscript of the Four Gospels from the library of the monastery of St. Michael of the Desert, Fayum, Upper Egypt. It is made of papyrus boards covered with dark brown leather, to which is stitched an elaborate panel of red leather openwork tracery over a gilt parchment background

German jeweled binding, a characteristic medieval altar book binding on the Sion Gospels, from the Cathedral of Sion, Valais, Switzerland; c. A.D. 1000. The embossed figure of Christ and surrounding foliage date from the 12th century. The boards are of beechwood overlaid with gold. Each frame is set with precious stones; cloisonné enamels decorate the outer frame

Late 7th-century English binding on the Stonyhurst manuscript Gospel of St. John, found when the shrine of St. Cuthbert (d. 687) at Durham was opened in 1104. The binding is red goatskin over thin birch boards; the central vine-leaf ornament and inner and outer frame lines are molded over cords. The interlacing ornament has been coloured in yellow, blue and perhaps green

12th-century Romanesque binding on the Winchester Domesday Book (Liber de Terris Regis Reddentibus *Langabulum* et *Brugium* in *Winton*); c. 1148. The original brown leather sides are mounted on a modern binding. They are tooled in blind (without using gold) with individual hand tools; most of the designs portray fabulous monsters

COPTIC AND EUROPEAN BINDINGS OF THE 7TH TO THE 12TH CENTURIES

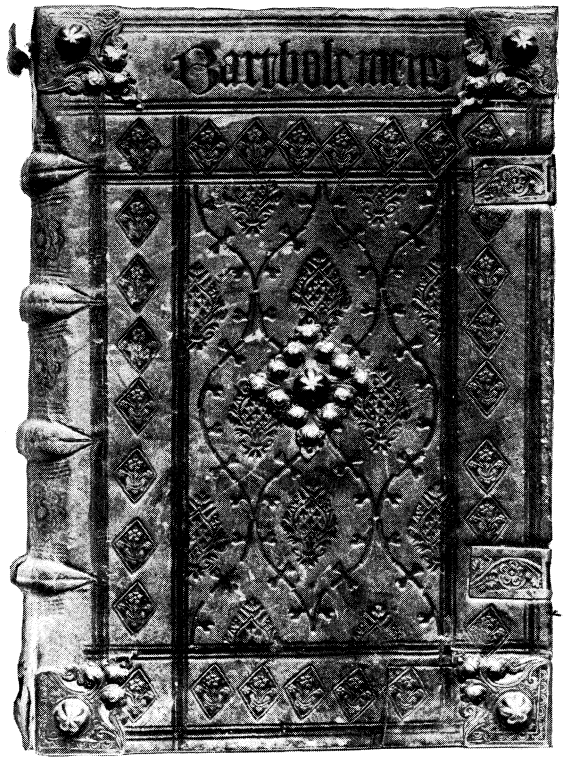
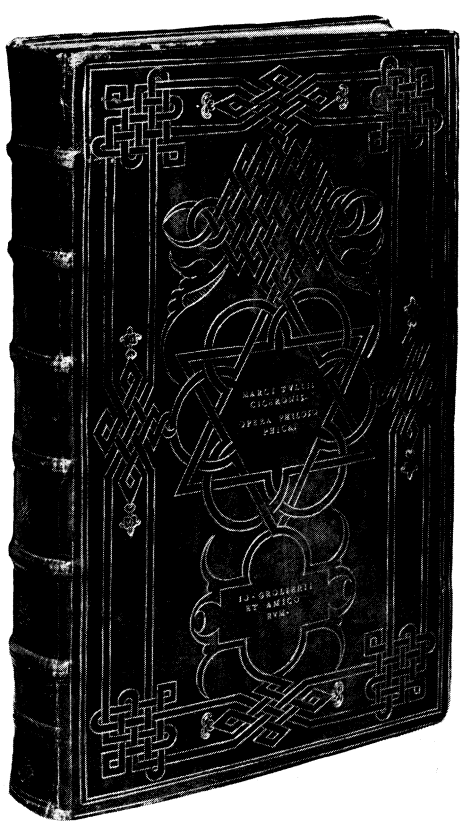
BOOKBINDING

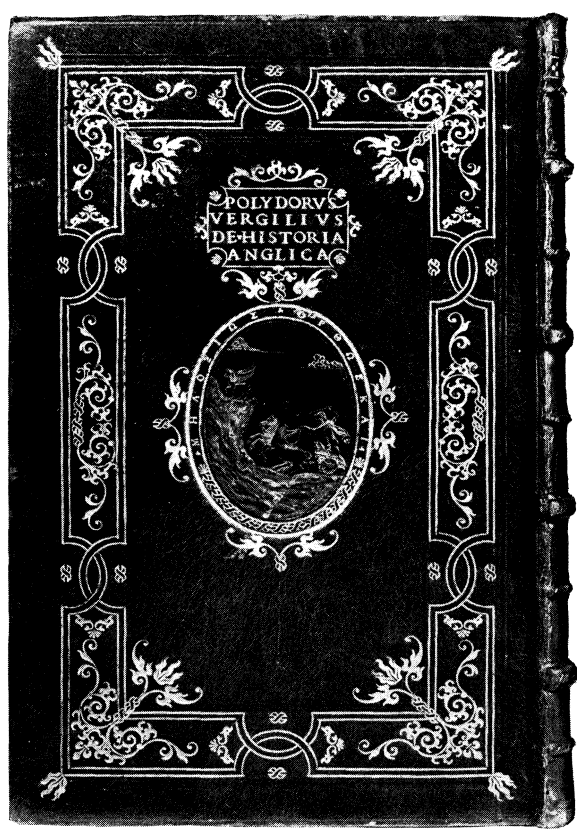
Persian binding on an early 15th-century manuscript Koran. The cover is of light brown morocco leather (goatskin) tooled in gold; the *doublure* (inside of the cover, illustrated here) is of red morocco leather. The centre and corner pieces and the panels of the frame are cut out and filled with delicate filigree work of brown leather over blue grounds and gold designs



German 15th-century Gothic binding on Bartholomaeus Anglicus' De *proprietatibus rerum,* Nürnberg, 1483. It is made of wooden boards covered with blind-tooled brown leather and fitted with metal clasps, bosses and corner pieces. The design of the central panel and the inclusion of the author's name on the upper cover are characteristic of Nurnberg work



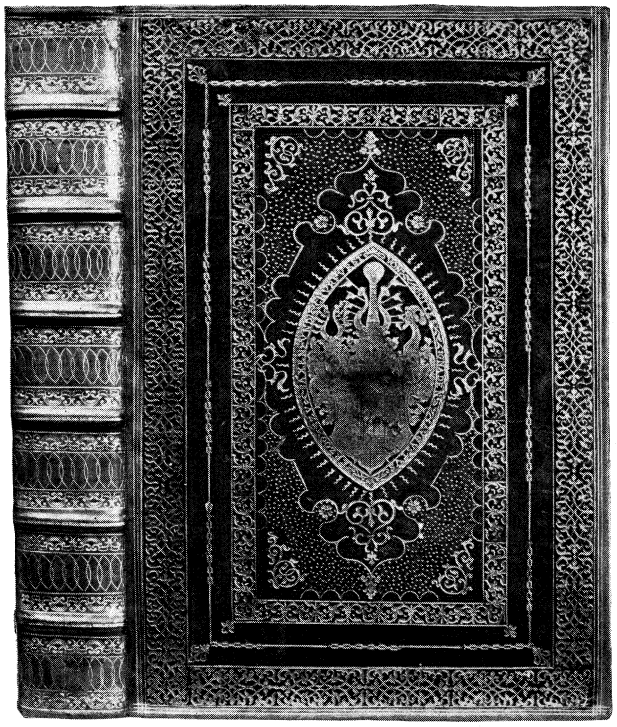
French binding on a volume of Cicero, *c.* 1545. Bound in Paris for Jean Grolier, one of the earliest great French book collectors, it carries the ownership inscription *Jo.* Grolierii et *Amicorum* ("Jean Grolier and his friends"). The binding is made of green morocco leather with an elaborate gold-tooled interlaced geometrical design



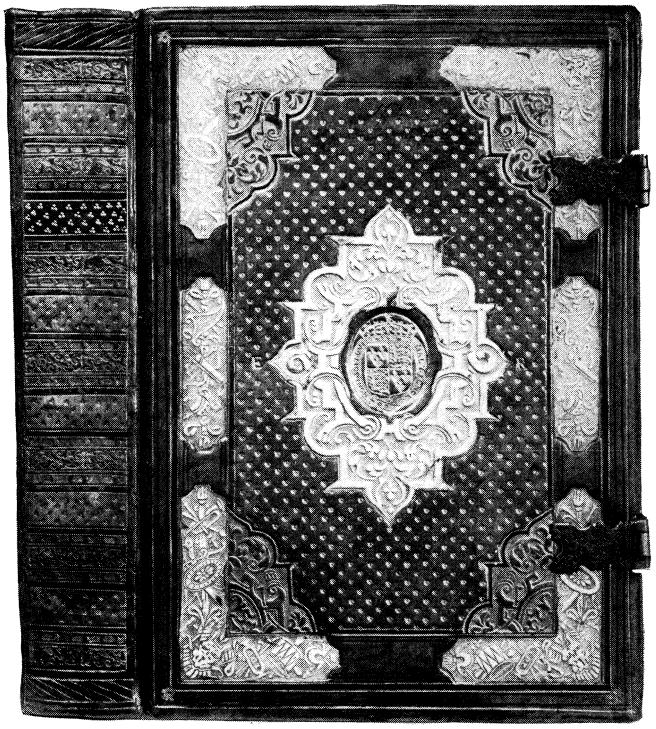
16th-century Italian binding on Polydore Virgil's *Anglicae* historiae *libri* ***XXVI,*** one of a series of Roman medallion bindings probably executed for Pierluigi Farnese. It is made of gold-tooled green morocco leather with a central painted medallion representing Apollo driving his chariot toward Mt. Helicon, on which Pegasus stands

PERSIAN AND EUROPEAN 15TH- AND 16TH-CENTURY BINDINGS

BOOKBINDING

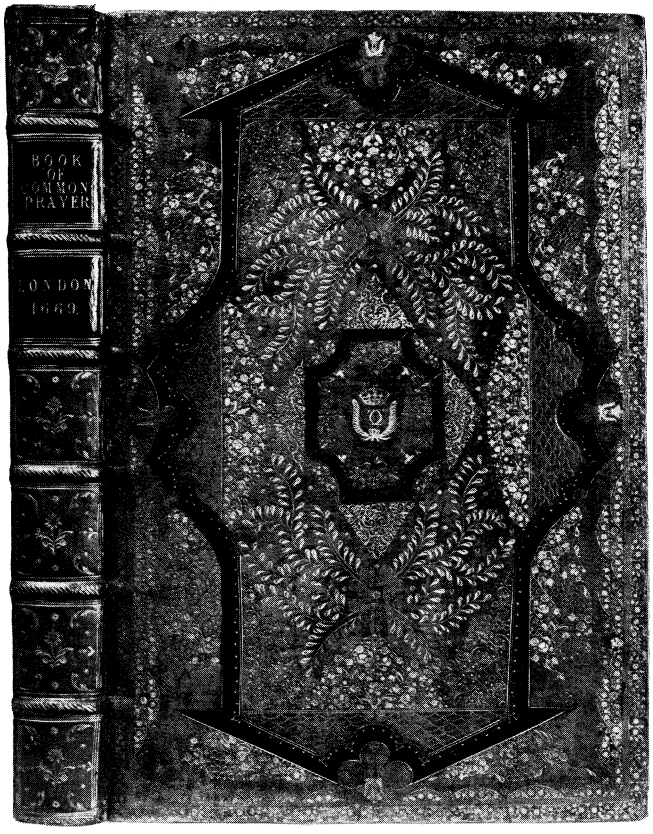


German binding on Plutarch's Vitae *illustrium* virorum, *c.* 1580, by Jakob Krause, whose initials appear on the fore-edge. It is made of gold-tooled brown calf. The edges of the leaves are gilt, goffered and painted. In the centre is the coat of arms of Augustus I, Elector of Saxony, for whom Krause was court bookbinder



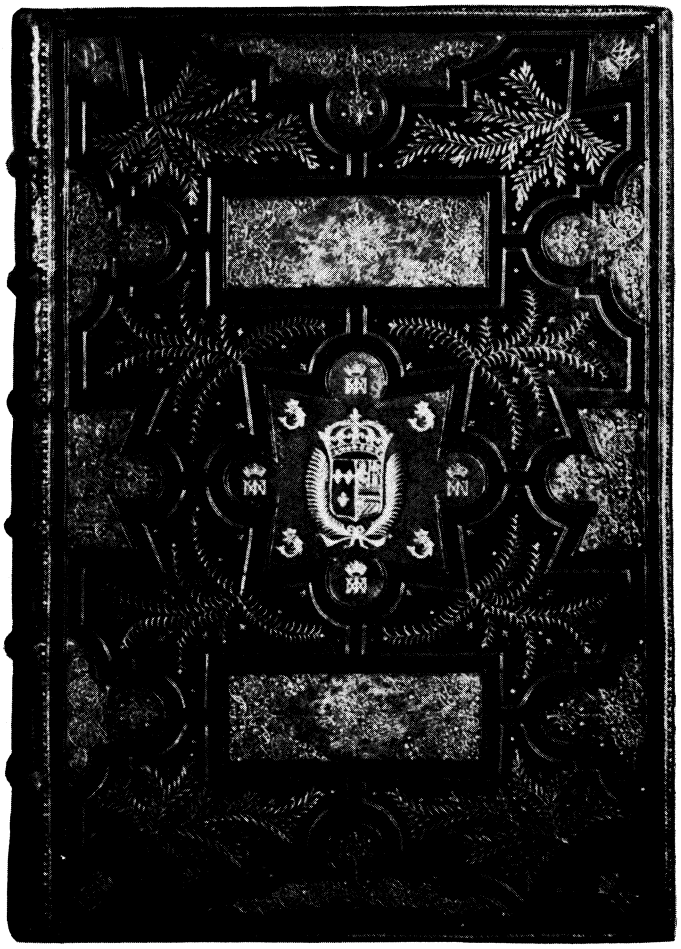
16th-century English binding on "Matthew of Westminster," *Flores historiarum,* bound for Queen Elizabeth I; 1570. The brown calf binding is blocked and tooled in gold with onlays of white leather. The gold tooling is French in style; and the initials IDP, in the L-shaped corner pieces, are possibly those of the Huguenot binder, Jean de Planche

French binding on Poetae Graeci, bound in Paris; *c.* 1575. The binding is of red morocco leather and bears tne coat of arms of the historian J. A. de Thou as a bachelor. It is decorated with a gold-tooled fanfare design produced by an elaborate pattern of interlacing strapwork, a characteristic style of French bookbinding during the late 16th century

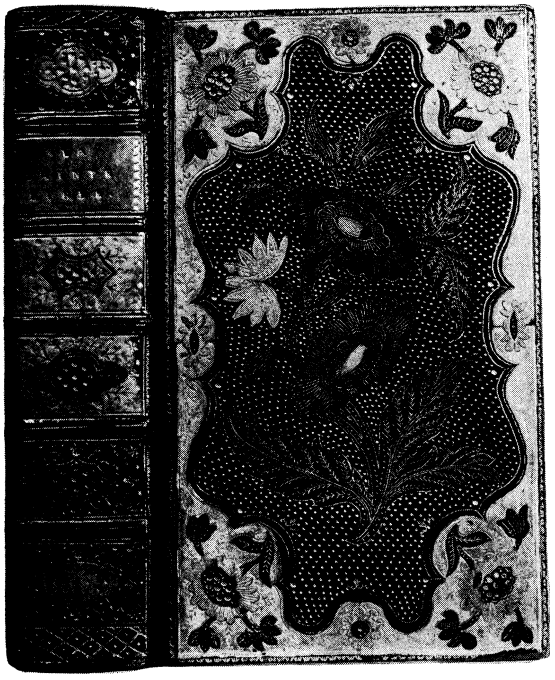


English Restoration binding by Samuel Mearne on a Book of Common Prayer, London; c. 1669. A cottage-roof binding, so-called because of its broken pediment design painted in black, it is made of gold-tooled, red morocco leather. Bound for one of the royal chapels, it carries the cipher of King Charles II

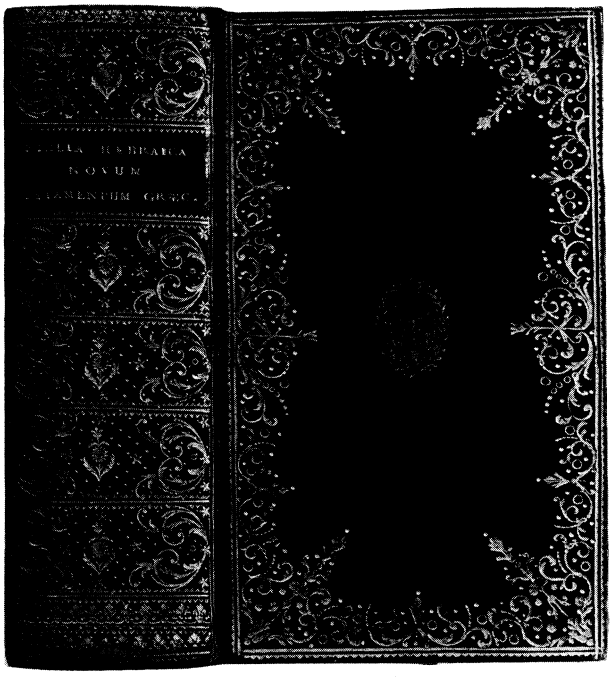
GERMAN, ENGLISH AND FRENCH BINDINGS OF THE 16TH AND 17TH CENTURIES



French mosaic binding bound for Queen Marie Thérèse; 1661. Made of gold-tooled red morocco leather with brown and olive inlays, it carries the arms and cipher of Louis XIV's consort. The crowned dolphins probably are in honour of the dauphin, born in the year in which this presentation copy was bound



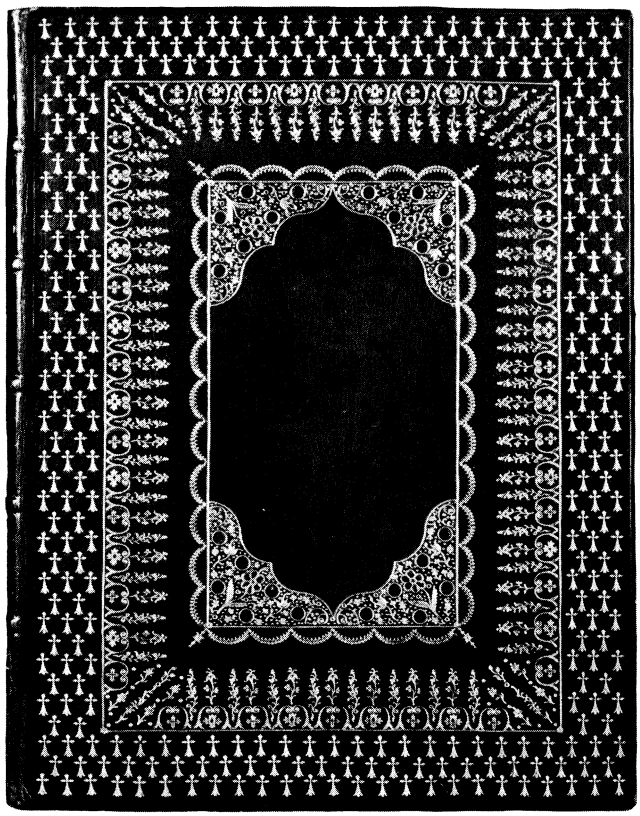
French mosaic binding on *La Sainte* Bible, Cologne, 1739, bound by Le Monnier; c. 1750. It is made of gold-tooled red morocco leather with cream, citron and olive onlays which form a floral design. It is signed at the foot of the cover MONNIER FECIT



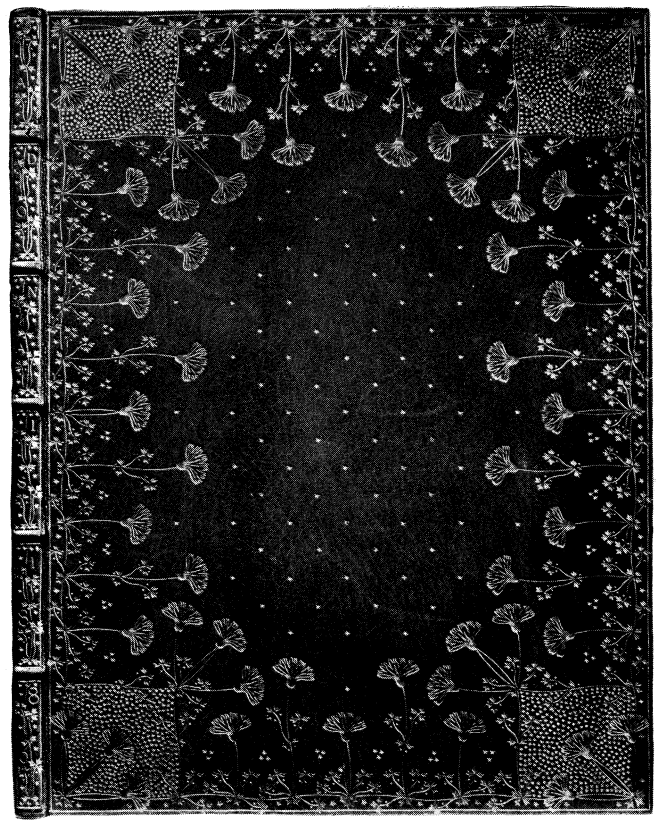
French binding on *Biblia Hebraica;* Novum Testamentum Graec., Glasgow, 1750, bound by N. D. Derôme; c. 1770. A dentelle binding of blue morocco leather with a gold-tooled lacework border. The coat of arms of C. M. Cracherode was added later

FRENCH BINDINGS OF THE 17TH AND 18TH CENTURIES

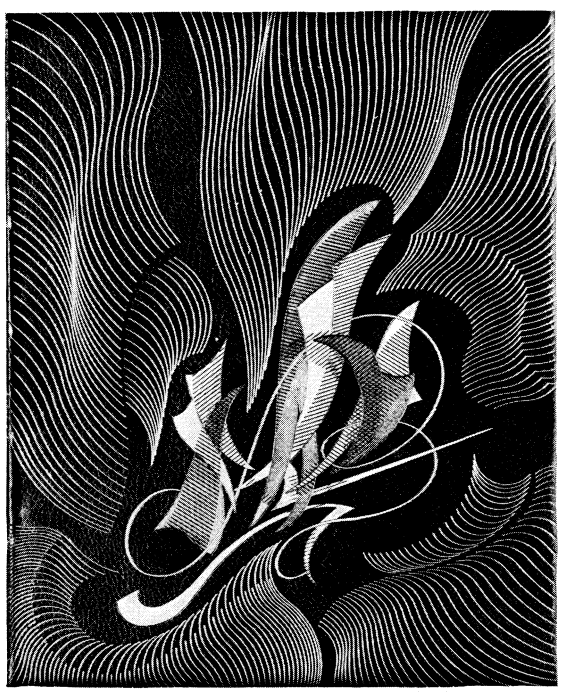
BOOKBINDING



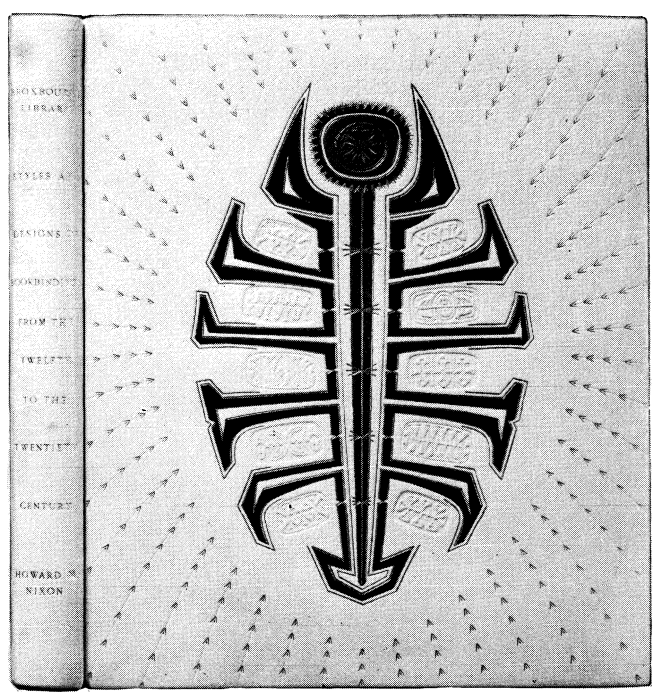
English binding on An Account of the *Bedford* Missal bound about 1794 by Roger Payne, an influential London binder during the late 18th century. The binding is made of olive morocco on which is a gold-tooled panel design. Payne's designs were among the few English styles to be copied in Paris



English binding on Shelley's Adooais bound by T. J. Cobden-Sanderson of London; 1888. Made of brown morocco leather, the binding is delicately decorated in gold with floral tools which the binder designed himself. Cobden-Sanderson's designs gave new impetus to leather binding in England



French binding on Léon-Paul Fargue's *D'après* Paris bound by Paul Bonet: 1945. The binding is of black morocco leather, tooled in gold, with onlays of blue, red, brown and white leather. The central motif is an abstract "Ship of Paris" plunging through the waves



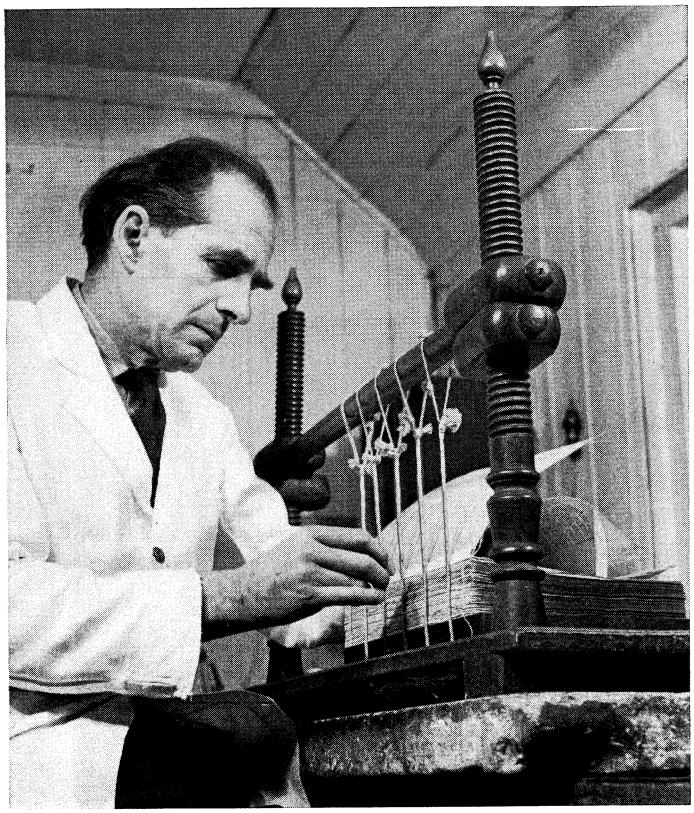
Alum-tawed pigskin binding on H. M. Nixon's Styles and Designs of Bookbinding from the Twelfth to the *Twentieth* Century, bound by Peter Waters of England; 1960. Tooled in gold and blocked in blind, it has onlays of orange, brown, gray, dark and light blue leather

ENGLISH AND FRENCH BINDINGS OF THE 18TH TO THE 20TH CENTURIES

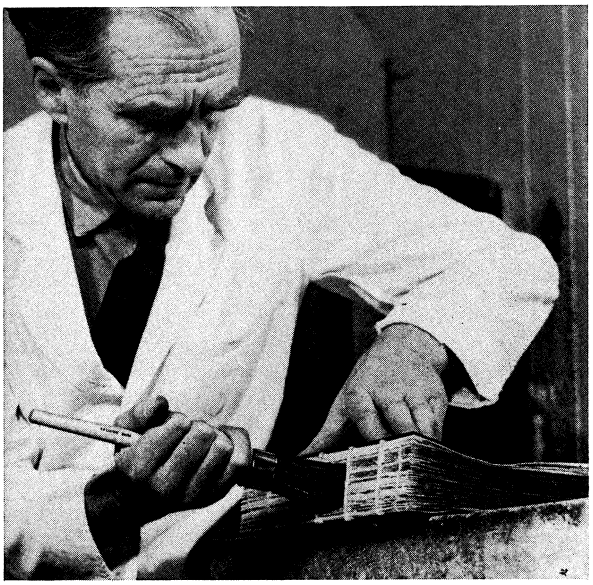
BY COURTESY OF (TOP LEFT) LORD ROTHSCHILD, (TOP RIGHT) THE TRUSTEES OF THE BRITISH MUSEUM, (BOTTOM LEFT) LIBRARY OF CONGRESS LESSING J. ROSENWALD COLLECTION; PHOTOGRAPH, (BOTTOM RIGHT) PETER WATERS

BOOKBINDING

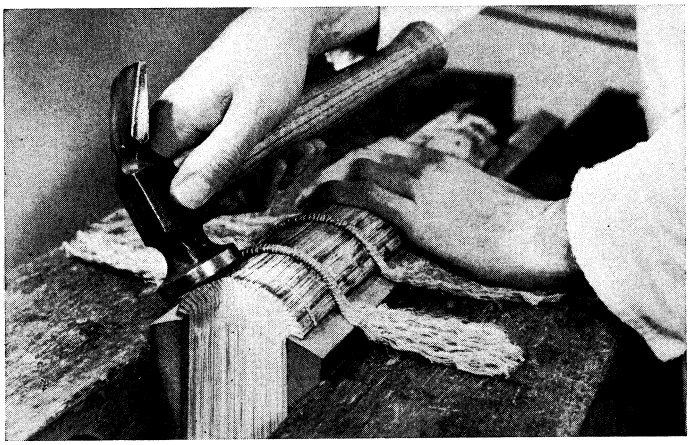
PRINCIPAL STAGES IN THE BINDING OF A BOOK BY HAND



1. Sewing the sections, or signatures, to hemp cords on a sewing frame. The bookbinder in this series of photographs is Sydney M. Cockerell, English binder

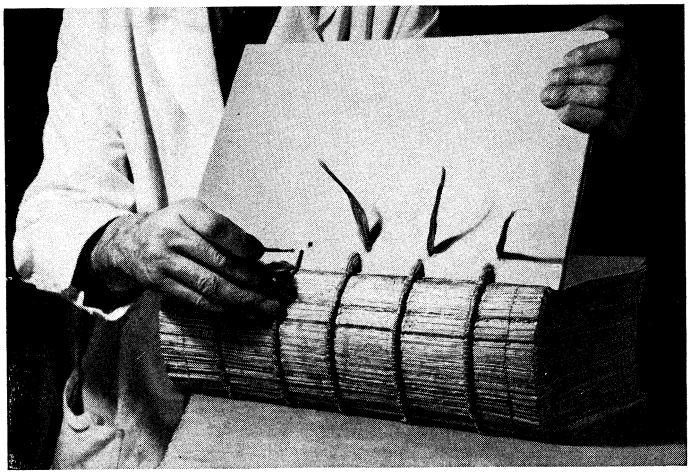


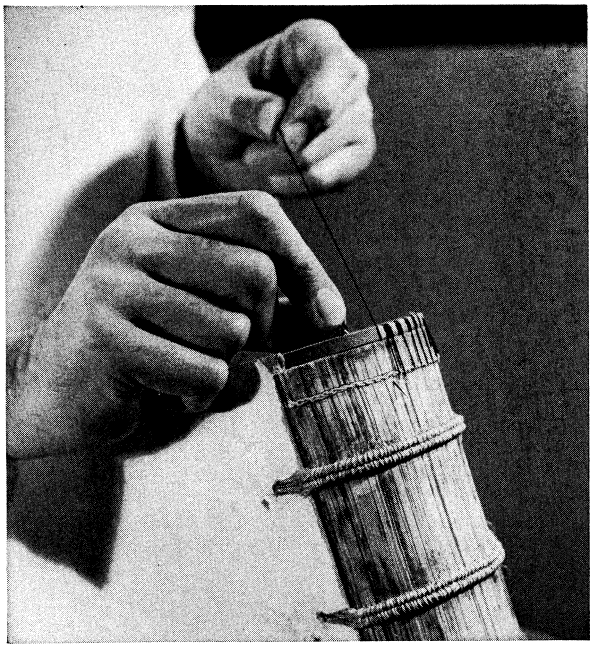
2. Applying the adhesive to the spine of the sewn book



3. Backing: forming the joints on the spine of a book in a lying press

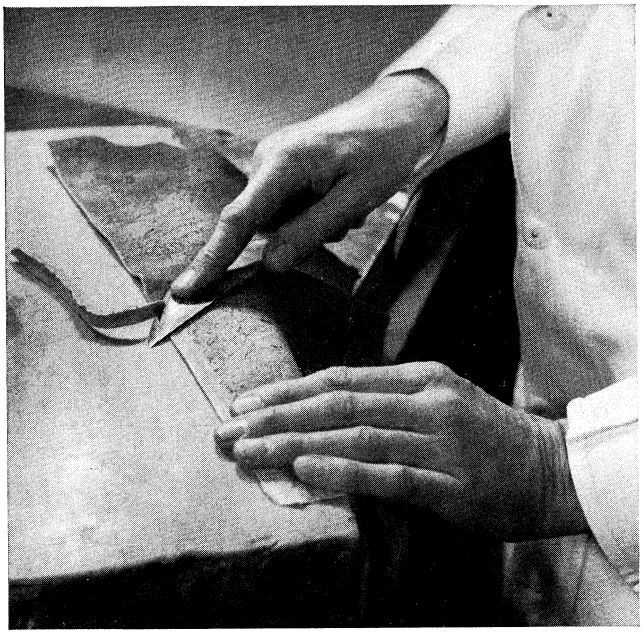
4. Lacing the ends of the sewing cords (slips) into the boards





5. Making the headband with silk thread

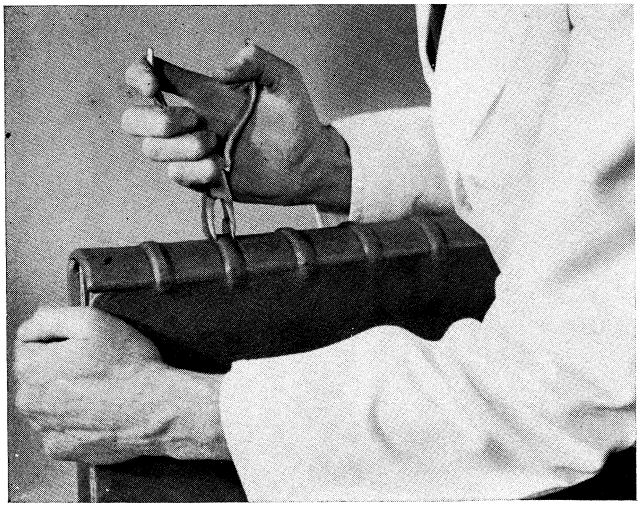
PHOTOGRAPHS ON BOTH PAGES BY COURTESY OF THEO COCKERELL



6. Thinning the edge of the covering leather with a paring knife

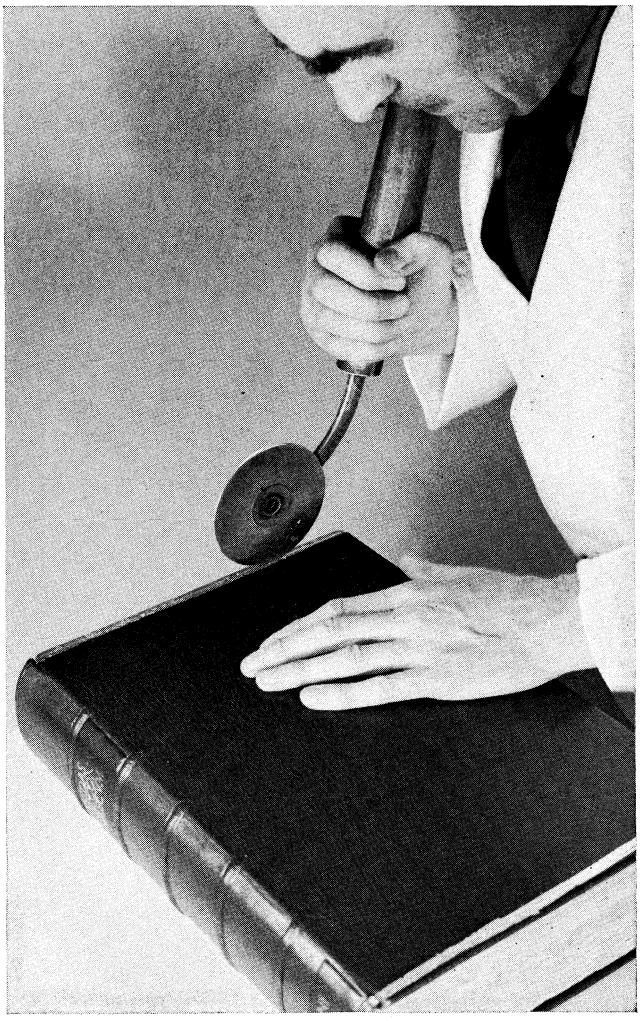
7. Paring the inner surface of the covering leather with a spokeshave

8. Shaping the damp leather to the bands of the covered book with band nippers



9. Tooling the title on the spine with handle letters through gold leaf

10. Running a gold line on the covered book with a fillet through gold leaf



Bartlett of Oxford, Richard Balley and Alexander Cleeve. Some of the tools they used are in the French *pointillé* style; others, including small floral volutes, are typically English. A feature of many of the designs is the broken pediment of the so-called "cottage" or "cottage-roof" bindings, while other designs, such as those used by the "Naval binder" in making his mosaic bindings. are strongly reminiscent of oriental carpets.

18th *Century.*—The regency (1715–23) introduced a new spirit into French binding marked by the mosaic bindings of Augustin du Seuil and Antoine Michel Padeloup. Later in the century bindings in this style signed Lemonnier show an astonishing technical virtuosity. High standards of execution were also maintained on the dentelle bindings with their lacelike gold-tooled borders — the work of N. D. Derôme and others — and on the simpler armorial bindings of red morocco. Rome remained the most important binding centre in Italy, but most of the bindings produced there were rather clumsy imitations of French dentelle bindings, as were most of the Netherlandish and Spanish bindings of the century.

English binding degenerated markedly in the first half of the 18th century. The "cottage" style long outstayed its welcome and the Harleian style with its diamond-shaped centre ornament and rectangular border proved uninspired and mechanical, except in the hands of Moore of Cambridge. Both designs and standard of technique improved markedly in the 1760s. Robert Adam and James ("Athenian") Stuart each produced one fine neoclassical design. Rococo elements were introduced by Andreas Linde and Johann Baumgarten, earliest of the German-born craftsmen who almost monopolized fine binding in London at the end of the century. The most influential London binder of the 1790s was, however, Roger Payne. one of the very few English binders whose style was copied in Paris. The Edwards brothers of Halifax patented in 1785 a process involving the painting of figures and coats of arms on the underside of transparent vellum.

19th Century.—In the 19th century neoclassical, Pompeian and Egyptian influences mere ousted by "romantic" bindings employing coloured onlays and often tooled in the cathedral style with a central design resembling that of a Gothic rose window. From about 1840 to 1880 in all countries there was little new design in leather binding, the emphasis being on delicacy and precision of finish in carrying out pastiches of earlier styles. Meanwhile designers were devoting their attention to the opportunities afforded by the cloth-cased gift books of the period. In the 1880s new life was injected into leather binding design by Marius Michel in Paris and the ex-barrister T. J. Cobden-Sanderson in London.

20th Century.—The first six decades of the 20th century saw a flourishing school of modern binders in Paris with Pierre Legrain as its pioneer in the 1920s and Paul Bonet, Rose Adler and Pierre Lucien Martin among its leading figures. In England notable work was carried out by Douglas and Sydney M. Cockerell, Sybil Pye, George Fisher of the Gregynog Press bindery. Roger Powell in partnership with Peter Waters, and Edgar Mansfield.

Influential 20th-century binders in other countries included Otto Zahn, Edith Diehl, Curtis R'alters. Marguerite Lahey and Harold Tribolet in the United States; Paul Kersten, Otto Dorfner, Franz Weisse and Ignaz Wiemeler in Germany; Anker Kyster in Denmark; Giovanni Pacchiotti and Pio Colombo in Italy; and Emilio Brugalla in Spain.

Fore-Edge Painting.— The edges of the leaves of medieval manuscripts were sometimes painted, and gold-tooled bindings have usually had the edges gilt with burnished gold, often goffered with heated tools and occasionally coloured. From 1650 onward a number of London binders, including Stephen and Thomas Lewis, Fletcher. Henry Evans, and Samuel and Charles Mearne as well as A. Ogstoun, Erskine and A. Hislop in Edinburgh, practised a new decorative method. In this method floral scrolls or scenes were painted upon the fanned-out fore-edge of the leaves and concealed by a normal gilt edge nhen the book was closed; they became visible when it was opened. In the 18th century the method was continued by John Brindley, who bound for Queen Caroline, and later by the Edwards of Halifax bindery. A few genuine examples were produced during the 19th century, but the great majority of those found on early 19th-century books are modern. (H. M. N.)

HAND BINDING

Books now are produced by machinery and bound by machinery. though some books are still bound by hand because the machine cannot deal economically with single copies. nor can it repair a rare book or produce a work of art. Therefore there are hand binders to deal with the binding of single copies. Their work includes the making of fine tooled bindings, binding reference books and books of special economic or personal value and the repair of rare medieval manuscripts, early printed books and historical documents.

Materials for Bindings.— The traditional binding material is leather because it is flexible and can be molded to fit the book. If properly prepared it is very durable The book can be covered all over in leather (whole or full binding) or it may have a leather-covered spine with leather corners and paper or cloth sides to the boards (half binding in Britain. three-quarter binding in U.S.); without the corners it is called a quarter binding (in U S., half or French binding). Vellum made from calfskin is also an excellent covering material provided the construction of the book is suitable and the book is not subjected to large changes in humidity. Small vellum corners (vellum tips) are often used in place of leather corners. The skins of numbers of different animals have been used for leather bindings. Goatskin (morocco) is one of the most suitable. The leather should be tanned for binding, free from injurious acids and chemically protected against the acid rot that can be caused by the sulfur dioxide of urban areas. Besides leather there are sound binding cloths (coloured cloths that are fast to light). Polyvinyl acetate adhesives are replacing animal glues; they can be used cold and are less liable to insect attack.

Construction.— The binder's job is to fasten together the folded leaves of the codex form of book. This is done by seuing with linen thread through the fold of the sections around hemp cords or over linen tapes. stretched at right angles across the spine of the book. As a rule the binder makes up end paper sections that may be of coloured paper and sews them with the book. When the book is sewn the ends of the cords are cut off, leaving a projection of about $1\frac{1}{2}$ in. on each side of the spine of the book. These projections are called slips and are of vital importance because they provide the attachment for the boards of the binding.

The spine of the book is next coated with thin glue; this holds the sections together and enables the book to be shaped. The edges of the book may be cut at this stage. Before the glue has set, the spine is made convex by tapping it with a hammer (rounding); this causes the fore edge to become concave. The setting of the glue holds the book in this shape. When the book is opened the spine becomes concave, therefore any material stuck to the spine must be flexible, or the book will be stiff to open.

Backing.—Ridges (joints) are formed on each side of the spine by fanning the backs of the sections over backing boards held in a lying press (backing). This fanning is done with a hammer, the joints forming a groove for the boards to hinge in. At one time wood was used for book boards, hence the name codex, derived from the earlier Latin *caudex* ("tree trunk"). Wooden boards are still used occasionally but the majority of books are now bound using hard cardboard (millboard). The board is cut so as to project slightly beyond the edges of the leaves; these projections are called squares. Holes are punched in the board, the cord slips are frayed out, pasted and laced through the holes, the burrs around the holes are hammered flat and the ends of the slips cut off flush. When the book is sewn on tapes split boards comprised of a thin and thick card stuck together are used, the tape slips being inserted betneen the two boards. Headbands are sewn on to make up to the height of the squares at the head and tail of the spine. The headbands can be sewn with coloured silks over vellum strips; they are securely attached to the book by frequent tie-downs through the backs of the sections.

Leather Covers.—A leather cover is cut from a skin, allowing for a turn-in all around; the turn-in of the leather is reduced

in thickness by paring with a knife or spokeshave (skiving) so that the edges of the covered boards will not be clumsy. The leather is pared along the joints so that the boards can be opened freely. The paring must be kept to a minimum since excessive thinning of the skin weakens it. The cover is well pasted with flour paste and allowed to soak. The moisture in the paste penetrates into the leather, making it supple so that it can be molded to fit the book; the pasted cover is placed on the book and drawn down over the spine. The leather is turned in over the boards and at the head and tail of the spine. Damp leather can be molded to almost any shape and a well-covered book looks as if the leather had grown on it. When the leather is dry the turn-ins are trimmed and the space filled level with thin cardboard.

Titling and Decoration.—The title is tooled on the spine with heated handle letters. A separate tool is used for each letter impressed on the leather. If the lettering is to be in gold the impressions are painted with white of egg (glair), gold leaf is laid on and the hot tools struck again through the gold. The heat of the tool sets the glair. which holds the gold in position, and the surplus gold is removed with a gold rubber. If the binding is to be tooled, the pattern is drawn on thin paper and the finishing tools struck on to the leather through the paper. The finishing tools can be engraved and cut to almost any shape—dots, rings, curves (gouges), straight lines, leaves, etc. Long lines are run with a rotating brass wheel (fillet); repeating strip patterns are made with a roll (a wide fillet with a pattern engraved on the periphery). Large emblems, arms and crests are put in with a blocking press since they require more than hand pressure to strike them. Coloured leathers can be used for decoration combined with the tooling, termed inlay when cut into the leather of the cover, or onlay, which is more usual, when very thin leather is applied to the surface of the cover.

Bindings can be further enriched with metal corners and clasps made of silver, sometimes gold-plated. Heavy books such as lectern Bibles may have metal or ivory bosses for the book to ride on or they may be studded with silver nails to protect the leather from friction. The latter treatment is usual for church service books and rolls of honour.

Design.—Technique is essential and it takes years to train a skilled binder. The most important factor in the making of a fine binding is the design; this includes the selection of the materials and methods as well as the decoration. On rare occasions a fine binding may be classed as a work of art. A sound binding will protect a book for several hundred years. (S. M. Co.)

MACHINE BOOKBINDING

The increasing demand for books throughout the world has forced manufacturers to look for machines that give high productivity and eliminate hand operations as much as possible. This has led to great advances in the mechanical methods of binding books and to the introduction of automation. Machine production is divided into two main classes, edition or hard-bound products and paperback publications.

Edition or Case Binding.—Folding and Gathering.—The sheets arriving from the press have to be folded into sections, or signatures. Machines designed for this purpose can fold 64-page sheets at speeds of up to 3,000 sheets an hour, delivering them as one 63-page, two 32-page or four 16-page sections. New types of printing machines also incorporate folding mechanisms that deliver all the sections for a small book at one operation.

Bundling removes air from between the leaves and facilitates stacking of the folded signatures. The sections are placed into a trough, between boards of the size of the sections, where they are compressed either mechanically or hydraulically and then are tied with cord or tapes.

End sheets or end papers are attached mechanically to the first and last sections of the book by automatic machines that handle up to 5.000 end sheets per hour. These machines are also used for tipping (pasting) illustrated plates to the outside of the sections, but plates that have to he positioned opposite a text appearing inside a section have to be pasted in by hand. Sections of books subjected to hard usage sometimes are reinforced with strips of linen or paper along the folded or binding edge; this is done on machines called strippers. Reinforced signatures, usually the first and last. help hold the book in the case since the reinforcing strips are glued to the case boards under the end sheets.

Machines for gathering or collating sections consist of a number of boxes or hoppers into which quantities of each signature are placed at the start of the operation; there is one hopper for each signature, and the signatures are arranged in the hoppers in consecutive order, *i.e.*, a pile of signature number one is placed in the number one hopper, of signature number two in the number two hopper, etc. The action of the machine is such that on each cycle a section is pulled by an arm or drum from the bottom of the pile of each hopper and dropped on a traveling conveyer; with each revolution of the machine, the conveyer belt advances the distance from one hopper to the next to receive the next signature. When the machine is in full operation one complete, gathered book is delivered at each cycle of the machine. A gatherer will deliver as many as 120 books a minute.

Sewing.—The sections, having been gathered into their correct order, are then ready to be connected together either by sewing, which is the usual method, or by threadless or unsewn binding (called "perfect" binding in U.S.), which utilizes glue instead of thread. Great progress has been made in the speed and versatility of the sewing machine, and the models in greatest use in the 1960s were either the semiautomatics, whereby the operator places the sections to be sewn over a stationary saddle from which they are conveyed automatically to the sewing position, or the fully automatic sewers. which are equipped with a hopper into which the sections are placed mith the subsequent operations of feeding and sewing and cutting-off being accomplished at speeds in excess of 100 sections per minute without any further action by the operator. It is possible for these machines to affix tapes to the backs of the books when extra strength is required. It is not unusual for large heavy books such as encyclopaedias, reference books and library books to be side sewn. Side sewing machines are equipped mith heads that drill holes through the books, with synchronized stitching heads sewing through the prepared holes.

Threadless or unsewn binding gained prominence during the 1950s. This system substitutes for the sewing operation the method whereby the backs of the sections are cut off so that the book block is of single leaves; hot or cold glue of a flexible nature is then applied with a strip of gauze or linen. This system of binding is often used in the production of novels and books of that general type, but it is not extensively employed for bonding together books composed of mixed types of paper.

Smashing and *Nipping*.—In order to reduce swell and bring the books down to a uniform thickness it is necessary to smash or nip. Nipping is the term used for reducing the back swell, and smashing applies to the allover compression of the book. Whether the book is nipped or smashed depends upon the type of paper used. With novels it is only necessary to nip the backs of the books whereas with Bibles allover smashing is essential to make sure that the air trapped between the large number of leaves is completely expelled. Nipping has assumed increased importance with the introduction of automation into the binderies, since automatic production depends to a great extent upon the uniformity of books.

Book-trimming is invariably performed on three-knife cutting machines that trim all three sides of a four-inch to six-inch pile of books at 15 to 25 piles per minute. They are usually automatically fed with delivery onto a moving belt. A machine developed in the United States trims books singly at speeds up to 70 books per minute, which facilitates the incorporation of the trimming stage into an automatic line.

Book back *gluing* is now carried out at high speed on automatic machines that pass the books after gluing along a conveyer where hot and cold air remove surplus surface moisture from the adhesive and permit the succeeding operation within a few minutes. Some machines perform both the back nipping and gluing in one operation.

Edge *Colouring*.—Edges of the book are coloured (stained) in various ways. Usually only the head is coloured. The most popu-

lar colouring method is that in which a gun is used to spray spirit or water colours; brush and sponge methods utilizing solid jelly colours are common in European countries. The gilt-edging of books by mechanical means is now possible with two machines patented in Great Britain and some machines developed in the United States. With one process. gold from a plastic backing is blocked (stamped) onto the edges; the second process utilizes heated rollers. The mechanical application of gilt to the edges of books has revolutionized the art of edge decoration. Books may now be edge-decorated with gold, imitation gold or coloured foils at speeds many times that of the hand method.

Rounding and Backing.—Several machines were used in the early 1960s for putting the round into the back of the books and making the joint or shoulder into which the cover boards hinge. One. operating at up to 40 books per minute, is equipped with an automatic feeder that transfers the books between two rollers that exert pressure while rotating and force the book into the rounded shape. The books are then clamped between steel jams with a predetermined amount of the back protruding according to the size of the joint required, and a concave steel former oscillates across the back of the books, splaying the signatures over the edges of the jaws and thereby forming the joint. A second machine is used for very long runs because it will handle two books at each cycle and, although the rounding and backing action is similar to that of the machine described first, this machine also glues off the backbone and applies the crash or super. the head and tail bands and the paper backbone lining. Recent hydraulic modifications to one rounder and backer made possible the handling of books of varying sizes without alterations to the settings and made the machine suitable for library rebinding.

Thumb indexing is still largely a hand operation but it has been speeded up considerably by the introduction of indexing guns operated by compressed air and by the printing of key marks on the margin of the book to facilitate the locating of the cutting position.

The gluing and lining of the backs is also performed by machines designed especially for this purpose. The machines will handle either rounded and backed books or flat back books. There is no provision on them for rounding and backing.

Casing-in, or affixing the book into its case (cover), is accomplished entirely by semiautomatic or fully automatic machines. Books are fed into a trough and automatically split onto an ascending blade that carries the book between paste rollers; the rollers apply adhesive to the end papers with allowance made for additional paste in the joints. The cases are automatically fed over a forming iron that is heated to give the correct size and shape to the backbone of the case and are then positioned accurately over the ascending book. The pasted book and the case are brought into contact and discharged from the machine. Semiautomatic casing-in machines can be equipped with a book back gluing attachment for tight back bindings, in which the case is glued directly to the backbone of the book, and a development called the joint and side gluing attachment can be fitted to the infeed so that the books being fed come into contact with two glue rollers that apply an exact amount of cold adhesive into the joint and along the mull (crash) of the book to give additional strength.

Books are fed automatically from the casing-in machine into a book forming and pressing machine. On entering this machine the books are forced accurately into contact with the case and then firmly gripped between clamp plates and transferred through the machine, where pressure is applied to the books and heated irons form the joint. The books are conditioned to a limited extent and hold their shape under varying temperatures better than with the earlier book press methods.

Jacketing has also been mechanized and machines are available that not only accurately position the jacket around the book but also heat-form it into a perfect fit.

The ntaking of *the* cases is now entirely a mechanical operation. Casemaking equipment can be divided into two classes: machines that make the cases from sheets of cloth already cut to size, and those that have the cloth fed into them from a roll cut to the proper width. With the sheet-fed casemakers the sheets of cloth are automatically fed onto a cylinder that revolves in contact with a glue roll. The glued cloth is transferred to a platform where the two boards and back lining are positioned accurately by a suction head and turn-in rollers fold the edges of the cloth securely over the boards. The cases then pass into a press that ensures firm contact of cloth to board over the entire case. In quarter-bound or three-piece cases it is usual for them to be passed twice through the sheet-fed casemaker although with roll-fed machines the case can be produced in one operation. Three-piece cases can also be made by first using a flat stripper to attach the two side pieces of cloth to the backbone strip and then finishing the case on a sheet-fed casemaker. A U.S. designed high-speed casemaker makes full-bound or quarter-bound cases in one operation at a speed of up to 40 cases per minute.

The modern casemaker is very versatile and will handle not only cloth but also paper, artificial leather and certain leathers of uniform thickness with round corners and with a centreboard in place of the back lining if required. The pieces of cloth for the casemaker are cut on cloth-cutting machines that cut reels (rolls) of various materials up to 72 in. wide and 24 in. in diameter. These cutters slit and cut off from reels of book cloth or artificiai leather at 40 crosscuts per minute, are equipped with a device for taking the curl out of the material and rewind the excess cloth. Board cutting is carried out at high speed and with great accuracy. with the board being cut in two directions in one operation. Blocking of the cases is performed on a variety of high-speed blocking presses. Some machines are capable of operating at 2,000 cycles per hour on some types of blocking and can feed cases either singly or two-up. A British rotary blbcker operates at speeds up to 8,000 an hour on ink and blind and up to 4,000 an hour with gold.

Automation was introduced into the binderies of the world during the 1950s. The invention of conveyer feeders incorporating a simple mechanical timing device made possible the linking together of many bookbinding machines into an automatic line, and by the early 1960s development had reached the stage where books could pass through the operations of sewing, smashing, trimming, gluing, rounding and backing. triple lining, casing-in, pressing, jacketing and packaging without intermediate handling.

Paperbacks.—Although a percentage of paperbacks is still produced on lines similar to those of the case-bound book with individual folding of the flat sheets into sections and sewing, wire stitching *or* gluing together of the pages, the specialist binderies have installed combination units that eliminate separate operations. These machines gather the sections into correct order, cut off the backs to form single sheets, glue, apply a strip of mull or super, apply the paper cover with adhesive and deliver the copies for trimming at speeds exceeding 3,000 an hour one-up or double this figure with two-up work. Single copy trimmers are often incorporated into these production lines. With two-up production, band saws part the books before they are moved to the three-knife pile trimmers for completion.

Packaging or wrapping for mailing is accomplished by automatic machines often in conjunction with addressing equipment synchronized with the wrapping device. (E. A. Bo.)

BOOKCASE: see CABINET FURNITURE.

BOOK COLLECTING, the exercise of taste, judgment and connoisseurship in the formation of a special kind of library. The collector's library is not formed primarily for reference, for current reading or for entertainment alone, though it may include these among other benefits as valuable by-products. The instinct to collect manifests itself in many fields. Persons who combine this urge with a love of the things of the mind and the spirit and a reverence for the past have often turned to the hobby of book collecting. There are many instances of omnivorous accumulators

who have made notable collections without any clearly defined rationale, and of collectors who have relied almost entirely on agents for the gathering and management of their libraries; but in its classical form. book collecting is a highly personal activity manifesting considerable intellectual discipline.

Other articles of interest in connection with book collecting include BOOK. which discusses how the content, form, making, distribution and use of books are related; LIBRARIES. which covers the public collections of books; and BOOKBINDING. A related field of interest is covered in the article BOOKPLATE. Readers wishing iurther guidance on BIBLIOGRAPHY will want to consult that article,

The avocation has had far-reaching consequences in the history of civilization. Private collections have provided the cornerstones of many of the world's great libraries and have enriched beyond measure existing foundations. It is no accident that Oxford's famous library bears the name of Sir Thomas Bodley (*q.v.*), or that the collection formed by Charles V lies at the heart of the Bibliothèque Nationale, or that the oldest university in the United States is named for John Harvard, who bequeathed his books to it. Through the efforts of past book collectors. basic sources of history and priceless monuments of art and literature have survived that might otherwise have been irretrievably lost. Apart from spectacular rarities, the background materials of history. ranging from works of primary importance to the merest ephemera, owe their preservation to collectors. The cost of such materials is often so modest that, book collecting is not beyond anyone's means. if he charts his course intelligently. The exercise of individual discrimination. frequently running counter to popular fashion. has played a large part in the survival of these records of the past. And an important element in the pleasure experienced by the seasoned collector is the satisfaction of backing his own choice and of slowly creating from apparently disparate materials an entity with point and significance, capped by triumphant vindication in the resulting harmonious collection. Only in very recent times have governments and institutions assumed some of the functions of the private collector; and institutional collections can seldom, if ever. indulge in the flexibility and the idiosyncrasy that provide much of the strength and charm of a private library.

THE PRINCIPLES OF BOOK COLLECTING

What Is Collected. — Much of the attraction of book collecting lies in the thrill of the chase. If the books he seeks were always easy to procure, the collector would not esteem them so highly. Their rarity provides an extra fillip, yet it is a rarity that is not necessarily reflected in price. Many books sought by collectors are far more uncommon than Gutenberg Bibles or First Folios of Shakespeare but, when they can be found at all, they sell for a small fraction of the price of the famous rarities. Many a collector has spent years of patient search to obtain some book. perhaps insignificant in itself, but important to him because it fills a vita! gap in his collection. Every book in a good collection gains by association with its peers.

Many of the books that are the objects of a collector's efforts fall into the class of first editions or first printings. The pursuit of first editions has often been dismissed as a kind of foolish sentimentalism. yet there are good reasons why the earliest appearance of a book should be the most desirable. The first edition frequently is the only one overseen by the author, and presents the best text of his work, while in later editions his intentions are obscured by careless errors that have crept in. In fact. the first edition is the only edition of many books. If later editions contain authorial revisions, the first is still necessary so that the changes can be analyzed. In illustrated books, the earliest impressions of the plates are often best. Later impressions may be less carefully printed in response to the demands of the market, and plates and blocks may be worn or injured. And even the charge of sentimentalism can be admitted and outfaced: a book that has made its mark in the world can hardly fail to arouse interest and even awe when we see it in the form in which it first presented its ideas to the public. Book collecting in its highest form is inevitably bound up with reverence for the past achievements of the human mind. There would be far fewer collectors if collecting were not rich in emotional overtones.

Building a Collection. — The successful collector marks out the scope and goal of his collection with some precision. The end must be suited to his means. These need not be great, but it is foolish to embark on a collection foredoomed to lack its central focus because the collector cannot afford it. Nor should he attempt to collect the uncollectible. Certain classes of books that were scarce to begin with have disappeared into permanent institutional collections to such an extent that it is virtually impossible for the longest purse to secure a good run of them, and there is no prospect that the supply will ever again increase. Such, for example, are Elizabethan dramatic quartos; nearly in the same class are medieval illuminated manuscripts. Such fields present great difficulties to the collector, and in them prime specimens command very high prices. As long as institutional libraries continue to grow at a rapid rate, more and more classes of books will approach the status of the uncollectible. By the same token, the collector will recognize which books in his field are verging on the uncollectible, and will be prepared to make great efforts to secure them whenever they are available. The chance may never occur again.

The wise collector also governs his activities according to the fashions of the day, avoiding when he can those kinds of books in popular favour and hence artificially overvalued. To appreciate the force of fashion: one need only contrast the prices of Kipling first editions in the 1920s, when they were very much in vogue, with those 30 years later, when Kipling had sunk in popular esteem. The same change of fortune can be observed in the works of numerous other authors and in many other fields of collecting. In the early 19th century certain specimens of 16th-century printing were valued as highly as they ever have been: a century later some original Aldine editions could be purchased for less than the cost of a microfilm of their text. A few well-informed collectors interested in the same specialty will create a competitive market. When they are joined by the uninformed multitude collecting by rote. inflation results; when fashion changes, values slump. Only the great classics of book collecting — the accepted masterpieces of literature and art in their most desirable editions — can be counred on to stand firm above the tides of fashion.

Approaches to Collecting. — The approaches to collecting are as varied as are books themselves, and as all-inclusive or as specialized as their topics. In general, there are three types: the author collection, the subject collection and the cabinet collection. In the first, the collector sets out to gather the works of his chosen author in all the forms in which they have appeared before the public, or he may concentrate on only one phase of his career or even on only one or two of his works.

Subject collecting can range from a field as sweeping as Martin Bodmer's collection of monuments of world literature or as comprehensive as Waller Barrett's collection of .American literature, to collections on chess, coffee, prize fighting, detective fiction or the development of nuclear energy. Two collections formed by George .-\rents and now in the New York Public library illustrate the variety possible in subject collecting: one is of books on tobacco, the other of books that were issued in daily. weekly or monthly parts. Each has its special points of interest, each marshals facts of significance in the history of society and human endeavour, and the published catalogues of each are of far wider potential use than the limitations of their particular subjects might suggest.

The third kind of collector limits his library to a small group or cabinet of choice specimens. although an author or a subject may form the basis of his collection. Whereas Sir Thomas Phillipps swept anything written by hand into his library. Henry Yates Thompson set himself the goal of gathering exactly 100 illuminated manuscripts. each the best of its type that he could find and afford; further manuscripts were to be added only upon the elimination of other manuscripts which they surpassed. This is a stern ideal, and one which Yates Thompson himself could not follow to the letter. But the principle of cabinet collecting has

always had its attractions for those whose resources are limited or whose library shelves are not indefinitely expandable. Bookbindings, publishing styles, fine printing, book illustration and many other topics lend themselves admirably to this approach. Many book lists famous in the annals of collecting represent the cabinet principle: the Grolier club's 100 books celebrated in English literature and 100 books in the history of science, A. Edward Newton's list of novels, and Merle Johnson's "high spots." The wise collector may profit by such examples, but he will not attempt to duplicate them, for books on such lists attain a celebrity that soon inflates their prices. Once again, it is advantageous for the collector to mark out his own path and avoid the most traveled roads.

Condition and Its Importance. — Condition is an important consideration common to all types of collecting. A very great difference of value separates a superlative copy of a book from a poor or even an average one. The factors determining condition vary widely among books of different kinds and periods. For most books since about 1770, when publishers' bindings began to be common, fine condition implies original boards or cloth closely approximating their freshness as they first stood on the bookshop shelf. For earlier books and others originally sold unbound, the collector's ideal is a good contemporary binding, or, failing that, a sound modern binding. Internally. the book should be complete and as clean and fresh as possible. Of course. some books are rare in any condition; a Caxton is a Caxton even if it lacks a number of leaves or is merely a fragment. The collector learns what condition can be reasonably expected for books in his field. If he is wise, he sets as high a standard as possible, avoiding the disheartening necessity of apologizing forever after for books in needlessly shabby condition.

Because of the interest and activity of private collectors. many books of every period have been preserved in original condition. No one will deny that the chief *raison d'être* of a book lies in its contents, but books may also be regarded as artifacts and documents in the history of the graphic arts. Most books in institutional libraries are intended for current use and are subject to normal wear and tear, though a few specimens may be set aside for special preservation. The private collector has generally assumed responsibility for books in fine condition, and has demonstrated that the unread book, far from being a paradox, has its place among the primary sources for cultural history.

Two Special Considerations. — Association is another important factor. A book annotated or otherwise inscribed by its author, or containing the markings of some other prominent or interesting person who has owned and used it, is particularly desirable to the collector. Entire collections have been built around these so-called association copies.

The study of provenance — the history of the successive ownership of individual volumes or collections — is more than an act of piety on the part of the bibliophile. For one thing, the taste and standards of certain former collectors guarantee the quality of almost any book traced to their collections. More important. a knowledge of provenance has often led scholars and collectors to books and manuscripts that otherwise would have been difficult or impossible to locate. An interest in provenance is an inevitable and a valuable concomitant of collecting.

Dealers and Catalogues. — The literature of book collecting abounds in tales of amazing finds in unlikely places. Such things do happen, particularly to the collector who has mastered his field and knows what he is looking for. But the core of every good collection comes through the normal channels of the book trade and the friendly intermediacy of specialist dealers. The collector obtains his books by private treaty, from dealers' catalogues, by the circulation of want-lists and at auction. In each of these transactions the dealer can play an important part, guaranteeing the bona *fides* of the books he handles, bringing to the collector's attention books he might otherwise never hear of, securing for him scarce titles he might otherwise have no chance to buy and generally making available a fund of experience and advice Indeed, want-lists can hardly be circulated except through a dealer. and buying at auction is best handled by a professional. In England and continental Europe it is virtually impossible to purchase at auction except through a dealer, and in any event the commission is not an excessive price to pay for *expertise*. At every stage of his career, the collector has much to learn and much to gain from the dealer. When he is making a beginning, a reliable dealer can guide him past many pitfalls and teach him the rudiments of his hobby. When the collector is old in experience and perhaps knows more about his specialty than the dealer, the bookseller is still his faithful ally, guiding essential books to his shelves.

The beginning collector has an extensive vocabulary to learn in order to consult catalogues and bibliographies profitably. He must also know something of the anatomy of books and the different methods of their manufacture at different times. He has "points" to learn or to discover for himself in his chosen field. "Points" are the distinctive variations or marks that distinguish one printing or edition from another. He will find that some time-honoured "points" are ambiguous or even totally mistaken; for only in the mid-20th century did the powerful tools of modern bibliography begin to be used systematically, and many fields of interest to the collector remain to be scientifically explored. Scarce and valuable books may be legitimately repaired and restored or dishonestly faked with almost incredible skill, and the collector should be able to recognize the signs of such work. There are numerous excellent books to guide him through this maze, but no substitute for experience; and experience is happily available in the interest and advice of his fellow-collectors and of librarians, bibliographers. dealers and scholars in the fields of history. literature and art. They can direct him to the best books of reference, provide examples and demonstrations, warn of dangers, produce other copies of books for comparison and the like. And the crown of his career comes when he, too, can settle some moot point or even, like Geoffrey Keynes or Michael Sadleir, produce a definitive bibliography; or like Carl H. Pforzheimer or J. R. Abbey, sponsor a catalogue based on his own collection that ranks as a major work of reference.

HISTORY

The Beginnings of Book Collecting. — Books have been collected ever since there have been books to collect, and we may perhaps go back to the libraries of clay tablets of the middle east for the earliest historical examples. The papyri of Egypt and the scrolls of ancient Greece and Rome preceded the book in codex form familiar to us, and there were notable collections at many places in the ancient world — Ephesus, Alexandria, Antioch, Constantinople and Rome, to name a few. All these collections were scattered in ancient times, and they are known only through contemporary accounts. In any event, they belong more to the history of libraries than of book collecting as it is now understood. There was no widespread literacy. Books were few and costly in the days of manuscript transmission. Collecting was mostly limited to the princes of church and state and a few patrician magnates — a tendency prevailing through the middle ages and still perceptible as a survival today, for example, in the Vatican library and the royal and imperial foundations of other great European libraries. The collections attached to monastic foundations also expanded during the middle ages through the activity of the trained copyists provided by their own writing schools But even with the spread of education, lesser private individuals necessarily collected on a very modest scale. Twenty books represented the height of ambition for Chaucer's Clerk in the 14th century.

Book collecting in the modern sense really began after the invention of printing in the middle of the 15th century, although there had been foreshadowings among the earlier humanists. The development of collecting was slow at first. The rapid multiplication of texts by printing, the lower price of books and the resulting increase in literacy all favoured its growth. But the absence of great public or semipublic libraries which might be consulted for reference purposes made it necessary for every large private collection to be in some degree a general library, and certainly during the 15th and 16th centuries the dominant purpose in book collecting was the formation of a working library. Even

very much later many private collections consisted of an antiquarian or artistic superstructure founded on a general or reference library. To be sure, the working library of one age is often the collector's library of the next. Voltaire's books, gathered by him without antiquarian intent, are a particular ornament of the State Public library in Leningrad. But only in the late 19th and the 20th centuries have collectors generally been able to rely extensively on public libraries and therefore to concentrate their energies and resources on specialties. Of course there are in every period exceptions to such a general rule.

Some Early Collections and Collectors. — The history of collecting is long and studded with illustrious names, and in a short account it is possible to select only a few persons representative of general tendencies. Some early collections have survived wholly or in part to modern times, so that trends and tastes can still be observed at first hand. Such, for example, was the library of Willibald Pirkheimer (1470–1530), German humanist and friend of Albrecht Diirer, purchased at Niirnberg more than 100 years after Pirkheimer's death by Thomas Howard, 2nd earl of Arundel. Arundel's grandson, the 6th duke of Norfolk, presented it to the Royal society in 1667, and the manuscripts were in turn sold to the British museum in 1831. Another collection, the Bridgewater library, begun about 1600 by Sir Thomas Egerton, descended for three centuries through the hands of direct and collateral relatives, growing the while, until it was purchased *en bloc* in 1917 by Henry E. Huntington of California; scattered volumes discarded by the Huntington library as duplicates have gone on to other collections. The descent of numerous other early libraries can also be traced. but these two may be taken as typifying the activities of royal and noble amateurs in the 16th and 17th centuries.

Distinguished collections which are now widely dispersed were formed by such men as Jean Grolier (1479–1565) and the French historian Jacques Auguste de Thou (1553–1617). Although they appreciated fine books as such, and had their libraries beautifully bound, they collected to a large extent for their own practical use. The words *et amicorum* ("and of friends") which Grolier and various others caused to be stamped on their books as part of the mark of ownership, symbolized the collector's willingness to share the use of his library with others of like interests. The day when men of learning and culture could consult public collections was still in the future, but already by the end of the 16th century public collections were beginning to grow. Sir Thomas Bodley established the library bearing his name in 1598, and soon others (for example, Richard Rawlinson) arranged to have their treasures added to it. Private collections were recognized as having public importance, and such libraries as the Harleian collection and that of Sir Hans Sloane became national property and a part of the newly founded British museum by purchase in 1753. At the same time a few specialist collectors flourished in the 17th century, such as Humphrey Dyson, who collected Elizabethan proclamations and reprinted some of them to fill out imperfect sets; and George Thomason, who collected the ephemeral publications of the Great Rebellion and interregnum as they came out, with careful notes as to price and exact day of issue. Thomason's pamphlets are one of the most valuable historical sources in the British museum.

Later Collections and Collectors. — In the early 18th century a new tendency in collecting appeared in England: for the first time anywhere a group of wealthy men began systematically and enthusiastically to collect early printed books. They were pioneers in forming antiquarian collections rather than working libraries; they first valued incunabula as such, and their collections provided reservoirs of early volumes still drawn upon by modern collectors. They included the 1st and 2nd earls of Oxford (the celebrated Harleys), the 3rd earl of Sunderland, the 1st duke of Roxburghe, the 8th earl of Pembroke and the 2nd duke of Devonshire. Their activities set a pattern for collectors ever since. Their collections were entirely or in great part dispersed over the two centuries following their deaths, and their sales often marked the genesis of important new collections.

Meantime an interest in 16th- and 17th-century literature was growing. Scholars and antiquaries such as Joseph Ames, William Herbert, George Steevens and Edmund Malone gathered and studied the printing and literature of the Elizabethan and Jacobean periods. Collecting in continental European countries followed (though not simultaneously) much the same pattern as in England, with the development of interest in incunabula leading to the collecting of the earlier national literatures. But in America most libraries were still working libraries, with only a few men such as Thomas Prince showing any antiquarian tendencies.

The early 19th century saw a resurgence of interest in incunabula that reached a climax at the Roxburghe sale of 1812, when George Spencer, then marquess of Blandford, paid a record price for the Valdarfer edition of Boccaccio (1471) and printed its description in his own catalogue in letters of gold. Perhaps the greatest collector of the generation was the 2nd Earl Spencer, whose books were headed by 56 Caxtons and first editions of all the Greek and Latin classics, and whose collection in 1892 became the nucleus of the John Rylands library in Manchester. Spencer's contemporary, Richard Heber, gathered an immense library, including continental literature and history but strongest in early English drama and poetry. The dispersal of his books in a long series of sales provided the opportunity for William Henry Miller to found his collection, which in turn passed on and continued to grow in the hands of a series of collateral descendants, forming the Britwell Court library, itself dispersed in a notable series of sales between 1916 and 1927. Another titan of the 19th century was Sir Thomas Phillipps, who during a long and contentious lifetime formed the greatest collection of manuscripts of all sorts ever owned by one man.

Book Collecting in the **U.S.**—Meanwhile collecting in the true sense had reached America, with the advent of James Lenox of New York, ouner of the first Gutenberg Bible in the new world, whose books are a part of the foundation of the New York Public library; John Carter Brown, founder of the library of Americana bearing his name; and George Brinley, whose colonial Americana was dispersed at auction. A later generation of financial tycoons founded great institutional libraries now named for them: Henry Clay Folger, Henry E. Huntington and J. Pierpont Morgan. A fine library eventually dispersed by public sale was formed by Robert Hoe, whose taste and collection in some ways resembled that of his English predecessor Heber.

20th-Century Book Collecting. — After the heyday of these great collectors and others like them, there still remained a few giants of the book world but their number decreased. In the 20th century, collections tended to be smaller as limitations of space governed the collector's activities and as confiscatory taxes restricted his scope. Collections also tended to be more critically selective, in part because of great advances in the science of bibliography. More and better aids became available to the collector: where, for example, the 1930s hailed a book like Merle Johnson's *American First Editions*, an excellent check list containing much valuable information, the 1950s saw the launching of Jacob Blanck's multivolume *Bibliography of American Literature*, with its full apparatus and careful reappraisal of all important points. How bibliographer and collector work together is shown by Wilmarth S. Lewis' remarkable collection of Horace Walpole and Professor Allen Hazen's distinguished bibliographies of Walpole and the Strawberry Hill press, partly in aid of the collection and partly inspired by it. How the world of letters profits thereby may be seen in the definitive edition of Walpole's letters, a monument of scholarly achievement impossible without the combined efforts of collector and bibliographer. The same trend appearing all through the sphere of bibliophily has meant that the collector is encouraged and helped and even to some extent forced to develop his bibliographical *expertise*.

Finally, many classically popular fields of collecting have been largely drained off into permanent institutional collections. Favourable tax laws, coupled with more assiduous and more intelligent collecting by professional librarians, have promoted this tendency. J. K. Lilly's American literature collection is at Indiana university, Arthur A. Houghton's collection of John Keats at Harvard, Lessing Rosenwald's illustrated books at the Library of Congress and so on. But year by year, more books are published

than ever before, and imaginative collectors open new fields for their endeavours. Of the collecting of books, like the making of them, there is no end.

BIBLIOGRAPHY.—Introductions to collecting include John T. Winterich and David Randall, *Primer of Book-Collecting* (1946); and John Carter, *A B C for Book-Collectors* (1952), particularly valuable as a guide to the specialized vocabulary.

An essential book on bibliographical technique is Ronald B. McKerrow, *Introduction to Bibliography* (1927 and later impressions).

For a history of collecting in the United States, there is Carl L. Cannon, *Anzerican Book Collectors and Collecting From Colonial Times to the Present* (1941); in England, Seymour De Ricci, *English Collectors of Books and Manuscripts* (1930); in Europe, G. A. E. Bogeng, *Die grossen Bibliophilen*, 3 vol. (1922).

Trends in sale prices can be seen in the annual *American Book-Prices Current* (1895 *et seq.)* and the English *Book-Prices Current* (1886 *et seq.)* and *Book-Auction Records* (1902 *et seq.);* these also have their counterparts in France and Germany. The weekly *Times Literary Supplement* (London) often reports book sales and other bibliophilic matters.

The leading collector's journal in English is *The Book Collector* (1952 *et seq.),* a quarterly; the weekly *Antiquarian Bookman* (1948 *et seq.)* is also of value. (W. H. BD.)

BOOKKEEPING is the recording branch of accounting (*q.v.*). Accounting is the art of recording, classifying and summarizing transactions of an enterprise and interpreting the results thereof. To make a distinction between bookkeeping and accounting is difficult. Accounting includes bookkeeping but is a broader subject. For example, an accountant designs the system of records used by the bookkeeper. The bookkeeper accumulates the figures; the accountant summarizes and interprets these figures.

Nearly all accounting systems use "double-entry bookkeeping." This method of keeping records (described below) originated in the middle ages. An explanation of the process was printed in Italy as early as 1494 in a book on mathematics by a monk. Luca Pacioli. Historically, double-entry bookkeeping developed as the standard method by which the economic activities of privately owned and operated business concerns are recorded.

Stockholders. investors, credit grantors and the management of a business firm all require a knowledge of bookkeeping. Management needs a knowledge of bookkeeping to interpret the results of operations, to control costs, to budget for the future and to make financial policy decisions. Investors use a knowledge of bookkeeping to make decisions about buying, holding and selling securities; they need to have a knowledge of bookkeeping in order to interpret the results of operations of business firms. Credit grantors need the knowledge to analyze the financial statements of a business enterprise in deciding whether to grant a loan. As financial statements are the end results of the bookkeeping process, intelligent analysis of financial statements reauires a knowledge of bookkeeping. Similarly, mercantile credit managers must have a knowledge of bookkeeping in order to make decisions about the size of credit limits.

History.—Financial and numerical records are found in nearly every civilization with a commercial background. Records of commercial contracts were found in the ruins of Babylon. Accounts for both farms and estates were kept in Greece and Rome. The double-entry method of bookkeeping began with the development of the commercial republics of Italy. The first double-entry books known to exist are those of the Massari of Genoa dating from the year 1340. As these books were in excellent double-entry form the system must have been in general use long before that time. Double-entry bookkeeping was also used by the members of the Hanseatic League, the banking houses of the Medici and the Fuggers, and by the great trading companies chartered by the governments of Great Britain, France, Holland and other countries; it was used by the monasteries, the papacy, and the individual merchants and adventurers in the early days of capitalism. Although the inherent nature of double-entry bookkeeping has remained the same, bookkeeping and accounting have adapted themselves to the demands made upon them.

Instruction manuals for bookkeeping were developed during the 15th century in various Italian cities, notably a work dated 1458 by Eenedetto Cortrugli, a forerunner of his fellow citizen Luca Pacioli. The thoroughness of Pacioli's volume, with his extended discussion of debit and credit, establishes him as a pioneer in double-entry bookkeeping, although the practices had been followed in central and southern Europe for several centuries preceding his time.

Many books of instruction based on Pacioli's material appeared in Germany, England and Holland during the 16th and 17th centuries, with technical modifications to suit the needs of international trading operations. According to best available records the first German work was written by Herman Schreiber in 1523. Hugh Oldcastle, an Englishman, and Jan Ympyn Christoffel of Holland published treatises in 1543. In 1586 Don Pietra, a Benedictine monk, made a contribution by stressing the fact that a business enterprise was a separate economic entity, distinct from its owner or owners.

The first Scots publication on the subject of bookkeeping, by Robert Colinson. was dated 1683, and an Irish work by John Herman appeared in 1719. In 1741 John Mair of Scotland wrote a bookkeeping text which was standard for 50 years. No American text is known to have appeared before 1796, when William Mitchell of Philadelphia published such a work. But the public schools of Boston had provided classroom instruction in bookkeeping since 1682, relying on European writings for subject matter. James Bennett, a bookkeeping teacher in New York, was the author of American System of Practical Bookkeeping, first published in 1818.

The Industrial Revolution provided an important stimulus to accounting and bookkeeping. The rise of manufacturing, trading, shipping and subsidiary services made accurate financial records a necessity. The history of bookkeeping is a reflection of the history of commerce, industry and government.

Bookkeeping has responded to many demands. The increased complexity of business and the accompanying need for cost accounting, internal control and budgetary control has created the need for new types of records. The income tax and other taxes have had important effects on bookkeeping. Bookkeeping has developed to provide the information about an enterprise which is essential to management, investors, credit grantors, tax authorities and other government agencies.

Bookkeeping Processes.—The basic procedures which customarily are included in the bookkeeping process are outlined below. The purpose here is to give an over-all picture of the bookkeeping process. Some of these items will be dealt with in greater detail later in the article. Depending on the size of the business, some of these procedures are handled by machines.

Preparation of Basic Documents.—Cash slips, check books, stock cards, deposit slips, time cards, sales slips, sales invoices, credit memos and purchase invoices are some of the original documents with which the bookkeeper is concerned. Transactions that are similar in kind are often summarized and entered in total in the books. For example, the total daily cash sales are entered in the books rather than each individual cash sale.

Journalizing.—Transactions are analyzed and entered in a journal. The journal is the book used to make the first record of a transaction. There are many different forms of journals. One journal may be designed to take care of only one kind of transaction such as cash receipts or sales on account, for example. In a small business all transactions may be entered in one journal. Transactions are entered chronologically in the journal. The analysis of a transaction indicates which accounts are affected; an account contains entries affecting only one item. For example, all entries affecting cash are summarized in one account with the title cash.

Posting.—The process of transferring journal entries to the accounts in the ledger is known as posting. The various accounts of an enterprise comprise the ledger; the ledger contains an account for each financial item.

Preparation of the Trial Balance.—Entries are made in accounts in terms of debits and credits. A debit signifies an entry in the left-hand side of a ledger account. A credit, on the other hand, signifies an entry in the right-hand side of a ledger account. The debits for each entry in the journal are always equal in amount to the credits for that entry. Thus if no errors are made in posting, the total of all debit amounts in the ledger equals the total of

all credit amounts in the ledger. The trial balance is a method of testing the accuracy of posting by proving the equality of the debits and the credits in the ledger. Each account title and debit or credit amount is listed. If the two totals of the trial balance are equal, the posting of the journal is assumed to be correct. (See Table I.) The trial balance, however, cannot catch certain errors such as the complete omission of an entry.

TABLE I.—*ABC Company*
Trial Balance, December 31, 19—

Account titles	Debit balances	Credit balances
Cash in bank	$ 10,000.00	
Accounts receivable	4,000.00	
Inventory	7,000.00	
Building	25,000.00	
Equipment	3,400.00	
Accounts payable		$ 3,200.00
Mortgage payable		15,000.00
John Jones, capital		32,010.00
Sales		62,000.00
Cost of goods sold	37,000.00	
Wages and salaries	22,310.00	
Depreciation.	2,000.00	
Utilities	1,500.00	
Total	$112,210.00	$112,210.00

Preparation *of the* Financial Statements.—The management of a firm is interested in determining whether its operations have resulted in a profit or loss. They are also interested in the financial condition of the firm. Each month, as a general rule, an income statement and a balance sheet are prepared from the trial balance. The purpose of the income statement or profit and loss statement is to present an analysis of the changes that have taken place in the ownership equity as a result of the operations of the period. (See Table II.) Revenues are listed at the amount earned upon delivery of goods or performance of service. Expenses incurred in getting the revenue are deducted to arrive at the profit. The ledger includes accounts for revenue and expense items as well as balance sheet accounts.

The balance sheet shows the financial condition of a company at a particular date in terms of assets. liabilities and the ownership equity. In general, assets are things of value owned by a business or other economic unit. Cash, buildings, machinery, inventory and land are examples of assets. Liabilities are the debts of a business. They are claims against the business other than the claims of the owners. The ownership equity is the difference between the assets and the liabilities of the firm. It is customary at the end of the fiscal period to make entries to record changes that have occurred during the fiscal period but that have not yet been recorded in the accounts. It is not practical each day, for example, to record the amount of wrapping paper. typing paper and twine used. General journal entries that are made at the end of the accounting period to bring the asset. liability, revenue, and expense accounts up to date are known as adjusting entries. Adjusting entries are made to adjust the merchandise and supply inventories; they are made to record depreciation and also the write-off of insurance premiums paid in advance.

Final Procedure.—The adjusting entries are entered in the journal and posted to the proper accounts in the general ledger. Next, the closing entries are journalized and posted. Closing entries transfer the balances from the revenue and expense accounts to the ownership account; the revenue and expense accounts are used to determine the periodic profit and, therefore, must be closed out at the end of each accounting period. Finally, the accounts are ruled and balanced and a final post-closing trial balance is taken.

TABLE II.—*ABC Company*
Profit and Loss Statement, May 19—

Sales		$21,900
Cost of goods sold		15,600
Gross margin		$ 6,300
Wages and salaries	$1,500	
Rent	400	
Utilities	120	
Depreciation.	80	2,100
Net operating profit		$ 4,200
Other income	300	
Otherexpense	$ 100	200
Netprofit		$ 4,400

Double-Entry Recording Process.—The financial condition of a business at any point in time can be expressed in the form of an equation which expresses the relationship between assets, liabilities and the ownership equity. This equation is important, for it is the basis for the double-entry recording process. The assets of any enterprise minus its liabilities must equal the ownership equity. That is. if the claims of outsiders other than the owners (liabilities) are subtracted from the things of value owned by the firm (assets) the result will be the value of the ownership equity. The basic equation is $A - L = P$, where A stands for assets, L for liabilities and P for the proprietorship or ownership equity.

However, the fundamental accounting equation is often stated in the form $A = L + P$. This equation states that the sum of the assets is equal to the sum of the claims against the assets. This equation is the same, algebraically, as the form $A - L = P$ except that we have moved the liabilities to the other side.

To illustrate, assume that Jones and Smith start a business to which Jones contributes $10,000 cash and Smith contributes merchandise worth $10,000 and fixtures worth $5,000. The business agrees to take over a $5,000 debt that Smith owes on the merchandise. The balance sheet equation would then show assets of $25,000, represented by the cash, merchandise, and fixtures; liabilities of $5.000, represented by the debt taken over by the business; and proprietorship of $20,000, represented by a $10.000 interest for Smith and a $10,000 interest for Jones. Assets ($25,000) equal liabilities ($5.000) plus proprietorship ($20,000).

Transactions are analyzed in terms of their effect on assets, liabilities and proprietorship. No matter how complex the transaction, the equation always stays in balance. The financial condition of a going concern is always changing as cash is collected, bills are paid and merchandise is purchased. These transactions must be analyzed in terms of their effect on the assets, liabilities and proprietorship. They must be recorded in the books of the enterprise. An account is established for each balance sheet item. As there are only tno ways in which an item can change—increase or decrease—accounts are set up so that increases are placed on one side of the account and decreases are placed on the other side.

Complete recording of the effects of any transaction means that a double entry is made in the ledger accounts. For example, if John Jones put $10.000 more in his business, the accounts of the business would show an increase in an asset cash of $10.000 and an increase in the proprietorship account, Jones, capital, of $10,000. Purchase of merchandise for $2,500 cash would result in an increase in an asset merchandise for $2,500 and a decrease in an asset cash of $2,500. For every transaction, more than one item is affected. Certain rules are established for recording increases and decreases in accounts; these rules maintain the equality of the fundamental equation. Increases in assets are entered on the left side of the account; increases in liabilities and proprietorship are entered on the right side of the account. If increases are entered on one side, decreases must be entered on the opposite side.

Rather than speak of increases or decreases in accounts, bookkeepers state that an account is debited or credited. The term debit is used to indicate the left side of an account; credits indicate the right side. This is the only meaning of debit and credit in bookkeeping. Established rules for increases and decreases and for debits and credits result in the fact that for any transaction, the debits and credits must be equal. If the amount of debits do not equal the amount of credits for any individual transaction, the bookkeeper knows immediately an error has been made. At various points in the bookkeeping process, the equality of debits and credits are checked as a means of detecting errors to that point.

The periodic determination of profit is vitally important to the management of the firm. In order to determine profit, revenue accounts and expense accounts are established. Revenues are measured by the charge the firm makes for selling goods or performing a service. Expenses are measured by the costs incurred in securing the revenues. Profit is determined by subtracting expenses from revenue. Rules for debit and credit are consistent with the nature

of the revenue and expense accounts. Revenue accounts are ownership accounts; revenue accounts are credited for increases and debited for decreases like ownership accounts. Expense accounts are deductions from revenue; expense accounts are debited for increases and credited for decreases. Thus there are five kinds of accounts: assets, liabilities, proprietorship, revenue, and expense. At the end of the accounting period the expenses are deducted from the revenues to arrive at the periodic profit; the profit is then added to the ownership account. In each transaction the sum of the debits must equal the sum of the credits. The double-entry debit and credit mechanism maintains the equality of the fundamental balance sheet equation.

Form of the Account.—The basic requirement of an account is that it must have one side for increases and one side for decreases. A common form of account is shown in Table III.

As the cash in bank account is an asset account, increases are placed on the left side of the account and decreases in the right-hand side. In the illustration there was $10.000 cash at the start of the period. During the period $22,000 was deposited in the bank. The CR 7 indicates a reference to page 7 of the cash receipts journal. Checks were written for $8,000.00 as indicated on the right side of the account. This entry came from page 12 of the cash disbursements journal. The balance of $24,000 can be determined by subtracting the amount of the right side from that on the left side.

TABLE 111.—Form *of Ledger Account*
Cash in Bank

Date	Explanation	Ref.	Amount	Date	Explanation	Ref.	Amount
1961							
Jan 1	Balance	—	$10,000.00	Jan 31		CD 12	$8,000.00
Jan 31		CR 7	22,000.00				

Ledgers.—A group of accounts is known as a ledger. The general ledger is the main book of accounts; it contains an account for each asset, liability, proprietorship, revenue, and expense account. The ledger contains the same information as the journals. However, in the journals each transaction is completely recorded as a unit. The entire effect of a transaction on the business is recorded in one place in the journal. Periodically the same information is posted to the ledger where it is accumulated according to individual items. The ledger includes all the basic accounts needed for the preparation of the financial statements.

Additional information is often desired concerning certain of the accounts in the general ledger. Groups of accounts called subsidiary ledgers are set up. Each subsidiary ledger contains detailed information concerning a general ledger account which is called a controlling account. For example, a department store would have an accounts receivable control account in the general ledger which would carry the total amount owed the store by its customers. A subsidiary accounts receivable ledger would also be maintained. In the subsidiary ledger there would be an account for each individual customer that owed the department store. Control is maintained by periodically adding the balances of the subsidiary accounts and checking to the total of the control account.

Balance Sheet.—The balance sheet is one of the important financial statements which results from bookkeeping procedures. The balance sheet shows the financial condition of an enterprise at a particular date. It is based on the fundamental equation that assets equals liabilities plus proprietorship. The balance sheet balances because the total dollar amount of liabilities and proprietorship of an enterprise must equal the total dollar value of assets. This does not mean that an individual creditor has a claim against any of the specific assets; the equality refers to the totals.

A balance sheet is illustrated in Table IV. Note that the assets are separated into two groups, current and fixed. Current assets include cash and other assets which will normally be converted into cash or used up within a short period of time (usually a year) in the operations of the business. Accounts receivable are considered to be current assets because they are usually collected in a short period of time; merchandise is listed as a current asset because it usually is sold within a year. Fixed assets include assets which yield services to the enterprise for a long period of time such as land, buildings and machinery. Patents and copyrights as well as long term investments are also listed in this category.

TABLE IV.—*ABC Company*
Balance Sheet, December 31, 19—

Assets		Liabilities and capital	
Current assets:		Current liabilities:	
Cash	$ 2,010	Accounts payable	$ 2,710
Accounts receivable	3,110	Notes payable	3,500
Merchandise	7,220	Total current liabilities	$ 6,210
Total current assets	$12,340	Long term liabilities:	
Fixed assets:		Bonds payable	$20,000
Land		Total liabilities	$26,210
Building		Capital:	
Total fixed assets	$52,000	Capital stock	20,000
Total assets	$64.340	Retained earnings	18,130
		Total capital	$38.130
		Total liabilities and capital	$64,340

The first section on the right-hand side of the balance sheet contains the amounts owed to outsiders (liabilities). Current liabilities are those which are to be settled within a short period of time, usually one year. Accounts payable represent amounts owed for purchases of goods or services made on credit without a formal written contract. Notes payable represent the face value of promissory notes used in connection with bank loans or in connection with the purchase of goods or services.

Bonds payable are listed under long term liabilities because they represent amounts borrowed by the business for a relatively long period of time. The capital or proprietorship section represents the ownership equity in the business. The illustration is that of a corporation. The amounts contributed to the corporation by the stockholders are generally recorded in the capital stock account. In some instances a portion of the contribution is added to an account called paid-in surplus. The ownership equity of a corporation increases if operations are profitable. A portion of these earnings is customarily distributed to the stockholders in the form of dividends. The earnings of the corporation which have not been paid out in dividends are shown in the retained earnings account. The laws of the various states determine the amount of dividends that a corporation can pay. Before a corporation can pay a cash dividend it must have the legal right to do so—as determined by the ownership section of the balance sheet—and it must also have the cash.

The ownership equity sections of individual proprietorships and partnerships differ from that of the corporation. On the balance sheet of an individual proprietorship, the owner's interest is usually shown as one item such as John Jones, capital, $64,340. In a partnership, each partner's interest must be shown separately. Thus the capital section of the Jones and Smith partnership would show John Jones, capital, $32,170; George Smith, capital, $32,170.

Modern Developments.—During the last 50 years there has been a great expansion of industrial activity based largely upon the products of scientific research. This expansion, plus the widespread ownership of business, has placed greater demands on accounting for financial control and reporting. The emphasis on increased productivity has resulted in the development of mass production systems and has contributed to the rapid development of techniques of cost accounting (*q.v.*). An important trend toward greater government influence in the affairs of business through taxation and regulation has added to the amount of record keeping.

The bookkeeping procedures concerned with achieving economies of production and distribution have become more general through both large and small firms. Financial planning and budgeting are not just a luxury of the large firms. Interpretations of the data supplied by the bookkeeping mechanism have become more important in the management of all business.

The process of recording transactions has continued to benefit through greater mechanization and simplification. Labour-saving devices are found in the office as well as in the production areas. There has been a rapid expansion in the use of electronic tabulating and calculating machines. These machines are used for many tasks such as payroll accounting and preparing analyses of sales by commodities. (See OFFICE MACHINES AND APPLIANCES.)

Techniques of budgetary control have improved. Records of past experience are used to guide future plans of the enterprise. Budgets are used to determine cash requirements as well as production requirements for such things as raw materials and manpower. Bookkeeping is more and more concerned with accumulating and recording the basic data which becomes the raw material for reports which will be used in the control functions of management.

Niven, *Elementary Accounting,* 2nd ed. (1956); P. Carlson, H. Forkner and A. Prickett, *20th Century Bookkeeping and Accounting,* 20th ed. (1952). (A. R. CE.)

BOOKKEEPING MACHINES: see OFFICE MACHINES AND APPLIANCES.

BOOKPLATE, or *ex libris,* is a label with a printed design intended to indicate ownership, usually pasted inside the front cover of a book. It may be produced by various methods, such as woodcut, wood engraving, line engraving, etching, lithography and modern photographic reproduction.

History. — The custom of using bookplates probably originated in Germany, where the three earliest known examples are found. The first of these, dated variously as about 1450 or about 1470, is a woodcut belonging to Johannes Knabensberg (known as Hans-Igler). Found inside the cover of a Latin vocabulary, the design represents a hedgehog with a flower in its mouth, above it the punning motto *Hanns* Igler das dich ein *Igel kus* ("Hanns Igler may a hedgehog kiss you"). Other early examples are woodcuts inside books given to the Charterhouse of Buxheim, Swabia, by Hilprand Brandenburg of Biberach, about 1480, showing an angel holding a shield upon which is an ox with a ring through its nose. The third example is found in a book presented by Wilhelm von Zell also to Buxheim, about 1480, and represents the arms of the donor with those of his wife, with helmets and crests.

The earliest dated bookplates found in Europe are those of Hieronymus Ebner, 1516, Germany; of Jean Bertaud de Latour-Blanche, 1529, France; of those books given by Sir Nicholas Bacon to the University of Cambridge, 1574, England; of Lodovico Romano, 1575, Italy; of Thure Bielke, 1595, Sweden; and of Anna van der Aa, 1597, Holland. In America the bookplate of Thomas Dering, 1749, is the earliest dated example by an American engraver.

Early bookplates in Germany include examples by Albrecht Diirer, Hans Holbein the younger, Bartel Beham, Hans Sebald Beham, Lucas Cranach the elder, Virgil Solis, Jost Amman and Hans Burgkmair. The absence of bookplates in France and Italy before the 17th century was due to the fact that in those countries book bindings were decorated with the owners' coats of arms, making the label of ownership unnecessary. The earliest signed bookplate in France is that of Alexandre Bouchart, engraved in 1611 by Léonard Gaultier, while the bookplate of Sir Edward Littleton, engraved by William Marshall before 1641, is the first in England to bear the engraver's name.

Types of Bookplates. — Armorial. — Early armorial bookplates in England at first consisted of a simple shield without ornament, helmet with symmetrical mantling, crest, and scroll beneath for a motto or owner's name. They show none of the elaboration to be found in German plates of the same period. However, a group belonging to the middle of the 17th century has cartouchelike shields, encircled by wreaths, festoons and ribbons. At the time of the Restoration in 1660, mantling became more decorative and heraldic tinctures were indicated by Petra Sancta's system, used by French engravers for at least 20 years previously. In France the helmet and crest were gradually replaced by a coronet, shields became oval-shaped, within decorative borders, and were placed on an architectural plinth or a grassy bank.

The main characteristics of the bookplate in the early 18th century, rather misleadingly named "Jacobean," were a decorated frame, having the appearance of carved work, surrounding the shield; the space between the shield and the edge of this frame was ornamented with a pattern of fish scales or a trellis; and the whole design was often placed upon a conventional support. The scallop shell appeared as a decorative feature and figures such as *putti,* angels. "Fame" and "Victory" were also used. In Germany the design tended to be purely armorial, while in France the development was much the same as in England.

The middle 18th century saw the development of the rococo in England, a taste reflected in the bookplates called "Chippendale." Whereas in a Jacobean plate the shield was always regularly shaped, in the Chippendale it was broken into by the incurving of the decorative surround, the shield itself often being oblique or pear-shaped. The border lost its solid appearance and was composed of open shellwork, outside which were sprays of natural flowers not arranged in conventional festoons. This style developed earlier in France and spread into Germany and other European countries. The heraldic helmet, if used, was of a debased form, while mantling had usually disappeared. Instead, crest and torse were placed directly on top of the frame. By 1760–80 the design became exuberant with festoons, animals and figures and with supporters no longer supporting the shield but introduced into the design, often in unusual attitudes.

Beginning about 1770 there was a return to simpler, semiclassical motifs. The first was the "Wreath and Ribbon": the shield was spade-shaped and surrounded by wreaths or sprays of foliage, loosely bound by ribbons at the centre of the base. Another form was the "Festoon," with sprays hung from rings or hooks on either side of the shield. The urn, a feature popular in decoration and on funerary monuments, also appeared: usually the shield was placed on the urn, which was often accompanied by a weeping female figure and a willow tree. Lastly there were landscape bookplates, where the shield leaned against the trunk of a tree or hung from its branches. In France, where many of the bookplates had been pictorial rather than armorial, there was a desire, after 1789, to remove from them all signs of noble rank until Napoleon I introduced a new form of heraldic insignia.

The heraldic bookplate in America followed much the same development as in Europe, although it was not common until the early 18th century. During the first three decades of the 19th century, bookplate design in Europe fell generally to a very low order, often being the product of heraldic stationers, and it did not improve until the revival of interest after 1880, mainly in the nonheraldic plate.

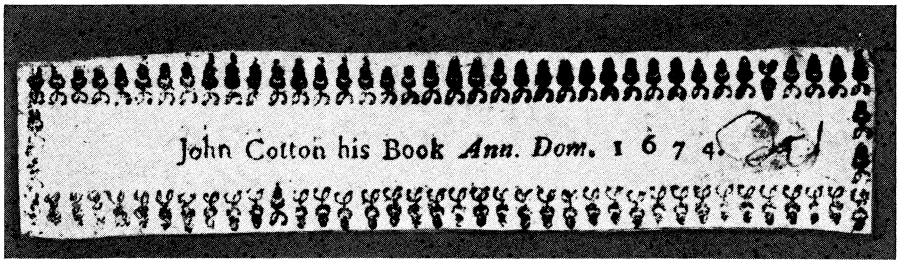
Pictorial. — The pictorial plate had also been used from comparatively early times. Examples include portraits of Willibald Pirkheimer, engraved by Diirer in 1524; of John Hacket, bishop of Lichfield and Coventry, engraved by William Faithorne in 1670; and of Samuel Pepys, engraved by Robert White. Other popular devices were arrangements of piles of books and views of libraries and landscapes. Allegorical bookplates were in favour in France during the reign of Louis XV and in England by mid-18th century. On these appeared personifications of the Christian cardinal virtues and other abstract ideas, such as Truth, Justice, Wisdom, Hope and Faith. Also introduced into the design were symbols of the interests and occupations of the book's owner, such as scales of justice, naval and military trophies, palettes and so on. In most of these heraldry played only a subordinate part.

Toward the end of the 19th century, German designers began to use nude figures as a major motif of bookplate design, and this fashion was followed in Europe and the United States. Figures were treated naturalistically, sometimes with erotic intention. With the revival of interest in the bookplate during the last two decades of the 19th century, many new ones were produced, some of the heraldic plates being well designed and engraved. However, due to the introduction of photographic printing processes, the pictorial bookplate, although many well-known artists designed them, gradually deteriorated, the style becoming confused, contrived and self-conscious. This decline, with few exceptions, went on until the 1920s, after which interest in the bookplate was not so great, though a high standard was achieved in many.

Bookplate Artists, Designers. — From early times artists were interested in bookplate design and engraving, and among them were: (17th century) Faithorne, Marshall, Gaultier, J. de Courbes, I. Briot, Hans Sibmacher, R. Sadeler, J. von Sandrart and the Kilians; (18th century) William Hogarth, George Vertue, Francesco Bartolozzi, Giovanni Cipriani, C. Audran, H. Gravelot, Jean

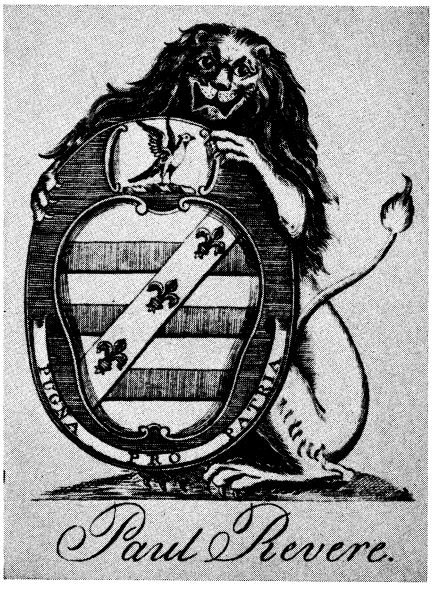
BOOKPLATE

15th-century woodcut, early German bookplate from a book given to the Charterhouse of Buxheim, Swabia, by Hilprand Brandenburg about 1480

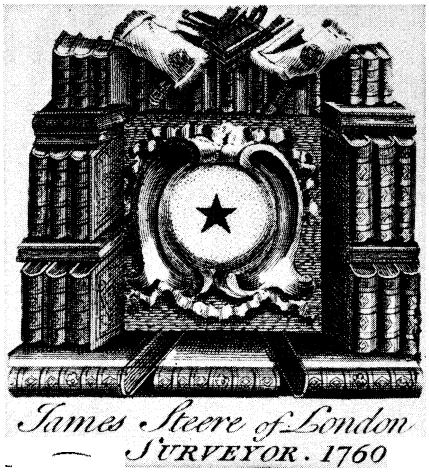


American bookplate bearing the date 1674 and belonging to John Cotton, one of the earliest-known examples in letterpress from the U.S.

Woodcut bookplate belonging to Johannes Knabensberg (Hans Igler). Dated about 1450 or 1470, it is one of the three earliest-known German examples



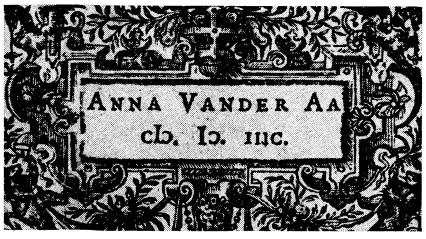
Early American bookplate belonging to Paul Revere. Although it is not signed, it is thought to have been engraved by Revere about 1775



English pictorial bookplate in the book-pile style: dated 1760 and belonging to James Steer of London

George Washington's bookplate, an armorial engraving in the Chippendale style; probably dating between 1765 and 1775

18th-century English armorial bookplate, Chippendale style, belonging to Nicholas Bacon (not to be confused with Sir Nicholas Bacon, 16th century)



Bookplate of Anna van der Aa, the Netherlands. Earliest-known Dutch bookplate, it bears the date 1597

Engraved plate by Albrecht Dürer, 1524, an early German portrait bookplate of Willibald Pirkheimer, councilor to emperors Maximilian and Charles V

Michel Moreau le jeune, François Boucher and, in America, N. Hurd, P. R. Maverick, Paul Revere and H. Dawkins. In the early 19th century Thomas Bewick produced his landscape plates. Later, as a result of the revival of interest, the list includes H. Stacy Marks, R. Anning Bell, Walter Crane, Randolph Caldecott, Sir John Millais. Charles Ricketts, Sir Frank Brangwyn, Gordon Craig, Kate Greenaway, Eric Ravilious, Eric Gill, Robert Gibbings, Stephen Gooden, Paul Nash, Paul Gavarni, Toulouse-Lautrec, Bac, Jules Chéret, Edouard Manet, Lucien Pissarro, Emil Orlik, Hans Thoma. Georg Barlosius, Mark Severin, Max Klinger, Alejandro de Riquer, Edwin Abbey, Rockwell Kent, J. Taylor Arms, McKnight Kauffer. Among bookplate specialists are C. W. Sherborn, G. W. Eve, Lord Badeley, Sidney L. Smith, Alfred Cossman, Karl Haselbock, Sidney Hunt, J. Vineycomb, J. A. C. Harrison, Franz von Bayros, Paul Voigt, Louis J. Rhead, J. W. Spenceley, Antonello Moroni, Bruno da Osimo, Willi Seiger, E. H. Garret and E. D. French.

The Fashion for Bookplates. — J. B. L. Warren's Guide to the *Study* of Book-Plates (1880) first made a general classification of styles. This led to a wave of interest and people began collecting bookplates. Many books on the subject were published and societies formed in Europe and the U.S., some of them lasting for many years. After World War I there were several attempts to revive interest and publish periodicals, but they were nearly all short-lived. Collectors often exchanged their own bookplates with others to swell their collections. Two large collections are to be found in the British museum. London. and Yale university library, New Haven, Conn.

BOOK SCORPION (FALSE SCORPION), a small arachnid (order Pseudoscorpiones), somewhat resembling tailless scorpions. Book scorpions occur widely throughout the world, living under stones, beneath bark or in vegetable detritus. Some are found in books and old chests, while others, mostly blind, live in caves. They feed upon minute insects and mites. See also ARACHNIDA.

BOOKSELLING. The trade in books is very ancient, the oldest reference to it occurring in Egyptian literature. The early poets and orators recited their effusions in public to induce their hearers to buy written copies of them Frequently they were taken donn from dictation, and transcripts sold to such as were wealthy enough to purchase. The scribes who copied the texts were, in fact, the earliest booksellers and supplied copies as they were demanded. Aristotle, it is said, possessed a somewhat extensive library; and Plato is recorded as having paid the large sum of 100 minae for three small treatises of Philolaus the Pythagorean. When the Alexandrian lsbrary was founded about 300 B.C., various expedsents were resorted to for the purpose of procuring books and this appears to have stimulated the energies of the Athenian booksellers.

In Rome, toward the end of the republic, it became the fashion to have a library; and the booksellers (*librarii* or *bibliopolae*) carried on a flourishing trade.

Their shops were chiefly in the Argiletum and in the Vicus Sandalarius; on the door, or on the sideposts, was a list of the books on sale. In the time of Augustus the great booksellers were the Sosii. According to Justinian (ii, 1, 33), a law was passed securing to the scribes the property in the materials used; and in this, perhaps, may be traced the first germ of the modern law of copyright.

The spread of Christianity naturally created a great demand for copies of the Gospels and other sacred books, and later on for missals and other devotional volumes for church and private use. The traveling bookseller was a typical medieval figure. Among the Jews bookselling was well recognized in the middle ages.

"The trade in bookselling seems," says Henry Hallam, "to have been established at Paris and Bologna in the 12th century; the lawyers and universities called it into life. It is very improbable that it existed in what we call the dark ages. The dealers were denominated stationarii, perhaps from the open stalls at which they carried on their business, though statzo is a general word for a shop in low Latin. They appear, by the old statutes of the University of Paris, and by those of Bologna, to have sold books upon commission, and are sometimes, though not uniformly, distinguished from the *librarii,* a word which, having originally been confined to the copyists of books, was afterwards applied to those who traded in them."

GREAT BRITAIN

Before the Reformation, the text writers or stationers (*stacyoneres*) who sold copies of the books then in use—the A B C, the Pater Noster, Creed, Ave Maria and 'other manuscript copies of prayers—in the neighbourhood of St. Paul's, London, were, in *1403,* formed into a guild. Some of these stationers had stalls or stations built against the very walls of the cathedral itself, in the same manner as they are still to be found in some of the older continental cities. In Henry Anstey's Munimenta *Academica* a glimpse may be caught of the "sworn" university bookseller or stationer, John More of Oxford, who apparently first supplied pupils with their books and then acted the part of a pawnbroker. Besides the sworn stationers there were many booksellers in Oxford who were not sworn; for one of the statutes, passed in the year 1373, expressly recites that, in consequence of their presence, "books of great value are sold and carried away from Oxford, the owners of them are cheated, and the sworn stationers are deprived of their lawful business." It was therefore enacted that no bookseller except two sworn stationers or their deputies should sell any book exceeding half a mark in value, under pain of imprisonment or, if the offense were repeated, of abjuring his trade within the university.

The modern system of bookselling arose soon after the introduction of printing. The earliest printers were their own editors and booksellers; but being unable to sell every copy of the works they printed, they had agents at most of the seats of learning. Anton Koberger, who introduced the art of printing into Nürnberg in 1470, had, we are told, agents for the sale of his books in every city of Christendom, besides his own *16* shops. Wynkyn de Worde, who succeeded to William Caxton's press in Westminster, had a shop in Fleet street.

The Reformation created a great demand for books; but in England neither Tudors nor Stuarts could tolerate a free press. The first patent for the office of king's prsnter was granted to Thomas Berthelet by Henry VIII in 1530, but only such books as were first licensed were to be printed. Even the purchase or possession of an unlicensed book was a punishable offense. In 1557 the Company of Stationers was incorporated and extensive powers were granted in order that obnoxious books might be repressed. In the following reigns the Star Chamber exercised a pretty effectual censorship; but. in spite of all precaution, many polemical books were printed abroad and surreptitiously introduced into England. Queen Elizabeth I interfered but little with books except when they emanated from Roman Catholics or touched upon her royal prerogatives; and toward the end of her reign and during that of her successor bookselling flourished. Archbishop William Laud introduced many arbitrary restrictions, but they were all, or nearly all, removed during the time of the Commonwealth.

An order of parliament in 1643 provided that no book should be printed or "put on sale" "unless the same be first approved of and licensed" by the persons appointed by the government. It was against this order that Milton wrote his *Areopagitica* (1644). The Restoration also restored the officer of licenser of the press, which continued until 1693.

In the first English Copyright act (1709), which specially related to booksellers, it is enacted that, if any person shall think the published price of a book unreasonably high, he may thereupon make complaint to the archbishop of Canterbury and to certain other persons named, who shall thereupon examine into his complaint and, if it be well founded, reduce the price; and any bookseller charging more than the price so fixed shall be fined £5 for every copy sold. Apparently this enactment remained a dead letter.

For later times it is necessary to make a gradual distinction between booksellers and publishers, whose business involves the production of the books from the author's manuscript and who are the intermediaries between author and bookseller; in the 19th century this distinction became fundamental. The article on publishing (*q.v.*) deals more particularly with this second class, who gradually took a higher rank in the book trade and whose influence upon the history of literature has often been great. The convenience of this distinction is not impaired by the fact either that a publisher is also a wholesale bookseller or that a still more recent development in publishing (as in the instance of the direct sale in 1902, by the *Times* [London], of the supplementary volumes to the 9th edition of the *Encyclopædia Britannica*, which were also "published" by the *Times*) started a reaction to some extent in the way of amalgamating the two functions. The scheme of the Times Book club (started in 1905) was, again, a combination of a subscription library with the business of bookselling; and it brought the organization of a newspaper. with all its means of achieving publicity, into the work of pushing the sale of books in a way which practically introduced a new factor into the bookselling business.

The wholesale bookseller is the important distributing agency between the publisher and the retail bookseller; it is to him that the latter looks for his miscellaneous supplies, as it is impossible for him to stock half of the books published. For more than 100 years up to 1940 (when it was practically demolished by bombing) the centre of the wholesale industry in London was 41, Paternoster row. At one of these establishments more than 1,000,000 books were constantly kept in stock. It was there also that the publisher called first on showing or "subscribing" a new book, for on the number thus subscribed might depend the success or failure of the book.

Underselling was rife in the 19th century in the retail book trade. One of the most notable attempts to stamp it out took place in 1852 when a booksellers' association bound its members not to sell books under the published price. But the then popular cry of "free trade" was raised and, after arbitration, judgment was given against the association by Lord Campbell. The association was dissolved and underselling went on as before. In 1890 a London booksellers' society was established to protect the retail booksellers: it aimed to restrict discounts to 25%, to arrange prices generally and to control all details connected with the trade. In 1895 the society widened its field of operations and became known as the Associated Booksellers of Great Britain and Ireland. In 1899 the association concurred in the Net Book agreement, which had previously been adopted by the Publishers' association. The agreement came into force on Jan. 1, 1900. The scheme protected the booksellers from undercutting and made certain that a book should be sold at its fixed published price, no more and no less. By the acceptance of this charter the long price war came to an end.

The trade in antiquarian and secondhand books is in a sense a more specialized class of business, requiring a knowledge of bibliography. Transactions are with individual books rather than with a number of copies; and in the antiquarian sense with copies of first editions and fine examples of binding, printing or illustration.

The periodical trade grew up during the 19th century and was in its infancy when the *Penny Magazine, Chambers' Journal* and similar publications first appeared. The growth of this side of the retail business was greatly promoted by the abolition of the newspaper stamp and of the duty upon paper and the facilities offered for purchasing books by installments.

(C. D. MY.; E. RH.)

20th Century. — During the 20th century the sale of new books separated itself from the sale of secondhand and antiquarian books just as. in the 19th century. publishing had separated itself from bookselling.

The practice of selling new books at a discount. which had been steadily ruining the trade during the 19th century, was halted by the introduction of the Net Rook agreement in 1900. This agreement. as noted above, mas in fact a statement of the conditions upon nhich publishers were prepared to supply books at trade prices. (Publishers could choose which books they were to issue "net"; in practice most books sold in bulk. *e.g.*, school textbooks, were issued "non-net." and booksellers could give discounts on these.) The Net Book agreement became subject to'the provisions of the Restrictive Trade Practices act, 1956.

The development of the retail trade in new books (indicated by the fact that signatories of the Net Book agreement increased from about 3,000 in 1900 to between 6,000 and 7,000 in the mid-1950s), which was helped by the stabilizing effect of the net-book system, resulted from the increase in the reading public and from the dispersal of the population. Most communities have their bookshop; hut outside London. the university towns and the larger provincial cities. there are few centres where the demand is sufficient to maintain a shop selling hooks exclusively. The sale of new books is therefore often allied to the sale of other goods, usually stationery or newspapers.

New books are bought outright from the publisher, and stock is returnable only in exceptional circumstances. The general bookseller has therefore to exercise great skill in buying if his profit is not to be offset by the depreciation of his unsold stock. His task of selection is made more difficult by the large number of new titles, reprints and new editions which appear each year (there were 20,719, for example, in 1957). Since there are well over 200 publishers of some importance, representing all shades of opinion and specialized knowledge, the bookseller has a great responsibility in maintaining a balanced exhibition of new books.

The Booksellers Association of Great Britain and Ireland (the name was changed in 1948) organizes correspondence and lecture courses throughout the country for booksellers' assistants; successful students are awarded the diploma in bookselling. The association also operates the book-tokens scheme. which enables the public to buy gift vouchers in one bookshop for honouring in any other bookshop in membership of the association.

In 1949 the Retail Bookselling and Stationery Trades Wages council was established; and the statutory minimum wage for managers, assistants and other workers in the trade was laid down by a wages regulation order.

UNITED STATES

The Colonial Period. — Early in the history of the book trade the functions of the printer on the one hand and of the publisher and bookseller on the other became separated. This distinction began early in the American colonies, where all its elements showed themselves fully developed in Boston by the second half of the 17th century. At the same time there existed a more primitive condition in which the functions of printer, binder, publisher and bookseller were united in a single person. This structure was normal to the book trade throughout the country virtually to the end of the colonial period.

The first bookseller of the colonies was Hezekiah Usher of Boston. Outside Boston, the first individual to describe himself as bookseller seems to have been Evan Jones of Annapolis, Md. William Bradford, pioneer printer of Philadelphia and New York,

and Benjamin Franklin were among the colonies' most prominent booksellers.

The booksellers in colonial America lived largely from the sale of imported books. Greek and Roman classics. the favourite standard English works in history, theology, philosophy and letters and the current English authors were to be found on the shelves of booksellers from Massachusetts to Virginia. From the start. pure bookshops were rare. Along with books one would find cough medicine, sealing wax. chocolate. lemons, stationery and fiddle strings on the shelves of the typical small-town colonial printer-publisher-bookseller. More discriminating were the bookselling departments of printing houses located in the larger cities. such as those of Franklin and Hall in Philadelphia, Hugh Gaine in New York city and Isaiah Thomas in Worcester. Mass.

Three other methods of distribution familiar in the European practice of the time were adapted to American conditions. The first, bookselling by subscription, began to assume extraordinary importance in the marketing of books in the 18th century. The older system of the single patron does not seem to have rooted itself firmly in the colonies. A notable exception, however. was the publication of Thomas Bacon's *Laws of Maryland,* printed by Jonas Green of Annapolis in 1765. Failing for political reasons to obtain the support of the assembly for his project. Bacon procured subscriptions from Lord Baltimore and some 20 gentlemen and merchants of the province. Before publication, Baltimore withdrew his subscription of £100 sterling from the general fund and gave that sum outright to Bacon in consideration of the proposed dedication to himself of the great book of laws. When William Parks published his collection of Virginia laws, he obtained subscriptions not only from local patrons but also from lawyers and officials throughout the middle and southern colonies, from many ship captains of London and Bristol and from merchants and gentlemen in various parts of England. Certain books which in England would have been published in the regular course of trade mere published by subscription in America to assure a reasonable sale in advance of publication in communities containing a relatively small number of cultivated people.

The second method was the hawking of books by chapmen and peddlers, a picturesque trade that prevailed in rural America of the colonial days and still prevailed there to some extent at mid-20th century. When in 1713 the Massachusetts assembly passed an act against "Hawkers, Pedlars. and Petty Chapmen," Cotton Mather wrote in his diary (vol. II, p. 283): "I must also assist the Booksellers, in addressing the Assembly, that their late Act against Pedlars, map not hinder their Hawkers from carrying Books of Piety about the Country." A considerable portion of the output of .the colonial press. in the form of small books or pamphlets which carried ballads and tracts and were called chapbooks (*q.v.*), went to the chapmen. They included among their ranks publisher Mathew Carey's celebrated agent. Parson Weems, creator of the story of George Washington and the cherry tree. Later on. Johnny Appleseed is reported to have carried books in his knapsack.

The third method, sale of books by auction, started early in the 18th century. Up to the end of that century about 860 auctions had been held in the colonies. Contrary to 20th-century practice, no fewer than 50 of these were held for the purpose of dispersing new books or mixed lots of new and old.

19th Century.— On June 25, 1788, George Washington had written a letter to Mathew Carey in which he referred to newspa ers and magazines: "I consider such easy vehicles of knowledge as more highly calculated than any other to preserve the liberty, stimulate the industry and meliorate the morals of an enlightened and free people." This priority of the periodical press over the book became the most distinctive character of the American book trade as compared with that of other countries and continents. The European press primarily nourished thought, the American press action. Almost from the start printing became a prime agent of colonization in the active westward expansion of the nation. As a result. book-trade conditions in the United States never proved so generally favourable as to allow the universal and permanent establishment of regular bookshops, exclusively or primarily devoted to books. such as existed in all large European cities and many small ones. Many 20th-century book-trade problems are rooted in this fundamental factor of social history.

The early 19th century saw significant changes in the centres of gravity of the U.S. book trade. Boston was gradually losing its position of uncontested leadership; Philadelphia and New York city became serious rivals. By 1850 the book trade had unquestionably found its centre in New York. Boston and Philadelphia were approaching equality; Baltimore and Charleston, S.C.. were advancing; and the west was beginning to surpass the south.

Publishers at first continued to use their own retail bookstores as primary distribution agencies. In the second quarter of the century, publishing and bookselling became more specialized and developed as separate occupations. Methods of distribution changed little from colonial days. The auction business. divided between Philadelphia. Boston and New York. tended toward concentration in the latter city. Advertising of books through printed catalogues (with lists of importations and locally printed titles) became a regular feature of the trade. A 32-page catalogue issued about the year 1790 by Benjamin Guild of Boston offered nearly 1,000 titles of books of English, French and classical origin; about 40 pieces of music, principally instrumental; and 1; charts of Nova Scotia and New England waters from the *Atlantic Neptune* of J. F. W. Des Barres. John West's *A Catalogue of Books Published in America* (1797) is the earliest American book trade bibliography known. The first professional organization was founded by 14 Boston firms in 1801, followed the next year by groups in Philadelphia and Boston. Kentucky and Ohio printers met in Lexington in 1805 to organize a similar group on the frontier. Book fairs after the model of the famous Leipzig and Frankfurt fairs in Germany were started by Mathew Carey. His efforts, while they failed to achieve permanency, led to the establishment of the first national booksellers' organization of the country, the American Company of Booksellers. This organization oifered gold medals as rewards for the best American-made ink, paper. binding, leather and printing. anticipating the endeavours of the American Institute of Graphic Arts by more than a century.

The 70th-century diversity of book outlets was clearly foreshadowed in 19th-century America. A large portion of U.S. books reached the public by way of the dry-goods houses and supply stores, at the newsdealers, stationers and in all sorts of mixed merchandise stores. Boston with its old corner bookstore and its retail centre on Cornhill maintained the old tradition of the trade. In New York city the section around Madison square, with Dutton's and Putnam's great bookshops on 23rd street. and Scribner's and Brentano's nearby on Fifth avenue. was one of the retail bookselling centres of the world. Apart from the older communities along the Atlantic coast it was particularly in the near west and in the middle west. in the days after the Civil War, that a good many bookstores were started. Missouri. Rfichigan. Illinois and Wisconsin were well provided with retail outlets, and Ohio exceptionally so. Cincinnati, which had become the most important book-trade centre west of the Alleghenies, was a popular convention place where in 1873 influential and long-lived book-trade associations were founded. In Chicago. vigorous retailing was practised by a group of firms which also engaged in publishing and acted as wholesalers. In the far west, too—in California and in what was then Washington territory — there were of course "booksellers and stationers." Anton Roman moved his bookstore from Shnsta City to San Francisco in 1857, where he operated also as a large-scale importer and wholesaler, covering besides the city about a dozen interior counties. In his lavishly equipped store in the Lick House block, he announced. the "noble hall has its long tables covered with the choicest mental food culled from all climes and served up in the most magnificent style of binding." The southern states of the union. and the southwest in those years did not have as many bookstores.

The booksellers bought their supply either directly from the publishers or from a small number of strong and energetic wholesalers scattered regionally about the country. Books also were

sold directly from publisher to customer. mainly by subscription. The absence of a well-developed, evenly distributed network of retail, outlets (the same thing which in the 20th century aided the phenomenal growth of the book clubs) made subscription selling feasible and necessary. Mark Twain was quick to recognize its special advantages. His connection with Elisha Bliss. Jr.. of the American Publishing company in Hartford. resulted in a vigorous and spectacularly successful sales campaign for *The Innocents Abroad*, closely co-ordinated with the lecturing schedule of the author, and later for *Roughing It* and *The Adventures of Tom Sawyer*. Mark Twain showed keen appreciation for the value of publicity and acquired a detailed knowledge of subscription selling methods. In spite of eventual abuses, such as high-pressure selling of cheap sets at exorbitant prices or working off antiquated works in new guise. subscription selling survived into the 20th century as a legitimate and generally accepted sales method.

The second half of the 19th century saw an important change in the function of the book auctioneer. He now became the agent for the American bibliophile, then affecting the auction field as its greatest factor. The Parke-Bernet galleries. New York city. leading book auctioneers at mid-20th century, could trace their history back. via the Xmerican Art association and the Anderson galleries and many earlier links, to the firm of Cooley and Bangs of the 1830s. Closely linked with the rise of the great collectors and the founding of great libraries were the rare book dealers. Joseph Sabin, bibliographer and distinguished Americana expert, Robert H. Dodd. James F, Drake. George D. Smith and Luther S. Livingston were some of the leading figures of the 19th and the early 20th centuries. They were followed in the first half of the 20th century by Charles Sessler and A. Edward Newton, Thomas F. Madigan, specialist in autographs, Gabriel Wells, Ernest Dawson, Lathrop C. Harper, specialist in incunabula, Charles E. Goodspeed and A. S. W. Rosenbach. Separated from the rare book trade. the secondhand trade found its centre on lower Fourth avenue. New York city. where Schulte's bookstore set the pace in the lower-priced field. (*See* also BOOK COLLECTING.)

20th Century. — The number of titles and the sales of novels increased early in the new century. The struggle for price maintenance continued to play an important role in bookselling. Department stores had looked on books as "loss leaders." to be sold at cut rates to attract customers. In 1914 the supreme court decided in favour of R. H. Macy & Co.. New York department store, against the American Publishers' association, on the grounds that the association's price-maintenance agreement with the American Booksellers association violated federal antitrust legislation. In 1934 a code of fair trade was adopted by the book trade under the National Recovery administration. In May 1935, the supreme court declared the NRA codes unconstitutional. and in October of that year prices were so low that some New York bookshops canceled orders with publishers and went to the loss-leader department stores to buy stock. There were continuing attempts to prevent underselling. In 1952 the McGuire Fair Trade bill was passed to validate fair-trade price-maintenance contracts for signers and nonsigners alike, in interstate commerce among states authorizing fair-trade price agreements.

The distribution of retail bookstores over the country remained uneven. the "strong" region extending along the Atlantic seaboard from Maine to New Jersey, and through Pennsylvania and Ohio as far west as Wisconsin and Illinois. with Minnesota, Iowa and hlissouri as "border" territories in the trade. The other parts of the country, with the exceptions of California and Texas, were "weak."

The continuing activities of stores dating from the 19th century were supplemented by the establishment of enterprising new stores, and by the mid-century development of such big-city chains as Doubleday and Womrath in New Tork city. Burrows in Cleveland, the expansion of Brentano's in several cities, and Fred Harvey's chain in the west and southwest. In the 1960s department stores accounted for a large percentage of U.S. book sales. A number of "personal bookshops" were started, especially in college communities. Professional education for the book trade had sporadic encouragement from institutions of higher learning. The 20th century saw the revival of the book fair, the inception of book weeks. and the rise of book and author luncheons, autographing parties and many other methods of book sales promotion.

Book clubs were the major innovation in bookselling in the 1920s. The success of the Book-of-the-Month club, started by Harry Scherman in 1926, was immediate; and within two years several other clubs were flourishing, including the Literary Guild. which was organized in 1927. By the early 1960s about 90 clubs were operating.

The mass distribution of inexpensive paperback books revolutionized bookselling in the 1940s and 1950s. Pocket Books. Inc., developed the idea of utilizing established magazine distributors as well as outlets in drugstores. chain stores, supermarkets, bus, train and airport waiting rooms, hotel lobbies and newsstands to reach the mass market; and in 1939, its first year, sold about 1,500,000 books. By the early 1960s the annual sales of 30 paperback book publishers exceeded 250,000,000 copies through more than 100,000 retail outlets. Western stories and mysteries led in popularity, but more and more works of nonfiction: self-help and how-to-do-it books, contemporary novels and literary classics were appearing. Sales of higher-priced paperback books and low-priced hard-cover reprints, primarily through traditional bookstore channels, had increased substantially by mid-century. Paper-bound textbooks had clearly found a market in the colleges.

Books for children became increasingly popular. with total sales of juveniles amounting to about half the total for adult fiction and nonfiction combined, Although one-half or more of juvenile books were sold to school and public libraries, juveniles represented a new class of books for the bookstores. Textbooks were sold primarily directly to school systems, and most technical books were sold by mail. Most general encyclopaedias and some professional (legal and medical) sets of reference works were sold by salesmen as subscription books direct to the customer on a time-payment plan. (*See* PUBLISHING: *Subscription Books.*)

Total book sales in the United States amounted to over $700,000,000 annually in the early 1960s. Among the estimated 4.500 stores selling hard-cover books, probably not more than 1,500 attempted to offer general book services or derived a major source of income from book sales. It was estimated that 60% of all bookstore sales were made in 25 cities which included 20% of the country's population.

In spite of many staggering internal and external difficulties (chief among the latter being competition from the various mass media of communication), the book trade continued to grow from year to year. In spite of its relatively small importance in the national economy (with total annual sales in the early 1960s amounting to about .2% of the gross national product) bookselling was of major importance; since the nation's cultural heritage and the rights and freedoms of the people require for their preservation a free and independent, courageous and relatively prosperous book trade.

BOOKWORM, the name given to various insects! moths, beetles, etc., whose larval (or adult) forms injure books by gnawing the binding and piercing the leaves with small holes. There is, however. no single species which may properly be called the bookworm. for a large number of the many insects that feed upon dry, starchy material or paper may cause damage to books. Among the most widely known bookworms aye the silverfishes (order Thysanura) and the booklice (order Psocoptera or Corrodentia).

BOOLE, GEORGE (1815–1864), English logician and mathematician. famous for his development of symbolic logic and. in mathematics. for his appreciation of the way in which the symbols of operation could be separated from those of quantity and treated as distinct objects of calculation. He was born at Lincoln on

Nov. 2, 1815, the son of a tradesman of limited means. and became assistant master in schools at Doncaster (from about the age of 16) and at Waddington, near Lincoln. He opened his own school in Lincoln. then became headmaster of Waddington and eventually. in 1840, moved this school to Lincoln. Meanwhile he had contributed his first published work. "Researches in the Theory of Analytical Transformations." to the *Cambridge Mathematical Journal* for 1839 (1841). Further contributions to learned periodicals led to his appointment in 1849 as professor of mathematics in Queen's college. Cork. Ire. He died at Ballintemple, near Cork, on Dec. 8, 1864.

Boole's well-known *Treatise on Differential Equations* (1859; posthumous supplement. 1865) was followed by a *Treatise on the Calculus of Finite Differences* (1860), designed as a sequel to it. In the 16th and 17th chapters of the *Differential Equations* there is a lucid account of the general symbolic method. the bold employment of which led to Boole's chief discoveries; and of a general method in analysis. originally described in his famous memoir in the *Philosophical Transactions* for 1844.

With the exception of Augustus De Morgan (*q.v.*), Boole was probably the first English mathematician since John Wallis to write upon logic. His ideas concerning a calculus of reasoning were first published in a pamphlet called *Mathematical Analysis of Logic* (183;); but Boole later regarded this as an imperfect exposition of his logical system and desired that his much larger work, *An Investigation of the Laws of Thought, on Which Are Founded the Mathematical Theories of Logic and Probabilities* (1854), should alone be considered as a mature statement of his views. He did not regard logic as a branch of mathematics, as the title of his earlier pamphlet might seem to imply; but he pointed out such a deep analogy between the symbols of algebra and those which can be made, in his opinion, to represent logical forms and syllogisms that we can hardly help saying that logic is mathematics restricted to the two quantities, 0 and 1. By unity Boole denoted the universe of thinkable objects; literal symbols. such as x and y, were used with the elective meaning attaching to common adjectives and substantives. Thus, if x = horned and y = sheep, then the successive acts of election represented by x and y, if performed on unity. give the whole of the class *horned sheep.* Boole showed that elective symbols of this kind obey the same primary laws of combination as algebraical symbols. whence it followed that they could be added, subtracted, multiplied and even divided, in almost exactly the same manner as numbers. Thus, $1-x$ would represent the operation of selecting all things in the world except *horned things;* that is, *all not horned things;* and $(1-x)(1-y)$ would give *all things neither horned nor sheep.* By the use of such symbols propositions could be reduced to the form of equations; and the syllogistic conclusion from two premises was obtained by eliminating the middle term according to ordinary algebraic rules.

(W. S. J.; X.)

Although his first concern was to provide an appropriate symbolism for Aristotle's logic of general terms, Boole saw that his algebra could be applied also in reasoning about the relations of propositions; and he devoted much thought to its use in the mathematical theory of probabilities. He was. indeed. one of the first mathematicians after Leibniz to consider seriously the presentation of a deductive system in an abstract fashion. The opening remarks of his *Mathematical Analysis of Logic* in which he set out his view of an abstract calculus were amply justified by later events. since the algebra which goes by his name (Boolean algebra) has found many applications of which he never dreamed (*e.g.,* in the theory of switchgear for telephone circuits and in the design of electronic computers). It is not, however, as his admirers once thought, the whole of logic. See LOGIC; LOGIC, HISTORY OF.

BIBLIOGRAPHY.—Boole's *Mathematical Analysis* of **Logic** was republished. together with some later papers and a selection of notes on logic from his manuscripts in the library of the Royal society, under the title *Studies in* **Logic** *and Probability* (1952). BOOMERANG, a curved throwing stick used chiefly by the natives of Australia for hunting and warfare. The Australian aborigines used two kinds of boomerangs and many varieties of boomerang-shaped clubs.

The returning boomerang (the name is from the native word used by the Turuwal tribe in New South Wales) is light. thin and well balanced. 12–30 in. long, $1\frac{1}{2}$–3 in. wide. $\frac{3}{16}$–$\frac{3}{8}$ in. thick and up to 12 oz. in weight. It varies in shape from a deep. even curve to almost straight ends of the same or unequal lenpth. Usually, one side is flat, but both may be convex. The edges are sharp or rounded. The ends are twisted or skewed in opposite directions (forward and backward) either as the boomerang is being made or after it has been heated in ashes.

The boomerang is thrown with a vigorous action in which the thrower may run a few steps to gain greater impetus. It is held at one end. above and behind the thrower's shoulder, with the concave edge to the front. and swung forward rapid!? with the flatter side underneath. Just before release, added impetus is given by a strong wrist movement. If thrown downward or parallel to the ground, it sweeps upn-ard to a height of 50 ft. or more. When thrown so that one end strikes the ground it ricochets into the air at terrific speed, spinning endwise. It completes a circle or oval 50 yd. or more wide and then several smaller ones. up to five. as it drops to the ground near the thrower. A Equre-of-eight course may be followed. The returning boomerang is a plaything used to train men in dodging weapons and in tournaments to see who can make it weave the greatest number of circles or return nearest a peg. Hunters spin it above flocks of ducks. parakeets and pigeons to imitate a hank and to drive the birds into nets strung from trees.

Returning boomerangs were used in eastern Australia and in Western Australia only. Early students believed that air, pressing on the lower flat suriace and passing over the upper rounded face, explained the boomerang's comeback flight. but T. L. Mitchell, in 1846. gave the real explanation; he said that it was caused by the skew combined with the spinning motion. The rerurning boomerang is generally considered to have developed from the nonreturning types which swerve in flight.

The nonreturning boomerang has a shallow curve in relation

to its length. 2–3 ft., and it weighs up to 1½ lb. With it animals are maimed and killed, while in warfare it causes serious injuries and death. It is thrown in the same way as the returning boomerang. One variety has a picklike hook at one end.

All boomerangs drop to the ground when they strike a man. animal, tree or other object. They are also beaten together as musical clapsticks, their sharp ends are useful for digging and in the Northern Territory one type was used for tribal rituals. Mulga, myrtle and mangrove are commonly used timbers for making boomerangs. They were not made in Cape York, Arnhem Land and parts of Western Australia.

Boomerang-shaped. nonreturning weapons were used by the ancient Egyptians and are still used by the Indians of California and Arizona and in southern India (where some are made of metal) for killing birds, rabbits and other animals.

(F. D. McC)

BOQNE, DANIEL (1734–1820), famous American hunter and pioneer, was born near the present city of Reading, Pa., probably on Nov. 2, 1734. He had very little formal schooling but learned to read and write. As a youth he moved with his family to the Yadkin valley on the North Carolina frontier. He served as a teamster in Gen. Edward Braddock's disastrous expedition of 1755. Most of his life was spent as a wandering hunter and trapper. He went as far south as Florida in 1765 and possibly as far west as the Yellowstone river in 1814.

Many white men had traversed the "dark and bloody ground" of Kentucky before Boone. so the legend that he was the discoverer and founder of Kentucky needs qualification. He first went a short way through the Cumberland gap (at the extreme southwestern border of Virginia) to hunt in the fall of 1767. Then, guided by John Finley, he and several companions returned to the Kentucky country to trap and hunt in the years 1769–71. Twice during this long hunt he was robbed of his furs and hides by Indians, and once he nas captured by them but he managed to escape He returned to his wife in North Carolina with little material gain to shon for his strenuous efforts But he nas rich in Information because he had explored the valleys of the Kentucky and Green rivers and north-central Tennessee so thoroughly that he knew the region better than any other white man.

In 1773 Boone undertook to lead his own and several other families to the western country but the pioneer band was attacked by Cherokee Indian5 in the Cumberland gap Two ot the party, one of them Boone's son James, were tortured and murdered, whereupon the survivors turned back, against Daniel Boone's wishes.

Governor Dunmore of Virginia sent Boone into Kentucky in 1774 to warn surveyors of Indian dangers. Then in March 1775 Boone and 28 companions were employed by Richard Henderson's Transylvania company to blaze a trail through the Cumberland gap. Despite Indian attacks they built a road and prepared the way for the opening of three settlements at Boonesboro. Harrod's Tonn and Benjamin Logan's. In Aug, 1775 Boone brought his family to Boonesboro. His wife and daughter were the first white women in Kentucky, and their arrival may be said to mark the beginning of permanent settlement in Kentucky.

Henderson's project called for the purchase of an immense tract from the Cherokees, and the establishment of a 14th colony. The project failed because Henderson could not obtain valid title to his lands. Instead of a 14th colony Kentucky was made a county of Virginia. Boone became a captain in the county's militia and a leader in defending Boonesboro against the Indians. Once he was able to rescue unharmed his daughter and two other girls who had been kidnaped by Indians.

Boone himself was captured a second time by Indians in 1778. He was adopted as a son by the Shawnee chief, Blackfish. After five months he escaped to warn Booneshoro settlers of an impending attack. When the attack by British and Indians came in Sept 1778 Boonesboro successfully nithstood a ten-day siege.

Boone was a courageous and resourceful Kentucky leader, but he did not prosper. He established extensive land claims, but could rarely make them good. After the American Revolution he worked as a surveyor along the Ohio river. He settled for a few years in Kanawha county, Va., (now West Virginia). Then in 1799 he followed his son, Daniel Morgan Boone, to Missouri, which was then under Spanish rule. Boone continued his familiar hunting and trapping pursuits in the Ozarks and had further land troubles after the Louisiana purchase.

When Boone died in St. Charles county, Mo., probably on Sept. 26, 1820, he was even then a legendary hero. The bodies of Boone and his wife were later moved to Frankfort, Ky.

See R. G. Thwaites, *Daniel Boone* (1903); John Bakeless, *Master of the Wilderness, Daniel Boone (1939).* (T. A. LN.)

BOONVILLE, a city in central Missouri, U.S., on the right bank of the Missouri river, 150 mi. N.W. of St. Louis and the seat of Cooper county. (For comparative population figures *see* table in MISSOURI: *Population.*) Named after Daniel Boone, it was settled in 1810, incorporated as a village in 1839 and chartered as a city in 1896. During pioneer days. it was an important trading post on both the Missouri river and the Santa Fe trail. During the American Civil War, it was in hotly contested territory and an engagement took place there June 17, 1861.

The natural resources of the region include rich agricultural land. clays and shales, stone and coal. Industries include a chicken hatchery, dairies, a stone quarry, a shoe factory. bottling plants and a walnut veneer plant. The bfissouri Training School for Boys (1889) and Kemper Military academy (1864) are there. There are three Indian mounds in Harley park. (C. ST.)

BQORDE (BORDE), **ANDREW** (1490?–1549), English physician and author of the first English guide hook to Europe. was born at Borde hill. Cuckfield. Susses. He was educated at Oxford and admitted as a member of the Carthusian order while still a minor. In 1521 he was "dispensed from religion" to act as suffragan bishop of Chichester. though he never filled the office. and in 1529 he was freed from his monastic vows, not being able to endure. as he said. the "rugosyte off your relygyon." He visited the universities of Orleans. Poitiers. Toulouse. Montpellier and 15-ittenberg, saw "much abhominable vyces" at Rome and went on pilgrimage to Santiago de Compostella. In 1534 Boorde was again in London at the Charterhouse and Thomas Cromwell seems to have entrusted him with a mission to find out the state of public feeling abroad about Henry VIII's policies. In 1536 he was studying and practising medicine at Glasgow. About 1538 Boorde traveled extensively, visiting nearly all the countries of Europe except Russia and Turkey and later making his way to Jerusalem. He settled for a time at Montpellier and before 1532 had completed his *Fyrst Boke* of *the Introduction of Knowledge,* in prose and "ryme dogrell" (1548), which ranks as the earliest continental guide book. his *Dyetary of Helth* (1542?) and his *Brevyary* (1552). He probably returned to England in 1532. He made his will in the Fleet prison in April 1539. His writing is unpolished; but lively and full of interesting lore and anecdote.

See F. J. Furnivall's reprint of the *Introduction* for the Early English Text Society, extra series no, x (1870, reissued 1906). (X.; N. D.)

BOOS: MARTIN (1762–1825), Bavarian Roman Catholic priest, who started a movement among Catholics closely allied to the pietist movement in the Lutheran churches. was born on Dec. 25, 1762. He pursued his propaganda from about 1799 to 1812 in Austria, but repeated accusation:: in consistorial courts compelled him to return to Bavaria. The Prussian government gave him a professorship at Düsseldorf in 1817, and in 1819 a pastorate at Sayn, near Neuwied. He died on Aug. 29. 1825.

BOOT: *see* SHOES.

BOÖTES, a constellation of the northern hemisphere (Gr. *bootes,* "herdsman." from *boos,* "ox"). The ancient Greeks symbolized it as a man walking, with his right hand grasping a club, and his left extending upward and holding the leash of two dogs, which are apparently harking at the Great Bear (Ursa Major). The brightest star is Arcturus (*q.v.*). Another interesting star is ϵ Boötis, a beautiful double star composed of a yellow star of magnitude 3 and a blue star of magnitude 6½. *See* CONSTELLATION.

BOOTH, a family whose name is intimately connected with

the founding and early development of the Salvation Army (*q.v.*).

WILLIAM BOOTH (1829–1912), founder of the Salvation Army, was born in Nottingham, Eng., on April *10, 1829.* His father, an unsuccessful builder, apprenticed him to a pawnbroker because the profession often enriched those who engaged in it. The early contact with human misery that pawnbroking gave him roused Booth to a lifelong passion of anger against the poverty and degradation in which far too many 19th-century Englishmen lived. In *1844* he experienced, in a Wesleyan chapel, religious conversion, and in *1846,* influenced by the American evangelist, James Caughey, he seriously ratified his dedication by beginning to preach. He became a Methodist "local preacher" in *1847* and always retained his love for the Methodist Church. His apprenticeship over in *1848,* he vainly sought work in Nottingham before going to live in London, where he was finally employed by a pawnbroker in Walworth. Long hours at a distasteful and tiring job did not lessen his religious zeal. His official lay preaching did not give him enough evangelical work to do, so he began to hold open-air meetings. This caused friction with his minister, and he attached himself to the Methodist New Connexion, in which, after a period of study, he was ordained *(1858).* In the meantime, he had married in *1855* a remarkable woman, Catherine Mumford *(see* below). He conducted ardent evangelical campaigns in various parts of the country, during which he evolved the methods afterward used to great effect by the Salvation Army. Though successful as a regular minister, he resigned in *1861* to dedicate himself to his true vocation, itinerant evangelism.

In *1865* the family moved to London, and in July of that year William Booth was invited to speak at, and then lead, open-air and tent meetings in the Whitechapel district. From this attempt to reach the churchless masses came the Christian mission, renamed *(1878)* the Salvation Army. Booth was forced by the numbers of his converts to found the religious organization of which he became first general, and within ten years all England was stirred. There was violent persecution from ignorant and alcohol-crazed roughs; in *1882,* for instance, *669* Salvationists *(251* of them women) were "knocked down, kicked, or brutally assaulted," and *56* properties either wholly or partially wrecked. Some magistrates also prosecuted his followers: in *1884* no fewer than *600* Salvationists were sent to prison for preaching the gospel. The disorder gradually ceased. and Booth even received friendly overtures from the Church of England, though these did not lead to any close union. Converts carried the work to the United States in *1879,* and to Australia in *1880.* Booth's eldest daughter Catherine (called "la maréchale") began preaching in Paris in *1881.* By *1890* the Salvation Army was established in most European countries, in India, in South Africa and in South America. In *1890* appeared the most influential of Booth's many books, In *Darkest England and the Way Out,* in which he had the help of W. T. Stead (*q.v.*). It contained concrete proposals for relieving pauperism and fighting vice; homes for the homeless; training centres to prepare emigrants for overseas countries; rescue homes for women and girls in moral danger; homes for released prisoners; legal aid for the poor; practical help for the alcoholic. There was vast public support. and much of the scheme came into operation.

Toward the end of the century, Booth's religious and social genius began to be recognized. London made him a freeman of the city, Oxford university gave him an honorary doctorate. He was officially invited in *1902* to the coronation of Edward VII, and he opened a session of the United States senate with prayer. His life was saddened by the death of his wife in *1890,* and by the defection of two of his sons and a daughter, who, after having played leading roles in the phenomenal progress of the army, resigned because of personal differences and disciplinary disagreements. Increasing blindness could not prevent Booth's continuing his evangelical and social activities until he was over *80.* He died in London on Aug. *20, 1912.*

Booth had a passion for righteousness and for social justice, coupled with a genius for organization and leadership. His theology has been described as simple. Though by no means superficial, it certainly concentrated on essential matters, clearly expounded for the understanding and inspiration of the common man. His outstanding gifts as a preacher and leader inspired a movement that resulted not only in scenes of religious enthusiasm but also in practical Christian social work of immense value and far-reaching influence.

CATHERINE BOOTH (1829–1890), wife of the founder of the Salvation Army, herself an eloquent preacher and untiring social worker. was born on Jan. *17, 1829,* at Ashbourne. Derbyshire Eng. Her father was a carriage builder and sometime Methodist lay preacher, her mother a deeply religious woman of Puritan type. Catherine. in adolescence an invalid, was educated principally at home, and early acquired some competence in the theology of her day. The family moved to London in *1844* and she became an active member of the Wesleyan Methodist church in Brixton. When this church expelled a group of "reformers." she and her future husband joined them. They were married in *1855* and Catherine became her husband's most fearless critic and most devoted helper, giving much time to visitation among the very poor. It was largely because of her influence that William Booth left the assured career of a Methodist minister for the uncertainties of itinerant evangelism.

Catherine Booth was a convinced believer in women's right to preach the gospel, and her pamphlet *Female Ministry* (1859) is still cogent. She herself began to preach in her husband's church at Gateshead in *1860.* She became a notable orator, and in *1880–84* conducted highly successful meetings in various halls in the West End of London. In *1885* she took part in a campaign that secured the passing of the Criminal Law Amendment act, designed to protect young girls. She died of cancer at Clacton on Oct. 4, *1890.* She did not believe that the sacraments are essential to salvation. Her views were not lightly adopted, but were based on her study of Holy Scripture and theology, and on an examination of the practical effects of the sacraments on church unity and in the personal life of church members. Although the evolution of the sacramental attitude of the Salvation Army must not be wholly attributed to Catherine Booth, her beliefs were undoubtedly influential.

WILLIAM BRAMWELL BOOTH (1856–1929), second general of the Salvation Army and eldest son of William and Catherine Booth, was born at Halifax, Eng., on March *8, 1856.* He became an active full-time collaborator in *1874,* and from *1880* was the Army's chief organizer. He carried into practice the social services plans outlined by his father. In *1885,* together with W. T. Stead. he stood trial at the Old Bailey on a technical charge connected with the successful attempt to secure legislation protecting young girls in moral danger, but was acquitted. The trial—and Stead's vigorous press campaign—proved to a skeptical public that in 19th-century England girls could be bought and sold for immoral purposes, not only without their consent but against their will. An able speaker, a tireless exponent of the doctrine of Christian perfection, a fine writer—he published nine books, of which *Echoes and Memories (1925)* and *These Fifty Years (1929)* are perhaps the best known—William Bramwell Booth was also an enthusiast for religious work among young people. He became general on his father's death, and died on June *16, 1929,* in London.

EVANGELINE CORY BOOTH (1865–1950), seventh child of William and Catherine Booth. was born at Hackney, Eng.. on Dec. 25 1865. From her youth she took an active part in the organization of the movement. In *1896* she went to Canada and in *1904* took over command of the Salvation Army in the United States, where she remained until *1934,* when she was elected general. She retired in *1939.* and died in New York on July *17. 1950.*

BOOTH, CHARLES (1840–1916), English shipowner and social reformer who made significant contributions to knowledge of social problems and to the methodology of statistical measurement. He was born at Liverpool on March *30, 1840.* His chief work. *Life and Labour of the People in London* (17 vol., 1903), contains a series of celebrated maps in which various colours show

the degrees of poverty found street by street Booth's purpose was to describe the conditions under which various classes lived and to show the relationship between poverty and depravity on the one hand and regularity of income and resulting standards of living on the other hand.

The lot of the nged poor also engrossed his attention. He was a member of the royal commission on the poor law (1905–09), and although ill health forced him to retire, he published his viens separately as *Poor Law Reform* (1910). His achievements earned him a privy councilorship a fellowship of the Royal society and doctorates of the universities of Cambridge. Liverpool and Oxford.

Booth died on Nov 23. 1916. In 1871 Booth married Mary Macaulay, a niece of Thomas B. Macaulay, the historian She was the author of *Charles Booth,* a *Memoir,* published in 1918.

(A. W. M.)

BOOTH, EDWIN THOMAS (1833–1893), U.S. actor and one of the outstanding 19th-century Shakespearean tragedians was born Nov. 13, 1833, near Belair, Md. His father. the Anglo-U.S. actor Junius Brutus Booth (born in London. 1796), moved to the United States in 1821 and became a favourite on the American stage, continuing the successes achieved in London, where he was regarded as a serious rival to Edmund Kean.

Edwin Booth's stage debut was made at the Boston museum on Sept. 10. 1849, as Tressel to his father's Richard III, in Colley Cihher's version of the Shakespeare play. Two years later at the National theatre. New York city. when his father refused to perform one night. Edwin took his place in the character of Richard III. It was not until after his father's death in 1852, however, that Edwin won renown for himself. Between 1852 and 1856 he played in California, Australia and the Sandwich Islands. In 1857 he appeared as a star in Boston, Mass., and New York city, and at the end of three years challenged and overcame the dramatic supremacy of Edwin Forrest.

In 1863 Booth became comanager of the Winter Garden theatre, New York, presenting there a series of Shakespearean productions of unprecedented grandeur and finish. There the three Booth brothers, Junius Brutus (1821–83), Edwin and John Wilkes (*q.v.*), appeared together as Cassius, Brutus and Mark Antony, respectively, in a memorable performance of ***Julius*** *Caesar.* From Nov. 26, 1864, to March 22, 1865, Edwin played Hamlet for 100 consecutive nights. His triumph was dashed when in 1865 his brother John Wilkes Booth assassinated Pres. Abraham Lincoln. Edwin's reputation, though not his spirit, eventually recovered from this blow, which caused his retirement until Jan. 3, 1866, when he reappeared at the Winter Garden as Hamlet.

Booth then built his own theatre, at 23rd street and Sixth avenue, New York city, which he opened in 1869. There he produced practically his entire repertory of Shakespearean and other plays. He used the true text of Shakespeare, anticipating by years a similar reform in England, and his productions were outstandingly good. Booth had little business acumen. however: his trust in ill-chosen financial advisers cost him his theatre and brought him to bankruptcy in 1874. But by hard work, acting from this time under the management of others, he again earned a fortune.

In 1861 Booth had played in London. which he revisited in 1880 and 1882, playing there and in the provinces with moderate success. At Henry Irving's invitation, he alternated with Irving in the parts of Othello and Iago at the Lyceum theatre, London. In 1883 he toured Germany, where his acting was received with immense enthusiasm, and this German engagement he considered the peak of his career. In 1886 Booth formed a highly successful business and acting partnership with Lawrence Rarrett. During April and May 1886 Booth and Tommaso Salvini played together in *Othello* and *Hamlet,* and in the season of 1889–90 Booth appeared opposite Helena Modjeska. His last appearance was as Hamlet. in 1891 at the Academy of Music, Brooklyn. N.Y.

Booth died on June 7, 1893.

Booth's genius was for tragedy. He was small. slight and dark, with a magnificent voice. His acting developed from the bombastic style characteristic of the early 19th century into a quieter. more natural manner that foreshadowed the realism of 20th-century acting. Hamlet was generally considered his finest role. In later life he largely confined himself to playing Hamlet, Lear. Macbeth, Iago. Othello, Brutus, Shylock and Richard III, of Shakespeare: and to the title role in *Richelieu* by Bulwer-Lytton, and Bertuccio in Tom Taylor's *The Fool's Revenge.*

His public life. except for the disaster of his brother's crime. was splendid. hut his personal life was consistently sad. The nobility of his character, his achievement in his art and his zeal to improve both the moral and social standing of actors combined to make him one of the great figures of the American stage. In 1888 he founded and became the first president of a club, the Players, New York city. where he made his home in his last years.

(E. R.)

BOOTH, JOHN WILKES (1838–1865), U.S. actor, the assassin of Pres. Abraham Lincoln. was born in Hartford county, Md., in 1838. He was the son of Junius Brutus Booth and brother of Edwin Thomas Booth (*q.v.*). He sympathized with the south in the American Civil War, and in 186.3 organized a conspiracy to assassinate the president, the vice-president and members of the cabinet.

On the night of April 14, 1865, while Lincoln was watching a play, *Our American Cousin,* from a box at Ford's theatre in Washington, D.C.. Booth stealthily entered the box and discharged a pistol at the head of the president from behind, the ball penetrating the brain. Brandishing a huge knife, the assassin leaped down upon the stage, shouted ***"Sic*** *semper tyrannis!* The south is avenged!" and escaped from the building. He was pursued. and 12 days later was shot in a barn near Bowling Green, Va., where he had concealed himself.

BOOTHIA PENINSULA, the northernmost portion of mainland Canada. reaching 71° 58' N. Area 11,741 sq.mi. Pop. (1956) 143. mostly coastal and seminomadic. Administratively within Franklin district, the peninsula is a treeless, plateaulike arm of the Canadian shield. rising to 2,000 ft. It is truncated on the north by the navigable Kellot strait, merges in the south with Boothia isthmus and is flanked on the northeast and west by limestone lowlands. Spence bay and Thom bay are the only settlements. The peninsula was named in honour of Sir Felix Booth, who financed the Ross expedition which discovered and partly mapped it in 1829–33, and established the location of the north magnetic pole. See ARCTIC. THE: *Exploration of Arctic Regions.* (H. R. TN.)

BOOTLE, a municipal, county (1888) and parliamentary (1918) borough in southwest Lancashire. Eng. Pop. (1961) 82,-829. It contains the northern part of the Mersey river docks which employ many of its inhabitants. A great variety of other industries include engineering. wire-rope works, tin-box factories, electrical works, dye works, flour mills and large timber yards. Bootle has also large storage accommodations for cotton, grain, etc. The town possesses many parks and recreation grounds, including a golf course and sports stadium. A proposal to merge Bootle in the adjacent city of Liverpool was rejected by parliament in 1903. From 1918 Bootle returned one member to parliament.

BOOTLEGGING. This term, which came into general use in the midwestern states of the United States in the 1880s to denote the traffic in illegal whisky, apparently derived from the practice of carrying flasks concealed in boot tops. It became one of the most familiar terms in the American vocabulary during the era of national prohibition (1920–333. and is sometimes used to describe illegal dealings in oiher commodities, such as prohibited books or nonexportable currencies. After repeal of prohibition the bootlegging of liquor continued to represent a formidahle problem. According to Licensed Beverage Industries, Inc., the public relations agency of the U.S. distillers, this traffic was operating at a rate

of about $1,000,000,000 a year in the early 1960s; 40.000 to 60.-000 persons were engaged in the operation of unlicensed stills; and there were at least 150,000 distributors of the illegal product. *(See* also LIQUOR LAWS AND LIQUOR CONTROL; NARCOTICS; OPIUM.)

Historical Background. — In U.S. history, violators of liquor laws have ranged from colonial merchants rebelling against taxation without representation to the gangsters associated with the prohibition era. In frontier days, the illegal traffic in whisky with the Indians caused outbreaks of violence, and created resentment on the part of white settlers against the entire liquor trade. Anti-liquor sentiment became associated with the religious revival of the early 19th century, and gradually became an organized movement. Local option, permitting each community to regulate or forbid the sale of liquor, was adopted in 1829 by Maine, and within a few years by several other states, including New York and New Jersey. In 1880 Kansas became the first state to incorporate prohibition in its constitution. It was in this state, according to the 1891 edition of the *Cyclopedia of Temperance and Prohibition,* that the term "bootlegger" became current.

By 1906, 40% of the population of the U.S. lived in localities in which the sale of liquor was outlawed. A corresponding increase in bootlegging was attributed to the fact that liquor was being smuggled from "wet" communities into the "dry" ones, and the campaign for universal prohibition was intensified.

National Prohibition and Bootlegging. — The 18th amendment, writing prohibition into the federal constitution, was ratified Jan. 16, 1919, effective a year later. *(See* PROHIBITION.) In preparation for the new era, a prohibition unit was organized in the treasury department. This unit was exempt from civil service, and appointments to it were a form of political patronage. In their first five weeks on the job, five of the new agents were arrested on charges of taking bribes from bootleggers or going into the business thernselves.

In the early phase of the prohibition era, the efforts of most bootleggers were concentrated on getting a supply of genuine liquors. Their activities included smuggling across the Canadian and Mexican borders and in ships under foreign registry. Favourite sources of supply were the Bahamas, Cuba and the French islands of St. Pierre and Miquelon, off the southern coast of Newfoundland. Great quantities were also obtained from government-supervised warehouses, supposedly for medicinal use or for export, by those who possessed strong political connections.

In addition to the medicinal whisky that reached the bootleg market in wholesale consignments, millions of bottles were sold across drugstore counters on real or forged prescriptions. Less than five months after the 18th amendment had gone into effect, the federal administrator for Illinois estimated that 300,000 spurious prescriptions had been filled in Chicago alone. By mid-June of the first year the courts were already congested with cases awaiting trial, and Chicago had a backlog of more than 500 cases. Officials of the prohibition unit complained in July that the law was being disregarded in the big cities, and that their force of 1,550 agents was inadequate to cope with the situation. The 9,500 illicit stills that were seized during the first six months were admittedly only a small fraction of those in operation.

The first group of sea captains to go into the business of smuggling liquor included such stalwarts as Capt. William McCoy, who had never been on the wrong side of the law before and took pride in having his cargo known as "the real McCoy." Only a few skippers of this type survived, for the agents with whom they had to deal had many ways of tricking them out of their cargoes, sometimes even taking these at gun point. The later recruits to the rum-running fleet were of the same breed as the gangsters with whom they did business. Many of them carried narcotics and illegal immigrants as a sideline.

A favourite rendezvous of the rum-running ships mas a point opposite Atlantic City. N.J., just outside the three-mile limit beyond which the government lacked jurisdiction. They anchored in this area and discharged their loads into high-powered craft that were built to outrace coast guard cutters.

In May 1924 the U.S. authorities negotiated a treaty with Great Britain that permitted the halting and searching of ships within one hour's steaming distance from the coast. The bootleg fleet now made a practice of anchoring 20 mi. offshore. Some of the small boats making the run from this point were caught, and others dumped their cargoes overboard when the chase became too hot. However. profits were so great that the bootleggers could afford these occasional losses.

Smuggling became increasingly expensive when the coast guard began trailing the small boats with fast launches of its own. Most of the bootleggers now placed their reliance on the alchemy of the 1920s—a process in which industrial alcohol that had been more or less "washed" of noxious chemicals, plus tap water and colouring matter and perhaps a dash of real liquor for flavour, became a valuable commodity. In the big cities, thousands of boatleggers delivered such wares to the homes of their private clientele or to "speak-easies"—cellars, apartments and simulated business establishments. In these, guards watched from slots in the barred doors, admitting only those whose faces or credentials were familiar. In 1930 Mayor Fiorello LaGuardia of New York estimated that 22,000 speak-easies were operating in that city. Practically all of the traffic with these establishments came under gangster control.

The most notorious gangster of the era was "Al" Capone, who rose from the ranks of petty crime to a position of dominance in the bootleg traffic of Chicago. The New York market was shared by such underworld characters as "Waxey" Gordon: "Dutch" Schultz, and "Legs" Diamond. In the late 1920s, many of the New York night clubs came under the partial or complete ownership of veteran criminals of this type. These highly publicized gangsters, in turn, deferred to the authority of such behind-the-scenes manipulators as Arnold Rothstein and Frank Costello, who had powerful political connections.

Conditions in New York and Chicago were duplicated in many other communities. The Anti-Saloon League of Iowa stated in May 1925: "Dubuque boasts of 41.000 citizens and 1,000 bootleggers." Gradually local and intercity co-operation was practised by the bootleggers in their defense against hijackers and against honest enforcement agents. Underworld organization reached a high degree of efficiency: and was applied not only to bootlegging but to the narcotics traffic, gambling rackets, and organized prostitution and extortion.

In *The Wrecking of the Eighteenth Amendment* (1943), Ernest Gordon maintained that prohibition had the compliance of a great majority of citizens during the first years, and that widespread disrespect for the law developed only after it became known that federal officials were conniving with bootleggers. Those officials who were seriously trying to enforce prohibition met with steadily increasing frustrations. In 1921 they began to apply for court orders permitting the padlocking of premises that had been used for some phase of bootlegging. Many offenders simply moved to new places of business.

The small-scale bootlegger was usually not a gangster, although he could not hare operated without paying tribute, directly or indirectly, to gangsters. To his customers he was a glamorous personality — a genial adventurer who was taking great risks in order to provide "stuff right off the boat." To eliminate this familiar character from the New York scene, according to Mayor LaGuardia, would require a force of 250,000 policemen — and a second force. almost as big, to watch the first. If this statement was an exaggeration, it was one that reflected the prevailing mood.

Repeal of the 18th amendment in Dec. 1933 left the states free to return to individual regulation. Some of the states permitted the sale of liquor only in government-operated package stores; others instituted local option or various other types of limitation. Wherever a restriction existed, bootleggers were ready to close the gap—and some of them operated even in nonprohibition areas, making huge profits by putting liquor of their own concoction into bottles bearing expertly counterfeited tax stamps and brand labels.

Although bootlegging is generally associated with the U.S., other nations have also encountered the problem. When the Soviet government came into power in Russia in 1917, the sale of vodka had been forbidden as a war measure, and the Communist regime continued the prohibition. However, bootlegging was widespread

until the government legalized vodka and took over its sale in 1925. Among other experiments in prohibition that stimulated bootlegging and mere abandoned were those of Norway and Iceland

(J. AY.)

BOPP, FRANZ (1791–1867). German philologist. born at Mainz on Sept. 14. 1791, educated at Aschaffenburg in Bavaria. In 1812 he went to Paris to study Sanskrit. In 1816 he published, at Frankfurt am Main, *Über* dus *Conjugationssystem* der *Sanskritsprache.* The object of Bopp's researches was to trace the common origin of the grammatical forms or inflections of Sanskrit, Persian. Greek. Latin and German, a task which had never before been attempted. By a historical analysis of those forms, as applied to the verb, he furnished the first trustworthy materials for a history of the languages compared.

Bopp visited London and brought out, in the *Annals* of *Oriental Literature* (London. 1820), an essay entitled, "Analytical Comparison of the Sanskrit. Greek. Latin and Teutonic Languages." in which he extended to all parts of the grammar what he had done in his first book for the verb alone.

In 1821 Bopp was appointed to the chair of Sanskrit and comparative grammar at Berlin, and was elected member of the Royal Prussian academy in the following year. He brought out, in 1827, his *Ausführliches Lehrgebäude* dcr *Sanskrita-Sprache,* on which he had been engaged since 1521. At the same time he compiled a Sanskrit and Latin glossary (1830) in which. more especially in the second and third editions (1847 and 1867), account was also taken of the cognate languages. His chief activity. however. centred on the elaboration of his *Comparative Grammar,* which appeared in six parts (1833–52) as *Vergleichende Grammatik* des *Sanskrit, Zend, Griechischen, Lateinischen, Litauischen, Altslawischen, Gothischen, und Deutschen,* Eng. trans. by E. B. Eastwick (1856). Two other essays (on the "Numerals," 1835) followed the publication of the first part of the *Comparative Grammar.* The Old Slavonian began to take its stand among the languages compared from the second part onward. A second German edition. thoroughly revised (1856–61), comprised also the Old Armenian. Bopp tried in his grammar to give a description of the original grammatical structure of the languages as deduced from their intercomparison. to trace their phonetic laws and especially to investigate the origin of their grammatical forms. He also wrote monographs on the vowel system in the Teutonic languages (1836), on the Celtic languages (1839). on the Old Prussian (1853), and Albanian languages (1854), on the accent in Sanskrit and Greek (1854), on the relationship of the Malayo-Polynesian with the Indo-European languages (1840) and on the Caucasian languages (1846). He died on Oct. 23. 1867; at Berlin.

See M. Bréal's translation of Bopp's *Vergleichende Grammatik* (1866), introduction; T. Benfey, *Geschichte der Sprachwissenschaft* (1869); A. Kuhn in *Unsere Zeit,* Neue Folge, iv, 1 (1868); Leimann, *Franz Bopp* (1891–97).

BOQUERÓN, the largest department of Paraguay, occupies the heart of the Paraguayan Chaco. It is a region of scrub forest and grassland on a gently dipping plain of sand and clay debris swept eastward from the Andes. and is crossed by a network of unstable river courses. It has a humid, tropical climate. Although its area of 64.876 sq.mi. makes it larger than England and Wales. its population was estimated to be only 45,234 in 1960. Quebracho. cut for hardwood and extraction of tannin. is exported by narrow-gauge railways to Puerto Sastre. Puerto Casado and Puerto Pinasco on the Paraguay river. Mariscal Estigarribia, the capital, is named after the general whose strategy in the Chaco War (1932–35) established Paraguayan sovereignty over the area, which was set up as a department in 1944. (G. J. B.)

BOR, a Yugoslav town. lies in eastern Serbia. Pop. (1961) 18.612. A French company began mining copper at Bor in 1904 and continued until 1944. The town is linked by a narrow-gauge railway with Zajecar and Paracin. It has its own power station. and there are a high school and a mining college. More than 3.000 persons are employed in mining and nearly 2,000 in other industries. (V. DE.)

BORA: *see* WIND: *Local Winds.*

BORACITE, a mineral composed of magnesium. boron, oxygen and chlorine, which typically occurs as colourless or white crystals (often with a gray, yellow or greenish tinge) embedded in sedimentary deposits of anhydrite, gypsum and halite. A massive variety known as stassfurtite. however, is found as nodules in the carnallite and kainite layers of the salt deposits at Stassfurt, Ger.. where it has been mined as a source of boron. The mineral was first observed in 1787 as small crystals, bounded on all sides by sharply defined faces, in the salt deposits in the district of Luneburg. Ger.

Typical crystals are pseudo-isometric in external form, their internal structure being actually orthorhombic. Cubelike shapes predominate, the cube form being sometimes modified by the presence also. in different degrees of development, of dodecahedra1 or tetrahedral faces. or both. Heated above 265° C. the internal crystalline structure inverts relatively instantaneously to a truly isometric type: cooled below 265° C. it inverts back to the low-temperature orthorhombic form.

A ferrous variety (huysennite) is distinguished by the substitution of appreciable amounts of iron (up to 7% by weight) for magnesium. the colour then becoming dark green with increased iron content. The variation in density, from 2.91 to 3.10 for different crystals, has been attributed to the variation in their iron content. The hardness of boracite is 7 to 7.5 on Mohs' scale; its lustre is vitreous. Cleavage is generally presumed to be absent. although a poor cleavage parallel to the two (pseudo-isometric) tetrahedra is occasionally reported.

Boracite. which has the formula $Mg_3B_7O_{13}Cl$, is slowly hut completely soluble in hydrochloric acid and even more slowly decomposed by water. Under the mineralogist's blowpipe it fuses readily to form a clear, yellowish bead. which becomes opaque white on cooling. Artificial crystals may be produced by cooling a fusion of magnesium oxide and boric acid in the presence of a great excess of magnesium chloride and sodium chloride.
(F. D. B.)

BORAGE, an herb (*Borago officinalis*) with bright blue flowers and hairy leaves and stem. grown as a potherb. medicinal and honey plant. It is used also in salads and as a flavouring in claret cup and other drinks to which it imparts a cool, cucumberlike bouquet. A native of the eastern Mediterranean region, borage has become naturalized in various parts of Europe, Great Britain and North America. *See* also BORAGINACEAE.

BORAGINACEAE, a family of plants, rough-haired annual or perennial herbs or. especially in the tropics, shrubs or trees. Few of the species of the Boraginaceae are widely known or have any special economic importance. The best-known members of the family are the garden heliotrope (*Heliotropium arborescens,* of coastal Peru) and the true forget-me-not (*Myosotis* species, chiefly European). Also garden plants, but less well known, are the Chinese forget-me-not (*Cynoglossum amabile,* from southwestern China). large-leaved forget-me-not (*Brunnera macrophylla,* of the Caucasus mountains), large-flowered bugloss (*Anchusa azurea,* of southern Europe). Bethlehem sage (*Pulmonaria saccharata,* of Europe) and the Virginia bluebell (*Mertensia virginica,* of eastern United States). The borage (*Borago officinalis*) is a European species with a long history as a folk medicine. It is sometimes used as a salad plant. The comfrey (*Symphytum asperrimum*), originally from southern Russia, is a nutritious cattle food and has been tested at various times as a possible forage crop.

These plants belong to the sympetalous section of the dicotyledons, and are a member of the series Tubiflorae. The leaves are generally alternate arid usually entire. The inflorescence is a specialized one-sided cyme or. less commonly. in paniculate cluster. The scorpioid cyme of the herbaceous species is a special type that is common and well developed only in the related family Hydrophyllaceae. The corolla is white or blue, sometimes yellow or orange, but seldom red. It is usually regular and has a definite. short to very elongate, tuhe. The throat may be partially closed by five hairy areas or five faucal appendages.

PHOTOGRAPH, J. HORACE MCFARLAND CO

FIG 1.— FORGET-ME-NOT (MYOSOTIS PALUSTRIS)

The ovary, composed of two carpels, is seated on a ringlike nectary. In the woody tropical members of the family the fruit is usually drupelike, but among the herbaceous members the fruit is dry and usually four-parted, each of the lobes (known as nutlets) representing only one-half of a carpel. The style arises independently at the centre of the flower between the four lobes of the fruit. a very unusual position duplicated in only two other families, the Verbenaceae and Labiatae. The nutlets, small to large, are usually one-seeded. They vary in attachment and direction, surface or margin. The many very diverse types of fruit in the Boraginaceae provide useful characters in dividing the family into major groups and in distinguishing and defining its genera and species. many of both not being identifiable with precision when fruit is lacking.

PHOTOGRAPH, J. HORACE MCFARLAND CO.

FIG 2 — BORAGE (BORAGO OFFICINALIS) SHOWING THE HAIRY LEAVES AND STEMS TYPICAL OF MANY MEMBERS OF THE BORAGINACEAE FAMILY

The family contains more than 1,800 species and 90 genera classified under four subfamilies. The least highly evolved members of the family belong to the subfamilies Cordioideae, Ehretioideae and Heliotropioideae. of which the most important genera are *Cordza, Ehretia, Tournefortia* and *Heliotropium*. These are predominantly trees and shrubs confined to the tropics, where they occur not in the primeval forest. but chiefly in disturbed areas. The highly evolved members of the family and the majority of its species belong to the subfamily Boraginoideae. Most of these are herbs and range outside the tropics. They are represented by one or a few native species in practically every part of the temperate zone. Several even range north of the Arctic circle The greatest variety of genera and the greatest concentration of species however. occur chiefly in areas uith semiarid or desert climate. especially the Mediterranean region. the near and middle east, the drier mountains and plateaus of northern India. eastern China and central Asia. and the drier parts of western America, particularly California and Chile. (I. M. J.)

BORAH, WILLIAM EDGAR (1865–1940). U.S. senator from Idaho for over 30 years, mas born at Fairfield. Ill., June 29, 1865. His formal education was limited, terminating before the end of his freshman year at the University of Kansas, but as he was always a serious student and a prodigious reader. he continued his education to the end of his life. Admitted to the bar in 1889, he practised in Lyons, Kan., but soon moved to Boise, Ida.: where in a few years he became a leading attorney and took an active part in Republican politics. In 1906 he won his first election to the U.S. senate. Re-elected five times by large majorities, he remained in the senate until his death (Jan. 19, 1940).

Senator Borah was in the lead in pushing the constitutional amendments for a national income tax and the popular election of senators and the statute to establish the children's bureau. He was succescful in promoting reclamation legislation an3 was often active on other matters of interest to farmers. From 1924 to 1933 he was chairman of the senate committee on foreign relations. An individual performer rather than an expert in the arts of the conference room, his legislative record is less impressive than a senator of his intelligence and industry might have been expected to make. He mas perhaps most widely known for his large part in preventing the United States from joining the League of Nations and World Court, and for his persistent advocacy of the recognition of the Soviet Union. His "God has made us neighbors; let justice make us friends" speeches in advocacy of a fair deal for Mexico during the "oil confiscation" controversy (1926–28) entitle him to a high place on the list of authors of the Good Neighbor policy. In the years of repression following World War I, he urged an amnesty for the war's political offenders. He maintained that free speech was the right of all men except those who counseled the immediate commission of crime or violation of law.

See Claudius O. Johnson, *Borah of* Idaho (1936). (C. O. J.)

BORAN: *sea* GALLA.

BORÅS, a town of Sweden, in the *lan* (county) of Älvsborg, 73 km. (45 mi.) E. of Goteborg by rail, is pleasantly situated on the Viskan river. Pop. (1960 est.) 66.457. It was founded in 1622 by King Gustavus Xdolphus. The town has many old timber houses, a modern town hall (1957), a city hall and local museum. In the west of the town there are the *Ramnasjön* with bathing facilities. the *Ramnaparken* and the wooden Kinnarumma church with a curious painted ceiling. Based on the old domestic craft, the town has become the biggest centre of the textile and ready-made clothing industry in Sn-eden with cotton and woolen mills, dye works, hosiery factories and a textile school. Borås also is a rail and road junction.

BORAX, a colourless crystalline substance, found in major quantity in the salt deposits of California and also in Chile, Tibet. Peru and Canada. It has an alkaline taste and is moderately soluble in water. When heated borax foams vigorously. losing the water shown in its formula ($Na_2B_4O_7.10H_2O$), and melts to form a clear glass. Molten borax dissolves many metallic oxides or salts to form boron glasses, some of which have characteristic colours.

Borax is used for the removal of oxide slags in metallurgy and in welding or soldering, for the detection of metals and for the production of coloured glazes on pottery. It is an important ingredient in many glasses and in enamels for ironware. It also finds application as a soap supplement or water softener. The discovery of the role of boron in plant nutrition led to the extensive use of borax in fertilizers.

Major quantities of borax are found as tincal, $Na_2B_4O_7.10H_2O$, in the salt crusts of dry lakes. especially Searles lake in California. Brines from wells drilled through the crust average 1.51% $Na_2B_4O_7$, which is separated from other salts by selective crystallization. The mineral rasorite. $Na_2B_4O_7.4H_2O$, which occurs in great deposits near Kramer. Calif., also is a major source of borax. For many years prior to the 1930s, the chief supply of borax was obtained by treating the mineral colemanite, $Ca_2B_6O_{11}.5H_2O$ (*q.v.*), from Death Valley. Calif., with a solution of sodium carbonate. The insoluble calcium carbonate was removed and the borax crystallized after evaporation. During the decade 1930–40 this source was largely supplanted by rasorite and the Searles lake brines. About 90% of the world production of borate minerals comes from California and about 4% from Argentina, Chile. Turkey and Italy.

The common decahydrate form of borax is obtained as monoclinic prisms by crystallization from solution at ordinary temperatures. Above 60° C., the crystals which form are the octahedral pentahydrate. $Na_2B_4O_7.5H_2O$ ("Jewelers' borax"). Electrolysis of a borax solution. or treatment with hydrogen peroxide, yields sodium "perborate" (peroxyborate), $NaBO_3.4H_2O$, used as a bleaching or oxidizing agent. Although molten borax acts as an acid toward metal oxides, because of the excess of boron oxide in the formula (empirically $2NaBO_2.B_2O_3$), the aqueous solution is alkaline because of hydrolysis. The equilibrium constant of the reaction. $B_4O_7 = + HOH \rightleftarrows HB_4O_7^- + OH-$. is 10^{-5}, a basicity comparable to that of ammonia or soda ash. Equilibriums among the various polyboric acids in solution permit the easy formation of borax by neutralization of boric acid; any metal ion forms the least soluble of its possible borates.

All polyborates of known structure contain the BO, unit, in which a boron atom is at the centre of an equilateral triangle outlined by three oxygen atoms. Such units share oxygen atoms to form condensed systems. Thus in pyroborates such as $Co_2B_2O_5$, the anion is $(O_2BOBO_2)^{4-}$; in $K_3B_3O_6$ there is a plane six-membered B_3O_3 ring; and $Ca(BO_2)_2$ contains an infinite BOBO chain. In potassium pentaborate, $KH_4B_5O_{10}.2H_2O$, two pyroborate ions share pairs of oxygen atoms with a central boron atom in a spiran (complex ester) situation. (A. B. BG.)

BORDA, JEAN CHARLES DE (1; 33–1799), French mathematician and nautical astronomer. who was associated with J. H. J. Delambre and P. F. A. Méchain in the attempt to determine an arc of the meridian — the greater number of the instruments employed in the task being designed by him—was born at Dax in the Landes and died at Paris.

Entering the army at an early age Borda transferred later to the navy. In 1782 he was taken prisoner at sea by the English, but was immediately released on parole. He contributed a long series of valuable memoirs to the Academy of Sciences. His researches in hydrodynamics were highly useful for marine engineering, while the reflecting and repeating circles, as improved by him, were of great service in nautical astronomy.

BORDEAUX, a city and port of southwestern France, the capital of the *département* of Gironde, lies on the left or west bank of the Garonne, 24 km. (15 mi.) above its junction with the Dordogne and 96 km. (60 mi.) from its mouth, in a plain cast of the \vine-growing district of Médoc. 578 km. (3.59 mi.) S.S.W. of I'aris. Pop. (1954) 250.306; with suburbs 415.763.

The Garonne (550–750 yd. wide), sweeping northward in a broad curve. separates the city proper from the suburb of La Bastide on the right bank. It is crossed by only one bridge for pedestrian and vehicular traffic, the early 19th-century Pont de Bordeaux. which is 1.533 ft. in length and has 17 arches, and by a railway bridge. From the I'ont de Bordeaux, the view westward embraces a crescent of wide quays five miles long with a background of tall warehouses. factories and mansions. The streets and squares of the central portion of the city are symmetrically planned in the 18th-century manner. Outside this quarter, which contains most of the important buildings, the streets are narrow and quiet and bordered by the low white houses characteristic of Bordeaux.

The whole city is surrounded by a semicircle of boulevards. beyond which lie the suburbs of Le Bouscat. Cauditran. Mérignac, Talence and Bègles. In the 18th century the city lost its fortifications, but several of the old gateways remain.

Near the centre of Bordeaux is the Allées de Tourny. between which and the river is the Place des Quinconces. The latter, planted with plane trees. contains two huge statues. of Montaigne and Montesquieu, and terminates upon the quays with two rostral columns decorated with the prows of ships which serve as lighthouses. On its west side is a monument to the Girondist deputies proscribed under the convention in 1793. At its southwestern corner the Place des Quinconces opens into the Place de la Comédie, the heart of the city. which contains the Grand Théâtre (1775–80, restored in 1864 and 1881). The Rue Sainte Catherine enters the Place de la Comédie on the south. The I'ont de Bordeaux is continued by the Cours Victor Hugo, leading to a square

CHURCH OF STE. CROIX. BORDEAUX. BUILT IN THE 12TH AND 13TH CENTURIES

in which stands the cathedral of St. André with its richly decorated north and south facades. The Pey Berland bell tower, named after the archbishop of Bordeaux who erected it in the 15th century. is a separate building standing near the east end. The broad nave of the cathedral, begun in the 12th century, contrasts with the lofty 14th-century Gothic choir. Of the numerous other churches of Bordeaux the most notable are St. Seurin (dating from the 11th century). with a finely sculptured south door: Ste. Croix (12th and 13th centuriesj, which is remarkable for its romanesque façade; and St. hlichel (14th and 16th centuries), which stands near the Quai des Salinikres and has three sculptured portals. The bell tower of St. Michel (15th century) has the highest spire (357 ft.) in southern France and also stands apart from its church. The prefecture, the bourse and the customs house are all 18th-century buildings standing along the river bank south of the Place des Quinconces. The hôtel de ville, close to the cathedral, was formerly the archiepiscopal palace built in 1770–81 and restored in 1862. To the south are the law courts and the hospital of St. André (founded 1390) dating from the early 19th century. The Palais Gallien, which consists of remains of a Roman amphitheatre, is to the west of the public gardens, in which are palms and exotic plants. a botanical garden and a museum. The large Municipal stadium was built in 1939.

Bordeaux is the seat of an archbishop, the centre of an *académie* (educational division) and the seat of a court of appeal. A court of assizes is held there. and there are tribunals of first instance and of commerce, a council of trade arbitrators and a chamber of commerce. The university, southeast of the cathedral. was founded in 1441. The tomb of Montaigne is located there. There are several museums, chief among which is the Musée des Beaux Arts, a library with over 600,000 volumes. and numerous learned societies.

Commerce **and** Industry. — Thetrade of Bordeaux, one of the biggest of the French ports. is chiefly carried on by sea. Its port, eight miles long. is formed by the basin of the Garonne and divided into two by the Pont de Bordeaux. There are large marshal-

ing yards and two wet docks, and railways serve both banks of the river Five ports below Bordeaux are administered by the. city. The city trades chiefly with Great Britain, Spain, Argentina, Portugal and the United States. It is the centre of the trade in "Bordeaux" wines, and the nine cellars of the quays are one of its principal sights. Other important exports are brandy, fruit, walnuts, turpentine, chemicals, petroleum products and timber. The chief imports are coal, gasoline, pyrite, grain. oilseeds, sugar, coffee, tropical timbers and raw materials for chemicals.

A large fleet leaves annually for the codfisheries of Newfoundland and Iceland. Important industries are shipbuilding and marine engineering; warships as well a5 merchant vessels are constructed. Railway coaches are also built. The industries subsidiary to the wine trade. such as wine-mixing, cooperage and the making of bottles, corks, straw envelopes and wooden cases. employ many persons. Other aorks include chemicals, fruit and vegetable canning, breuing and distilling and tobacco processing.

Bordeaux is on the main railway line from Paris to Spain Other lines run to Toulouse and Narbonne, Limoges, La Rochelle, Le Verdon, Blaye and Miramont. From the airport at Mérignac (10 km., 6 mi. W.) there are regular services to Paris and to other major cities in Europe and north Africa.

History. — The dry soil of Médoc attracted settlement as early as the Bronze Age and. at least since Roman times, Bordeaux has been a flourishing town and port, with connections particularly with Spain and Great Britain. As Burdigala it was the chief town of the Bituriges Vivisci. Under the Roman empire it became a commercial city and in the 4th century it was made the capital of Aquitania Secunda. Ausonius, a contemporary native writer, describes it as a square walled-city and one of the greatest educational centres of Gaul. It declined after the disintegration of the empire and did not recover until the 10th century. Along with the old French province of Guienne it belonged to the English from 1154 to 1453 and was for a time the seat of the court of Edward the Black Prince, whose son Richard was born in the city. Commerce developed between Bordeaux merchants and their fellow subjects in London, Hull, Exeter, Dartmouth, Bristol and Chester and various privileges were granted by the English as trade increased. The influence of Bordeaux increased still further when several neighbouring towns, *e.g* , St. Emilion and Libourne, united in a federation under its leadership. The defeat of the English at the battle of Castillon in 1453 ended their domination in the province. The privileges of the city were at once curtailed and only partially restored under Louis XI, who organized the *parlement* of Guienne and the university. In 1548 the inhabitants rebelled against the salt tax.

The reformed religion found numerous adherents at Bordeaux, and after the massacre of St. Bartholomew (*q.v.*) in Paris nearly 300 of its inhabitants lost their lives. The 17th century was a period of disturbance. The Fronde (*q.v.*) insurrection found great support among the populace. In the 18th century a period of commercial and architectural activity for Bordeaux, the marquis de Tourny. *intendant* of Guienne, made the city a spacious and beautiful town with fine public and commercial buildings and squares. It was the headquarters of the Girondists (*q.v.*) during the Revolution and in the Reign of Terror suffered severely. The city's commerce was much reduced under Napoleon I and this led it in 1813 to declare for the Bourbons. Louis XVIII afterward gave the title of duc de Bordeaux to his grandnephew.

After the coming of the railways, the great improvements to the port and the increase in trade with west Africa and South America led to increased prosperity. In 1870 the French government was transferred to Bordeaux from Tours on the approach of the Germans to the latter city, and the government was at Bordeaux when Paris was threatened by the Germans in Xug. 1914. In June 1940, during World War II, when a German advance became again a menace to Paris, the French government moved first to Tours dnd later to Bordeaux. There Premier Paul Reynaud led a minority in the government favouring "war to the finish." Among his supporters were Charles de Gaulle and Georges Mandel. Reynaud sent appeals for immediate help to the Cnited States and Great Britain. He was overriden by the opposition, however. and resigned on June 16, two days after the Germans entered Paris. Bordeaux was severely bombed before its occupation by German troops and again. by the Allies, when it was an important German air and submarine base. The city was reoccupied. largely by French patriot forces. in Aug. 1944.

Since 1945 Bordeaux has continued to expand. New suburbs have been built. and with the surrounding districts the total population in 1960 was nearly 450,000 inhabitants.

BORDEN, SIR FREDERICK WILLIAM (1847–1917), Canadian statesman, was born in Cornwallis, Nova Scotia, on May 14, 1847. He was educated at King's college Windsor. and at Harvard medical school, and for some years practised medicine at Canning, Nova Scotia. In 1874 he was elected to the Canadian parliament as a Liberal member for King's county and. except for the years 1882–86, represented this constituency until his defeat in 1911. Borden served as minister of militia and defense in the Liberal administration from 1896 to 1911. Although he improved its standards of training and discipline, the militia remained unspecialized and poorly equipped. His department accepted greater responsibilities when Canada took over the administration of the naval establishments at Halifax and Esquimalt and undertook to build a Canadian navy. Mainly as a result of his insistence, the practice of appointing a British officer to command the Canadian militia was abandoned. Borden died at Toronto on Jan. 6. 1917.

(H. B. NE.)

BORDEN, GAIL (1801–1874), U.S. inventor who developed the first commercial method of condensing milk, was born in Norwich, N.Y., on Nov. 9. 1801. As a youth he helped survey the future city of Covington, Ky., taught school in southern Mississippi, and emigrated to Texas in 1829. There he prepared the first topographical map of Texas, helped write the first state constitution. was co-founder of the first permanent Texas newspaper and laid out the city of Houston.

Borden's chief interest, however, was invention. After unsuccessful experiments with other foods, including a meat biscuit which won a gold medal at the Great Council exhibition in London in 1851. he developed a condensed milk process receiving U.S. and British patents in 1856. His invention received little notice until the Civil War focused attention on its advantages. By the time of his death in Borden, Tex., on Jan. 11. 1874, he was wealthy and had a reputation as a philanthropist. The dairy company founded by Borden and named after him has continued to expand and diversify.

(J. B. Fz.)

BORDEN, SIR ROBERT LAIRD (1854–1937), Canadian prime minister during the World War I era, was born at Grand Pré, Nova Scotia, on June 26, 1854; his parents were of English and Scottish origin. He was educated at Acacia Villa seminary near his home. After two years as a teacher of classics and mathematics he took up the study of law and was called to the bar in 1878; four years later he became a junior partner in a leading Halifax legal firm, Graham, Tupper and Borden. Although his family was traditionally Liberal, Borden was alienated from the Liberal party by its campaign of 1886 for Nova Scotia's secession from Confederation and by its advocacy of unrestricted reciprocity with the United States in the election of 1891. He took no active part in politics until persuaded to contest a Halifax seat for the Conservatives in the federal election of 1896. He was successful and in 1901 agreed, reluctantly, to assume the leadership of the Conservative party, provided that he be relieved at the end of a year.

The first decade of the 20th century was a very difficult one for the Conservative party; it had held office for 18 years, prior to 1896. and had little experience of effective opposition; moreover. it non lacked colourful leaders of the stamp of John Macdonald and Charles Tupper, and a thorough rebuilding of the party was required. On the other hand, the Liberal party was

favoured by the leadership of the personally popular Wilfrid Laurier (*q.v.*) and by unprecedented national expansion and prosperity, and had a firm hold on the voters. Defeated in Halifax in the Liberal sweep of 1904, Borden was re-elected in 1905 in a by-election in Carleton. Ont. Re-elected in Carleton in 1908 and also winning Halifax, he chose to represent Halifax and continued to do so until 1917. He was returned as a member for Ring's, Nova Scotia, in 1917, which he represented until his retirement. Despite much internal criticism and some intrigue against his leadership. Borden persevered in his efforts to strengthen the party. A new platform adopted in 1907 emphasized civil service reform, public ownership of the telephone and telegraph. and imperial preferential trade. In 1911 the Conservatives mere at last presented with an issue on which they could attack the Liberals decisively, when Laurier announced a reciprocity agreement with the United States. Although some of his followers at first thought that opposition to the agreement might be politically unwise, Borden had no doubts and soon united the party around this issue. He had the support of powerful manufacturing and railway interests who mere averse to having their position in the Canadian economy disturbed; this group included a number of prominent Liberals in eastern Canada who bolted their party. The majority of the electors were persuaded that reciprocity was a threat to Canadian political independence, and in the election of 1911, which was fought mainly on this issue, they supported Borden in his rejection of the policy. The Conservatives made some gains in every section of the country, even in Quebec where they formed a loose alliance with the Nationalists under Henri Bourassa. Co-operation between the Conservatives and the Nationalists was short-lived, for the pro-British character of the Conservative party, whose strongest support came from Ontario, was fundamentally uncongenial to the French Canadians. During the long naval debate, Nationalist. support for the Conservatives dwindled rapidly and ended when Borden introduced conscription.

Once in office, Borden proceeded to deal with a question which had been the second issue in the election—naval policy. Britain's attempt after 1909 to meet the challenge of a growing German navy and its desire to secure assistance from the dominions precipitated a vigorous debate on imperial relations in Canada. Borden rejected Laurier's plan for a separate Canadian navy as inadequate; his discussions with the committee on imperial defense in Britain during the summer of 1912 convinced him that Britain faced a defense crisis and that Canada must make an emergency contribution to the British navy. He proposed that Canada contribute $35,000,000 for the construction of three capital ships for Britain's naval forces, a measure which would not preclude the eventual building of a Canadian navy. At the same time he argued for the development of co-operative control of imperial foreign policy and defense in which the dominions would have a voice. Borden's naval bill mas debated. Responding to the Liberal opposition's tactics, the government introduced rules for the application of closure to end debate. The senate's Liberal majority then rejected the measure. Borden did not reintroduce his bill and Canada entered World War I without a positive naval policy.

Borden directed the mobilization of Canada's resources in a war effort which was remarkable for a nation of 8,000.000 persons. It was characterized by rapid industrialization, a great extension of government activities, the institution of the income tax and the transformation of Canada from a debtor to a creditor nation. Although there were scandals connected with supplying the armed forces, and some public outcry against the large fortunes which were undoubtedly accumulated by some during the war, the program was carried forward creditably. By the early summer of 1917 Borden was convinced that the 500,000 men he had pledged to put into the fight could not be provided under the existing system of voluntary enlistment and that conscription of manpower was essential. He knew that this measure would be highly unpopular, not only in Quebec, but also among farmers and organized labour. although large sections of the population were demanding conscription as the only fair means of securing equality of sacrifice. Thus the dictates of political strategy and patriotism combined to convince Borden that the conscription issue must be removed from partisan politics. He invited Laurier to join a coalition in which the two parties would have equal representation; when this offer was rejected the government introduced a conscription bill which received the approval of the house of commons in July 1917; a minority of the Liberals supported the measure. Borden shortly renewed his efforts to form a coalition and his patience and diplomacy were rewarded in Oct. 1917. when representative Liberals from every section of the nation except Quebec entered a Union government which won the overwhelming approval of the electorate outside of Quebec in the election of Dec. 1917.

The conduct of so great a war effort inevitably raised complications in Canada's relations with Britain. Borden was irritated by the failure of British statesmen and military leaders to take him and his Canadian colleagues more fully into their confidence; at the same time he rejected any form of consultation which might involve imperial centralization during or after the war, and his views on this subject were embodied in Resolution IX of the imperial conference of 1917. These war-time difficulties were remedied to a considerable extent by the establishment of the imperial war cabinet and imperial war conference in 1917.

The war produced a marked increase in national feeling and Borden was an impressive spokesman for the new Canadian nationalism. At the end of the war he argued for, and won, separate status for Canada among the nations. similar to that enjoyed by the smaller independent powers. Thus Canada and the other dominions had representation in the British delegation at the Paris Peace conference of 1919. They signed the peace treaty and were granted separate representation in the League of Nations and the International Labour organization. Borden still believed that a common imperial foreign policy was desirable and possible; this was not the direction which subsequent developments took, but as one of the architects of dominion autonomy he had no essential quarrel with the later development of the British Commonwealth.

Borden was plagued by ill-health throughout the war and was forced to retire from public life in July 1920. Once free of the burdens of office his health was restored. He represented Canada at the Washington Disarmament conference of 1921. was chancellor of Queen's university. 1924–30, president of the League of Nations society, 1922, and president of the Canadian Historical association, 1931. He renewed his study of Canadian constitutional questions and published *Canadian Constitutional Studies* (1922) and *Canada in the Commonwealth* (1929). He died on June 10, 1937. His nephew, Henry Borden, edited the *Memoirs* which Borden had been preparing for some years, and they were published in 1938. *See* also CANADA: *History*. (M. E. P.j

BORDES, CHARLES (1863–1909), French composer, choirmaster and musicologist who played an important part in reviving Renaissance polyphonic choral music. Born at La Roche-Corbon, near Vouvray (Indre-et-Loire), May 12, 1863, he was a pupil of César Franck. In 1890 he became chapelmaster of St. Gervais, Paris, and made it the centre of the study and practice of 15th-, 16th- and 17th-century vocal music. With the organist Alexandre Guilmant and Vincent d'Indy, he founded (1894) the Schola Cantorum, a society that in 1896 became a school for church music with Bordes as professor. Its publication. *La Tribune de St. Gervais* (1895), became the main organ of French musicology. Me also began publication of the *Anthologie des maîtres religieux primitifs*, which provided choral societies with invaluable material. By 1905 he had moved to Montpellier, where he started a provincial branch of the Schola Cantorum.

Also interested in folksong. Bordes toured the Basque country in 1889 to collect traditional melodies, 100 of which were published in *Archives de la tradition basque* (1889–90). As a composer, he achieved particular success with his songs. He also wrote piano music. sacred and secular choral works. a *Suite basque* for flute and strings. *Danses béarnaises* and a symphonic poem for orchestra. He died at Toulon, Nov. 8, 1909. (F. E. G.)

BORDET, JULES (1870–1961), Belgian physician and bacteriologist who won the Nobel prize for medicine in 1919 for his discoveries in immunology, was born at Soignies. June 13, 1870. In lb92 he graduated as doctor of medicine at the University of

Brussels. From 1894 to 1901 he worked at the Pasteur institute at Paris; then he returned to Brussels to found and direct a Pasteur institute for the province of Brabant. He was also appointed professor of bacteriology at the Cniversity of Brussels.

His early studies showed that human blood normally contains a group of chemical substances called "complement," alexin. cytase or end-body. He showed that complement is absorbed and made inactive, or "fixed." by the complexes formed when antigens unite with their specific antibodies. Thus if a foreign protein such as a disease germ has entered the blood stream of a person who has acquired antibodies as a result of immunization or previous exposure to the disease, then free complement will not be present in the blood or will be present in below-normal amounts. Complement fixation became the basis for the laboratory identification of many disease organisms, including those of syphilis, typhoid fever. tuberculosis and glanders.

Bordet also studied the formation of anaphylactic poisons and coagulin. He and Octave Gengou in 1906 isolated the bacillus later known as Bordetella pertussis and laid the basis for the generally accepted opinion that this organism causes whooping cough. He died in Brussels on April 6. 1961.

BORDIGHERA, a resort of Imperia province. region of Liguria. Italy, is on the coast of the Riviera di Ponente. with stony mountains rising to the northward, 5 km. (3 mi.) E.N.E. of Ventimiglia by road. Pop. (1957 est.) 9,861 (commune). Bordighera is a well-known winter resort with fine coast scenery and gardens. The Institute of Ligurian Studies. formerly Bicknell museum. contains a unique collection of the flora of the Riviera, and the English library contains about 25,000 volumes. Bordighera is on the main coastal railway from Genoa to Ventimiglia and France. Apart from tourism: there is a large export trade in flowers; Bordighera's gardens also supply palm branches for St. Peter's at Rome and other churches for Palm Sunday.

BORDONE, PARIS (1500–1571), Venetian painter of the Renaissance. who painted religious pictures. mythological scenes. allegories. nymphs. cupids and subjects from Ovid's fables. but excelled as a portraitist, was born at Treviso. He entered the *bottega* of Titian at an early age but did not spend many years there, according to Vasari, who knew him. He was invited to France either by Francis I in 1538 or by Francis II in 1559; he painted many portraits at the French court, though no trace of them is to be found in French collections. the two portraits at the Louvre being later acquisitions. He also is said to have visited Augsburg and worked for the Fuggers, probably in 1548.

His pictures are of unequal merit. They have a harmony of colour derived from Titian and a certain nobility of style, but his figures are sometimes coarse and not very penetrating. His principal historical painting, signed and dated 1540, is the "Fisherman and Doge" at the Venice academy. The National gallery, London, has a "Daphnis and Chloe" and a portrait of a lady.

Other important works are the "Madonna" in the Tadini gallery at Lovere, the "Adoration of the Shepherds" in the Duomo of Treviso, two mythological pictures at the Villa Borghece and the Doria palace in Rome. the "Chess Players" in Berlin. "Christ among the Doctors" in the Gardner museum at Boston and a "Baptism of Christ" in Washington, D.C. Bordone died in Venice on Jan. 19, 1571.

BORE, in physical geography, a high tidal wave occurring where incoming tidal water is forced into a narrow estuary or tidal river, causing the water to rise with a high, abrupt front; examples are found in the Amazon and Severn rivers and the Bay of Fundy. *See* also TIDES: *General Description* of *Phenomena.*

BOREAS, in Greek mythology, a personification of the north wind. He was said to have carried off the beautiful Oreithyia. a daughter of Erechtheus, king of Athens. when he found her leading the dance at a festival or gathering flowers on the banks of the Ilissus. He had before wooed her in vain and now carried her off to his home in Thrace, where they lived as king and queen of the winds and had two sons. Calais and Zetes (*q.v.*).

To show his friendliness for the Athenians, Boreas wrecked the fleet of Xerxes off the promontory of Sepias in Thessaly, in return for which they built him a sanctuary or altar near the Ilissus and held a festival (*Boreasmos*) in his honour.

In works of art Boreas was represented as bearded, powerful, draped against cold. and winged. On the Tower of the Winds at Athens he is figured holding a shell. such as is blown by Tritons. Roreas carrying off Oreithyia is the subject of a beautiful bronze relief in the British museum, also of many painted Greek vases.

BOREL, (FÉLIX ÉDOUARD JUSTIN) ÉMILE (1871–1956), French mathematician who made important contributions to several branches of analysis and to the theory of probability, was born on Jan. 7, 1871, at St. Affrique, Provence. After an appointment in the University of Lille (1893–96), the remainder of his professional life was passed in Paris at the Sorbonne and the École Normale.

As the creator of the first effective theory of the measure of sets of points he shares with his contemporaries R. Baire and H. Lebesgue the distinction of having launched the modern theory of functions of a real variable and. although not the first to define a conventional sum of a divergent series: he was the first to conceive and develop a systematic theory of such series. Following his discovery in 1896 of the so-called elementary proof of C. E. Picard's theorem, he created a theory of integral functions and the distribution of their values which largely dominated the theory of functions of a complex variable during the next 30 years.

His other achievements include his introduction of the notion of enumerable probabilities, thus inaugurating an important new chapter in that theory. He sat in the chamber of deputies (1924–36) and was minister of the navy (1925). He died in Paris on Feb. 3. 1956. (E. F. Co.)

BOREL, PETRUS (real name JOSEPH PIERRE BOREL, later BOREL D'HAUTÉRIVE) (1809–1859), French poet, novelist and critic, who called himself *le lycanthrope* ("the wolfman"). The most notorious of the young writers of the 1830s. he outlived his reputation. but his work foreshadowed and inspired Baudelaire. Born at Lyons. June 29. 1809, he was the 12th of an ironmonger's 14 children. After training as an architect, he turned to literature, becoming the most important member of *le petit Cénacle* (1829) and organizing *La Bataille d'Hernani* (1830). After the victory of the Romantics, he became leader of the eccentric and advanced writers known as *les Bousingos,* among whom were Gérard de Nerval and Théophile Gautier; with the classical revival his supremacy waned and he fell into extreme poverty. He tried to retrieve his fortunes with the horror novel *Madame Putiphar* (1839), but it failed, and he struggled to make a living by contributing to and himself founding several eccentric and unsuccessful journals. In 1847, through the influence of Gautier, he became *inspecteur de la colonisation* in Algeria. He was not successful, however. being proud, touchy and inefficient, and was dismissed in 1855. He had built himself a Gothic mansion at Mostaganem, and continued to live there, working on the land. Little remained of the daring leader of the 1830s. who had seemed to contemporaries like a Spanish grandee, but who now resembled a decrepit Don Quixote with unkempt gray beard and bald pate, dressed in rags. He died at Mostaganem, July 17, 1859.

His works, belonging to the period of horror and melodrama, include *Rhapsodies* (1832), a collection of poems showing originality in subject and treatment, which influenced the early Baudelaire; short stories, *Champavert, contes immoraux* (1833), which enjoyed a *succès* de *scandale* and had in it much of the Baudelairean mood; and the mistimed *Madame Putiphar,* with a prologue in verse which is his finest poem and foreshadows Baudelaire's spiritual style.

See A. Marie, *Petrus Borel* (1922); *E.* Starkie, *Petrus Borel en Algérie* (1950) and *Petrus Borel, the Lycanthrope* (1954). (E. ST.)

BORELLI, GIOVANNI ALFONSO (1608–1679), Italian physiologist and physicist who was the first to explain muscular movement and other body functions according to the laws of statics and dynamics, was born at Naples on Jan. 28, 1608. He was appointed professor of mathematics at Messina in 1649 and at Pisa in 1656. In 1667 he returned to Messina but in 1674 went to Rome, where he lived under the protection of Christina, queen of Sweden; and died on Dec. 31, 1679. His best-known work is *De motu animalium* (1680–81), in which he sought to explain

the movements of the animal body on mechanical principles; he thus ranks as the founder of the iatrophysical school.

In a letter, *Del movimento della cometa apparsa il mese di decembre 1664,* published in 1665 under the pseudonym Pier Maria Mutoli, he was the first to suggest the idea of a parabolic path; and among his many astronomical works was *Theorica mediceorum planetarum ex causis physicis deducta* (1666), in which he considered the influence of attraction on the satellites of Jupiter.

BORENIUS, TANCRED (1885–1948), Finnish art historian, born July 14, 1885, at Vyborg (Wiborg), began his studies at Helsinki and went from there to Italy, where he laid the foundations of his profound knowledge of Italian painting. In 1914 he was appointed lecturer and in 1922 professor of the history of art at University college. London. When Finland became independent. he acted as secretary to the diplomatic mission (1918) and in 1919 mas the temporary diplomatic representative of Finland in London. His works include *The Painters of Vicenza* (1909); *Catalogue of the Collections of Sir Frederick Cook,* vol. i, "Italian Schools" (1913); *Catalogue of Viscount Lee of Fareham's Collection* (1923); *Four Early Italian Engravers* (1923); *English Primitives* (1924); *Florentine Frescoes* (1930); catalogues of the collections of the earl of Harewood (1936) and Sir Robert Mond (1937); *English Painting in the XVIIIth Century* (1938); and *Field-Marshal Mannerheim* (1940). He died Sept. 2, 1948, near Salisbury.

BORGA: *see* PORVOO.

BORGERHOUT, a municipality and dormitory suburb on the eastern outskirts of Antwerp, Belg.. from which it is separated by no distinguishable boundary. Pop. (1955 est.) 49,959. Originally a village lying between Antwerp and Deurne, its early history is mainly connected with the latter parish. It was occupied by German forces during World Wars I and II. In 1936 Borgerhout celebrated 100 years existence as an independent town of mainly Flemish character. It has bleaching and dye works and manufactures candles. tobacco and tapestries. Gallo-Roman burials (urn type) were discovered in the vicinity.

BORGHESE, a noble Italian family, of Sienese origin, which settled in Rome during the 16th century and quickly rose to distinction in wealth and property when Camillo Borghese was chosen pope in 1605, taking the title of Paul V.

Paul showed particular favour to his nephew, Marcantonio (d. 1658), whom he created prince of Vivaro and on whom Philip III of Spain conferred the title of prince of Sulmona. Marcantonio carried the family to an eminent place among the Roman nobility by his territorial acquisitions. by his marriage with Camilla Orsini and by the marriage of his son Paolo (d. 1646) with Olimpia. heiress of the Aldobrandini. Once established, the family preserved its position until the fall of the value of land as a result of the agricultural crisis in the 1890s.

In 1803 Camillo Filippo Ludovico, 6th Prince Borghese (1775–1832), married Marie Pauline, sister of Napoleon and widow of Gen. Jacques Leclerc *(see* BONAPARTE). He was made duke of Guastalla in 1806 and acted as governor of the Piedmontese and Genoese provinces for a few years. He was induced to sell the great Borghese art collection to Napoleon but recovered part of it in 1815. The Borghese palace, one of the most magnificent buildings in Rome, contained a splendid gallery of pictures; most were transferred to the Villa Borghese outside the Porta del Popolo, now the property of the Italian government.

BORGIA, SAINT FRANCIS (FRANCISCO DE BORJA Y ARAGÓN) (1510–1572), 4th duke of Gandía and third general of the Society of Jesus. was horn in Gandía, Valencia, Spain, on Oct. 28, 1510. He was educated at Saragossa under his uncle. the archbishop Juan de Aragón. Presented to the court of Charles V in 1528, he married in 1529 Eleanor de Castro, a Portuguese noblewoman and childhood iriend of the empress Isabel. After holding court appointments, in 1539 he was made viceroy of Catalonia, where he tried to carry out badly needed social and economic reforms. He resigned in 1543, when he succeeded to his father's dukedom.

After his wife's death in 1546, Borgia entered the Society of Jesus. He founded the Jesuit college in Gandia, which was made a university by papal bull in 1547. In 1550 he went to Rome. where he was received by St. Ignatius Loyola and his entry into the society was made public. Early in 1551 he returned to Spain. where he was ordained to the priesthood. He devoted himself to the religious and social improvement of Guipuzcoa. In 15j the emperor recommended him to Pope Julius III for the cardinalate, a choice seconded by the pope and acceptable at first to Borgia hut opposed by Loyola. The latter named him commissary general of the Spanish provinces in 1554, the appointment being renewed by Diego Lainez on his election as second general of the society in 1558. After Lainez' death in 1565 the second general congregation chose Borgia general of the order. His tenure of office was marked by the erection of new provinces and numerous colleges in Europe, the sending of the unsuccessful mission to Spanish Florida and the establishment of the provinces of Peru and New Spain. Internally he strengthened and formalized the institute of the order. His generalate coincided almost exactly with the reign of Pius V, whom he urged to adopt two important policies regarding the foreign missions: first, to centralize their government through a Roman congregation similar to the later Congregation for the Propagation of the Faith; second, to insist that the civil rulers treat the natives humanely in order to win them to the faith. In 1571 Pius V sent him to Spain, Portugal and France to strengthen the league against the Turks. He fell ill on the return journey, and died in Rome during the night of Sept. go–Oct. 1, 1572. He was canonized in 1671, and his feast day is Oct. 10.

A selection of Borgia's letters was edited in *Monumenta historic societatis Jesu, S. Franciscus Borgia,* 5 vol. (1894–1911).

See C. Sommervogel, *Bibliothèque de la compagnie de Jésus,* vol. i (1890); P. Suau, *Histoire de S. François de Borgia* (1910); M. Yeo, *The Greatest of the Borgias* (1936). (E. J. Bs.)

BORGIA, CESARE (1475 or 1476–1507), known to 16th-century Italy as the DUCA VALENTINO from his French title of duc de Valentinois, the Renaissance captain whose motto was *Aut Caesar aut nihil* ("Either Caesar or Nothing"), whose greatest real achievement was the execution of his father's temporal policy for the papal state, but who is also remembered both as his father's associate in bringing the church to the extreme of worldliness and as Niccolò Machiavelli's political hero. He was the second son of the Spanish cardinal Rodrigo Borgia (Borja), later pope as Alexander VI, and his Roman mistress Vannozza dei Catanei. Alexander VI made him archbishop of Valencia in 1492 and then cardinal, with the title of Santa Maria Nuova, in 1493. In June 1497, however, Cesare's elder brother Giovanni, duke of Gandia and of Benevento, was killed in mysterious circumstances (perhaps with Cesare's complicity); and in Aug. 1498 Cesare renounced his cardinalate and was released from holy orders to enter secular politics. The pope obtained for him the duchy of Valentinois from Louis XII of France in return for the annulment of that king's first marriage and a dispensation for his second. Having gone to France on this occasion (1498). Cesare in May 1499 married Charlotte d'Albret, sister of the king consort of Navarre. The pope then made him "gonfalonier and captain-general of the Holy Roman Church."

Alexander VI, with nhose plans Cesare was always to be engaged, wanted to see his son established in a principality either in the kingdom of Naples or in papal territory. His designs on Naples were obstructed by the Aragonese dynasty there, but within the papal dominions he had good reason for taking action against his insubordinate vassals or temporal vicars in Romagna and in the Marche. Though Venetian hostility prevented the Borgias from profiting fully from their alliance nith Louis XII, Cesare began the conquest of central Italy in order to carve a state for himself there. He took Imola in Dec. 1499, and Forlì and Forlimpopoli in Jan. 1500 and secured the submission of Cesena. Returning to Rome, he was in March 1500 made vicar of Romagna.

In July an attempt was made on the life of his sister Lucrezia's husband, Alfonso duke of Bisceglie, one of the last members of the Neapolitan house of Aragon, and in August the duke was murdered. Cesare's responsibility for this is clearly stated by the Venetian ambassador Paolo Cappello. Apart from the Borgias' designs on Naples, the crime served to set Lucrezia free for another political marriage, but it may have been simply an act of blind malevolence, like others of which the Borgias were accused.

Resuming his campaign in central Italy, Cesare took Rimini and Pesaro in Oct. 1500. At Pesaro, where the people were exasperated by Giovanni Sforza's tyranny, Cesare was welcomed as a liberator, and the great humanist Pandolfo Collenuccio was frankly on his side. In Faenza, however, which Cesare took, despite Venetian objections, in April 1501, the people were devoted to their *signore*, Astorre (Astorgio) Manfredi, who was taken to Rome and there, in Jan. 1502. foully murdered. Cesare meanwhile took the title of duke of Romagna. The peak of this policy of brutal aggression and duplicity was reached with the seizure of Urbino (June 2, 1502) and Camerino (July). Under the dynasties of Montefeltro and Varano these two duchies had been well administered and both moreover had regularly paid their dues to the papacy, so that the usual pretext that the pope found to justify his son's action could hardly be offered in this case. Venice and Florence were now directly threatened by the expansion of the Borgia duchy in Romagna and Val di Chiana. Both states accordingly sympathized with the conspiracy of La Magione (so called from the plotters' meeting place) in Oct. 1502. In this, some of Cesare's officers combined with certain *signori* in a plan to combat the growing power. Cesare, however, entered into relations with some of the conspirators individually and then succeeded in decoying four of them. Vitellozzo Vitelli, Oliverotto da Fermo, Paolo Orsini and Francesco Orsini, duke of Gravina, to Senigallia (Dec. 31, 1502), where he treacherously seized them. Vitellozzo and Oliverotto were killed at once, the Orsini some time afterward. This ruthlessness shocked even 16th-century Italy. Meanwhile in Rome the pope. feigning hostility to Cesare, subdued the remaining Orsini opposition and was preparing to desert the French alliance for the Spanish when he died suddenly on Aug. 18, 1503.

Alexander VI's death meant the ruin of Cesare, though by now he had recovered from the setback caused by the conspiracy of La Magione and had occupied Citta di Castello, Perugia, Città della Pieve and some lands in the Siena region.

All the dispossessed despots of the Romagna raised their heads, and after Pius III's brief pontificate Giuliano della Rovere, a relative of the Montefeltro family of Grbino and the most implacable enemy of the Borgias, became pope as Julius II. At the same time the Venetians: whom Louis XII's attitude had hitherto prevented from resisting the rise of Cesare, began to seize lands in the Romagna. Cesare in vain implored the new pope to put him at the head of fresh troops to keep Romagna in subjection. Instead he was arrested (Kov. 1503). Released in April 1504, he went to Naples under a safe-conduct from the viceroy, Gonzalo de Córdoba, but in May the viceroy had him arrested on the order of the Spanish king Ferdinand of Aragon. After two years of captivity in Spain, first at Chinchilla, then at Medina del Campo, Cesare escaped in Oct. 1506 and took service with his brother-in-law, the king of Navarre. He was killed at the siege of Viana, in Navarre, on March 12, 1507.

Cesare has been wrongly praised as a great soldier, as a great statesman and as a great patron of the arts, and he was idealized by Niccolb Machiavelli in the seventh chapter of *Il Principe*. In fact he merely carried out his father's rapacious policy, in which "reasons of state" meant only dynastic aggrandisement and in which perfidy and assassination were the principal methods. Though many of the crimes popularly ascribed to the Borgias may be figments of morbid imagination, their playing off of France against Spain, their seizure of Urbino and their coup at Senigallia set an example of such turpitude in politics that the conduct of the Venetians stands out by contrast as especially praiseworthy.

As for his military qualities, Cesare contributed no new ideas either to strategy or to tactics; his conquests were largely the result of fifth-column activity and treason against his opponents; and his troops pillaged the cities that fell to them without any constraint from discipline. Contemporaries estimated his army at 15.000 men and his expenditure on it at 60,000 ducats per month (in 1510 the total revenue of the papal states was 350.000 ducats). To maintain these troops the Borgias could only resort to extortion. confiscation and simony: Alexander is said to have seized 100,000 ducats from the property of the victims of Senigallia, and in May 1503 he raised 50.000 by the sale of new church offices.

Apart from his having terrorized his subjects into silence, Cesare's fragile reputation for efficient government rests only on two actions: the killing, without trial, of Ramiro de Lorqua, who as his governor of the Romagna had accumulated on his own head all the hatred provoked by Borgia oppression; and the belated institution of the tribunal of the Rota in the Romagna.

Men of genius such as Leonardo da Vinci, Michelangelo, Pietro Torrigiano. Antonio da San Gallo, Pandolfo Collenuccio and, above all, Machiavelli are sometimes described as Cesare's protégés. Collenuccio was indeed closely attached to him, but for the most part Cesare's court was a conglomeration of insignificant people, with which Leonardo and Michelangelo had only occasional contacts. His relations with Machiavelli are of greater interest. In his *Legazioni* (the reports that he made to the Florentine government on his embassies to Cesare), Machiavelli shows him degraded and bewildered after Alexander's death; but in *Il Principe* he presents him as a man with a great mind and a noble aim. This portrayal gave rise to the myth of Cesare as a statesman whose ideal of a united Italy, or at least of a united central Italy. was frustrated only by an unlucky chance. In reality he was a political adventurer whom circumstances enabled to rely on France just as the despots of Romagna whom he overthrew had relied on Venice.

BORGIA, **LUCREZIA** (1480–1519), by her last marriage duchess of Ferrara, was born at Subiaco in the papal state in April 1480, the daughter of the Spanish cardinal Rodrigo Borgia, later pope as Alexander VI, and his Roman mistress Vannozza dei Catanei. Though legend has associated her with her father and her brother Cesare in extremes of iniquity, she can in fact hardly be accused of more than resignation to their will.

Lucrezia's first betrothal (Feb. 1491). to the Spanish nobleman Cherubin de Centelles. was broken off within two months, when she was betrothed instead to another Spaniard, Gaspar de Aversa, count of Prócida. On becoming pope (Aug. 1492), her father planned greater things for her, the commitments with Gaspar were overruled and Lucrezia was married, in June 1493, to Giovanni Sforza, lord of Pesaro. At this moment Alexander VI was relying on the support of the Sforzas of Milan against the Aragonese dynasty of Naples. The subsequent political realignment. when the Milanese took the side of Charles VIII of France and the pope allied himself with the Neapolitans, alarmed Giovanni, who used every available pretext to absent himself from Rome, evaded military action on the Neapolitan side and corresponded with Milan (privately alleging incestuous relations between the pope and Lucrezia). Finally, in Dec. 1497. the marriage was annulled, on the 'grounds of nonconsummation. Lucrezia is thought to have given birth to a child by another man in March 1498.

In July 1498 Lucrezia was married to Alfonso of Aragon, duke of Bisceglie, an illegitimate son of Alfonso II of Naples. Kext year, however, the papal-Xeapolitan alliance, which this marriage was supposed to cement, collapsed when Alexander and Cesare came to an understanding with Louis XII of France, and in Aug.

1499 Alfonso fled from Rome. He returned with Lucrezia in October. Then, on July 15, 1500, as he was leaving the Vatican, he was attacked by assassins, and on Aug. 18, as he was recovering from his wounds, he was murdered in his house, apparently at Cesare's behest. Grief-stricken, Lucrezia retired for a time to Nepi.

Finally Alexander arranged Lucrezia's marriage to Alfonso d'Este, son of Ercole I, duke of Ferrara (Dec. 30, 1501). With Alexander's death in 1503 she ceased to be an instrument of policy. Alfonso succeeded his father as duke in 1505, and the court of Ferrara became a centre for poets, painters and humanists, including Ariosto, Titian, Dosso Dossi, Pietro Bembo and Aldus Manutius. Apart from the murder of the poet Ercole Strozzi in 1508, allegedly ordered by the duke in jealousy of Strozzi's attentions to her, the rest of Lucrezia's life was tranquil, being devoted to charitable works and to the education of her children. By Alfonso of Bisceglie she had one son, Rodrigo of Aragon (1499–1512). By Alfonso of Ferrara she had seven children: Alessandro (Sept.–Oct. 1505), Ercole II (1508–59), Ippolito (1509–72), Alessandro (1514–16), Leonora (1515–75), Francesco (1516–78) and Isabella Maria (June–Nov. 1519). Lucrezia died on June 24, 1519.

See M. Bellonci, *Lucrezia Borgia* (1939; abridged Eng. trans., 1953).

BORGLUM, (JOHN) GUTZON (DE LA MOTHE) (1867–1941), U.S. sculptor, created in the Mount Rushmore memorial in South Dakota colossal portrait sculptures. He was born of Danish parents near Bear Lake, Ida., March 25, 1867. His brother and pupil, Solon (1868–1922), was also a distinguished sculptor. After a boyhood schooling in Nebraska and at St. Mary's college, Xavier, Kan., Gutzon studied art in San Francisco, Calif., then in Paris at Julien's academy, 1890–93. Both his painting and his sculpture were admitted to the salon there. In England he received important commissions and royal recognition.

In 1901 Borglum established himself in New York city. A bronze group called "The Mares of Diomedes," showing a wild stampede, was the first piece of American sculpture bought for the Metropolitan Museum of Art, New York city. He poured forth with prodigal versatility such small bronzes as his "Dying Nero" and "Portrait of Ruskin"; such heroic figures as the twelve apostles for the Cathedral of Saint John the Divine, New York city, portrait statues of Lincoln, John P. Altgeld, Woodrow Wilson, Thomas Paine, two equestrian statues of Gen. Philip H. Sheridan, and many other civil and military figures; also memorial groups of soldiers and pioneers as well as figures from mythology and poetry. But his genius turned toward what his wife, Mary Montgomery Borglum, a scholar in cuneiform and other oriental lore, described as "the emotional value of volume." From a six-ton block of marble he executed the colossal head of Lincoln in the capitol rotunda at Washington, D.C. This suggested to southern women a similar head of Robert E. Lee. But Borglum was moved to begin instead a titanic procession of Lee and his staff and soldiers marching in the Stone mountain memorial (*q.v.*) in Georgia. Disputes stopped what might have proved one of the wonders of sculpture. He was then engaged on a government stipend to turn another mountain into a monument.

In the Mount Rushmore National memorial Borglum carved with sublimity the heads of Washington, Jefferson, Lincoln and Theodore Roosevelt. His engineering genius invented new methods. He died on March 6, 1941 in Chicago, Ill., leaving the last details to be completed by his son, Lincoln.

The patriotic exaltation that gave these huge works spiritual grandeur was also expressed in his exposures of corruption in airplane manufacture during World War I, and in ardent political activities. (Ru. H.; X.)

BORGOGNONE, AMBROGIO (Ambrogio di Stefano da Fossano) (*fl.* 1473–1524), Italian painter, who represented the tendencies of Lombard art anterior to the arrival of Leonardo da Vinci, was born at Fossano in Piedmont. He was approximately contemporary with Leonardo, but represented, at least during a great part of his career, the tendencies of his predecessors Vincenzo Foppa and Bernardino Zenale, which he had adopted and perfected. His fame is principally associated with that of one great building, the Certosa, at Pavia. He seems to have lived there from 1486 to 1494, when he returned to Milan. Only one known picture, an altarpiece at the church of S. Eustorgio Milan, can with probability be assigned to a period of his career earlier than 1486.

For two years after his return to Milan Borgognone worked at the church of S. Satiro in that city. From 1497 he was engaged for some time in decorating with paintings the Church of the Incoronata in the neighbouring town of Lodi. In 1508 he painted for a church in Bergamo; in 1512 his signature appears in a public document of Milan; in 1524—and this is the last authentic record—he painted a series of frescoes in the portico of S. Simpliciano at Milan illustrating the life of St. Sisinius.

The National gallery, London, has two fair examples of Borgognone's work. His serenity and conservatism are salient characteristics of his work.

BORGU (Borgou), an inland region of west Africa, included partly in Dahomey and partly in Nigeria, and bounded northeast and east by the Niger, south by the Yoruba country and northwest by Gurma country. Its name probably comes from the aquatic grass called *borgu*, a valuable cattle food. The pagan Negro tribes of the region were formerly dependent mainly on the sultan of Borgu (resident at Nikki) and the chief of Bussa. In 1894 Borgu was the subject of a territorial dispute between France and Great Britain until the convention of 1898 declared the western part French and the eastern British. (J. D.)

BORIC ACID, known also as boracic acid, a water-soluble, white crystalline substance found in trace quantities throughout the living and inanimate world and concentrated in certain minerals. It is a mild antiseptic used in salves and bandages for burns and wounds and especially in eye lotions. It stops the growth of some microorganisms (notably fungi), but is tolerated by others; for the latter reason and because of its poisonous effects its use as a preservative in foods and cosmetics has been generally prohibited or discouraged. Fabrics impregnated with boric acid become resistant to fire; it also protects wood against friction (as on dance floors) and against the effects of bacteria and weather. It is used in solutions for electroplating nickel and as an ingredient in catalysts for numerous organic chemical reactions.

The discovery of boric acid is credited to W. Homberg (1702), who made it by the action of sulfuric acid on borax (*q.v.*) and called it *sal sedativum*. It forms leaflike laminar crystals of triclinic structure, soft and soapy to the touch and having a pearly lustre. The molecular formula is H_3BO_3.

For many years the chief commercial source of boric acid was the volcanic waters (hot springs, steam jets or *soffioni* and muddy lagoons) in Tuscany, Italy, where the natural heat was more than adequate for the concentration of the very dilute (less than 0.1%) solutions by evaporation. With increasing demand, more of it was obtained by the action of sulfuric acid on borax. The solubility of boric acid in water at 0° C. is 2.6%; at 107° C., 37%. It may therefore be purified by recrystallization and, because of its volatility, by distillation in a current of steam, the boric acid constituting 2.8% of the saturated vapour.

Upon heating, boric acid partially vaporizes and loses water to form metaboric acid (HBO_2) and finally boron oxide (B_2O_3). Boron oxide forms mixed oxides with silica and if added to glass in proportions up to 12% improves the working qualities, durability, insolubility and resistance to crystallization. It is a constituent of the heat-resistant borosilicate glasses such as Pyrex. The use of boric acid and its salts as fluxing ingredients in glazes for crockery dates back to ancient times.

Intermediate polyboric acids are not definitely recognizable, although their salts are known; on the other hand true salts of boric acid are not known. Most of the metaborate and polyborate salts except those of nitrogen bases or alkali metals are nearly insoluble. The glassy boron oxide, known also as boric anhydride, can be combined with other oxides to form mixed anhydrides of the type $(RCO_2)_3B$ or mixed oxides such as $ScBO_3$, B_2SO_6, $B_2S_2O_9$, BPO_4 and $BAsO_4$. The so-called boron phosphate and arsenate are structurally like some forms of silicon dioxide, and have similarly high melting points.

Boric acid is recognized chemically by its action upon curcumin

(turmeric yellow) to give a bright red colour. A slight trace of a volatile boron compound imparts a green colour to a flame.

The acidity of boric acid is too weak for complete reddening of litmus. and its titration by a strong base is not feasible. However. the titration becomes quite satisfactory if a polyhydroxyl organic compound. such as mannitol. glycerol or certain sugars, is used to increase the acidic ionization. This effect, which is the basis of the usual method of quantitative analysis for boron, is ascribed to the formation of complex esters called spirans. Evidence for such structures was found by the preparation of an asymmetric spiran and the separation of its optical isomers (J. Boeseken and J. A. Mijs, 1925). Similar spiran structures may occur in the polyhoric acids which are thought to be present with boric acid in concentrated solutions, accounting for abnormally high acidity in such solutions. Spiran formation also occurs when boric acid is used to enhance the acidity of leather-tanning agents.

The formation of borospirans by many sugars may help to explain the beneficial effects of boric acid upon the germination, growth and yield of many plants (H. Agulhon, 1910). Most plants require at least 0.2 mg. of boron per litre of nutrient solution (or per 10 kg. of soil); without it there is little transport of sugars from the leaves, and growth is seriously hindered.

The seed itself often contains enough boric acid for a start. but boron-deficiency symptons (dry rot. stunted growth or sterility) appear later and are cured only by the addition of boric acid or borax to the soil or stem. Too much boron (10–100 mg. per litre) is toxic to plants, although some species develop tolerance during growth.

Numerous volatile esters of the type formula $B(OR)_3$ may be made by the reactions of alcohols with boron oxide. or with boric acid in the presence of sulfuric acid. Such esters react with Grignard reagents. RMgX, and u-ith proper control of conditions organic boric acids of the type $RB(OH)_2$ may be obtained. Some of these compounds. especially the derivatives of phenylboronic acid. $C_6H_5B(OH)_2$, have been suggested for use as antiseptics. All such compounds easily lose water to form anhydrides of the type $(RBO)_3$, in the structure of which boron and oxygen atoms alternate to form a six-atomic ring analogous to the B_3N_3 ring in borazole (*see* BORON). The same B_3O_3 ring is found in potassium metaborate.

For a bibliography, *see* BORON. (A. B. BG.; X.)

BORIDES, a class of hard substances in which boron (*q.v.*) is chemically combined with various metals, usually forming crystal structures of the metallic type (*see* METALS). The chemical formulas are governed by the possible structural patterns rather than by any simple rules of valence (*see* ALLOYS); indeed, some borides have slightly variable compositions because of systematic defects of structure. The structural types range from those in which the boron atoms are separately imbedded in lattices formed of metal atoms through boron chain, ribbon and layer structures to the class in which the metal atoms are isolated within boron lattices. The borides usually are harder, higher melting, chemically less reactive and electrically more resistant than the corresponding pure metallic elements; such enhancement of properties is slight for the isolated-boron type. but increases sharply for more and more complex boron patterns. Some of the borides are among the hardest and most heat-resistant of all known substances, and find important uses based upon these extreme characteristics.

Preparation. — Most of the borides can be made by direct union of the elements or by reactions involving boron oxide (*see* BORON; BORIC ACID) with a metal oxide or salt and a strong reducing agent such as an active metal. The temperatures required for such reactions range from 1,000° to 2,000° C., and it is expedient to employ an electric furnace of the carbon-arc or the induction type, with an inert gas to protect the charge against oxidation.

Borides can also be made by electrolysis of molten mixtures of boron oxide with metal oxides. often with some added fluoride, at 1,000° to 1,200° C. (J. L. Andrieux, 1929). All known borides of the formula type MB_6 have been made by this method, as a-ell as the MB_2 borides of Ti. Zr. V, Nb, Ta. Cr. Mo and W. and certain of the MB type as well. Finely powdered boron is usually present in the product. but can be removed by a careful treatment with nitric acid, toward which the crystalline boride is often almost inert.

K. Moers (1931) made crystalline wires of borides of titanium, zirconium, hafnium and vanadium by mixing the vapour of a volatile halide of the metal with hydrogen and boron bromide and leading the mixture across a glowing metal filament of diameter 0.05 mm. The boride built up on the filament. which was afterward dissolved. The products were of low-boron types, having electrical resistances almost as low as the metals themselves. The zirconium boride, in fact. became superconducting below 3.0° K.

Probably the longest-known and most easily made of all borides is the compound AlB_{12}, a dull-metallic crystalline material which was long mistaken for boron itself. It is made from metallic aluminum and boron oxide, with sulfur present to raise the temperature by reaction with the excess metal. It is extremely hard and chemically unreactive. but can be converted to the far more reactive AlB_2 by heating with aluminum.

Structure and Properties. — Investigations of metal boride structures by X-ray methods (*see* CRYSTALLOGRAPHY), summarized at an early stage by G. Hägg (1929) and at a more advanced stage by R. Kiessling (1950), show a definite series of types to which most borides conform. In the tetragonal borides of formula type M_2B, the metal atoms form layers of packed tetrahedrons, leaving holes wherein each isolated boron atom is uniformly surrounded by eight metal atoms. In such borides of Ta. W, Mo. Mn, Fe, Co and Ni, the radii of the holes range from 1.11 to 0.96 Å, always far larger than any reasonable radius for the boron atom, and permitting a structural looseness which accounts for the relative softness of these borides. In the MB-type borides, the metal atoms form triangular prisms which pack together in any of three different ways, resulting in three types: (1) MnB, FeB, CoB; (2) MoB, WB; (3) NbB, TaB, CrB—in each of which there is a boron atom at each prism centre.

The boron atoms form infinite zigzag chains, with B-B bond distances greater than would be expected of regular single bonds; the valence electrons of boron evidently are shared liberally with the metal lattice. One of these borides, MnB. is reported to be ferromagnetic, with a Curie point of 300° C. Nickel boride has a hardness below 8 Mohs.

In the borides Nb_3B_4, Ta_3B_4, Mn_3B_4 and Cr_3B_4 pairs of parallel boron chains. lacing through triangular prisms of metal atoms, are cross-linked through alternate boron atoms in each chain by B-B double bonds, forming ribbons of hexagonal rings embedded in the metal lattices. At this stage of organization of boron, the hardness increases sharply, but some of the metal softness persists.

Graphitelike sheets of boron atoms, forming alternate-layer structures a-ith metals. are found in the hard but chemically reactive AlB_2 and MgB_2 and in the more refractory MB_2 compounds of Ti. Zr. V, Nb. Ta. Cr, Mo and possibly W. Here the B-B distances. in the hexagonal-ring mosaic planes, are abnormally long, indicating true participation of boron in the electron-deficient metallic bonding. The compounds Mo_2B_5 and W_2B_5 have similar boron planes.

The hardest and least metallic of the borides are those of the boron-lattice types, of which the MB, variety offers the greatest number of examples. In these, the boron atoms pack together in groups of six, forming regular octahedrons which join together at their vertices to form an infinite cubic array. This lattice provides truncated-cubic holes in which any of the metals Ca, Sr, Ba, Y, La, Ce. Pr, Nd, Gd, Er. Yb and Th can be placed, with 24 equidistant boron neighbours.

In UB_{12} each uranium atom also has 24 equal boron neighbours, at the vertices of a cubically truncated octahedron. In C_3B_{12}, known as boron carbide. regular icosahedral B_{12} units alternate with linear C_3 units in a simple cubic lattice. All of these borides are nearly as hard as diamond and almost as electrically resistant as boron itself. Boron carbide (*see* CARBIDES) has been used to make mortars for grinding especially hard materials, such as

Calcium boride has been used as an additive to steel, in which it acts at high temperatures to convert oxides to a borate slag. For making very hard machine tools, TaB_2, Mo_3B_4 or WB_2 in powder form may be mixed with 3% to 15% of iron, cobalt or nickel and sintered into durable form.

Chromium borides may be used in a similar manner. or employed directly as abrasives. Some borides have such high melting points and such resistance to oxidation as to make them interesting for use in high-temperature equipment.

Borides of Be, Mg, Al, Ce, Mn, Fe and Ni have been reported to react with aqueous acids, forming boron hydrides (*q.v.*) in small yields. Magnesium boride reacts vigorously with water, yielding hydrogen and solutions of strong reducing agents (M. W. Travers, 1913). By treatment of such solutions with potassium hydroxide, R. C. Ray was able to isolate the dry salts $K_2B_4O_6$, $K_2H_4B_2O_2$ (two isomers), $K_4H_2B_2O_2$ and $K_2H_2B_2O_2$, in all of which it would appear that B-B bonded units must occur.

BORING (MINING) : *see* DRILLING MACHINERY.

BORIS: *see* GODUNOV, BORIS FEDOROVICH.

BORIS I (d. 903), Bulgarian tsar, succeeded his father, Pressian (or Presiam), in 832. Some territorial gains that he made in Macedonia were of far less importance in Bulgaria's history than his adoption of Christianity as the state religion and of Slavonic as the official language. While his own conversion to Christianity sprang from a genuine leaning toward a pious and austere life. he also found in the Christian faith a potent means of unifying the Bulgars and the Slavs, over whom he ruled, as well as an effective device for curbing the arrogance of the boyars. Moreover, during the long struggle between the papacy and the Byzantines for spiritual ascendancy over the Balkans, Boris tried to secure every possible advantage by negotiating with both contenders in turn. His final choice of the Orthodox Church drew Bulgaria spiritually and politically away from central Europe for centuries.

Abandoning his alliance with Louis the German, Boris made a treaty with the Byzantine emperor Michael III and was baptized in 865, compelling his people to follow suit. in spite of fierce opposition from the boyars. Constantinople, however, did not grant Boris his wish for a truly independent national church! and in 866 he turned to Rome and obtained Pope Nicolas I's promise to appoint a patriarch to the Bulgarian Church. As the appointment was delayed, Boris changed his mind again and, at the Council of Constantinople, in 870, finally chose the Orthodox Church. Having achieved his ambitions, he abdicated in favour of his eldest son, Vladimir, in 889 and retired to spend the rest of his life in a monastery. Vladimir, however, proved a bad ruler, and Boris returned to active life to depose him, to have him blinded and to put his youngest son, Simeon, on the throne instead (893). He then went back to his monastery, where he died in odour of sanctity in 903. He was canonized a saint in the Orthodox Church and his feast is celebrated on May 15 (new style; May 2 old style).

(N. I. M.)

BORIS III (1894–1943), king of Bulgaria, born at Sofia on Jan. 30, 1894, the eldest son of Ferdinand I of Bulgaria and Maria Luisa of Bourbon-Parma, received at birth the title of prince of Trnovo. In 1896 his religion was changed, for political reasons, from Roman Catholic to Orthodox. He was educated at the military academy of Sofia and served in the two Balkan wars and in World War I. When Ferdinand abdicated Boris succeeded him on Oct. 4, 1918.

At the beginning of the reign, political power was in the hands of Aleksandr Stamboliski and the Agrarian party, which was greatly strengthened by its consistent opposition to the war. With tact and patience Boris won the peasants' confidence, but they resented his passive acceptance of Aleksandr Tsankov's regime after the overthrow of Stamboliski; the left wing of the Agrarian party joined hands with the Communists in the bloody risings of Sept. 1923 and in the attempts on Boris' life in 1925.

Boris eventually got rid of Tsankov and restored constitutional government; but this came to an abrupt end through the Military league's coup d'état on May 19, 1934. The leaders of the conspiracy were republicans, and though Boris accepted the change without resistance, his position became critical. A warning by Great Britain, conveyed verbally to the cabinet, saved the monarchy. In blunting the edge of the officers' rule Boris played his hand less inconspicuously than he had in the removal of Tsankov. His part in the conduct of affairs, particularly foreign affairs, became henceforth more strongly felt.

Up to the outbreak of World War II, Boris used all his pliancy to avoid committing himself either to the Axis or to the Allies. In March 1941, however, he sent his prime minister to sign the Axis pact; German troops were given free hand in Bulgaria. In Dec. 1941 Boris authorized his government to declare war on Great Britain and its allies—in his own admission his worst mistake. He did, however, consistently refuse to take up arms against the U.S.S.R., mistakenly hoping that Bulgaria might earn some remission on this account when the reckoning came.

Boris died on Aug. 28, 1943, shortly after a stormy interview with Hitler. Whether his death was caused by a heart attack or by assassination was uncertain. He was succeeded by the six-year-old Simeon II. son of his marriage (1930) with Giovanna, daughter of Victor Emmanuel III of Italy. (N. I. M.)

BORISOV, a town of Minsk *oblast* of the Belorussian Soviet Socialist Republic, U.S.S.R., stands on the Berezina at its confluence with the Skha. Pop. (1959) 59,000. Founded in the 12th century. Borisov has always been an important centre of routes and trade. There the Moscow-Warsaw railway and highway cross the navigable Berezina. Borisov was occupied by the Germans in World War 1 It is a major timber-working centre, producing saw-timber, matches, paper, furniture, veneer, parquet, wood chemicals and pianos. Glass-, enamel- and zincware and cranes are also manufactured. "New" Borisov on the right bank, where most industries are located, has far outstripped in size the old town across the river. (R. A. F.)

BORKU (BORGU), a region of the Republic of Chad (*q.v.*), Africa, lies between latitude 17° and 19° N., and longitude 18° and 21° E. The northern valleys are inhabited by a settled population of Tibbu stock, the Daza, who merge to the south with Negroid peoples. The nomadic and seminomadic population consists of Tedas, Nakazzas, Arabs and Berbers from the north, particularly the Ouled Slimans.

Borku (also called Borgu but not to be confused with Borgu region in Nigeria) was important because of the lucrative trade. particularly in slaves, carried on through Borku between Cyrenaica and central Africa. Formerly a vassal state of Wadai (*q.v.*), an Anglo-French agreement (1899) gave Borku to France, but Senusi control over the region (Fr. Borkou) was not broken until 1913–14.

(J. G. W.; J. D. F.)

BORN, MAX (1882–), German physicist, was awarded, with Walther Bothe (*q.v.*), the 1954 Nobel prize for physics for his statistical studies on wave functions. He was born in Breslau on Dec. 11. 1882. He was educated in the universities of Breslau, Heidelberg. Zürich and Gottingen, from the last of which he received his doctorate of philosophy in 1907. After teaching and research at Gottingen, Berlin and Frankfurt am blain, he was elected professor of theoretical physics at Gottingen in 1921. In 1933 he took refuge in Great Britain, and taught in Cambridge. He was elected to the Tait chair of natural philosophy in the University of Edinburgh in 1936 and retired in 1953. He became a British subject in 1939. His work on wave functions led to the replacement of the original quantum theory, in which electrons mere regarded as particles, by an essentially mathematical description representing more accurately the observed behaviour of the electrons. Born also applied the perturbation theory to problems of scattering; he shared in the formulation of the Born-Oppenheimer theory of molecules; and he contributed to the study of crystallography and to the kinetic theory of fluids. He was elected a fellow of the Royal society in 1939. (D. McK.)

BÖRNE, LUDWIG (1786–1837), German political journalist and satirist of radical views, was born Juda Low Baruch on May 6 or 24. 1786, at Frankfurt am Main. After studying first medicine and later public administration at the universities of Halle. Heidelberg and Giessen, he became police actuary at Frank-

furt in 1811 under the new freedom accorded to Jews; but when the earlier restrictions were restored in 1815 he was dismissed. In 1818 he changed his name to Borne and became a Lutheran, partly to avoid prejudicing his journalistic ventures. Of these the periodical *Die Waage* (1818–21) was notable for its disguised radicalism and for the social awareness of Borne's dramatic criticism. but trouble with the authorities, coupled with ill-health. led to his partial withdrawal from journalism between 1822 and 1830. A supporter of the July Revolution, he settled in Paris in 1830 and, though soon disillusioned, mediated French liberal ideas through his *Briefe aus Paris* (1830–34). He died there on Feb. 12, 1837. Borne gave journalism in Germany a new subjectivity and intensity; his style: witty. epigrammatic and at times savage, is at its most typical in *Menzel, der Franzosenfresser* (1837). He and Heinrich Heine are often regarded as the forerunners of the Young German movement *(see* GERMAN LITERATURE), though they were personally at odds.

BORNEO, one of the great islands of the world. lies southeast of the Malay peninsula between 7° N. and 4° 20' S., 108° 53' W. and 119° 22' E. Roughly kidney-shaped, very mountainous, largely covered in dense rain forest and sparsely populated (by Asian standards,. it is 830 mi, long from northeast to southwest, with a maximum breadth of 600 mi. Its area is 286,914 sq.mi.—about five times as large as England and Wales or the state of Michigan.

Politically Borneo is divided in two. By far the larger part is Indonesian (until 1949 Dutch). known as Kalimantan. Along the west coast and northern tip are three territories within the British commonwealth: North Borneo (including Labuan). Sarawak. and between these oil-rich Brunei. a Malayan sultanate with the governor of Sarawak as high commissioner. *(See* BORNEO, NORTH; BRUNEI; SARAWAK; INDONESIA.) There are many variations in social and political structure. racial and religious grouping. within these four countries; and in the early 1960s reliable information was not available for Kalimantan, where no accurate census had been taken (see *Population* below).

This article is divided into the following sections:

I. PHYSICAL GEOGRAPHY

1. Geology. — The geology of Borneo is still imperfectly known. Extensive advances were being made, however, in the early 1960s through the technical explorations of the Shell Petroleum company and its subsidiaries and of the British Borneo Geological survey in the three British territories. These researches were of necessity largely directed toward immediate practical problems. Thus, from the coastal plain, which carries the major population and production potential. an obvious geological feature is the absence of really hard rock in many reasonably accessible places. It was only after the Japanese occupation of World War II that good supplies of quarrying stone, road-surfacing material and fill were discovered—including a previously unrecognized stratum of granite at Sebuyau in southwest Sarawak and a very hard limestone at Batu Gading in the Baram river.

Until recently, the general conception of Borneo's geology has been largely one of a great island of sandstone with some other deposits and a few igneous areas, mostly in the extreme south-southwest. It was not until the 1950s that extensive new outcrops of igneous rock were first encountered in the far interior: the Usun Xpau plateau, in the far headwaters of the Rajang river of Sarawak, and the 6,600-ft. Hose mountains. the very existence of which had previously been in doubt. The most striking topographical feature in the island, Mt. Kinabalu. rises to more than 13,000 ft. in a great tangle of jagged peaks of bare. black granite (see *Relief and Drainage* below).

Borneo is composed principally of sedimentary rocks, largely Tertiary: but along the coast are extensive Quaternary sectors, particularly in the delta country, and dead level and often deadening s\\-amp, characteristic of the whole of Borneo's coast line except in the extreme north. Outcrops of limestone are few and far between, but where these occur they make conspicuous features of the landscape, rising sheer out of the sandstone in impressive shapes and reaching 7,798 ft. on Mt. Mulu. All the significant caves of Borneo are centred in these limestone outcrops, which, though numerically few, thereby attain a special importance; for these caves—the most famous are Gomanton in North Borneo and Niah in Sarawak—are the homes of millions of swiftlets, which provide the edible bird's-nests of commerce (see *Animal Life* below), and bats, which provide guano extracted as fertilizer. In the great cave at Niah (26 ac.) extensive excavations by the Sarawak museum reveal a succession of prehistoric occupation down to the Middle Paleolithic (see *Archaeology* below).

The great spinal range, which corresponds roughly with the political boundary between British and Indonesian territory in the interior: consists chiefly of crystalline schists together with slates, sandstones and other rock, all much disturbed and folded. From this spinal range, lateral and parallel ranges strike out in all directions. characterized by large-scale disturbance. The low-lying country between the mountain ranges is frequently covered with Tertiary and sometimes with Cretaceous deposits. There are igneous bands on the eastern side! in Indonesian Borneo, mostly south of Longnawan.

2. Relief and Drainage. — The general character of the island is mountainous. The highest peak is Mt. Kinabalu, 13,455 ft., a great jagged outcrop of granite emerging out of a sandstone formation almost from sea level to form the highest mountain in southeast Asia and one of the splendid mountains of the world.

Seen from the summit of Kinabalu or any other of the high mountains. Borneo appears as a confused, irregular tangle of ranges, hillocks and great winding valleys with none of the symmetry characteristic of Burma or Java. Sumatra or Malaya. Thus it is one of the hardest countries in the world to move around in on foot. To follow a compass bearing is an unbearable experience; it will inevitably involve crossing and recrossing stream after stream and climbing hillsides, gullies and landslides in wearisome succession. The stranger to Borneo who is fortunate enough to get off the beaten track is usually irritated by the tortuous trails n-hich the native peoples use to travel vast areas of jungle. But, from centuries of experience and an unsurpassed feeling for jungle life. these people—once head-hunters. now peaceable—have usually worked out the best routes, however indirect these may appear.

Fortunately. a very large part of the island, including the whole southern half. is intimately drained by navigable rivers. Farther north, as the island narrows and the mountainous centre becomes relatively more formidable, few rivers are navigable for more than 100 mi., often much less; after that, men must walk, wade and climb. This is largely why the northern interior of Borneo has until recently remained one of the least-known parts of the world. Throughout the south. but to a less extent else-

TOPOGRAPHICAL MAP OF BORNEO

nhere, the great waterways are the principal and often the only life lines of human trade and commerce.

The Kapuas river is the waterway of the southwest, rising near the centre of the island and reaching the sea in a great delta south of Pontianak, the chief town in this part of Indonesian Borneo. Small steamers can travel as much as 400 mi. when tide and rainfall are suitable. The Barito is the great river of the south coast, rising in Kuti Lama lake and entering the Java sea at 114° 13' E. Like most of Borneo's rivers, the upper reaches are rocky, with gorges, rapids and waterfalls. The lower Barito forms another great delta with very extensive areas of nipa palm, sago, mangrove and other swamp, mainly inhabited and exploited by Muslim Malays. The Barito alone drains 38,000 sq.mi. Farther east, the Mahakam (or Kutaij is the major river; at a great distance from its mouth it still has a depth of three fathoms.

North of the Mahakam, flowing into the sea opposite the oil field on Tarakan Island, is the Kajan (Batang Kayan) river which traverses northeastward from the very centre of Borneo. As the name implies, the river is the headquarters of the Kayan (and Kenyah) peoples, riverine folk of the southern interior who live by shifting cultivation of rice and have developed the highest level of arts in Borneo—wood carving, ironwork, music and dancing. From the headwaters oi the Kajan these people have spread north and west to populate a large inland area of Sarawak. They are the great boatmen of Borneo, and on the Kajan, above all, they need to be, for this is the fiercest of rivers and would barely be regarded as navigable at all by most standards. The worst rapids on the river are the Brembrem, which are indeed impassable. While the Dutch still occupied this part of Borneo they built a graded road for 20 mi. around this tremendous gorge, with boat depots at either end to facilitate traffic. They also built the only far-inland government post in the island: with hospital, troops, etc., stationed at Longnawan, near the head of the Kajan.

To the west, the Rajang is the greatest river, rising from Mt. Batu Tiban, the Nieuwenhuis mountains and the Usun Apau plateau in many sources which merge above Kapit and flow through Sibu, a commercial centre and second most important town in Sarawak, to the South China sea, 30 mi. farther down. The upper reaches of the Rajang are inhabited by Kayan, Kenyah and related peoples: the middle reaches are densely populated by Iban Dayaks who, over the past several centuries, have been pushing up the west centre of the island from the headwaters of the Kapuas. The Rajang is navigable for about 160 mi. by large launches, but above Kapit it is broken by formidable rapids: notably the Pelagus.

Farther to the northwest the Baram is also a mighty river, but difficult for navigation after the first 100 miles. However, by the early 1960s light outboard motors attached to native canoes had begun to revolutionize the speed and load of small-scale transport in these more difficult rivers.

North of the Baram on the west coast and the Kajan on the east, the belt of coastal delta and subcoastal plain country narrows, and in the extreme northwest amounts to only a few miles between the sea and the beginning of the 500-ft. foothills which rise behind Papar, Jesselton and Tuaran almost directly into the tormented mountain massif of Mt. Kinahalu and the Crocker range. Whereas much the larger part of the other Borneo territories is lowland country below 500 ft. (and much of this at sea level), the greater part of the territory of North Borneo is 700 it. and over. This highland has a rainfall of over 200 in. a year, which drains with great energy outward to form rivers beyond the capacity of any boatman. Therefore much of North Borneo is only approachable on foot. Moreover, the Kinabalu-Crocker massif continues southwestward, roughly along the boundary between North Borneo and Sarawak to Mt. Murud (7,950 ft.), nhere the borders of both these territories and Indonesian Borneo meet. Southwest of Murud the spinal range continues at over 3.000 ft. to Batu Tiban (5,590 ft.), then turns west with irregular, broken extensions running south into the Müller mountains, nhich seldom rise beyond 5.000 ft.

Within this really rather complicated pattern of central mountains lies an irregular series of upland plateaus or plains, isolated from the lowlands by impassable rivers and untii the mid-20th century isolated culturally and economically as well. The highest of these upland plains is at Bario, south of Mt. Murud, and it is probably the highest permanently inhabited point in the island (3,500 it.). Wide valleys, impressively set among mountains and cultivated by wet rice, they are in striking contrast to anything on the outer side of the central massif. In the north, around Ranau, these plains are inhabited by the Dusun peoples; farther south, from Keningau, by the Murut; and south of the Murut, by the Kelabit. The Kelabit country became thoroughly known during World War II when Allied parachute forces were dropped into these rich and well-populated places to organize—with considerable success—guerrilla operations against the Japanese

occupying the coastal areas and at first quite unaware of any such threat in their rear.

South of the Kelabit uplands, between the headwaters of the Baram and Rajang rivers, another system of tablelands on the west side of the border was first suspected and then explored by a Sarawak museum expedition in 1951, then further by geologists and fully by an Oxford university expedition in 1956. This inaccessible region is non- only inhabited by a few wild bands of the nomadic Punans. But evidences of large populations, including ancient long houses (a dwelling housing many families), burial grounds and widespread sago cultivation discovered in 19ji, were confirmed by excavation in 1956. This strikingly supports the myths and sagas among the lowland people on both sides of the border, who often refer nostalgically to previous centres of population in cooler and more fertile highlands called Usun Apau ("mountain garden").

Native legends suggest that in very ancient times much of the interior was covered with lakes. Very few lakes now exist in Borneo. the only important ones lying in the headwaters of the Kapuas and possessing a highly specialized aquatic bird not found elsewhere. Over many centuries there was a migration trend from the south and east across the spinal range to the north and west, in recent centuries accelerated by powerful pressure from the aggressive and rapidly increasing Iban Dayaks. Cnder European influence this process has ceased and a converse sequence commenced. With peace. security and trade in the lowlands, more and more Borneo people have moved out of the interior toward the coast, and at the same time immigrant peoples, notably the Chinese since about 1870, have come in from the sea and met with the indigenous people on the coastal plain.

Thus, in the middle of the 20th century, vast tracts of the interior south of the Kelabit uplands were inhabited sparsely or not at all. while most of the good land on the tidal reaches of the rivers and down to the coast was occupied (and sometimes overpopulated). It may well be that with improved communications, a movement back toward the uplands will seem desirable to people who have traditional roots there and who. in the middle reaches of the rivers, are being pressed. Corninunications have rapidly improved in the Eritish territories, and by the 1960s air strips with feeder services were operating far inland at Ranau and Keningau in North Borneo and Lio Matu and Belaga in Sarawak.

The coastal plain. although the least attractive. is the most productive portion of Borneo. If a figure of 500 ft. is accepted as a general limit inland. well over half of Borneo falls into this category. The coast line itself generally consists of long. white coral sand beaches, interspersed with great river deltas and occasionally (mostly in the north) minor cliff formations. Largely because of the violence of monsoon storms. as well as the historical factors already mentioned, it is possible to travel for many miles along the coast without finding any human habitation. The villages are usually tucked away out of sight in the estuaries or behind the headlands. With a few insignificant exceptions the coastal and subcoastal people are Muslims and live in separate houses grouped into villages of from 20 to 200 homes: the long house. characteristic unit of the interior. is not to be found there. (See *The People* below.) A large part of this population gains its livelihood by fishing the wide and shallow offshore waters. or working the produce of the great expanse of delta swamps, which are at their most extensive in southwest Sarawak and the Bandjermasin division of southern Indonesian Borneo. Many of the river mouths are blocked by difficult sand bars and narrow. shifting channels. with a complicated network of tides (twice a day along much of the coast'). Thus while the rivers provide very efficient lines of inland communication, the problems of communication for larger vessels may be acute. In about 2,500mi. of coast line there are only 15 ports in any way worthy of the name, of vihich Victoria on Labuan Island in the mouth of Brunei bay in the northwest is probably the best all-mather sea anchorage.

Islands are not numerous off the coast. The main ones are the Natuna group on the west, the Tawi-Tawi group to the east: Banggi and Balambangan between the northern extremity of Sorth Borneo and the Sulu archipelago? Labuan (*q.v.*), oil-bearing Tarakan to the east, Laut to the southeast and the Karimata group to the southwest. The population of these islands is predominantly Malay stock with a strong seafaring tradition which h a served to link coastal Borneo with other land masses for many centuries.

Tiny in size and human population, but coinmercially valuable and scientifically fascinating. are the "turtle islands." The most interesting and significant of these are three which lie just east of Cape Datu and where on a total beach surface of less than five acres 2.000.000 eggs a year may be laid by edible turtles (see *Animal Life* below).

3. Climate. — The climate is characteristically equatorial — hot and damp. Humidity is normally very high. In the flat, windless deltas and swamps of the coastal plain. in the sweltering sun, a man may feel as uncomfortable as anywhere in the world. By contrast, in the Kelabit uplands the temperature is generally cool and at night cold inside the long house at Eario. Ice — but not snow — has been recorded in February from the top of Mt. Kinabalu (Low's peak. 13,45j ft.). In the Usun Apau uplands. now uninhabited. the daily maximum range is not above 85° F. at about 2.000 ft., and the minimum is 35° F. In the lowlands over the island generally. the thermometer rarely falls below 70° F.. while on very hot days it mounts to as high as 98" F. in the shade (recorded at Kuching in August).

There is a fairly distinct division into two seasons: the monsoon (*landas*) between October and March. and a relatively drier. calmer period of summer (*tedoh*) for the rest of the year. But this is much complicated by latitude. longitude and the local climates built up around the big mountain ranges. There is no distinct, extensively dry season, though the least amount of rain tends to fall in July. August and September. Sine-tenths of native agriculture is based on the assumption or hope that during these months it will be dry enough for the felled jungle to be burned off. so that rice seed may be planted in the cleared areas. But such is the Borneo climate that at least once in every five or six years this goes wrong; in some years, on the other hand, excessive rains at the end of the monsoon ruin the ripening grain before harvesting.

The average rainfall for most localities is about 150 in. a year, most of which falls between late afternoon and early morning.

4. Vegetation. — The flora is very rich, the far greater portion of the surface of the island being clothed in thick evergreen forests. Above about 3,000 ft. dwarf trees covered in mosses and lichens replace the rain forest. The king of the forest is *Koompassia excelsa,* which rises to a great height without fork or branch to a splendid dome of foliage, beneath which may often be seen 50 to 70 nests of wild bees on the larger branches. The official seats of some of the native chiefs are constructed from the wood of this tree. Ironwood, remarkable for its durability, is abundant; it is used by the natives for the pillars of their homes, and forms an article of export, chiefly to Hong Kong. In all, about 60 kinds of timber of marketable quality are furnished, but the difficulty of extraction, even in the regions near the large waterways, renders it improbable that the timber trade of Borneo will attain very great dimensions until other easier sources of supply have become exhausted. Palm trees are abundant in great variety. including the atap (the leaves of which are used for roofing); others are the cabbage. fan. sugar, coconut and sago palms. The last two furnish large supplies of food to the natives. Most of the tropical fruits flourish. including the evil-smelling durian. a large fruit with an exceedingly strong outer covering of stout pyramid spikes. like a huge horse chestnut.

There are nearly 300 genera of flowering plants found in Borneo but not found east of the Makassar straits, and 59 endemic genera are known. Ten Asiatic genera and several Australian plants. *e.g., Styphelia suaveolens* and *Trochocarpa learmonthiana,* are not found elsewhere in Malaysia. *Philbornea* has only been reported from Borneo and the Philippines. *Pandanus,* also found in the Malay peninsula and in Sumatra but not in Java, obstructs many of the rivers. Among the more beautiful of the flowering

plants are rhododendrons (of which there are 32 known species), orchids and pitcher plants, the last reaching extraordinary development, especially in the northern mountains Kinabalu, Trus Madi and Mulu. Epiphytous plants are common. many that are usually independent assuming in Borneo a parasitic character: the orchid *Arachnanthe lowii,* for example, grows on the loner branches of trees: and its strange pendant flower stalks often hang down almost to the ground. Rafflesia. the largest flower in the world, named after Sir Stamford Raffles who discovered it, grows in the south. Ferns and allied plants are abundant everywhere, particularly on the limestone mountains.

5. Animal Life.—The fauna of Borneo comprises a great variety of species. Among the large mammals the most remarkable is the orangutan (Malay *ôrang* utan, "jungle man"), the huge ape (Pongo *pygmaeus*) called maias by most natives. The maias, now restricted to a few lowland areas of Borneo and Sumatra, is protected by law, being in danger of extinction because of its popularity in zoos and circuses. Borneo has another of the four living apes which is much commoner: the gibbon (native; *wawa*), graceful and easily tamed. The island is also the only home of the astonishing proboscis monkey (*Nasalis*), which inhabits the delta swamps of Sarawak, where they have increased and become tame since they have been protected. There are numerous other primates. The large-eyed *Tarsius* spectrum and the loris, *Nycticebus coucang,* also deserve mention.

The bigger beasts of prey are not found in Borneo, and there is little check on the plant eaters. The clouded leopard (*Neofelis nebulosa*) is the largest feline on the island. The honey bear is common and is the only mammal in Borneo of which the people are afraid. The largest mammals are the Asiatic two-horned rhinoceros and the elephant. The rhinoceros, a purely jungle beast, was once common, but the introduction of shotguns to the inland people in the 20th century has led to its near extermination. The horn, hoofs and hide are greatly esteemed by the Chinese for medicinal purposes. Since 1947 full measures of protection have been enforced in time to save a few remaining survivors in the interior. Elephants are possibly not endemic but a considerable herd of feral Indian elephants roam the Kinabatangan area of the northeast. The third large mammal is the wild ox (*Bos sondaicus*), a finely built brown animal with white markings like socks. It has not suffered like the rhinoceros, since it can move faster and is of no value economically. Wild pigs abound, moving in scattered hordes following supplies of fallen fruit in the jungle, often in turn followed by the nomadic Punan who hunt them with blowpipe and poisoned dart.

Four species of deer are common, including the mouse deer or plandok, of remarkable grace and beauty. about the size of a hare but considerably less heavy. There are also civet cats, bear cats, flying foxes. otters. porcupines, squirrels, flying squirrels. tree shrews (Tupaia), rats, bats and the curious little badger *Mydaus.* Crocodiles are found in all the rivers. but the gavial occurs less frequently. Lizards are in great variety, some of the genus *Draco* being able to fly; snakes of various kinds, from the python downward, are abundant, including the most deadly of snakes. the king cobra or hamadryad—one of the few which will sometimes aggressively attack and even pursue man. The remarkable "flying snake" is a true serpent which can extend its ribs to make a flattened plane on which it can glide from a tree or bush to earth. Frogs are abundant. especially in the lowlands; some of the giant toads are larger than a Pekinese dog.

There are more than 500 kinds of birds recorded in Borneo. Several are confined to the islands, including the handsome blue-wattled Bulwer's pheasant (*Lobiophasis bulweri*) and a brilliant scarlet and black partridge (*Haematortyx sanguiniceps*) found only in jungle above the 3,000-ft. contour line.

There is a distinct montane fauna with many species both of vertebrates and invertebrates not found in the lowlands. Only Mt. Kinabalu runs above 10,000 ft. and at this height there is a limited and peculiar fauna, including a primitive shrew, two tree shrews (although there are no trees) and a little brown bird (*Androphilus accentor*), found nowhere else in the world. Two birds are of economic significance. Small finchlike manakins (*Munias*) descend in droves upon the ripening rice and do serious damage in some years. In limestone caves swiftlets (Collocalia) make edible bird's-nests—one of the most expensive foods in the east.

Some travelers say that Borneo is spoiled by its biting bugs. Jungle tracks are infested with leeches, river banks with sand flies, and mosquitoes are everywhere. There are also two kinds of fire ants whose sting is particularly painful. Hornets, bees and wasps of many varieties abound. Butterflies, moths and beetles are remarkable for their number. size, variety and beauty. *Ornithoptera* brookeana, or Raja Brooke's bird wing, one of the many swallowtails found in Borneo, is widely regarded by entomologists as the most beautiful of butterflies.

Fish are periodically caught in great quantity by poisoning several miles of water with the pulped tuba vine. this event being an occasion for excitement, carnivals and feasting over a whole district. Fish plays a major part in the diet of the coastal Malays and Chinese, but is not so plentiful as in some seas. There appears to be a shortage of plankton and other microscopic food to attract them in large numbers. Nevertheless there are many fine sea fish, and the coastal peoples have met their difficulties by using a wide variety of techniques with net, hook, stake, trap, light and spear. In the straits between Banggi Island and North Borneo. a successful tunny fishery run by the Japanese before 1941 was recommenced in 1957. Shark fishing is undertaken particularly for the fins, a Chinese soup delicacy. Turtles, sea cucumbers and pearl shell are also of some commercial importance. The eggs of the edible turtle (*Chelonia mydas*) are marketed to Chinese and Malays, who regard them as great delicacies. Marking experiments prove that one turtle may lay five times in a few days, and more than 100 eggs at a time.

The dog. cat, goat, pig and fowl are domesticated. The buffalo, a smaller breed than that found in the Malayan peninsula, and in some districts bullocks of the Brahmin breed. zebu and small horses and goats are the principal domestic animals. The buffaloes are used not only as draft animals in agriculture but also as beasts of burden. Horses, introduced by Europeans and owned only by the wealthier classes, are raced regularly in Kuching and Jesselton. The use of native pack ponies has been encouraged by the government of North Borneo for many years. As a result, quite a good system of bridle paths (also used by zebu carrying trade goods) has been developed as far inland as from Mt. Kinabalu into the rich uplands farther south.

II. NATURAL RESOURCES

1. Water Resources.—Borneo is essentially a land of rivers. In all but the northern extremity of the island and the small but rapidly developing state of Brunei to the northwest, normal communications are by river. Between the interior and the coast. traffic, both passenger and commercial, is by the numerous, often mighty and frequently dangerously rapid rivers (see *Relief and Drainage* above). From one river system to another there is often no normal overland communication, nearly all contact and trade being made out of one river mouth by sea and into another. As rainfall is high and Borneo seas are tempestuous and wild during part of the year (see *Climate* above), this has been a considerable factor in sloning up the development of natural resources.

In such a setting, water resources tend to be too plentiful. But along parts of the coastal plain the Malay fishing communities may be short of nonsaline water, which is limited in time of drought (mainly August through September). Piped water is still almost unknown outside the towns.

2. Soils.—Generally speaking. Borneo soils are poor, largely leached out from sandstone and in the coastal area even from deposited (coralline) sands. Some of the swamp soils and those of the far uplands are good, however. But little is known about this scientifically, and serious soil research only began in the late 1950s (Sarawak and North Borneo) Outstanding volcanic soils occur in the now uninhabited Usun Apau (see Geology above) and in the northeastern corner of North Borneo, where valuable crops of tobacco and sisal are grown on a large scale.

3. Mineral Resources.—Borneo as a whole is poor in mineral resources which are sufficiently accessible and concentrated to be

exploited commercially. Thus gold, diamonds, antimony, mercury, gypsum and iron have all at some time since the beginning of the 19th century been exploited in inland deposits by predominantly native methods and mainly on an individual-producer basis. The story of gold extraction in southwest Sarawak goes back to the T'ang dynasty, when the Chinese bartered ceramics and cloth for gold from the headwaters of the Sarawak river over 1.000 years ago. Early in the 19th century antimony, which also occurs extensively at Bau, was highly valued, and it was this which largely influenced Sir James Brooke to settle in the area in 1841, to become the first white raja of Sarawak; mercury was important in the 1870s, and then coal (which occurs at several points behind the west coast) became important.

From about 1900 to 1910 gold was the significant export product of the Borneo territories; from 1910 onward major oil strikes were made along the coastal plain—at Balikpapan in the southeast, Tarakan Island in the northeast, Miri in the northwest and Seria in the state of Brunei 70 mi, north of Miri. The earlier fields have all faded; hfiri dwindled to about 66.000 long tons. while the two easterly fields suffered from the disturbed political conditions in Indonesian territory. The Brunei field, on the other hand, has prospered exceedingly and is one of the greatest in the world. exporting more than 90% of that tiny state's revenue. By the early 1960s Brunei was rapidly becoming the richest country, per capita. in the far east.

Gold is still mined in the south, even from Bau. Limestone for cement. granite for road and house building and cave guano for pepper fertilizer are all absorbed locally. But an important new resource, bauxite. first studied by the Japanese during World War II. has been developed near Cape Datu at the southwestern tip of the island. Effective extraction by a joint Swiss-Japanese-Canadian concern began in 1958.

4. Land Use.—About 75% of Borneo is covered in virgin jungle. high primary rain forest. or only secondarily man-influenced coastal swamp. The coastal plain reaches its greatest extent in the southeast. where waters may be tidal for up to 200 mi.. and vast deltas carry only nipa palm and mangrove swamp. Minor industries. mainly in Malayan hands. centre in these swamps.

The rain forest, clothing hill and mountain areas inhabited only by nomadic Punan groups. supplies a mean source of cash economy for most of the native peoples: gutta-percha: damar gum (a dye base); camphor; rattan; timber, floated down to coastal sawmills (and exported to Australia. Hong Kong and Europe): and the more esoteric but valuable items peculiar to Chinese pharmacy. notably—now that the rhinoceros is almost extinct—the intestinal "bezoar" stones of certain monkeys and other forest animals.

But the jungle. which until the introduction of rice in protohistorical times must have dominated everywhere, is slowly receding before the encroachments of the rapidly increasing population. Rice is the staple food. but not enough is produced on the island to meet the demand, Cultivation over much of the island is done by felling jungle on a cyclic basis. planting rice. supplemented by maize, cassava (manioc). cucumber and pumpkin, in a new clearing each year. Where the cycle is long enough. normally over ten years. this is an effective if laborious way of farming hill country. But it is evident that the system requires extensive available land. Borneans are conservative about splitting up communities or moving far from the crowd. In some areas, too. where the population is increasing rapidly: the felling cycle tends to grow shorter because of soil impoverishment. Fortunately new methods are being learned. Many are turning to their inland neighbours to learn by example. The outstanding native agriculturists are those inhabiting the upland plains—the Dusun in North Borneo, the Kelabit in northeastern Sarawak and the Murut in the northwestern corner of Indonesian Borneo—who have independently devised advanced methods of irrigation.

Tobacco is grown in the uplands and traded to the lo\l-land natives. Experimental plantings of coffee, cocoa and hemp have also suggested possibilities for the future. Throughout Borneo the problem of cash crops to supply needs in addition to family diet is difficult.

The introduction of *Hevea* rubber did much to meet the expanding demand for imported consumer goods in the first half of the 20th century Most of this rubber is gronn on small native plantations run at veiy low cost and is of inferior quality. After 1946 pepper was gronn increasingly by the indigenous people but on a large scale only by the Chinese Newer markets are for vegetables taken from the seeds of the *Shorea* palm, and for chicle a wild rubber used as the foundation of chewing gum and processed in a U S -owned factory at Bintulu (Sarawak). Coastal area exports are sago copra from coconuts cutch from mangrove bark and of course, marine products. (T. HN.)

III. THE PEOPLE

The ethnic composition of Borneo peoples, while less complex than much of Malaysia, presents some puzzling situations. On the island of Palawan, just north of Borneo, and in other parts of the Philippines as well as in the Malay peninsula are bands of nomadic pygmies, the Negritos. It is assumed that they once occupied most of the islands of the Malay archipelago, where they now appear as remnant groups. But no Negritos have been found in Borneo, although it would seem to be in the direct line of movement between present-day groups. and presents ideal conditions for their way of life. Traces of Negroid ancestry may appear in the modern population, but there is no evidence that the intermixture took place on Borneo.

Another problem is presented by a people known as Punan. Early explorers in Sarawak and other portions of North Borneo reported the existence there of nomadic peoples who built only flimsy shelters and lived on jungle produce or by hunting and fishing. They were described as of medium height and slender build! with round heads, noses medium but sometimes narrow, lips intermediate. Their skin colour ranged from light reddish-brown to yellowish tones. A. C. Haddon, who measured and photographed a considerable number of these people, considered them related to the dominant Malayan population, but still pronounced them a "puzzle." In central Borneo the term Punan in known but is there applied to all persons making temporary excursions into the jungle in search of rattan and other products. There is evidence of a unique, nomadic. Punan people in Sarawak and the north, with possible extensions to the south.

1. The **Dayak** Peoples.—The term Dayak or Dyak (Dajah), which has been generally applied to the non-Muslim groups of Borneo. should not be understood to refer to a uniform physical or cultura! type. It has about the same significance as the term Indian has for the American aborigines. In general it can be said that the interior Dayak seem to represent a population intermediate between the proto-Malayan and Malayan. (See MALAY ARCHIPELAGO.) Head form tends to be round. Stature is about 5 ft. 3 in.. noses are broad. lips full. hair dark brown usually straight but sometimes with a slight wave, eyes are dark and skin colour varies from light to dark brown. But such a general description does not take account of the considerable amount of variation that occurs within each group, perhaps due to intermixture prior to the population's reaching the island.

While there is no strong tribal grouping among the Dayak peoples it is customary to class together those having considerable in common, either in the dialects spoken, in cultural status or in social and religious organization.

The time of arrival in Borneo. the routes traversed and the earlier homelands are matters of speculation, but it is assumed that the earliest of the Dayak settlers are represented by a number of hunting-agricultural peoples in the interior, often classed together as Klemantan. Following them were the Kenyah and Kayan (sometimes called Bahau i. groups of higher culture that exerted considerable influence on the earlier peoples. The Kenyah and Kayan occupy the upland regions of the Kajan and Rajang river systems as well as the Baram basin. Still later came such peoples as the Ngadju of the upper Rarito and Kahajan systems; the Land Dayak of Sarawak and Sadong drainage: and the Iban or Sea Dayak, of the upper Rajang and Kapuas. The latter were ardent head-hunters, and because of their forays to the coast

were called Sea Dayak by the Europeans. They are. however. a riverine people. Other aboriginal groups to be noted are the Murut and a subdivision known as the Dusun of North Borneo. They are \vet-rice cultivators. On the plains near the coast in Sarawak is a group called the Melanau, which has maintained its identity despite its location and the fact that it has accepted Islam. Within these broad categories are many subdivisions presenting minor variations.

The Dayak *Village.*—The general form of Dayak residence is the long house. A single dwelling may take care of all the people in a village, or a settlement may have two or more such structures. Kenyah and Kayan and Land Dayak houses sheltering as many as 50 families have been reported. While there is considerable variation in size, construction and interior arrangement. the long house can be described as a ridge-roofed building raised high above the ground on hardwood piles. It is divided lengthwise into an outer hall or corridor and inner family compartments. Entrance is by means of a notched log or bamboo ladder. The undivided hall serves as a general gathering place; there also are stored paddles, fish traps, pots and various other articles of daily use. The heads of enemies secured in battle were hung near the entrance. In such a village the family is the basic unit and children remain with their parents until married. A boy usually seeks his bride outside his own village and goes to live in her community. There is no tribal or other organization above the village: but there is a feeling of unity between those closely related in language, custom and marriage. Among the Iban and Land Dayak class distinction is absent. but three strata of society are recognized by the Kayan and Kenyah. The upper class consists of the family and near relatives of the village chiefs, while the lowest is made up of captives of war and other persons looked down upon for various reasons. W. R. Geddes characterized the religious practices of all the Dayak as concerned with promotion of the general 11-ell-being of the people. the growth of crops and with curative practices. Malevolent forces must be appeased, while friendly ones should be rewarded by gifts and ceremonies. Wishes of superior beings may he made knon-n by omens. such as the flight of birds: the appearance of the liver of a sacrificial animal, or by dream experiences. Favourable beings comprise, for the Iban, a pantheon of more than 300 individuals, each with special interests or powers. Certain persons communicate with the spirit world during ceremonies. Invocations which are chanted may describe a journey to the skies and the eventual visit of the superior beings to the long house. Belief in multiple souls, some of which may wander. leads to soul-catching by the mediums.

An intimate picture of a people who spend most of their lives wresting a living from the jungle was given by J. Provinse for the Siang Dayak of central Borneo. The Siang are found in about 50 small villages situated on the Barito river or streams tributary to it. Each settlement has a headman and an informal council chosen by adult men. An unorganized group. usually men known as *blians,* conduct ceremonies. Head-hunting, carried on for prestige. revenge or to gain favour with the spirit world. was formerly prevalent there as in most of Borneo, but under Dutch rule was nearly stamped out.

In connection with the ceremonies. war celebrations and the like. dances are held in the corridor of the long house. Men clad in breech clouts and rattan caps adorned with argus pheasant feathers enter the open space armed with spears, shields and long knives. Then to the music of copper gongs beaten by women, they go through all the movements of combat. At such times much rice wine is consumed and there is considerable promiscuity.

Agriculture.—The major activities of the people are connected with the cultivation of dry-land rice. A gently sloping hillside is chosen and the underbrush is cut. Starting at the bottom of the plot the larger trees are deeply notched on the up- and downhill sides. One or two key trees near the top of the hill are felled in such a manner that they carry the trees below them to the foot of the hill. Large branches are cut off and the felled trees and brush are allowed to dry until ready for burning. A second burning may be necessary to get rid of larger branches not fully consumed. Such a cutting and burning takes much time, but it furnishes a field free from grass and fertilized by the ash. Planting consists of punching holes in the ground with sharpened sticks and dropping in three or four kernels of rice. There is little need of weeding, but the growing crop must be guarded against monkeys, deer, rats and birds. Small houses are constructed in the fields and from these women and children watch and drive off intruders. In five or six months the grain is ripe and is cut, spear by spear, with small crescent-shaped blades. Finally the grain is threshed and is stored in large baskets. There is no private ownership of land beyond the period of use. To clear a chosen plot requires co-operation, and at least two or three families will exchange labour. In some cases 10 or 20 persons may work together, spending a day in succession at each plot. At this time the occupant furnishes food for the day. A field may be used for two or three seasons, but eventually it becomes less productive and is invaded by a rank grass. It is then abandoned and the entire process is repeated on another site.

Some of the men's time is spent in hunting, in which they use the spear and a blowgun fitted with poison darts. They fish and gather jungle fruits and other produce — such as gutta-percha and rattan. Women and children also fish: gather shellfish and roots. Travel for any distance is by means of a dugout canoe, for movement through the dense forest is difficult and formerly was hazardous for all but war parties.

2. Malays. — Along the coasts. and in some areas penetrating the lower river courses, are the Islamic peoples generally classed together as Malays. This population doubtless comprises early comers to the island as well as later immigrants from various parts of Malaysia--Java, Sumatra. Celebes and the Malay peninsula. Prior to the 15th century the influence of the Sumatran and Hindu-Javanese empires to the south had led to the development of petty states along the coasts with resulting cultural changes; particularly in the ruling class. Later these courts, and ultimately most of the coast peoples. were converted to Islam. Trade centres of considerable influence and wealth had developed prior to the arrival of the Europeans. Of particular importance was Brunei in northwest Borneo, described by early Spanish explorers as a place of wealth and splendour. partially built out over the water.

The culture of the Borneo Malays follows the general Malay pattern but represents various stages. There are simple interior settlements dependent on dry-land agriculture and raft villages of Malays who travel far up the southern rivers to trade with Dayak peoples. On the coast are fishing villages which stand in sharp contrast to the rather elaborate courts of the sultans. The bilateral family is the typical unit, but since Islam permits polygyny and easy divorce, marriage unions are rather brittle. Wealth and political position lead to class distinctions, particularly in the larger settlements.

3. Chinese. — Chinese contacts go back more than 1.000 years but were not important in modern times until the 19th century. Chinese traders, artisans and labourers are found in most of the Malay areas. especially in Sarawak and North Borneo. They dominate small business concerns and are important in commerce. They are also engaged in the production of rubber, rice,, coconuts and vegetables, usually in small holdings,

Europeans. while exercising great influence in recent centuries, are few in number. consisting mostly of government officials, traders, planters or miners.

(F.-C. CE.)

IV. ARCHAEOLOGY

Little was known of the great island's rich prehistory until 1947, and nothing had then been excavated. Since 1947, energetic excavational and related fieldwork has been carried out by the Sarawak museum throughout Sarawak, the adjacent state of Brunei and, on a small scale, in North Borneo. Existing information for a great area of Indonesian Borneo is almost negligible, apart from the well-established finds of certain Bud-

dhistic and Hindu-related figures in southern Borneo years ago.

For the western half of Borneo. the three British territories. the picture is now considerably clearer. The classic site to date was discovered in 1947 and has since been excavated on a very considerable scale. This is the great cave at Niah. 400 mi. northeast of Kuching. the capital of Sarawak, and 1 j mi. inland along a small river behind the South China sea. The present Niah picture includes a carbon (C^{14}) dating of 40.000 years at what is only a medium level in the deposit. much of which remains to be excavated. From 40,000 years ago and more. there is an almost unbroken succession of human frequentations and occupations of the cave continuing on into the arrival of a massive Chinese trade starting in the T'ang and Sung dynasties (A.D. 618 to 1279).

S o pre-hominid types, such as *Pithecanthropus* of Java: have yet been found in Borneo — though there is fair reason to expect them. Meanwhile. the Niah site provides a unique sequence of the evolution of stone tools from early hand-chopping axes. which are massive pebbles simply struck on one side to a point; through the development of flake tools; then finely edge-ground tools of the Mesolithic; on into the beautiful black polished adzes and axes of the Seolithic or Late Stone Age. A fine set of wall drawings. provisionally attributed to the Early Metal Age. has also been found in one of the caves. These, too, are so far unique in southeast Asia. They are associated with decorations showing the journey of the "ship-of-the-dead" to the spirit world. Underneath the drawings, on the floor of the cave. more than 100 ft. above the valley floor. beautifully carved model boats have been used as coffins for the deceased.

The Early Metal Age materials at the Niah caves are closely paralleled by those found in other excavation sites in the Sarawak river delta. at the southu-est corner of the island. There about 30 separate places have been mapped as prehistoric monuments. in n-hat must have been an enormous trade between the Asian mainland and western Borneo reaching back for more than 1.000 years. The mainland appears to have brought primarily ceramics. metal and probably clothing. In return they received edible bird's-nests. rhinoceros horn, hornbill ivory (*ho-ting,* one of the most valuable materials for carving in ancient China. and only to be obtained from this area). camphor, spices. woods, bezoar stones! rattans. etc. With whom they actually traded is not yet clear. The nature of an earlier people is overlaid by many generations of interbreeding n-ith existing groups. It is probable, however. that the Kelabit of the far uplands. who still practise an active Megalithic culture with the erection of stone monuments and many other specialized features. may be a survival in comparatively pure form of an earlier stock. The Ngadjus of southeastern Borneo, who still have survivals of the "ship-of-the-dead" cult in their contemporary beliefs and art. are also probably near to Niah man in his later phases.

From the existing information and reasonable amount of speculation, the sequences ior western Borneo in particular, which probably apply also to much of Bornco. may be tentatively stated thus:

About 300,000–500,000 years ago	Lower Paleolithic: *Pithecanthropine* pre-*Homo* fossils not found in Borneo but certain in Java, which was then connected by land bridge
About 100,000–50,000 years ago	Mid-Paleolithic; *Homo* types, with hand-chopping tools; at Niah
c. 40,000–10,000 B.C.	Cpper Paleolithic; developing stone and bone tool;; rich at Niah
c. 10,000–5,000 B.C.	Mesolithic; reworked and edge-ground stone tools; Niah and elsewhere
After *c.* 5,000 B.C.	Neolithic; polished stone tools, beginnings of other arts (pottery, careful burials, etc.); widely distributed
c. A.D. 10	Bronze Age; enriched culture with much outside contact; widely distributed
A.D. 500	First Iron Age: Chinese and Indian trades benin; widely distributed on coastal plain
A.D. 1000	Full Iron Age; major mainland commerce, very widely distributed (to west and north); reaching iar inland
A.D. 1550 onward	European (Spaniards. Portuguese, etc.)

Borneo is placed at the corner of southeast Asia in such a way that, in relation to monsoon winds, sailing routes and straits. it must long have held a vital position in the prehistoric trade between east and west. This has made the local picture particularly complicated for the later periods. On the other hand, lying at the extremity of Asia in the continental shelf. Borneo's position is easier to interpret for the stone ages. In some respects. it shows specializations and localizations of Stone Age technique different from those found anywhere else. Others are paralleled as far afield as the Sohan culture in northwest India.

See especially *Sarawak Museum Journal* no. 3–13 (1950–59); T. Harrisson, in Man (1959). (T. HN.)

V. HISTORY

Borneo was one of the last areas of Malaysia to be explored and exploited. Early Arab legends depicted the island as a land of spices. gold and jewels, much exaggerating the limited production of these prized commodities. In general the swampy coast line, the difficulty of access to the interior. the poor weathered soils and the warlike disposition of and constant friction between the various native groups combined to discourage intervention and settlement in Borneo until the more productive areas had been utilized. Very little is known about the prehistory of Borneo. There have been scattered archaeological excavations in many parts of the island. but investigation on an extensive scale started only after World War II, mostly in Sarawak. (See *Archaelogy* above.) So far these excavations indicate that Chinese influence was probably greater than previously supposed; Indian influence less important; and that little as yet can be determined about the early inhabitants of the island. Evidence of the presence of man in Borneo dates from the end of the Ice Age. perhaps about 25,000 to 50.000 years ago. Since that time successive migrations from Malaysia spread over Borneo. each being influenced by. but displacing. the preceding wave. Each migration contributed to the composition of the present population. but the predominate element has remained Indonesian. who started to settle in Borneo about 2,000 years before the Christian era. (See The People, above.)

1. Early History. — Perhaps the earliest external influence was Chinese. Many specimens of Han period sepulchral pottery found in east Borneo indicate Chinese trade (and the remote possibility of settlement) in the 1st century B.C. and perhaps as early as 400 B.C. Early Chinese contact with Borneo was primarily for trade in gold; resins and medicinal items such as the prized Borneo camphor (borneol). Such trade was facilitated by the Chinese sea route to southeast Asia. which probably passed along Formosa to the Philippines and thence to Borneo: thus the island was known at an early stage of Chinese exploration in Malaysia. Buddhist pilgrims and travelers from China also visited the area in the 4th century A.D.

While early Chinese contact with Borneo was mainly commercial. the major cultural influence was Indian, coming to Borneo via Sumatra. Java and Malaya. The earliest evidence of Indian or Indian-Javan influence is the Sanskrit religious inscriptions of King Mulavarman in the Mahakam or Kutai area of east Borneo. which date from about 400 A.D. In addition. Gupta-style statues of Buddha. dating from the jth century, have been found in the Kapuas river area and other areas of western Borneo. It is possible that Borneo is the Yavadvipa, or the land of gold and silver, referred to in the Hindu epic *Ramayana.*

It is probable that the great Sumatran sea state of Sri Vijaya controlled sections of the coast of Borneo during the 12th century. During the late 13th century, southwest Borneo acknowledged the suzerainty of Kertanagara, the great king of the Singasari period in Java. With the rise of Majapahit, Singasari relinquished control and the mid-14th century much of Borneo became a protectorate of this great Hindu-Javan state. m-ith the decline of Majapahit in the early 15th century and the rise of Islam in Malaysia, the local states in Borneo were converted to Islam and assumed greater individual power. Although the Dayaks and other tribal groups of the interior never accepted Islam. the southern coastal areas were rapidly converted by Xrab and

Javanese traders. In the north. the state of Brunei was converted to Islam when the ruler married a princess of the royal house of Johore. and relations with the Malay peninsula became closer. When Antonio Pigafetta visited Brunei in 1521 the ruler had been converted to Islam. Brunei threw off the suzerainty of Muslim Malacca in the late 15th century. After the rise of Portuguese power and the capture of Malacca by the Portuguese, many Muslim. merchants moved to Brunei, which became an important centre of Islam in Malaysia. A considerable sea power, Brunei extended control over all of Borneo, the Sulu archipelago, and even captured Manila in the Philippines. It mas one of the great sea states of Malaysia. and via early European travelers gave its name to the entire island. The name Borneo. which appeared first on 16th-century European charts, is a variant of Brunei. and was probably used because Brunei was the most powerful state on the island at the time of the first European contact with the area. The native or Indonesian name for the island has long been Pulau Kalimantan (Klemantan).

European knowledge of Borneo dates from travelers who passed through southeast Asia in the 14th century, although it is first mentioned in western literature in Ptolemy's *Guide to Geography* of *c.* A.D. 150 where "Iabadiou" ("Island of Barley") probably refers to Borneo. Marco Polo reported considerable junk traffic between Brunei and China, but probably never visited Borneo. The first European visitor was the Franciscan friar Odoric of Pordenone, returning to Europe from China in 1330, to visit Talamasim in Borneo. (*See* ODORIC.) Other travelers include Borneo in their reports. but the first accurate descriptions came from the Portuguese in the 16th century who sailed via the coast of Borneo on the way to the Moluccas, or Spice Islands, and called at some of the ports along the way.

After the capture of Malacca, on the west coast of the Malay peninsula, by Portugal in 1511, Affonso de Albuquerque dispatched Antonio d'Abreu with three ships on a voyage of discovery to the Moluccas. D'Abreu, sailing in a southeasterly direction from the Strait of blalacca, skirted the southern coast of Borneo and laid up his ships at Amboina. He returned to Malacca in 1514, leaving one of his captains. Francisco Serrão, a kinsman of Ferdinand Magellan, at Ternate, where the latter's followers found him still living in 1521. After Magellan's death, his comrades. sailing south-south-by-west, entered the Brunei river and landed at Brunei town. Pigafetta. the historian n·ith Magellan's expedition, described the city of Brunei as having more than 25.000 families. and described too the splendour of the court of the sultan. In 1526 Jorge de Menezes visited northern Borneo; in 1530 Gonsalvo Pereira described the area; and a map of the Indies by Mercator. published about 1595, shows many place names of Borneo. During the remainder of the 16th century Borneo was frequently visited by the Portuguese: who established a trade with Brunei. Of this the Spaniards tried unsuccessfully to win a share. which they attained in 1580, through supporting a claimant to the throne of Brunei who had appealed to them for aid. Thereafter the commercial intercourse between Brunei and the Spaniards mas intermittent and hostilities frequent.

At the beginning of the 17th century the Portuguese and Spanish monopoly of trade with and around Borneo was broken by the Dutch and British, who were attracted by diamonds, gold and the pepper trade. However, most of these contacts were short-lived and attempts to control the trade of the island were periodic and unsuccessful. Javanese had settled along the south and east coasts, and Malays and Bugis were scattered along the other coasts. Borneo at this time was composed of a series of small sultanates or states; often mutually antagonistic, and each jealous of its own rights and prerogatives.

One of the main reasons for British and Dutch intervention in Borneo was the prevalence of piracy in the area. Many of the people along the Borneo coasts and adjacent areas had a long tradition of seafaring. and during the pre-European period were the middlemen in trade throughout Malaysia. With the arrival of Europeans and the establishment of trade monopolies, native commerce mas curtailed, and many of the sea people turned to piracy—long a highly respected and profitable occupation in the Malay world. European vessels were usually too well armed to attack, so the pirates chiefly attacked other native traders. wiping them out of business and in turn creating more pirates. As their fleets grew larger their zone of activity expanded, and pirate empires were created. such as those of Brunei and the Sulu archipelago. Pirates dominated the coasts of Borneo. raided in the Strait of Malacca and even into the Indian ocean. Most notable were Balanini of the Sulu archipelago, the Lununs of southern Mindanao. the Bruneis and Sea Dayak of the Xorth Borneo coast, the Malays of the Malacca strait, at one time the Bugis of the Makassar area and later the Chinese. European powers gradually eliminated'them from the waters around the Malay peninsula, but found it more difficult in the Borneo area where they did not control the land. It was with the aim of controlling piracy that led to Dutch and. particularly. British intervention in Borneo.

2. Dutch Influence. — In 1600 a Dutch expedition under Olivier van Noort called at Brunei. In 1606 the Dutch East India company (*q.v.*) entered into trade relations with the sultan of Sambas. In 1609 they built a factory in the Sambas district of the west coast, and appointed a factor at Landak and Sukadana. In 1606 the Dutch opened trade relations with Bandjermasin, and in 1635 trade with Kutai on the east coast commenced. Most of these early contacts were short-lived, and the changing fortunes of local dynastic disputes, trade rivalries and wars between different sultanates resulted in the expulsion of the Dutch and the closing of their factories. In 1623 the factory at Sambas was abandoned, and in 1669 the Dutch relinquished their interests in the Bandjermasin area.

Bandjermasin attained importance as a smuggling centre. which prompted renewed Dutch attention to retain control of commerce in the East Indies. In 1711 the Dutch opened trade relations with Bandjermasin, and built a factory there and another on Tatas Island in 1747. Somewhat later. a fort was erected at Tabanio to protect the factories. In 1787 the sultan was induced to cede his whole state to the Dutch East India company. but trade with the area was not rich in comparison with other areas of the Indies, and in 1809 the factories were abandoned as unprofitable. The Dutch had also established relations with the state of Pontianak, west Borneo, in 1771, and factories were built in Pontianak and Mampawah; these, however, were abandoned in 1791.

When the British occupied Dutch holdings in Malaysia during the period of the Napoleonic wars, Sir Stamford Raffles, then the British governor-general of Java. answered a request for aid from the sultan of Bandjermasin by sending Alexander Hare to act as agent. The British worked to establish themselves in Borneo during this period, but in 1816 the peace treaty restored Dutch interests in the island and the British withdrew. Dutch influence gradually reasserted itself in the south, and in 1826 a treaty was signed with the sultan of Bandjermasin, who ceded to the butch areas on the east coast of Borneo. gave them the right to appoint a successor to the throne and to administer the state. War in Java turned Dutch attention and resources away from Borneo, and resentment at their interference with the succession eventually resulted in revolt. After a prolonged period of friction, the Dutch abolished the sultanate and declared Bandjermasin and its dependent areas to be Dutch territory. Opposition and revolt continued for many years and was not finally settled until 1886.

The state of Kutai. in east Borneo. had no official connection with the Dutch, but George Müller, while exploring in this area, obtained an acknowledgement of Dutch authority, and in 1844 a treaty was signed. A resident was appointed in 1846 and by 1908 a large measure of Dutch control was established in eastern Borneo. Tarakan Island, in the north. had come under Dutch control in 1850. The interior of Borneo. inland from Bandjermasin and Kutai, was explored in the late 19th and early 20th century and came under effective Dutch control in 1911. A. W. Nieuwenhuis, in the years 1893–98, explored much of the interior, but by the latter half of the 20th century the area was still not completely known.

The various states on the west coast had been constantly harassed by piracy and local quarrels, and the rulers and Chinese merchants gladly accepted Dutch overlordship to rid themselves of this menace. The Dutch were re-established by 1824, but were

constantly embroiled in local wars. In the middle of the 18th century, attracted by diamonds and gold, there was a large migration of Hakka or Kheh Chinese from south China to the Sambas and Landak areas of west Borneo. About 1760, Chinese gold miners employed by the sultan of Sambas' rebelled (with ample provocation) and took over the gold mines and considerable territory. This led to clashes with the Dayak population and coastal Malays. and added to the chaotic situation in this part of Borneo. The Chinese pushed inland and cut timber, planted pepper and engaged in extensive trade. Jungle produce, *bêche-de-mer*, rattan. shark fins, tortoise shell, bird's-nests, as well as pepper and Borneo camphor. were important items of commerce, and trade with China boomed.

As the number of Chinese increased in west Borneo they formed themselves into so-called "Kongsis." or small self-governing communities which paid small attention to the local sultans or the Dutch government. When the Dutch resumed control of their Borneo territories they were determined to establish control over western Borneo. They were attracted to the rich Chinese-controlled mines. and their subsequent actions were facilitated by an appeal from the sultan of Sambas for aid against the Kongsis. The sultan gave the Dutch the authority to purchase the mines. and starting in 1818 they sent military expeditions into the Chinese areas. A long period of warfare commenced. Eventually. because they controlled the sea, the Dutch won. and the Kongsis were defeated by 1854. The Chinese revolted in 1884 because they felt the Dutch were violating the terms under which Kongsi power had been abdicated. The Dutch victory over the Kongsis was an empty one, for during the long period of war the Chinese in the interior had been cut off from trade and had learned to live without it. Moreover. all immigration from China had ceased. The main ports, such as Singkan-ang and Pontianak. once prosperous trading centres for Chinese junks. did not recover their forsner importance. Mines had been abandoned. and some observers considered that by the early 1960s western Borneo had not recovered from this painful period.

3. British Influence. — The British had reached Borneo in 1609. but proceeded slowly in establishing trade relations. There was intermittent trade with the Bandjermasin area as early as 1614. but the British East India company was not able to establish a factory there until 1701. A good trade in pepper developed. and in' 1706 the British solidified their hold by the construction of a fort, but were expelled the following year. with the assistance of the Chinese. because they had been interfering n-ith native shipping. The pepper trade with southern Borneo was resumed in 1737, and continued until 1756 when the Dutch obtained from the sultan of Bantam a trading monopoly in his Bornean territory. In 1612 the British had established a factory at Sukadana. southwestern Borneo. Dutch competition stifled the British attempt. and when the factory was destroyed by a Javanese force in 1622 the British company withdrew.

By the middle of the 18th century the British had failed in attempts to establish trade n-ith south Borneo. but in 1762 a British expedition sent to capture Manila was ceded the island of Balarnbangan and the Sabah peninsula at the northernmost tip of Borneo. by the sultan of Sulu in gratitude for his release from Spanish captivity. The British also briefly occupied the island of Labuan (*q.v.*) at this time. A fort was built on Balarnbangan Island in 1771, but four years later n-as attacked and destroyed by the local chiefs who resented the cession of their territory. This action also negated a treaty of trade which had been signed with Brunei in 1774, and ended. for the time being. British influence in Borneo, partly because British interests had turned to the Malay peninsula as a control point on the sea route to China.

Chaotic conditions in Sarawak. the southern province of the sultanate of Brunei. provided the opportunity for the re-establishment of British influence in northern Borneo. In 1839. the Dayaks and Malays in Saran-ak rebelled against the oppressive rule of the sultan's governor. At this time James Brooke, a former officer with the East India company. arrived in Sarawak. and in return for his services in putting down the rebellion he n-as promised the title of raja and control of a large area of Sarawak. After some difficulty in getting the sultan to honour this agreement, Brooke was installed as raja of Sarawak in 1841. The next few years were spent in the suppression of piracy and head-hunting. often with the aid of British naval forces.

During the wars between the Dutch and the Kongsis in the 18 jos, there was considerable migration of Chinese from the Samhas district into Brooke's domain. The Chinese, aroused by the second Anglo-Chinese war then in progress. formed a secret society intent on taking control from Raja Brooke and establishing an independent state. In 1857 the Chinese seized the capital, Kuching, and forced Brooke to flee. but the Malays and Dayaks of Sarawak put down the revolt and restored order. The Chinese remained in Sarawak, and aided by migrants they formed one of the important elements in the country. Chinese also continued to migrate to Brunei and their migration to North Borneo was encouraged in the 19th century by the British Chartered company in order to obtain a supply of labour for the exploitation of the country. In the late 19th century large-scale Chinese immigration saturated the labour market; since that time sounder immigration policies have been established.

Under the provocation of the pirates who kept moving their bases of operation eastward. Brooke extended his control over all of Sarawak west of the Rajang river by 1861. By stages, the Brooke family extended control over more Brunei territory, under the rationale that the sultan's control was either ineffective or oppressive. By 1890 the sultan of Brunei controlled only a small portion of his original domain. In 1850 the United States recognized Sarawak as an independent domain. and recognition was given by Britain in 1864. In 1888 an agreement with the British government placed Sarawak under British protection. but the Brooke family maintained control over all domestic affairs. (See BROOKE. SIR JAMES; SARAWAK.) At this time there was great need for a coaling station to serve the rapidly growing steamship traffic to China. and Brooke had observed seams of coal in Brunei and on the offshore island of Labuan. In 1846 the British government accepted an offer from the sultan of Brunei to cede Labuan. and appointed Brooke governor of the new colony. The Dutch. also anxious to obtain coaling stations, protested the cession as a violation of a treaty signed in 1823 by which the British renounced activities in the Indies. Their protests were unsuccessful; but the activities of Britain in the north tended to stimulate Dutch interests in the consolidation of southern Borneo, and they developed coal supplies in Kutai on Laut Island off the southeastern coast of Borneo. Labuan became a British naval base, important in the suppression of piracy in Borneo waters.

Toward the end of the 16th century the power oi Brunei started to decline, principally due to the loss of trade to the European pon-ers. Anarchy and piracy prevailed, and under a variety of circumstances the sultans of Brunei were forced to give up the territories comprising Saran-ak. North Borneo and the island of Labuan. so that within a period of 100 years Brunei was reduced in area from the northern third of Borneo to a small territorial enclave surrounded by its own lost territory. In 1847 the sultan had entered into a treaty with Britain to expand commercial relations and aid in the iuppression of piracy. In 1888 a new treaty made Brunei a British protectorate. and in 1906 Brunei agreed to accept a British resident. Conditions gradually improved during the period before World War II. and a productive oil field near Seria was developed which made the small sultanate very prosperous. (See BRUNEI.)

North Borneo came under British control at the end of the 19th century. In 1872 the sultan of Sulu gave William Cowie, a gunrunner, permission to establish a base on Sandakan hay. Cowie was also given other trading privileges in North Borneo, but he ran into oppoaition from an American. Joseph William Torrey. who claimed trading privileges for the area under an older grant from the sultan of Brunei. Torrey joined n-ith Baron Gustavus de Overbeck nho represented a private syndicate headed by two English brothers. Alfred and Edward Dent, and although the sultan of Brunei had no right to cede the territory and despite the protests of the Spanish and Dutch governments who had claims in the area. the Dents became the possessors of a large par: of North

Borneo for which they paid an annual rent to the sultan of Brunei. They then formed a limited provisional association. which became the British North Borneo company in 1882, incorporated by royal charter. In 1833 the state was made a British protectorate. and for the next 20 years territorial consolidation took place, the final boundaries being defined in 1905. (See BORNEO, NORTH.)

4. Mid-20th Century. — During World War II. the Japanese invasions of Borneo in 1941–42 quickly eliminated the token British and Dutch forces on the island, and all of Borneo passed under Japanese control. The three and one-half years of occupation was marked by oppressive measures, particularly directed toward the captive Europeans and the Chinese community. Borneo was one or' the first areas in the Indies to feel the force of .Allied action. From 1944 on the Allied air forces raided all over Borneo, concentrating on the oil fields and port installations. The island of Labuan was reoccupied by Australian forces in June 1945, and Tarakan Island shortly thereafter. British military government was established in the northern areas of Borneo, and reconstruction began. The raja of Sarawak ceded the protectorate to Great Britain, and on July 1. 1946, it became a crown colony. The reconstruction and development of Borneo was beyond the resources of the chartered company, and North Borneo, including Labuan, became a crown colony on July 1j. 1946. Adjustment in legal and administrative procedures resulted in a greater integration of the three British holdings, but they retained their separate identity. There has been expanding political awareness in these colonial areas, but no widespread move for independence.

In Dutch Borneo a strong nationalist movement developed. and led to fighting between Indonesians and the Dutch forces. British troops were landed to restore order, but the independence movement flourished. Transier of sovereignty by the Netherlands to the Indonesians took place on Dec. 27. 1949. (See INDONESIA.) In Aug. 1950 a new constitution was proclaimed and Dutch Borneo became part of the Republic of Indonesia. It constitutes one of the ten provinces of the republic, under its traditional name. Kalimantan. (L. A. P. G.)

VI. POPULATION

The population of Borneo is extremely varied. with two-thirds of it in Indonesian territory (Kalimantan), for which no reliable statistics have been available since before Japanese occupation in World War II (1941). The population in general is rapidly increasing. especially among the Sea Dayaks and Chinese. But the island as a whole. including huge tracts of the interior, is sparsely inhabited by Asian standards. The total is probably still less than 5,000,000, of whom 648,362 were estimated for Sarawak (end of 1957), rather less in North Borneo, 74,646 in the state of Brunei and the balance in Indonesia.

This population may be divided into four main elements: the native Dayak and other inland inhabitants. about 2,500,000; Chinese, about 1.000.000; Malays and other coastal Muslims, about 750,000; others (Europeans. Indian, Javanese, etc.). about 25,000. The first of these: the Dayak peoples. the former head-hunters of Borneo, are divided into a multitude of cultural and dialect groups of which the largest are the Iban or Sea Dayaks (about 300.000 in Sarawak and Indonesia). the Kayan and Kenyah (about 100,000, mostly in the Kajan section of Indonesia ı and the hill peoples of the northern interior — Kelabit. Murut, Tagal and Dusun especially. These pagan animists are rapidly being converted to various branches of Christianity. Most of them live in long houses, continuous dwellings housing many families. But the Bisaya and Belait of the subcoastal northwest and the Tidong in the northeast live in square houses with no walls. About 5,000 nomadic Punans roam the mountainous hinterland of northern Sarawak and western Indonesian Borneo.

The Dayak peoples are Borneo's farmers and primary suppliers of jungle produce. Trade is largely in the hands of Chinese middlemen. Although there is indisputable evidence of the presence of Chinese traders for the past 1,000 years (see *Archaeology* above), there was a break in occupation during the Ming dynasty, and the present Chinese population — of many iubraces — is relatively recent. The Malays play a major part in the adrninistration of all the territories. having a tradition of public service. The others live in the larger towns and are concentrated about the administrative centres of Sambas, Jesselton. Sandakan. Brunei town. Sibu, Kuching, and in the oil fields of Seria, Kuala Belait, Miri, Tarakan. Balikpapan and Bandjermasin (see Tlze People, above). See also references under "Borneo" in the Index volume. (T. HN.)

BORNEO, NORTH, a British colony since 1946; formerly a protected state under the British North Borneo chartered company. It occupies the northern tip of the island of Borneo (*q.v.*) in the East Indies and is about the same size as Ireland. It is largely composed of mountainous jungle terrain, and much of it is sparsely inhabited. An extensive coastal plain on the west and rich volcanic soil to the southeast provide centres of activity and development.

Physical Geography. — A strongly irregular, 900-mi. coralline coast line encloses an area of 29,388 sq.mi., mostly of sandstone soils and jungle. The area is dominated by Mt. Kinabalu (13,455 ft.), the greatest mountain massif in southeast Asia. first ascended by Sir Hugh Low in 1851. Kinabalu appears on the coat of arms of the colony. is the spirit homeland for the indigenous Dusuns, and has a specialized fauna and flora on its upper levels of nearly bare black granite. Trus Madi (8,500 ft.), to the south is the second highest mountain, in a great tangle of ranges which serrate the interior; there are. however, a series of alluvial upland plateaus stepped down from Ranau through Tambunan southward to Keningau and the Padas river. which are fertile and closely irrigated by the inland Dusuns. Unlike the other territories. North Borneo has only one great river: the Kinabatangan, that is navigable far inland. Travel is predominantly overland, by jeep, pony. buffalo or on foot, and is often arduous. Several deep bays provide good ports. Victoria on the island of Labuan (formerly one of the Straits Settlements). Jesselton (the capital). Kudat and Sandakan (the centres of the export tradej and Tawau near the Indonesian border.

Population. — The inhabitants numbered 454.328 in 1960 as compared with 334.141 in 1951. There were three main native groups: the Dusuns (145,650), living mostly in small villages to the north and west as rice agriculturalists; the Murut (*q.v.*) or Tagals (22.313). who lived in jungle long houses in the southeastern interior: and the formerly seagoing Muslim Bajaus (61,838), many of whom had moved inland and become cattle and irrigation farmers on the Kinabalu foothills. Smaller Muslim coastal groups included the Brunei Malays, Illanuns. Suluks. Kedayans and Bisayas. In 1960 there were 104.855 Chinese, who controlled most of the country's trade. At the same date there were 1,807 Europeans and Eurasians. mainly in administration. commerce and on the larger plantations.

History. — North Borneo's connections of the past have largely been with the Philippines to the north, and included many move-

ments of men and ideas to and fro over thousands of years. The largest indigenous group, the Dusuns, are closer to the Visayan and Sulu peoples of the Philippines than to the Dayaks of Sarawak and Kalimantan in Borneo. Only the Muruts represent a strongly southern stock. Contacts with the Asian mainland were never so strong as farther south and west in this great island. The first Portuguese and Spaniards came to Borneo in the 16th century, but it was not until the Scottish voyager. Alexander Dalrymple (*q v.*), sailed the Sulu sea in 1759, that western contacts reached large proportions. The East India company settled Balambangan Island, off the northern tip of Borneo, in 1773, abandoned it in 1775, re-opened it in 1803 and finally gave up in 1805 (14 years before Sir Thomas Stamford Raffles founded Singapore).

The British occupied Labuan as a crown colony in 1846 but did not return to the mainland until 1877, when a private syndicate (later to become the British North Borneo company) obtained grants of land from the sultans of Brunei and Sulu, hitherto unchallenged sovereigns in the north. Among those associated with the group was Admiral Sir Henry Keppel, intimate and ally of Sir James Brooke in founding Sarawak (*q.v.*) 40 years before. After some initial competition from the Sarawak administration, the company, under royal charter, reigned unchallenged from 1882. Good government slowly won control over a situation previously bordering on anarchy. because of intertribal feuding, the decay of outside Muslim leadership and local but vicious piracy. By a series of further land grants from the Brunei nobility, North Borneo acquired its final shape in 1898. although in 1948 some small "turtle islands" to the north were handed back to the Philippine government, in settlement of an old claim that the Sulu sultanate had acted out of order by ceding them.

These measures of control aroused sporadic opposition from certain native peoples. who felt their own interests had been inadequately considered. In 1899, this opposition flared into wider revolt, led by a Muslim Bajau, Mat Salleh, long an irritant influence. It required Borneo's first major paramilitary operation finally to liquidate his forces and destroy him in a long and bloody siege of his last-stand fortress. (nith stone walls 8 ft. thick) near Ranau. in the shadow of Mt. Kinabalu. early in 1900. His disciples continued to give trouble, and made one serious raid on the hamlet of Kudat, but harmony eventually prevailed.

During the first half of the 20th century extensive rubber plantations and smaller coconut plantations were developed with European capital, followed by tobacco (at Lahad Datu) and timber extraction. The peaceful pattern was harshly broken during World War II by the Japanese, who forcibly took over all of Borneo in 1941–42. During the next four years, administration. social services and business organizations came nearly to a standstill. Interior areas reverted almost to the Stone Age The return of British officers of the Service Reconnaissance department led by Col. G. Chester and Maj. N. Combe raised a second paramilitary operation of all races to expedite the country's liberation. This was finally achieved by the landing of the Australian 9th division on Labuan and near Beaufort in June 1945. After a year of military administration. crown colony status was granted to the area and the island of Labuan (previously administered from Malaya) was incorporated as an integral part. In the years that followed, North Borneo developed without disturbance.

Administration and Social Conditions.— The colony is divided into four residencies: Tanau. Sandakan, Jesselton and interior Keningau, with Labuan Island as a semiautonomous senior district and, since 1956, a free port. Much administration and traditional law is handled by native chiefs and village headmen, who are also represented on a legislative council of 22 members, presided over by the governor, Notable strides were made after 1946 in education, medical work (including malaria eradication through World Health organization units), decentralization to local authorities, telecommunications and the improvement of both air and ground communications over rough inland terrain. Despite difficulties, in this last respect North Borneo forged ahead of other Borneo territories.

Extensive war damage from Allied bombing made necessary the rebuilding of four centres, Jesselton, Sandakan, Labuan and Tawau. They became bustling modern towns with many new buildings. of which the most impressive nas the Jesselton secretariat, centre of the government's 24 departments. A large part of the native population continues to live, by preference, in palm-thatch detached houses or communal long houses This way of life is in some nays well suited to the country's conditions of equatorial heat, rain, mud and wind.

The Economy.— Rubber remained North Borneo's main export for nearly 50 years, but in the late 1950s it began for the first time to be surpassed in value by timber, although new methods of grafting and contour planting have been adopted to ensure future rubber production. Other export commodities include copra, tobacco. abaca hemp (a postnar crop around Tawan) and cutch (mangrove bark for tanning). Exports to Japan rose rapidly and exceeded 30% of the total in the early 1560s with the United Kingdom and Singapore as the next best customers.

Imports from the Cnited Kingdom averaged about 25% of the total The bulk of the remainder came from the Philippines the United States and Japan; imports from the Philippines and Indonesia were largely ran materials for re-export. Chief import commodities include food, especially rice, sugar, flour and milk, machinery and building materials, processed tobacco and textiles There is regularly a favourable trade balance, although no major finds of natural resources have aided the economy An intensive search for oil, both on land and offshore, had met with no success by 1961.

North Borneo's steady prosperity is based on a decreasingly peasant economy. Much of the population is not primarily dependent on working for money; many family requirements are rnet by their own harvesting of rice, vegetables and fruit. along with hunting. shooting and fishing This, however, can operate against urban and estate development by causing temporary shortages of long-term labour. On the one hand is a deep wish to preserve the country's present character and racial composition; on the other. keen pressures for the introduction of fresh blood and new technical skills. Controlled immigration (mainly of skilled Chinese from Hong Rong) is maintained and careful legislation (including a Pioneer Industries ordinance granting special privileges to desired enterprises) has been enacted.

Current history and statistics are summarized annually under "British Borneo" in *Britannica* Book of *the Year*. (T. Hn.)

BORNEOL (also known as Borneo camphor): see CAMPHOR.

BORNHOLM, a Danish island and anzt (county) of 588 sq.km. (227 sq.mi.) in the southwestern approaches of the Baltic sea, lies 169 km. (105 mi.) S.E. of Copenhagen and 36 km. (22 mi.) S.E. of Skaane. Swed. Rhomboid in shape, from northwest to southeast its length is 35 km. (22 mi.) and its average width 21 km. (13 mi.). Pop. (1955) 48,632. The northern two-thirds of the island consists of a block of Pre-Cambrian granite, giving a rocky cliff coast and a hilly interior reaching 162 m. (531 ft.) in Rytterknaegten. Deep fissure valleys, such as Dyndal and Ekkodal, lie within the glaciated granite upland. The southern. more populous, part of Bornholm forms an undulating lowland of sandstones, limestones and shales of Cambrian to Silurian age with Triassic, Jurassic and Cretaceous rocks in the southwest. On the boulder-clay covered surface barley, oats and wheat are grown; the raising of dairy cattle and pigs is extensive. Granite. sandstone and limestone are exported, while porcelain, pottery, tiles, drain pipes and refractory bricks are made from local kaolin and clays around Ronne. Fishing for salmon and cod is carried on from Ronne, Hasle. Allinge, Gudhjem, Tejn, Listed, Svaneke and Neksö, the smoking of herring being important in summer. The island's sole railway links Ronne (pop. [1955] 13,160), the capital and chief port, with Neksö (3,276). Many tourists visit the ruined 13th-century castle of Hammershus and the fortified churches which testify to Bornholm's eventful history. Controlled by Sweden, the Hanseatic league, Denmark, and then by the city of Lübeck. it finally passed to Denmark in 1660. (Ha. T.)

BORNITE, a copper-iron sulfide, is an important ore of copper. It usually occurs as a vein mineral in massive aggregates intergrown with chalcocite and chalcopyrite (*qq.v.*) and also important ores of copper. The colour of a freshly fractured surface of

bornite is coppery, but in moist air this rapidly tarnishes with iridescent blue and red colours; hence the names peacock ore, purple copper ore, variegated copper ore (Ger. *Buntkupfererz*), horseflesh ore and erubescite (from the Latin erubescere, "to grow red"). The lustre is metallic. and the streak grayish-black; hardness is 3: specific gravity is 5. Occurrences of bornite are common and widespread being nearly always of plutonic origin. It occurs in dikes (Gilpin county, Colo.); in basic intrusive formations (Namaqualand, S.W.Af.); and in contact metamorphic deposits (Marble Bay. B C.). It is also mined at Butte. Mont.; Bisbee, Globe and Ajo, Xriz.; Braden, Chile; and Redruth, Cornwall. Crystals of bornite are rare and have been found only in druses, or crystal-coated surfaces, in veins. as at Bristol, Conn. Above 220° C. bornite crystallizes in the cubic system, inverting upon cooling to a pseudocubic crystal of lower symmetry but maintaining the cubic morphology. The formula of bornite is Cu_5FeS_4.

(A. J. F.)

BORNU, a region of the central Sudan. southwest of Lake Chad, now a province (area 40.584 sq.mi.) of the Northern Region of Nigeria, was formerly the centre of one of the longest-lived and most notable of Sudanic empires, that of Kanem-Bornu. The greater part of the province lies in the Sudan savanna belt and comprises a flat sandy plain, with a little latcrite in the west.

History.——In about the 8th century A.D.. Kanem, north of Lake Chad, then, Iike Bornu, inhabited by groups of Negro agriculturists collectively known as So. was invaded by the Sefawa, non-Negro horsemen, who gradually established their hegemony over the country. The Sefawa claimed descent from Sayf ibn Dhu Yazan. the 6th-century Himyarite hero who called in the Sassanids to rid the Yemen from Axumite rule. Sayf himself is riot supposed to have gone to Kanem, the effective founder of the dynasty and first *mai* ("king" or "chief") of Kanem being Dugu, traditionally thought to be Sayf's grandson. If Dugu is a historical personage, he may be dated *c.* 800. The trend of modern opinion follows accounts of the central Sudan by Arab writers from Ya'qubi (c. 891) onward, that the invaders were members of the Zaghawa, the great confederation of Libyan nomads then dominating the eastern Sahara; any Yemeni or Nubian influence in early Kanem would thus be at best indirect.

Initially the Sefawa kept themselves distinct from the Negroes they dominated, avoiding settlement in any one place and eschewing intermarriage. But through their contacts with the desert nomads, trade developed between Kanem and north Africa via the Fezzan, and Njimi emerged first as the commercial centre of the country and then as its political capital. With trade. Islam came to Kanem; Umme (1085–97) was the first Muslim *mai*. The process of converting the irregular nomad hegemony into a formal Muslim state seems to have begun with Umme's son Dunuma (1097–1150). Through trade arid the hadj ("pilgrimage"), regular relations were established with Tunis and Egypt, and Muslim concepts of law, administration and taxation, as well as such material innovations as building in burned brick, were introduced and blended with the conciliar and feudal notions of nomadic times. A regular army was raised from vassal nomad horsemen and levies of Negro bowmen and spearmen, and an empire was built up which reached north to the Fezzan and embarked on the colonization of Bornu. After political stabilization, the Sefawa began to merge with the conquered Negroes (the sobriquet Silim, "the Black," applied to *mai* Abd al-Jalil [c. 1193–1220] is significant) and in this way the distinctive Kanuri people and language began to develop.

By about 1300, Kanem was a Sudanic centre of Islamic civilization comparable to Mali in the west, but then dynastic jealousies and the rise of a rival group of nomad invaders, the Bulala, led to the disruption and downfall of the empire. But by the time of Xli Dunamani (c. 1475–1505), the Sefawa had re-established themselves in the erstwhile province of Bornu, and N'gazargamu was becoming a new imperial capital. During the 16th century the power of the revived monarchy steadily increased. The eastern Hausa states were made tributary and Kanem was reconquered, though its administration was left to Bulala vassals. Aïr was brought within Bornu's influence, and relations with Tunis were re-established. The new empire reached its peak under Idris Alooma (*c.* 1575–1610). Going early on the hadj, Idris introduced firearms and Turkish military instructors to Bornu, building up a formidable pou·er which enabled him not only to dominate neighbouring states but also to make the authority of his rule and of Muslim law unquestioned among unruly vassals within his own domains.

Idris Alooma's achievement was maintained by his sons for about 50 years, but then the *mais* began to concern themselves too much with the etiquette and pleasures of court life, the administration deteriorated and the empire declined under pressures from the Tuareg nomads of the Sahara and the Kwararafa in the south. Hausa cities like Kano and Katsina replaced Bornu as the major entrepôts for the central Sudan's trade with north Africa.

Early in the 19th century a new political power appeared on the scene when the Fulani jihad (religious war) against the Hausa kings resulted in the establishment of the empire of Sokoto under Usuman (Othman) dan Fodio and his son Mohammed Bello. Bornu. into which Fulani had been infiltrating since the 13th century, was attacked in 1808. The *mai* was driven from N'gazargamu, but his appeal for aid was answered by a remarkable fakir from Kanem, the *shehu* (sheikh) Mohammed al-Amin al-Kanemi (Laminu), who was convinced that, whatever may have been the case with the Hausa states, Bornu and its people were as rightfully Muslim as Bello and his Fulani. Laminu led a national revival which expelled the Fulani and made him the real. if not the titular, master of Bornu, Kukawa becoming the new capital. When he died in 1835 the remaining Sefawa sought to expel his son 'Umar, but they were defeated and killed, 'Umar assuming the titular kingship with the title of shehu.

In 1893 Bornu was conquered by Rabah Zobeir (*q.v.*), but it was now rapidly coming within the European sphere of influence. Dixon Denham, Hugh Clapperton and Walter Oudney had been the first European visitors in 1823; they were followed by Heinrich Barth, who got to know the country well during 1851–55, and by Gerhard Rohlfs (1866) and Gustav Naehtigal (1870). Rabah was eventually defeated and killed by the French in 1900, but in 1902 Bornu mas occupied by Frederick Lugard's British forces who reinstated the heir of the shehu killed by Rabah, and made Bornu a province of the British protectorate of Northern Nigeria. From then on. its history was associated with that of Northern Nigeria and subsequently of the Northern Region (see NIGERIA).

(J. D. F.)

The People.—Bornu province in Nigeria, though but the central fragment of the old Bornu state and empire, is populated by many tribes, their ethnic, linguistic and cultural variety reflecting the history of that empire. The Kanuri are the dominant people. They occupy the plain of the eastern Chad basin, now Bornu division, the largest of the five divisions of the province and the realm of the *shehu* of Bornu. In 1960 they numbered, together with some Kanembu clans: about one-half of the total population of 1,833,209 in the province. A very dark-skinned people of Negro appearance, their ancestry may nevertheless include a Berber strain. Their language, resembling neither the Berber spoken by the Tuareg north of Chad nor any of the Nigerian languages. is cognate with Teda (Tubu) in the Tibesti area of the southeastern Sahara. In the International African institute's classification of African languages Kanuri is classed as a member of the Eastern Saharan group whereas J. H. Greenberg puts it in the Central Saharan family. The Bornu state has long administered Koranic law, and Muslim rules of marriage prevail among the Kanuri, though not among many of the tribes in the former empire. Like all the people of Bornu province, the Kanuri are patrilineal. Like all except the Fulani, they bear distinctive patterns of tribal markings cut into the face; an element of these patterns characteristic of the Kanuri (though shared by the Bade and Tera) is a single vertical line down the forehead.

A ring of tribes descended from an earlier population encircles the Kanuri: on the islands of Lake Chad, the Buduma and Kuri; in the high, broken massif to the south, the Gamergu, Bura, Margi, Tera and others; westward in the open country with its scattered hills that was once the marchland with Kano and Zazzau, the

Ngamo (Gamawa). Karekare and Ngizim; and in the Sahel savanna from the middle Yobe north toward the Sahara, the Bade (Bedde) The Bade. who have drifted southward pressed by the Tuareg, are becoming Muslims and their culture has borrowed much from the Kanuri; they have a *mai* who is now the head of Bedde division. The petty states to its southwest. Yuyo, Techena and Shira. are probably of Bade origin. The rest of these tribes, less influenced by the Kanuri, have many cultural features in common. religions characterized by sky and earth deities and ancestor worship, and a stateless social organization in which jural authority is confined within the local group or exogamous patrilineage. Between the Bade and Lake Chad are the Manga, a Kanuri-speaking people perhaps descended from the So. reputedly a race of giants driven from the eastern shores of the lake by the Kanuri when they left Kanem. The Bolewa of Fika, speaking a Chad language, are ruled by a king (*moi*), who formerly exacted annual tribute from the Ngamo, Ngizim and Karekare. They claim to have arrived with the Kanuri, as do the Pabir of Biu to whose chiefs the Bura bring cases for settlement. Members of all these tribes except the Kanuri number about 575.000 in Bornu.

The two exclusively pastoral peoples in Bornu, the Shuwa Arabs (98.909) and the Fulani (*q.v.*) (168,944), arrived later; a 16th-century *mai* of Bornu is recorded as the first to have allotted grazing rights to the Fulani. The numbers of both greatly increased in the 19th century. when the Fulani carved the emirates of Hadeijia (Kano province) and Katagum (Bauchi province) out of the Bornu empire, and al-Kanemi invited in more Shun-a to subdue those in central Bornu. BORODIN, ALEKSANDR PORFIREVICH (1833–1887), Russian composer of symphonies and opera in an epic-heroic style. and also a scientist notable for research on aldehydes and amarine. was born in St. Petersburg, Nov. 12 (new style; Oct. 31, old style), 1833 He was the illegitimate son of an Imeretian prince by the wife of an army doctor.

He early showed marked gifts for languages and music, learned to play the piano, flute and cello, and composed even as a schoolboy. From 1850 to 1856 he studied at the Medico-Surgical academy. where he specialized in chemistry; in 1858 he was granted a doctorate for his thesis on the analogy of arsenic acid with phosphoric acid. From 1859 to 1862 he studied in western Europe. mostly at Heidelberg and in Italy, and made the acquaintance of a young Russian pianist, whom he married on his return to Russia

He was at once made "adjunct-professor" of chemistry at the Medico-Surgical academy and became full professor in 1864, yet from the same period dates his first important composition, a symphony in E flat written between 1862 and 1867 as a result of his acquaintance with Balakirev and his circle. The success of this symphony when performed in 1869 led to the composition of a second, in B minor. From the same year until the end of his life Borodin was engaged desultorily on an opera, *Prince Igor;* he also found time to write two string quartets and a dozen remarkable songs. But Borodin's musical work was never more than a relaxation from his professional work: research, teaching and administration He was active not only in the academy but in the medical courses for women which he helped to found in 1872, and during the 1880s pressure of work and ill-health left little leisure for composition. He died suddenly at a ball in St. Petersburg Feb. 27 (N.S., 15. O.S.), 1887.

Few though they are. Borodin's compositions are outstanding. His two completed symphonies) with the torso of a third (in A minor), and his quartets place him in the front rank of Russian instrumental composers; *Prince Igor*, completed by Rimski-Korsakov, is a classic of Russian opera. Borodin had a strong lyrical vein but was also outstanding in both the epic-heroic and the epigrammatic manner.

See S. A. Dianin, *Borodin* (1355); *Pis'ma A. P. Borodina, ed. by* Dianin, 4 vol. (1928–1950). (G. AB.)

BORODIN, MIKHAIL MARKOVICH (1884–1953?), known also by his original surname, Grusenberg. was a Russian diplomat and political adviser. Born July 9, 1884. in Yanovichi. Vitebsk province. Russia, Borodin as a young man joined various anti-tsarist movements and in 1906 attended the Stockholm conference of the Russian Social Democratic Labor party. In that same year he was arrested and exiled. After emigrating to the United States, he attended Valparaiso university, Valparaiso, Ind.. and then founded a school for *émigrés* in Chicago. After the Bolshevik revolution of 1917 he returned to his native country and was dispatched as a Communist agent to Spain. Mexico, Scotland, the United States and elsewhere. He reached the peak of his career between 1923 and 1927 when he served as chief Cornintern agent in China and as adviser to the Kuomintang government. When the Kuomintang broke with the Communists in 1927 he returned to Moscow and became editor of the *Moscow Daily News,* published in English. During the 1930s he disappeared from public life and is believed to have died in a Siberian prison camp some time before Sept. 3, 1953, when his death was announced. (R. C. N.)

BORODINO, BATTLE OF, the battle fought on Sept. 7, 1812, between Napoleon's French and allied forces and M. I. Kutuzov's Russian troops. After Napoleon's invasion of Russia with greatly superior forces late in June 1812 the Russians had been withdrawing before him, fighting rear guard actions but avoiding a major battle. When Kutuzov halted his retreat at Borodino. 70 mi. W.S.W. of Moscow, Napoleon's *masse* de *manoeuvre* had been reduced to 130.000 men. The Russians. 127.000 strong. adopted a strong defensive position. constructing redoubts along the heights east of Borodino, their left flank protected by woods, their right wing by the tributary to the Moskva river. which covered their right flank and rear. Ignoring Davout's advice against an almost exclusively frontal assault, Napoleon massed his main forces. 90,000 men, on a front of only two miles, retaining behind his centre a reserve (27,000) of two divisions and the guard. On the far French right J. A. Poniatowski was to lead 10.000 men. too few to exert a decisive effect on the battle, against the extreme Russian left wing. After a day of preparations, the battle began before 6 A.M. on Sept. 7. On the French left Eugène de Beauharnais captured the advanced posts in Borodino but was halted before the central redoubt. On the right Ney and Davout, supported by Murat, at length established themselves in the emplacements near the village of Semenovskoye. Russian counter-attacks could not oust the French, supported by massed artillery. from the ground won, or prevent the eventual loss of the central redoubt. Napoleon refused to commit the guard, and it is doubtful whether the use of his remaining reserve could have transformed an inconclusive advantage into an undeniable victory. After more than 12 hours fighting the Russians had been forced back 2.000 yd. Retiring in reasonable order. they then withdrew to the south of Moscow to observe the French, who entered the city on Sept. 14. The Russians had lost about 45,000 killed and wounded, the French 30,000. (J. H. N.)

BORON, a semimetallic element, occurs in nature as boric acid (boracic acid, sassolite), as borax (tincal) and in numerous other widely distributed borate minerals *(see* BORAX and *BORIC* ACID), which may represent as much as .001% of the earth's crust. As borax it was known to ancient peoples (Arabic, *buraq;* Persian, *burah*) but was often confused by medieval writers. The name boron, analogous to carbon, was coined by Sir Humphry Davy. In the

form of boric acid or borates, this element is necessary for the growth of plants, and thus is essential to the continuation of animal life as well.

Small quantities of boron (from .0005% to .005%) are used for the manufacture of steel of special hardness. Boron is used also in the manufacture of glass, and, in conjunction with aluminum, for the manufacture of highly conductive electrical wire. The boron hydrides (boranes) range from compounds so reactive as to be employed as rocket fuels, to materials so inert as to be promising in the field of heat-resistant plastics. Quite different from either is the boric acid derivative used in gasoline to minimize preignition.

Properties.--Boron is the lightest member of the third group of the periodic system. Symbol B, atomic number 5, electronic structure $1s^2 2s^2 2p^1$, ionization potential for first electron 8.257 v., atomic weight 10.82, stable isotopes 10 and 11, radioactive isotopes 8, 9 and 12 (half lives <1 sec.).

The free element was first recognized with certainty in 1808, by J. L. Gay-Lussac and L. J. Thénard, who made it in the form of a black powder by heating boron oxide (B_2O_3) with metallic potassium. Magnesium is more convenient than potassium for this reduction, but any oxide method allows impurities which are very difficult to eliminate. E. Weintraub (1909) passed a mixture of hydrogen and boron chloride across an electric arc, forming rods of pure boron on the water-cooled copper electrodes. A. W. Laubengayer and associates (1943) deposited pure crystalline boron upon a tantalum filament heated to 800°–1300° C. in an atmosphere of hydrogen and boron bromide; this method has been extended to make pure boron rods more than two inches in diameter. Large batches of boron can be made by passage of direct electric current through a melt containing boron oxide, magnesium oxide and magnesium fluoride at a temperature of 1,100° C. (J. L. Andrieux, 1927).

Pure boron in fine-powder form is jet-black, but the massive form has a dull metallic lustre. Its density is 2.31; the covalent single-bond radius has been variously estimated from 0.80Å to 0.88Å (10^{-8} cm. units), and may actually lack definition. Boron is hard enough (9.3 Mohs) to scratch carborundum, but it is too brittle for use in tools; the fracture is conchoidal. Its slight electrical conductance increases not more than one hundredfold on heating from 20° to 600° C. and its specific heat rises from 0.3 to 0.6 cal. per gram degree. It melts and boils above 2,200° C.

Boron is chemically almost inert at ordinary temperatures, although the fine powder is ignited by elementary fluorine or slowly converted to boric acid by the action of hot nitric acid. At elevated temperatures it acts like carbon: heavy metal oxides are reduced to metals, often with formation of borides (*q.v.*). At 600° C. or higher, water vapour converts the powder to boric acid, or molten alkali hydroxides oxidize it to borate, with liberation of hydrogen; also, boron chloride, bromide, sulfide, selenide, oxide, nitride or carbide can be formed from the elements. Of these compounds, the first four are most easily hydrolyzed to boric acid and volatile hydrogen compounds, or similarly attacked by alcohols, ammonia or amines.

In accord with its place in the periodic system, boron can be assigned a valence of three in many of its compounds, but the valence concept becomes somewhat indefinite because the boron atom has a strong tendency to complete an electron octet — either by electrons which form extra bonds from adjacent atoms (halogen, oxygen, nitrogen or others) in planar BX_3 atomic arrangements, or by single, bonding to four atoms at once, as occurs in many compounds of elements in Group IV.

Boron Halides. — The ability of boron to form a fourth bond is especially evident in the chemistry of the boron halides (formula type BX,), which form innumerable compounds with ethers, amines and other substances able to offer electron pairs for bonding. or undergo reactions of hydrolysis type through the intermediate formation of such molecular addition compounds. Boron fluoride (boiling point −100° C.) has important catalytic effects which are ascribed to its electron-acceptor bonding power; it may be even more versatile than aluminum chloride for promoting condensations. rearrangements, isomerizations and substitution reactions of carbon compounds. Four-co-ordinate boron appears also in the BF_4^- ion (fluoborate), salts of which can be made by direct addition of boron fluoride to a metal fluoride or by the action of hydrofluoric acid upon a metal borate, in aqueous solutions.

Boron fluoride can be generated in the laboratory by heating boric acid with calcium fluoride and sulfuric acid, but a more pure product is obtained from a fluoborate salt with boron oxide and sulfuric acid or by heating benzene-diazonium fluoborate.

Boron chloride (BCl_3; b.p. 12.5° C.) and boron bromide (BBr_3; b.p. 91° C.) may be prepared by the action of the halogens on boron or calcium boride (500°–800° C.) or by halide exchanges between boron fluoride and the aluminum halides at 200°–300° C. Boron iodide (BI,; m.p. 50°, b.p. 210° C.) can be made by the action of hydrogen iodide upon the chloride or bromide, or by the action of iodine on an alkali metal borohydride. It is unstable relative to the elements and polymeric subiodides.

The subhalides B_2Cl_4 and B_2I_4 are formed from boron chloride or iodide by removal of halogen in an electric discharge at 1 mm. pressure. Their room temperature decomposition forms lower halides such as B_4Cl_4. Hydrogen is avidly absorbed by B_2Cl_4, which also adds as BCl_2 units to the C=C double bond.

The hydrolysis of boron fluoride is incomplete, whereas the other boron halides rapidly form hydrogen halides and boron oxyacids. The similar ammonolysis produces indefinite polymers such as $(HNBNH_2)_x$ and finally boron nitride at high temperatures.

Boron Nitrides, $(BN)_x$.—Ordinary boron nitride can be made from the elements or from many compounds containing them. Its refractory and electrically resistant soft, white crystals have a layered-plane structure like that of graphite except that all B and N atoms are on BNBN . . . lines perpendicular to the planes. Under a pressure of 70,000 atmospheres at 1,600° C.. it converts to a form called borazon (Wentorf, 1957). This has the structure and hardness of diamond; moreover, it resists action by the open air at 1,900° C.. whereas diamond burns below 900° C. It may become a uniquely valuable component in tools meant for high-temperature machining of hard refractories and, if made available in larger quantities, would serve as an important refractory in its own right.

Organo-Boron Compounds. — Compounds with boron attached to carbon can be made most easily by the action of a Grignard reagent, RMgX, upon a boron halide or a boric acid ester. Dialkyl-zinc compounds were used for the same purpose by E. Frankland (1862). The trialkylborines, R_3B, usually inflame in air but hydrolyze or ammonolyze only at elevated temperatures. They form a weak fourth bond to ammonia or amines, but bond strongly to an alkide ion, as in the fairly stable $LiB(CH_3)_4$ and $LiB(CH_3)_3C_2H_5$. The triarylborines, such as $(C_6H_5)_3B$, are less active toward air, but form far more stable complexes with ammonia. They react with sodium to form coloured free-radical ions analogous to triphenylmethyl (E. Krause, 1924):

$$2Na + 2R_3B \longrightarrow (Na_2B_2R_6) \rightleftarrows 2Na^+ + 2BR_3^-$$

With some aryl groups, salts of the type Na_2BR_3 are formed; probably analogous is $Na_2HB(CH_3)_2$, a very strong base.

Compounds of the type R_2BX are formed by carefully controlled oxidation or halogenation of R_3B compounds. Hydrolysis of R_2BX compounds yields R_2BOH, which may be dehydrated easily to form R_2BOBR_2. Many compounds of type RBX_2 are known, and lead to alkyl and aryl boric acids by hydrolysis (see BORIC ACID), or to (RNBR), compounds by aminolysis.

THE HYDRIDES OF BORON

The boron hydrides (boranes) offer an unusual variety of structural principles and chemical behaviour. They had been known only as the unstable and self-inflaming gaseous reaction product of magnesium boride in aqueous acids, and were misconceived until A. Stock (1912) developed high-vacuum methods and apparatus whereby the individual compounds were shown to be as follows: an unstable tetraborane (B_4H_{10}; m.p. −120°, b.p. 18° C.). a stable pentaborane (B_5H_9; m.p. −47°, b.p. 48° C.), very little of a somewhat unstable hexaborane (B_6H_{10}; b.p. about 100° C.) and traces of a well-crystallized and very stable decaborane ($B_{10}H_{14}$;

m.p. 100°, b.p. 213° C.). On standing tetrahorane yielded diborane (B_2H_6; m.p. −165°, b.p. −93° C.; too easily hydrolyzed to have escaped from the HCl solution!. a further yield of decaborane. a very unstable pentaborane (B_5H_{11}; m.p. −123°, b.p. 63° C.j and indefinite solid products. The yields of volatile hydrides from the aqueous acid system were low, and the whole process was tedious and expensive.

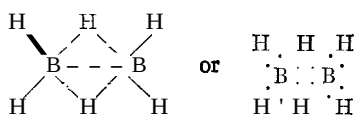
More efficient n-as the method of H. I. Schlesinger and A. B. Burg (1931): hydrogenation of horon trichloride in a silent electrical discharge (possibly through formation of B_2Cl_4, which absorbs hydrogen rapidly). and disproportionation of the resulting chlorodiboranes; thus

$$6B_2H_5Cl \rightleftarrows 2BCl_3 + 5B_2H_6$$

This claborate process was superseded through the discovery (Schlesinger and associates, 1947 *et ante*) of convenient methods based upon alkali metal hydrides. Thus sodium hydride reacts with an alkyl borate to form $NaHB(OR)_3$, from which diborane can be generated by treatment with the ether complex of boron fluoride; or lithium hydride under ether will convert a boron halide to diborane. best through intermediate formation of borohydride (BH_4^-); or lithium aluminum hydride (see HYDRIDES) can be used with a boron halide to produce diborane.

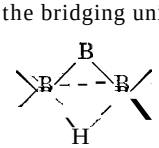
Dihorane, tetraborane, the unstable pentaborane and hydrogen form a system of easily reversible reactions (greatly favouring diborane), from which the stable pentaborane. decaborane and indefinite nonvolatile solids are formed irreversibly at elevated temperatures. Hence any of the higher boranes can be made by heating diborane under conditions favourable to the desired product; however, hexahorane is difficult to obtain in this way.

The formulas of the boranes were considered anomalous even as they were being discovered; for any arrangement of the atoms in space. there are not enough valence electrons to meet the G. N. Lewis concept of electronic saturation (1916), such that every boron atom would have a filled octet and no electron pair would be shared by more than two atoms. But the quantum theory permits electrons to he shared among as many atoms as can offer open space into which they can fall with loss of energy. In the case of diborane the evidences of spectroscopy, heat capacity and electron diffraction all favour the model



in which two electron pairs occupy energy states (orbitals) established by the two B–H–B groupings of atoms. Dihorane thus is far more stable than separate BH_3 groups. for it represents a step toward electronic saturation; hon-ever, the bridge system is easily broken by any substance offering electrons for a more normal completion of the electron octet of boron. Hence most reactions of diborane occur through formation of BH_3 complexes: H_3NBH_3, R_3NBH_3, R_3PBH_3, R_3AsBH_3, CH_3CNBH_3, R_2OBH_3, R_2SBH_3, BH_3CO, BH_3PF_3 and many others.

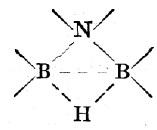
In the higher boranes, the bridging unit may be



or something more complicated; however. a tertiary amine breaks such bridges also, forming R_3NBH_3 and inert aminated $(BH)_n$ polymers. In B_5H_9. X-ray and electron diffraction results show a tetragonal-pyramidal arrangement of boron atoms. with four B–H–B linkages holding the square base together; and $B_{10}H_{14}$ is like a regular icosahedron with a pair of boron atoms removed. Both B_5H_9 and $B_{10}H_{14}$ have been mentioned as sources of high-energy fuels, the use of which would add substantially to the distance traveled hy a rocket or guided missile n-hich carries its own fuel for long-range propulsion. Such materials are less dangerous to handle than certain more energetic highly volatile borohydrides.

Protolytic **Reactions.**—Diborane reacts with hydrogen chloride slowly, liberating hydrogen and forming B–Cl bonds; the similar reactions of BH, complexes are much faster. suggesting that activation for a hydride-type reaction is easier. The rapid reaction of diborane with water yields only boric acid and hydrogen, hut may well go through stages such as $H_2O.BH_3$. $HOBH_2$, $HOBH_2.H_2O$. etc. With methanol $(CH_3O)_2BH$ (m.p. −130°, b.p. 26° C.) is ohtained; similar compounds form quickly at −78° C. from aldehydes or ketones — again through formation of BH_3 complexes which cannot be isolated.

With ammonia or amines. borine complexes and definite steps in their protolyses are easily recognized. By absorbing dihorane into dimethylamine (1:2 mole ratio) and heating. dimethylaminoborine, $(CH_3)_2NBH_2$ (m.p. 74° C.; forms an N-bridged dimer), may be formed easily. and this absorbs diborane to form dimethylaniinodiborane. $(CH_3)_2NB_2H_5$ (m.p. −54°, b.p. 50° C.), a stable liquid having the



unit in its molecular structure. The corresponding ammonia product, $H_2NB_2H_5$ (m.p. −66°, b.p. 76° C.). easily loses a BH_3 group as diborane. leaving a white polymeric solid $(H_2NBH_2)_n$. A far more stable XBH_2 polymer is $[(CH_3)_2PBH_2]_3$ (m.p. 85°, b.p. 312° C.), which is made from $(CH_3)_2PH.BH_3$ by heating above 150° C. (Burg and Wagner, 1953). It is chemically almost inert, requiring temperatures above 300° C. for hydrolysis. The tetrameric form is only slightly less stable. However, $[(CH_3)_2AsBH_2]_3$ is less stable and more reactive: and $(CH_3)_2SbBH_2$ is a reactive monomer.

Another stage of protolysis is represented by borazine ($B_3N_3H_6$; m.p. −58°, b.p. 53° C.), a liquid analogous to benzene but capable of forming addition compounds by bonding electron donor.: to B or electron acceptors to N; thus it is capable of self-condensation to form high polymers. Many substitution derivatives of borazine can be made by the action of ammonia or primary amines on derivatives of diborane.

Radical-Transfer Reactions. — Boron trihalides (except BF_3) react with diborane easily at room temperature. exchanging halide for hydrogen and forming chiefly compounds of the type B_2H_5X, all unstable in the sense of the reverse reaction. With similar ease, diborane exchanges hydrogen lor alkyl groups in trialkylborons (BR,), forming compounds of types B_2H_5R, BH_3BHR_2, RBH_2BHR_2 and $(HBR_2)_2$, all chemically like diborane and each unstable in :he sense of the reverse exchange;. Trialkylborates, $(RO)_3B$, with dihorane easily form $(RO)_2BH$ compounds, also unstable in the sense of the reverse reaction. Even the relatively stable $(CH_3)_2NBH_2$ undergoes some disproporiionation at 100° C.:

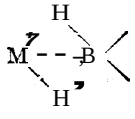
$$3R_2NBH_2 \rightleftarrows R_2NB_2H_5 + (R_2N)_2BH$$

and the resulting bis-amino-borine reacts with diborane even well below room temperature to form $(CH_3)_2NBH_2$ again. Exchange reactions such as these have been important in the elaboration of the chemistry of substituted boron hydrides.

Borohydrides.—The hydride ion H−, having great bonding power because of its unshared electrons. easily receives BH_3 groups to form the stable borohydride ion BH_4^-. Lithium borohydride is formed in solution in ether by leading diborane into lithium hydride suspended in ether; and sodium borohydride can he made from $NaHB(OR)_3$ by heating to cause disproportionation. or more simply by using diborane to displace the alkyl borate $B(OR)_3$. The product of addition of dihorane to sodium amalgam, once thought to be the salt $Na_2B_2H_6$, has been shown to be a mixture of $NaBH_4$ and the ether-soluble NaB_3H_8. The alkali borohydrides. water-soluble. though destroyed by acids or heavy-metal ions, act as powerful reducing agents in water or other solvents.

If a positive ion is difficult to reduce, it usually can form a borohydride. and if the ratio of ionic charge to radius is large. the compound may well be volatile. Thus. $Be(BH_4)_2$, $Al(BH_4)_3$ (b.p. 45° C.), $Ti(BH_4)_3$, $Zr(BH_4)_4$, $Hf(BH_4)_4$, $Th(BH_4)_4$ and $U(BH_4)_3(CH_3BH_3)$ are all the most volatile compounds of the

respective metal ions. In each of these, the BH_4 group is attached to the metal ion through the



type of bonding, like that in diborane but less symmetrical. They are violently reactive compound:: undergoing explosive reactions with air or water, reacting with hydrogen chloride at low temperatures to form the metal chloride, dihorane and hydrogen (an evidence of strong hydridic character:) and bonding strongly to amines or ammonia or even ethers — sometime. with a removal of BH, groups. The general method of making the volatile borohydrides is by the action or' the appropriate metal halides on an alkali metal borohydride. Or, from a volatile borohydride, a saltlike borohydride may be obtained by treating it with the appropriate metal alkyl compound. usually in a suitable solvent.

BORORO, a tribe of South American Indians occupying a large area near the headwaters of the Paraguay river in southern Mato Grosso, Brazil. Their language is thought to be related to the Ge languages spoken by many of their neighbours. They are a settled people who cultivate a variety of crops, although hunting and fishing provide a substantial part of their subsistence. Clothing is minimal, but decorating the body is common, and the most spectacular ornament is a large headdress of red macaw feathers which is worn by the men on ceremonial occasions.

Villages are built in the form of a circle, with a ring of thatched dwellings surrounding a men's clubhouse. A moiety organization divides the village into two halves; each moiety is composed of several clans. Membership in both moiety and clan is traced matrilineally, and residence after marriage is matrilocal. In keeping with matrilineal descent, the chief of the village usually passes on his somewhat nominal authority to his nephew.

Most of the major ceremonies are connected with funerals, which last for several weeks. Elaborate dances are held, during which costumed performers act out incidents from mythology, and at one point the souls of all the recent dead are invited to share a communal meal. This phase of the ceremony is directed by a religious leader who is believed to be able to contact and control the spirits of the dead, and who on other occasions uses his supernatural power in the treatment of disease. The funeral ceremonies also serve as initiation rites for adolescent boys, who at this time are accepted as members of the men's house and are allowed to witness ritual forbidden to women and uninitiated children.

For the Bororoan family of languages, see the table in the article INDIAN, LATIN-AMERICAN.

BOROUGH, in Britain, an incorporated town with special privileges, or a district entitled to return a member of parliament The medieval English borough was an urban centre identified by the grant by charter of privileges autonomy and, later, incorporation From Tudor times onward, the Importance of boroughs as units of local government declined, but they gained a new importance as parliamentary constituencies. The reform of municipal corporations in 183j gave English boroughs a uniform constitution anti transiormcd them into modern units of local government. In some parts of the United States the term denotes a town, village or other municipal unit.

Origins.—There is no evidence of continuity between the Romano-British municipality and the Saxon borough. F. W. Maitland showed that the oldest boroughs had their origins in agricultural communities. The term "burgh" implies a fortified place of defense, but the Saxon boroughs were also commercial centres with trading privileges. In the reconquered Danelaw they were administrative centres around which the shires were organized. Judicially, from the 10th century the borough already showed its distinctive character as an area excepted from the general hierarchy of shire and hundred, and there were borough courts in which the borough's own legal customs could be enforced.

Medieval English Boroughs.— The Norman Conquest brought increased economic activity to the English boroughs; they were influenced by the continental developments in municipal autonomy, though they never succeeded in freeing themselves of royal control to the same degree as the continental communes. Many new boroughs were founded both by the king and by baronial lords on their lands and were known as mesne or seignorial boroughs.

The character of the borough was marked by varying degrees of freedom from the manorial system and the royal administration. A serf became free after a year and a day in a borough; land holding was by hurgage tenure, under which land was held by payment of money rent, instead of manorial obligations, with freedom to sell or devise. The economic privileges granted by charter were also often exemptions, such as the freedom from tolls, as well as the right to hold markets and fairs, to levy tolls on nonburgesses, and to regulate trade. Administratively, the first step mas usually for the burgesses to obtain from the crown the right to collect the customary royal dues (the "farm" of the borough) and account for them at the exchequer. This enabled the burgesses to exclude the sheriff from collection of the revenue 'from the borough. Though the practice of selling the right to farm the borough began in the 12th century, the grant by charter of privileges greatly increased under Richard I and John because of the crown's chronic need for money.

In the 13th century more charters were granted and the reeves or bailiffs began to obtain the title of mayor; the borough officials were now regularly chosen locally. The borough bailiffs obtained the right of return of writs, though they still had to report on the execution of them to the sheriff, who could execute them himself if the bailiffs failed. The sheriff was completely excluded only from the few boroughs which had obtained the right to appoint their own sheriffs and had become in fact counties corporate. Incorporation was also granted to boroughs by charter; in the mid-14th century the five rights recognized as denoting the incorporation of a horough were perpetual succession, power to sue and be sued in the name of the corporation, power to hold land in mortmain. a common seal and power to make bylaws.

Attempts of the poorer townsmen to obtain a share in control in the 13th and again in the 15th century proved vain. Oligarchic constitutions were embodied in charters of incorporation and, from Tudor times, it became royal policy to strengthen the tendency to close corporations, both to enforce central control and because the borough corporations returned members to the house of commons.

Parliamentary Boroughs.— Sheriffs summoned representatives of boroughs to parliament from Henry III's time (see PARLIAMENT: *Early History* of the British Parliament). Representation was at first unpopular because of the expense, and the smaller towns dropped out. By the mid-Ijth century, however, representation became attractive, and later Edward VI began the practice of creating new boroughs, especially where the crown could hope to influence the choice of members (*e.g.*, the small boroughs of Cornwall) and so control parliament. By the end of the 17th century zoo English boroughs were returning about four-fifths of the lower house. 'The franchise was in most cases limited to a self-renewing corporation or a limited number of freemen. 'The close corporations were normally dominated by one political party and were socially and religiously exclusive. A borough controlled by one person or one family was often referred to as a pocket borough. for it was said that a single man carried control of such a borough in his pocket. As time passed, some boroughs such as "Old Sarum" (Salisbury), declined in population and lost their earlier importance; their proprietors, nevertheless, continued to name representatives in parliament. Reformers of the

early 19th century denounced this practice and referred to these communities as rotten horoughs. (*See* REFORM MOVEMENT).

The boroughs were little concerned with the provision of local government services. When, in the 18th and early 19th centuries, new functions. such as the paving, lighting and watching of the streets. were required, they were entrusted to commissioners appointed for the purpose under local acts. The main local importance of boroughs between the 16th and the 19th centuries was that leading members of the corporation acted as justices of the peace. The appointment of at least one member of the corporation as a justice of the peace was regarded by Sidney and Beatrice Webb as the criterion of borough status in this period. The possession of a court of petty sessions by virtually all boroughs, and of quarter sessions by a considerable number. gave them a degree of exemption from the contemporary county system of control comparable with that enjoyed by boroughs in the middle ages.

The Reformed **Corporations.**—The age of reform dealt with the boroughs in two measures. The first. in 1832, disfranchised 56 boroughs with less than 2,000 population and took seats from others: the redistribution of seats was accompanied by the introduction of a uniform franchise. Second, the boroughs in their municipal aspect were investigated by a royal commission. The 1835 Municipal Corporations act that followed the report dealt with 178 corporations (the most notable exception being the City of London which remained "unreformed"). The act provided for a uniform municipal franchise (adult householders who had been ratepayers 1or 3 years) and a uniform constitution for all boroughs: a council elected by the ratepaying householders, a third of the council retiring and being replaced by election every year. The council elected a mayor and aldermen (a number one-third that of the councilors). who did not need to be, but usually were, members of the council. Aldermen differed from councilors only in dignity and in having a six-year instead of a three-!.ear term of office. The constitutional pattern of the 183j act was re-enacted in the consolidating Municipal Corporations act of 1882, and again in the Local Government act of 1933, which dealt also with other types of local authority.

Boroughs in Modern English Local Government. — The 1835 act gave the reformed boroughs few specific powers to provide local government services. The development of these services in the 19th century was either by parliamentary acts dealing u·ith specific subjects (*e.g.*, the Public Health act. 1848) or by local legislation. The number of boroughs increased from the 178 dealt with by the act of 1835 to 402 in 1958; new charters were granted to urban districts and, in a few cases: to previously unreformed boroughs not affected by the act of 1835. Borough status was greatly appreciated by growing unincorporated urban districts, not so much because of the relatively minor diiference in powers, but because of its dignity. Some boroughs, usually the seat of a cathedral and bishop, received the title of city and a few the right to style their mayor as lord mayor; these diiferences did not affect powers.

There was, however. a difference in powers between county boroughs and other boroughs. The Local Government act of 1885, which established county councils. also provided that certain boroughs should be county boroughs. exercising the same functions as county councils in addition to those of ordinary municipal or noncounty boroughs. They exercised the powers of both city and county governments. The act provided for 61 county boroughs with populations generally over 50,000. The number of county boroughs in England and Wales had increased to 83 by 1926; after that date no new county boroughs were formed. The population requirement ior county borough status was increased to 75,000 in 1926; after 1945 it was virtually 100,000.

In the 20th century there has been considerable conflict between county councils and county boroughs seeking extension of their areas at the expense of counties. Friction has also resulted from the efforts of noncounty boroughs to achieve promotion to county borough status. The Local Government act of 1958 entrusted the task of reviewing the main local government structure to a Local Government commission empowered to make proposals for change to the minister of housing and local government, who would submit them in orders for the approval of parliament. The act of 1958 also aiiected the position of noncounty boroughs in the administrative counties. For example. rhe county council could propose the absorption of a noncounty borough by a rural district. This would involve. in effect. the loss by the borough of its status as a county district, though it would retain at least the powers of a rural parish.

The structure of local government in Greater London was reviewed by a royal commission appointed in 1958. In the county of London since 1900 there had been 28 metropolitan boroughs, as well a3 the unreformed corporation of the City of London. The metropolitan boroughs. constituted by the London Government act. 1899, were, broadly speaking, similar to noncounty boroughs outside London.

Boroughs in Scotland and Ireland. — The medieval and later unreformed Scottish burghs were broadly similar to their English counterparts, though their trade monopolies were generally greater. They were founded either by the Scottish crown or by feudal lords with royal licence. They sen: reprcscntatives to the Scottish parliament from 1295 and to the British parliament after the Act of Union in 1707. The reform of the Scottish burghs in 1833 preceded that of the English horoughs. In local governlnent the large burghs (generally those with over 20.000 population) correspond to the English county boroughs, though with not quite such wide independence of the county as is enjoyed by the English and Welsh county boroughs. apart from the four Scottish counties of cities. Scottish burghs are also classified according to origin. as royal, parliamentary or police burghs. All Scottish urban local government units are termed burghs. there being no authorities equivalent to the English urban districts.

The Irish boroughs and municipal corporations followed more closely on the English pattern. Charters were granted in the 12th and 13th centuries, followed by others in the 17th century. After the corruption of close corporations in the 18th century, reform both for parliamentary and local government purposes came in the 19th century.

Boroughs in the **U.S.**—The term borough appeared occasionally in colonial Virginia, where the representative assembly was known as the House of Burgesses. But the term was not widely used in the United States after the Revolution. Village, town and city were the terms most commonly applied to municipal units. The .American city corresponded most closely to the English borough as a full-fledged urban unit. In only four states, New Jersey. Pennsylvania, Connecticut and Minnesota, was the term borough officially recognized, and in these areas it indicated an incorporated town or village of lesser status than a city. The New York legislature adopted the term in 1897 when it combined five large municipal areas: known as the boroughs of Manhattan, Brooklyn. Queens. the Bronx and Richmond, to form the city of Greater New I'ork.

Hart and W. O. Hart, *An Introduction to the Law of Local Government and Administration*, 4th ed. (1949). (V. D. L.)

BOROUGH ENGLISH, the English form of ultimogeniture, (*q.v.*) was the rule of inheritance by which real property passed to the youngest son or. failing sons, to the youngest daughter. and was essentially the rule for the unfree peasant. The land of free peasants tended to pass by equal division among sons or daughters. Just as it was to the king's interest to preserve the unity of the feudal inheritance. thus ensuring the proper performance of due military service, so it was the lord's interest to preserve the unity of a peasant's inheritance. whether in the hands of the youngest or the eldest ion. The custom of ultimogeniture was an ancient one in England and in other parts of Europe and may well have arisen

because elder sons went out to provide for themselves and the youngest. remaining longer in his father's house, was still there when his father died. Of a family of sons, he was the least well able to find other land than his father's and sometimes he was still a child on his father's death. The name Borough English became the accepted legal name for this custom after a famous case of 1327 drew the attention of lawyers to the fact that in the French borough of Nottingham, which after the Norman conquest grew up beside the English borough, land passed to the eldest son, while in the English borough it passed to the youngest son. Ultimogeniture was very general in English boroughs. At Leicester Earl Simon de Montfort in 1255 changed the rule of inheritance from ultimogeniture to primogeniture (*q.v.*) at the request of the burgesses for the welfare of the town, which "on account of the feebleness and youth of the heirs for a long time past has almost fallen into ruin and decay." The custom continued in many rural manors into the 20th century, particularly in the south and southeast of England. but in a single field in Nottinghamshire in the 19th century it was accepted that some strips should pass by Borough English, some by partible inheritance, and some by common law. The custom was abolished by the Administration of Estates act, 1925, s. 45.

BORROMEAN ISLANDS, four islands on the west of Lago Maggiore (*q.v.*), Italy, off Baveno and Stresa. Isola Bella, named for Isabella, Countess Borromeo, is famous for its château and terraced gardens, built by Count Vitaliano Borromeo (d. 1690); northeast of this is the Isola Madre, the largest of the group, with a palazzo and gardens; north again, off Pallanza, is the little Isola San Giovanni. The westernmost is Isola dei Pescatori. occupied by a fishing village. (G. KH.)

BORROMEO, SAINT CHARLES (1538–1584), Italian cardinal and archbishop of Milan, was born at Arona, Oct. 2, 1538. His studies at the University of Pavia won him the doctorate in civil and canon law in 1559.

Upon the election of his maternal uncle as Pope Pius IV that same year, he was called to Rome, where he was created cardinal-deacon (1560) and later cardinal-priest (1564). On May 12, 1560, he was named archbishop of Milan, and upon the completion of his 25th year was consecrated a bishop by Cardinal Serbellone on Dec. 7, 1563.

As cardinal-nephew, the young prelate filled many functions at Rome, chief among them that of heading the Consulta, which thus made him secretary of state to Pius IV. The pope leaned upon him heavily in directing the third convocation of the Council of Trent (1562–63). When the council closed, Borromeo sat as a member of the commission to execute its decrees and was largely instrumental in bringing out the Roman catechism in Sept. 1566. Increasingly, the archbishop desired to reside at Milan, a permission at length granted by his uncle in 1565. Recalled to Rome by the illness and death of Pius IV, the archbishop took part in the conclave which elected Pius V on Jan. 7, 1566, and then was allowed to return to his see, where he resided thereafter.

At Milan, serious administrative problems confronted him. He was responsible for more than 1,000 parishes scattered over a territory in part subject to King Philip II of Spain, in part to Venice, Genoa, Novara and the Swiss cantons. In regular fashion. the cardinal visited every section of his archdiocese. Eleven diocesan synods ordered the ecclesiastical life of the see, while six provincial councils extended the reforms of the Council of Trent to the 15 bishoprics suffragan to Milan. Clerical education was fostered by the establishment of a Seminario Maggiore (1565) and of a Collegio Elvetico (1579), both at Milan, and of minor seminaries at Inverigo and Celano. For lay students, the Collegio Brera (1572), entrusted to the Jesuits, and the Collegio dei Nobili (1573) were erected. The archbishop's last undertaking was the public opening of the college at Ascona in 1584. He widely employed the Confraternity of Christian Doctrine for the instruction of about 40.000 children in 740 centres. Though embroiled with the Milanese senate, and in conflict with Gov. Luis de Requeséns, as well as with the rebellious canons of Sta. Maria della Scala and the order of the Humiliati, the archbishop had the support of many religious congregations, including his own Oblates of St. Ambrose. His heroic behaviour during the plague of 1576–78 won him the admiration of his flock.

The archbishop died at Milan on Nov. 3. 1584. He was canonized on Nov. 1, 1610, by Pope Paul V, who set the feast day as Nov. 4.

BORROMINI, FRANCESCO (1599–1667), Italian architect, who in his very dynamic use of space and lighting was the chief exponent of the baroque style in architecture, was born at Bissone in Lombardy on Sept. 25, 1599. Trained as a stone cutter at Milan for five years from the age of nine, Borromini went to Rome in 1614 to work in that capacity under the architect Carlo Maderno at St. Peter's. From 1629 he was the chief assistant of Giovanni Lorenzo Bernini at the Palazzo Barberini and at St. Peter's, where he mas responsible for the execution of Bernini's great altar canopy. Borromini's first independent commission was the small cloister and church of San Carlo alle Quattro Fontane in Rome (1634–44), whose façade he added in 1662–67. The plan of the church was composed of a series of intersecting ovals capped by an oval dome with intricate coffering. The serpentine wall and intersecting spaces created a very dynamic interior and façade. He also designed the church of Sant'Ivo alla Sapienza in Rome (1642–60) on the basis of a six-pointed star-shaped plan covered by a complex dome rising out of the plan. Other principal works by Borromini in Rome are the Oratorio di S. Filippo Neri (1637–42). next to Santa Maria in Vallicella, the interior refurbishing of San Giovanni in Laterano (1646–50), the church of Sant'Agnese in the Piazza Navona (1653–57) and a perspective colonnade (1632–36) added to the Palazzo Spada.

Borromini used the classic architectural vocabulary in a much freer manner than Renaissance architects or his eminent contemporary Bernini. and created a much more personal style which was very effective for expressing the religious emotion of 17th-century Italy. He consistently used an undulating wall surface and made a great effort to unite as completely as possible all the elements of an architectural composition without losing any of the elements in the totality. Borromini died at Rome on Aug. 2, 1667. Engravings of his two most important buildings were published in two posthumous volumes, *Opus architectonicum equitis Francisci Boromini* (1720 and 1725).

BORROW, GEORGE HENRY (1803–1881), English traveler, linguist and one of the most imaginative minor prose writers of the 19th century, was born at East Dereham, Norfolk, July 5, 1803: the son of a professional soldier who had risen slowly from the ranks. and of the daughter of an East Anglian yeoman. He led a wandering childhood, as his father's regiment was moved around the British Isles; these peregrinations inspired memorable passages in his masterpiece, Lavengro. But between 1815 and 1818 he attended the grammar school at Norwich, where Captain Borrow eventually settled, and it was at Norwich that he began to pick up a smattering of many languages, including Latin, Greek, French, German. Hebrew, Armenian and Romany; and, under the influence of a local sage, William Taylor, he imbibed "infidel notions" and tormenting philosophic doubts. An attempt to apprentice him to the law proved unsuccessful, and early in 1824 he decided to try his luck in London. There he remained, he tells us, for about a year, scraping a bare livelihood from various types of hack work. At length his health collapsed and he experienced a severe attack of a nervous affliction that he called "the Fear" or "the Horrors," which drove him off on a long bohemian pilgrimage

through the fields and heaths of rural England. His adventures provided some of the background of *Lavengro* and *The Romany Rye*, which describe how he consorted with gypsies, fought the "Flaming Tinman," encountered the Amazonian virgin Isopel Berners and was "drabbed" by the ferocious Mrs. Hearne.

He strayed back again, however, to Norwich, where he completed *Romantic Ballads*, translated from the Danish (1826). For the next six years, known to his biographers as the "veiled period." the record of his moyements is obscure, though he liked to imply that he had traveled as far as the frontiers of China. Having returned to Norwich, he was oppressed by a sense that he had already failed in life; he was "drifting on the sea of the world" without occupation or real purpose. and he did not discover the incentive he needed until in 1833, helped by a Norfolk friend, he became the agent of the British and Foreign Bible society. walking the 112 mi. from Norwich to London for the interview. He went first to St. Petersburg to superintend a Manchu translation of the New Testament, and later to Portugal and Spain to promote the circulation of the Holy Scriptures. In Spain he found his literary homeland, whence he drew the raw materials of *The Zincali: or an Account of the Gypsies in Spain* (1841) and of his brilliantly picturesque, yet highly informative travel book *The Bible in Spain* (publ. Dec. 10, 1842; title page date 1843). Its success was "instantaneous and overwhelming."

Meanwhile, Borrow had married (1840) a motherly widow seven years older than himself. who possessed a cottage at Oulton Broad, Norfolk, and there he rusticated for two decades after his retirement from the service of the Bible society. In 1851 he published *Lavengro*— "a dream, partly of study, partly of adventure"—in which poetic glimpses of his childhood and youth, and of the vanished England through which he had wandered as a boy, are presented and linked with great imaginative freedom. It is neither a novel nor a straightforward autobiography, but has some of the qualities of both.

Yet *Lavengro* was coolly received by the critics; and so was its sequel, *The Romany Rye* (1857). and a new travel book, *Wild Wales* (1862). Borrow gradually grew more and more cantankerous and eccentric. He still traveled widely, both in Great Britain and on the continent. but there was no repetition of his former triumphs; his last book, *Romano Lavo-Lil, Word-Book of the Romany* (1874). proved an inadequate and ill-digested work. His mother, whose influence had always been strong, died in 1858, and in 1860 he moved to London. His wife died in 1869, and in 1874 he returned to Oulton Broad, where he died, alone, on July 26, 1881.

Physically, George Borrow was a splendid figure—muscular, strongly built, "standing six foot two in his stockings"; temperamentally. he was a prey to fits of profound dejection and introspective gloom. No doubt it was the blend of these two contrasted personalities—the man of action and the melancholy introvert—that helped to give his two great books, *The Bible in Spain* and *Lavengro*, their strange and fascinating character.

BIBLIOGRAPHY.—The standard life of Borrow is W. I. Knapp, *The Life, Writings and Correspondence of George Borrow*, 2 vol. (1899); of many others the most interesting are those by H. Jenkins (comp.), *The Lije of George Borrow* (1912); *E.* Thomas, *George Borrow: The Man and His Books* (1913); C. K. Shorter, *George Borrow and His Circle* (1912); *M.* D. Armstrong, *George Borrow* (1950); *E.* Bigland, *In the Steps oj George Borrow* (1951); and B. Vesey-FitzGerald, *Gypsy Borrow* (1953). BORSIPPA (modern BIRS or BIRS NIMRUD), an ancient city about 15 mi. S.W. of Babylon (*q.v.*) and 10 mi. S.W. of the modern town of Al Hillah in southern Iraq, on the canal connecting the Hindiyah and Euphrates rivers. It was the sister city of Babylon; its patron god was Nebo. Borsippa became an important religious centre after Hammurabi had made Babylon his capital (*c.* 1790 B.C.). Hammurabi built or rebuilt the temple E-Zida at Borsippa, dedicating it to Marduk, subsequent kings recognizing Nebo as the deity of E-Zida and making him the son of Marduk; and his temple mas second only to that of Marduk in Babylon. As with Babylon, the time of Nebuchadrezzar (reigned 605–562 B.C.) was the period of Borsippa's greatest prosperity: there is evidence that the temple school of astrology and astronomy. for which Borsippa had for centuries been famous: was still in existence in the late 6th century B.C. A famous archaeological text entitled *Enuma Anu Enlil*, a list of omens and prognostications about the kings of Assyria and Babylon, was edited there.

The site of the ancient city extended over a wide area and was excavated at intervals from the middle of the 19th century onward. The first systematic and productive work was that of R. Koldewey, who was concurrently excavating Babylon in 1902. At that time he undertook the clearance of the incomplete and ruined ziggurat built on the site of a predecessor by Nebuchadrezzar. This now forms a hillock over 100 ft. high and consists of a pointed core of vitrified brick split down the centre. around which lie masses of rubble and some enameled bricks: inscribed with the name of Nebuchadrezzar, twisted and broken, apparently by great heat. This extraordinary phenomenon has been accounted for by spontaneous combustion activated by matting and bitumen in the core of the structure. Not far distant from the ziggurat there was a vast temple erected to Nebo on a typical Babylonian ground plan. These buildings were enclosed by a sacred *temenos* which comprised a series of magazines. Roldewey interpreted these structures as designed to accommodate pilgrims. If this theory is correct there is a close analogy to be drawn with the layout in the neighbouring Muslim city of Kufa. Borsippa was destroyed by Xerxes I of Persia in the early 5th century B.C. and partly restored by the Seleucid king Antiochus I in the 3rd century B.C., but was in ruins long before the middle ages.

BORSTAL SYSTEM. The Borstal system, as established in England by the Prevention of Crime act. 1908. derived from the concern of the Gladstone committee of 1805 with the penal treatment of offenders between 16 and 21 years of age and their suggestion that they should be removed from the prisons to a "penal reformatory." There they should be given sound education and industrial training, with a staff "qualified to exercise the best and healthiest kind of moral influence" and .'special arrangements for receiving and helping them on discharge." Sir Evelyn Ruggles-Brise (1857–1935), then chairman of the prison commission. determined to follow this course. He went first to the United States to study the reformatory at Elmira. N.Y. In Oct. 1902, he took over an old convict prison at Borstal, Kent, "for the special location and treatment on reformatory lines of young prisoners aged 16–21 selected from the ordinary prisons." Rules for giving effect to this system were approved by parliament, but it mas not until 1908 that "Borstal detention" mas prescribed as a separate sentence which the courts might pass in lieu of imprisonment. These legal provisions were replaced by sec. 20 of the Criminal Justice act, 1948. Borstal detention became "Borstal training" and the eligibility for sentence was based on the need of the offender for such training: to assess this the courts were required to consider a report on the offender made by the prison commissioners. The effect of the sentence is that the offender is under control for four years, of which not less than nine months nor more than three years is spent in an institution, the remainder in controlled freedom under supervision.

The basic principles of Borstal training were laid down by Alexander Paterson, who became a prison commissioner in 1922: individual personal training by a trained and dedicated staff, based on progressive trust and responsibility, in conditions as little like those of a prison as possible. To further this system the institution was divided into houses of, ideally. not more than 50 each leading its separate and corporate life under its own housemaster or housemistress and house staff. The training is nevertheless exacting, based on a full day's hard and interesting work. There are vocational training courses in skilled trades for all who can profit by them. with six hours a week of evening education either in the Borstal or in local technical colleges. Physical education and sport are highly developed and activities outside the institution are

encouraged. Every opening is sought for contacts. whether social or sporting, with young people outside. The period of training. though decided in each case on individual considerations, is related to an over-all average of about 16 months and governed by the progress of the inmate through a grade system. In the latter part of the training five days' home leave is allowed. On release the inmate comes under the care and supervision of the Central After-care association and may be recalled for further training if necessary.

The Borstal system for boys includes centres for those recalled from supervision and transferred for absconding or serious misconduct, and reception centres at which inmates are studied for some weeks, so that they may be sent to the Borstals best suited to their characters and requirements: About half of the Borstals are "open." the otters of various degrees of security. The program for girls is less extensive. In one five-year period from 1952 to the end of 1957 about 10.000 boys passed through the Borstal system of whom, by the end of 1959, about 4.700 had not again been convicted. For girls the numbers were 700 and 500.

The Borstal system set a pattern widely followed in the commonwealth and many other parts of the world. A new future n-as proposed for it in a report of the Advisory Council on the Treatment of Offenders, *The Treatment* of *Young* Offenders (1959): imprisonment for young offenders for terms of under three years would he abolished: sentences of detention up to six months would he served in detention centres; below three years there would be an indeterminate sentence from six months to two years, on the lines of the existing Borstal sentence. followed by two years' supervision. These proposals were accepted by the government in principle. *See* also PRISON.

See L. W. Fos, The English *Prison and* Borstal *Systems* (1952).

BORT (BOART) is an inferior kind of diamond, or pure carbon. unfit for cutting but useful as an abrasive agent. The typical bort occurs in small spherical masses. of grayish colour, rough or with a crystal-coated surface, and showing on fracture a radiate crystalline structure. These masses. known in Brazil as bolas, are often called "shot bort" or "round bort." Much of the bort consists of irrepular aggregates of imperfect crystals. In trade, the term bort is extended to all small and impure diamonds and crystalline fragments of diamonds, useless as gem stones. A large proportion of the output of some of the South African mines consists of such material. This bort is crushed in steel mortars to form the diamond powder used by lapidaries for grinding and polishing gem stones. *See* also ABRASIVE; DIAMOND.

BORUJERD (BURUJIRD), chief town of a district (Shahrestan-e Borujerd) in western Iran, in the *ostan* (province) of Khuzistan and Luristan (Lorestan). Pop. (1056) 49.228, mostly Lurs. It lies 5.500 ft. above sea level at the eastern foot of the high ranges of Luristan, in a wide and fertile valley drained by a tributary of the Sexar which joins the Dez. Borujerd is a flourishing regional centre profiting from its position on the main highway from the Persian gulf and Khuzistan via Khorramabad to Teheran, with good communication to Hamadan and Kermanshah. The Trans-Iranian railway can be reached 30 mi. away at Dow Rud.

Borujerd district (pop. 130,277 including the town) comprises mainly the valley and has many traces of ancient settlement in the form of *tappehs* ("mounds"). (H. Bo.)

BOSANQUET, BERNARD (1848–1923), English philosopher. the last major representative of Neo-Hegelianism in England, was born on June 14, 1848, the son of the Rev. R. W. Bosanquet, of Rock hall, near Alnwick, Northumberland. He was educated at Harrow and at Balliol college, Oxford, where he came under the influence of Benjamin Jowett and of T. H. Green and was a younger contemporary of R. L. Nettleship. Elected a fellow of University college in 1870, he worked as tutor there for ten years. Then, in 1881, he moved to London. where he devoted himself to philosophical writing and to work on behalf of the Charity Organization society and of various associations. In 1895 he married Helen Dendy, with whom he set up house at Oxshott, Surrey. in 1899. In 1903 he was appointed professor of moral philosophy at St. Andrews, a post which he held until 1908. In 1911 and 1912 he delivered his Gifford lectures at the University of Edinburgh on *The Principle of Individuality and Value* and *The Value and* Destiny of *the Individual*. He died in London on Feb. 8, 1923.

Although Bosanquet. like F. H. Bradley. owed much to Hegel, his first writings, *Knowledge and* Reality (188 j) and Logic (1888), show the influence of R. H. Lotze (English translations of Lotze's *Logic* and of his *Metaphysics* had appeared under Bosanquet's editorship in 1884). The fundamental principles in these works, which are brought out more clearly in the later and smaller *Essentials* of Logic (189;) and *Implication and Linear* Inference (1920), turn on the dynamism of logical thought and on the notion of system and coherency and are summed up in Bosanquet's remark: "Logic, or *the* spirit of *totality,* is the clue to reality, value and freedom."

In middle life. Bosanquet turned to aesthetics and ethics. Already in 1886 he had introduced a comparatively new subject into British philosophy by his translation of the Introduction to Hegel's *Philosophy of* Fine *Art*. His own History *of Aesthetic* (1892) and *Three Lectures* on *Aesthetic* (1915) show his belief that aesthetics can reconcile. as he himself says, "this world and the other, the a posteriori and the *a priori,* the natural and the supernatural." In his ethical and social philosophy, the more practical side of which appears in *Some Suggestions in Ethics* (1918), he shows the same desire to think of reality as a concrete unity wherein "the other world" and "this," pleasure and duty, egoism and altruism are reconciled. This desire, he says, was inspired by Plato's passion for the unity of the universe, a passion which reappeared in Christianity as the doctrine of the divine spirit present in human society. In social life, the most valuable thing. for Bosanquet, is that communal will which grows out of individual co-operation and at the same time supports the individual. making him free and bestowing upon him the fruits of participation in the whole. This doctrine is developed at length in his famous *Philosophical Theory* of *the State* (1899; 3rd ed., 1920) and in his *Social and International Ideals* (1917).

In later life, Bosanquet became more interested in metaphysics. In the Gifford lectures, he started with Hegel's concept of the dynamic character of human knowledge and experience. Insisting that the content and the object of thought are inseparable and that thought. as he was to express it in *Three Chapters* on *the Nature of Mind* (published posthumously in 1923), is "the development of connections" and "the sense of the whole," Bosanquet eventually arrived at the conviction of an indispensable reality beyond and behind experience, a reality which determines the true mutual relations of all beings. He observes in his contribution to J. H. Muirhead's *Contemporary British Philosophy* (1924) that experience has value insofar as the fullness of the whole is reflected in it and that knowledge is true in proportion as a system has adequate determination and the minimum of alternative possibilities. It was his overemphasis on the incoherencies and hazards of finite personality which led him to deny to this ultimate reality or Absolute the applicability of the word "personality" and to prefer "individuality"; and just as he believed that it could not be the supreme end of the Absolute to give rise to beings such as he experienced himself to be, so he concluded that the desire for personal immortality is unworthy. since the content of the self and the continuance of that for which we care most is secured in the Absolute.

BOSCÁN ALMOGÁVER, JUAN (Catalan JOAN BOSCÀ ALMUGÀVER) (*c.* 1490–1542), Catalan poet who wrote exclusively in Castilian and adapted the Italian hendecasyllable to that language. was born in Barcelona between 1487 and 1492. Though a minor poet. Boscán is of major historical importance because of his naturalizing of Italian metres and verse forms. which had

only been sporadically cultivated in Spanish before the Venetian ambassador, Andrea Navagiero, persuaded him in 1526 to attempt them. Modest as the success of this experiment was, it sufficed to induce one of the greatest of all Spanish poets, Boscán's younger friend Garcilaso de la Vega, to follow his example. Their works appeared together posthumously in 1543, and the tide of Petrarchanism flowed over Spanish poetry for the next century and a half.

Boscán had published in 1534 a translation of Castiglione's *Il Cortegiano:* his prose was greatly superior to his verse. and El *Cortesano* is not only one of the influential books of the Spanish Renaissance but a work of art in its own right. He died in Barcelona on Sept. 21, 1542. (F. S. R.)

BOSCASTLE, a small seaport in north Cornwall, Eng., 19 mi. N. of Bodmin by road. Pop. (1951) 684 (civil parish of Forrabury and Minster). The village. with its precipitous street, rises from a small harbour in a very narrow cove into which the Valency flows; vessels have to be warped into the harbour by means of hawsers. One of the two jetties mas destroyed in World War II. A mound on a hill above the harbour marks the site of a Norman castle. Minster church is in the woods. but the parish church of St. Symphorian, Forrabury, stands high, overlooking the Atlantic from Willapark point. Its tower (1750) is without bells. The coast scenery near Boscastle is severely beautiful, with abrupt cliffs broken only by inlets such as Crackington and Pentargon coves. Inland are bare moors, diversified by narrow dales, rising to the mountain mass of Brown Willy (1,375 ft.). The National trust owns more than 400 ac. around Boscastle. including the harbour.

BOSCAWEN, EDWARD (1711–1761). British admiral who played a distinguished part in the Seven Years' War, was born on Aug. 19, 1711, the third son of Hugh, 1st Viscount Falmouth. He entered the navy at an early age, serving under Vice-Admiral Francis Hosier in the West Indies in 1726, and under Admiral Vernon at Porto Bello (1739) and at Cartagena (1731). On his return he married Fanny Glanville, a noted "bluestocking." whose conversation, said Dr. Johnson, was the best of any woman he had met. Boscawen became member of parliament for Truro in 1742, but continued to serve at sea, notably at the battle off Cape Finisterre in May 1747 when the French squadron suffered an overwhelming defeat. He was then sent out in command of a fleet to recapture Madras, and when the news of peace arrived in India the place was given up to him. His premature capture of the French ships "Alcide" and "Lys" off Newfoundland in April 1755 precipitated the outbreak of the Seven Years' War. In 1758 he was promoted admiral and in co-operation with Jeffrey Amherst and James Wolfe captured Louisburg. Cape Breton. The next year, when in command of the Mediterranean fleet, he chased a French fleet under M. de la Clue off Lagos, took three ships and burned two, thus defeating the proposed concentration of the French fleet at Brest for an invasion of Great Britain. As a reward, in Dec. 1760 he was given the lucrative post of general of marines, but his death on Jan. 10. 1761, cut short a brilliant career.

See P. K. Kemp (ed.), "Boscawen's Letters to His Wife, 1755–56" in *Naval Miscellany,* Navy Records Society, vol. iv (1952); C. Aspinall-Oglander (ed.), *Admiral's Wife: Life and Letters of the Hon. Mrs. E. Boscawen, 1719–61* (1940). (C. C. L.)

BOSCH, HIERONYMUS (c. 1450–c. 1516) was the signature used by Hieronymus van Aeken or van Aken, a Dutch painter famous for his fantastic allegorical paintings; it derives from his birthplace, Hertogenbosch in North Brabant. Possibly a grandson of the local artist Jan van Aeken, he is first mentioned in 1480–81 as "Jeroen the painter" in the records of the Confraternity of Our Lady, for which he is known to have worked, and his name recurs there intermittently until. in 1516, he is referred to as being dead.

None of Bosch's works is dated, but the earliest paintings ascribed to him seem to belong to about 1475–80. They are firmly rooted in the conservative north Netherlandish tradition, and include a painted table top of "The Seven Deadly Sins" in the Escorial, near Madrid, "The Stone Operation" in the Prado, Madrid, and an "Ecce Homo" in Frankfurt.

His personal style can be seen emerging from this early blend of archaism and intense originality in such works as "The Wedding Feast at Cana" now in Rotterdam, but it is in the great triptychs of his maturity, "The Hay-Wain" and "The Garden of Lusts" in the Escorial, "The Temptation of St. Anthony" in Lisbon. and "The Epiphany" in the Prado, that his genius is fully revealed. Also among his mature works are smaller paintings such as the "St. John on Patmos" in Berlin. the "St. Jerome in the Desert" in Ghent and the "St. John the Baptist in the Wilderness" in Madrid; the last-named is closely connected with a painting of a similar subject by Geertgen tot Sint Jans, whose art shows many links with that of Bosch. With the late works, such as the two versions of "The Crowning With Thorns" now in the National gallery, London, and in the Prado, Bosch's constant preoccupation with the embodiment of evil takes on a new emphasis that culminates in "The Carrying of the Cross," now in Ghent. There is indeed a pessimistic strain throughout his work, a stress on sin and folly and the forces of evil, upon death and damnation and the horrors of hell, which in part reflects the troubled religious and social currents of the day.

BY COURTESY OF NATIONAL GALLERY, LONDON
"THE CROWNING WITH THORNS" BY HIERONYMUS BOSCH. IN THE NATIONAL GALLERY, LONDON

The actual subject matter of some of Bosch's works is a source of great controversy. not only as regards the grotesque, part human, part animal, or half mechanical, half vegetable forms that populate them, but also as regards the general meaning.

On the one hand, it is argued that he was a member of an extreme, heretical, secret society. On the other, it is increasingly clear that much of what seems strange and esoteric in his art derives directly from local folklore, from popular sayings and traditions. and, more especially, from the local mystery plays and pageants with their elaborate *tableaux vivants,* and would therefore have been wholly familiar and intelligible to Bosch's fellow citizens.

Bosch was a vibrant colorist and his technique was based upon translucent glazes floated over a light ground with such extreme delicacy that the bold under drawing is often clearly visible. The pen work in his few existing drawings has a freedom that was new in Netherlandish art, and the apparent mass of detail in his mature works is characterized. in the areas of heavier pigment, by a brilliant liveliness of brush stroke that distinguishes his own works from innumerable copies and derivative paintings.

As a satirist, as a moralist and observer of the human scene, as a designer of landscape settings, and as a painter in the technical sense, Bosch was a pioneer upon the road that was followed by Pieter Brueghel half a century later.

Constantly imitated and misunderstood by lesser artists, his works were collected by the great, particularly in Spain where many of his paintings bear witness to Philip II's passionate interest in his art.

BOSCH, KARL (1874–1940), German industrial chemist. received the Nobel prize for chemistry in 1931 jointly with Friedrich Bergius (*q.v.*), for contributions to the invention and development of chemical high pressure methods. Bosch was born at Cologne. Ger., on Aug. 27. 1874. and educated in the University of Leipzig, where he studied under Johannes Wislicenus and obtained his doctorate in philosophy in 1898 for research in organic chemistry. His interests were, however, general and he studied engineering in Charlottenburg in 1894 and obtained workshop experience. Leaving Leipzig, he worked for the Badische Anilin und Sodafabrik, of which (when it became I. G. Farben Industrie) he

was later president; and here he succeeded in transferring from laboratory to industrial scale Fritz Haber's (*q.v.*) process for synthesizing ammonia from its elements. hydrogen and nitrogen, catalytically at high pressures. Researches on this process involved the carrying out of over 20,000 experiments, including an exhaustive search for catalysts among the metals and their compounds.

He invented also the Bosch process for preparing hydrogen on the manufacturing scale by passing a mixture of steam and water gas over a suitable catalyst at high temperature. He died on April 26. 1940, in Heidelberg. (D. McK.)

BOSCH, ROBERT AUGUST (1861–1942). German engineer and industrialist whose firm produced a range of precision machines and electrical equipment in plants throughout the world, was born at Albeck bei Ulm on Sept. 23, 1861. He was trained in the Cnited States, where he worked with Siegmund Bergmann and Thomas A. Edison.

In 1886 he founded the manufacturing company named after him in Stuttgart. In 1902 his co-worker G. Honold invented the Bosch spark plug. which promoted the development of the automobile. and Bosch also developed the Bosch magneto and the Bosch lamp. Bosch had advanced social views. He introduced an eight-hour day in 1906, and he advocated industrial arbitration and free trade. His *The Prevention* of *Future Crises in the World Economic System* (1934) was translated in 1937. Bosch died in Stuttgart on March 9, 1942.

See Theodor Heuss, *Robert Bosch* (1945). (M. J. Bi.)

BOSCO, SAINT JOHN (Giovanni Melchior Bosco) (1815–1888), a pioneer of education for the poor in Piedmont and the founder of the Salesian order, was horn at Becchi, near Chieri. Italy, on Aug. 16, 1815. His early years were passed in extreme poverty. He was ordained priest in 1841 and subsequently, in Turin, came under the influence of Joseph Cafasso, who turned his attention to the moral danger and destitution of many country boys who came to seek employment in,the city. John Bosco began his work for them in borrowed premises. providing them with education, religious instruction and recreation; eventually he was at the head of a large establishment containing 700 boys with a grammar and technical school and fine church attached, all built by his persistent begging and hard work. In addition he achieved a certain local reputation as a popular preacher and writer. His genial, affectionate approach to boys accounted for much of his success; he strove to lead rather than to drive them. His sunny disposition, readiness to help all who asked and capacity for hard work ensured him a wide sphere of influence. With those who had come to help him he founded in 1859 the Society of St. Francis of Sales (known as the Salesians), which before his death had spread to England. France. Spain and a number of South American countries. with several houses in Italy. With Mary Mazzarello he founded a congregation of nuns for similar work among girls. He died at Turin on Jan. 31, 1888. He was canonized in 1934. his feast day being Jan. 31.

See L. C. Sheppard, *Don Bosco* (1957). (L. C. S.)

BOSCOVICH, RUGGIERO GIUSEPPE (1711–1787), Serbo-Croatian astronomer and mathematician, was perhaps the first of the continental virtuosos to adopt Newton's gravitational theory. He was born at Ragusa (Dubrovnik) in Dalmatia on Play 18. 1711. Entering the Society of Jesus in 1726, he studied mathematics and physics at the Collegium Romanum where he was appointed professor of mathematics in 1740. His published work, of nearly 70 papers, concerns optics, astronomy, gravitation. meteorology and trigonometry.

A pioneer in geodesy. he measured. together with C. Maire, an English Jesuit, a meridian arc between Rome and Rimini in 17jo for the purpose of testing his theory that the earth is not an ellipsoid of revolution. He accepted the chair of mathematics at the Cniversity of Pavia in 1764 and also served as director of the Brera observatory. When the Jesuits were suppressed in Italy in 1773, Koscovich accepted an invitation from the king of France to settle in Paris as director of optics for the marine, a post created especially lor him. I-Ie returned to Italy in 1783 and died at Milan on Feb. 13. 1787.

See H. V. Gill, *Roger Boscovich S.J.* (1941). (O. J. E.)

BOSE, SIR JAGADIS CHANDRA (1858–1937), Indian plant physiologist and physicist. whose outstanding work in the field of animal and especially plant physiology was so much in advance of his time that the precise evaluation of it was controversial. He was born on Nov. 30, 1858, and educated at St. Xavier's college, Calcutta, and Cambridge university, gaining high honours in 1884 and being awarded the degree of doctor of science in 1896. He was professor of physical sciences at the Presidency college, Calcutta, 1885–1915. and founder and director of Bose Research institute. Calcutta! 1917–37. He died in Giridih, Bengal, on Nov. 23. 1937.

Bose introduced new experimental methods and invented many delicate and sensitive instruments, such as his crescograph for recording plant growth. magnifying a small movement as much as 10,000,000 times. He also devised apparatus for demonstrating the effects of air, food, drugs, etc., on plants and demonstrated a parallelism between the responses of plant and animal tissues. His publications are voluminous;, the most important are: *Response in the Living and Non-Living* (1902); *Plant Response* (1906); *The Motor Mechanism of Plants* (1928), etc.

See P. Geddcs, *The Life and Work of Sir Jagadis C. Bose* (1920) and *Sir* J. C. *Bose: His Life and Speeches* (1920); *Chron. Bot.*, vol. iv (1938) and *Nature,* vol. cxl (1937).

BOSELLI, PAOLO (1838–1932), Italian statesman, head of the government which declared war on Germany in World War I, was born at Savona on June 8, 1838. He was the first professor of financial science in the University of Rome. A deputy from 1870 to 1921, when he became a senator, he belonged to the right centre and was a member of the governments of Francesco Crispi, Luigi Pelloux and Sidney Sonnino; in 1899, as minister of the treasury under Pelloux, he reorganized the Bank of Italy. He became president of the Dante Alighieri society in 1907. In favour of Italy's entry into World War I against Austria-Hungary (1915), he made a notable speech in the chamber in defense of the enabling bill giving full powers to the government of Antonio Salandra. On Salandra's fall (June 1916), he formed a coalition government including all parties except the official Socialist party, which still opposed participation in the war. The Italians recovered ground after the Austrian offensive of May–July 1916 and, on Aug. 25, 1916, war was declared on Germany. The defeat at Caporetto, however, made the government's resignation on Oct. 30, 1917, inevitable. In March 1929, Boselli was government spokesman in the senate for the bill to approve the Lateran treaties between Italy and the Vatican. He was president of the Italian Historical institute and founded the museum of the Risorgimento. He died in Rome on March 10. 1932. (N. S. J.)

BOSKOP SKULL. In 1913 a portion of a calvaria (skull dome) was unearthed by labourers on a farm near Boskop, a village in the Potchefstroom district of the Transvaal. South Africa. The specimen consisted of the greater part of the frontal and parietal bones and a small portion of the occipital. The exact spot of the discovery was not determined by investigators who visited the farm shortly after, but it appeared to have been found in the lateritic deposit about four feet below the surface. There was no evidence whether there had been a prepared grave or not. A year later excavations at the site disclosed a nearly complete temporal bone, most of the body of the left side of a poorly preserved mandible (with a second molar) and a number of fragments of limb bones. The site was in a cultivated field about 250 ft. from the hank of the Mooi river and about 12 ft. above the river-bed level. No faunal or cultural remains were found in direct association, except for a single unusual stone artefact which was only described in 1954 (C. van Riet Lowe, "An Artefact Recovered With the Boskop Calvaria," *South African Archaeological Bulletin,* 9:135–137 [1954]). No geological age can be assigned to the skull.

The frontal bone is rounded and narrow (minimum breadth is 102 mm.) with a constriction above the nonprotruding, thin supraorbital ridges. Some degree of parietal bulging ("bossing") is present. and the thickness of the calvaria varies from 6 to 13 mm. The cranial capacity is approximately 1,800 ml. The

distinctive features are the length (205 mm.) and breadth (150 mm.).

The skull has at various times been called Neanderthaloid, Cromagnoid, Negroid, pre-Bush (*i.e.,* Bushman and Hottentot), pre-Negro, etc. Many anthropologists have associated the Boskop skull with a hypothetical Boskop race because of discoveries of apparently similar skulls at other sites in Africa. However, in a detailed review R. Singer ("The Boskop 'Race' Problem," *Man,* p. 232 [1958]) has pointed out that the Boskop skull is of Bushman-Hottentot nature and that its evolutionary significance is minimized in the light of the paucity of scientific data relating to its discovery. It presents no primitive features and there is no justification for utilizing the term Boskop race. (R. SI.)

BOSNIA-HERCEGOVINA (BOSNA I HERCEGOVINA), one of the six people's republics of the Federal People's Republic of Yugoslavia. Roughly triangular, it is bounded by Serbia and Montenegro to the east and southeast, and by Croatia to the north and west. The name Bosnia (Serbo-Croatian Bosna) is derived from that of the Bosna river and is probably of Illyrian origin. Hercegovina, the southern part, takes its name from the title herceg (Ger. Herzog, "duke"), assumed in the 15th century by a local ruler.

With an area of 19.741 sq.mi., Bosnia-Hercegovina is mostly a mountainous country. To the southwest about one-quarter of its area is covered by the so-called karst (krs), an arid limestone plateau with small depressions fit for cultivation. In the central and eastern parts of Bosnia there are forests of pine, beech and oak. Arable land represents about one-half of the republic's area but the fertile soils are mainly in the north. Hercegovina grows tobacco of high quality.

According to the census of 1961. Bosnia-Hercegovina had a population of 3,274,886. In the 1953 census 44 8% declared themselves as Serbs, 23% as Croats and 31 4% as Yugoslavs (or undetermined). The Serbs are Orthodox. the Croats are Roman Catholic; about one-third of Bosnians are Muslim. The capital of the republic is Sarajevo (*q.v.*), which is also the seat of the head of all Muslims in Yugoslavia (*reis-ul-ulema*) and also of a Serb-Orthodox metropolitan and of a Roman Catholic archbishop. The other main towns are Llostar and Banja Luka, both of which are the seat of a Serb-Orthodox and of a Roman Catholic bishop; Tuzla, the seat of a Serb-Orthodox bishop; and Travnik. the seat of a Roman Catholic bishop.

HISTORY

Traces of Paleolithic life have been found at the mouth of the Usora river. Considerable Neolithic remains have been found at Donja Mahala, Donji Klakar. Kakanj, Novi Seher and. the most important of all. at Butmir. In Hercegovina the main Neolithic location is at Lisicici, near Konjic. Bronze and Iron Ages are also well represented. the most important Iron Age sites being Donja Dolina, Glasinac and Ripac.

Ancient and Medieval Period.—The most ancient inhabitants of Bosnia-Hercegovina were Illyrian tribes (see ILLYRIA). After the Roman conquest the country was included in the Roman province of Illyricum, except for the region along the Sava, which belonged to that of Pannonia.

Serbian settlement in Bosnia-Hercegovina began in the 7th century A D. (see SERBIA). After the death of Prince Chaslav (960), Bosnia was detached from the rest of Serbia and became a separate political entity. King Bodin (1081–1101) united Bosnia with the other two Serbian principalities—Rashka and Zeta, the prince Stephen ruling in Bosnia on Bodin's behalf. After Bodin's death, however. Bosnia separated again.

Hungarian encroachment on Bosnia began in the middle decades of the 12th century. László, son of Béla II of Hungary, is described as ruling in Bosnia in 1137, and from 1138 the title "king of Rama" was added to the royal style of the kings of Hungary, after their conquest of the small province of Rama. The local representatives of the Hungarian kings had the title of ban (*q.v.*).

The rule of Kulin, "the great ban," began about 1180. He concluded an agreement with Dubrovnik (Ragusa) in 1189 guaranteeing freedom of trade for his country. Then the efforts of the papacy to extend Roman Catholicism in Bosnia, combined with further political pressure by the Hungarians, who wanted Bosnia to be under a Hungarian archbishop instead of the Slavonic archbishopric of Dubrovnik, provoked a strong national resistance in the country, and Kulin embraced the Bogomil (*q.v.*) heresy. Pope Innocent III preached a crusade against him and in 1203 Kulin renounced his heresy in the presence of a papal legate. Nothing is known of Kulin after 1204. A certain Stephen, perhaps Kulin's son, is mentioned as the next ban. Pope Honorius III preached another crusade against the Bosnian heretics. War was avoided but Bosnia came under the jurisdiction of the Hungarian archbishop of Kalocsa.

Matej Ninoslav became ban about 1232. His promise to embrace Roman Catholicism caused a serious disturbance in Bosnia which was considered by the papacy as a country "overgrown with thorns and nettle and a breed of vipers." When Andrew II of Hungary and his successor Béla IV attacked Bosnia, Ninoslav sided with his people, and war went on from 1235 to 1239, the Hungarians making little progress. Ninoslav disappears from history after 1250. In 1252 the seat of the Roman Catholic bishop of Bosnia is recorded as being at Djakovo.

The **Kotromanic** Dynasty **and** Hum.—Ban Prijezda, who ruled in Bosnia as a vassal of Hungary from 1254 to 1287, was the founder of the dynasty of Kotromanic. His successor was Stephen Kotroman (1287–1316). Kotroman's son, Stephen Kotromanic (1322–53) extended Bosnia toward the south, conquering the province of Hum or Zahumlye (the future Hercegovina), styling himself count of Hum from 1326.

At the end of the 12th century Hum had been in the possession of the Serbian prince Miroslav, brother of the great *zupan* Stephen Nemanya of Serbia. Miroslav's successor was Petar (probably his son). He was defeated by Nemanya's son Stephen, but retained the part of Hum between the Neretva and Cetina rivers, the rest being divided between Andrija (probably also Miroslav's son) and Stephen's eldest son Radoslav. The Orthodox bishopric of Hum, the seat of which was first at Ston and later at the monastery of Holy Apostles on the Lim, was founded by St. Sava in 1219. Petar's successor in Hum was his nephew Toljen, who perished in battle during the Hungarian invasion of Bosnia (1235–39). Andrija's son Radoslav became a vassal of Hungary, but disappears from history after 1254. Subsequently the situation in Hum underwent a number of changes, but the whole country is known to have been subject to King Milutin of Serbia (d. 1321).

After his conquest of Hum. Stephen Kotromanic was prevented from further conquests by Milutin's grandson Stephen Dushan, but Dushan's struggle with the Byzantine empire prevented him from undertaking a counter offensive against Bosnia until 1350. Then Kotromanic was saved by a Byzantine invasion of Serbia, which forced Dushan to hurry to the south. Kotromanic was the first Bosnian ruler to coin money; his country extended "from the Sava to the sea and from the Cetina to the Drina."

Stephen Kotromanic was succeeded by his brother's son, Tvrtko I (1353–91), who ascended to the throne at the age of 15. Soon afterward Louis I of Hungary occupied part of Hum. claiming it as the dowry of his wife Elizabeth, daughter of Stephen Kotromanic. Relations between Tvrtko and Louis then worsened, leading to open war in 1363. After successfully opposing the Hungarians near Soko on the Pliva river and near Srebrnik on the Usora, Tvrtko was subsequently forced to leave the country by a revolt of the Bosnian nobles, which his brother Vuk supported. Eventually, however, he was restored to power by Louis. In 1377, in the monastery of Milesevo, at the tomb of St. Sava, Tvrtko crowned himself as "king of the Serbs and Bosnia, and the coastlands." In 1382, in order to make his trade independent, he built the town of Novi (the modern Hercegnovi) at the entrance of the Gulf of Kotor. Kotor itself was peacefully ceded to him by Hungary.

In 1386 the Turks invaded Bosnia. Their armies moved as far as the Neretva river but in 1388 were defeated by Tvrtko's commander Vlatko Vukovic at Bileca. Tvrtko also sent his forces under Vukovic's command to help his friend the Serbian prince Lazar, but the Serbs were disastrously beaten at Kosovo (1389).

Turning westward, Tvrtko in 1390 conquered Split, Trogir, Sibenik and the islands of Brac, Hvar and Korcula (Curzola). When he took the title of "king of Rashka, Bosnia, Dalmatia. Croatia and the coastlands," Bosnia was at the zenith of its power.

Tvrtko died in March 1391. His successor was Stephen Dabisa (1391–95), who at Djakovo, in 1393, concluded an agreement with Sigismund. king of Hungary (the future Holy Roman emperor). nominating Sigismund as his successor. After Dabisa's death, however, his widow Jelena assumed power, and Bosnia was not given to Sigismund, though no king was chosen instead. Sigismund's defeat by the Turks at Nikopol (1396), moreover! weakened his influence. In Bosnia two pretenders claimed the throne: Stephen Ostoja (believed to be an illegitimate son of Tvrtko I) and Tvrtko's legitimate son Tvrtko II. At the same time two magnates also rose to power: Sandalj Hranic and Hrvoje Vukcic, who soon were to play important parts in Bosnian history. Dissensions between these four contributed to the slow decline of the country, while the Hungarians and the Turks were still intervening in its affairs. When Ostoja (1398–1404) was dethroned by Hrvoje Vukcic, Tvrtko II became king (1404–09). Though a large number of Bosnian nobles were killed by the Hungarians at Doboj, Sigismund failed to conquer the country; and after Tvrtko II had been dethroned and Ostoja was reinstated (1409–18), the Hungarians were defeated at Doboj in 1415 by Hrvoje, who had received the help of the Turks. Ostoja's son Stephen ruled only two years and Tvrtko II then became king again (1420–43). His policy was now pro-Hungarian, but Sandalj believed that Bosnia must side with the Turks. After Sigismund's death, Turkish influence in Bosnia became greater. Sandalj. moreover, was master in Hum. Tvrtko then asked Venice for asylum and even offered Bosnia to Venice. The Venetians answered that they would receive him with pleasure but expressed their wish that he should retain his position.

Tvrtko II died in 1443 and Tomas, Stephen Ostoja's son, came to the throne (1443–GI). He continued the pro-Hungarian policy, but during his reign the Turks defeated János Hunyádi at Kosovo (1448), conquered Constantinople (1453) and occupied Serbia (1459). The pope preached in favour of a war against Turks but there was no unanimity for such an enterprise. Stephen Vukcic, as ruler of Hum (*see* below), told the Venetians through his envoy tha: he would rather give one of his strongholds to the Turks than have it in the hands of Tomas, who was occupying it.

Tomas' successor Stephen Tomasevic (1461–63) appealed to Pope Pius II for help against the Turks. "If you believe me and help me," he wrote, "I shall be saved; otherwise I shall perish and with me also the others." The pope sent him a crown and, despite the protests of Matthias Corvinus of Hungary, Tomasevic was crowned at Jajce in Nov. 1461. He then refused to pay further tribute to the sultan. On learning that the Turks were making preparations for an invasion of Bosnia, he sent envoys to Hum, to the republic of Dubrovnik and to Venice asking for help. He also sent envoys to the Turks, asking for a 15-year armistice. Four days after the envoys had left Istanbul with the promise of an armistice, the Sultan Mohammed II led his army into Bosnia. Bobovac, the capital, fell, and the king escaped to Kljuc. The Turkish commander, Mahmud Pasha Andjelovic, secured his surrender by promising him his life, but the sultan ordered the king to be beheaded. The execution took place at Jajce in 1463. Bosnia became a Turkish province. Matthias of Hungary in the same year seized northern Bosnia from the Turks and created two banats there: that of Srebrnica and of Jajce. The former was reconquered by the Turks in 1512, the latter in 1528.

Hum. however, resisted longer than Bosnia. After the death of Sandalj Hranic, the country passed to his nephew Stephen Vukcic, "a man of strong will, but of evil nature," who in 1448 proclaimed himself *herceg* of St. Sava. He died in 1466. His three sons were not able to withstand the Turks, who in 1482 conquered Hercegnovi. Hercegovina, too, became a Turkish province.

Bosnia as a Turkish Province. — The seat of the Turkish governor or pasha was at first at Banja Luka, later at Sarajevo. In 1580 the Bosnian pashalik was divided into eight *sanjaks*. The governor interfered little with local affairs so long as the taxes were paid. The real power lay in the hands of 48 hereditary *kapetans*, exercising feudal jurisdiction over their tenants and liable to provide military service for the sultan. The religious discords which had rent the country in medieval times were perpetuated in a new form: the nobility — partly to save their lands and power, partly because as Bogomils they preferred Islam to Roman Catholicism — apostatized as a class. Thus numbers of Bosnian Slavs became Muslim, though they continued to speak Serbian and never adopted polygamy. Few true Turks settled in Bosnia-Hercegovina.

The Turkish era saw an economic decline in Bosnia. The mining industry, which had prospered in the middle ages, decayed and finally disappeared; trade languished. The manufacture of weapons and wrought metals alone survived. Many Bosnians, however, rose to high distinction in the Turkish service — among them such famous grand viziers as Mohammed Sokollu (Sokolovic).

During the 16th and 17th centuries Bosnia was an important Turkish outpost in the constant warfare with the Habsburgs and with Venice. When Hungary was at last reclaimed from the Turks, the Austrians in their turn penetrated into Bosnia and in 1697 Prince Eugene of Savoy captured Sarajevo. By the treaty of Karlowitz (1699) the Sava, forming the northern boundary of Bosnia, became also the northernmost limit of the Turkish empire; and by that of Passarowitz (Pozarevac; 1718) Hercegnovi and part of Bosnia east of the Una river were ceded to Austria. These were restored to Turkey in 1739, and the frontiers remained unchanged until 1878.

In the 19th century the great conservative Bosnian families resented all interference from Istanbul. A revolt broke out in 1821, during the Greek rising, and another during the Russo-Turkish War of 1828, under the leadership of Mustafa Skodra Pasha, a reputed descendant of the Bosnian noble family of the Crnojevic. More formidable was the rising of 1831, when the *kapetan* Husein, Gradascevic, known as the Dragon of Bosnia, preached a holy war against the sultan and denounced the reforms of the sultan hlahmud II. He and Mustafa together overran most of Macedonia and northern Albania. After a severe struggle the grand vizier Reshid Pasha quelled the rebellion, helped largely by internal dissensions. Eventually the Dragon mas driven across the frontier into Croatia and ended his days in banishment at Trabzon (Trebizond). In 1837 the abolition of the *kapetanates* led to fresh trouble and the reforms with which Abdul Mejid inaugurated his reign were keenly resented. The Hercegovinian chief, Ali Pasha Risvanbegovic, who had sided with the Turkish government during the earlier rising, made himself virtually independent. The sultan's authority mas restored in 1850 by Omer Pasha, the renegade Croat. By ruthless measures Omer destroyed the old feudal regime in Bosnia, introduced a new, centralized administration and a system of taxation which opened the door to every kind of licence and exaction. In 1862 the Christians in their turn revolted under Luka Vukalovic. They were eventually reduced, but unrest was chronic and discontent universal; Christians and Muslims, despite acute differences, united in their dislike of Ottoman bureaucracy and corruption. (M. A. P.)

Bosnia Under Austrian Occupation. — In 1875 local troubles in Hercegovina spread rapidly into insurrection throughout the two provinces. In August the Austrian, Russian and German consuls tried to mediate between the Turkish authorities and the insurgents, but without success; and the sultan's decree of Oct. 2, offering reduction of taxes, religious liberty and a provincial assembly, was also rejected. The joint note presented by five European poxers on Jan. 31, 1876, proposing a limited autonomy, did not go far enough. The situation was complicated by the Bulgarian rising and massacres and by a revolution in Istanbul itself.

On June 30, 1876, Serbia and Montenegro declared war upon Turkey, while the insurgents proclaimed union with them, and numerous Russian volunteers joined the Serbian army. Turkey's speedy victory upset the calculations on which Francis Joseph and the Russian emperor Alexander II had reached a secret agreement at Reichstadt in July (*see* EASTERN QUESTION). Serbia. defeated again in October, after the expiry of the armistice, lost all hopes of winning Bosnia. By the secret convention of Budapest (Jan.–

March *1877)* Russia recognized Austria-Hungary's right to occupy Bosnia-Hercegovina in return for Austro-Hungarian neutrality in the impending war with Turkey. At the congress of Berlin after the Russo-Turkish War of *1877–78,* Serbia's aspirations and those of the insurgents were disregarded, and Bosnia-Hercegovina was assigned to Austria-Hungarian occupation, though it was still to be nominally two Turkish provinces. The insurgents attempted armed resistance, and Austria-Hungary had to mobilize an army of *200,000* men. Sarajevo mas occupied on Aug. *19, 1878,* and with the fall of Bihac a month later the rising was virtually at an end.

The two provinces were at first administered by a special commission inside the foreign office at Vienna, but in 1880 they were placed permanently under the control of the joint Austro-Hungarian ministry of finance. the local administration being concentrated in Sarajevo under a governor.

Benjamin Kállay, who became finance minister in *1882,* was for *21* years to direct every department of Bosnian policy. Six years' residence as Austro-Hungarian diplomatic agent in Belgrade had given him a unique knowledge of South Slav problems, but his whole influence u-as exercised in an anti-Serbian sense. He tried to evolve a "Bosnian" consciousness, to check Serbian national feeling and to create dissensions between Serbs and Croats Meanwhile he set himself to establish public order and material prosperity and achieved remarkable results; he built a network of roads and railways and many public institutions, founded an incorruptible bureaucracy and a system of law and fostered trade and industry.

On Kállay's death *(1903)* Bosnian affairs were again entrusted to a Magyar, Baron Stephen Burián. During the next decade there was a rapid growth in national feeling in the provinces. Burián, faced by the clamour of the Bosnian Serbs for self-government, made certain concessions. In *1905* the Orthodox Church received a charter of autonomy and its Serbian nationality was recognized for the first time. In *1907* an assembly of 71 Serbian delegates from every district was allowed to put forward a program of reform, in whieh figured the demand for an autonomous position "as part of the Turkish empire."

Annexation by Austria-Hungary.— Faced by the growing ferment inside the provinces. Austria-Hungary was already convinced of the need for some change in status when the Turkish revolution of *1908* brought matters to a head. The Young Turks contended that Bosnia-Hercegovina must be represented in the new parliament in Istanbul, and the Bosnian nationalists saw in this demand a convenient legal basis for their agitation. Influenced also by the strategic considerations pressed upon him by the general staff, Aloys, Graf Lexa von Aehrenthal (*q.v.*), the Austro-Hungarian foreign minister, advised Francis Joseph to annex Bosnia-Hercegovina to the dual monarchy and thus solve once and for all their constitutional status. On Sept. 15, *1908,* at Buchlau, A. P. Izvolski, the Russian foreign minister, gave Aehrenthal to understand that Russia did not object to such an annexation. Accordingly, by a rescript of Oct. *7, 1908,* Bosnia-Hercegovina was annexed to Austria-Hungary.

Vienna was committed to the grant of some measure of representative government to Bosnia-Hercegovina and as neither Austria nor Hungary would consent to its being attached to the one rather than the other, or to its partition between them, a hybrid form of constitution was devised. by which the two provinces received a diet (*sabor*) and special laws of association and assembly. but were not represented in the two central parliaments and delegations and thus had no say in foreign affairs. The new constitution, proclaimed on Feb. *7, 1910,* had the capital defect of stereotyping sectarian and social differences by dividing the electorate into three electoral colleges and by assigning in each of these a fixed proportion of seats to the Orthodox, to the Roman Catholics, and to the Muslims. The diet, composed of *72* elected and *20* nominated members, had no control of the executive.

These concessions were badly received. The emperor's visit to Bosnia in the summer of *1910* was intended to symbolize to the outside world the permanence of Austro-Hungarian rule; but the opening of the diet, on June 15, was marred by an attempt on the life of the governor, Gen. Marian Varesanin, by a student. Bogdan Zerajic, who at once committed suicide. Burián now tried to nin the Serbian element for co-operation with the government and openly described them as the most progressive element in the country. But the situation in Croatia reacted more and more on Bosnia, rendered Burián's half-measures ineffectual and strengthened the self-confidence of the Serbs. In Feb. *1912* Burián was succeeded by Leon Bilinski (1846–1923), a prominent Polish Conservative who enjoyed the confidence of Francis Joseph; but any hope of clearing up the internal situation u-as frustrated by Hungary's establishment of a dictatorship in Croatia (April *1912*) and by the victories of Serbia in the Balkan War (Oct.–Nov.)— events which excited the whole Yugoslav population of Austria-Hungary.

The "Young Bosnia" *(Mlada Bosna)* group was especially active among the Yugoslav students in Prague, Vienna and Zagreb as nell as Sarajevo. The younger generation devoted itself to inculcating revolutionary ideas among the university and secondary school youth in Bosnia with such success that confidential memoranda prepared by high officials in Sarajevo and Vienna on the eve of World War I show them to have been altogether at a loss as to what policy to adopt.

The Bosnian situation was further complicated by the increasing jealousy between the provincial government in Sarajevo and its nominal superior, the finance ministry in Vienna. or, in personal terms, between the military governor, Gen. Oskar Potiorek, representing the views of the general staff, and of the archduke Francis Ferdinand (*q.v.*) and the civilian minister Bilinski as the confidant of the emperor. In May *1913* Potiorek. despite Bilinski's disapproval, had closed the Bosnian diet and dissolved various Serbian societies. He continually urged the adoption of still more stringent measures and tended increasingly to act without consulting Bilinski. The most notorious instance was the decision reached between Potiorek and Francis Ferdinand that the latter should attend the military maneuvers in Bosnia in June *1911.* Bilinski was not consulted or even notified, and the entire arrangements remained in military hands. To the circumstance must be ascribed a large share of the blame for the assassination of the archduke Francis Ferdinand and his consort, the duchess of Hohenberg. during their visit to Sarajevo on June *28, 1914.* by a Bosnian Serbian student, Gavrilo Princip.

Union With Yugoslavia.— During World War I all political life ceased, but when Austria's Balkan front collapsed in Oct. *1918* a national committee was formed in Sarajevo, which acted in close accord with the Yugoslav National council in Zagreb. After its formal recognition of union with the Kingdom of Serbs, Croats and Slovenes, on Oct. *26, 1918,* the fate of Bosnia was bound up with that of the new Yugoslavia (*q.v.*).

(R. W. S.-W.; M. A. P.)

BOSPORUS (KARADENIZ BOĞAZI or ISTANBUL BOĞAZI), the strait that unites the Black sea with the Sea of Marmara and forms part of the boundary between Europe and Asia. The channel is *19* mi. long, and has a maximum breadth at the northern entrance of 2¼ mi.. a minimum breadth of *787* yd.. and a depth varying from *20* to *68* fathoms in midstream. In the centre there is a rapid current from the Black sea to the Sea of Marmara, but in the opposite direction a countercurrent sets in below the surface carrying more saline water from the Sea of Marmara to the Black sea. The scenery on both sides is varied and beautiful. Many villages line each well-wooded shore, while on the European side are numerous fine residences; the city of Istanbul (*q.v.*) is at the southern end of the strait, on the European side. After the treaty of 1841. no ship of war other than Turkish was allowed to pass through the strait (or through the Dardanelles) without the consent of the Turkish authorities. They in turn were under the control of

an International Commission of the Straits after 1918. In 1923, however, under the terms of the treaty of Lausanne, Turkey was given more power in the straits zone and the commission, put under a Turkish chairman, lost much of its independence. In 1936 it was abolished and Turkey was allowed to remilitarize and reoccupy the straits. *(See* also STRAITS QUESTION.)

The Bosporus is the only passage between the Black sea and the Aegean, and is used by migratory fish coming from and going to the Black sea seasonally. It is therefore one of the richest fishing grounds of Turkey and is famous for species such as red mullet.

In antiquity the name Bosporus, signifying strait, was applied both to this strait (Bosporus Thracius) and to the Strait of Kerch (Bosporus Cimmerius). It means literally oxford and is traditionally connected with Io, who crossed the Thracian Bosporus in her wanderings, in the form of a heifer. (N. TU.; S. ER.; E. TU.)

BOSPORUS, KINGDOM OF THE (or CIMMERIAN BOSPORUS), an ancient state on the Straits of Kerch, which connect the Black sea with the Sea of Azov. A number of Greek colonies were established in this region in the 7th and 6th centuries B.C. The most important was the Milesian colony of Panticapaeum (mod. Kerch) on the western side of the straits at the extreme eastern tip of the Crimea. Close to it lay Nymphaeum, 10 mi. S. of Kerch; on the eastern side, Phanagoria (near modern Taman), founded from Teos, Hermonassa, founded from Mytilene, and other small settlements.

The colonies' early history is unknown. Panticapaeum is said to have been founded by permission of the Scythians, who then ruled the area that is now southern Russia except the southern Crimea. and these colonies may have depended on the good will of neighbouring Scythian chieftains, at least in the early stages.

From 480 to 438 B.C. Panticapaeum was ruled by the Archaeanactid dynasty, and from 438 to the end of the 2nd century B.C. by the Spartocid dynasty. Of the former nothing is known. The latter are fairly well known because of their relations aith Athens. To judge by the names, the Archaeanactids were probably purely Greek in race, the Spartocids half Thracian. The growth of Athenian imperial power in the second half of the 5th century brought the Bosporan cities within its sphere of influence, and an Athenian cleruchy was settled at Nymphaeum. It is not clear whether the Bosporan cities were tribute-paying members of the Athenian empire or not. Athens, however, acquired a monopoly of local trade. Before then Bosporan exports had gone freely to all parts of the Greek world, a state of affairs resumed after the Athenian defeat in the Peloponnesian War (404). As the largest importer of foodstuffs among the Greek cities, however. Athens remained in the 4th century, as earlier, the principal market and the most reliable customer of the Bosporus. In successive agreements the rulers of Panticapaeum were granted Athenian citizenship and other honours in return for privileges given to Athenian merchants.

The earlier Spartocids governed as archons and the royal title was not used until the Hellenistic age. This was merely a matter of form, however, since there was no free political life at Panticapaeum, the power of the ruling family being absolute. Their position was very similar to that of the tyrants who ruled at different times in various parts of the Greek world. They maintained strong forces of mercenaries and adopted an aggressive policy where it seemed profitable. First Nymphaeum, then Theodosia (Feodosiya in the eastern Crimea), an important harbour for grain exports, were annexed. Later the Sindian kingdom in the Taman peninsula was incorporated and Spartocid power was extended northeastward beyond the mouth of the Tanais (Don) river.

This able dynasty, which, among its other achievements, largely suppressed piracy in the Black sea, reached its greatest strength in the 4th century. Wise management of the trade in grain, fish and slaves had made the state extremely prosperous, as is shown by fine coinage. vases and jewelry. But from about the middle of the 3rd century the power of the dynasty and the kingdom's wealth slowly declined, partly perhaps through internal struggles and partly through external events, in particular the disruption of the Scythian empire by invading Sarmatae and Sacae. After the Spartocid dynasty came to an end about 110 B.C. the kingdom passed under the control of the kings of Pontus. About the beginning of the 1st century A.D. a new dynasty was established that ruled for over three centuries under the protection of the Roman empire. The coinage of its kings ceased in A.D. 342. Thereafter the country was at times in barbarian hands. at other times under the protection of the Byzantine emperors.

The Bosporan state constituted an original civilization of a distinctively Greek type in an environment markedly unlike that of the Aegean world. The prosperity of the Greek cities depended on native serf labour on the adjoining land. In the field of artistic work Iranian influences were strong, but Hellenic culture prevailed in a state that was only partially Greek in population and exposed to many non-Greek influences, an interesting parallel to the Greco-Asiatic states of Hellenistic Asia Minor that it preceded.

BOSS, LEWIS (1846–1912), U.S. astronomer best known for his compilation of star catalogues, was born in Providence, R.I., Oct. 26, 1846. and mas graduated from Dartmouth college, Hanover. N H.. in 1870. He worked for the U.S. government at Washington, and on the northern boundary survey until 1876, when he became director of Dudley observatory at Albany, N.Y. Besides supervising the observatory, Boss led the 1882 expedition to Santiago, Chile, to observe the transit of Venus.

About 1895 Boss began to plan a general catalogue of stars, their positions and motions. The project was supported by the Carnegie Institution of Washington. which in 1906 founded it as the department of meridian astrometry. With an enlarged staff Boss observed the northern stars from Albany and the southern from San Luis, Arg , and older catalogues were corrected and embodied with the new data. He wrote papers on precession and solar motion. and in 1910 published his *Preliminary General Catalogue of 6,188 Stars for the Epoch 1900.*

Boss died in Albany, Oct. 12, 1912, leaving his work unfinished. He was succeeded by his son Benjamin, who completed the task in 1937. The work is in five volumes, entitled *General Catalogue of 33,342 Stars for the Epoch 1950.* (HY. R)

BOSSUET, JACQUES BÉNIGNE (1627–1704), French bishop, historian and orator, was born in Dijon on Sept. 27, 1627, into a deeply religious middle-class lawyer's family. Educated by the Jesuits of his native town, he went to Paris in 1642 and for ten years studied at the Collkge de Navarre under Nicolas Cornet, a master of method, to judge from the terms of Bossuet's funeral oration for him in 1663. By 1652 Bossuet had submitted theses for the licentiate and doctorate in theology, had come under the influence of St. Vincent de Paul and had been ordained priest. Subsequently he spent seven years in Metz, laying the foundations of his skill as preacher and controversialist. His discussions with Paul Ferry, minister of the Reformed Church at Metz. continued over many years and seem to have set a new tone in polemic by the mutual courtesy and respect with which they were conducted. Recalled to Paris in 1659, Bossuet preached several series of Advent and Easter sermons in the Louvre. As a popular preacher he was called upon to pronounce the *Oraisons funèbres* on which his literary reputation perhaps mainly rests. These panegyrics, customary after the death of an important national figure, included those on the queen mother, Anne of Austria (1667; not extant), on Henrietta Maria of England (1669), on her daughter (Madame; 1670), on Queen Marie Thérèse (1683), on the princess palatine (Anne de Gonzague; 1685), on Chancellor Le Tellier (1686) and on Condé (1687). Nominated bishop of Condom in 1669, Bossuet resigned the see in 1671 after his appointment as tutor to the dauphin, which brought with it his election to the Académie Française. Apart from preaching he seems to have devoted his entire time and energy during this period to his pupil, in study and in writing textbooks. the most famous of which, the *Discours sur l'histoire universelle,* appeared in 1681 and the others posthumously. *Traité de la connaissance de Dieu et de soi-même* (1722); *Politique tirée des propres paroles dc l'écriture sainte* (1709); *La Logique* (1828).

His tutorial duties completed, Bossuet was made bishop of Meaux

in 1681 and remained so until his death. He was a "residing" bishop and declared that to be pastor of a diocese was the only dignity to which a Christian should aspire. His country house at Germigny was not only a conference centre but also a place of constant hospitality.

No sooner had Bossuet accepted the new see than he became involved in the Gallican controversy, perhaps the most protracted and most serious polemic of his life *(see* GALLICANISM). His famous serrnon on the unity of the church, preached by invitation to the assembly of the French clergy, was an irenic attempt to avoid the schism which the conflict between pope and king was rendering imminent. Behind the fair words, however, lay difficult negotiations concerned with the dispute over the royal insistence on its right to revenues of vacant sees, in which Bossuet was concerned to modify the intransigent attitude of Louis XIV without giving in to the Ultramontane position. The result was a declaration in four articles issued and accepted by all parties in 1682.

Concurrently, Bossuet played a leading role in the campaign against the Protestants that culminated in the Revocation of the Edict of Nantes in 1685. Here again he took a middle position, supporting the royal policy but disagreeing with actual persecution. He held that it was for the state to persuade, and to coerce if necessary, but for the church to convince and to make the orthodox position clear to fair-minded inquirers. Hence his writings: *Traitk de la communion sous les deux espèces* (1682); *Catkchisme du diocèse de Meaux* (1687); *Histoire des variations des églises protestantes* (1688). *Six avertissements aux protestants* (1689–91) and the *Dkfense de la tradition et des saints-pères* (1692. published 1753). Much earlier (1671) he had published, on the same subject, *Exposition de la doctrine de l'église catholique sur les matikres de controverse,* which attracted the attention of the pope and was immediately translated into English.

The third and most spectacular of Bossuet's major controversies was that against Quietism (*q.v.*), which occupied the last six years of the century. After the failure of an attempted settlement at Issy (1694–95), Bossuet and Fénelon gradually drifted into a duel of pamphlets. When in 1697 FCnelon appealed to Rome, Bossuet represented this as an Ultramontane move and himself as the guardian of Gallican liberties. The Holy See's condemnation of FCnelon in 1699 was no more than a Pyrrhic victory for Bossuet, who no doubt was as aware as his critics of the scandal and damage caused to the church by the long, open and unscrupulous wrangle between two leading prelates.

Bossuet's last years were a hard fight against physical disability and theological dissent. He died in Paris on April 12, 1704.

Bossuet's Reputation. — A controversialist is always sooner or later himself a centre of controversy. Bossuet was not spared, either during his life or since. Much has been made of a story that he nas secretly married to a Mlle de Mauléon, whom he is known to have helped financially. It has been said that a "contract" (whether actually of marriage is not stated) was found after his death and that inquiries were silenced by royal command. Modern scholars conclude that an affirmation either way cannot be justified by the evidence available.

On the whole Bossuet emerged from a long career spent in the limelight of public discussion with a reputation for plain speech and fair dealing and for a rugged strength of character. His polemic seems on the whole to have been grounded on extreme industry in determining the facts, on respect for the courtesies of dignified discussion and on an apparently unquenchable faith in the power of argument. Though modern scholarship has been severe on Bossuet's intrigue and diplomacy, and suggests that the traditional picture may be due for revision, most people have been persuaded that Bossuet was honest and FCnelon subtle. This, allied to a pulpit reputation for outspokenness, has had the perhaps more sentimental than logical result that in Sainte-Beuve's words "la gloire de Bossuet est devenue une des religions de la France."

This is the more surprising in that almost all the positions he defended were discredited within a century of his death. The Revocation of the Edict of Nantes, which he thought the miracle of the age, was treated by historians as a serious blunder. Biblical criticism. which he did everything to suppress (his condemnations of the Old Testament critic Richard Simon extend from 1678 to 1702), soon won the field. His notion that Protestants and not Catholics had "varied" in doctrine was put out of date by J. H. Newman. His wholesale condemnation of the theatre was shared only by the most rigorous Puritans. His providential explanation of history hardly survived Voltaire. His notion that heresy and individualism were almost the same thing seemed nonsense to many even before Rousseau.

As a Preacher. — *It* is remarkable that a man so universally wrong should stand so high, even with those who share none of his credal faith. The main cause of this reputation would seem to be his preaching. Much work has been done on the text of his sermons, and it is doubtful whether what was published was very close to what he said. The manuscripts seem to consist either of his own notes for discourses that in the event were largely extempore, or of hearers' notes of what they heard. But even so, it is impossible to miss the force and range of his rhetoric or to doubt its effect on its audience. The sermons explain why good judges among his own nation rate him as the most magnificent manipulator of the French tongue, unique in his handling of both thought and emotion. Among many widely quoted passages are the soliloquy of the young St. Bernard from the sermon of 1653 ("cette heure fatale viendra, qui tranchera toutes les espkrances trompeuses par une irrévocable sentence") and the pen-picture of Cromwell (1670): "un homme s'est rencontrk. d'une profondeur d'esprit incroyable." Some of his finest passages occur in pastoral addresses such as the "Discours sur la vie cachée en Dieu" composed as an Easter meditation in 1692. In the formal panegyric Bossuet's success seems to have been due to the effort to make the formal and official simple and homely, to what the abbé Brémond called their "miraculous simplicity." But the simplicity is never flat or trite, as with a small mind it would be; it seems dependent on a deep and indeed acute sense of mortality, of sin, of the temporal seen in the context of the eternal, of the mystery of self-knowledge, all or any of these coming to light in a single phrase.

The secret of Bossuet's appeal thus is largely poetic. His prose is never far from that poetry which accompanies a classical sense of the paradox of human life, so bounded by time and earth that rank and power are an illusion. There is poetry again in his view of history as a procession, impressively contrasted with the brief appearance of any individual life. If we remember that life in the 17th century was drab and cruel and that most of his hearers were taught to regard this world as a vale of tears, then the power of Bossuet's appeal is clearer.

As a Thinker. — *But* those. like Paul Valéry, who praise the form and disregard the matter of his writing would have seemed blind to Bossuet. The 19th century's image of him as an incomparable writer and insignificant thinker must be discarded or revised in the light of more modern scholarship. Though the causes he championed may have been doomed to defeat, there may well have been in 1680 no other way in which the church could be defended. Even his "providential" view of history is not now as irrelevant as it seemed in an age of progress such as the 19th century. Without Bossuet it is hard to see how Voltaire, Gibbon and Michelet could have achieved what they did. Apart from the assumption (natural to Bossuet and to his age) that only a Christian can understand or explain history, his search, both patient and informed, for a thread of meaning through the upheavals of the ancient world must be counted an important new departure in historical writing. Hardly less original is the method of the *Histoire des variations des églises protestantes,* which establishes the principle that in order to refute an opponent it is necessary to learn what he means. Bossuet was ahead of his time in treating Luther and Calvin seriously. He was unusual in the range of his contacts. being a correspondent of Leibnitz, Mabillon and Arnauld. In his dealings with the Jansenists he preserved both their respect and his own independence.

In a sense our view of Bossuet depends on our view of his king. For those who in Louis XIV see only a tyrant unscrupulously working for national aggrandizement, Bossuet must seem little more than a time-server, working for what Sainte-Beuve called "l'autel adossé au trône." To modern historians who see the French mon-

archy as a delicate balance of forces beyond the power of any individual to bend to his own ends, Bossuet's defense of Gallican orthodoxy seems both rational and dignified. Strangely enough, it is from a historian sympathetic to Fénelon that the most generous summary of Bossuet's career comes: H. Brémond held that his real achievement lay in his lifelong, honest and passionate struggle to bring home to men the things of God.

BOSTON, JOHN, OF BURY, early 15th-century English bibliographer, was a monk of the Benedictine abbey of Bury St. Edmunds. He compiled an alphabetical catalogue of Latin writers and of their works, with references given in the form of numbers to which there is a key, at the beginning of the catalogue, to English monastic libraries where copies of them were to be found. When he could. Boston entered the opening and closing words of a book. Like most bibliographers. Boston was largely dependent on his predecessors. He drew his list from St. Jerome. *De viris illustribus,* and his continuators: Gennadius and Isidore; from Cassiodorus. *Institutiones;* from Vincent of Beauvais, *Speculum historiale;* from one of the lists of Dominican writers, and from the *Catalogus* (or *Registrum*) *librorum Angliae* compiled by English Franciscans in the second half of the 13th century. Their list provided Boston with most of his references to the monastic libraries throughout England and Wales where copies of a given work could be found. Boston's additions came from the extensive library of his own abbey and from those of a few other houses, chiefly in the neighbourhood.

A manuscript of Boston's catalogue belonged to the London bookseller, Awnsham Churchill, who commissioned an edition from Thomas Tanner in 1694. The edition was never completed but David Wilkins. who edited Tanner's *Bibliotheca Britnnnico-Hibernica* in 1748, printed the preface, the names of the writers and the lists of works of English writers. The manuscript is lost but Tanner's transcript survives in the Cambridge university library (ms. add. 3470).

It is not known whether Boston had a part in an edition of a work on monastic origins and writers, *Speculum coenobitarum,* originally compiled by a monk of Bury in the first half of the 14th century but attributed to Boston by John Bale (1495–1563).

(RI. W. H.)

BOSTON, a municipal borough and seaport in the Parts of Holland (of which it is the county town), Lincolnshire, Eng.. lies on the river Witham, 4 mi. from its mouth in the Wash. Pop. (1961) 24,903. Area 5.1 sq.mi. Once known as Botolph's Town, after St. Botolph who founded a monastery in 654, Boston lies in flat, rich agricultural country. intersected by numerous watercourses or "drains." In the 13th century it was a great Hanseatic port trading in wool and wines and paying more dues than London. Although Henry VIII made Boston a borough by a charter of 1545 (which is still preserved), by then the dissolution of the monasteries and trade guilds and the silting up of the river had caused the town's prosperity to decline. In 1764, however, the river bed was deepened and the Grand Sluice opened. In 1882 a dock, seven acres in extent, was constructed to accommodate vessels of more than 2,000 tons, and a new cut of three miles was made into deep water. A riverside quay 2,640 ft. long was built in 1938 and a large grain silo erected in 1951. The docks, controlled by the corporation as the Port of Boston authority, are now fully equipped to deal with i50.000 tons of cargo a year. The main imports are timber, grain. fruit, vegetables and fertilizers, the chief exports being coal, grain, agricultural machinery, potatoes and cattle.

The church of St. Botolph is a Decorated building; its western lantern tower (1309–1460), known as Boston Stump, is 272½ ft. high and is a landmark for 20 mi. A chapel in the church was restored by citizens of Boston, Mass., in 1857 in memory of a former vicar. the Rev. John Cotton, who followed the Pilgrim fathers to New England in 1633. The church was extensively restored with a further American gift in 1931. On the river bank at Scotia creek. near Boston, stands a granite memorial to those early Pilgrims who in 1607 made their first, but unsuccessful. attempt to escape to religious freedom. The cells in which they were imprisoned may be seen in the guildhall. Several 18th-century explorers of Australia, such as Joseph Banks. George Bass and Matthew Flinders, also originated in Boston and district. In the town are a guildhall (1450). now a museum; Shodfriars' hall, a half-timbered house of the 15th century much restored; the grammar school, founded in 1555; Hussey tower. part of a late 15th-century mansion; remains of the 13th-century Dominican friary: Fydell house (1726); assembly rooms (1822): municipal buildings (1904); and the Maud Foster windmill with five sweeps.

The tonn's principal industries are fruit and vegetable canning. fish preserving. the making of tags. labels, shoe laces, beds and pillows, and shellfishing. A cattle market is held weekly and a general market twice a week. Each May there is a pleasure fair, which includes livestock fairs. (C. L. H. G)

BOSTON, the capital city of Massachusetts, U.S. comprises the greater part of Suffolk county. The city is 13th in population in the United States: (1960) 697,197. (For comparative population figures *see* table in MASSACHUSETTS: *Population*) Its standard metropolitan statistical area is 7th in population: (1960) 2,589,301 *(see* also *Population,* below). Boston is the central city of this standard metropolitan statistical area which also includes all of Suffolk county, 9 cities and 20 towns in Middlesex county. 4 cities and 11 towns in Essex county, 1 city and 18 touns in Norfolk county and 9 towns in Plymouth county

PHYSICAL GEOGRAPHY

Physical Features. — Boston and its harbour stand at the head of hlassachusetts bay. 42° 21′ 27–6″ N., 71° 3′ 30″ W. Boston occupies much of the Boston basin, a territory within a ring of hills. It stands on a surface of granite, conglomerate, slate and lavas between geological "faults" at the Blue hills on the south and Arlington heights on the north. It was, in its colonial days, rocky and irregular. a peninsula lying between the south bay. the Charles river and the Back bay flats. The town was almost an island, being connected with the hlassachusetts mainland by the very narrow Roxbury neck.

No U.S. city has undergone greater physical change than Boston after the American Revolution. There remain only a few blocks in two sections on the water front which were on the original boundary. A town of 780 ac. became a city of 28,019 ac. of land area, so increased by annexation of surrounding territory and by 2,944 ac. of made land. The total area including water is 42.176 ac. or 65.9 sq.mi. (land area alone, 47.8). Of the hills which dominated Boston in colonial days, Copp's hill alone stands unaltered. Fort hill, near the water front, has entirely disappeared. while Mt. Vernon, the western peak of the Trimountain — once the most conspicuous feature of Boston — and its eastern peak. Cotton or Pemberton hill. were leveled in building developments between 1799 and 1835. The central peak, Beacon hill. which was shorn of its top 60 ft. between 1811 and 1624, is the only surviving remnant of the Trimountain. The tops of these hills were used to fill the coves as the shore line of Boston was extended and the narrow neck connecting the peninsula was widened. During the 19th century the city became almost surrounded by made land. The greatest project of reclamation was the conversion of the Rack bay from mud flats to land, commenced in 1856; this extraordinary enterprise — for which Needham gravel, dug by steam shovel, was transported in special railway trains — produced Commonwealth avenue and other adjacent streets that were for a century the city's most attractive residential section.

The Charles river dam, completed in 1910, removed the flats previously exposed at low water. The dam and machinery of control maintains the water of the basin at an even height. Covered canals on either side of the river take the excess sewage and de-

Additions. — East Boston, an island in the harbour settled by Samuel Maverick almost coincidentally with the mainland and having no regular municipal entity, was annexed in 1637. In 1804 South Boston, a peninsula coming close to the city, was annexed. It contains Dorchester heights, the fortification of which by the Continental army made British occupation of the city untenable in 1776.

In 1868 Roxbury. which until the filling in of the Back bay had been the only town through which Boston could be approached by land, was annexed. It was a city at the time and, like Boston and the surrounding colonial towns, has an individual history of its own (see ROXBURY). Six years later. in 1874, four communities were added: the city of Charlestown (*q.v.*), and the towns of Dorchester (*q.v.*), Brighton and West Roxbury. No further annexations were made until 1912 when Hyde Park was added from Norfolk county.

Boston Harbour. — The harbour is almost landlocked and is only $6\frac{1}{2}$ mi. from the open sea. The main ship channel is 35 ft. deep at low water. Its wharfage extends along what can roughly he called three sides of an open rectangle, comprising the water front at South Boston. Boston proper and East Boston. with a broad passage northeast of Boston leading to the Charlestown water front along the Charles and Mystic rivers.

HISTORY

Colonial and Provincial Period. — It is possible that the early Norsemen explored Boston harbour. Capt. John Smith made explorations and mapped the locality in 1614. A party from the Plymouth plantations visited it in 1621. It was known to the white man long before a real settlement was made and there were several individual settlers living within the borders of the present city—William Blaxton (Blackstone) on the Trimountain peninsula, Thomas Walford in Charlestown and Samuel Maverick on Noddle's Island. In 1628 the Massachusetts Bay Colony, the first great Puritan settlement: was inaugurated at Salem, under John Endicott as governor. He was joined in a few months by John Winthrop (*q.v.*), who in 1630 with his followers settled temporarily at Charlestown. Finding some difficulty in water supply, he crossed the river at the invitation of Blaxton and made his settlement in Shawmut. or Trimountain, as it was variously called. The accepted day from which the city dates its beginning is Sept. 17, 1630, when it was ordered by the court of assistants that the town should be called Boston after the Boston in Lincolnshire, the leading town of the region from which the principal Puritan leaders had come.

For a short time, Boston. New Towne (Cambridge) and Charlestown flourished in about equal degree but the excellent commercial situation of Boston soon put it to the fore and in 1632 it was made the capital of the colony. During the first ten years 20,000 settlers came to Massachusetts bay, most of whom landed in Boston, a great proportion settling there. Oliver Cromwell and John Hampden were among those who contemplated settling in New England. Then the political tide turned in England and with the rise of the Puritan party, the stream of emigration largely subsided.

The Congregational churches, the first to flourish in the Massachusetts Bay Colony, were the outcome of this Puritan influx. It is to be borne in mind that the Puritans, unlike the pilgrims of Plymouth. were not Separatists. They were originally reformers within the English church. But when they came to the new country they found nothing to reform, either in church or government; thus they were forced to create. This brought into being a church alrnost the duplicate of that of the Separatists in the adjoining colony, a self-sustaining, self-governing religious unit. 'The first church of the Boston settlement had been founded before they left Charlestown under a covenant adopted by Winthrop, Thomas Dudley, Isaac Johnson and the pastor John Wilson. It bound the members "to walk in our ways according to the rule of the gospel, and in all sincere conformity to His (Christ's) holy ordinances, and in mutual love and respect to each other, so near as God shall give us grace." Under the intent to reform, qualified by the conditions of pioneering, there was thus brought about, naturally and peaceably, a great religious revolution.

In Boston as well as in all the rest of the Massachusetts Bay Colony the religious test came to be applied to citizenship. In the general court held in Boston, it was ordered "that for time to come no man shall be admitted to the freedom of this body politic but such as are members of some of the churches within the limits of the same." This was at first no very oppressive test, for the early settlers mere all of one mind religiously, but it did establish a state church.

The church government was liberal. Within this church there was pure democracy. The ministers had great influence but they were not entrenched as to powers. A sermon regularly preceded an election, but it was not to be one in which the citizens were to be told for whom to vote, and, when in an election sermon Rev. John Cotton preached upon the inadvisability of superseding experienced officials. Governor Winthrop was immediately defeated.

Boston was governed by town meetings: assemblages of citizens were held at least once a year to decide upon municipal improvements, fix taxes: vote appropriations and elect officers. In meetings all citizens had equal rights of voting and speaking.

The early Puritan settlers, though desirous of freedom to worship in their own manner: had been intolerant of dissident groups or individuals, going so far, for example, as to banish Roger Williams (*q.v.*) and Anne Hutchinson (*q.v.*). The narrowness and zeal of its prevailing religious mood perhaps served to make Boston a prey to the superstitions about witchcraft common in both the old and the new worlds. While Salem exhibited the most virulent examples of persecution, several accused witches were also executed in Boston. The notable Boston clergyman Cotton Mather defended his belief in witchcraft in various writings. and even went to an execution in Salem, where, when a speech by the victim had almost aroused the spectators to the point of rescue, he declared the sentence was just.

As the 17th century progressed, the Puritans were joined by other settlers, attracted not so much by the religious climate as by Boston's growing commercial advantages. Certain able and intelligent men came who did not join a Congregational church. Accordingly it became more and more difficult to maintain the theocratic principle in Boston. A party among the Puritans which espoused the traders' cause came to be known as the Moderates, and was strongly opposed by the radical Theocrats. The struggle was finally carried to England, where the influence of the trading class brought about the abrogation of the old colonial charter in 1684. This led to the first defiance of authority in the New England colonies.

The abrogation of the charter was succeeded by a brief interval under the presidency of Joseph Dudley, son of one of the original settlers, Gov. Thomas Dudley. Then the new royal governor arrived in the person of Sir Edmund Andros. He was an honest and well-intentioned man but he governed autocratically. His administration drove the divided Puritans, radical and moderate. together again. The residents of Boston, learning that William of Orange had landed in England, made common cause with that revolution and on April 18. 1689. they rose, seized and deposed Andros, kept him in comparatively easy confinement for nearly a year and sent him back to England.

A nen charter was granted by William. It assured the colonists their liberties and freedom of worship, but it protected the English churchmen in their right of worship and extended the franchise so that it no longer rested on church membership. The election of governor was never restored to the people while under English rule. Under the provincial charter, which approximately began the 18th century, Boston and Massachusetts history are closely interwoven (*see* MASSACHUSETTS. History). In the middle of the 18th century, the population nas about 15.000, the houses were principally of wood. some of brick and stone The town maintained a town watch and an organization of fire wards but it suffered from destructive fires in 1676, 1690, 1711, 1747 and 1760. The town had 17 churches in 1750, the larger number being Congregational, but there were other denominations represented as well—Episcopal, Anabaptist. French Huguenot and Quaker. Although the religious test had been abolished for suffrage, the

town continued to make money grants to the Congregational churches and foster them officially.

Revolutionary Period. — During the second half of the 18th century the relations of the colonies with England became more and more strained. The Quebec act (1774), recognizing the Roman Catholic Church in that province, gave the Protestant citizens in the colonies some uneasiness. Most of their earlier grievances, however, were financial and political rather than religious. In Boston the first important outward manifestation of discontent occurred when Charles Paxton, the collector of customs, through a deputy at Salem petitioned the court for "writs of assistance," which would enable the customs officers to enter homes and warehouses in the exercise of their duty.

On a hearing of the petition, James Otis made a dramatic plea built largely around the legal axiom that "an Englishman's house is his castle." The writs having been established in legislation by the British parliament, the court sustained the officers of the crown. But Otis had profoundly stirred the people and as John Adams afterward said, "then and there the child independence was born." This was in 1761. The Sugar act of 1764 was followed by the Stamp act of 1765, which was strenuously resisted. On Aug. 26, 1765, the most destructive and disgraceful riot of the period attacked the house of Thomas Hutchinson, then lieutenant governor and later chief justice, gutted it and destroyed his magnificent library containing many irreplaceable sources of Massachusetts history.

Other and soberer methods were legitimately and effectively used. Businessmen refused to use the stamps. Trade came to a practical standstill since the tax stamps had to be affixed to invoices and other written evidences of transactions. Even the courts closed for lack of triable causes, for the writs and all other documents had to be stamped. The Stamp act was a failure and nothing remained for parliament to do but to repeal it, which it did in 1766. Of all the American towns Boston was the most enthusiastic in the opposition and at the back of Boston was the Caucus club of active citizens bent on influencing opinion and action. The most influential member of this club was Samuel Adams, whose activities have given him the title of "father of the American Revolution."

With the repeal of the Stamp act came the Declaratory act, in which parliament declared its right to tax the colonies. Under this declaration of policy the Townshend acts were passed, placing duties on lead, glass, papers, paint and tea. This led to a prompt boycott by the Boston merchants. They were not revolutionaries at heart but they made common cause with Samuel Adams and the proletariat for trade purposes. Probably they thought they were making use of Samuel Adams for their own purposes while he was quite as certain that he was using them for his. The time was to come when he would lead them further than they probably intended and they would find themselves in a position from which they could not draw back. The matter was now so acute that it had mounted to chronic defiance and two regiments of regulars were dispatched to the town and camped on the common, being denied housing among the citizens. Friction was inevitable. At last, on March 5, 1770, a group began to harass a sentinel on King (now State) street near the town house. Finally the squad called to his support fired, killing several men. The Boston massacre, as it came to be called, showed that in view of the feeling of the moment, troops could not be quartered in the town without danger both to the citizens and the troops themselves. A committee, with Samuel Adams at its head, demanded the withdrawal of the regiments to the castle. Hutchinson, then acting governor, demurred and sought to compromise on one regiment but to Adams' reply, "both regiments or none," he yielded. It became evident to the British parliament that these acts could not be enforced and they were repealed except for the tax on tea, which was kept for the assertion of the principle involved. Samuel Adams and his associates led the opposition to the principle.

After three vessels laden with tea had arrived in the harbour and been moored at Griffin's wharf, Adams organized meetings and conferences! trying to bring about the return of the tea to England. On Dec. 16, 1773, a town meeting adjourned following Adams' statement. "This meeting can do nothing more to save the country," whereupon a group of responsible citizens, more or less thoroughly disguised as Indians, proceeded to the wharf, boarded the vessels, broke open the chests and threw the tea in the water. So orderly nas the crowd, and so conservatively was their performance carried out as to prove the act not a spontaneous but a premeditated one. It became all the more incumbent on the British government, if it wished to maintain more than ostensible sovereignty. to take notice of the occurrence. Accordingly the Boston Port bill, closing the port and ruining its trade, was passed, and more troops, under the mild and well-meaning command of Thomas Gage, were dispatched to the disaffected city. These measures, however, only served to promote open revolt.

The colonists formed a skeleton military organization called minutemen, prepared to muster on the shortest possible notice and gathered ammunition and supplies. Gage promptly sent a detachment to that part of Charlestown now Somerville and destroyed some of these stores. In April 1775 he decided to send a secret expedition to capture or destroy military stores at Concord. His plans were suspected by the insurgents and his movements noted. On the evening of April 18 an expedition was sent out. By an agreed plan of signals Paul Revere, waiting at the Charlestown shore, learned the route by which it had started and on a horse borrowed for that purpose, rode through the country arousing the inhabitants. He was joined by William Dawes, who had left Boston by another route and by the time the regulars reached Lexington green, their pathway was obstructed by a small company of minutemen. This was the first armed resistance. After an exchange of volleys, in which eight of the militia were killed, they gave way. The regulars proceeded to Concord but found that the greater part of the stores had been carried to safety. There occurred the fight at the bridge (in which both sides lost men) and the withdrawal of the British. As the minutemen came in from the country they harassed the British column until the withdrawal became a retreat and the retreat a rout.

Thus the American Revolution began with the British troops out of Boston, contesting with militia aroused by Boston men. The war was accepted by the colonies. Siege was immediately laid to the town by a half ring of forts erected on the land side. These New Englanders were reinforced by troops from the other colonies. The continental congress, though it had not yet declared independence: made George Washington commander in chief of the American armies. Before he reached Cambridge, Gen. Artemas Ward, in command. sent a detachment of troops under William Prescott and Israel Putnam to fortify Bunker hill in Charlestown, which commanded the town on the north. The colonials actually occupied nearby Breed's hill. William Howe, in command of the British forces, decided to carry the hill by storm. The colonials were courageous men and excellent marksmen. They repelled the first attack with great slaughter; a second was made, the steady Britishers reforming and mounting the hill again only to meet another sanguinary repulse.

On the third attack the ammunition of the colonials was exhausted and after a bayonet struggle they made an orderly and soldierly retreat. Technically a victory for the British, it was purchased at such a cost that it gave the colonies great encouragement and its anniversary (June 17) is celebrated in Boston to this day. The siege continued unabated until, after the colonials occupied Dorchester heights closely overlooking the town, Howe evacuated the city on March 17, 1776.

Boston nas never again in the theatre of the war during the Revolution. Its entire population was not in accord with the revolt. Howe carried with him great numbers of Loyalists to Halifax and others remained to bear reprisals.

Four years before the treaty of peace was signed, a convention was held in Boston and formed a state government for Massachusetts. The town, under the Articles of Confederation and the constitution, maintained the old town meeting system.

Post-Revolutionary Period. — From the ratification of the treaty of peace until 1822 when it became a city, Boston was mingled in the broader history of the state and the nation. During Shays's rebellion (see MASSACHUSETTS: History) its inhabitants

strongly supported the firm policy of Gov. James Bowdoin, and later favoured the ratification of the federal constitution. Jefferson's embargo was felt to be nearly as destructive of trade as the Port bill had been a third of a century earlier, arousing such anger as to cause John Quincy Adams to warn the administration that treason and secession were being discussed in Boston. However that might be, Boston supplied the chairman, George Cabot, and sent delegates to the disgruntled Hartford convention. The behaviour of this body set New England and its chief city apart from the rest of the country.

A movement which had a deep effect on the life of Bostonians was the shift of religious belief from the Trinitarian to Unitarian Congregationalism, marking the disintegration in many of the old historic churches of the Puritan theology. Jonathan Mayhew, one of the patriot ministers of the middle of the 18th century, began the movement. It progressed slowly at first but with increasing momentum. By 1780 many pulpits were filled by liberal ministers. The rector of King's chapel, at the time of its separation from the Church of England after the American Revolution, made his own revision of the Prayer Book, leaving out the Trinity. He was refused ordination by two American bishops and in 1782 he was ordained by the congregation. This was the first Unitarian Church organized in America (see UNITARIANISM). In 1825 the American Unitarian association was organized and its headquarters has always been maintained in the city.

The City of Boston.—By 1822 Boston had outgrown the town meeting and adopted a city charter, with a mayor, a board of aldermen and a common council. The legislative branch for many years had certain administrative functions through its committees and elected certain officers such as assistant assessors. The first mayor was John Phillips, elected after one trial which had resulted in a stalemate between Josiah Quincy and Harrison Gray Otis. Both were chosen subsequently. Josiah Quincy, the second mayor, ranks as the executive of the greatest activity, broadest municipal outlook and practical sense of any Boston mayor. The original charter has been changed many times by the state legislature. The mayor's term was extended first to two years, then to four. The administrative functions of the committees of the city council were abolished and the police department was put under state control, removing it from local politics. The board of aldermen and the common council were abolished, and a comparatively small single chamber, with greatly curtailed powers, was substituted. A finance commission appointed by the governor was created, with powers of summoning witnesses and administering oaths. Party designations at elections were abolished with the intent of focusing municipal attention on local rather than national issues; party nomination was changed to nomination by petition, thus abolishirig party responsibility but leaving nothing in its place.

The Antislavery Movement.—After the organizing of the city under the original charter, the next important event was the Boston antislavery movement. The abolition movement began in 1831, when William Lloyd Garrison, a native of Newburyport, moved to Boston and began the publication of the Liberator. A year later the New England Antislavery society was organized. Opinion was so divided in the city as to lead to occasional violence. After a public proslavery meeting, presided over by the mayor, Garrison nas mobbed in his office on Oct. 21, 1835. He was, however, soon joined in his activities by Wendell Phillips, son of the first mayor, a young lawyer stung to espouse the cause largely by the defense of the conservatives in the murder of Elijah Lovejoy in Illinois. They attracted others. Even "the best people" found their enthusiastic kinsmen joining the movement. In 1850 the south played into the hands of the abolitionists by the passage of the Fugitive Slave law. Opposition to the act reached its peak following the arrest of Anthony Burns on rendition process on May 24, 1854. The antislavery leaders determined upon mob violence. Clergymen, philanthropists, scholars, felt it their duty to engage in this attempt. But the sortie, which was to follow a protest meeting, failed because the tentative plans leaked out. Burns was carried to the ship by the entire military strength of the county, with loaded muskets and cannon loaded with grape at street corners, between rows of buildings draped in black as though for the death of a national ruler. Abraham Lincoln himself once inferentially stated that Boston more than any other city was responsible for the agitation which led to secession and the American Civil War.

In the Civil War, Boston at Lincoln's first call sent organized troops to the relief of Washington, D.C. It organized the 54th regiment consisting of Negro soldiers, the first Negro gesture of earned freedom. Like all large cities it had its disloyal elements whose disturbances culminated in a riot at the Cooper street armoury at which the commander of the artillery swept the street with grape shot.

Changes After the Civil War.—The greatest physical calamity within the history of the city was the great fire of Nov. 9–10, 1872. It broke out on a Saturday night in the wholesale district and spread rapidly over 67 ac., on which stood 767 buildings filled with merchandise. Property, real and personal, to the estimated amount of more than $75,000,000 was destroyed in less than 24 hours. Beyond the loss of 14 lives, the disaster was almost entirely commercial, since there was little residential property within the burned district. The city made a quick recovery and a new district soon was built of better material, with streets straightened and widened.

Before and after the Civil War Boston was the Iiterary centre of the United States. The chief essayists, historians, poets, philosophers and novelists lived in and around the city. Nearly contemporary with one another were Ralph Waldo Emerson, Nathaniel Hawthorne, George Bancroft, W. H. Prescott, J. L. Motley, Francis Parkman, Henry David Thoreau, John Greenleaf Whittier, Henry Wadsworth Longfellow, Oliver Wendell Holmes, James Russell Lowell and R. H. Dana, Jr.

Until the end of the 18th century Boston remained a pleasant, uncrowded seaport. Its comfortable air came from the circumstance that, while its merchants were making respectable fortunes overseas, the population had increased only slightly during a half century. The 1790 figure of 18,038 was an extremely modest advance over 16,382 inhabitants of 1743, when Boston was the largest town in British North America. In the first half of the 19th century, immigration rapidly swelled the population and changed the character of the city. Many early immigrants who had arrived in Boston moved on to regions of greater opportunity. The later great exodus from Ireland, accentuated by the famine (1846). brought to Boston thousands who, having only the funds for the passage, and no skilled craft or trade to recommend them in the newer parts of the country, remained in Boston to eke out a miserable existence by unskilled labour. Although the Irish were the most numerous. other nationalities, Jewish (largely from Russia), Italian, Canadian, Polish, Scandinavian, Armenian, Lithuanian and Balkan peoples followed in large numbers. By the beginning of the 20th century Boston had become a non-Anglo-Saxon city with strong influential threads of old-time English, Scotsmen and Scotch-Irish running through the fabric, and predominantly Irish in influence.

By the middle of the 20th century Boston had largely lost the heritage of Puritanism, which for generations had given it a distinctive character. Although it has long since lost the leadership in letters, on nhich it had prided itself in the post-Civil War period. Boston maintained its position as a leading centre of education and learning.

Landmarks.—Landmarks still cherished in Boston include public buildings, residences, old graveyards and the Boston common. The common, purchased by the town from William Blaxton, the first settler, in 1634, was originally set aside for training and common pasturage. Since a burial ground was early set off within it, it has never been encroached upon for any utilitarian purpose except when, in 1895. part of the Boston subway was built under its eastward edge. It contains various monuments, a small artificial pond known as the Frog pond and the "parade ground," often used for military events.

The old Boston cemeteries are the King's Chapel burial ground containing the bodies of John Winthrop and John Cotton; the Old Granary burial ground, in which are interred John Hancock. Sam-

uel Adams, James Otis, the parents of Benjamin Franklin and many other Boston notables; and Copp's hill, wherein lie the Mathers. The burial ground on the south side of the common is not so old as these colonial burial places, having been put to that purpose after the Revolution.

From the tower of Christ church (Episcopal) built in 1723 on Copp's hill, the oldest surviving church in the city, it is said, lanterns were hung to warn Paul Revere of the route of the British to Concord. The old South meetinghouse (1729) was used for many of the public meetings that led to the Revolution. The old state house (1748) was the seat of the provincial government. There Otis delivered his oration against the writs of assistance and the Declaration of Independence was read to the people from the balcony. The Boston massacre occurred almost beneath its windows. Faneuil hall, given to the town as a market house in 1742 by Peter Faneuil, was enlarged to its present form in 1805. The meetings held in the hall above the market have given the building the popular name of the Cradle of Liberty.

The greater market house adjoining it, known as Quincy market, was the first municipal improvement of importance after Boston became a city. King's chapel was the first Episcopal church in Boston (the first edifice erected in 1688 was replaced in 1749–54). It was also the first Boston church to become Unitarian.

The dominating building of Boston since it was built in 1795–98 has been the state capitol of Massachusetts, familiarly known as the state house, occupying the present summit of Beacon hill, the original portion having been designed by Charles Bulfinch. The central or original structure is of red brick, with a pillared portico surmounted by a dome, which has been gilded since 1874. Additions were made in 1831, 1859, 1889 and 1914. It is now flanked by two great wings of white marble standing at right angles to the old edifice and joined to it by buildings of the same material, while a large addition in the rear bridging Mount Vernon street extends for two blocks. It has a total floor area of nearly 500,000 sq.ft. It contains many paintings, tablets and sculptures of a memorial nature and its Memorial hall contains glassed-in niches, in which are the Massachusetts battle flags of the Civil, Spanish-American and World Wars I and II. Opposite it, on the common, at the street boundary, is Saint-Gaudens' bas-relief memorial to the heroism of Robert Gould Shaw and his Negro regiment, the first such unit mustered during the Civil War.

Federal Buildings.— The post office. 22 stories high, houses not only the post office but the subtreasury, the federal courts and other U.S. government activities. It is located on Post Office square, convenient to the office-building centre of Boston.

One of the most famous of Boston buildings, the custom house, was built in 1838. To provide additional office space, a tower just under 500 ft. was added in 1915. Long the tallest building in the city, this first Boston skyscraper was overtopped by four feet in 1949 by the John Hancock Mutual Life Insurance Co. building in the Back bay section.

Churches.— There are two cathedrals in Boston—the cathedral of the Holy Cross (Roman Catholic) and St. Paul's cathedral (Episcopal). Neither is among the notable cathedrals of the country although St. Paul's (in the retail district opposite the common) is a fine example of early 19th-century architecture. It was built as a parish church and became a cathedral only in 1912. The most notable church edifice is Trinity church (Episcopal) on Copley square, built in the romanesque style of southern France. It has a number of large memorial windows by John LaFarge, William Morris, Sir Edward Burne-Jones and others. Christ church, in the north end, is a fine example of the colonial meetinghouse, as is the Old South, not used for church purposes. The First church in Roxbury, built in the first decade of the 19th century, is a beautiful example of a 17th-century Puritan meetinghouse, the style of architecture surviving at that time. The largest church building is the extension of the First Church of Christ. Scientist, built adjoining the original Mother Church.

POPULATION

The population of Boston was 18,320 in 1790, the year of the first U.S. census. After 1840 it exceeded 100,000, and exceeded 500.000 after 1900. Growing steadily throughout the 20th century, the population was 801,444 in 1950, and 697,197 in 1960. The citizens of colonial antecedents are only a small minority, the number of foreign born is decreasing.

The trend toward urban decentralization brought about by the automobile and declining immigration was reflected in the declining population of the central city by 13.0% (1950–60) as compared with a growth of 17.1% for the metropolitan area outside the central city in the same period. This area is an economic and social unit with no physical indications of the political boundaries of such large cities and towns as Brookline, Cambridge, Somerville, Newton and Quincy. Thirty-seven of these cities and towns form a metropolitan district, which controls their water supply and park system.

INDUSTRY, COMMERCE AND TRANSPORTATION

The Federal Reserve bank of the New England district is in Boston. Boston is the chief U.S. wool market and, combined with nearby Gloucester, the chief U.S. fishing port. Small factories and a great diversification of industry are characteristic of Boston. The leading industries are woolen textiles, food products, clothing, leather, footwear, meat packing, boot and shoe machinery, printing and publishing, rubber products, confectionery, electrical and other machinery, transportation equipment, iron and steel products, chemicals and beverages.

Local transportation in Boston and the surrounding communities is provided by the Metropolitan Transit authority by surface cars and buses, an elevated system and a municipal system of subways, built by the city and leased to the authority.

The Charles river is spanned by about a dozen bridges between Boston and its northern shore. Among them may be mentioned the Charlestown and Warren bridges, connecting the city with the Charlestown district. The granite Longfellow bridge, which connects the west end of Boston with East Cambridge, is the most striking and ornate large bridge over the river, built from a Russian original with eight large towers. The Viaduct bridge is used at the Charles river dam by the elevated railway. Still farther west, the Harvard bridge connects the upper Back bay at Massachusetts avenue with the most direct road to Harvard square and the college buildings. The Boston university bridge, formerly known as the Cottage Farm bridge, crosses the river directly west of the Boston university campus. The Larz Anderson bridge connects Cambridge and Brighton district and the road between Harvard university and the Soldiers' field. The John W. Weeks Memorial bridge crosses the river opposite the Harvard graduate school of business administration.

Boston is the nearest major Atlantic port to Europe. It is served by more than 100 steamship lines that link it with almost 300 ports of the world. It has freight service on 19 world trade routes classified as major by the Federal Maritime board. Its total port activity (foreign, coastal and intercoastal) amounts to more than 20,000,000 tons annually. The port is served by three class I railroads and by 1,500 motor truck lines. Berths for ocean-going steamships have railside connections; warehouse space is 5,000,000 sq.ft. including cold storage, and grain elevator capacity is 2,000,000 bu.

Boston's Logan International airport was acquired by the state in 1941, and is used by several passenger and cargo air lines.

During World War II extensive additions were made to the facilities of the U.S. navy at the South Boston army base, the air base at Squantum and the navy yard at Charlestown. These, with the Bethlehem Steel company's Fore River shipbuilding plant at Quincy, make Boston one of the most important centres of naval building.

EDUCATION AND CULTURAL ACTIVITIES

Educational Institutions.— Boston is the centre of a large district in which are situated many notable educational institutions. Just across the Charles river in Cambridge are: Harvard university (founded in 1636), which, while never located in Boston, has had a profound influence on Boston life; Radcliffe college,

a women's college (founded in 1879) associated with Harvard; and the Massachusetts Institute of Technology (founded in 1861), famous for scientific training and research. Nearby are Boston college, a Jesuit institution (founded in 1863), Chestnut Hill; Tufts university (founded in 1852) at Medford; and Wellesley college, for women (founded in 1870), at Wellesley. In the city are Boston university (founded in 1839), with its numerous schools and colleges; Northeastern university (founded in 1898), noted for its engineering training; Suffolk university (founded in 1906); Portia Law school (founded in 1908); Emmanuel college. Roman Catholic. for women (founded in 1919); Emerson college (founded in 1880); and Simmons college (founded in 1899), as well as many of the schools and colleges of Boston college, Tufts university and Harvard university.

Public and Private Schools.—Boston's school system is the oldest in the United States. The present Boston Public Latin school was the first public school in America, established in 1635. Soon after its establishment it became. and remained, devoted mainly to preparing young men for college. A similar school, the Grammar school. now the Roxbury Latin school, was founded in 1645. These two schools survive. both as free schools, the first as a part of the Boston public system, the second as an endowed institution in which tuition is free to all boys living within the limits of the original Roxbury survey.

Libraries.—The Boston Public library, now in Copley square, is one of the most famous libraries in the world. It was founded in 1852 and for many years occupied a convenient site opposite the southern boundary of the common. Its present building was erected in 1888–95 at a cost of nearly $2,500,000 and enlarged in 1918. It is a very simple and striking building in the Italian Renaissance style. The library contains a statue of Sir Henry Vane by Frederick MacMonnies; in Bates hall. the main reading room and the corridors are busts of notable Bostonians, eminent writers and benefactors of the institution. The most famous decorations in the library are the three series of mural paintings. That by Pierre Puvis de Chavannes illustrates the ancient growth of literature and art. The John S. Sargent paintings with the notable frieze of the prophets and heavily decorated symbolic paintings depict the growth of religion. Edwin A. Abbey's contributions in the delivery room are illustrations of the legend of the Holy Grail.

The library contains more than 2,000,000 volumes. The central library has a lecture hall and maintains a course of free lectures each year. Among the special collections owned by or loaned to the main library are: the New England library collected by Rev. Thomas Prince before 1758; the private library of Pres. John Adams. one of the best existing collections of original letters bearing on the antislavery movement; and the gold medal presented to Gen. George Washington on the evacuation of Boston in 1776.

Other important libraries include the Boston Athenaeum, founded in 1807 and containing more than 400,000 volumes; the library of the Massachusetts Historical society with one of the largest and most valuable historical manuscript collections in the United States; and numerous specialized, technical and institutional libraries.

Art.—The Boston Athenaeum at one time maintained a large art gallery. This gallery led to the founding (1870) of another great endowed institution, the Boston Museum of Fine Arts, the art works of the Athenaeum (which include the well-known portraits by Gilbert Stuart of George and Martha Washington) being the nucleus of its collection. Its first building was situated on Copley square; its present building, on the upper part of Huntington avenue, was opened in 1909 and is one of the chief art museums of the United States. The museum's collection of Chinese and Japanese art is one of the most remarkable in the world. There are notable collections of classical, Egyptian and Indian art, as well as European and American paintings, prints, sculpture! decorative arts and textiles. The museum, which is free to the public, is privately supported.

The Isabella Stewart Gardner museum, in the Fenway near the Museum of Fine Arts, was built by Mrs. John Lowell Gardner between 1899 and 1903 in the likeness of an Italian palace to house the aorks of art that she had collected during the previous two decades. 'The Italian Renaissance paintings are notable. The arrangement of the galleries. unchanged since Mrs Gardner's death in 1924 in accordance nith the terms of foundation, is of interest as an example of the taste of a cultivated collector in the last years of the 19th century.

Musical Organizations.—Symphony hall. on Huntington avenue, is the home of the Boston Symphony orchestra. Founded in 1881 by Henry L. Higginson, banker and civic philanthropist, the orchestra is the chief musical organization of Boston and in the front rank in the United States. Symphony hall was erected in 1900 It is dignified and simple in its lines and its acoustics make it an ideal hall for music on a large orchestral scale. Nearby is the Jordan hall of the New England Conservatory of Music. There are three choral societies in Boston. the Handel and Haydn, the Cecilia and the Apollo clubs and various other vocal and instrumental organizations. The Boston "Pops" orchestra is also an Important feature of the city's musical activity.

PARK SYSTEM

Boston's park system forms a semicircle around the city. The Marine park at South Boston is connected by a parkway with the Franklin, the park of greatest acreage, which contains besides much pleasant woodland, a zoo, an aviary, tennis courts, golf links, a children's playground and some beautiful gardens in which the natural beauties are stressed more than artificial landscaping. From Franklin park a parkway leads to the Jamaica pond, passing the Arnold arboretum, the Harvard college botanical garden which, being open to the public, is practically part of the system. On the shores of Jamaica pond is the Children's museum. From the Jamaica pond reservation the parkway extends along the Muddy river, which separates Boston and Brookline, to the Back bay fens and thence to the Charles river embankment. Boston common is connected with this system by the adjoining Public garden, laid out more conventionally than the natural gardens of Franklin park, with its tiny artificial lake on which are rowboats and foot-propelled "swan boats." From the Public garden a parkway runs through Commonwealth avenue to the Back bay fens. The Metropolitan District commission has reserved much wild land in the district, some of which is in West Roxbury, within the city limits.

BOSTON, a game of cards invented during the last quarter of the 18th century. It is said to have originated at Boston. Mass., during the siege by the British. and also by the officers of the French fleet. which lay for a time off the town of Marblehead; and the names of the two small islands in Marblehead harbour. which have. from the period of the American Revolution, been called Great and Little Misery, correspond to expressions used in the game. William Tudor, in his *Letters on the Eastern States* (1821), however, wrote that "A game of cards was invented in Versailles and called in honour of the town, Boston; the points of the game are allusive, 'great independence,' 'little independence,' 'great misery,' 'little misery,' etc. It is composed partly of whist and partly of quadrille, though partaking mostly of the former."

The game, played for high stakes, maintained its popularity in Europe, and to a lesser degree, in the United States until the middle of the 19th century, after which its favour steadily declined.

In the rules of Boston as recognized in English-speaking countries, two packs of 52 cards were used, both for cutting and dealing; rank was from the ace downward as in whist (*q.v.*). Four players took part, and there were usually no partners. The entire first pack was dealt out by fours and fives: and the second pack was cut for the trump, the suit of the card turned being "first preference,"

the other suit of the same colour "second preference" or "colour," while the two remaining suits were "plain suits." The different bids were called by various names, but the usual ones were: (1) to win 5 tricks, "Boston"; (2) (to win) "6 tricks"; (3) (to win) "7 tricks"; (4) to lose 12 tricks, after discarding 1 card that was not shown, "little *misère*"; (5) (to win) "8 tricks"; (6) (to win) "9 tricks"; (7) to lose every trick, "grand *misère*"; (8) to lose 12 tricks, after discarding 1 card that was not shown, the remaining 12 cards being exposed on the table but not liable to be called, "little spread"; (9) to lose every trick with exposed cards, "grand spread"; (10) to win 13 tricks, "grand slam." In French Boston the knave of diamonds arbitrarily won over all other cards, even trumps. A simplified version of the game has survived as solo whist (see WHIST). (A. H. MD.; G. MH.)

BOSTON FERN (*Nephrolepsis* exaltata bostoniensis), variety of the sword fern originated in cultivation. It was introduced in 1895 by F. C. Becker and named in honour of the city of Boston, Mass., in the vicinity of which it was discovered. It is a strong, free-growing plant, with drooping, dark-green foliage, and is much less stiff in habit than the typical sword fern. It is one of the best ferns for decorative purposes, growing well indoors in pots or baskets, and is hardy out-of-doors in gardens and rockeries in the southern states. From this mutant, or from variants derived from it, have arisen numerous remarkable forms with very finely cut, crisped or otherwise peculiarly developed leaflets. Among these are elegantissinza, robusta, *magnifica* and *superbissima,* which are interesting also as examples of rapid evolutionary development.

BOSTONITE is a fine-grained, pale-coloured, gray or pinkish igneous rock. which consists essentially of alkali-feldspar (orthoclase, anorthoclase, microperthite, etc.). Some bostonites contain a small amount of interstitial quartz (quartz-bostonites); others have a small percentage of lime, which occasions the presence of a plagioclase feldspar (lime-bostonite). Other minerals, except apatite, zircon and magnetite, are typically absent. The bostonites have very much the same composition as the trachytes (*q.v.*), and many rocks of this series have been grouped with these or with the orthophyres. Typically they occur as dikes or as thin sills, often in association with nephelite-syenite.

BOSTON IVY (JAPANESE IVY) (*Parthenocissus tricuspidata*), a high climbing, much branched vine, with short adhesive tipped tendrils by means of which it adheres firmly to walls or other surfaces. Its leaves are variable, ovate to orbicular, simple to three-lobed or three-parted and shining above. Its fruit is a bluish-black berry. The species, and some of its varieties, are hardy and extremely useful climbers, thus making it one of the favourite vines in cities. The shining foliage which stands the smoke and dust unusually well changes to a brilliant orange and scarlet in autumn. (J. M. BL.)

BOSWELL, JAMES (1740–1795), Scotsman, friend and biographer of Samuel Johnson, revealed also by the publication of his journal in the 20th century as one of the world's greatest diarists, was born in Edinburgh on Oct. 29, 1740. His father, Alexander Boswell, advocate, laird of Auchinleck in Ayrshire from 1749, was in 1754 raised to the bench with the judicial style of Lord Auchinleck. The Boswells were an old and well-connected family, and James was subjected to a strong pressure of family ambition.

Alexander Boswell was hard-headed and undemonstrative, his wife retiring and mystical. James, a delicate child, was coddled physically but given Calvinistic instruction in the "last things." He grew up timid, afraid of hell, with painfully vivid images of fatalism fixed in his mind, and at the age of 12 suffered some sort of acute nervous illness.

Boswell hated the select day school (Mundell's) to which he was sent at the age of 5. and from 8 to 13 was taught at home by tutors. From 1753 to 1758 he went through the arts course at Edinburgh. An encounter with metaphysics in the logic class (1756–57) revived the terrors of his childhood and induced a serious depression. On his recovery, he threw off all outward signs of delicacy and attained apparently robust health. He was rather under average height and tended to plumpness, with very swarthy skin, black eyes and black hair. His expression was alert and masculine and he was conspicuously good-humoured. But his nervous limitation persisted, manifesting itself in recurrent periods of depression all the more painful for not being prostrating. And he never outgrew the adolescent faculty of entertaining incompatibles simultaneously.

His conduct began to give his father concern. Returning to the university in 1758 to study law, he became enthralled by the theatre and fell in love with a Roman Catholic actress. Lord Auchinleck thought it prudent to send him to the University of Glasgow, where he attended the lectures of Adam Smith. In the spring of 1760 he ran away to London and made his submission to the Roman Catholic Church. He had hitherto been completely continent and entertained notions of becoming a monk. But a blackguard man of letters, Samuel Derrick, introduced him to various ladies of the town and the earl of Eglinton, an Ayrshire neighbour, schooled him in Deism and brought him into the company of the young duke of York and of Laurence Sterne. Boswell discovered London and himself simultaneously. He was, he found, passionately fond of metropolitan culture, gregarious, high-spirited, sensual and attractive to women, and London offered just the combination of gross and refined pleasures that seemed to fulfill him. In order that he might stay permanently in London, he fixed his heart on a commission in the foot guards. When Lord Auchinleck finally went to fetch him (June 1760), he found him suffering from gonorrhea, an affliction that he was to endure many times in the course of his life.

From 1760 to 1763 Boswell was in open though unhappy rebellion. He studied law in his father's strict family and sought release from boredom in gallantry, in a waggish society called the Soaping club, and in scribbling, his crony and literary model being a young army officer, the Hon. Andrew Erskine. His publications (mostly in verse) give no indication of conspicuous talent. During these years he deliberately fashioned the personality which he was to show to the world, completing the unfinished structure of his good breeding with a façade of boisterousness, buffoonery and impudence. His famous vanity consisted simply in avowing what other people think but do not say. He had remarkable gifts as a mimic, and at this time exercised them freely.

Boswell came of age (on Oct. 29, 1761) still stubborn in his guards scheme. Lord Auchinleck then agreed that if he would pass his trials in civil law, he would supplement his annuity of £100 and allow him to go to London to seek a commission through influence. Boswell passed the examination in July 1762.

It was in anticipation of this great era in his life that he began, in the autumn, the journal which was to be the central expression of his genius. His great zest for life was not fully savoured until life was all written down, and he had a rare faculty for imaginative verbal reconstruction of his past in terms of average human perception. His journal is much more dramatic than most because he writes up each event as though he were still living through it, with no knowledge of anything that had happened later. People in his journal talk and are given their characteristic gestures. His gifts for the imaginative reporting of conversation have never been paralleled. If he made brief notes on a conversation soon after it occurred, he could at any distance of time recall "the heads and the very words of a great part" of that conversation and construct a miniature having the vividness and economy of fiction while keeping within the bounds of historical circumstance. His power of eliciting memorable conversation was no less remarkable. He had a generousness of mind which enabled him, as he once remarked, so to tune himself to the tone of any bearable man that that man would be as free with him as with another self.

Boswell's second London visit lasted from Nov. 1762 to Aug. 1763. Soon after his arrival, he was informed of the birth in Scotland of a son, Charles, for whom he arranged Anglican baptism. The mother (Peggy Doig) was probably a servant. He laid siege to a handsome actress, one Mrs. Lewis ("Louisa"), and paid for victory with an infection. He and Erskine roused Lord Auchinleck's fury by publishing a book of their own bantering letters. He met Oliver Goldsmith and John Wilkes. And on May 16, 1763, in the back parlour of the actor and bookseller, Thomas Davies, he secured an unexpected introduction

to Samuel Johnson, whose works he admired and whom he had long been trying to meet. Johnson was rough with him, but he kept his temper, went to call a week later, found himself liked, and the great friendship was cemented. There was condescension on both sides, Johnson deferring to Boswell's superior birth and Boswell to Johnson's superior wit and wisdom. Having become genuinely convinced that the guards scheme was not practicable, Boswell capitulated to his father and consented to become a lawyer. It was agreed that he should spend a winter studying civil law at Utrecht, and should then make a modest foreign tour. Johnson, with touching kindness, made a four-day journey to see him off from Harwich.

Boswell had been deeply affected by Johnson's piety and goodness, and in Holland made a sincere effort to study hard and to keep out of mischief. On Christmas Day, in the ambassador's chapel at The Hague, he received communion for the first time in the Church of England. He engaged in a sparring courtship with that exquisite ironist Belle de Zuylen *(see* CHARRIÈRE, ISABELLE AGNÈS ÉLISABETH DE), who told him that she found him odd and lovable. His strict program proved stimulating for a time, but palled when it had lost its novelty. He received word that his little boy had died. In the depression that ensued he had recurring nightmares of being hanged. He was discouraged to find that dissipation brought him more happiness than chastity and hard work, and soon lapsed into his former promiscuity.

From Utrecht Boswell traveled to Berlin in the company of the old Jacobite Earl Marischal, friend and counselor of Frederick the Great, but was never able to meet the king—his greatest and almost his only social defeat. In his tour of the German courts he was received with special graciousness by Karl Friedrich of Baden Durlach. Passing through Switzerland (Dec. 1764), he secured interviews with both Rousseau and Voltaire. His approach to Rousseau was a characteristic piece of bravura. Lord Marischal had provided him with a letter. but he chose to present one of his own describing himself as a man of singular merit.

Boswell stayed nine months in Italy, devoting himself systematically to sight-seeing. He established an intimacy with Wilkes (then outlawed) at Naples and traveled with Lord Mountstuart, eldest son of the earl of Bute, the chief target of Wilkes's scurrilities. His cherished dream of high intrigue—he made blunt proposals to three countesses almost simultaneously on arriving in Turin—finally came true in Siena at the very end of his tour, when Girolama Piccolomini, wife of the chief official of the city, fell deeply and touchingly in love with him.

The most original act of his life followed when he made a six weeks' tour of the island of Corsica (autumn 1765) to interview the heroic Corsican chieftain, Pasquale de Paoli, then engaged in establishing his country's independence of Genoa. Paoli succumbed to his charm and became his lifelong friend. On his return to the mainland, he sent off paragraphs to the newspapers, mingling facts with fantastic political speculation.

At Paris he met Wilkes again and was stunned to read of his mother's death in an English newspaper. He was disappointed not to see Rousseau, who had just left for England, but Thérèse Le Vasseur, Rousseau's mistress, accepted his offer of an escort. The passage turned into a farcical *voyage à Cythère,* Boswell vainly seeking compliments on his performance, and Thérèse (who was nearly 20 years his senior) reading him lectures on the art of love.

Boswell was admitted to the Faculty of Advocates on July 26, 1766, and for 17 years practised law at Edinburgh with complete regularity and a fair degree of assiduity. His cherished trips to London were by no means annual, and until 1784 were always made during the vacations. He had plenty of business though an uncomfortable amount of it consisted of causes which his father was to try. He mas an able courtroom lawyer, especially in criminal cases, but in Scotland neither fortune nor fame could be won in the criminal court and an ambitious lawyer needed to give all and not part of his vacations to study. Also. Boswell hurt his reputation for professional soundness by emotional involvement in his clients' fortunes, and by resorting to extralegal tactics in matters *sub judice.*

In Feb. 1768 Boswell published *An Account of Corsica, the Journal of a Tour to That Island, and Memoirs of Pascal Paoli* and stepped into fame. France had unmasked its intention of annexing the island. and people were greedy for information about Corsica and Paoli. Boswell's book (which was promptly translated into French, German, Italian and Dutch) embarrassed both the French and British ministers, the French because they thought it might force British intervention, the British because they had already uritten off Corsica. The *Account* is a graceful *ad hoc* compilation; *The Journal of a Tour to That Island,* Boswell's first work exploiting his journal, is a minor masterpiece. Motives of propaganda caused him to present himself as a complete *ingénu* and to cut the tour to a mere frame for the memoirs of Paoli, but the result is still very pleasing. Paoli, probably wisely, is presented in the Plutarchan manner.

Between 1766 and 1769 Boswell amused himself with various well-hedged schemes of marriage, maintaining meantime a liaison with one Mrs. Dodds, a young grass widow. Their daughter Sally, like Charles, seems to have died in infancy. He ended by marrying (Nov. 1769) the only woman he had ever wanted to marry, his first cousin, Margaret Montgomerie. Lord Auchinleck was deeply disappointed, for the match brought neither lands nor money, and took a new wife himself on the very day of his son's wedding.

During the first few years of his marriage, Boswell was on the whole happy, hard-working, chaste, and confident of getting a seat in parliament, a good post in the government, or at :he very least a Scots judgeship. Paoli visited him in Scotland in 1771; in 1773 he was elected to The Club; and later in the year Johnson made with him the famous tour of the Hebrides. He ultimately had five healthy and promising children. He was made an examinator of the Faculty of Advocates and one of the curators of the Advocates' library; he served twice as master of the Canongate Kilwinning Lodge of Masons, and declined nomination for the Grand mastership of Scotland. But by 1776 he began to feel strong intimations of failure. A headlong entry into Ayrshire politics—repudiated by Lord Auchinleck—had ranged him in opposition to Henry Dundas, who was then emerging as a political despot in the management of the Scottish elections. His practice was not becoming more notable. He began to drink heavily to recruit his spirits. not. as formerly, to give them vent. He returned to his old traffic with women of the town when separated from his wife by distance, by her pregnancy or by her frequent complaints. As early as 1778 it was obvious that she was critically ill with tuberculosis.

Between 1777 and 1783 he published in *The London Magazine* a series of 70 essays, significantly entitled *The Hypochondriack,* which deserve to be better known, though they do not engage his full powers. At the end of 1783, in the hope of attracting the attention of Pitt's new government, he published a pamphlet attacking Fox's East India bill. Pitt sent a chilly note of thanks but made no move to employ him.

Boswell succeeded to Auchinleck in 1782 and managed his estate with attention and some shrewdness. But he thought he could be happy only in London, and encouraged himself in the childish notion that he could be more successful at the English than at the Scots bar.

Johnson died on Dec. 13, 1784. Boswell decided to take his time in writing the *Life,* but to publish his journal of the Hebridean tour as a first installment. In the spring of 1785 he went to London to prepare the work for the press, but became diverted by dinners and girls and by the writing of a frothy pamphlet against Henry Dundas' bill for diminishing the number of the lords of session. Edmond Malone, a fellow-member of The Club but not previously a close friend, got sight of the work in progress and offered his daily assistance in preparing the remainder of the copy. Boswell's journals show little variation in literary excellence but in matter the Hebridean journal tops all the others. It comes from the soundest and happiest period of Boswell's life, the narrative of the tour is interesting in itself, and we get 101 consecutive days with Johnson. The book was a best seller. but it provoked the scornful charge of personal fatuity that has dogged Boswell's name ever since. His intelligence was not really in ques-

tion. Boswell had a good mind, and his imprudences and sins were of the sort that the world usually tolerates in artists. But he deliberately defied the basic and unchanging literary convention which rules that when a man writes about himself, he must somehow manage to make himself seem formidable. Boswell analyzed and recorded his own vanity and weakness with the objectivity of an historian; and in his Johnsonian scenes he ruthlessly subordinated his own personality, reporting the blows that Johnson occasionally gave him without constantly reassuring the reader that he understood the implications of what he had written.

In 1786 Boswell was called to the English bar from the Inner Temple and moved his family to London. Thereafter he had almost no legal practice. His principal business was the writing of the *Life of Johnson,* which he worked at irregularly but with anxious attention. The revision of manuscript and proofs was labyrinthine. Malone again gave him tactful support and sat with him during much of the rewriting.

Though straitened in income, he gave his children expensive educations. He visited Edinburgh only once after his emigration and then almost surreptitiously. Mrs. Boswell pined for Auchinleck and insisted on being taken there when her health grew desperate. Bosnell felt that he had to be in London in order to finish the *Life* and to be at the call of the earl of Lonsdale, who had given him unexpected encouragement and caused him to be elected recorder of Carlisle. When she died (June 4, 1789), he was not at her side, and when he tried to detach himself from Lonsdale. he was treated with shocking brutality.

The *Life of Johnson* was published on May 16, 1791. Contemporary criticism set the pattern of acclaim for the work and derision for its author which was to receive consummate expression from Rfacaulay in his well-known essays (1832 and 1856). Boswell took intense pleasure in his literary fame, but felt himself to be a failure. His later years were prevailingly unhappy. His eccentricities of manner seemed merely self-indulgent in a man of 50 or over; people were afraid to talk freely in his presence fearing that their talk would be reported; and his habit of getting drunk and noisy at other people's tables (he was never a solitary drinker) made him a difficult guest in any case. But his five children loved him deeply, and he never lost the solicitous affection of Malone and a few other friends who recognized his worth and his need. He saw the second edition of the *Life* through the press (July 1793) and was at work on the third when a sudden illness put an end to his life on May 19, 1795.

The *Life of Johnson* will always be regarded as Boswell's greatest achievement, but we can now see that its unique values are derivative. It is the stretches of Johnson's conversation that make it superior to all other biographies, and those conversations were lifted bodily from the journal, sometimes with so little change that the journal-leaves served as printer's copy. The extended commercial publication of the journal, by proving his ability to compete nith 20th-century authors on their own terms. has confirmed and added to his stature as artist. It is also for the first time giving the general reader a properly complex portrait of him as a man.

BIBLIOGRAPHY.—Boswell's private papers, long believed to have perished, were sold in 1927 and 1928 by his great-great-grandson, Lord Talbot de Malahide, to Lieut. Col. R. H. Isbam, for whom Geoffrey Scott and F. A. Pottle edited a de luxe edition: *Private Papers of James Boswell From Malahide Castle* (18 vol., 1928–34; index, 1937). More papers were iound at Malahide in 1930, 1937 and 1940. In 1930 C. Colleer Abbott turned up a large quantity of Boswell papers at Fettercairn house, Aberdeenshire, among the papers of Sir William Forbes, Boswell's executor. All these finds were ultimately acquired by Col Isham, whose collection was purchased in 1949 for Yale university. *See* F. A. Pottle, "The History of the Boswell Papers," in Heinemann's limited edition of Boswell's *London Journal* (1951) and *C.* Colleer Abbott's introduction to his *Catalogue of Papers . . . Found at Fettercairn House* (1936). The "research" series of the Yale editions of the private papers of James Boswell will print most of the papers.

Among biographical studies may be cited Charles Rogers's memoir accompanying his edition of *Boswelliana* (1874); W. Keith Leask, *Janzes Boswell* (1897); C. B. Tinker, *Young Boswell* (1922); Peter Quennell, "James Boswell, The Biographer," in *Four Portraits* (1945; U S title, *The Profane Virtues)*; D. B. Wyndham Lewis, *The Hooded Hawk* (1946; reprinted as *James Boswell,* 1952). The commercially published volumes of the Yale editions are a virtual autobiography. Seven have appeared: *Boswell's London Journal* (1950), *Boswell in Holland* (1952), *Boswell on the Grand Tour: Germany and Switzerland* (1953), ed. by F. A. Pottle; *Boswell on the Grand Tour: Italy, Corsica, and France* (1955), *Boswell in Search of a Wife* (1956, 1957), ed. by Frank Brady and F. A. Pottle; *Boswell for the Defence* (1959, 1960) ed. by W. K. Wimsatt and F. A. Pottle; *Boswell: The Ominous Years* (1962) ed. by Charles Ryskamp and F. A. Pottle. C. B. Tinker's *Letters of James Boswell,* 2 vol. (1924) prints nearly 400 letters. F. A. Pottle, *The Literary Career of James Boswell* (1929) provides a full bibliographical account of Boswell's publications.

Boswell's *Journal of a Tour to Corsica* has been ed. by Sir Sydney C. Roberts (1923); Morchard Bishop (1951); and in *Boswell on the Grand Tour: Italy, Corsica, and France* (1955). Boswell's original journal of the Hebridean tour was published in 1936 by F. A. Pottle and C. H. Bennett and reprinted, with additions, in 1962; his printed *Journal of a Tour to the Hebrides* appears in the "Everyman Series" (1938), ed. by L. F. Powell, and with Johnson's *Journey to the Western Islands* of *Scotland,* ed. by *R.* W. Chapman (1924). The 3rd ed. of the *Life oj Johnson,* 4 vol., (1799), by E. Malone was the last that Boswell had a hand in. J. W. Croker's ed. in 5 vol. (1831) made many identifications but was justly slated for its method. Much the most useful edition for scholars is L. F. Powell's revision, 6 vol. (1934–1950) of G. Birkbeck Hill's ed., 6 vol. (1887). (The fiith volume is the *Journal of a Tour to the Hebrides,* the sixth a massive index.) The best one-volume edition is that oi the "Oxford Standard Authors," revised (1953) by R. W. Chapman with an introduction by C. B. Tinker.

Among critical studies may be mentioned Thomas Carlyle's two essays, "Biography" and "Boswell's *Life of Johnson"* (originally a review of Croker; 1831) in *Critical and Miscellaneous Essays;* A. E. Newton, "James Boswell—His Book," in *The Amenities of Book-Collecting* (1918); Geoffrey Scott, introductions to vol. 1–5 of Isham's *Private Papers* and especially vol. 6, *The Making of the Life of Johnson* (1928–29); *D. A.* Stauffer, *The Art of Biography in Eighteenth Century England,* vol. 1, pp. 411–455 (1941); B. H. Bronson, "Boswell's Boswell," in *Johnson and Boswell, Three Essays* (1944, reprinted 1946 as *Johnson Agonistes and Other Essays);* F. A. Pottle, "The Power of Memory in Boswell and Scott," in *Essays on the 18th Century presented to D. Nichol Smith* (1945) and "The Life of Boswell," in *The Yale Review!* (Spring, 1946); C. Colleer Abbott, *Boswell,* Literary and Philosophical Society of Newcastle upon Tyne (1946). (F. A. P.)

BOSWORTH FIELD, BATTLE OF, an engagement of great historical consequence fought on Xug. 22. 1485, 12 mi. W. of Leicester. Eng.. and 3 mi. S. of the small town of Market Bosworth, from which it was named. It was between the usurper Richard III and Henry Tudor, then not technically earl of Richmond, for he had been deprived in 1471. Henry. latterly an exile in France, claimed to inherit the Lancastrian right to the English throne. He sought to prosecute his claim by force, and his victory at Bosworth, although it did not seem of particular consequence to contemporaries. firmly established the Tudor dynasty and all that it was to involve. To this end Henry landed at Milford Haven on Aug. 7, 1485. and reached Shrewsbury on Aug. 1 j. gathering only moderate support on the way. He then proceeded through Nen-port in Salop. Stafford. Lichheld and Tamworth, reaching Atherstone. on the Watling street and the Leicestershire border. on Aug. 20. There he met the brothers Stanley, both with strong contingents in the neighbourhood. Lord Stanley was Henry's stepfather, and Sir William Stanley had already been declared a traitor by the Yorkists. For the moment they both preferred to stand aloof. but they assured Henry of their support when the crisis came. Next day Henry encamped at White Moors. near Shenton, on the southwest edge of what was to, be the battlefield. That night Richard's host halted three miles to the northeast on rising ground at Sutton Cheney. Lord Stanley was away to the southeast near Dadlington, and his brother lay northwest near Nether Cotton.

Reliable details of the battle are few. The only strictly contemporary account is in the *Historiae Croylandensis Continuatio,* but the writer was unacquainted with the site and says little about the actual fighting. Polydore Virgil wrote the first full account nearly 20 years later, and its limitations are obvious. The ground itself has been much altered by 18th-century enclosure and by the making of the Ashby canal and the Nuneaton to Xshby railway, both of which traverse the site. It appears that early on Xug. 22 Richard, a better soldier than his opponent, ordered the duke of Norfolk, commander of his vanguard, to seize Ambien hill, a slight eminence roughly midway between the opposing armies. He himself would then move up with the main body. followed by the earl of Northumberland. who commanded the rear. Henry had the same purpose, but was less expeditious, and his troops found Am-

bien hill occupied by the Yorkists. while their own progress was hampered by a marsh on its southern side. There followed a desultory and ill-organized engagement on the slope. The crisis came when the Stanleys moved against the Yorkist flanks and Northumberland failed to intervene. The Yorkist army melted away and there was no real pursuit. while Richard. preferring death. was unhorsed and killed in the bog. The Torkists had about 8,000 men engaged. but it is probable that, at the last. they were outnumbered. Of the casualties nothing certain is known. (GY. T.)

BOTANICAL AND HORTICULTURAL SOCIETIES: **see** HORTICULTURE AND BOTANY, SOCIETIES OF.

BOTANICAL GARDENS. The original concept of a botanical garden was that literally implied by the name; that is, a garden with the plants arranged according to some system of botanical classification. In the forerunners of the modern botanical garden. such as the gardens of simples commonly associated with schools of medicine in the 16th and 17th centuries, the planting was primitive and possibly based on the use of the plants. in medicine or otherwise, rather than on the more or less crude botanical concepts of the time. A botanical garden differs from a park. where the plants are usually arranged solely with reference to securing a beautiful landscape effect. The primary purpose of a park. moreover. is recreation. while that of a botanical garden has always been science and education. A botanical garden is properly defined as a scientific and educational institution whose purpose is the advancement and diffusion of a knowledge and love of plants.

A collection of living plants. out-of-doors or under glass or both, is always a major feature of botanical gardens, but the modern garden usually possesses. in addition, a herbarium, a library. experimental grounds for plant breeding and other investigations, laboratories. classrooms. lecture hails and sometimes botanical museums. together with scientific. educational and administrative staffs. Different institutions place the emphasis on different aspects of the work; this may be determined by climate, area. tradition. resources or ideals.

Botanical gardens have gradually developed by evolution from such gardens as the early olive orchards and the temple gardens. like that, for example, at Karnak. Egy., one of the earliest of which there is authentic record. dating from the reign of Tuthmosis III, about 1500 B.C. It seems probable that the very earliest gardens were utilitarian in purpose. for the growing of food and fibre plants and fruit trees. Temple grounds, however, were early planted: and to this practice we are probably indebted for the preservation of the maidenhair tree, Ginkgo biloba. One of the first gardens developed for the purpose of facilitating the study of plants was that of Aristotle, an ardent student of plants, who wrote books on botany, now lost. This garden was in charge of his pupil Theophrastus, who continued and improved it after the death of the master. It would thus appear that, in modern terminology, the first patron of botany of whom there is record was Aristotle (c. 350 B.C.) and the first "director" of a botanical garden Theophrastus, who also wrote books on botany, two of which are still in existence. Diogenes Laertius is authority for the statement that Demetrius Phalereus provided Theophrastus with the necessary funds for improving this garden and thus became, after Aristotle, one of the first wealthy patrons of botany.

The history of botanical gardens during the period between those of antiquity and the 15th or 16th century appears never to have been traced in detail. During the 16th and 17th centuries the herbalists (predecessors of the modern botanists) began to cultivate private gardens for the purpose of plant study. Perhaps the best known of these is the garden of John Gerard in Holborn. London. These private gardens were the forerunners of the modern botanical gardens. The botanical garden idea spread rapidly in countries of older civilization during the 18th and 19th centuries. In the new world, botanical gardens were early established by John Bartram near Philadelphia in 1728, by André Michaux near Charleston. S.C., in 1787 and by David Hosack (the Elgin Botanic garden) on the site of Rockefeller centre in New York city in 1801. Under the patronage of Charles III of Spain a flourishing botanical garden was established in Mexico in 1788 Notwithstanding the phenomenal growth of the United States the botanical garden idea was slow to take root. and it was nearly 60 years from the Elgin garden to the establishment of Shaw's garden (the modern Missouri Botanical garden), at St. Louis. Mo., in 1859. This garden appears to be the oldest existing botanical garden in America organized as an independent institution. The Cambridge (Mass.) Botanic garden. a part of Harvard university, was, at the time it ceased to exist in 1948. the oldest botanical garden in the United States; it was established in 1807.

Modern botanical gardens in all countries are organized along closely similar lines. There is a director with a scientific (and sometimes an educational) staff. a head gardener and a force of gardeners and labourers for the maintenance of walks, driveways, conservatories, borders and lawns. The director of a government-supported garden (*e.g.*, Kew near London; Edinburgh; Glasnevin at Dublin; Paris; Berlin; the United States Botanic garden in Washington. D.C.; Buitenzorg in Java; Singapore: Port of Spain in Trinidad; Hope and Castleton gardens in Jamaica; and others) reports to a governmental minister or bureau. and the financial support comes wholly or chiefly from governmental appropriations. For independent institutions (*e.g.*, Missouri Botanical garden at St. Louis. Rancho Santa Ana Botanic garden at Claremont. Calif., Boyce Thompson Southwest arboretum at Superior. Xriz.. and others) there is a board of trustees who administer finances. Gardens that form integral parts of universities or other institutions (*e.g.*, Cambridge in England: the Hortus Botanicus at Amsterdam: Brooklyn in New York city) are administered by the trustees of the institution. A fourth group comprises gardens which are supported in part by municipal or other governmental appropriations and in part by private funds administered by a board of trustees, as is the case, for example. with the New York Botanical garden.

MISSOURI BOTANICAL GARDEN IN ST LOUIS DATING FROM 1859

(Top) Formal gardens; (bottom) climatron, geodesic dome greenhouse, built in 1960

Various botanical gardens in Europe derive their support wholly or chiefly from the cities in which they are located, as, for example, Bath in England, Bern in Switzerland, Marseilles in France and Valencia in Spain.

Among botanical gardens that form an integral part of the botany departments of colleges and other schools or are closely affiliated with them may be mentioned the following: Aberdeen, Dundee and St. Andrews universities in Scotland; Birmingham, Cambridge and Oxford universities and the Royal Agricultural college at Cirencester in England; Trinity college. Dublin; those at the universities of Budapest in Hungary, Czernowitz and Cluj in Rumania, Cracow and Lwow in Poland, Prague in Czechoslovakia; those at Vienna in Austria, at Ghent and Liège in Belgium. at Copenhagen in Denmark, at the Catholic university in Lille. France. at the medical college and the veterinary college in Lyons. France. at Strasbourg and at Madrid; those at the universities of Bonn. Breslau. Gottingen. Halle. Munich and Würzburg in Germany. and at Athens. Greece, Groningen. Leiden and Utrecht in the Netherlands, Genoa and Modena in Italy, Kiev, Odessa and Leningrad in the U.S.S.R., Basel in Switzerland and the Jardins Alpins de l'Université de Grenoble. also in Switzerland: those at Nikko and Tokyo in Japan; the Botaniska Tradgard of the University of Helsinki in Finland; in the United States those of the University of California (Berkeley). Smith college (Northampton. Mass.), Mt. Holyoke college (South Hadley. Mass.), Michigan State university (East Lansing). the University of Michigan (Ann Arbor), the University of Minnesota (Minneapolis), the University of Pennsylvania (Philadelphia) and the Johns Hopkins university (Baltimore, Md.); and in Canada those of the University of British Columbia (Vancouver) and McGill university (Montreal). Harvard university maintains a botanical garden at Soledad. near Cienfuegos, Cuba — the Atkins institution of the Arnold arboretum.

By the early 1960s there were approximately 325 botanical gardens outside the United States. The more notable of these are mentioned below (dates in parentheses are dates of foundation,.

Europe. — Italy. — The garden at Pisa, (1543, *fide* Emilio Chiovenda and Lavellée), founded by order of the grand duke Cosimo I de' Medici, is one of the earliest gardens devoted to the public study of botany; it became famous under its second director, Andrea Cesalpino. His work (De *plantis*, 1583) marks the beginning of modern systematic botany and influenced botanical science for more than 100 years. The Padua botanical garden. established by a decree of the senate of the republic of Venice enacted June 29. 1545, contends with Pisa for first place in antiquity. The controversy is discussed in C. Stuart Gager's "Botanic Gardens of the World," Brooklyn Botanic *Garden Record*, vol. 26, pp. 149–353, July. 1937.

France. — The Muséum National d'Histoire Naturelle, Paris (1635), has long been known as the Jardin du Roi. Of naturalists who have worked there Lamarck is perhaps the most illustrious; he was appointed curator of plants in 1789. It is famous also for a remarkable school of botanical painting, of which P. J. Redouté is the best-known exponent. The garden proper, generally known as the Jardin des Plantes. occupies an area of 34.6 ac.

Great Britain. — The Chelsea Physic garden. London (1673), was established on the bank of the Thames by the Society of Apothecaries for the express purpose of advancing the teaching of botany and of providing study material for research and teaching. In the earlier years the garden grew medicinal plants in sufficient amounts to supply the members of the society with crude drugs in commercial quantities. The original plot of four acres was enlarged in 1722 by additional ground deeded as a gift by Sir Hans Sloane. with the provision that the growth of drug plants for commerce cease and the garden thenceforth be devoted exclusively to scientific and educational work. Its influence along these lines can scarcely he overestimated. Among its famous directors were Philip Miller, author of the classic *Gardener's* Dictionary, and John Lindley (appointed in 1835), author of *Flora Medica* and other important botanical works. Many important publications grew out of the work of the garden, including William Curtis' *Botanical Magazine* and Flora *Londinensis*, Lindley and Thomas Moore's *Treasury* of *Botany* and others. The private library of Charles Darwin is housed in the laboratory building

The Royal Botanic gardens are located at Ken, near London (1759) The nucleus of the collections at Ken nas the plants grown by Lord Capel who came into possession of Kew house by marriage Frederick prince of Wales leased the property about 1730 and aiter his death his widow Princess Augusta of Saxe-Gotha engaged a former pupil ot the Chelsea garden William Aiton to develop a physic garden in 17j7 From that year Kew ranked as a true botanical garden The total area is 288 ac It was Aiton who inaugurated the plan of sending botanical exploring expeditions to foreign countries. The material collected on these expeditions greatly enriched the scientific collections at Kew, and also knowledge of the vegetation of the world from the point of view not only of pure science but of economic botany as well. The gardens (as stated in a Kew guidebook) stand in relation to botanical science much as Greenwich does to astronomy. The botanical survey of the British commonwealth has resulted in the publication of floras of most of the overseas dominions. Among commercial plants distributed by Kew to new centres are those which yield breadfruit. pineapple, banana, tea. coffee. cacao, rubber, various fibres, timbers. dyes and quinine and other drugs. The quinine plant (*Cinchona*) was introduced by Kew from South America to India in 1860. Most of the crude rubber used extensively throughout the world is derived from trees of the Pará rubber plant (*Hevea brasiliensis*) raised from seeds collected by Sir Henry Wickham under the auspices of Kew in Brazil in 1875. Kew acts as botanical adviser to all governmental departments. The garden maintains a school of horticulture for the training of gardeners. It is visited by more than 1.000.000 persons annually. One of the most important publications is the *Index Kewensis*, an alphabetical list of all flowering-plant names published. with citations of the places of publication. This project was originally conceived and financed by Charles Darwin: it is kept up to date by supplements which appear at irregular intervals. The *Index Londinensis* (8 vol.) to the published illustrations of flowering plants. ferns and fern allies was prepared under the auspices of the Royal Horticultural society at the Kew garden. The *Kew Bulletin* contains the results of scientific researches by members of the staff.

Germany.—The Botanischer Garten und Botanisches Museum, Berlin-Dahlem. Ger. (1679), was established in Schoneberg. near Berlin, as an exhibition or model garden (*Mustergarten*). There it remained for more than 200 years. A new site was chosen at Dahlem. where in 1897–1907 the present garden was laid out under the direction of H. G. A. Engler, who was director from 1889 to 1921. The area is approximately 100 ac. It is primarily a research institute for botanical science and instruction of Berlin university. The plantations comprise five main sections: (1) plant geography; (2) morphology-ecology; (3) the arboretum; (4) systematic botany; and (5) economic plants. The botanical museum. which housed the large and extremely valuable library and herbarium besides public exhibits. was demolished in March 1943, during World War II.

Others.—Among other important European botanical gardens may be mentioned those at Amsterdam where Hugo de Vries (*q.v.*) carried on his investigations leading to the formulation of his mutation theory. Budapest (1771), Cambridge (1762), Oslo (1811), Coimbra. Port. (1773), Copenhagen (1600), Hanbury (Mortola, near Ventimiglia, Italy. 1867), Helsinki (1828), Leiden, Neth. (1587). Leningrad (1843). Madrid (1755), Rome (1884), Stockholm (Hortus Botanicus Bergianus, 1791) and Uppsala, Swed. (1787).

Asia and the Pacific Islands. — There are botanical gardens at Tokyo (1684); Sibpur, near Howrah. India (1787); Bogor, Java (1817); Hong Kong (1864); Peradeniya, Ceylon (1810); Melbourne, Austr. (1842); and Hobart, Tasmania (1844).

Africa. — Botanical gardens are located at Durban (1849) and Kirstenbosch at Cape Town (1913).

South America. — The gardens at Rio de Janeiro (1808) and Buenos Aires (1892) are well known.

North America.—*Missouri Botanical* Garden. — This garden (St. Louis, Mo.. 1859) is known locally as Shaw's garden. from the name of the founder, Henry Shaw, who first opened his garden to

the public about 1859. The area is about 75 ac.

The garden co-operates closely with the Henry Shaw school of botany at Washington university, St. Louis, members of the scientific staff of the garden serving as professors in the university. During the administration (1889–1912) of the first director, William Trelease, the *Annual Reports,* enriched with scientific contributions, became known throughout the scientific world. Under his successor, George T. Moore (1912–1953), the *Annals,* a scientific quarterly, and a monthly *Bulletin,* devoted mainly to the horticultural and floricultural activities of the garden, were initiated, and the scientific and educational work was expanded.

In 1925, 1,600 ac. of land 35 mi. S.W. of the city were acquired to be developed as an arboretum and to be used for maintaining plants injured by the smoke of the city. This serves as a source of plants for the city garden, affords areas for establishing a pinetum, a wild flower reservation and other features not possible in the city, and provides greenhouses for 20,000 orchids. The tropical station established in the Panama Canal Zone in 1926 was released to the Canal Zone government in 1937.

Arnold Arboretum.—This, at Boston, Mass. (1872), is the living tree museum of Harvard university. The principal collection of trees and shrubs was planted in 1886. The area of approximately 250 ac. includes meadow, hill and valley, and the permanent endowment is nearly $2,862,000. There is a library of about 50,000 volumes and many pamphlets, now combined with that of the Gray herbarium in Cambridge, Mass. Most of the herbarium of woody plants of the world (more than 500,000 specimens) has also been combined with the collections of the latter institution. Publications include: *Journal of the Arnold Arboretum, Arnoldia* (formerly *Bulletin of Popular Information*), *Sargentia,* which replaced the *Contributions* in 1938, the *Bradley Bibliography* (a guide to the literature of the woody plants of the world before the 20th century) and the *Bibliography of Eastern Asiatic Botany.*

As a part of the Arnold arboretum the Atkins institution of 230 ac. at Soledad, near Cienfuegos, Cuba, was developed as a tropical botanical garden. It has a small endowment of its own.

New York Botanical Garden.—Located in Bronx park (New York city, 1895), this garden comprises an area of approximately 280 ac.; its permanent funds exceed $2,500,000. In addition to extensive outdoor plantings there is a large range of conservatories. The museum building houses the public exhibits, the herbarium of more than 2,400,000 specimens, the library of more than 60,000 bound volumes and 150,000 pamphlets, together with classroom, lecture hall and administrative offices. A separate building contains laboratories for research in physiology and pathology. Free public lectures and classes in gardening and botany are given; the facilities of the garden are used by garden clubs, public schools and other groups. The garden was early devoted to botanical exploration of the West Indies and of continental North America, and later to that of northern South America. Publications include: *Garden Journal* (successor to the *Journal,* 1900–50), *Mycologia, North American Flora, Memoirs, Brittonia, Addisonia.* The garden is supported by both municipal and private funds. The first director was N. L. Britton (*q.v.*) (1896–1929). The garden is affiliated with Columbia university and offers graduate instruction also to students of Fordham university.

Brooklyn Botanic Garden.—This garden, in Brooklyn (New York city, 1910), includes an area of about 50 ac.; its work includes anything scientific or educational based upon plant life. Many popular courses are given for the public, both children and adults. Its program of public education is probably more extensive than that of any other botanic garden. There is a children's garden and children's greenhouse and building. Boys and girls frequently take consecutive voluntary instruction for periods of from five to ten years, finally entering upon a botanical or horticultural career or upon some other aspect of plant science or industry. Research work is in the experimental aspects of botany (pathology, genetics, physiology). Graduate work done at the garden has been credited toward advanced degrees by Columbia university and New York university. The garden co-operates extensively with public and private schools. Thousands of pupils with their teachers visit the garden in one year for instruction, and pupils are supplied annually with vegetable and flower seeds for planting in school and home gardens; more than 1,500,000 packets were distributed in 1943. The library, containing more than 25,000 volumes and as many pamphlets, is open daily to the public. The conservatories contain tender and tropical economic and other plants. The garden is supported in part by appropriations by New York city and in greater part by private funds. It was developed under the supervision of the first director, C. Stuart Gager (1910–43). Publications include: *Plants and Gardens* (successor to the *Record,* 1912–44), *Memoirs, Leaflets, Seed Exchange Lists* and *Guides* to the plantations and collections.

United States Botanic Garden.—This garden, at Washington, D.C. (1850), was initiated by act of congress, May 8, 1820, on a site of 5 ac., which was increased to 22.5 ac. in 1824. After about 20 years it was discontinued, and the property, which had been assigned to the Columbian institute for botanical garden purposes, reverted to the federal government. It was re-established by act of congress, May 15, 1850, on a site on the Mall. The name botanic garden was not applied to the site until 1856, when congress placed it under the supervision of the joint committee on the library. A preliminary report on the garden by the house committee on the library, Congressman Kent E. Keller, chairman, published in 1934, stated that the activities of the garden formerly consisted chiefly in the raising of ornamental flowering plants and cut flowers for members of congress and friends. This was discontinued by act of congress approved June 30, 1932. The garden was moved from the Mall to a new site south of Maryland avenue in 1933 and is conducted chiefly as a display garden. Botanical research and the botanical library and herbarium are administered by other branches of the federal government.

National Arboretum.—Established by act of congress, March 4, 1937, the National arboretum is located at Washington. The national congress in 1927 authorized the secretary of agriculture to establish a national arboretum on a tract of nearly 400 ac. on the Anacostia river about 4 mi. N.E. of the centre of Washington. The act provides that "the arboretum shall be administered by the Secretary of Agriculture, separately from the agricultural, horticultural, and forestry stations of the Department of Agriculture, but it shall be so correlated with them as to bring about the most effective utilization of its facilities and discoveries."

Boyce Thompson Institute for Plant Research.—This institution (Yonkers, N.Y., 1921) was established by a gift of William Boyce Thompson of approximately $10,000,000, the larger part of which was set aside as a permanent endowment. The institute was incorporated and the laboratories were opened in 1924. The stated purpose is the carrying out of every phase of research on plant life and the dissemination of information relative thereto. In 1928 a tract of about 325 ac. on the eastern edge of Yonkers was secured for the development of an arboretum, where it was planned to grow every hardy species of woody plant. This collection serves as a basis for the study of methods of propagation and of disease control. Publications include the *Contributions* and *Professional Papers.*

Others.—Among other botanical gardens in the Americas are the Letchworth Park arboretum, north of Portage, N.Y.; the Morton arboretum, Lisle, Ill.; and the botanic gardens at various colleges and universities, among them Marsh (at Yale university), University of Pennsylvania, Smith college, Mt. Holyoke college, University of Michigan and Michigan State university, University of California, University of North Carolina, Havana, Cuba, and Hamilton, Bermuda. *See* also ARBORETUM; HORTICULTURE.

(C. S. G.; H. W. RT.)

BOTANICAL SOCIETY OF AMERICA. This society, open to all who are interested in plants and plant science, was founded in its present form in 1906 when the union of the original society with the Society for Plant Morphology and Physiology and the American Mycological society occurred. The society was incorporated in 1939.

Its membership exceeded 2,000 in the second half of the 20th century, the members being largely from the U.S. and Canada. There is a significant body of foreign members and periodically up to 40 of these distinguished plant scientists are elected to cor-

responding membership. The society holds annual meetings for all members and the four geographical sections of the society also meet annually and separately. At these meetings. field excursions, symposia and presentation of the results of original research take place.

The society is broad in scope including seven topical sections, namely, general, teaching, paleobotanical, physiological, microbiological, systematic and phycological. Publications include the *American Journal of Botany* for research reports, the *Plant Science Bulletin* for botanical news and special articles and a biennial yearbook. (H. C. BD.)

BOTANY (ARTICLES ON). The understanding of living organisms begins with botany. No known animal life, past or present, seems to have been capable of existing without depending upon the photosynthetic capacity of green plants; the earliest traces of plant life are three times as old as the most ancient animal fossils. The article BOTANY outlines the major branches of the science, and summarizes the development of its basic principles by such men as Linnaeus, Mendel, Darwin, etc. Another survey that will be helpful as a general introduction to the subject is BIOLOGY, in which plant life is discussed in the perspective of life as a whole.

PLANTS AXD PLANT SCIENCE is designed as an elementary textbook. It explains the classification of plants; basic phenomena such as the alternation of generations; the anatomy and physiology of plants; the interrelationship of plants with their environment; and the meanings of the technical terms that botanists have adopted—terms that may seem forbidding to the beginner but that are useful because they compress a maximum of meaning into a minimum of space.

Articles devoted to primitive members of the plant kingdom include ALGAE; DIATOMS; FUNGI; and LICHENS. Individual articles are devoted to the more important fungi; *e.g.*, MUSHROOM, TRUFFLE, SMUT AXD BUNT, YEAST.

Another primitive group of plants lacking differentiated roots, stems and leaves is discussed in general outline in BRYOPHYTA, and treated in greater detail in the individual articles LIVERWORTS and Moss.

Along with the liverworts and mosses, the club mosses, horsetails and ferns represent the transition of plants from aquatic to terrestrial life. PTERIDOPHYTA discusses these versatile groups, which range from tall treelike bodies to herbs so small as to go generally unnoticed.

Seed plants (spermatophyta) are discussed in two general surveys: ANGIOSPERMS deals with flowering plants, the dominant plants of the earth, whose flower-structures envelope the mechanism of reproduction: and GYMNOSPERMS describes the conifers and other groups associated with them because of exposed seeds. POLLINATION describes the methods of transfer of pollen from the anther to the pistil, as a consequence of which fertilization—a process in which the pollen tube reaches and combines with the ovum to produce a seed—is facilitated.

Articles dealing with broad classifications of plant life include GRASSES; TREE; VEGETABLE; WEED; and WILD FLOWER. Subdivisions of these groups are dealt with in separate articles. For example, GRASSES is supplemented by BAMBOO; BARLEY; RICE; WHEAT; etc.; and individual articles are devoted to major species of tree, vegetable, weed, and wild flower.

Separate articles deal with families of plants and individual species—for example, ROSACEAE and ROSE. Individual articles are devoted also to such groups as CARNIVOROUS PLANTS and POISONOUS PLANTS. Sectional combinations of genetically different varieties in a single plant, which used to be known, erroneously, as "graft hybrids," are discussed in CHIMERA.

FLOWER, FRUIT, and NUT discuss the biological functions of these components of plants. Individual articles deal with specific types—for example, AZALEA, LILY; APPLE, STRAWBERRY; ALMOND, WALNUT. The embryonic development of higher plants is described in SEED. Other components of plants and their contributions to life processes are discussed in LEAF; ROOT; and STEM.

The principles of gardening are outlined in HORTICULTURE. Related articles include ARBORICULTURE; FRUIT FARMING; GRAFTING (IN PLANTS); GREENHOUSE; LAWNS, CARE OF; PLANT BREEDING; and PLANT PROPAGATION. Soilless culture is treated in HYDROPONICS. The study of life processes by the cultivation of isolated groups of plant cells such as root tips, meristems, etc., is described in PLANT CELL (TISSUE) CULTURE.

Exhibits designed for the study of botanical specimens are discussed in ARBORETUM; BOTANICAL GARDENS; and HERBARIUM.

PHOTOSYNTHESIS describes the process by which the chlorophyll of plants, upon activation by sunlight, maintains life by renewing the earth's supply of oxygen and carbohydrates: **A** section of this article indicates how the world's food supply could be multiplied. Other aspects of this topic are treated in PLANKTON, which discusses the drifting plant life of the sea in conjunction with corresponding forms of animal life; and in ALGAE: *Utilization* of *Algae.*

BACTERIOLOGY describes the minuscule forms of plant life that constitute a bridge between inanimate matter and higher organisms.

In the competition for the means of survival, dissimilar organisms sometimes enter into mutually useful relationships. Partnerships of this type between fungi and the roots of plants are described in MYCORHIZA.

Slime molds, a disputed group of organisms in the twilight zone between primitive forms of plant life and animal life, are discussed in MYCETOZOA.

The evolutionary history of plants, as written in the rocks, is discussed in PALAEOBOTANY. The study of pollen grains and spores of immense antiquity has had a practical application in oil geology; this is described, along with the medical phase of pollen study. in POLLEN GRAINS. Pollen and spores of bygone geological eras are discussed also, in conjunction with the fossil remains of minute animals, in MICROPALEONTOLOGY.

The evolution of plants is treated, as part of the over-all story of the development of living organisms, in EVOLUTION, ORGANIC; GENE; GENETICS; HEREDITY; and VARIATION. The methods of classification of plant and animal life are described in TAXONOMY.

Biographical articles summarize the achievements of the great leaders of botanical science.

Articles on botany necessarily contain much material of a technical nature. As far as possible, however, important general principles are explained in nontechnical terms in the introductory sections of its major subdivisions.

For a comprehensive view of the *Britannica's* resources on any topic the Index volume should be consulted, since various aspects of a subject may be discussed in many different articles.

BOTANY is the science which deals with plants. This article deals with the historical development of the science and with its main subdivisions; for a discussion of the form and function of plants *see* the article PLANTS AND PLANT SCIENCE.

Since plants are necessary to human life and since vegetation was conspicuous in the surroundings of the earliest human beings, it is natural that plants have always been of interest to man. It has been shown that at an early period men distinguished and named the kinds of plants they encountered. As civilizations developed, men began to arrange and record their knowledge of plants, and in this way botany began. Men's interests were manifold; as time went on, they concerned themselves not only with the kinds and names of plants but also with their structure, their mode of life, their chemical composition, the functions of their parts and their reproduction. Moreover, from the time man learned to cultivate plants, the study of plants embraced the proper methods of feeding, growing and propagating them, the breeding and selection of better kinds and the treatment of their diseases; in short, botany was the parent of many of the agricultural and horticultural sciences, and in this way has contributed greatly to human welfare.

Fundamentally botany remains a pure science, including any research into the life of plants and limited only by man's technical means of satisfying his curiosity. It has often been considered an important part of a liberal education, not only because it is necessary to an understanding of agriculture, horticulture, forestry, pharmacology and other applied arts and sciences, but also because to understand plant life is to know something of life in general, including our own.

Since man has always been dependent upon plants and sur-

rounded by them, he has woven them into his designs, into the ornamentation of his life, even into his religious symbolism. A Persian carpet and a bedspread from a New England loom alike employ conventional designs derived from the forms of flowers. Medieval painters and great masters of the Renaissance represented the divine persons surrounded by roses, lilies, violets and other flowers, which symbolized chastity, martyrdom, humility and other Christian attributes.

The Divisions of Botany. — The scope of botany is now so vast that the modern botanist cannot be expert in all its branches; he is a taxonomist, morphologist, physiologist or some other sort of specialist, according to the division of the subject in which he is most interested. These divisions are as follows: (1) taxonomy (systematic botany), the study of classification (including floristics, the identification of plants of particular regions); (2) morphology, the study of form and structure (including anatomy, which treats internal structure, and histology, concerned with the properties of particular kinds of cells); (3) physiology, the study of functions or behaviour (closely allied to biochemistry); and (4) genetics, the study of inheritance (hence connected with work on evolution). Such divisions are not absolute. It is necessary to know something of the structure of plants in any attempt to understand their behaviour. Since the taxonomist classifies plants on a theory of descent, he is also concerned with evolution. Cytology, the study of the individual cell, is partly morphology, partly physiology and partly genetics. Ecology, the study of plants in relation to their environment, is even vaguer in its definition, since it involves floristics as well as physiology, besides methods peculiar to itself; closely associated with it are plant geography (phytogeography), the study of plants in relation to the earth's surface, and plant sociology, the study of plant communities. Mycology is the study of fungi; and other groups of plants also may be studied by specialists who may refer to their subjects as algology (concerned with the algae), bryology (with mosses and liverworts) or pteridology (with ferns). Economic botany treats plants in relation to their uses. Plant pathology (phytopathology) deals with diseases of plants. Paleobotany, a division of paleontology, is concerned with extinct plants. Since the bacteria are usually classed as plants, bacteriology also is a division of botany; but because of its vast agricultural and medical applications and its special techniques, bacteriologists are highly specialized and usually not thought of as botanists. (See also PLANTS AND PLANT SCIENCE.)

Early History. — The roots of botany extend far into the past, and the subject, though it developed almost entirely in western Europe, is not limited by national boundaries, by races, languages or creeds. It apparently attained scientific status first among the Greeks. Aristotle left no authentic work on botany, but his pupil Theophrastus wrote, about 300 B.C., a work whose title is translated as the *Historia plantarum* or *Inquiry Into Plants.* This was an attempt to classify plants on philosophical principles and to describe their parts, habits and uses; it was based largely on Theophrastus' own observations but drew also on the reports of the scientists whom Alexander took with him on his conquest of Persia and India. Botany was represented among the Romans by the elder Pliny (*c.* A.D. 23–79), who assembled all the knowledge of his time in the 37 books of his *Historia naturalis.* This encyclopaedic compilation of fact and fable was drawn from approximately 2,000 books by more than 400 authors, and in its lack of originality may be contrasted with Theophrastus' work. At about the same time a Greek physician named Pedanios Dioscorides wrote a famous *Materia medica*, in which about 600 kinds of plants were briefly described and their medicinal uses cited. These classical works mere lost to European scholars during the dark ages but rediscovered in the Renaissance, when they were promoted to the rank of authorities. Dioscorides in particular became the basis of further efforts to describe plants for the use of physicians. In the 15th and 16th centuries, with the development of printing, European physicians and botanists produced a number of herbals, based largely on Dioscorides and to a varying extent on original observation. Among the most valuable of these were those of Otto Brunfels (1532–37), Hieronymus Bock (1539), Leonhard Fuchs (1542) and Valerius Cordus (brought out by Konrad von Gesner in 1561 after the death of the author) in Germany; of Rembert Dodoens (1554, 1563), Charles de l'Écluse (1601) and Matthias de l'Obel (1570, 1571) in the Netherlands; of Pierandrea Mattioli (1544) in Italy; of William Turner (1551–62) and John Gerard (1597) in England. The increasing insistence on actual observation of the plants themselves was reflected in the woodcuts with which these books were illustrated.

Classification. — Since as a result of the revival of learning and of increased facilities for travel and study in Europe and Asia many more plants were becoming known, some botanists turned from medical botany to attempts to name and catalogue all known kinds of plants. The most celebrated work of this kind was the *Pinax theatri botanici* of Gaspard Bauhin (1623), in which approximately 6,000 species were listed and described. Other students were attempting to classify plants. In 1583 Andrea Cesalpino published his *De plantis,* in which the plant world was divided largely on the basis of characters of seed and fruit. A century later John Ray (1627–1705), one of the greatest botanists of all time. published a detailed scheme of classification, in which he divided flowering plants into monocotyledons and dicotyledons (plants with single and with double seed leaves), as they are still divided. and included many plant families that are still recognized. Ray insisted that botanists must consider all characters of a plant in determining its affinities, instead of relying, as Cesalpino had done and as Joseph Pitton de Tournefort was doing. on the characters of single parts (Tournefort used the petals of flowers); this is the distinction between a "natural" and an "artificial" system of classification.

The great Swedish botanist Linnaeus (1707–78) unfortunately followed Tournefort's method rather than Ray's when he published his "sexual system." It had been known since earliest times (*e.g.,* by the Egyptians and Assyrians) that pollen is necessary to the development of certain fruits. Nehemiah Grew in 1673 advanced a theory to account for the role of the pollen; and in 1694 Rudolf Jakob Camerarius published the results of experiments confirming the occurrence of sex in plants. Linnaeus based his 24 classes chiefly on the number of stamens in a flower; each class was divided into orders according to the number of styles. The simplicity of this system won it ready acceptance and thus stimulated botanical collecting and inquiry; but this very success was a detriment to botany by obscuring the beginnings of "natural" classification. A system which brought lily and barberry together in one order but separated sage and mint was not adapted to further the understanding of nature. Linnaeus' most valuable and lasting contributions were his careful descriptions of approximately 6,000 species arranged in genera (the same arrangement used today); his collation of the species he knew with the names and descriptions of previous botanists; and his rules of nomenclature. He introduced binomial nomenclature; *i.e.,* the naming of each species by two words, of which the first is the name of the genus to which it belongs. the second a qualifying word, usually an adjective (*e.g.,* white oak is *Quercus alba,* barley is *Hordeum sativum,* pear is *Pyrus communis*). The names of genera (*Quercus, Hordeum, Pyrus*) can be used for other species which are included in them. but each genus and each species has only one correct name, and that name is used for no other genus or species. Binomials appeared first in Linnaeus' *Species plantarum* of 1753, now the official starting point of plant nomenclature; they were immediately adopted by other botanists and greatly simplified all subsequent references to species. Only since 1753 has it been possible to trace a plant easily from one author to another.

Specialization. — Even in this early period, botany was becoming specialized. While many botanists were occupied only with the classes and names of plants, the foundations of anatomy were being laid by Nehemiah Grew and Marcello Malpighi in works which appeared between 1670 and 1674. Jans and Zacharias Janssen had made a compound microscope about 1590, and various models were available in the 17th century. Grew and Malpighi were able to distinguish such internal parts as the woody vessels and fibres. the cells of the pith and the resin canals., The word cell is traced to Robert Hooke in 1665. His concept of a cell (as

his selection of the word suggests) was of a hollow space surrounded by solid material: it was derived from examination of thin slices of cork, the cavities in which doubtless impressed him as similar to the cells of a honeycomb. It was long, however, before botanists realized that such cavities contain living matter (at least when they are young) and that plants are entirely composed of such units. The first morphologists thought of plants as formed of various sorts of elements, including vessels. fibres. bladders, etc. M. J. Schleiden. with his colleague the zoologist Theodor Schn-ann. is usually credited with the first statement of the "cell theory" in 1839; however. the idea that plants and animals are composed of the same units, and that their entire structure may be understood in terms of such units. was in the air at that time and was arrived at independently by a number of biologists, among whom may be mentioned René Joachim I-Ienri Dutrochet (1824). With Robert Brown's description of the nucleus in 1831. and the recognition of the importance of the living matter of cells, named protoplasma by Hugo von Mohl in 1846, cytology began to take shape as a distinct science.

Physiology also had its beginnings in the time of Grew and Ray; its progress was dependent upon the development of the experimental method. While Grew, Linnaeus and others contented themselves with fantastic conjectures on the nutrition and growth of plants. Ray experimented on the movement of sap, the germination of seeds and other functions of plants. Stephen Hales in his *Vegetable Staticks* (1727) recorded the results of 124 experiments on flow and pressure of sap. loss of water by transpiration and exchange of gases with the air; he is regarded as the founder of plant physiology. Further understanding had to wait for the development of chemistry. Joseph Priestley in 1774 showed that plants in sunlight give off a gas. named oxygen by the chemist Antoine Laurent Lavoisier (who also named carbon dioxide). The relationships of these gases with plants were further elucidated by Jan Ingenhousz in 1779 and Nicolas de Saussure in 1804: the latter introduced quantitative methods into this study, and showed that water as well as carbon dioxide is absorbed and that the plant gains weight. Thus did the beginnings of knowledge of the manufacture of food in plants keep pace with chemistry.

The foregoing brief survey of the early development of botany illustrates its specialized fields. The state of the science in the middle of the 20th century may be conveniently treated under its several branches. broadly conceived; but it must be borne in mind that such a treatment is at several points arbitrary.

Taxonomy. — Attempts at a "natural" system of classification continued even during the popularity of Linnaeus' sexual system, the most notable being that of Antoine Laurent de Jussieu in 1789. In this, as in Ray's classification. many "natural orders" were described which are still recognized. Augustin I'yrame de Candolle (1778–1841) based his system on that of De Jussieu and used it in his great work (completed by his son). the *Prodromus systematis naturalis regni vegetabilis* (1824–73). The classic work of George Bentham and Sir Joseph Dalton Hooker, the *Genera plantarum* (1862–83), was framed on a modification of De Candolle's system. But the entire theory of classiiication was, as it were, reborn with the publication of Darwin's *Origin of Species* in 1859 and the subsequent acceptance of the doctrine of evolution.

It is sometimes difficult to understand just what the pre-Darwinians meant by a "natural" system. Sometimes it seems to have been an attempt to reveal the divine plan of nature. sometimes merely an effort to bring things together that seemed to "belong" together. Once evolution is accepted. however, the goal of taxonomy becomes a system in which species related by descent are placed in one genus, genera so related in one family and so on. The great work of Heinrich Gustav Adolf Engler and Karl Anton Eugen Prantl. *Die natürlichen Pflanzenfamilien* (1887–99; 2nd ed. 1924 *et seq.*), treats families as groups of related genera and places these families in a series supposed to represent their actual evolution from primitive to advanced. Since evidence of relationship is chiefly inferential, being derived from mostly morphological characters. such theories of relationship are subject to constant revision. Charles Edwin Bessey in 1915 proposed a scheme that was more in accord with modern concepts; it has since been variously modified, as, for example, by John Hutchinson in 1926.

The 19th and 20th centuries produced also an imposing array of manuals and floras of particular regions and of monographs of particular groups of plants. based on botanical exploration of almost all parts of the earth and the accumulation of specimens in the great herbariums at Kew. Paris. Geneva, Berlin. New York city, Cambridge. ;\lass.. and Washington, D.C., and in many smaller collections. From the 6,000 species described by Linnaeus and the 100,000 conjectured by the elder De Candolle, botanists by the second half of the 20th century have come to an estimate of more than 300,000 species (many divided into subspecies. varieties, etc.), with several thousand new species being named every year. Paleobotanists are similarly busy extending knowledge of extinct plants. Ecologists and plant geographers have been responsible not only for floristic accounts of vegetation in various parts of the world but also for analysis of the causes of changes in vegetation. Such work is of great importance to foresters and to those concerned with conservation of natural resources.

Most of the taxonomic work outlined above was based on the morphological features of plants. chiefly on those visible to the unaided eye or with the help of a hand magnifier. Such work has been supplemented by evidence of relationship drawn from anatomy, cytology. genetics and plant geography, often involving experiments in transplanting or breeding. Modern taxonomy includes not only the results of botanical exploration (which still continues, but also the investigation of relationships by all known techniques. Taxonomists not only describe species from preserved specimens but also study the populations of living plants, which may or may not be easily fitted into the classical categories.

Closely associated with taxonomy is nomenclature. As the number of species increased. names also were multiplied; several names were often applied to the same group, and the groups were variously divided or combined by individual taxonomists. To resolve the resulting confusion. rules of nomenclature were formulated by a series of international botanical congresses beginning in Paris in 1867. International accord was reached with the publication of the third edition of the *International Rules of Botanical Nomenclature* in 1935, revised by action of the congress at Stockholm in 1950 and again by that at Paris in 1954 as the *International Code* of *Botanical Nomenclature* (1952). (*See* also TAXONOMY.)

Morphology. — The work of the great botanist Robert Brown from 1810 to 1850 opened the way to an understanding of the reproductive parts of plants, the transfer of pollen to pistil and the growth of the pollen tube toward the ovule. During the same period Wilhelm Friedrich Benedict Hofmeister published the first clear accounts of the two kinds of individuals which make up the normal life cycle of ferns. mosses and other plants. Investigation of the details of pollen and ovule and of the "alternation of generations" continued well into the 20th century. As a result of the work of such men as Philippe Édouard Léon van Tieghem in 1870, of Gottlieb Haberlandt in 1884 and of Edward Charles Jeffrey in 1900, cells were classified into their several types (whose functions were related to their structure). the different patterns in which these tissues occur were revealed. and their origin from undifferentiated tissues (meristems or regions in which new cells are formedj was described. Details of cell structure and particularly the mechanism of cell division were studied by cytologists, among whom Eduard Strasburger (1844–1912) was eminent. The name of Karl von Goebel (18j5–1932) is associated with morphology in all its aspects, and his great work *Die Organographie der Pflanzen* remains a classic in this field.

In the 20th century attention has been focused on the meristems (tissues composed of cells retaining their power to divide). particularly at the tips of stems, and their relation with the new parts to which they give rise. This has even been treated experimentally; microdissection has been employed and the resulting changes have been related to normal morphology. The science of experimental morphology tends to bridge the gap between morphology and physiology.

Physiology. — The older plant physiologists experimented mostly with entire living plants in their efforts to understand their activities. Besides the early studies of sap flow and nutrition

already mentioned. there were experiments on tropisms (turnings) of plant parts in relation to light and gravity by Thomas Andrew Knight in 1806 and by Darwin in 1880; on the absorption of substances from the soil by Justus von Liebig and Jean Baptiste Boussingault about the middle of the 19th century: on osmosis and the pressures within cells by Hugo de Vries in 1884; and many other studies. A marked feature even oi work so early as Knight's was its insistence on a "mechanical'! explanation; that is. the description of the processes of living matter in the same terms as those used for nonliving matter. Chemistry and physics came therefore to be more and more important. and the attention of plant physiologists became more and more fixed on the physicochemical properties and processes of protoplasm. Since such studies may concern the composition and activities of individual cells, physiology here passes into cytology. The earlier work on nutrition led to numerous researches on the essentially biochemical problem of photosynthesis. the process by which green plants manuiacture carbohydrates and oxygen from carbon dioxide and water: chiei among the investigators was Julius von Sachs (1832–97). In the 20th century one-celled algae have been used in the attack on this problem and in the investigation of other fundamental processes such as respiration. In the study of the absorption of materials from the soil, the boundary between botany and soil science (pedology) tends to disappear. As a result of physical work on nuclear fission, radioactive materials have been used in the study of the entrance of atoms into the plant and their course within it.

Two significant developments of modern plant physiology may be cited to illustrate the trend toward biochemistry and biophysics. One is the study of substances n-hich for lack of a better name are often referred to as "growth substances." such as auxin and the vitamins. which are widely distributed in plant cells and which are involved in the most important processes of living matter — often in the same way in plant cells as they are in animal cells; some of them are often compared with the hormones of animals. Understanding of the growth substances followed the greatly improved techniques ior isolation and measurement of substances in minute quantities. The production of antibiotics by plants (*e.g.*, of penicillin by the fungus *Penicillium* ı is also studied by plant physiologists. The other development is the study of tissues detached from the plant and kept alive under artificial conditions. Such tissue culture yielded iniormation on nutrition and growth and was also pursued partly in the hope that from such often amorphous masses of living and growing cells something might be learned about cancer.

Genetics. — Although speculation about heredity goes back to the Greeks. the experimental study of inheritance is the youngest branch of biology, dating from the work of Gregor Mendel published in 1866 and unnoticed by other scientists until 1900. Mendel's success was based on treating the characters of plants as distinct units and on a mathematical analysis of their appearance in breeding experiments. The idea of unit characters led to knowledge of the genes, the units which control the development oi characters. The improved cytological techniques of the 20th century made it possible to relate the genes directly with the chromosomes of cells. the threadlike bodies especially conspicuous during cell division: the genes have not yet been seen. but the exact location of many of them on particular chromosomes is definitely known. Modern plant genetics (*see* PLANT BREEDING) is concerned both with the improvement of domestic plants. by combining in the same race such desirable characters as heavy yield, resistance to disease and so forth, and with the more theoretical study of the nature and behaviour of the genes. Changes in chromosomes and genes, called mutations. occur naturally and are a principal cause of the variability oi plants and animals and hence of evolution. The rate of mutation has been greatly accelerated in experimental organisms by irradiation with X-rays or other rays. and this has been used to study the nature of such changes. In plant cells the sets of chromosomes may be multiplied. so that one cell may contain from three to ten or even more sets instead of the normal one or two: chromosomes may also be added or subtracted in numbers less than complete sets. and may individually undergo reconstructions of various types. Such changes, like mutations, may be induced by irradiation as well as by certain drugs. such as colchicine. They are reflected in changes in the structure. appearance or behaviour of the plants in which they occur, and. since they may affect the reproductive cells and may prove permanent through many generations, may result in the origin of new races and so in evolution. They are therefore of interest to the taxonomist as well as to the geneticist.

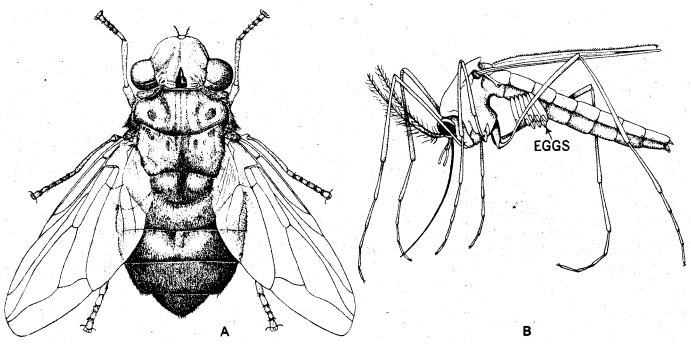
BOTANY BAY, an inlet 5 mi, south of Sydney, Xustr.. discovered by Capt. James Cook (*q.v.*) on April 29, 1370-the first European landing on the east coast of Australia. Cook's original name (Sting-Ray harbour) was changed by him in recognition of the wealth of new plants discovered there by the naturalist Joseph Banks (*q.v.*). Banks's too vivid impressions were responsible for the projected location there of the convict establishment (1788) under Capt. Arthur Phillip of the Royal Navy. A brief reconnaissance convinced Phillip that, because of poor soil and lack of water at Botany bay, a site on Port Jackson was preferable; but the name of Botany bay as a place of penal exile lingered on in British and .Australian iolklore. Botany bay is included in the suburbs of Sydney. with the Kingsford Smith airport to the northwest, an oil refinery on the southern headland and national reserves at La Perouse (named after the French navigator) on the north and around Cook's landing-place at Kurnell. See also NEW SOUTH WALES: *History.* (O. H. K. S.)

BOTETOURT, NORBORNE BERKELEY, BARON DE (1718–1770), colonial governor of Virginia, was born in England. After military and parliamentary service he was made a peer in 1764. and four years later was appointed governor of Virginia. Popular with the colonial assembly at the outset and secretly in sympathy with their strong position of protest against the transfer of political prisoners to England, he nevertheless dissolved the assembly after it passed resolutions demanding exclusive powers of taxation. He attempted by correspondence with the British secretary of state for the colonies to bring about a repeal of all parliamentary taxes, but failed to modify the action of the parliament. His brief service of two years as governor had won the approval of the colonial assembly, and a life-size statue of him was erected by the assembly in Williamsburg, where he died on Oct. 15. 1770. (E. E. R.)

BOTEV, KHRISTO (1848–1876), Bulgarian patriot and poet whose lyrics are among the best in his country's literature and whose revolutionary actix-ity did much to inspire its national revival, was born in Kalofer. central Bulgaria. on Jan. 5, 1838 (new style; Dec. 23, 1847. old style). Sent to Russia in 1863 to complete his education, he came under the influence oi revolutionaries in Odessa. In 1867 he returned to Bulgaria but then fled to Rumania. There he lived in poverty: devoting himself to the Bulgarian liberation movement, of which his literary genius and talent for organization made him one of the leaders. He collaborated in the publication of several Bulgarian patriotic journals, and a collection of his own *Pesni u stihove* ("Songs and Verses") appeared in 1875. These few poems combine a consummate mastery of technique with a moving expression of his patriotic ideals and aspirations. Believing that the nation would rise against the Turks, Botev invaded Bulgaria with less than 200 companions on May 16. 1876, and reached Mt. Veslez in the western Balkans, but was there surrounded and killed, on May 20. by regular Turkish troops. There is a collected edition of his writings by A. Burmov (1940).

BOTFLY, a name applied to flies of the small families Gasterophilidae, Cuterebridae and Oestridae (see FLY), the larvae of



BY COURTESY OF U S DEPARTMENT OF AGRICULTURE

HUMAN **BOTFLY** (DERMATOBIA HOMINIS)
(A) Adult; (B) eggs attached to mosquito

which are parasitic in mammals. The adult flies are robust and beelike in appearance, hairy but without bristles.

Horse botflies (Gasterophilidae) occur wherever horses are found. *Gasterophilus intestinalis* deposits its eggs on the horse's forelegs and body. When the horse licks itself. the eggs ingested hatch. and the larvae make their way to the stomach. where they attach by their heads and take nourishment from the stomach wall. Other species of *Gasterophilus* oviposit on the horse's nose and lips, and the larvae attach to the intestinal lining. Horse bots obtain sufficient oxygen from the contents of the alimentary canal.

The Cuterebridae include the North American and European deer nose bots. *Cephenomyia,* capable of 50-m.p.h. flight, perhaps the swiftest insects. Species of *Cuterebra* are subcutaneous parasites of small rodents. rabbits. opossums and monkeys. The human botfly. *Dermatobia hominis* attacks livestock and deer. rarely man. The female attaches her eggs to mosquitoes. stable flies or other insects. which in turn carry the eggs to the actual host. Body warmth of the host causes the eggs to hatch, and the tiny larvae penetrate the skin. In tropical America, *Dermatobia* causes great loss of beef and hides

The Oestridae include cattle grubs (or warble flies. heel flies) and nose flies all parasitic in large mammals Viviparous *Oestrus ovis,* the sheep botfly, deposits active young larvae in the nostrils of sheep; the larvae develop in the nasal passages or sinuses and often cause in the host a nervous condition called blind staggers. Warble flies (*Hypoderma lineatum* and *H. bovis*) greatly disturb cattle when they oviposit on the animals' legs. The young larvae penetrate the skin. migrate through the body for several months. then come to rest beneath the skin of the back; here each larva causes a characteristic lump or warble nhich is perforated by a hole through which the larva breathes atmospheric oxygen. At maturity the cattle grub emerges and drops to-the ground to pupate and transform into a fly. (G. W. Bs.)

BOTH, JAN (1618?–1652), Dutch painter and etcher. the leading master of the "Italianate" trend of Dutch landscape painting in the 17th century. was born in Utrecht about 1618. From 1635 to 1641 he lived in Rome; in the latter year he returned to Utrecht, where he became a prominent member of the guild but died prematurely in 1652 (buried on Aug. 9). His views of the mountainous and wooded surroundings of Rome, filled with golden sunlight and enlivened with figures of Italian peasants on their way to or from the market. show the influence of Claude Lorrsin (whom Both met in Roine) hut are masterpieces in their own right. The tradition according to which the figures in many of his paintings were done by his brother. Andries Both (born in Utrecht in 1613. lived in Rome *c.* 1633–41, died in Venice in 1641; known as painter and etcher of genre scenes). has not been borne out; in fact, no works of Jan prior to 1641 have been identified. The figures in his knonn landscapes were usually painted by himself. in a few cases by Cornelis van Poelenburgh, who also painted Both's portrait. Both's etchings. based on some of his paintings. are most delicately done; good impressions have become rare.
