Although greatly weakened, the society was not yet extinct, however. In 1911, popular attention was drawn to the fact of its survival by a famous case, the Cuocolo murder, in which some 20 persons were brought to trial. They were all accused of being affiliated to the Camorra, among them the man reputed to be its chief, who was extradited from the United States. The case, which lasted over a year, was transferred from Naples to Viterbo to insure an impartial verdict, and the severe sentences which were passed dealt a shattering blow to the organization. See also MÁFIA. (S. W. HN.)

CAMOUFLAGE, the military art of concealment and deception. It is the means of defeating enemy observation by concealing or disguising installations, activities or equipment. (The protective coloration, or camouflage, found among animals is dealt with in ANIMAL COLORATION.) The fundamental principles of camouflage have not changed since the Chinese military writer Sun Tzu stated in his book *The Art of War* in 500 B.C.:

All warfare is based on deception. Hence when able to attack, we must seem unable; when using our forces, we must seem inactive; when far are near, we must make the enemy believe that we are away; when far away, we must make him believe we are near. Hold out baits to entice the enemy. Feign disorder, and crush him.

In the conventional use of the term, camouflage is restricted to passive defense measures. The surface camouflager, for exam-

ple, does not try to prevent aerial surveillance by jamming the enemy's radar. He is more likely to invite aerial surveillance, especially by photography, so that he will have an opportunity to deceive the enemy. Thus the conflict is mental rather than physical, with one side seeking information through surveillance while the other side not only attempts to deny it but proffers misleading visual information. The camouflager requires a knowledge of the enemy's operating methods and military doctrine in order to predict how he will respond to specific deceptive visual information.

Both concealment and deception adversely affect the enemy's intelligence effort. The withholding of information compels him to increase his collection effort, especially surveillance, and thus to divert from combat a greater number of men and machines. The receipt of incorrect reports along with correct information may confuse the enemy and force him to devote more time to analyzing the data. Camouflage may thus contribute to indecision on the part of the enemy commander, cost him critical time and resources and may even lead him to make wrong decisions.

Camouflage as a means of deceiving the enemy is different from countermeasures. Camouflage does not give itself away by obviously impairing the ability of the sensing device to "see" its target, for that would merely forewarn the observer. False information must be given to the enemy without arousing his suspicions. Countermeasures, on the other hand, do impair the ability of the sensing device to "see" and are not concerned with whether the enemy is aware of this action as long as the ability to detect is destroyed. For example, the dropping of chaff from aircraft in flight and the launching of diversionary guided missiles are designed to confuse, divert and saturate air defense systems; they are normally considered countermeasures rather than camouflage.

History.—Camouflage, from the French word *camoufler* (to disguise), came into English usage during World War I when air warfare was introduced. Development of military aircraft exposed enemy dispositions to the air observer and the aerial camera. Each major army therefore organized a camouflage service of specially trained troops to practise the art of deception. Concealment effort was generally limited to positions within artillery range, for aircraft were used to spot targets for the artillery. By World War II the increased capabilities of aircraft for long-range bombing threatened warring countries in their entirety, not just the front lines. At the same time, camouflage concepts were broadened to include active deception of the enemy as well as passive concealment against observation and photography. World War II gave marked impetus to both camouflage and surveillance in their traditional competitive roles. Practically everything of military significance was camouflaged to some degree. Almost all tactical vehicles carried camouflage nets and were painted in dull colours. All military personnel received training in camouflage fundamentals during basic training. The soldier was taught the

importance of choice of position, camouflage discipline and camouflage construction. He learned to conceal himself by blending into his background and to avoid silhouetting himself against the skyline. He was taught how to camouflage his helmet, to guard against shiny equipment: to camouflage the spoil from his entrenchment and to hide the glow from his cigarette at night. He became familiar with camouflage materials such as twine nets, chicken-wire netting, cloth garnishing and the use of natural foliage.

In Great Britain entire airfields and large manufacturing plants were camouflaged to protect them against aerial attack. At the close of the war the British air ministry reported that:

A network of 500 dummy cities, airfields, shipyards and other targets so realistic they blazed at night under enemy attack caused thousands of tons of German bombs to drop harmlessly in open fields during the Battle of Britain. Mock airfields drew even more raids than the real ones—443 compared with 434 on actual installations. The fields appeared so genuine that Allied pilots had to exercise great care to avoid trying to land on them.

In evaluating German camouflage in World War II, the United States Strategic Bombing survey reported that:

Protective concealment was practiced with greater variety of materials probably with greater ingenuity, and certainly with greater expenditures of manpower: than had been used by any warring nation previously. One of these ambitious camouflage projects was undertaken in Hamburg where the inner basin of the Alster, measuring roughly 500 by 450 yards, surrounded by the main business district, was covered to make it appear like terrain.

Dummies, displays and decoys were widely used during World War II to accomplish varied objectives. The extent of dummy displays ranged from crude improvisation of coconut logs for guns in Burma and on Pacific islands to an elaborate simulation of an entire army in England. Prior to the Normandy invasion German reconnaissance aircraft many times reported "loaded fleets in British ports and large size mechanized units in the field." This display in reality consisted of pneumatic decoys made to resemble different types of weapons and pieces of equipment arranged to represent large convoys and concentrations of landing craft; tanks, trucks and artillery. Dummy fleets of landing craft appeared and disappeared overnight in invasion harbours. Dummy assault boats drew some of the defensive fire during the assault on the Normandy beaches.

British Field Marshal Bernard L. Montgomery surprised Erwin Rommel, the German commander, at El Alamein through the use of dummies combined with a feint. His intention to force a gap through the German defensive system in the north was masked by a long-term cover plan designed to make the Germans think that the prospective attack was to take place in the southern sector. By skilful use of dummy material; the armour and other equipment required for the northern attack was shifted to the north without any visible decrease of strength in the south. Simultaneously, active measures designed to suggest a southern attack took place. Dummy pipelines and supply dumps were built and a radio deception program was operated by a bogus divisional headquarters. The deception was maintained through the first three days of the battle, during which time the XIII corps gave the appearance of attempting to make a breakthrough in the south. This kept Rommel guessing and prevented him from repositioning his 21st panzer division.

The protective concealment provided by smoke was also effective during World War II. Land and sea movements, both large and small, were blanketed by smoke. Huge smoke screens covered fleets at anchor when air-raid alerts sounded. Preparations for river crossings were similarly hidden. The 60-mile smoke screen along the Rhine that covered the reorganization of the 21st army group and its subsequent crossing of the river in March 1945 was probably the greatest smoke cover ever produced.

The Korean war (1950-53) brought little change in camouflage techniques. It was mostly a post-graduate course to World War II training with emphasis upon seasonal and geographic factors. During the years that followed, concepts as to the importance of camouflage in future warfare varied widely among the military services and even within each service. By the 1960s it was generally recognized that greater emphasis should be placed on de-

ception operations in atomic warfare. Concealment and deception, it was felt, should become commonplace — everyday activities of the small units that were visualized as the basic combat units of the future. Through such tactics, it was argued, the enemy's stockpile of atomic weapons might be wasted on fictitious targets while his means of delivery would be more easily located.

As the result of a relatively greater development effort, a variety of new detection devices appeared. Some were supersonic aircraft and drones equipped with television, radar, infrared scanning devices, acoustic detection and high-speed photographic equipment with multiple filters. Ground battle area surveillance equipment included television, radar and aids to night vision. Other developments were earth satellites carrying radar, television and photographic equipment. Camouflage research and development meanwhile provided new techniques, materials and equipment for countering such surveillance devices. Methods and materials for effective concealment and deception throughout the electromagnetic spectrum from the ultraviolet through the visual infrared and radar region were developed. Improved pneumatic devices were produced to simulate items of military equipment such as trucks, armoured vehicles, artillery and guided missiles. These devices could be used in combat deception schemes where military forces were simulated. They provided effective visual, infrared and radar simulation. Other materials were developed to simulate bridges, convoys, bivouac areas, airstrips, marshaling yards, post activities and supply dumps. Some diversionary equipment could be used to represent a paratroop drop and gunfire.

Basic Principles. — The basic principles of camouflage remain constant in that they are governed by natural phenomena such as light, heat and colour. Recognition is the fundamental issue in the contest between surveillance and camouflage. The objective of camouflage concealment is to prevent recognition; the objective of camouflage deception is to induce false recognition. This implies that camouflage is not always designed to be a "cloak of invisibility"; sometimes camouflage is designed to permit detection, and although nature and circumstances do not always permit the denial of detection, recognition can be made difficult or even impossible. An example of permitted detection is the use of improperly garnished drape nets over decoy equipment. Recognition through appearance is the result of conclusions drawn by the observer from the position, shape or other characteristics of the objects or persons under surveillance. Recognition through behaviour or movement includes deductions made from the actual movements themselves, from the tracks of persons or vehicles, or by other violations of camouflage discipline.

Regardless of the type of observation, there are certain factors that help to identify an object. These are the telltale elements that determine how quickly the object will be seen or how long it will remain unobserved. The eight factors of recognition are position, shape, shadow, texture, colour, tone, movement and shine. These factors must be considered in camouflage to ensure that no one of them reveals the location of the concealed object.

Position, of course, is the relation of an object or person to

its background, while shape is the outward or visible form of an object or person. Shape refers to outline or form and is distinguished from surface characteristics and colour. At a distance the form or outline of objects can be recognized before the observer can make out details in their appearance, such as colour or texture. For this reason, camouflage has much to do with concealing the shape of an object or person. But shape alone will sometimes not be enough for identification. A vertical photograph, for example, could show several different objects with rectangular shapes; they might be buildings, swimming pools, trucks or parking lots. To determine their true identity, other factors must be studied, particularly shadow.

Shadow may be more revealing than the object itself, especially in photographs taken from the air. Objects such as factory chimneys, utility poles, vehicles and tents have distinctive shadows. Conversely, shadows sometimes may assist in concealment, for an object in the shadow of another object is more likely to be overlooked.

Texture affects the tone and apparent coloration of things because of its absorption and scattering of light. Rough surfaces tend to appear dark and to remain constant in tone regardless of the direction of view and lighting, whereas relatively smooth surfaces change from dark to light with the change of direction of viewing or lighting. Altering the texture of an object often has the added advantage of disrupting its shape and the shape of its shadow, thus making it more difficult to detect and identify.

Colour is an aid to an observer when there is contrast between the colour of an object and its background. The greater the contrast in colour, the more visible the object appears. Colour differences or differences in hue, such as red and green-yellow, become increasingly difficult to distinguish (or tend to merge) as the viewing range is increased. This is because of atmospheric effects. Colours in nature, except for certain floral and tropical animal life, are not brilliant. The impression of vividness of nature's colours results from the large areas of like colour involved and the contrast of these areas with each other. The principal contrast is in their dark and light qualities. However, the dark and light colour contrast does not fade out quickly and is distinguishable at greater distances. Therefore, as a first general principle, the camouflage must match the darker and lighter qualities of the background and be increasingly concerned with the colours involved as the viewing range is decreased or the size of the object or installation becomes larger. A second general rule is to avoid contrasts of hues and when treating mobile objects in foliated terrains, light-toned colours are to be avoided as they tend to attract attention.

Tone is the effect achieved by the mixing of light, shade and colour. In a black-and-white photograph, the shades of gray in which an object appears are known as tone. By adding texturing material a smooth or shiny surface can be made to produce a darker tone in a photograph because the textured surface now absorbs more light rays. Objects become identifiable because of contrasts between them and their background. Camouflage blending is the process of eliminating or reducing these contrasts. The principal contrast is that of tone; *i.e.*, the dark and light relationship existing between an object and its background. The two principal means available for reducing this contrast or difference in tone are the application of matching coloration and the use of texturing. As an example of coloration effects, a light-coloured aircraft on a light-coloured runway is most easily located by its shadow, while the same aircraft on a darker runway is easily picked out through its own contrast with its background. If all colour contrasts are reduced, a dark-coloured aircraft on a dark-coloured runway is relatively inconspicuous or practically disappears from view. Installations subject only to high aerial observation can best be concealed by toning down contrasts in shade and colour rather than by attempting complicated disruptive patterns. Poorly chosen disruptive patterns tend to make the object more conspicuous instead of concealing it.

Movement is the strongest factor in attracting attention. The eye is very quick to notice any movement in an otherwise still scene. The aerial camera can record the fact that something has

moved when two photographs of the same area are taken at different times. If an object has moved, the changed position is apparent when the two photographs are compared.

Shine is a particularly revealing signal to an observer. Whenever light strikes smooth surfaces such as truck windshields, headlights, mess gear or even a person's face, light may be reflected directly into the observer's eye or the camera's lens with striking emphasis.

Photographic Film. — Different types of film have been developed for use in aerial photography including the following four types used for photography camouflage detection.

The most common film is the ordinary black and white variety. Although its sensitivity is different from that of the eye and does not reproduce colour, it provides a permanent record of tonal differences that may be subjected to prolonged study. Selected filters may be used to improve the photograph or to record only the light that is known to give the greatest tonal differences between natural backgrounds and the object being sought.

Colour film approaches the sensitivity of the human eye. Because of its chemical makeup and its principle of operation, however, this film will give the best results only in bright sunlight. The advantages of colour film are two-fold. First, it provides colour contrasts; second, because colour film is slightly different from the human eye in sensitivity, it often reveals camouflage by recording colour differences not discernible to the unaided eye.

Infrared film is sensitive to radiation of wave lengths not detectable by the human eye. Infrared photographs may be made of objects and terrain utilizing these wave lengths of radiation exclusively by filtering out the visible wave lengths of light. This film has many advantages in that it can be used to take photographs in darkness, provided there is a source of infrared radiation. Of particular advantage for camouflage detection is the fact that living green vegetation reflects the infrared waves very readily. Because of this characteristic, it provides pictures showing contrasting tones between living green vegetation and artificial plants and materials. However, infrared reflective paints have been developed that greatly limit this advantage.

Camouflage detection film is a colour film in which the sensitivity has been altered from recording blue, green and red light to recording green, red and infrared radiations. Since live green plant life has a particular and consistent relative reflection of these radiations, the film is made to reproduce an image of live plant life as red. All other combinations of reflection are recorded as some other colour. Thus camouflage is reproduced in some colour other than red in the photograph—usually green or blue-green. A photo interpreter trained in the use of this film is better able to detect camouflage positions because of the high colour contrast of the position and its background when the position is situated in an area of living vegetation. (C. W. HE.)

CAMP, WALTER CHAUNCEY (1859–1925). U.S. athlete called the "father of American football." was born in New Britain, Conn., April 17, 1859. A former Yale halfback and captain, he was a member of the Intercollegiate Football rules committee for 48 years. He changed the game from Rugby to American football, creating the scrimmage line, 11-man team, signal calling, and the quarterback position. He originated the rule whereby a team had to give up the ball unless it was advanced a specified distance within a certain number of downs. (See also FOOTBALL: U.S. Football.)

Camp studied medicine at Yale for two years, but gave it up to go to work in his uncle's watch factory and to coach the 1888 Yale football team. He and Casper Whitney picked the first All-American team in 1889. His publications included *Football: How to Coach a Team* (1886), *American Football* (1891) and *Walter Camp's Book of College Sports* (1893). Camp died in New York on March 14, 1925. (J. D. McC.)

CAMP, a military term denoting an area for temporary or semipermanent sheltering of troops in tents, huts, or other structures, sometimes called cantonment. It is usually distinguished from a bivouac, a temporary encampment where the troops have no shelter or, at most, "pup tents" carried in sections by the men

themselves. Camps are also distinguished from billets or quarters. In earlier centuries army commanders billeted or quartered their troops, individually or in small groups, in the houses of a town or countryside, for food and shelter. In modern U.S. army usage, temporary military posts are generally designated camps while permanent installations are designated forts. (For civilian aspects see CAMPING.)

The modern use of the word to designate a military post comes from the practice that prevailed among the ancient Romans of fortifying every encampment. With their genius for the practical, the Romans made a science of camp construction, a fact that accounted for much of their success in war. Under the republic, an army of two legions, numbering about 10,000 men in all, occupied a square of 50 ac. Even if the camp was only for one night and was in friendly territory, Roman discipline required the digging of ditches and erection of earth walls and palisades with well-guarded gates of entry on each of the four sides.

The three main avenues of the tent community (see fig.) had always the same names and locations. The same spot was assigned each night to the same unit so that the legionary always found himself oriented in surroundings so familiar that on the darkest night he could form into ranks to repel an enemy assault

Such strict sanitary regulations were observed, moreover, that the Romans escaped the epidemics that are the penalty of carelessness. Only on rare occasions was a Roman camp surprised and successfully attacked.

Military camps of later centuries bore little resemblance to those of ancient Rome. The development of firearms of ever increasing powers of penetration made obsolete the wooden barricades of the Roman era. As a rule, they were located at some distance from the combat area and were therefore not heavily fortified or kept in a state of constant readiness to repel attacks. In the 17th and 18th centuries soldiers not on campaign were quartered in private homes

or in public buildings temporarily taken over for the purpose, though tent camps where soldiers could be closely guarded were sometimes necessary to cope with the problem of desertion. When linear tactics were replaced by mobile warfare during the French Revolutionary campaigns, the weight of tents was regarded as excessive. The armies of the Napoleonic wars usually bivouacked when not occupying billets. In the early months of the American Civil War, hastily mobilized troops lived in tent camps.

In the 20th century when millions of men (and women) were quickly mobilized the armed services built camps for temporary housing and training. These camps occupied thousands of acres of land and included hundreds of huts, two-story barracks, or tents, along with buildings for administrative offices, recreation, and medical care. Some also had extensive areas for drill and maneuver. Such camps had extensive water, sewage and electrical facilities, and were, in fact, self-contained communities. The sites for such camps were usually selected with an eye to healthful living conditions and a climate suitable for outdoor training the year around. (Ls. Ms.)

CAMPAGNA DI ROMA, the low country surrounding the city of Rome, bounded on the northwest by the hills surrounding the lake of Bracciano, on the northeast by the Sabini mountains, on the southeast by the Alban hills and on the southwest by the sea. See LATIUM and ROME: *Modern City*; and, for origin of the name, CAMPANIA.

CAMPAGNOLA, DOMENICO (c. 1484–after 1563), Italian painter and print maker, was one of the first professional draftsmen. His chief activity centred around Padua, at which

PLAN OF A ROMAN CAMP SHOWING TRANSPORT, BAGGAGE, SUPPLY AND HEADQUARTERS SERVICES ON EITHER SIDE OF AVENUE (A): TENTS OF TRIBUNES AND CENTURIONS, EACH OPPOSITE HIS OWN COMMAND, ALONG AVENUE (B); AND THE ROMAN LEGION SEPARATED FROM THE ALLIED LEGION BY AVENUE (C)

city he was probably born and where he remained to decorate many of the churches and palaces with frescoes. He is also renowned as an engraver and as a cutter and designer of woodcuts. He was a prolific draftsman, usually working in pen and ink, and was among the first to make his drawings ends in themselves rather than preparatory studies.

Early in his career, he is known to have assisted Titian with a series of frescoes in Padua. Titian remained a great stylistic influence on him. He was also a pupil, and possibly a relative, of Giulio Campagnola, but did not follow his stipple technique, preferring a looser touch and picturesque effect.

CAMPAGNOLA, GIULIO (c. 1482—after 1514). Italian painter and engraver, was born in Padua. His only recognized work consists of his engravings. Much of his significance derives from the special character of his engraving technique: a system of delicate flicks and dots with the graver, by means of which he achieved subtle nuances in his modeling. He anticipated by over two centuries the development of stipple engraving. His mature style was most influenced by Giorgione, after whom he engraved several prints.

CAMPANELLA, TOMMASO (originally GIOVAN DOMENICO CAMPANELLA) (1568–1639). Italian utopian philosopher who tried to reconcile the naturalistic theories of the Renaissance with Counter-Reformation orthodoxy, was born at Stilo, in Calabria, on Sept. 5, 1568. In 1583 he entered the Dominican Order, assuming the name of Tommaso. While studying Aristotelian philosophy he read widely and was much impressed by Bernardino Telesio's naturalistic theories. In 1589 he went to Naples without his superiors' permission. On the publication in 1591 of his *Philosophia sensibus deneonstrata*, he was brought to trial on suspicion of heresy and imprisoned for a few months. Released on the condition that he should return to Calabria, he went instead to Padua, where he met Galileo Galilei (a defense of whose work he was to compose in 1616). There he was involved in an inquiry into allegations of sodomy (1592) but was acquitted. Next, charged with having disputed with a Jew on matters of faith, he was transferred to Rome, where in 1596 his trial ended with a formal abjuration of his suspected heresy. A fourth trial, in 1597, led to his being required to return to Calabria, which this time he did.

From allegations made against him in these early trials it appears that Campanella's theories were then influenced by Neoplatonic animism as well as by Democritean materialism. Pragmatic and political interests were already manifest in his early writings—including the *De monarchia Christianorum* (1593), the *De regimine Ecclesiae* (1593), the *Discorsi ai principi d'Italia* (1595) and the *Dialogo politico contra Luterani, Calvinisti ed altri eretici* (1595)—many of them now lost. In these works he expounded the theory of a regeneration of humanity through religious reformation founded on a universal ecclesiastical empire. On his return to Stilo, however, the misery of the local population made him adopt a more limited but no less utopian plan of reform, to begin in Calabria itself with a republican community ruled according to naturalistic principles. In summer 1599 he became the spiritual leader of a plot organized by the Calabrese. The plot was discovered and on Sept. 6, 1599, Campanella was arrested. Taken in chains to Naples (Nov. 8), he was charged both with political sedition and with heresy. On Feb. 7, 1600, in the course of his political trial, he was tortured and made to confess his own responsibility in the Calabrese plot. Two months later, to avoid capital punishment, he started to feign madness. As he maintained this simulation even through the most atrocious tortures, his madness was juridically recognised, and at the end of the trial for heresy (1602) he was sentenced to life imprisonment.

In prison Campanella finally reverted to acceptance of Catholic dogma and tried to reconcile his own missionary ideas with the authority of the church. In 1602, however, he produced his most interesting work, *La Città del Sole*, a design of a republic ruled by pure reason, obviously reflecting his state of mind at the time of the Calabrese plot. He also began to write lyrics, his collection of metaphysical *canzoni*, madrigals and sonnets being perhaps the most original in Italian literature of that period.

Campanella's *De Gentilismo non retinendo* (1609–10) expresses

his new philosophical and religious outlook, but from the philosophical point of view his most important work is the *Metafisica*, in 18 books, which survives in a Latin version published in Paris in 1638. His metaphysics are based on three principles—power, wisdom and love—which form a trinitarian structure equally recognized in the human mind as in God. In his *Theologiu*, in 30 books (1613–14), Campanella reconsidered Catholic dogma in the light of his new metaphysics. He expounded the political consequences of his views in *Quod remaniscetur*: Christian religion should be accepted by all the nations since, given the correspondence between human reason and divine mind, it is only within the Catholic Church that humanity can attain its unity.

On May 23, 1626, Campanella was released. Going to Rome, he tried to have his doctrine accepted by the church. Since, however, he now looked no longer to Spain (as he had done in his *Monarchia di Spagna*, written in 1600) but to France to unify the world politically, he found strong opposition, particularly in the Spanish faction of the Roman curia. When in 1634 an anti-Spanish plot was discovered in Naples, he fled to France, where he was welcomed by Louis XIII and Richelieu. He died in Paris on May 21, 1639.

There is a collected edition of Campanella's works by L. Firpo (1954–). There are English translations of his sonnets by J. A. Symonds, *The Sonnets of Michelangelo and Campanella* (1878); of *La Città del Sole* by W. J. Gilstrap, in Glenn Negley and J. M. Patrick (eds.), *The Quest for Utopia* (1952); and of *The Defense of Galileo* by G. McColey (1937).

CAMPANIA, a region of southern Italy comprising the provinces of Avellino, Benevento, Caserta, Naples and Salerno (*qq.v.*), with a total area of 13,595 sq.km. (5,249 sq.mi.) and a population (1961) of 4,756,094. Campania extends from the Garigliano (the lower Liri river: ancient Liris) in the north to the Gulf of Policastro in the south, facing the Tyrrhenian sea; on the inland side it is bordered by Latium (Lazio), Abruzzi e Molise, Apulia and Basilicata. Its physiography is dominated by volcanic and seismic phenomena that characterize the area surrounding the Gulf of Naples (Campi Flegrei or Phlegraean fields; Vesuvius *q.v.*). Around these areas of volcanic activity extend the principal lowlands of Campania: the Volturno lowland; the plains called Terra di Lavoro from the middle Volturno (*q.v.*; ancient Volturnus) river to the eastern flanks of Mt. Vesuvius; while the only other lowland of any size, the plain of the lower Sele river (ancient Silarus), is separated from the others by the Lattari mountains between Pompeii and Salerno. To the east are the complex uplands of the region, part of the Apennine system, the Matese mountains (Mt. Miletto 2,050 m.; 6,726 ft.), the Picentini mountains (Mt. Cervialto 1,809 m.; 5,935 ft.), the Cilento (Mt. Cervati 1,899 m.; 6,230 ft.) and, beyond these, the Neapolitan Apennines (Apennino Napoletano). The only rivers of any size are the Volturno in the northern and the Sele in the southern part of the region. Among the intermontane basins that of Benevento is the most important. While communications between the coastal areas of Campania are relatively easy, the highly dissected character of the interior makes rail and road travel "across the grain," in the west-east direction, very difficult.

The most important farming areas of Campania are the lowlands of the Terra di Lavoro and of the circum-vesuvian plain. The land is fertile and utilization is extremely intensive, characterized by interculture, with plots of land producing cereals on the ground, fruit on trees along the edges of the plots, and grapes from vines trailing between trees. Farms are usually small, and human labour is used for most farming operations. The most important crops are fruit (apricots, apples, peaches, nuts, citrus and grapes), early vegetables and flowers, and such industrial crops as tobacco and hemp. Wines of Campania, especially those from Vesuvius (Lacrima Christi), from Ischia (Epomeo) and from the Sorrento pen-

insula. are famous throughout Italy. Fishing is important in the bay of Naples, Procida and Torre del Greco being the leading ports. Campania is the only region of southern Italy with a major concentration of industry, most of it centred on Naples. Metallurgy (steel and iron at Ragnoli and Torre Annunziata [*q.v.*]), chemicals (San Giovanni a Teduccio), machinery and tools (Pozzuoli [*q.v.*]), textiles, agricultural industries (canning, flour milling, tobacco) and shipbuilding (Castellammare di Stabia [*q.v.*]) are the most important branches. In Naples and its suburbs there is a flourishing artisan industry working coral, pearls, tortoise shell: leather and lace. The tourist trade in Naples, on the Sorrento peninsula and on the islands of Capri and Ischia (*qq.v.*) is an important source of income. Naples is the leading Italian port, second only to Genoa. The transportation system is also centred on Naples. Main lines connect the city with Rome (via Formia and via Cassino), with Benevento, Foggia and the Adriatic coast, with Potenza and Taranto, and with Reggio di Calabria and Sicily. A motorway (Autostrada del Sole) connects Naples with Rome and Milan, with extensions southward to Salerno and others planned eastward to Foggia and Bari. (G. K.H.)

History.—Ancient Campania was smaller than the modern region and roughly extended over the area now comprising the provinces of Naples, western Caserta and northern Salerno. It was bounded on the northwest by the territory of the Aurunci, on the northeast by Samnium, on the south by the Sorrento peninsula and on the west by the Tyrrhenian sea. By the 1st century A.D. the northwestern boundary extended as far as Sinuessa (near Mondragone) and the Volturnus (Volturno) river, and the northern boundary came between Venafrum (modern Venafro) and Casinum (Cassino); the Volturnus valley and foothills of the Apennines as far as Abellinum (Avellino) formed the boundary on the northeast. The southern boundary remained unchanged.

Campani was the Roman name for inhabitants first of the town of Capua (*q.v.*; mod. Santa Maria Capua Vetere) and its district and then for inhabitants of the Campanian plain. The name is pre-Roman and appears with Oscan terminations on coins of the early 4th or late 5th century B.C. struck for or by the Samnites (*q.v.*), the conquerors of the Etruscans in Campania at the end of the 5th century. Cumae (*q.v.*) was taken in 428 or 421. Nola (*q.v.*) about the same time, and the local dialect, henceforth known as Oscan (*q.v.*), spread over all Campania except for the Greek cities, although Etruscans remained for at least another century. Latin became general soon after the Social War (90–89 B.C.) except in Neapolis (Naples) where Greek was the official language during the Roman empire. The Samnites took over many Etruscan customs; the haughtiness and luxury of the men of Capua were proverbial at Rome. This town became the ally of Rome in 338 B.C. By the end of the 4th century Campania was completely romanized, and was granted a limited form of Roman citizenship (*civitas sine suffragio*). Certain towns with their territories (Neapolis, Nola, Abella [Avella], Nuceria Alfaterna [Socera Inferiore]) were nominally independent in alliance with Rome. These towns were faithful to Rome throughout the war against Hannibal (218–202 B.C.), but Capua and its satellite towns revolted. After its capture by the Romans in 211 the people of Capua were severely punished and their land confiscated. During the Roman empire, however, it flourished as a *colonia*. In the division of Italy into *regiones* by the emperor Augustus, Campania with Latium formed the first region. From c. A.D. 285 the name Campania was extended northward to include the whole of Latium. This district was governed by a corrector who received the title of *consularis* c. A.D. 333.

The fertility of the Campanian plain (*regio felix*, "fruitful country") was famous in ancient as in modern times; the best portion was the Campi Laborini or Leborini (called Phlegraei by the Greeks) between the roads from Capua to Puteoli and Cumae. The loose black volcanic earth (*terra pulla*) was easier to work than the stiffer Roman soil and gave three or four crops a year. The spelt, wheat and millet were especially mentioned, as also fruit and vegetables; the roses supplied the perfume factories of Capua. The wines of the Mons Massicus (Monte Massico) and of the ager *Falernus* (the flat ground to the east and southeast of it) were

the most sought after, though other districts also produced good wine. The olive was better suited to the slopes than the plain, though that of Venafrum was good.

Puteoli (modern Pozzuoli), the chief ancient harbour, was most important in the 2nd–1st century B.C. The harbours constructed by Augustus by connecting the Lacus Avernus (Averno) and Lacus Lucrinus (Lucrino) with the sea, and that at Misenum (Miseno), were mainly naval. (Misenum was the station of one of the chief divisions of the Roman navy, the other fleet being stationed at Ravenna.) Neapolis also, though less important than Puteoli, had a considerable trade.

The road system of Campania was extremely well developed, the most important road centre being Capua. The Appian way (*q.v.*) met the Via Latina at Casilinum, 3 mi. to the northwest. The Via Popilia extended from Capua to Regium (mod. Reggio di Calabria). The so-called Via Campana, together with the Via Domitiana, led to Puteoli, where it met the Via Xantiniana.

After the fall of Rome the region was occupied successively by the Goths and Byzantines. The Normans conquered it in the 11th century and it was incorporated in the kingdom of Sicily in the 12th century. After the Sicilian Vespers (see *VESPERS, SICILIAN*) it became part of the kingdom of Naples until it was united with Italy in 1861. See also references under "Campania" in the Index volume.

CAMPANILE, a bell tower, most commonly built beside or attached to a church; the word is oftenest used in connection with Italian architecture. The earliest campaniles, variously dated from the 7th to the 10th century, were plain round towers with a few small round-arched openings grouped near the top. Typical are those beside the churches of S. Apollinare in Classe and S. Apollinare Nuovo, Ravenna. Round campaniles appeared occasionally in later periods—the famous leaning tower of Pisa (11th–12th century), for instance, is a more elaborate version of this type, sheathed in a series of superimposed arcades.

Roman.—From the 10th century onward, most campaniles were based on a square ground plan, which seems to have been developed simultaneously in Rome and Lombardy. This type was generally decorated with projecting vertical strips, known as pilaster strips, and ranges of arcaded cornices which divided the tower into several stages, each stage having single-, double- or triple-arched openings on all four faces. The roof, particularly in early examples, was usually a pyramid of low pitch, invisible from the ground. Such, with minor variations, was the Roman type of campanile throughout the middle ages, as we may see it at S. Prassede (1080), Santi Quattro Incoronati (1123) and S. Maria in Trastevere (1139). The Roman campanile in general tended toward an effect of horizontality rather than verticality, which was often increased by treating all the horizontal stages with identical ranges of wall arcades, as in the campanile of S. Giorgio in Velabro (early 12th century), and by emphasizing the immediate surface through built-in fragments of Roman ornament.

Lombard.—Campaniles in Lombardy basically resembled the Roman type, but their elements were usually more complex and elaborate. The early tower of S. Satiro in Milan, for instance, at the end of the 9th century showed an advanced composition of horizontal stages, arcaded cornices which connected the corner pilaster strips, and arched openings, single below and double above. In the later, and much larger, northern campanile of S. Ambrogio in Milan (early 11th century) semicircular projections like engaged columns broke up the stages and gave additional vertical lines. The top story was developed into a kind of crown to the whole composition—effectively unifying the whole—and a pyramidal, or occasionally conical, spire was added. The result was an increasing emphasis on verticality. This may be seen in the famous campanile of Florence, designed by Giotto, Taddeo Gaddi and others in the early 14th century. It followed the Lombard tradition of horizontal stages but attained a sense of lightness by daring use of octagonal corner buttresses, a tremendous enlargement of the belfry

stage to approximately twice the height of any other and a consistent vertical patterning in decorative marble sheathings and ranges of sculpture.

Venetian.— It was mainly around Venice that the possibilities of this development were fully realized and brought to mature expression. Venetian campaniles consisted of tall, square, slim shafts, frequently tapered or battered, which rose unbroken to open belfries at the top. The belfry had one or two stages of arcade and was often in stone, although the rest of the tower was brick. Above the belfry cornice rose the spire, sometimes square, as in the famous 320-foot campanile at St. Mark's in Venice (lower portion 10th and 12th centuries, belfry story 1510, the whole rebuilt in 1908 in exact imitation of the original), sometimes octagonal, as in the campanile of S. Zeno at Verona (12th century). (See VENICE.)

19th and 20th Centuries.— Campaniles of this mature type continued to be built in the region of Venice far into the Renaissance period; but elsewhere, as the Renaissance preference for other forms (particularly domes) developed, they became obsolete and remained so until the early 19th century. Then, an Italian Roinanesque revival made "Lombardic-style" churches with their characteristic campaniles an alternative to neo-Gothic in northern Europe (English examples are Christ Church, Streatham, and SS. Mary and Nicholas, Wilton—both begun 1840). Later in the century, under the influence of John Ruskin, the Venetian form of campanile became popular; it may be said to have inspired the tower at Westminster Cathedral (by G. F. Bentley, 1897). It was characteristic of 19th-century eclecticism, however, that the revived campanile form was not limited to its original uses, but appeared also in connection with factories, country houses, blocks of flats, markets and collegiate buildings—sometimes with bells, sometimes with clocks, often with neither, but simply for picturesque effect.

Twentieth-century building materials greatly encourage the construction of free-standing forms such as the campanile. Stone, brick or wooden towers require heavy bases, but there is no such necessity in steel-frame construction. Great possibilities of expressing the nature of such materials as steel, concrete and glass are offered by the campanile form; it has become one of the commonest types of tower for churches and is widely used elsewhere. See also BASILICA. (AN. G.)

CAMPANOLOGY: see BELL.

CAMPANULA (BELLFLOWER), in botany, a genus of plants (family Campanulaceae) containing about 300 species, found in the temperate parts of the northern hemisphere, chiefly in the Rlediterranean region. The name is taken from the Latin for a little bell. *Campanula rotundifolia* is the harebell (*q.v.*) or Scottish bluebell. *C. medium*, Canterbury bell, with large blue, purple and white flowers, is a handsome biennial! of which there are numerous varieties. *C. persicifolia*, the peach bell, is a perennial with more open flowers. The Eurasian *C. glomerata* has crowded flower heads.

In North America there are about 20 native species of bellflower, widely distributed throughout the continent. Among these are the tall bellflower (*C. americana*), found in moist woods from New Brunswick to South Dakota and southward to Florida and Oklahoma, which grows six feet high, with shallow, blue flowers, an inch across, borne in a dense spike often two feet long; the harebell, found from Labrador to Alaska and southward to New Jersey, Nebraska and California; and the California bellflower (*C. prenanthoides*), a delicately beautiful plant, native to wooded moun-

tain slopes from Monterey to southern Oregon. In northeastern United States and adjacent Canada the creeping bellflower (*C. rapunculoides*), the Coventry bell or throatwort (*C. trachelium*) and the clustered bellflower (*C. glonzterata*) have become widely naturalized.

While the bellflowers are of no economic value, the beauty of their flowers is so great and the garden possibilities are so obvious that over 120 kinds are cultivated in Great Britain, and about 40 in the United States. One of them, the rampion (*C. rapunculus*), is a biennial and yields in Europe salad greens from its radical leaves, which are boiled; the scraped root is eaten raw. See RAMPION.

The garden species may be divided into four divisions: (1) annuals or biennials, (2) perennials for the open border, (3) rock garden species and (4) pot plants. Some of the more desirable species in each group, together with their height and country of origin, are given below. All are blue-flowered unless noted to the contrary.

Annuals and Biennials: Sow seed about $\frac{1}{2}$ in. deep in April for the annuals and in June for the biennials. A selection could include: *C. drabifolia*, an annual 4-6 in. high from Greece and Asia Minor; *C. erinus*, a rough-hairy annual from southern Europe, 4-9 in. high, with white or pinkish flowers; *C. medium*, a biennial 2-4 ft. high from southern Europe; and *C. ranzosissima*, 8-12 in. high, an annual from southern Europe.

Rock Garden Species: Their culture demands a loose, gritty soil, and the specialized conditions found in the moraine or scree. A selection might include: *C. barbata*, 4-18 in. high, with pale blue flowers, from the Alps; *C. garganica*, a Dalmatian sprawling herb, the flowers pale blue; *C. pulla*, a creeping herb 3-4 in. high, from eastern Europe; and *C. saxifraga*, a Caucasian crevice plant hugging the ground. All are perennials.

Perennials: This is the largest group and the easiest to grow. They require open sunlight and a rich loam. There are so many species that enumeration is impossible here. They range in height from *C. bellardi* (4-6 in.) to the chimney bellflower, *C. pyramidalis* (3-5 ft.).

Pot Plants: Some of the outdoor perennials can be so used. In addition, the following, which are rather tender, should always be grown in pots and sheltered over the winter: *C. colorata*, a Himalayan perennial; *C. isophylla*, a trailing Italian perennial fine for hanging baskets; *C. jacobaea*, a woody perennial from Cape Verde Islands; and *C. versicolor*, a Grecian perennial 4-6 ft. high. (N. TR.)

CAMPBELL, ALEXANDER (1788-1866), U.S. religious leader and one of the founders of the Disciples of Christ and Churches of Christ, was born in County Antrim, Ire., the son of Thomas Campbell (1763-1854), a Presbyterian minister who urged Christian unity. In 1807 Thomas Campbell emigrated ahead of his family to America, where he formed the Christian association of Washington, Pa., to promote "simple evangelical Christianity" as the way to church union. Following a breach with Presbyterianism he produced a Declaration and Address for the association in 1809. Alexander Campbell, after a year at the University of Glasgow, emigrated with the rest of the family in 1809. The son espoused his father's program for Christian unity and emerged as the leader of the movement for religious reform. He began preaching without salary, in 1810 and married in 1811, settling in what is now Bethany, W.Va. Biblical study led him and his followers to adopt immersion in 1812, and in 1813 they joined the Baptists; tension on other issues led to dissociation in 1830. In 1832 Campbell's followers, known as Disciples, or Christians (nicknamed Campbellites), joined Kentucky "Christians" under Barton W. Stone to form the Disciples of Christ, or Christian Church.

Influenced by John Locke's epistemology, Campbell presented a rationalistic and deliberative Christianity based on the New Testament and opposed alike to speculative theology and emotional revivalism. He exercised his leadership through preaching, addresses and extensive debates with the Roman Catholic bishop John Purcell of Cincinnati, the secularist Robert Owen of Scotland and others. His major writing and publishing began with a periodical, the *Christian Baptist*, in 1823, continued as the *Millennial Harbinger* after 1830. He wrote or edited over 60 volumes, including *The Living Oracles*, a version of the New Testament first issued in 1826, and a hymnal. Thomas Campbell gave his son much editorial assistance. Alexander Campbell was a member of the constitutional convention of Virginia in 1829. He founded Bethany college in 1830, and was its president till his death. In 1849 he

CAMPBELL, SIR COLIN: see CLYDE, COLIN CAMPBELL, BARON.

CAMPBELL, DOUGLAS HOUGHTON (1859–1953), U.S. botanist whose chief work was in the study of mosses and ferns. Was born at Detroit, Mich., Dec. 16, 1859. After study at the University of Michigan at Ann Arbor (Ph.D., 1886) and in Germany, he became in 1888 professor of botany at Indiana University, Bloomington. When Stanford University was assembling its first faculty in 1891, Campbell was selected to organize and head the department of botany. His researches before moving to Stanford centred around the morphology of ferns, and his first years at Stanford were spent on similar studies on the mosses and liverworts. Study in these two fields formed the basis for a treatise, *The Structure and Development of Mosses and Ferns*, that was the standard work in the field for 50 years. Other of Campbell's interests included plant evolution and geography. He died at Palo Alto, Calif., Feb. 24, 1953.

Principal publications include: *Elements of Structural and Systematic Botany* (1890); *The Structure and Development of Mosses and Ferns* (1891, 1901, 1918); *A University Textbook of Botany* (1902); *Plant Life and Evolution* (1911); *An Outline of Plant Geography* (1926); and *The Evolution of Land Plants (Embryophyta)* (1940).

CAMPBELL, JOHN CAMPBELL, 1ST BARON (1779–1861), lord chief justice of England from 1850 to 1859 and lord chancellor from 1859 until his death, was, like many of the famed lawyers of his period, a Scot, born at Cupar in Fife on Sept. 15, 1779. He was the second son of a clergyman, George Campbell, and he too was originally destined for the clergy. He entered St. Andrews University at the age of 11 and concluded his work for an M.A. at the age of 17, beginning then on the four years of divinity training required by the general assembly. In 1798, however, he went to London as a tutor and was sufficiently enchanted with the opportunities for fame at the English capital to give up the church in favour of the bar. To finance his way, he became a reporter for the *Morning Chronicle*, and his newspaper training stood him in good stead at later periods of his life. He entered Lincoln's Inn in 1800 and in 1804 secured a desk in the chambers of William Tidd, the famed special pleader. Campbell's immediate predecessors in Tidd's office were the younger John Singleton Copley, Charles Pepys and Thomas Denman. The first of these was to become Baron Lyndhurst, thrice lord chancellor; the second, as the 1st earl of Cottenham, was also to be chancellor; and the third was to be lord chief justice.

Campbell was called to the bar in 1806, an impoverished barrister with no connections but with great ambition and self-confidence. For three years he languished on the home circuit, supporting himself by revising Watson's treatise on partnership, writing for the *Chronicle*, doing special pleading for Tidd and answering cases for Marryatt. He started on his road to success when he undertook to report cases at nisi prius for the legal publisher Henry Butterworth. His reports, especially of Lord Ellenborough's decisions, were first-rate and earned him fame as well as income. He changed from the home to the Oxford circuit, where the competition was less keen, and soon moved to the head of the bar. In 1821 he married the daughter of James Scarlett, later Lord Abinger, perhaps the pre-eminent advocate of the day. The marriage was a happy one, also providing Campbell with entrée into the great Whig homes, and he turned his attention to politics as a means to place.

In 1826 Campbell ran unsuccessfully for the seat for Stafiord, a borough of extraordinary corruption even in those corrupt times. He subsequently ran successfully for Stafiord after the accession of William IV. In 1827 he became king's counsel. Peel put him at the head of the Real Property commission: after Edward Sugden had declined the post, in 1828. Characteristically, Campbell claimed credit for the bills drawn as a result of the commission's efforts, though Lord St. Leonards later said "that Campbell had no more to do with it than his footman." Campbell was also offered a puisne judgeship by Lyndhurst, which he peremptorily refused.

In parliament, Campbell was content to follow where his party led, even to the point of supporting the Reform bill of 1832, though he thought it "Jacobin." After being made solicitor general in 1832, he helped carry through several measures of reform of the real property law. In commons he was indefatigable and, though far from a brilliant speaker, most effective. As solicitor general he assumed all the functions of the chief law officer, and when Sir William Horne was forcibly retired, Campbell was promoted to attorney general. This resulted in his displacement from parliament for three months, since he failed to be elected at Dudley, but the Whigs provided him with a seat for Edinburgh. When the mastership of the rolls became vacant, Campbell applied for the post but was passed over in favour of Pepys, the solicitor general.

When the Whigs were turned out in 1834, Campbell's father-in-law, James Scarlett, was appointed chief baron of the exchequer, as Lord Abinger, removing Campbell's greatest competition at the bar. He was again returned for Edinburgh in 1835. Pepys was made chancellor and Bikersteth was sent to the rolls, again over Campbell's claim to priority. Campbell threatened resignation, but his feelings were assuaged by the elevation of Lady Campbell to the peerage. The Whigs asserted that he was too valuable in the house of commons to permit his removal to the bench. He was largely responsible for the Municipal Corporations act of 1835 and the Prisoners' Counsel act of 1834, among others.

Campbell's practice of law flourished, and he successfully defended Blalbourne, who was then prime minister, in the infamous suit by George Norton for criminal conversation with Norton's wife. Campbell's skilful and etiective defense saved the government. He remained attorney general until 1841, when pressure on Plunket caused him to resign the post of lord chancellor of Ireland in favour of Campbell. He was elevated to the peerage as Baron Campbell of St. Andrews. But shortly thereafter the Whigs were turned out.

Campbell found himself disqualified from practice and moved to the comparative quiet of the house of lords, where he served as a judicial officer. Under these circumstances, Campbell found that time was heavy on his hands, and he turned to the preparation of his famous volumes on the lives of the chancellors and the chief justices. They were a great literary success, though they are marred by plagiarism, unscrupulous misrepresentation and venom, the last especially directed to those whom he had known best. The last volume on Brougham and Lyndhurst, published after Campbell's death, did greater damage to Campbell's reputation than to those of his subjects, but neither of them, ever came out from under the cloud that Campbell created. As Sir Charles Wetherell remarked, these volumes "added a new sting to death."

In 1846, on the return of the Whigs, Campbell was made chancellor of the duchy of Lancaster and was given a place in the cabinet. When Denman became ill, the government again resorted to pressure to bring about his removal so that Campbell could be appointed (1850) lord chief justice. His judgments were of the highest order, but he browbeat counsel and wooed juries to bring about the results he wanted. He was most anxious to bring about decisions, especially at nisi prius, that would be agreeable to the populace. Courage was not one of his strong points.

When the Whig party regained power in 1859, there was difficulty on the question of the chancellorship, for the Whigs could not spare Bethell (Lord Westbury) from his duties in the commons. Campbell was appointed chancellor on condition that he mould resign when Bethell was available. He served with some distinction as

chancellor for two years before his death at the age of 81 on June 22, 1861. He left behind the record of a great judge: but a small man.

(P. B. K.)

CAMPBELL, SIR MALCOLM (1885-1948), British racing motorist who set world speed records on land and water, was born at Chislehurst, Kent, on March 11, 1885. In 1906 he became a member of Lloyd's, but, after serving as a dispatch rider and as a pilot in the royal flying corps during World War I, he became interested in motor racing. In 1924 he achieved his first world's land speed record at 146.16 m.p.h., and increased it to 150.86 m.p.h. in 1925. In 1927 with the first "Bluebird," a Napier-Campbell, he reached 174.88 m.p.h., a record which he raised to 206.97 m.p.h. in 1928. In 1931 he was knighted after achieving 246.09 m.p.h. This record was followed by four others, 253.97 m.p.h. in 1932, 272.46 in 1933, 276.82 and 301.13 in 1935.

Having realized his ambition to reach 300 m.p.h. on land, Sir Malcolm Campbell built the first "Bluebird" hydroplane (he gave the name "Bluebird" to all his racing cars and boats) and in 1937 captured the world's water speed record from the United States at 129.5 m.p.h., increased to 130.93 m.p.h. in 1938. In 1939, with a new "Bluebird" containing a Rolls-Royce engine, he established a record of 141.75 m.p.h. on Coniston water, Westmorland. He held this record when he died in Reigate, Surrey, on Dec. 31, 1948.

In 1959 his son, Donald Malcolm Campbell, using a jet-powered "Bluebird," set a world water-speed record for unlimited hydroplanes of 260.35 m.p.h.

CAMPBELL, MRS. PATRICK (née BEATRICE STELLA TANNER) (1865-1940), English actress, famous for her portrayal of characters at once passionate and intelligent, was born at London on Feb. 9, 1865. She made her name in 1893, when her performance as Paula Tanqueray in Arthur Pinero's *The Second Mrs. Tanqueray* put her very high in her profession. In 1895 she played Juliet to the Romeo of Sir Johnston Forbes-Robertson (*q.v.*), and afterward appeared with him in many plays. In 1907 she was a memorable Hedda Gabler and in 1914 created the part of Eliza Doolittle in *Pygmalion* by George Bernard Shaw, with whom she maintained a warm friendship.

Gifted by nature with talent, beauty and wit, she was always a fascinating character, but her temperament rebelled at discipline and this—as Shaw's letters to her clearly show—made her difficult to work with. This told against her as she grew older, and was the chief reason why she was seldom seen on the London stage after World War I. She was twice married—in 1884 to Patrick Campbell (*d.* 1900) and in 1914 to George Cornwallis-West. She died in Pau, France, on April 9, 1940. (W. A. DN.)

CAMPBELL, (IGNATIUS) ROY (DUNNACHIE) (1901-1957), South African poet, whose vigorous extrovert verse contrasted with the uneasy self-searching of the more socially conscious poets of the 1930s. Campbell led a roaming life, and his latter years were spent mainly in Europe. His poem *The Flaming Terrapin* (1924) exalts the instinctive vital force that brings forth intelligent human effort out of apathy and disillusionment. *The Wayzgoose* (1928) is a satire on South African intellectuals and *The Georgiad* (1931) attacks the literary figures of the Bloomsbury group. His lyrical works include *Adamaster* (1930), *Flowering Reeds* (1933) and *Talking Bronco* (1946). Campbell translated Spanish, Portuguese and French writers, and wrote two autobiographical books, *Broken Record* (1934) and *Light on a Dark Horse* (1952). He was also noted as a bullfighter and steer thrower. He fought for Gen. Francisco Franco in the Spanish civil war and during World War II he served in Africa. He died in a car accident near Setubal, Port., on April 22, 1957.

CAMPBELL, THOMAS (1777-1844), Scottish poet, chiefly remembered for his sentimental and martial lyrics, was born in Glasgow on July 27, 1777. In 1799 he published *The Pleasures of Hope, With Other Poems*, in heroic couplets, in the 18th-century

tradition of the broad survey of human affairs. It was highly derivative, with a special debt to Alexander Pope and Mark Akenside, but its theme of freedom earned Campbell immediate popularity. In the following year he went to Germany, visited Friedrich Klopstock in Hamburg, and eventually returned to Altona on the Danish bank of the Elbe, after witnessing some military action near Ratisbon. There he planned some of the martial lyrics on which his reputation rests: "Ye Mariners of England," "The Soldier's Dream" and "Hohenlinden." Returning to England in 1801, on the outbreak of war with Denmark, he wrote "The Battle of the Baltic," inspired, it is said, by the sight of the Danish batteries at Gluckstadt.

In these lyrics Campbell experimented with metrical forms. He wrote also a number of ballads and poems on legendary subjects, notably "Lord Ullin's Daughter" (1804), but he was not in the romantic tradition, belonging rather to the sentimental school of the 18th century. His aim, not often achieved, was a polished perfection of utterance, and preoccupation with this resulted in weaknesses in other respects. His other main works were *Gertrude of Wyoming* (1809), *Tlzeodric* (1824) and *The Pilgrim of Glencoe and Other Poems* (1842); he also edited *Specimens of the British Poets* (1819). Campbell knew most of the prominent men of his time, and in 1805 was awarded a pension. In 1825 he was one of the instigators of the scheme for founding London university. He died at Boulogne, France, on June 11, 1844.

Hadden, *Thomas Campbell* (1899); W. M. Dixon, *Thomas Campbell, An Oration* (1928). (P. M. Y.)

CAMPBELL, WILLIAM WALLACE (1862-1938), U.S. astronomer, exerted great influence on observational astronomy, particularly through his determinations of the radial velocities of stars. He was born on a farm in Ohio on April 11, 1862, and died in San Francisco, Calif., on June 14, 1938. He studied civil engineering and astronomy at the University of Michigan, Ann Arbor, graduating in 1886. In 1890, after a two-year period as instructor in astronomy at Michigan, he joined the staff of the Lick observatory on Mt. Hamilton, Calif., and became its director in 1901. Campbell was president of the University of California, Berkeley, from 1923 to 1930, and president of the National Academy of Sciences from 1931 to 1935.

Using a powerful three-prism spectrograph attached to the 36-inch telescope at Lick observatory, Campbell pioneered in obtaining accurate radial velocities for thousands of stars. To extend the measurements to stars visible only from the southern hemisphere, he sent a 36-inch reflecting telescope, equipped with a stellar spectrograph, to Santiago, Chile. Combining the data, he determined the sun's motion in our galaxy as well as the average random velocities of stars of various spectral types. He led seven solar eclipse expeditions from the Lick observatory, and brought back a wealth of material on the corona and the flash spectrum. See also SPECTROSCOPY, ASTRONOMICAL: *Historical Development*. (P. W. M.)

CAMPBELL, WILLIAM WILFRED (1858-1918), Canadian poet, was a contemporary of Archibald Lampman and Duncan Campbell Scott. Born in Berlin (now Kitchener), Ont., on June 1, 1858 (sometimes given as 1861), he was educated in Toronto and in Cambridge, Mass., for the Anglican ministry, and served parishes in West Claremont, N.H., St. Stephen, N.B., and Southampton, Ont. *Lake Lyrics* (1889), celebrating the scenery of the Lake Huron-Georgian Bay country near his boyhood home of Wiarton, established his reputation. He left the church in 1891, and entered the civil service at Ottawa. Like Lampman and Scott, he wrote about nature; but his principal books, *The Dread Voyage* (1893), *Beyond the Hills of Dream* (1899), *Poems* (1905) and *Sagas of Vaster Britain* (1914), reveal that he took an independent course—characterized by transcendentalism! distrust of "neopagan naturalism," missionary zeal for the culture of the British "race." warmth and acidity in addressing his public and an interest in primitive mythology uncommon among poets before 1918. His robust, melo-

dramatic imitations of Shakespearean plays were published in *Mordred and Hildebrand* (1895) and *Poetical Tragedies* (1908). He also wrote two novels, *Ian of the Orcades* (1906) and *A Beautiful Rebel* (1909); and descriptive works, *Canada* (1907), *The Canadian Lake Region* (1910) and *The Scotsman in Canada* (1912). He was well received abroad in 1897, 1901 and 1906.

See *The Poetical Works of Wilfred Campbell*, ed. with a memoir by W. J. Sykes (1923); Carl F. Klinck, *Wilfred Campbell, a Study in Late Provincial Victorianism* (1942). (C. F. Kk.)

CAMPBELL-BANNERMAN, SIR HENRY (1836–1908), British statesman who led the Liberal party successfully through a period of bitter internal dissension, and was prime minister from 1905 to 1908, was born at Glasgow on Sept. 7, 1836, the second son of Sir James Campbell, afterward lord provost of the city. Henry Campbell added Bannerman, the surname of his mother's family, to that of his father in 1871 when he inherited a property from his maternal uncle. He was educated at Glasgow high school, Glasgow university and Trinity college, Cambridge. For ten years from 1858 he worked (although not too onerously) for J. and W. Campbell, a family firm of Glasgow merchants, marrying in 1860 Charlotte Bruce, a daughter of the general commanding the garrison at Edinburgh. He was unsuccessful radical candidate at a by-election in the Stirling Burgh in March 1868, but at the general election, later in the same year, he reversed this result and was first elected for the constituency which returned him to parliament for the remainder of his life.

Early Career.—After three years in the house of commons Campbell-Bannerman was appointed financial secretary to the war office and served in that department under Edward (afterward Lord) Cardwell until the fall of Gladstone's first government (1874). When Gladstone returned to office in 1880 Campbell-Bannerman was appointed to the same post, but was transferred to the parliamentary and financial secretaryship of the admiralty in 1882, when, the first lord being a peer, Campbell-Bannerman became admiralty spokesman in the house of commons. There were strong suggestions in 1883 that he might be offered the speakership, but these fell through and he was appointed chief secretary for Ireland (1884) but without a seat in the cabinet. He served under the viceroy, Lord Spencer, with great loyalty and considerable skill during a year when the Irish scene was even more than usually troubled.

In Gladstone's third government, Campbell-Bannerman, an easy convert to the policy of Home Rule for Ireland, achieved cabinet rank as secretary of state for war (1886). This administration was too short-lived for him to make much mark in his department, but when the last Gladstone government took office in 1892 and Campbell-Bannerman returned to the war office he was able to begin a tenure of some distinction. He introduced the eight-hour day into Woolwich arsenal and in 1895 (having retained his office when Lord Rosebery replaced Gladstone as prime minister in 1894) he secured without ill-feeling the resignation of the duke of Cambridge as commander in chief. The duke had held this appointment for 39 years and had become a major and seemingly irremovable obstacle to army reform, but Campbell-Bannerman succeeded where successive secretaries of state had failed, and the queen, who was not predisposed in her cousin's favour, recognized Campbell-Bannerman's achievement by awarding him a knighthood.

On the day of his success Campbell-Bannerman was by ill chance responsible for the fall of the government. A snap vote in a thin house of commons on a Conservative motion to reduce the war minister's salary, found the government supporters in a minority of seven. Had the government possessed a vigorous hold on life this decision could easily have been reversed; but Rosebery and his colleagues, already in a sad state of disarray, seized the opportunity to resign. The incident did little to detract from the general respect which Campbell-Bannerman had earned as a minister.

Liberal Party Leader.—Resignation did equally little to correct the Liberal party's disunity. From 1895 to 1902 it presented a spectacle of confusion and weakness. In 1896 Rosebery resigned from the leadership. The earl of Kimberley was appointed his suc-

cessor in the house of lords, and Sir William Harcourt carried on in the commons. Two years later, however, Harcourt himself decided upon an unexpected resignation on the ground that the party was "rent by sectional disputes and personal interests," and John Morley made it clear that he was retiring with his chief. The succession to which Campbell-Bannerman was the senior claimant was a singularly unappetizing one. His most likely rival was H. H. Asquith, certainly a more formidable parliamentarian but one whose close association with Rosebery made him rather doubtfully acceptable to the majority of the Liberal party and whose professional commitments made him loathe to rush at political promotion. In the event, Asquith proving less eager and Campbell-Bannerman less reluctant than had been anticipated, the latter was elected without opposition on Feb. 6, 1899.

Although the new leader applied himself strenuously to trying to hold his party together, the internal disputes, so far from showing signs of abatement, were exacerbated by the outbreak of the South African War in 1899. In one famous vote on the war in July 1900 the Liberal party split three ways: 40 of its members, including Asquith, Sir Edward Grey and R. B. Haldane, voted with the Unionist government; 35 abstained with Campbell-Bannerman; and 31, including John Morley, James Bryce, David Lloyd George and Henry Labouchere, voted for an amendment condemning the government. As his position in this vote indicated, Campbell-Bannerman was trying to steer a middle course and avoid both the outright opposition to the war of the "pro-Boers" and the support for its prosecution of the Liberal imperialists. In its later stages, however, he delivered himself of one of the most memorable of the antiwar statements: "When was a war not a war?"—he asked at a banquet of the National Reform union on June 14, 1901—"When it was carried on by methods of barbarism in South Africa." The result of this statement—and of a counterstatement by Asquith ten days later—produced the sharpest crisis of Campbell-Bannerman's leadership. For a time a Liberal imperialist secession seemed likely. This danger was avoided, however, and his leadership was unanimously confirmed on July 9 at a party meeting attended by both Asquith and Grey.

This was not only the most acute but the last of the major Liberal quarrels of this period. A year later the war ended and greatly eased the tension within the party. At the beginning of 1903 Joseph Chamberlain launched the first effective challenge to free trade for half a century and provided his opponents with the greatest unifying force they had ever enjoyed. Carried forward by this wave they were even able to compose their differences on Home Rule. Campbell-Bannerman secured a fair degree of unity on the point by reaffirming the party's belief in this policy, but making it clear that there was to be no repetition of the 1886 and 1892 practice by which it was made the central and immediate purpose of a Liberal government. By-elections in 1904–05 went heavily against Arthur Balfour's administration, and Campbell-Bannerman built up close relations with King Edward VII, whose first minister he seemed highly likely soon to become.

Prime Minister.—Balfour resigned on Dec. 4, 1905, without defeat either at the polls or in the house of commons, and Campbell-Bannerman immediately accepted office from the king. There were considerable difficulties about cabinetmaking and with them some revival of the old South African War division. Asquith, Grey and Haldane had come to an understanding in Sept. 1905—the "Relugas Compact"^x—the terms of which were that none of them would accept office unless all three were satisfied. This was intended to mean that the new prime minister should take a peerage, leaving the leadership of the commons to Asquith, and that Haldane should become lord chancellor. But Asquith was unwilling to split the party on a personal issue and when he accepted office unconditionally, Campbell-Bannerman was able to defeat both these propositions and secure the adhesion of all three men, although Grey stood out for three days before accepting the foreign office. Asquith became chancellor of the exchequer and Haldane secretary of state for war. The other members of what was generally agreed to be a distinguished administration included Morley, secretary of state for India; Lloyd George, president of the board of trade; James Bryce, chief secretary for Ireland; Lord Ripon,

lord privy seal; Lord Crewe, lord president of the council; Herbert Gladstone, home secretary; and John Burns, president of the local government board.

The dissolution of parliament followed quickly and the general election (Jan. 1906) resulted in an immense Liberal victory. The differences which had arisen in forming the cabinet were dissolved in the great success of this campaign and the government began under happy auspices. Campbell-Bannerman, fortified by his great majority, was able to establish an early ascendancy over the house of commons which was epitomized by his successful rebuke to such an accomplished parliamentarian as Balfour: "I say, enough of this foolery!"—when the latter had indulged in a notable display of dialectics. The prime minister's command did not extend to the house of lords, however, and much of the legislative work of the government was nullified by the Conservative majority in the upper chamber. In the first session an education bill and a plural voting bill both perished in this way. Campbell-Bannerman's reply was to bring forward a plan for limiting the veto of the house of lords, so that "within the limits of a single parliament the final decision of the commons must prevail." He pushed this through the cabinet against some opposition and then carried it as a house of commons resolution by a large majority. It formed the basis of the Parliament act of 1911.

The most important Campbell-Bannerman measure with which the lords did not dare to interfere was the Trades Disputes act (1906), which removed the restrictions upon trades unions imposed by the Taff Vale decision of 1902 (see ENGLISH HISTORY: The Twentieth Century) and gave the unions a very favourable legal status. But his greatest personal triumph was outside the legislative field in the grant of responsible government to the Transvaal and Orange River colonies (see SOUTH AFRICA. UNION OF: History). It was a controversial and courageous step, based on his belief that the relationship between the imperial government and the Boers could only be maintained on a basis of mutual confidence.

Campbell-Bannerman's wife died in Aug. 1906 and in 1907 his own health began to fail. As a result he was less active in parliament than most prime ministers, and much of the day-to-day work fell on Asquith. It was fortunate for the government that, in office, relations between the prime minister and the chancellor of the exchequer were far smoother than they had been in opposition. Campbell-Bannerman made his last appearance in the house of commons on Feb. 12, 1908, and, becoming seriously ill, he resigned as prime minister on April 5 of that year. He died at No. 10 Downing street, on April 22, 1908.

Character.—Campbell-Bannerman was not a great prime minister but he earned the deep affection of his own party and the respect of the whole nation during his relatively brief tenure of office. Most of the major achievements of the pre-World War I Liberal government were carried through under Asquith, who was a more notable figure) but, in view of the latter's identification with the extreme right wing of the party during the South African War, the government probably got off to a better start under Campbell-Bannerman than it would have done had Asquith occupied the highest office from the beginning. Campbell-Bannerman was above all a unifying force. His modest, loyal and simple (although by no means uncultivated) outlook on life is well summed up in one of his last speeches to his constituents: "Altogether I have no fault to find with anybody. And it is because I have no fault to find with anybody that I am where I am . . . It has not been by my seeking that I am where I am . . . An old friend was accustomed to say: The man who walks a straight road never loses his way. Well, I flatter myself that I have walked on a pretty straight road, probably because it was easier, and accordingly I have not gone astray. I trust that that will be continued to the last which cannot be long deferred now."

See J. A. Spender, *The Life of . . . Sir H. Campbell-Bannerman* (1923). (R. J.)

CAMPBELTOWN, a royal and small burgh and seaport in Argyll, Scot. Pop. (1961) 6,525. It is situated on Campbeltown loch, toward the southeastern extremity of the peninsula of Kintyre, 11 mi. N.E. of the Mull and 83 mi. S.W. of Glasgow by water, but 134 mi. by road. There is a daily air service from

Machrihanish airport (4 mi. W.N.W.) to Glasgow.

Campbeltown, originally known as Dalruadhain, was the seat of the Dalriadan kings. After they had moved to Lorn, St. Ciaran (Kieran), one of the Twelve Apostles of Ireland, landed there in the 6th century whence it was renamed Kilkerran, afterward Kinlochkerran. Later, James V transferred the territory from the MacDonalds to the Campbells of Argyll, who gave it their family name. No memorial of its antiquity has survived, but a finely sculptured granite Celtic cross (c. 1500) stands in the market place, and there are ruins of an old chapel. It became a royal burgh in 1700. The staple industries are coal mining (a new pit was sunk in 1946), whisky distilling, fishing; dairy products and net making. On the Atlantic shore ($5\frac{1}{2}$ mi. W.) are the well-known golf links of Machrihanish; 10 mi. S. is Southend, the most southerly village in Kintyre. Davaar Island with its lighthouse lies at the entrance to Campbeltown loch.

CAMPECHE, a southeastern state of Mexico, named for the ancient Maya province of Kimpech or Canpech on the peninsula of Yucatán. Area 19,672 sq.mi. Pop. (1960) 164,256, mostly mestizos and Indians. Campeche comprises much of the westward portion of the peninsula; it is bounded north and east by the state of Yucatán, from which it seceded in 1867, and northwest by the Gulf of Mexico. The state lies on a low, level limestone plain, broken at the north by low hills. The northern half is arid and semiarid, chiefly composed of a district called Chenes (Maya, "wells") and marked by deep grottoes and caverns which are the principal supply of water. Where water is available, agriculture and stock raising are found. East and south of the state capital, Campeche, excessive rainfall produces forested tracts that become tropical rain forest; high temperatures make much of it unhealthy and uninhabitable.

Rivers running through the southern half of the state drain into a large tidewater lake at Laguna de Términos, at the gulf entrance to which is the chief depot of the area, Ciudad del Carmen.

In 1951 the rail line that connected Campeche to Mérida, Yucatán, was linked to the trunk lines on the Mexican mainland, but coastwise and river shipping are still extensive. Airlines link the area with Veracruz, Mérida and Mexico City.

There was considerable commercial fishing and a promising oil potential in the second half of the 20th century; but the state's main products came from its forests—hardwoods, chicle, *palo de Campeche*. Chemical dyes almost killed the old dyewood trade. Fustic, hides and guitars are other products. (J. A. Cw.)

CAMPECHE (CAMPECHE DE BARANDA), a port of Mexico and capital of the state of Campeche on the Yucatan peninsula. Pop. (1960) 43,087. About 90 mi. S.W. of Mérida, Campeche is connected with Mexico City by rail links completed in 1951 and with Mérida by extension of the same route. Campeche is a relatively poor port. Vessels drawing more than 9 ft. cannot clear its bar and must stand off nearly 10 mi. to discharge cargoes into lighters. Port works accommodating vessels up to 2,500 tons were constructed at nearby Lerma. Both places are unprotected and therefore are troubled by tropical "northers," strong winds which prevail from October through April.

The town, an attractive place with its historic walls erected for protection against 17th-century pirates and filibusters, fine public buildings, shady squares and colourful houses, lies on the western extremity of a fertile plain in a natural amphitheatre formed by small hills encircling the bay. The Spanish town was founded in 1540 on the site of an earlier Maya village (Kimpech) whose remains are visible. In the 18th century Campeche was opened as one of three ports on the gulf and thrived on its monopoly of Yucatán trade, mainly exports of dyewood and salt. At various times in the early 19th century, Campeche was the capital of Yucatan. When the province seceded, it became the capital of the new state (1867). Opening of competitive ports at Sisal, then Progreso (1874), plus displacement of vegetable by chemical dyes, reduced its economic importance, though it continued to do a brisk trade in dyewood, cotton, rice, sugar cane, tobacco, cigars and guitars. The old citadel, colonial churches, a theatre and market are chief sights. (Hd. C.; R. B. McCk.)

CAMPEGGIO, LORENZO (1474-1539), Italian cardinal, humanist and lawyer. entered the service of the church in 1510 and at once became one of the most valued representatives of the papacy. Between 1511 and 1539 five popes employed him almost continuously as nuncio or legate; his political and religious embassies gave him a particular knowledge of Germany, where he was nuncio to the emperor Maximilian in 1511 and 1513 and legate at the diets of Regensburg (1524) and Augsburg (1530). In Rome his knowledge of curial procedure made him a realistic advocate of reform, though always loyal to the papacy. He first visited England on an unsuccessful mission for Leo X (1518-19), was given the see of Salisbury in 1524, and in 1528 went to England to enquire into the king's marriage with Catherine of Aragon as co-legate with Cardinal Wolsey; the case was withdrawn to Rome before a decision had been given.

After serving on preparatory commissions for the Council of Trent. Campeggio died in Rome on June 19, 1539. (M. Dk.)

CAMP FIRE GIRLS. Founded in 1910 by a group of prominent educators including Luther Halsey Gulick and his wife, who established the first camp for girls in the United States in 1888, Camp Fire Girls offers membership to all girls 7 to 18 years of age and, during its history, has enrolled more than 4,000,000 of them. The purpose of the organization is to perpetuate the spiritual ideals of the home and to stimulate formation of habits of health and character. The name was chosen for two reasons: because the fire on the hearth has always signified home, and because the campfire suggests the outdoors. The insigne, crossed logs and flame, symbolizes the name.

In keeping with the Gulicks' belief that a maturing girl's experiences affect her entire life. Camp Fire's educational program offers a wide range of activities through which girls may develop into homemakers and citizens. Camp Fire's national program is designed to serve four age brackets: Blue Birds, 7 and 8; Camp Fire Girls, 9, 10 and 11; Junior Hi Camp Fire Girls, 12 and 13; and Horizon club girls, 14 through high school.

The program of the Blue Birds is built around family and community life. They take part in such activities as water colouring, clay modeling and finger painting.

Camp Fire Girls and Junior Hi Camp Fire Girls participate in a program based on the seven crafts: home, creative arts, outdoors, frontiers (of physical science), business, sports and games and citizenship. The four ranks which mark progress in Camp Fire are Trail Seeker, Wood Gatherer, Fire Maker and Torch Bearer. The law of the Camp Fire Girls is: worship God, seek beauty, give service, pursue knowledge, be trustworthy, hold on to health, glorify work, be happy. Horizon clubs provide teen-age girls with a program that emphasizes personality development, vocational exploration, social relationships and community service.

Blue Bird, Camp Fire Girls and Junior Hi Camp Fire Girls individual groups are limited to 20 members; Horizon clubs may have 30. Women 18 years of age and older serve as leaders and club advisers. Men serve as council and committee members and group sponsors.

Publications include the *Camp Fire Girl* (published monthly except July and August) and *The Book of The Camp Fire Girls*. National headquarters are in New York city.

See *Wo-He-Lo, the Story of the Camp Fire Girls, 1910-1960* (1961). (E. M. McS.)

CAMPHOR is a white, waxy substance which is rather volatile and possesses a penetrating, somewhat musty, aromatic odour. For centuries camphor has been known and valued in the far east for its medicinal properties and for its odour. As trade routes to the east developed, it was introduced into Europe and became known to the alchemists. They did not, however, make a clear distinction between true camphor and borneo camphor (borneol). The first chemical investigations of camphor were carried out by A. Lavoisier, R. Boyle and J. B. Dumas. Lavoisier, in particular, demonstrated by chemical analysis that camphor was a compound of carbon, hydrogen and oxygen. The correct molecular formula of the compound, $C_{10}H_{16}O$, was established as early as 1833.

Historically, the term camphor was used to designate any of a

considerable number of different compounds having the physical characteristics of camphor and possessed of aromatic odours. Examples are: borneol, $C_{10}H_{17}OH$; mint camphor (menthol), $C_{10}H_{19}OH$, and buchu camphor (diosphenol), $C_{10}H_{16}O_2$. (See also TERPENES.)

The production of camphor from the camphor laurel (*Cinnamomum camphora*) has been carried out on the island of Formosa and in neighbouring regions of China and Japan for centuries, and still represents an important industry there, although about half of the camphor used commercially is made synthetically from a-pinene, the principal component of turpentine.

Natural camphor is readily isolated by blowing steam through the chopped-up wood of the camphor laurel and condensing the vapours. Camphor crystallizes from the oily portion of the crude distillate. It is purified by pressing and sublimation. The oil left after the camphor has been removed is known as camphor oil. It still contains a considerable amount of dissolved camphor which is frequently isolated by fractional distillation. Camphor oil finds uses in the scenting of soaps and as a flotation agent in mining operations. Because of the commercial importance of camphor and camphor oil, reforestation programs to replenish the supply of camphor laurel trees were undertaken in Formosa and Japan during the 1950s.

Camphor finds some use as a plasticizer or softening agent in cellulose nitrate plastics. It is also used as a plasticizer in some plastic film and in nitrocellulose explosives. Much of the production of camphor goes into cosmetic and medicinal products, where its use depends upon its odour and mild antiseptic and anesthetic properties.

CHEMISTRY OF CAMPHOR

The camphor molecule is unsymmetrical and the substance occurs in two optically active forms known as d-camphor and l-camphor (see STEREOCHEMISTRY). Of the two forms, d-camphor, which in solution rotates the plane of polarization of light in the clockwise direction, is the more abundant natural form. When pure it has a melting point of $178^{\circ}C.$, and a specific optical rotation, $[\alpha]_D^{20}$, of 44.2° (20% solution in absolute alcohol). The left-rotating form, l-camphor, was not found in nature until 1848 when it was isolated from the oil of *Matricaria parthenium*.

Although the correct molecular formula for camphor was known early in the history of organic chemistry, the structure of the molecule was not determined until the beginning of the 20th century. Some idea of the structure problem can be gained from the fact that in the period 1870-95 more than 30 proposals for the arrangement of the atoms in the camphor molecule received consideration. The source of the problem was the unusual arrangement of seven carbon atoms in two rings (I) in the camphor molecule. Such bicyclic systems were unknown at the time, and, indeed, once it had been established that such a system was present in the camphor molecule, progress in the elucidation of other bicyclic structures became rapid.

The correct structural formula for camphor (II) was proposed by J. Bredt in 1893, and although his hypothesis was not promptly accepted, it was fully validated by unambiguous synthesis within ten years. It had long been known that camphor on oxidation was converted into camphoric acid (III) from which camphor could be

reformed by well-understood means, and it was in fact the proof of the structure of camphoric acid by rational synthesis that validated Bredt's formula for camphor.

Camphor (II) is a ketone in the class of oxygenated bicyclic monoterpenes, and it conforms to the isoprene rule since its carbon skeleton can be divided into two isoprene units as indicated by the numbering in II. Reduction of camphor with sodium in alcohol gives borneol (IV), while catalytic hydrogenation using platinum black as catalyst produces mainly isoborneol (V). These two alcohols derived from camphor differ in the disposition of the OH group with respect to the $\text{CH}_3\text{—C—CH}_3$ unit. In borneol the OH group is directed away from the $\text{CH}_3\text{—C—CH}_3$ unit, while in isoborneol the OH group is directed toward it.

Both borneol and isoborneol when treated with dehydrating agents such as sulfuric acid yield camphene (VI). Isoborneol undergoes the change somewhat more readily. The formation of camphene from the borneols involves a rearrangement of the carbon skeleton (Wagner-Meerwein rearrangement), and it was just such rearrangements that plagued the efforts of early investigators to determine the carbon skeleton of camphor, for molecular rearrangement was but poorly understood at the time. In fact, the elucidation of the structures of camphor and the rearranged products contributed greatly to the present understanding of the processes by which one carbon skeleton is converted into another. The identifying numbers of the carbon atoms in the formula for isoborneol (V) are carried over into that for camphene (VI) to demonstrate the complexity of the change in skeletal structure accompanying the rearrangement.

To supplement natural sources of camphor several processes have been developed for its production from α -pinene, a very abundant terpene. Treatment of pinene with hydrogen chloride gas produces a mixture of bornyl and isobornyl chlorides with the former predominating. These chlorides correspond in structure to borneol (IV) and isoborneol (V) with Cl replacing OH, and their formation involves a molecular rearrangement of the carbon skeleton of pinene. Bornyl chloride has been known as "artificial camphor." Removal of hydrogen chloride from bornyl chloride by the action of alkali converts it into camphene (VI). Camphene is oxidized to camphor in one process. Another method for the production of camphor involves the addition of formic acid to camphene to form isobornyl formate (the formic acid ester of isoborneol) and subsequent saponification of the formate to produce isoborneol. Isoborneol is then oxidized to camphor. Catalytic processes for the formation of camphene from pinene have been developed in recent years. The synthetic camphor from these sources (dl or racemic camphor) is usually of low optical activity and consists mainly of a mixture of equal amounts of the dextro- and levo-rotatory forms.

CAMPI, GIULIO (1502–1572), Italian painter and architect, who led in the formation of the Cremonese school, was born at Cremona. His work, and that of his followers, was elegant and eclectic. Campi was a prolific painter, working in both oil and fresco. At its best his work was often distinguished by the richness of its colour. He first studied under his father, Galeazzo Campi (1471–1563), and Bernardo Gatti (c. 1495–1575), and later formed his style under the influences of Giulio Romano (whom he reportedly once assisted on a painting in Mantua) and Pordenone. Among the earliest of his school were his brothers, Vincenzo (1536–1591) and Antonio (1536–c. 1591); the latter was also a sculptor and historian of Cremona.

BERNARDINO CAMPI (1522–c. 1592), a pupil of Giulio Campi, did extensive work as a painter of portraits and sacred subjects, and was active in many Italian cities outside of Cremona. Son of the goldsmith Pietro Campi, he early followed his father's profession, later turning to the study of painting under Giulio Campi and Ippolito Costa. Giulio Romano and Correggio had great influence upon his style. He died at Reggio.

CAMPIN, ROBERT (c. 1378–1444), a painter of the school of Tournai (Belgium), is named in the archives of that city between 1406 and 1444 as being entrusted with decorative work by the town council. Two pupils are mentioned as entering his studio in 1427—Rogier van der Pasture (generally identified with Rogier van der Weyden [*q.v.*]) and Jacques Daret. Campin died on April 26, 1444. An identification of Campin with the Master of Flémalle (the painter of the panels wrongly supposed to come from an abbey at Flémalle near Liège and now at Frankfurt) has been made on a stylistic basis. The only documented work by Jacques Daret, an altarpiece executed for the abbey of St. Vaast near Arras (panels of which have survived and are now at Berlin, Paris and Lugano), shows close stylistic analogies with works by Rogier van der Weyden on one hand and works earlier in style by the Master of Flémalle on the other. Both seem to proceed from common models, for they obviously are not copies of one another. As the Tournai records give the name of Campin as master of both Daret and Rogier, it has been generally assumed that the Master of Flémalle may be reasonably identified with Campin. However, some scholars have considered the works ascribed to the Master of Flémalle as early works by Rogier van der Weyden, also on a stylistic basis. One of Campin's masterpieces is the triptych of the "Annunciation" with the donors and St. Joseph on the wings, formerly in the Merode collection at Westerlo, Belg., and now in the Metropolitan Museum of Art in New York city. Another important work, at the Städel art institute in Frankfurt am Main, Ger., consists of two wings of an altarpiece said to have come from the abbey of Flémalle and shows the "Virgin and Child" and "St. Veronica" (with a "Trinity" on the reverse). Other works generally ascribed to Campin are the "Virgin and Child before a Firescreen" and a double portrait, at the National gallery, London; a fragment from the right wing of a lost triptych of the "Descent From the Cross" representing one of the thieves, at Frankfurt; a "Madonna" at Aix in Provence; two heads of "Christ and the Virgin" in the Johnson collection at Philadelphia, Pa.; a "Marriage of the Virgin" in Madrid; a "Nativity" at Dijon; an "Entombment" in the collection of Count Seilern in London; a "Trinity" and a "Madonna and Child at the Chimney" in Leningrad. To Campin's last period belong the wings of an altarpiece in Madrid dated 1438 and painted for Heiarich von Werl, a notable professor at Cologne.

CAMPINAS, a city in São Paulo state, Braz., 65 mi. N.W. of the city of São Paulo by rail and 114 mi. from the port of Santos, with which it is connected by the Paulista and Santos-Jundiaí railways. Pop. (1950) city 99,156, municipality 152,547; (1955 mun. est.) 156,126. Campinas is the commercial centre of one of the state's oldest coffee-producing districts and the outlet for a rich and extensive agricultural hinterland. The Mogiana railway starts from this point and extends north to Minas Gerais state, while the Paulista lines extend northwest into settled and very fertile regions; the Sorocabana railway also reaches the city. Locally, coffee has given way to diversified farming. The industries of Campinas include foundries, textile mills, and packing and processing plants; agricultural equipment is also manufactured. The state agronomical institute with large experimental plantations and other institutions devoted to raising agricultural production are located there. The city has a faculty of pharmacy and dentistry affiliated with the University of São Paulo, and higher in-

stitutions for liberal arts, economics and law. (R. M. M.)

CAMPING is a way of life that began with man. It was his mode of living, with the sky as his roof, and earth his bed, and the wildlife about him his source of food and clothing. In modern times camping has become a back-to-nature, educational and recreational movement wherein man gains knowledge, understanding and enjoyment through the use of nature and its resources. In the second half of the 20th century two distinct categories were recognized, organized camping and individual or family camping. The range of camping extends from the lone camper sleeping in the open near his campfire to congregate groups with specialized equipment, extensive facilities and highly organized programs.

Organized Camping. — Organized camping varies from country to country in extent, type and sponsorship. France has a large national camping program, known as Vacation colonies, sponsored and in large part financed by government and industry. The Soviet Union maintains an extensive government program of camping for youth. In Sweden camps for youth and adults are operated by cities. Camping for school children, under the term of outdoor education, is prevalent in Australia: Denmark, Egypt, Germany, India, Japan, New Zealand and South Africa. These camps are sponsored by the schools and subsidized by the governments. Teachers are given special training for their camping responsibilities. Youth service agencies, such as the Boy Scouts, Girl Scouts, Girl Guides and the Y.M.C.A., international in scope, have led the organized camping movement in Canada, the United States and Great Britain and operate a limited number of camps in other lands in which they serve. Great Britain, in addition to camps operated by such agencies, provides youth camps through the Boy's Brigade, Boys Leagues and British Schools Exploring society. Youth hostels are popular in Great Britain and on the continent, as are camping tours and trips.

Organized camping in the United States started with a camp for boys in 1861. In that year Frederick William Gunn, founder of the Gunnery School for Boys in Washington, D.C., and his wife took the student body to Milford-on-the-Sound for two weeks. The experiment proved so successful that it was continued for 13 years. Within a short time other camps developed. In 1876 the first private camp was begun by Joseph Trimble Rothrock. The first church camp was started by the Rev. George W. Hinckley in 1880 at Gardners Island, R.I. The oldest existing camp is Camp Dudley, a Y.M.C.A. camp founded in 1885 by Sumner F. Dudley. The first camp for girls was established in 1888 by Luther Halsey Gulick and his wife for their daughters and their friends on the Thames river in Connecticut. Gen. Robert Baden-Powell, who started the Boy Scout movement in England, emphasized camping as a major part of the program (see *BOY SCOUTS*). In 1908 Ernest Thompson Seton visited and observed the scouting movement in England. Upon returning, he headed the committee to establish the Boy Scouts of America in 1910. The Girl Guides, which began in Great Britain in 1910, and the Campfire Girls (1910) and the Girl Scouts (qq v.; 1912), in the United States, also stressed organized camping. Also active in the movement were the Y.M.C.A., the Y.W.C.A., the Y.M.H.A., the Boys' Clubs of America, the Federation of Girls' Clubs, Four-H Clubs and other youth-serving organizations. In 1916 Charles W. Eliot, former president of Harvard university, said, "The organized summer camp is the most significant contribution to education that America has given to the world."

At the turn of the 20th century camp directors began meeting together to discuss mutual problems and interests. By 1910 the Camp Directors association was formed; and out of it grew the American Camping association. The membership of this professional organization, originally made up of camp directors, was

broadened to include others associated with or interested in camping. Among its services the association establishes camping standards and provides leadership certification. Many colleges and universities offer courses in camping. A high percentage of camp leadership is recruited from colleges and the teaching profession.

Organized camping may be divided into three groups: camps operated by the youth-serving agencies and by churches, civic clubs, industries, labour organizations, co-operatives and other nonprofit groups; public camps operated by schools, municipalities and other agencies of government; and private camps operated for profit. Within these groups are numerous types of camps: resident, day, caravan, family and specialized camps. Specialized camps include modified camping programs for physically and mentally retarded children and handicapped and crippled children. Fresh-air camps provide camping experience for families and children from congested areas. Camps facilities may include tents as well as buildings of more permanent nature, such as sleeping cabins, dining halls, lodges, an infirmary or health centre and in many cases an administration building. Such camps cater for groups of children under adult supervision or may accommodate whole families. The activities of a camp are usually adapted to the geographical location to include special emphasis on canoeing, mountaineering, ranch life, pack trips or other activities in keeping with the environment. Learning skills in campcraft, woodcraft, nature lore and other activities not commonly practised in urban areas usually is the central theme of the organized camping program.

Among U.S. groups that do not possess camping sites but plan, provide and supervise camping activities for individuals and groups are the Appalachian Mountain club, the Sierra club, the Long Trail council, the Adirondack Mountain club and the American Youth hostels.

Leading the organized camping movement in Canada have been the Boy Scouts association, the Canadian Girl Guides, the Y.M.C.A., churches and other community groups. Several of the provinces, especially Ontario (through the department of lands and forests) and British Columbia (junior wardens), provide organized camping programs for youth. The Canadian Camping association promotes camping throughout the provinces.

Individual and Family Camping. — Individual family camping is widely enjoyed in many countries. Both public and private lands are made available for this purpose. It is impossible to determine the number of individuals and families who each year spend days, week ends and vacation periods camping. Their objectives range from fishing and hunting to simply enjoying the scenery. They may camp on the shores of a lake one night and on the mountain slopes another night. They may canoe or sail on lakes or streams. They may climb mountain trails by horse or on foot, fly to remote wilderness areas or pitch a tent in their own back yard. In the United States the trek back to nature has become so popular that governmental licensing and regulation have become necessary in many states.

In Canada, as well as the United States, campsites are made available in national, state or provincial, county and city parks. Facilities range from primitive, for wilderness camping, to the provision of cabins, hot and cold running water, showers, electricity, etc. In many states and provinces, roadside overnight

park areas are provided and there are many privately operated camping areas. Camping in the United States and Canada has become an avocation for millions and a vocation for thousands, with the annual income derived by suppliers of camping equipment well beyond \$1,000,000,000. Detailed information on camp facilities is readily available from state or provincial park departments and tourist bureaus and local chambers of commerce. (S. N. G.)

Camping in Europe.—Camping for pleasure started in England about 1880 and developed rapidly with the use of the bicycle. The Association of Cycle Campers was formed in 1901 and by 1907 had merged with a number of other camping clubs to form the Camping Club of Great Britain and Ireland, of which it is still a flourishing part. Before World War I the camping kit was very lightweight (two-man tent with poles weighing only 4 lb.) and largely homemade. By 1910 appreciable numbers of British cycle and pedestrian campers were touring Europe and the idea of pleasure camping began to spread. After World War I camping began to flourish in western European countries and national camping clubs were formed. The industry which manufactured tents, groundsheets, kerosene and gasoline pressure stoves and sleeping bags grew to a considerable size. World War II interrupted this growth but from 1936 onward camping increased rapidly in popularity throughout western Europe.

As in the United States and Canada, this postwar growth of camping was accompanied by considerable new technical developments. Cottage tents, small bivouac tents and single-pole (umbrella) tents continued to be made, but down-to-earth flysheets were designed which enclose the inner tent completely and are anchored by short, elastic guy lines. An extension to the flysheet gives a cooking and living area, and a detachable bell-shaped end encloses this area completely at night or in bad weather.

The frame tent appeared and began to replace the more traditional tents, particularly in France, Italy and Germany. It consists of a strong jointed tubular frame (often spring-linked so that it is easy to pitch) in the shape of a small cottage. Over the frame is fitted an outer canvas tent of considerable dimensions, 12 x 8½ x 8 ft. being quite normal. The outer tent comes down almost to the ground and is pegged by many short metal pegs attached to elastic guys. There is a large picture window, usually

mosquito-netted and with a protective awning which zips down at night; a front awning with its own frame which sometimes stretches the full width of the tent; and often a rear kitchen-bathroom with splashproof walls and draw curtains. The outer tent holds one, two or three sleeping tents with built-in groundsheet, mosquito-netted window(s) and zippered doors.

Cooking stoves, which burn bottled propane or butane gas and have one or two burners and even a grill, are placed on a folding table of the correct height, adding greatly to the comfort of camping. Cooking pans in spun aluminum—light, hygienic and neat—are available and a pressure cooker is a great asset for family camping. Bottled-gas lighting (and heating in cold weather), folding chairs and tables and plastic crockery are all in common use. Folding camp beds or air beds and sleeping bags filled with down or man-made fibre are used. A latrine tent and compact chemical toilet may complete the outfit.

It should be noted that kerosene is not readily obtainable in all European countries and that methylated spirit (alcohol) is very expensive in some, so that bottled gas or petrol stoves are probably the most suitable. Gas-bottle exchange or filling stations are available on an increasing scale.

Pedestrian campers hitchhike their way throughout Europe and cycle campers, scooter and motorcycle campers abound, but it is the great number of family campers with cars that has brought about the rapid development of campsites on a commercial basis, much as the growing number of car, camp trailer and station wagon campers has boosted camping in the U.S. and Canada.

The most popular camping areas are the French and Italian rivieras, but Switzerland, the Italian lakes, the Spanish Costa Brava and Germany attract more and more campers. In France almost every town offers a site indicated by the "Camping" sign which is used everywhere. Finland, Norway, Sweden and Denmark, Belgium, the Netherlands and Luxembourg, Portugal and Austria all cater for campers on a considerable scale. Facilities are developing in Yugoslavia and in Greece. The tiny countries of Andorra in the Pyrenees, San Marino on the Adriatic and Liechtenstein on the Austrian border all offer well-equipped campsites. Lists of organized campsites are obtainable from national tourist offices, motoring organizations and camping clubs, or from book-stalls in big cities of many western European countries.

Many of the European campsites are equipped with baths, showers, electric razor outlets, flush lavatories, clothes-washing facilities, shops, restaurants and games areas. Prices are usually modest. Sites in Great Britain, on the whole, are less well equipped. The Camping Club of Great Britain issues to its members a list of more than 2,000 sites in the British Isles. Overseas visitors may join the club and use its facilities including advice about camping in other parts of Europe.

FIG. 5.—PYRAMID TENT

When camping in western Europe it is essential to carry a camping carnet or permit and identification book issued by the national camping clubs affiliated to the Federation Internationale de Camping et de Caravanning or by the national motoring organizations affiliated to the Alliance Internationale de Tourism. These carnets provide insurance against third-party risks while camping. They require campers to use authorized sites or to camp only when permission is given, to avoid fire risks, to leave no rubbish, to pay particular attention to sanitation, to respect other people's peace, property and local conventions and to be quiet between 10 P.M. and 6 A.M. Carnets are almost invariably required by campsites (other than in Great Britain) and lack of one may lead to permission to camp being refused. With a carnet, one may camp on any of the thousands of sites throughout western Europe.

Starting in 1960 it has been possible for motorists to camp in the Soviet Union on a number of well-equipped sites (reservations are required in advance through a tourist agency). Poland, Czechoslovakia, Hungary, Rumania, Bulgaria and the German Democratic Republic all offer facilities to tourists and these are being extended.

Apart from the use of organized sites it is possible to camp freely in many parts of Europe simply by seeking permission from the local farmer, forester, police or administrative authority. This type of camping is becoming popular with vacationers who are canoeing, fishing, mountaineering, painting, etc. Drinking water is suspect in some areas and water purifying tablets should be used. Ice is fairly readily obtainable in France, Switzerland and Italy. It is worthwhile carrying a small icebox and possibly a folding flyproof larer.

Camping in this way, shopping in the villages and markets, eating and drinking the local foods and wines, is very enjoyable and usually very inexpensive. Perhaps more than any other form of vacation, camping brings closer contact with the people and gives a greater insight into the ways of the country concerned.

Some indication of the extent of camping in Europe is given by the fact that, in a typical year, 1960, more than 5,000,000 French men and women were active campers and the rate of increase was estimated at 300,000 a year. In July of that year the International Rally of Camping and Caravanning, which is held in a different country each year, attracted 6,500 campers from 20 countries to a spectacular site 3,500 ft. up in the high Savoy area of France. No less than 125,000 British campers crossed the English Channel with their camping equipment. In Britain itself, the Camping club's annual Feast of Lanterns, held on the first week end in September, brings more than 5,000 Camping club mem-

bers together for a week end. The production of camping equipment has developed into a large-scale industry. Trade fairs are held annually in London, Paris and Cologne and the turnover of the industries connected with camping approaches £100,000,000 a year. (AL. R.)

HOW TO CAMP

A good camper may be likened to a good woodsman. He does not go with scanty outfit to endure as many hardships as he can stand—reveling in his stamina—but rather he makes the most of his equipment and the resources of nature and lives happily and comfortably in the moods. He goes camping to have a good time and returns to his work with increased health and vigour. This is possible only when he dresses comfortably, sleeps well at night and eats properly.

The Site.—A good campsite provides adequate drainage and protection from severe storms and wind. It is as free as possible from poisonous plants and animals, possible landslides, flash floods and other natural hazards. It provides a source of water, shade and firewood. If the source of water is in doubt, the water should always be boiled or chlorinated. Contrary to popular belief, running water does not always purify itself and fast-flowing streams may be polluted. The summer camper requires only a little fuel, but the cold-weather camper needs considerable amounts for warmth as well as for cooking.

The site should provide shade at least during the hottest period of the day (2 to 4 P.M.). The directions of prevailing winds are shown by standing timber, which bends away from the seasonal blow. In cold weather, camp is made with a windbreak of woods or rock at the rear. Thickets, low marshy areas and dense woods should be avoided. These are damp and unwholesome and may be infested with insect pests. Camp is best made in the open, where the tent will quickly dry after rain or dew and there is no danger of falling limbs or trees. Drainage is aided by digging a six-inch trench around the tent.

The Tent.—The tent is a convenient shelter for the camper because of its versatility. It may range from a small lightweight nylon tent of the explorer type to a large sidewall or pyramidal canvas tent for family use (see *Camping in Europe*, above). Tents should be made as waterproof as possible and, unless they are made of nylon, they should be dried out thoroughly before packing to avoid mildew and rot. Tents can be used in both summer and winter. They should be well ventilated for summer use. Particular care should be taken in pitching a tent. A sloppy, loosely pitched tent will not shed rain or snow. Wooden tent-pegs are lighter to carry than steel pegs. When tent pegs cannot be used, a frame of heavy logs to which the guy ropes may be fastened may circle the tent. Heavy rocks may also be used to anchor the guy ropes. Ropes should be loosened in wet weather to prevent damage to the tent and prevent the stakes from being pulled.

The Bed.—The camper's bed should be comfortable, warm and dry. A bed can be made with pine boughs, waterproof groundcloth, woolen blankets and blanket pins. An old-time tick can be filled with materials found at the campsite—leaves, grass, pine needles, etc.—to make a comfortable bed. However, a variety of sleeping bags are available to suit every camper's needs. Air pillows and

mattresses that can be readily inflated add still more comfort. Folding canvas cots can be used but they are cold underneath and require additional blankets (or layers of paper) under the sleeper.

Food.—Open-fire cooking should be over hardwood coals—only when unavoidable over a flame or softwood ashes. Charcoal, gas and alcohol portable grills and stoves are available. Cooking equipment should be simple. Pots and pans should be selected on a basis of multiple use. Aluminum ware is light and comes telescoped in kits or "nests." For all-around cooking, a deep iron skillet, a small open grill and a dutch oven are practical utensils. Twists on sticks and reflector ovens may also be used for baking. Dishes should be of an unbreakable variety such as aluminum and stainless steel. Many campers prefer plastic cups that do not burn the lips. Various staple foods, available in dehydrated form, can be supplemented by the efforts of the hunters and fishermen in the group. Variety in menu is not only possible but highly desirable. To keep foods cool, watertight containers may be sunk in a stream and portable iceboxes and vacuum containers may be used. Food should be protected from flies, insects and animals. Unburnable garbage should be buried at least two feet deep and all campfires should be put out by soaking and tamping. (S. N. G.)

CAMPION, EDMUND (1540–1581), English Jesuit executed as a traitor by the government of Elizabeth I, was born in London on Jan. 25, 1540, and educated probably at Christ's hospital or at St. Paul's and at St. John's college, newly founded at Oxford by Sir Thomas White, a patron of Campion. His Catholic tendencies became known and his scholarship benefactors demanded an assurance that he was a sincere Protestant. Rather than give this, he left Oxford and, after a stay in Dublin, eventually went, to escape the attentions of the English government, to Douai in northern France to join the English college founded there (1568) by William Allen. He was received into the Roman Church and in 1573 went to Rome to join the Society of Jesus. He was sent to Prague and conducted successful missions among the Hussites. In 1580, under the leadership of Robert Persons, he was sent on a dangerous mission to England, where Catholic practices were strictly proscribed. After precarious ministering in Berkshire, Oxfordshire, Northamptonshire and Lancashire, Campion caused a sensation by having 400 copies of his *Decem Rationes* against the Anglican Church distributed in St. Mary's, Oxford, before the degree-giving ceremony on June 27, 1581. Shortly afterward: on July 14, while preaching at Lyford, Berkshire, he was arrested by a spy named George Eliot and taken to London. He was several times examined, gave word of his loyalty to Elizabeth, impressed his hearers by his strength of argument and his gaiety and was then racked in an effort to make him recant and deny his adherence to Roman Catholicism. On Oct. 31 he was accused at Westminster of having conspired with others at Rome and Reims to dethrone the queen. On Nov. 20, after being found guilty, he claimed: "If our religion do make us traitors we are worthy to be condemned; but otherwise we are and have been as good subjects as ever the Queen had." Campion was sentenced to death as a traitor and executed on Dec. 1, 1581. Of all the English Jesuits who suffered for their allegiance to Roman Catholicism Campion is the best known. His life and his aspirations were pure, his zeal true and his loyalty unquestionable. He was beatified in 1886. Campion hall at Oxford is named after him.

See E. Waugh, *Edmund Campion*, new ed. (1961). (P. CN.)

CAMPION, THOMAS (1567–1620), English poet and musician! the most musical of the Elizabethan lyric poets, was born in London on Feb. 12, 1567, and christened at St. Andrew's, Holborn. He was the son of John Campion of the Middle Temple, who was by profession one of the cursitors of the chancery court, the clerks "of course," whose duties were to draft the various writs and legal instruments in correct form. His mother was Lucy Searle, daughter of Laurence Searle, one of the queen's sergeants at arms. Upon the death of Campion's father in 1576, his mother married Augustine Steward and died herself soon after. Steward sent him in 1581 to Peterhouse, Cambridge, as a gentleman pensioner. He left the university, it would appear, without a degree, but strongly imbued with those tastes for classical literature which exercised such powerful influence upon his subsequent work. In April he was admitted to Gray's Inn, but he does not appear to have been called to the bar. In 1591 he seems to have taken part in the expedition under Essex, sent to France for the assistance of the Huguenot Henry IV against the Catholic league; and in 1606 he first appears with the degree of doctor of medicine. He practised as a physician until his death in London on March 1, 1620. A group of five anonymous poems by Campion was included in the *Songs of Divers Noblemen and Gentlemen*, appended to Newman's surreptitious edition of Sidney's *Astrophel and Stella*, which appeared in 1591. In 1595 appeared under his own name the *Poemata*, a collection of Latin panegyrics, elegies and epigrams. This was followed in 1601 by *A Booke of Ayres*, the music of which was contributed in equal proportions by himself and Philip Rosseter, while the words were almost certainly all written by him. The following year he published his *Observations in the Art of English Poesie*, in favour of rhymeless verse on the model of classical quantitative poetry. The challenge thus thrown down was accepted by Samuel Daniel whose *Defence of Ryme* was published in 1603.

In 1607 Campion wrote and published a masque for the marriage of Lord Hayes, and in 1613 he issued a volume of *Songs of Mourning* (set to music by Coperario or John Cooper) for the loss of Prince Henry. The same year he wrote and arranged three masques, the *Lords' Masque* for the marriage of Princess Elizabeth, an entertainment for Queen Anne at Caversham house, and a third for the marriage of the earl of Somerset to Frances Howard, countess of Essex. If, moreover, as appears likely, his *Two Bookes of Ayres* (both words and music written by himself) belongs also to this year, it was indeed his *annus mirabilis*.

Some time in or after 1617 appeared his *Third and Fourth Booke of Ayres*; while to that year probably also belongs his *New Way of making Foure Parts in Counter-point*, a technical treatise which was for many years the standard textbook on the subject. It was included, with annotations by Christopher Sympson, in Playfair's *Brief Introduction to the Skill of Musick*, and two editions appear to have been bought up by 1660. In 1618 appeared *The Ayres that were sung and played at Brougham Castle* on the occasion of the king's entertainment there, the music by Mason and Earsden, while the words were almost certainly by Campion; and in 1619 he published his *Epigrammatum Libri II. Umbra Elegiarum liber unus*, a reprint of his 1595 collection with considerable omissions, additions (more epigrams) and corrections.

While Campion had attained a great reputation in his own day, after his death his works were forgotten. The masque was practically extinguished by the Puritan revolution, which also, with its distaste for all secular music, put an end to the madrigal. Its loss involved that of many hundreds of lyrics, including those of Campion, and it was only when A. H. Bullen published a collection of the poet's works in 1889 that his genius was again recognized.

Campion set little store by his English lyrics; they were to him "the superfluous blossoms of his deeper studies," but we may thank the fates that his precepts of rhymeless versification so little affected his practice. His rhymeless experiments are certainly better conceived than many others, but they lack the spontaneous grace and freshness of his other poetry. Not one of his songs is unmusical; moreover, the fact of his composing both words and music gave rise to a metrical fluidity which is one of his most characteristic features. Rarely indeed are his rhythms uniform,

while they frequently shift from line to line. His range was very great both in feeling and expression, and whether he attempts an elaborate epithalamium or a simple country ditty, the result is always full of unstudied freshness and tuneful charm. In some of his sacred pieces he is particularly successful, combining real poetry with genuine religious fervour.

CAMPISTRON, JEAN GALBERT DE (1656–1723). French dramatist, whose classical tragedies achieved great success, was born in Toulouse in 1656 and served with distinction under the duc de Vendôme. He was received into the French Academy in 1701. Of his nine extant tragedies, the most successful were *Andronic* (1685), *Alcibinde* (1686) and *Tiridate* (1691). Success was probably in part due to the acting of Michel Baron (*q.v.*), but Campistrion's stagecraft and sense of dramatic surprise can still be admired. Two comedies have survived, *L'Amante amant* (1684) and *Le Jaloux désabusé* (1709), and three opera texts written for Lully. Campistrion died in Toulouse on May 11, 1723.

CAMP MEETING was the name given to three- or four-day outdoor revival meetings held along the American frontier during the 19th century by the various evangelical denominations either singly or jointly. The origin is obscure, but historians have generally credited James McGready, a Presbyterian, with inaugurating the first typical camp meetings in 1799–1801 in Logan county, Ky., along the Gasper, Muddy and Red rivers. Other ministers who associated with McGready (William and John McGee, William McKendree and Barton W. Stone) spread his methods throughout the southwest. As the name implies, those who attended such meetings came prepared to camp out, gathering at the prearranged time and place from as far as 30 to 40 mi. away. Families pitched their tents around a forest clearing where log benches and a rude preaching platform constituted an outdoor church in almost constant session for four days. As many as 10,000 to 20,000 were reported at some meetings. People came partly out of curiosity, partly out of a desire for social contact and festivity, but primarily out of their yearning for religious worship. Camp meetings, through their preaching, their prayer meetings, anxious bench, hymn singing, weddings and baptisms, filled a definite ecclesiastical and spiritual need in the unchurched settlements of the west which itinerant home missionaries were not numerous enough to supply. Often scenes of wild enthusiasm and hysteria in the early years, camp meetings acquired a bad reputation among conservative churchmen. The Presbyterian Church refused to countenance participation in them after 1805. Nevertheless they were vigorously carried westward with the frontier by the Methodists, Baptists, Shakers, Disciples, and Cumberland Presbyterians, the latter two denominations being direct outgrowths of the camp meetings. The Methodist Church profited most by their popularity and gradually institutionalized them into its system of evangelism. By 1811 the Methodist bishop Francis Ashury reported in his journal that over 400 camp meetings were being held annually along the frontier from Georgia to Michigan. Although the theology of camp meeting preachers varied from a modified Calvinism to pure Arminianism, the insistent emphasis upon a sudden conversion experience reduced doctrinal preaching to a minimum, broke down the old creedal standards and undermined the concept of a learned pastoral ministry. But the individualistic and activist elements in Protestantism stressed in these meetings comported well with the character of frontier life and eventually pervaded the religious outlook of rural America. Camp meetings lingered archaically as summer Bible conferences into the 20th century, but their significance passed after 1890 with the frontier society that created them. Despite their occasional fanaticism and frenzy they helped in a crude way to bring the stabilizing and humanitarian force of religion to the raw wilderness settlements. See also REVIVAL, RELIGIOUS.

CAMPOAMOR Y CAMPOSORIO, RAMÓN DE (1817–1901), Spanish poet and politician, chiefly remembered for some short epigrammatic poems, was born at Navia (Asturias) on Sept. 24, 1817. As a member of a generation which missed the early idealism of Liberal excitement he rather reflects the calculated plot and counterplot characterizing mid-century parliaments and observes a moderate conservatism. He excels in epigrammatic verses of worldly wisdom, which have the simplicity and force of proverbs and earned him in his day an undeserved reputation as master poet and philosopher. His permanent value lies in his lively, economic expression of contemporary social attitudes and preoccupations with their bittersweet ironies of detail and their mass sentiment disguised as individual thought. Certain of his collected verses—*Doloras* (1846), *Pequeños poemas* (1871, etc.), *Humoradas* (1886)—were regarded by himself and others as symbolizing innovations in form and ideology. In fact they are neither original nor greatly different from each other, but present, in varying proportions, his basic ingredients of satire and sensibility. On large canvases (*El drama universal*, 1869, or the drama *Dies irae*, 1873) his inadequacy becomes more apparent. His early lyrics correctly forecast his facile talent. He died in Madrid on Feb. 12, 1901. (I. L. Mc. C.)

CAMPOBASSO, chief town of Campobasso province, Abruzzi e Molise region, southern Italy, and an episcopal see, lies in a fertile plain. Pop. (1957 est.) 31,398 (mun.). The old town stood on a hill, surrounded by a wall with six towers and five gates and joined to the Castello de Monforte. In 1732 the people abandoned their feudal town and built a new town in the plain. The old town contains the castle (1459), lately restored, and the Romanesque churches of S. Leonardo, S. Bartolomeo and S. Giorgio (13th century). The new town has the neoclassical cathedral and a museum with relics of the Samnites, Frentani and Campani. Agricultural products include the well-known pears which ripen in winter and the popular *scamorze* cheeses. The making of cutlery, long a speciality, has dwindled, but paving tiles and soap are made. The town is on the Benevento-Termini railway (junction for Isernia). (M. T. A. N.)

CAMPODEA, a small whitish, wingless insect of the order Diplura (allied to the thysanurans), subclass Apterygota (*q.v.*), with long flexible antennae and a pair of elongated caudal filaments. The best-known species (*Campodea staphylinus*) is widely distributed in Europe and North America where it occurs under stones and logs or in rotting leaves and soil.

CAMPOS, an inland city of Brazil in the state of Rio de Janeiro, is located 140 mi. S. E. of Rio de Janeiro city. Pop. (1960) 99,557. It is situated on the Rio Paraíba, 23 mi. from the river mouth and about 69 ft. above sea level. The use of the river for navigation is blocked a short distance upstream by falls and rapids, and at the mouth by sand bars. Campos has rail and all-weather highway communications. It is connected southwest to Rio de Janeiro and Niterói, and also north to Vitoria.

The city is the chief commercial centre of an important agricultural district on the Paraíba delta. First founded in 1634 it became a major cattle-shipping centre for the market in Rio de Janeiro, and it still performs this function. Campos has long been the centre of sugar-cane plantations and its chief industries are sugar refining and alcohol distilling. There are also food processing plants, leather and textile factories, and manufacturers of soap, furniture and building materials. An aluminum plant is supplied with power from a hydroelectric plant upstream on the Paraíba. (P. E. J.)

CAMPRA, ANDRÉ (1660–1744), the most important French opera composer between Lully and Rameau, was born of Italian descent at Aix-en-Provence, Dec. 4, 1660. He is supposed to have been *maître de musique* at Toulon cathedral at the age of 19 and certainly held similar posts at Xrlés in 1681 and Toulouse in 1683. In 1694 he went to Paris as director of music at Notre Dame, where he was the first to introduce instrumental music into the services. Already well-known for his motets, he turned to

secular music and produced his first dramatic work, *L'Europe galante*, in 1697 under an assumed name. In 1700 he gave up his church appointment and for 40 years enjoyed a wide reputation for his stage works. The opera-ballet in his hands became a charming vehicle for chain upon chain of danced and sung diversissements uncomplicated by any great dramatic unity. His religious music does not compare with that by Clérambault or Lalande but is nevertheless of power and beauty. Campra died at Versailles, June 29, 1744. (B. P.)

CAMUS, ALBERT (1913–1960), French essayist, novelist and playwright, whose influential and penetrating analyses of the predicament of the modern human conscience won him the Nobel prize for literature in 1957, was born in Mondovi, Algeria. Nov. 7, 1913. His father was killed in World War I and he was brought up by his mother in difficult circumstances. He studied philosophy at the University of Algiers but illness prevented his proceeding to postgraduate studies. He held various positions such as meteorologist, stockbroker's agent, temporary civil servant and journalist while directing an amateur theatrical company. He remained keenly interested in the technical aspects of the stage.

His first books, *L'Envers et l'endroit* (1937) and *Noces* (1938), collections of essays, revealed, in a richly sensuous prose, his intense feeling for North Africa. His first journey outside it was in 1938, when he visited Spain, Czechoslovakia and Italy. He went to France in 1939 and joined the Resistance movement in 1942. His first novel, *L'Étranger* (1942; Eng. trans., English title, *The Outsider*, U.S. title, *The Stranger*, 1946), illustrated his favourite themes—the irrational nature of the world and its absurdity and suicide—which were reasoned out in his essay *Le Mythe de Sisyphe* (1942; Eng. trans., *The Myth of Sisyphus*, 1955). After the liberation of Paris, his leading articles in the former underground newspaper *Combat* attracted considerable attention. They seemed to bridge the gap between journalism and literature.

Several plays followed: *Le Malentendu* (1944; Eng. trans., *Cross Purpose*, 1948); *Caligula* (1945; Eng. trans., 1948); *L'État de Sikge* (1948). In *Les Justes* (1950) Camus opposed the idealist and humanitarian to the realist and implacable revolutionary. Later he devoted himself to ambitious dramatic adaptations; e.g., William Faulkner's *Requiem for a Nun* (1956) and Dostoevski's *The Possessed* (1958).

In 1947 he published *La Peste* (Eng. trans., *The Plague*, 1948). An allegory of the Resistance, this novel describes in a sober classical style a plague epidemic in North Africa. It raises the problems of responsibility and commitment for the believer and the unbeliever. In 1951 *L'Homme révolté* (Eng. trans., *The Rebel*, 1953), a discussion of the ideology of revolution, had a mixed reception. Camus attempted to analyze the implications of ends and means. He examined the "individual terrorism" of the Russian nihilists and contemporary "state terrorism" ("irrational" with the Fascists, "rational" with the Communists). Camus' conception of revolt had been attacked by the surrealist leader André Breton. It was now severely criticized by the head of the French existentialists, Jean-Paul Sartre.

In 1956, with *La Chute* (Eng. trans., *The Fall*, 1957), a complex, ironical and semiautobiographical monologue, Camus seemed to return to his earlier pessimism. *Réflexions sur la Peine de Mort* (1958), written jointly with Arthur Koestler, was an appeal for the abolition of the death penalty.

Camus insisted that he was a moralist and not a philosopher. He was a characteristic representative of the 20th-century European rationalist tradition in which literature, ethics and philosophy overlap. Confronted with the impossibility of religious belief he tried to define the basic tenets of an atheistic humanism. Like so many French writers of the 1940s he was obsessed with what seemed to him the theoretical failures of Hegelianism and Marxism as well as the political errors and crimes of Communism. Camus' talent as an artist has rarely been seriously questioned. He was an acknowledged master of French prose. Many commentators, and especially those with an empiricist slant, have disputed his method of reasoning.

He died in a car accident near Sens (Yonne), France, on Jan. 4, 1960.

CANA, in Galilee, the scene of Jesus' first miracle (John ii) and an act of healing (John iv); also the home of Nathanael (John xxi, 2). It perhaps was situated at Kefar Kana, about 4 mi. N.E. of Nazareth, where Latin and Greek churches were built because the site was thought to be the ancient Cana, and where an Aramaic mosaic inscription found under the Latin church may indicate an ancient synagogue site. Much more likely it was situated at Khirbet Qana, about 9 mi. N. of Nazareth, where ruins, cisterns and Hellenistic and Roman pottery have been found.

(F. V. F.)

CANAAN, probably meaning "Land of the Purple," is the ancient name for Palestine, found both in the Old Testament and in earlier Egyptian and cuneiform writings. Originally, it would seem, it denoted only the coastal strip from Acre (Akko) northward, being derived from the fact that the principal commodity of that area was a rich purple dye extracted from the murex shellfish in the adjoining waters. In this stricter sense—sometimes retained by biblical writers (Num. xii, 29; Josh. v, 1; Isa. xxiii, 11; Zeph. ii, 5)—it was translated into Greek as Phoenicia, from *phoinix*, "purple." From early times, however, the name was also used in a wider and looser manner. Thus in the Amarna letters of the 14th century B.C. Canaan designates the entire Egyptian province of Egypt and lower Syria; in Gen. x, 19 it is said to extend from Hamath in the north to Gaza in the south, and in Josh. xi, 3 it includes territory east as well as west of the Jordan. On the other hand, "Canaanite" is employed at times in the Hebrew scriptures to denote only one element of a complex population (Gen. xiii, 7; xv, 21; Ex. iii, 18); sometimes, too, it is simply a synonym for "merchant" (Isa. xxiii, 8; Zech. xiv, 21; Prov. xxxi, 24; Job xl, 30).

History.—Modern knowledge of Canaanite history and culture is derived both from archaeological excavations and from literary sources. The former, conducted mainly during the 20th century, have brought to light the remains of many important Canaanite cities—e.g., Ai, Beth-shan, Byblos, Gezer, Hazor, Jericho, Lachish, Megiddo, Qatna, Shechem and Ugarit—as well as several of the temples and "high places" of the country. Among the literary sources, special importance attaches to the Amarna letters (see TEL EL-AMARNA)—a series of dispatches sent, in the 14th century B.C., by governors of Palestinian and Syrian cities to their Egyptian overlords—and to the celebrated Ras Shamra texts (discovered after 1929), which include, besides administrative records of the city of Ugarit, a series of mythological poems and cultic documents of the same period. These writings are in turn supplemented by references to the Canaanites in Egyptian literature (e.g., the narrative of a certain Wen-Amon's journey to Phoenicia, c. 1100 B.C.), in Mesopotamian texts and in the Old Testament, as well as by sundry information furnished (in garbled form) by later Greek and Roman authors.

The civilization of Canaan can be traced to Paleolithic times. Skeletons of Neanderthal type (*Paleanthropus palestinensis*), estimated to date about 30,000 B.C., have been discovered in caves near Mt. Carmel and the Sea of Galilee (Sea of Chinnereth); while at Wad' en-Natufeh, northwest of Jerusalem, and at a site in the vicinity of Athlit, evidence of a Mesolithic culture (c. 8300–5000 B.C.) has been unearthed. The people involved seem to have been of Caucasian race and to have possessed some knowledge of farming.

Settlement in fixed towns and villages first appears in the subsequent Neolithic Age (c. 7000–4000 B.C.). There was then, of course, no acquaintance with the use of pottery, but crude mud figures of animals have been unearthed in the lowest levels of Jericho. The following Chalcolithic Age (c. 4000–3000 B.C.), characterized by the use of pottery and copper, is represented by excavations at Megiddo and Beth-shan, and especially at Teleilat

el-Ghassul, north of the Dead sea. Typical of this period are houses of uncut stones; with walls made of mud brick and ornamented with geometrical designs. There is also evidence of the burial of infants in jars.

The introduction of metal in the Early Bronze Age (c. 3000–2100 B.C.) brought about a cultural revolution, marked by a decline in painted pottery, offset by the development of sculpture and metallurgy. Egyptian influence now presents itself, as attested especially at Ai in the central highlands and at Byblos on the coast of Syria. Greater protection against marauders is also characteristic of this period; at Xi, the settlement is girded by a triple wall, and at Megiddo by a massive bulwark. It was in this age that the Semites first entered the land.

With the Middle Bronze Age (c. 2100–1500 B.C.) the era of recorded history is entered. The dominant element of the population was now the Semitic Amorites (*q.v.*), who penetrated from the northeast and whose culture is represented especially by the discoveries at Mari (Tell el Hariri), on the upper Euphrates. These, however, were not the only invaders. The Egyptian Sesostri III descended upon the land c. 1350 B.C., capturing a city named S-k-m-m, identified by some scholars as Shechem; and a century later, Canaan was overrun by the Hyksos (*q.v.*), or "foreign princes," a mixed horde of Asiatics and others who appear to have swept down from the north and who succeeded also in dominating Egypt. Their settlements are distinguished by great rectangular enclosures surrounded by earthen ramparts—evidently designed to fence in the horses, which these invaders introduced into the country. The Hyksos appear to have established a more or less feudal form of society. Moreover, in the wake of the Aryan advance into the southern Caucasus, a people called the Hurrians (*q.v.*; the Horites of the Old Testament) now migrated southward into Syria and Palestine. Indeed, by the close of this period they had become so prominent an element of the population that the land now came to be designated by the Egyptians "the land of the Hurrians" (Huru).

The Late Bronze Age (c. 1500–1200 B.C.) is one of Egyptian domination. In the 15th century B.C., Thutmose III invaded Canaan and captured, among others, the cities of Joppa, Lydda, Gezer, Taanach and Megiddo, pushing northward as far as Aleppo. In the north, however, he came into contact with the powerful Hittites (*q.v.*) of Asia Minor and found his further progress impeded. In the following century, the Hittites took the initiative and marched southward as far as Byblos. Canaan now became something of a shuttlecock between the two empires, and its woes were further increased by constant incursions of marauders called Hapirue or Apiru. These people, a multi-ethnic group who for some reason possessed no full civil rights anywhere, are identified by many scholars with the original Hebrews, of whom the later Israelites were only one branch or confederation. The Xmaria letters contain several references to their marauding expeditions.

During the reign of Ikhnaton (1379–62 B.C.), a king more preoccupied with religious reforms than with the preservation of his empire, Egypt increasingly lost its grip on Canaan. An attempt to regain this power was made later by Seti I, who conducted campaigns there, and, more intensively, by his imperialistic son, Ramses II (1304–1237 B.C.). The Hittites, however, now offered formidable opposition. Ramses engaged them at Kadesh-on-the-Orontes (1288 B.C.), but the victory which the Egyptian records claim for him appears to have been somewhat academic. Within a few years, a treaty was concluded between the two powers, the Dog river (north of Byblos and south of Ras Shamra), being determined as the boundary between them. Thenceforth, however, Egypt's dominance waned, and at the end of the Bronze Age the Hittites collapsed under the assault of enemies from the north.

It was during the transition from the Late Bronze to the Early Iron Age—roughly, about 1250 B.C.—that the Israelites, a confederation of the Hebrews, entered Canaan, settling at first in the hill country and in the south. The land was now clear of Egyptian sovereignty, but the stronger cities were still in the hands of the native Canaanites (Judg. 1, 19, 21, 27–36). Archaeological investigation has shown that the scriptural account of the invasion represents a foreshortened version of events that had been

FROM "WESTMINSTER HISTORICAL ATLAS TO THE BIBLE"
LAND OF CANAAN BEFORE ISRAELITE CONQUEST

taking place during the preceding two centuries and that Jericho, for instance, must have fallen to earlier Hapirue invaders, not to the Israelites under Joshua. Israel's invasion, says the Book of Judges, was opposed not only by the Canaanites but also by Moabites, Midianites and Ammonites from the east.

In the following century, Canaan suffered further invasion at the hands of the Philistines (*q.v.*), who appear to have come from Crete, in alliance with other "sea peoples." Although they were headed off from Egypt by the vigorous measures taken against them by Ramses III, some of them managed nonetheless to gain a foothold on the southern coast of Canaan, where they eventually established a coalition of five city-states (Gaza, Ascalon, Ashdod, Ekron and Gerar), each ruled by a "tyrant" or headman. (It is from this people that the name Palestine is derived, though that name was later extended by the Romans to cover the entire country.) The Philistines were technologically in advance of the Israelites, having already learned the use of iron (*cf.* Josh. xvii, 16; Judg. i, 19). For a time they endeavoured to maintain their superiority by denying to their rivals the services of blacksmiths (I Sam. xiii, 19 ff.). Eventually, however, when the increasing extension of their power gave real cause for alarm! the Israelites rallied against them until, under the leadership of David, the main power of the Philistines was effectively broken. At the same time, the native Canaanites too were vanquished, and Jerusalem was wrested from them. Thenceforth Canaan became, to all intents and purposes, the Land of Israel. To be sure, an attempt was made at Sidon, around 1000 B.C., to revive the ancient civilization and, since the Canaanites were extensive maritime traders, they established colonies in Cyprus, Sicily, Sardinia and other parts of the hediterranean area, even voyaging so far as Spain. Most of

these colonies, however, collapsed within 200 years, and although some of those that survived proudly affected the ancient name even down to late Roman times; Canaan in the old sense of the term had by then long ceased to exist.

Culture and Religion.—Canaan stood at the crossroads of several cultures, and throughout its recorded history it manifests in its art and literature a mixture of many elements. Figurines of its principal goddess appear now in Egyptian, now in Mycenaean and now in Cypriotic styles, and other deities are often portrayed alongside Egyptian symbols. Its pottery likewise shows the influence now of Egypt, now of Crete. Among the Ras Shamra texts is a Canaanite translation of a Hurrian myth, while elsewhere on Canaanite soil fragments of the Mesopotamian Gilgamesh epic have come to light.

Most of what is known about Canaanite religion is derived from a series of tablets, in alphabetical cuneiform script, discovered after 1929 at Ras Shamra, site of ancient Ugarit, on the north coast of Syria. The tablets themselves were inscribed in the 14th century B.C., but their contents, being traditional, are doubtless far older. The principal god was El, but the effective disposition of rainfall and fertility was delegated to Baal, or Hadad. Other important gods were Resheph, lord of plague and the nether world, and Kothar, the divine craftsman. Goddesses included Asherah, consort of El, Astarte and the virgin Anat.

The principal myth relates the combat of Baal, as genius of rain, against Yamm, lord of the sea and rivers, and Mot, the power of death and sterility. It is basically an allegory of the seasons. Another myth describes how a mortal youth named Aqhat came by chance into possession of a bow belonging to the goddess Anat. Refusing to surrender it, he was put to death. His death was avenged: however, by his sister, who slew the goddess' hired assassin. Aqhat was apparently resuscitated. This story has been explained as a Canaanite version of the classical myth of Orion. A third myth relates the adventures and misadventures of a king named K-r-t in search of a bride and offspring. The Canaanite myths throw light on several passages of Old Testament poetry, previously obscure. They make mention, for instance, of the dragon Leviathan. Similarly, figures of griffins flanking representations of Canaanite sacred chests at last clarify the identity of the cherubim who similarly protected the Israelitic Ark of the Covenant (*see* ANGEL).

Language and Script.—The language of the Canaanites may be described most conveniently as an archaic form of Hebrew, standing in much the same relationship to that of the Old Testament as does the language of Chaucer to modern English.

The Canaanites are the first people, so far as is known, to have used an alphabet. A form of script recognized by most scholars as the parent of the Phoenician, and thence of the Greek and Latin alphabets; has been found in Late Bronze Age levels at Lachish. Beth-shemesh and elsewhere, while at Ras Shamra a curious cuneiform alphabet was in use. Furthermore, a peculiar form of writing, probably syllabic but as yet undeciphered, occurs on inscriptions of the Late Bronze Age from Byblos (*see* ALPHABET). Side by side with these innovations, however, the traditional syllabic cuneiform of Mesopotamia was regularly employed. *See* also PALESTINE: *History*; PHOENICIA.

Gaster in *Thespis: Ritual, Myth and Drama in the Ancient Near East*, 2nd ed. (1960).

Reports of archaeological work relating to Canaan appear regularly in the *Bulletin of the American Schools of Oriental Research*.

(T.-H. G.)

CANACHUS, a Greek sculptor of the city of Sicyon in the latter part of the 6th century B.C. He made two great statues of Apollo with a stag and a bow, one in bronze for the temple at Miletus and one in cedarwood for Thebes. The former is represented on coins of Miletus

CANADA is the largest self-governing country in the Commonwealth of Nations. although, with a population of 18,238,247 in 1961, it is by no means the most densely populated. With a total area, including land and fresh water, of 3,851,809 sq.mi., it is the largest country in the western hemisphere, being 6.5% larger than the United States (3,615,208 sq.mi.) and 17% larger than Brazil (3,287,195 sq.mi.). The only national territory in the world larger than Canada is the U.S.S.R. (8,649,489 sq.mi.).

TABLE I.—*Area of Canada*
(in square miles)

Provinces and territories	Land	Water	Total
Newfoundland	143,045	13,140	156,185
Prince Edward Island	2,184	—	2,184
Nova Scotia	20,402	1,023	21,425
New Brunswick	27,835	519	28,354
Quebec	523,860	71,000	594,860

Mackenzie	493,225	34,265	527,490
Total	3,560,238	291,571	3,851,809

Canada comprises the northern half of the continent of North America and its adjacent islands, except Alaska, a state of the United States. Its boundary on the south is parallel of latitude 49°, between the Pacific ocean and Lake of the Woods, then a chain of small lakes and rivers eastward to the mouth of Pigeon river on the northwest side of Lake Superior, and the Great Lakes with their connecting rivers to Cornwall, on the St. Lawrence. From there eastward to the state of Maine the boundary is a line corresponding to latitude 45"; then an irregular line partly determined by watersheds and rivers divides Canada from Maine, terminating on the Bay of Fundy. The western boundary is the Pacific on the south, an irregular line following mountain crests a few miles inland from the coast along the panhandle of Alaska to Mt. St. Elias, and the meridian of 141° to the Arctic ocean. On the east are the Atlantic ocean, Davis strait, Baffin bay and the waters separating Ellesmere Island from Greenland; on the north lies the Arctic ocean. The most northerly point of land in Canada is Cape Columbia at 83° 06' N., the most southerly is Middle Island in Lake Erie at 41° 41' N. From east to west, Canada extends from Cape Spear (52° 37' W.) to the Alaska boundary (141° W.). Canada is divided into ten self-governing provinces and two territories which are administered by the federal government. The names and areas of these divisions are given in Table I. For historic sites *see* separate articles on the provinces and territories (*See* also NATIONAL PARKS.)

Following are the main sections and divisions of the article:

I. Physical Geography

I. PHYSICAL GEOGRAPHY

1. Geological Structure. — Canada contains some of the oldest rocks in the world. They are found near the surface in an area of 1,850,000 sq. mi. surrounding the depression of Hudson bay, known as the Canadian shield. Belonging to the Pre-Cambrian, these rocks include granites, gneisses, schists, quartzites and many other crystalline rocks. These rocks contain many valuable mineral ores yielding gold, silver, platinum, copper, nickel, cobalt, iron, lead and zinc, making Canada one of the greatest mining countries in the world.

Rock structures indicate that there were once great chains of mountains in the shield, but by the end of Pre-Cambrian time they had all been worn down to a relatively low level which was later invaded by the sea. Somewhat later the northeastern portion was tilted up so that, in northern Labrador and Baffin Island, it rises to more than 5,000 ft. above sea level.

The weathered debris from this ancient land was deposited around it to form the stratified sandstones, limestones and shales comprising the Paleozoic system. In the central part of the continent where they rest on the unyielding rock mass of the shield they have been deformed relatively little, but along the southeastern edge they have been pushed and folded to form the Ap-

alachian mountains. To the west and southwest, later Mesozoic sediments were laid down upon large areas of the Paleozoic. Both the Paleozoic and Mesozoic rocks contain coal, petroleum and natural gas, gypsum, salt, potash and other useful minerals adding greatly to Canada's natural wealth.

Toward the end of Mesozoic time there was crustal unrest along the western margin of the continent. Under tremendous pressure, thick rock formations were folded, faulted and upraised to form the Cordilleran region, 500 mi. wide from the Albertan foothills to the open Pacific, and containing the lofty peaks of the Rocky mountains, the Columbia mountains, the Coast mountains and the mountains of Vancouver Island.

In the Mesozoic also, and perhaps somewhat earlier, there was crustal unrest along the northeastern edge of the Canadian shield giving rise to the Innuitian ranges of the northern arctic islands.

In parts of western Canada, particularly in southern Alberta, some younger Tertiary rocks, derived from the erosion of the early Rocky mountains, were laid down. They also have been eroded but some remnants of Tertiary gravel remain in the upper levels of the Cypress hills and in the Rocky mountain foothills. Thus the hard old mass of crystalline rocks, the Canadian shield, which gives shape and permanence to so much of North America, may in places be buried by as much as 10,000 ft. of younger strata. (See also PRE-CAMBRIAN TIME.)

Canada was almost completely glaciated during the Pleistocene, thus the surface deposits are composed of either unsorted rock debris, or till, or water sorted gravels, sands, silts and clays. The coarser materials are often found associated with the courses of the ancient melt water rivers, while the finer materials settled out on the floors of glacial lakes. Many of the best agricultural areas in both eastern and western Canada are to be found on the former floors of Lake Agassiz and other ancient lakes. (See PLEISTOCENE EPOCH.)

2. Surface Relief and Land Form. — Canada may be likened to an irregular basin, the lowest part of which is occupied by Hudson bay. Almost all around this central depression lie the hard old rocks of the Canadian shield, which locally may have a rough and rocky surface, but low and even, distant horizons. South and west of the Canadian shield lie vast plains underlain by horizontally bedded rocks. The lowlands along the St. Lawrence and lower Great Lakes, and the lowlands of southern Manitoba, have large areas of little relief, and for the most part are less than 1000 ft. above sea level. The Great Plains of Saskatchewan and Alberta are from 2,000 to 3,500 ft. above sea level. Vast areas have little or no relief, except that provided by the valleys of the Saskatchewan river system. Other areas such as the Cypress hills and Wood mountains have a considerably rougher surface.

The greatest relief is to be found in the western rim of the Canadian basin where the young Cordilleran mountain systems have many peaks between 10,000 and 20,000 ft. above sea level. The eastern rim of Canada is also mountainous, although not so elevated as the west, for the ranges are older and more worn down. Nevertheless, some of the peaks in southeastern Quebec reach to about 1,000 ft., while the Torngats of Labrador are from 1,500 to 5,500 ft. high. The northeastern part of the rim is even higher, with peaks in the United States range of Ellesmere Island ranging up to 9,600 ft.

3. Lakes and Rivers. — The surface of Canada is well marked with lakes and rivers. Besides the Great Lakes, of which Canada's share is nearly 33,000 sq. mi., there are ten others varying from 1,600 sq. mi. to 12,000 sq. mi. in area; the three largest being Great Bear (12,000 sq. mi.), Great Slave (11,170 sq. mi.), and Winnipeg (9,094 sq. mi.). There are more than 110 lakes with areas between 100 and 1,500 sq. mi. The total extent of surface water could not be realized until recent years when aerial photography revealed tens of thousands of lakes of all shapes and sizes. Accurate mapping of 11,388 sq. mi. on the Canadian shield disclosed no less than 10,500 small lakes.

The lakes often contain many islands; thousands can be counted in Georgian bay, Lake of the Woods and Island lake. Small lakes are often rimmed with marsh and are slowly filling with peat to become bogs, or muskegs as they are known throughout northern

TABLE II.—Drainage Areas

Drainage basin	Area drained (square miles)	Per cent of total area
Atlantic drainage	695,370	18.1
Hudson bay drainage	1,160,420	30.1
Arctic mainland drainage	941,280	24.5
Pacific drainage	387,210	10.1
Gulf of Mexico drainage	8,600	0.2
Arctic islands	655,000	17.0

Canada. It is, in fact, difficult in some cases to distinguish between lake and marsh. It is probable that water surfaces account for about 10% of Canada's total area.

The lake basins, great and small, are largely the result of glaciation. In some places the ice gouged out small rock basins while in others it overdeepened existing valleys, at the same time, perhaps, leaving dams of glacial moraine across them. Such appears to be the nature of the long mountain-valley lakes of British Columbia. The shallow lakes and sloughs of the prairie provinces result from the uneven surface of the glacial drift.

In most of Canada rainfall exceeds evaporation and plenty of water is available to fill lakes at all times, but in the southern part of the prairies and in the southern interior of British Columbia the summers are dry and small lakes may temporarily be transformed into alkali flats.

The surface drainage, with the exception of very small areas of interior drainage, may be divided into drainage areas as shown in Table II.

The largest, and longest, river in the arctic drainage area is the Mackenzie. Measuring 2,635 mi. from the Arctic ocean to its most distant source in the Rocky mountains, this river drains an area of approximately 700,000 sq.mi. Its chief tributaries are the Peace and the Athabasca. The Mackenzie waterway is navigable for 1,644 mi. for tugs, barges and river boats which serve the fur trading posts and mining camps in its area.

The largest rivers draining to the Pacific ocean are the Yukon, the Fraser and the Columbia. The Yukon has a length of 1,979 mi., of which the Canadian section is 714 mi. Long of service as a transportation route; the river has a large power potential. The Fraser is 850 mi. in length. It contains the most important spawning grounds of the Pacific salmon. Its deep valleys also have provided the corridors for the building of the Canadian Pacific and Canadian National railways to Vancouver, as well as routes for provincial highways. The Columbia (total length, 1,214 mi.) has a course of 459 mi. in Canada. The Kootenay, Arrow and Okanagan lakes in its basin were important for navigation for many years. The Columbia drainage is also an important source of power.

The important river systems draining into Hudson bay include the Dubawnt, Churchill, Nelson; Albany, Moose, Eastmain and Nottaway. All of these, and many smaller ones, were well traveled by the *vogayeurs* of fur trading days. The Churchill provides power for the Flin Flon mines. The length of the Nelson river, to the most distant source of the Saskatchewan in the Rocky mountains, is 1,600 mi. It drains an area of 344,550 sq.mi. in the interior of Canada and the U.S. In its mountain headwaters, and in its passage over the Canadian shield, it has important power sites. It is also used for irrigation in Alberta and Saskatchewan.

The largest river in the Atlantic drainage is the St. Lawrence. It drains an area of 306,900 sq.mi. and has a total length of 1,900 mi. The St. Lawrence and the Great Lakes provide a waterway into the heart of the continent which, since the opening of the St. Lawrence seaway, allows the entrance of large ocean vessels. The St. Lawrence and its tributaries provide several million horsepower of electrical energy for Canadian industries.

4. The Coast Line and Coastal Waters.—Canada has probably the most extensive and irregular coast line of any country in the world. On three oceans and Hudson bay, it totals about 60,000 mi., estimated as follows:

Mainland.—Atlantic, 6,110 mi.; Pacific, 1,580; Hudson strait, 1,245; Hudson bay, 3,155; Arctic, 5,770; total, 17,860 mi.

Islands.—Atlantic, 8,680 mi.; Pacific, 3,980; Hudson strait, 60; Hudson bay, 2,305; Arctic, 26,785; total, 41,810 mi.

The great length and irregularity of the coast indicates that the continental mass has been drowned by a rising sea level. Around

the margin of much of the continent there are large areas of shallow sea covering a continental shelf.

Off the eastern coast, the continental shelf extends about 250 mi. to the southeast of Newfoundland to form the Grand Banks, long noted as a major fishing area. A similar shelf off the southeast shore of Nova Scotia is crowned by the low, sandy crescent of Sable Island, on which many vessels have been wrecked. Fishing banks are found also in the Gulf of St. Lawrence and on the Labrador coast. There are also extensive continental shelves adjacent to the arctic islands. These have become noted for their oil reserves.

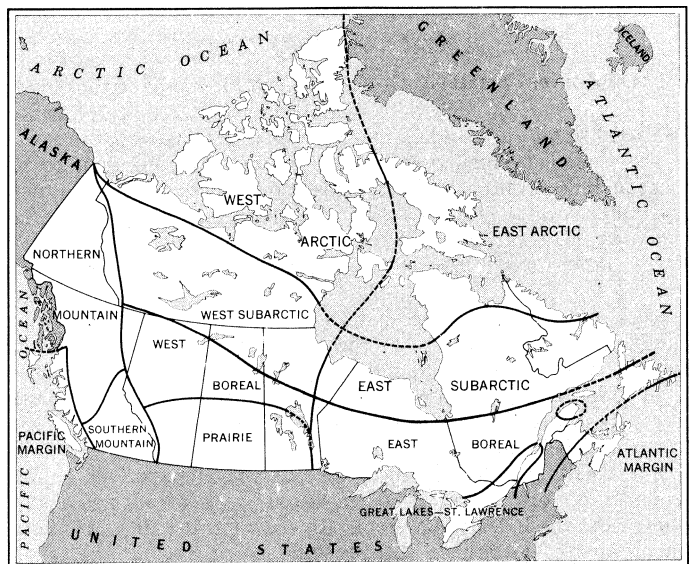

Cold arctic water tends to move south along the east coast, meeting the Gulf stream drift near the edge of the Grand Banks. This region thus becomes favourable for the growth of plankton upon which various fishes feed, while at the same time it is rendered subject to extensive surface fog. Drifting ice is also a hazard to navigation in spring and early summer.

Hudson bay is always cold, thus having an unfavourable influence on the climate of eastern Canada. Currents in the bay move in a counterclockwise direction, thus drifting the ice through the south side of Hudson strait into the Atlantic by the end of July. The Hudson bay ports are open to navigation from early August to mid-October.

The season of navigation decreases northward, varying with the winds and weather of the particular year, but the ice of the northwestern islands of the Queen Elizabeth group rarely breaks up, even in summer. With the exception of the southern coasts of Nova Scotia, New Brunswick and Xewfoundland, the whole of the eastern coast is icebound in midwinter.

The Pacific coast does not have a broad continental shelf, but it has many bays and islands formed by the flooding of the margins of the western mountain systems. The waterway from Puget sound northward through the island-sheltered Inside Passage forms the steamship route to Alaska, as well as being the famous Pacific salmon fishing ground. The western coast of Canada is never icebound because of the drift of warm water from the Pacific ocean.

5. Climate.—The climate of Canada is under the influence of three great air masses. Cold and usually dry air mores southward from the arctic regions by way of the Mackenzie valley and Hudson bay. In winter this very cold air reaches the Great Lakes and may penetrate far south into the United States as a "cold wave." In summer such outbreaks are not so frequent and tend to move eastward through Hudson strait. Warm, moist air from the Gulf of Mexico and the Atlantic moves north to cover much of southeastern Canada in the summer. In winter this warm air may appear as a "thaw" in southern Ontario and the maritime provinces. The third great air mass is the mild, moist air from the North Pa-

D. F. PUTNAM

FIG. 1.—CLIMATIC REGIONS OF CANADA

cific which impinges almost continually on the coasts of British Columbia and Alaska, bringing heavy winter precipitation. Crossing the mountains, it brings cloudy weather and scattered precipitation to the interior plains. Sometimes a fourth air mass, originating over the deserts of southwestern United States, may invade southern Canada in midsummer causing extended hot dry periods.

On the basis of temperature and moisture conditions, and the length of the growing season, Canada may be divided into climatic regions as shown in fig. 1.

Arctic climates are found north of the tree line, which is generally fairly close to the line of 50° F. average temperature for July. Low temperatures are compensated somewhat by long days. In the northern arctic the sun does not set for many weeks. On the other hand, the long, dark winters are bitterly cold. Permafrost, or permanently frozen subsoil, is almost universal. Much of the arctic gets only 5 to 10 in. of precipitation per year, most moisture being received in the eastern section. (See ARCTIC. THE: *Climate*)

Subarctic climates lie south of the tree line but have less than five months in which the average temperature is more than 43° F. Winter cold is severe and in much of the area the subsoil remains permanently frozen. The western subarctic may get 10 to 12 in. of precipitation annually while the eastern area gets somewhat more, especially in the form of snow.

Boreal climates have average July temperatures above 60°, and growing temperatures for more than five months. The western section, with a summer rainfall maximum, gets from 12 to 14 in. per year while in the east, with much heavier snowfall: the yearly total may be two or three times as much. This is the area of Canada's pulpwood forests.

In the Atlantic climate, midwinter monthly temperatures average from 15° to 25° F. with about three months above 60° in the summer. Total precipitation ranges from 40 to 55 in. per year, the maximum being in the colder half of the year. From eight to ten feet of snow may fall per winter in some parts of New Brunswick and Newfoundland. The Atlantic coast is noted for summer fogs.

The Great Lakes-St. Lawrence region has much the same winter conditions as the Atlantic, but spring comes earlier and the summer is longer and warmer. The July temperature is 70° at Montreal and Toronto and somewhat higher in the interlake peninsula of southern Ontario. Precipitation is almost uniform from month to month, with the annual average ranging from 30 to 40 in. in different parts of the area. There is, however, some chance of summer drought.

The prairie climate has a moderate supply of moisture, normally ranging from 12 to 16 in. per year, most of it falling as summer rain. Midsummer temperatures average about 65° F., while the midwinter average at Winnipeg, Prince Albert and Edmonton is around 0° F.

On the Pacific margin the winters are mild and wet! with temperatures seldom below freezing. Average summer temperatures seldom rise much above 60° F. Summer has less rain than winter with a tendency toward drought in the southern parts. Much of the area gets more than 80 in. of precipitation per year.

The western mountains have an extremely complicated set of climatic conditions, depending upon elevation and exposure to rain-bearing winds. High mountains, of course, have snow all the year round. On the other hand: summers are warm and dry in the valleys between the southern ranges. July temperatures may average 70° F. but the total rainfall may be only 10 in. per annum in the southern part of the Okanagan valley.

Much of Canada is too cold to be a desirable human habitat, while only the southern portion of the country has sufficient summer warmth and length of growing season to support a successful agriculture.

6. Vegetation. — The pattern of vegetation is in very close accord with the wide variation in climatic conditions. In general there are three great plant associations: forest grassland and tundra. Botanists, foresters and plant geographers, however, usually recognize 13 subdivisions, or vegetative regions.

Acadian.—Prince Edward Island, Nova Scotia and most of New Brunswick are characterized by forests of red, white and black

spruce, balsam fir, white pine, hemlock, sugar maple, beech and yellow birch as well as many lesser species

St. Lawrence-Great Lakes.—Covering a large part of southeast Canada, this area formerly had magnificent stands of white pine which gave rise to the early Canadian timber trade. There were also excellent stands of sugar maple, beech, yellow birch, hemlock, red pine, white cedar, elm, ash and, in some areas, red and white oak. Much of the lowland has been cleared for agriculture but second growth forest is found throughout the southern fringe of the Canadian shield.

Deciduous.—A small area in southwestern Ontario has deciduous hardwood forests resembling those of the adjoining United States. Sugar maple, beech, basswood, red and white oak and butternut hickory are characteristic. More rarely also, such southern species as black walnut, tulip tree, Kentucky coffee tree, mulberry, sycamore and sassafras are found.

Boreal.—North of these areas, extending from Newfoundland to Alaska, is a forest region in which coniferous needle-leaved trees are dominant. Among them are white and black spruce, balsam fir and jack pine (*Pinus banksiana*). There are large, poorly drained areas filled with a growth of sphagnum moss and other water-loving plants forming bogs, or muskegs.

Mixed Woods.—On the southern border of the Boreal region, stretching from Manitoba to British Columbia, the forest contains a large admixture of deciduous broad-leaved trees, mainly various species of aspen and birch. This belt is usually known as the mixed woods.

Parkland or Aspen Grove.—Between the mixed woods and the open prairie is a belt in which the grassland is interspersed with "bluffs," or small groves, of aspen and other deciduous trees.

The Prairies.—Stretching from the Red river (Red River of the North) in Manitoba to the foothills of the Rocky mountains in Alberta is the northern portion of the interior grassland of North America, known to Canadians as "the Prairies." Botanists sometimes subdivide the Prairies into the tall grass, mixed grass and short grass belts, the distribution patterns being closely correlated with the amount and reliability of rainfall.

Rocky Mountain or Subalpine Forest.—On the slopes of the Rocky mountains, from 3,500 to 6,000 ft., there is a coniferous forest with such species as Engelmann's spruce, alpine fir and lodgepole pine. Higher subalpine elevations have scrub forests and alpine tundra.

Columbia Forest.—Influenced by a belt of higher rainfall in the Columbia mountains is a belt of forest containing Engelmann's spruce, western red cedar, western hemlock and Douglas fir.

Montane Forest.—Found in the dry southern interior of British Columbia, the montane forest is characterized by ponderosa pine and is often interspersed with open grasslands.

Pacific Coast Forest.—The heaviest forest growth in Canada is found on the west-facing slopes of the mainland, Vancouver Island and other Pacific islands. There, such coniferous species as western hemlock, western red cedar and Douglas fir grow to tremendous size.

Subarctic Forest.—Constituting the northern border of the Boreal region and effecting a transition to the tundra is a belt of inferior coniferous forest, eventually giving way to small stunted growths which have caused this belt to be known as "the land of little sticks."

Tundra.—More than one-third of Canada is composed of treeless plains, covered with lichens, moss, sedges and other low-growing plants. Permafrost underlies most of the area, thawing to a depth of one to three feet each summer.

Natural vegetation is an indicator of climate. The mild winters, warm summers and adequate moisture of the region near Lake Erie encourage the growth of many deciduous hardwood trees. The deep, cold waters of Lake Superior, on the other hand, give a boreal character to its shores. On the plains of the interior, the dominating factor is moisture supply. In southern Saskatchewan and Alberta, where rainfall is 10 to 12 in. per year and summer evaporation is high, the natural vegetation consists of short grasses, sage and cactus. Northward, through the mixed grass and tall grass prairies, rainfall increases somewhat and evaporation de-

creases. In the parkland and the border of the forest, precipitation is 15 to 16 in. but is relatively more effective because of lessened evaporation. Much of the northern forest belt has no greater rainfall but its evaporation is still lower. In the mountains zonation of vegetation is influenced by altitude. Valley bottoms often have deciduous trees, lower mountain slopes have good commercial stands of conifers; the cool upper slopes have a rather stunted growth and finally the tree line is defined by the high winds and intense cold of the peaks.

7. Soils.—Like the vegetation, the soils of Canada may be considered in three great regional groups: tundra soils, pedocals or grassland soils, and the podsols and podsollic soils of the forested area.

Tundra soils have not been investigated fully. They are underlain by permafrost and the shallow surface layer which thaws in summer is chiefly composed of organic matter and usually is poorly drained.

The eastern podsols in the more humid environment of the Atlantic provinces are often intensively leached and somewhat infertile. Somewhat less leached brown podsollic soils are found in the Appalachian uplands of Quebec and on the southern fringe of the Canadian shield in Quebec and Ontario. Gray-brown podsollic soils in the lowlands of the lower Great Lakes and St. Lawrence developed on glacial and lacustrine materials, under a cover of mixed, deciduous forest. These are the most fertile soils in eastern Canada and helped to promote a vigorous and successful agriculture. The northern podsol region comprises the southern half of the Canadian shield. Most of its parent materials are acidic and the debris from the boreal coniferous forest also tends to have an acid reaction. This region contains large areas of rocky soils and much poorly drained land. Some agricultural settlement has taken place on the smooth terrain of the clay belt in western Quebec and northeastern Ontario. In the mixed woods region the soils are podsollic but not so highly leached as the true podsols; they are known as gray-wooded soils.

Three well-marked soil zones are recognized, in the grasslands of western Canada. Brown soils are found under the short grass vegetation of the dry area in southwestern Saskatchewan and southeastern Alberta. East, north and northwest of this dry belt is a crescent of dark brown soils, more or less agreeing with the area of mixed grass vegetation. The dark brown soil zone is the most noted wheat producing area in Canada. Still outward, another concentric zone, the black soil area, has a tall grass cover because of greater effectiveness of the moisture supply. Deep, and rich in organic matter, these are among the most fertile soils in Canada. Wheat is grown there but mixed farming, with oats, barley and livestock, is increasingly important.

The soils of the Cordilleras, as in any mountain area, are complex, owing to the variety of slope, climate and vegetation. Some areas of grassland soils in the southern interior valleys of British Columbia have been turned into highly successful fruit farms under irrigation and there is some mixed farming on the gray-wooded soils further north.

While only a relatively small area of Canada has been subject to detailed soil surveys, enough reconnaissance work has been done to show that most of the good agricultural soils are already in use. (D. F. Pr.)

8. **Animal Life.**—The larger animals of Canada are the musk ox and the caribou of the barren lands, both having their habitat in the far north; the caribou of the woods, found in all the provinces except Prince Edward Island; the moose, with an equally wide range in the wooded country; the Virginia deer, in one or other of its varietal forms, common to all the southern parts; the black-tailed or mule deer and allied forms, on the western edge of the plains and in British Columbia; the pronghorn on the plains; and small herds of the once plentiful bison in northern Alberta. The wapiti, or American elk, at one time abounded from Quebec to the Pacific, ranging as far north as the Peace river, but is now found only in small numbers from Manitoba westward.

In the mountains of the west are the grizzly bear and the black bear. The black bear is also common to most other parts of

Canada; the polar bear everywhere along the arctic coasts. The large or timber wolf is found in the wooded districts of all the provinces, and on the plains there is the coyote. In British Columbia roams the puma or cougar, and generally distributed in wooded areas are the common fox and its variety, the silver fox, also the lynx, beaver, otter, marten, fisher, mink, skunk and other fur-bearing animals. The wolverine is largely confined to the southern edges of the tundra, which is also inhabited by the arctic fox. Mountain, plain and arctic hares and rabbits are plentiful or scarce in localities according to seasons or other circumstances. In the mountains of British Columbia are the bighorn or Rocky mountain sheep and the Rocky mountain goat, while sheep of two or three other species also are found, from nearly pure white in the north to black in certain areas in the southern Canadian Rockies.

The birds of Canada are mostly migratory, and are those common to the northern and central states of the United States. Wild fowl are numerous, particularly in the west, their breeding grounds extending from Manitoba and the western prairies north to Hudson bay and the arctic lowlands. The several kinds of geese, including the Canada goose, the arctic goose or wavy, the brant and others, all breed in the northern regions, but are found in great numbers throughout several provinces, passing north in the spring and south in the autumn. There are several species of grouse, including the ruffed grouse, ptarmigan and sharp-tailed grouse of the plains. In certain parts of Ontario the wild turkey formerly occurred, and in the 1950s game conservationists successfully transplanted them from the southern Atlantic coast of the United States; the quail, or bobwhite, still inhabits the southern part of the province.

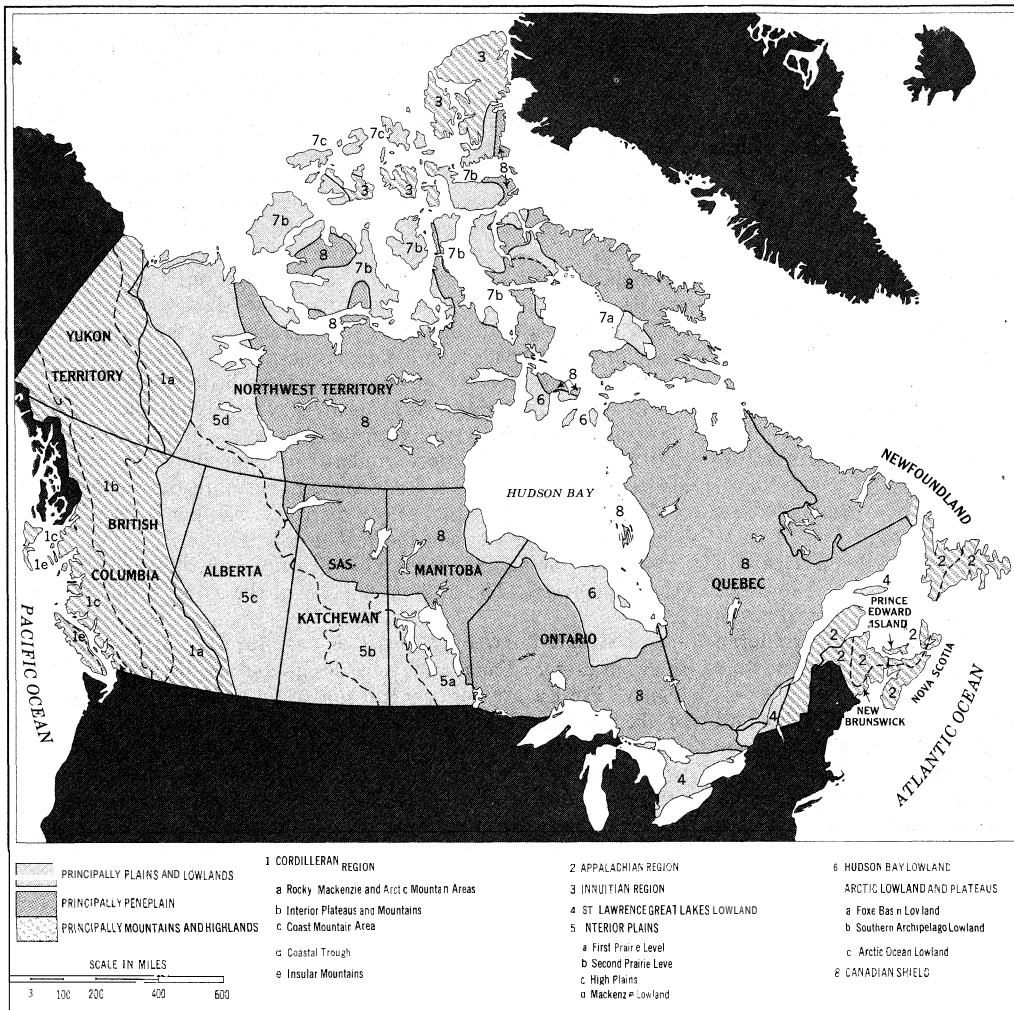

The golden eagle, bald eagle, osprey and a large variety of hawks are common in Canada, as are the snowy owl, the horned owl and other owls. The raven is found only in the less populated districts, but the crow is common everywhere. Songbirds are plentiful, especially in the wooded regions, and include the American robin, oriole, thrushes, the catbird and various sparrows: while the introduced English sparrow has multiplied excessively and become a nuisance in the towns. Spreading rapidly are the European starling in the east and the Japanese starling in British Columbia. The smallest of the birds, the ruby-throated hummingbird, is found everywhere, even up to timber line in the mountains. Sea birds include a variety of gulls, terns, guillemots, cormorants and ducks, and in the Gulf of St. Lawrence the gannet is abundant. Nearly all the sea birds of Great Britain are found in Canadian waters or are represented by closely allied species.

The Migratory Birds Convention act of 1923 involved an agreement between the United States and Canada for the protection of bird life. (E. M. W.; J. R. Dv.; J. L. R.)

II. GEOGRAPHICAL REGIONS

Canada is such an extremely large area that it cannot be comprehended properly unless it is divided into significant parts. The political boundaries of the provinces and territories, however, tend to be rather arbitrary and artificial. In fact, some of them are simply parallels of latitude and longitudinal meridians, which cut indiscriminately across both natural and human areas. The geographical pattern, on the other hand, is an integration of natural and human factors; hence it follows that in some cases political boundaries may subdivide geographical units, while in other cases a political unit may contain two or more distinct geographical regions.

Some regions of Canada show a high degree of uniformity or homogeneity, and the landscapes are recognizably similar throughout. In other cases visual similarities are not so strong, but the region may be distinguished by reason of the ties which bind the peripheral parts to the central core area. Some regions are remarkably distinct, and their boundaries clear cut; in other cases there exist broad transition zones. One of the strongest clues to the existence of the geographical regions of Canada may be found in the pattern of population distribution. In the sparsely populated areas, however, regional differentiation must be based upon physical criteria. Thus the physiographic map of Canada (fig.

ADAPTED FROM "THE CANADA YEAR BOOK, 1960," DOMINION BUREAU OF STATISTICS, OTTAWA, CANADA

FIG. 2. — PHYSIOGRAPHIC REGIONS OF CANADA

2) gives only a first approximation of the geographic pattern. Such a large geomorphic unit as the Canadian shield must be divided on the basis of climate, vegetation and human use; so, also, must the interior lowlands and the Cordilleran region.

1. Atlantic Region.— The provinces of New Brunswick, Nova Scotia, Prince Edward Island and Newfoundland are together known as the Atlantic provinces. The Atlantic region, for present purposes, however, does not include Labrador while, on the other hand, it does include the Gaspé area of Quebec.

Physiographic relationship is strong throughout; the region is all part of the northern extension of the Appalachian hilly region of eastern North America. The folded rock structures of its worn-down mountain ranges trend northeastward, paralleling the Atlantic coast. The summit elevations of the Shickshock mountains of the Gaspé peninsula exceed 4,000 ft. while the Long range of Newfoundland and the central highland of New Brunswick have elevations of more than 2,600 ft. above sea level. Southeastern Quebec, New Brunswick, Cape Breton Island and Newfoundland all contain extensive, rolling, plateaulike surfaces above 1,000 ft. Important, also, are the crustal depressions such as the Bay of Fundy and the maritime geosyncline which contains the Gulf of St. Lawrence and the adjoining lowlands of Prince Edward Island, northern Nova Scotia and eastern New Brunswick.

Prince Edward Island is nearly all farmland, and good farms are found in the Annapolis valley and the St. John valley, but by far the greater part of the region is still forest covered and forest products are important in the regional economy. Coal mines are in operation in Cape Breton, northern Nova Scotia and central New Brunswick; base metals are found in northeastern New Brunswick, while most of the world's asbestos is obtained in southeastern

Quebec. The outstanding feature of the region, however, is its long and sinuous coast line. No part of the area is more than 100 mi. from salt water. This influence is strongly reflected in the distribution of the human population. The largest cities, Halifax, N.S., Saint John, N.B., and St. John's, Newfoundland, are noted seaports. Most of the other cities and towns also are or have been, ports or fishing centres, and fishing is still an important enterprise. On the other hand, large areas of the interior uplands are practically uninhabited.

2. St. Lawrence-Great Lakes Lowland.— The St. Lawrence waterway provided the early European settlers with the best route to the interior and it is not surprising that the adjoining lowlands should have become the wealthiest and most populous part of the country, its economic and political core region. Underlain by nearly horizontal and relatively undisturbed limestones, shales and sandstones of Paleozoic age, its surface is composed of Pleistocene glacial till and the sands, silts and clays deposited during the high-level phases of the Great Lakes and the marine invasion of the St. Lawrence plain. Jutting through the floor of this plain, eight ancient volcanic plugs form the Monteregian hills and provide a welcome contrast in relief. Although quite

stony in some areas and poorly drained in others, the St. Lawrence-Great Lakes lowland affords the largest stretch of arable land in eastern Canada. A closely settled area of about 70,000 sq. mi., it provides about one-third of Canada's agricultural wealth. Mixed crop and livestock farming is the general rule with emphasis on dairying near the large cities, but there are also areas producing fruits, vegetables, tobacco, sugar beets and other special crops.

The St. Lawrence-Great Lakes lowland contains over 60% of Canada's population. Here are located the metropolitan cities of Montreal (2,060,000) and Toronto (1,800,000) as well as 50 smaller cities. (See also *Population*, below.) More than 70% of the population is urban, depending for employment upon manufacturing, trade and service industries. Being attributable to the strategic location of the area and the development of its communications, this economic activity may be expected to continue to increase under the long-term influence of the St. Lawrence seaway.

3. Prairie Region.— Located in the southern parts of the provinces of Manitoba, Saskatchewan and Alberta, the prairie plains of Canada constitute a northern extension of the Great Plains of the United States. More than 800 mi. wide along the international boundary, the plains are, for the most part, underlain by relatively undisturbed Cretaceous and Early Tertiary shales and sandstones. Many of these formations contain valuable coal seams. Deeper still lie the Devonian limestones and sandstones with their reserves of petroleum and natural gas. The surface materials here, as in eastern Canada, are of glacial and lacustrine origin. In general, the plains may be said to rise toward the west in three great steps: the Manitoba lowland being less than 1,000 ft. above sea level, the Saskatchewan plain about 2,000 ft. and the Alberta plain more than 3,000 ft. While there are vast flat areas such

as the Red river and Regina plains, there are also elements of considerable relief such as the Manitoba cuesta, the Missouri Coteau. Wood mountain and the Cypress hills. On the west the plains are terminated abruptly by the foothills of the Rocky mountains.

Developed beneath the prairie grasses, the dark soils of this region have been the basis of Canada's most extensive agricultural development. Settled, for the most part, in the 20th century, this is the spring wheat region, where annually 25,000,000 ac. are sown and 300,000,000 to 700,000,000bu. of wheat are harvested. Wheat farming dominates the central area but around it are found areas of mixed farming with other grains and livestock.

Since 1917, the year of the Leduc discovery, the prairies have become a land of oil as well as grain. Pipelines carry it west to the Pacific and east to Ontario. Agricultural populations are declining but prairie cities have begun to grow rapidly; Winnipeg, Edmonton, Calgary, Regina and Saskatoon, at the census of 1961, had a combined population of more than 1,200,000 inhabitants and are becoming strong regional centres of commerce and manufacturing.

4. Southern Cordilleran Region. — From the viewpoint of the geomorphologist and the geologist, western Canada, from the eastern edge of the Rocky mountain foothills to the Pacific, is regarded as one of the major physical regions of the country. From the viewpoint of the climatologist, and even more importantly from the viewpoint of human geography, the southern part of the Cordilleran area is a geographic region containing one of the major clusters of the Canadian population.

For a distance of 500 mi. from east to west this is a land of mountains; high relief is characteristic and gives similarity to all landscapes. But there are many differences. On the east, the Rocky mountains form a high barrier range with many peaks over 10,000 ft. Mt. Robson, the highest, stands 12,972 ft. above sea level. The Rocky mountain trench is a striking, linear depression which separates the Rocky mountains from the Columbia mountains, a series of ranges with peaks of 6,000 to 10,000 ft. elevation, which occupy the southeastern corner of British Columbia. Between these ranges there are deep troughs containing the Kootenay and Arrow lakes which form part of the Columbia river drainage. Further west is the interior plateau which is drained in part by the Okanagan to the Columbia and partly by the Thompson and Fraser rivers. Northward from the lower Fraser valley, the Coast mountains form a high granite wall, reaching 13,260 ft. in Mt. Waddington. The coastal trench or downfold west of the Coast range is drowned and there are many fiords similar to those of Norway. Finally there is the outer mountain range, also largely submerged, which forms Vancouver Island and the Queen Charlotte Islands.

The great contrasts in relief are paralleled by contrasts in climate. The lower western slopes of the mountains receive a great deal of rain and are heavily forested. The snow line in the south is from 7,500 to 9,000 ft., being lower on the seaward slopes; it declines gradually toward the north. The interior of British Columbia is relatively dry throughout, and in the Okanagan area, where some stations report less than ten inches of rain per year, sparse grass, sage and cactus comprise the vegetation. Forests, though not as luxurious as those of the coast, are found on the mountain slopes of the interior.

The focus of the geographical region is certainly the southern end of the coastal trench and the lower Fraser valley. Here are the two largest cities, Victoria (151,000), the capital of British Columbia, and Vancouver (777,000), the metropolis of the Canadian west coast. Here, also is about one-third of the agriculture of British Columbia. The cities of the interior are much smaller. Trail, on the Columbia river, is a noted centre of smelting of lead and zinc. Vernon, Kelowna and Penticton, on Okanagan lake, are centres of irrigated fruit growing areas. Prince George (13,000), an important lumbering centre, is the largest city in the northern part of this region.

The southern Cordilleran, or Pacific coast, region is an excellent example of a nodal region, with 75% of its total population in one small part of the area and the much more sparsely settled remainder firmly tied to it. The total population of the region is about 1,500,000.

5. Northern Cordilleran Region. — Stretching northward from the 55th parallel, between the Alaska boundary and the Mackenzie lowland, lies the northern portion of the Cordilleran region, 350,000 sq. mi. of mountains and high plateaus. In northern British Columbia the pattern resembles that to the south, with the high range of the Rocky mountains on the east and the granite peaks of the Coast range on the west, culminating in the St. Elias mountains on the Alaskan border; between lies the rugged upland of the Stikine plateau and the Cassiar mountains. The Rocky mountains die away in the Liard basin before the Yukon boundary is reached; north of it, the chief geomorphic units are the broad and deeply dissected Yukon plateau and the Mackenzie mountains. Much of this area is drained by tributaries of the Yukon river. Some of the valleys are well forested, especially toward the south, but most of the area is high enough to have little tree growth.

The complex geology is, in some areas, very favourable to mining. The gold rush to the Klondike gravels was one of the most spectacular ever staged, but most modern mining camps are based on shafts driven into rock lodes. Among these are the rich deposits of lead and silver in the Mayo district. Mining in the Yukon, however, suffers from transportation difficulties.

Notable among the geographic features of this region is the Alaska highway. The total population of the whole region is about 15,000.

6. Eastern Boreal Region. — A vast forested area of 900,000 sq. mi. in eastern Canada may be designated as the eastern Boreal region. For the greater part it is underlain by rough, rocky terrain of the southern part of the Canadian shield with elevations of 1,500 ft. above sea level north of Lake Superior and in Algonquin park and of more than 3,000 ft. in Quebec and Labrador. It comprises also the lowlands underlain by Paleozoic rocks which border Hudson bay and James bay. Its vegetative cover is made up of the various associations which comprise the Taiga, or Boreal forest region.

Scattered through the mass of Laurentian rocks which characterize most of the shield there are areas of Keewatin, Timiskaming and Huronian rocks, greenstone, schists and metamorphosed sedimentaries, with which are associated various ore deposits. The mining camp, therefore, is to be regarded as one of the most characteristic human phenomena of this region. Among these may be mentioned Sudbury, where, since 1900, most of the world's nickel has been obtained; Porcupine and Kirkland Lake, both noted gold camps of northeastern Ontario; the Red Lake gold field of northwestern Ontario; and the gold and base metal mines of western Quebec and the Chibougamau area.

Iron ore is found at Michipicoten and Steep Rock lake near Lake Superior, at Marmora in southeastern Ontario, and in the great Labrador trough shared by Quebec and Labrador. Noted uranium deposits are at Elliott Lake, north of Lake Huron, and Bancroft, north of Lake Ontario.

Forest activity, however, is older and more widespread than mining. Earliest was the pursuit of fur bearing animals which lived in the forest, but the fur traders' post is no longer of great importance. Later, in the area accessible to the tributaries of the St. Lawrence: great quantities of pine timber were cut, and vast quantities of saw logs. Most widespread in the second half of the 20th century was the cutting of pulpwood, while a whole series of towns and cities along the entire southern margin of the shield were engaged in making pulp and paper.

There have been many attempts, also: to induce agriculture to invade the southern margin of the shield. Fairly successful colonies are found in a number of pocket areas such as the Lake St. John basin. Abitibi, Cochrane, Timiskaming and the Nipissing lowlands. Farming, however, is clearly not favoured by either the terrain or the climate of most of the eastern Boreal region.

The rivers, lakes, hills and forests of this region combine in many attractive landscapes. Many areas such as Quetico Park, Lake of the Woods, Timagami, Algonquin park, Muskoka and the whole sweep of the Laurentians are well-known vacation resorts. They are not so spectacular as the western mountains, but they lie much nearer the homes of those who seek recreational activity.

7. Western Boreal Region. — Extending through the northern

parts of Manitoba, Sasratchewan and Alberta, and the Mackenzie lowland of the Northwest Territories, the western Boreal region has an area of almost 800,000 sq.mi. About half of the area is underlain by the Pre-Cambrian rocks of the Canadian shield, and half by sedimentaries similar to those of the Prairie region. Along this geological boundary are found a number of very large lakes: Great Bear. Great Slave. Athabasca. Reindeer and Winnipeg.

Neither forest activity nor mining activity have shown as great development here as farther east. There have been some notable mining camps such as Flin Flon, Uranium City, Port Radium, Yellowknife, Lynn Lake and Moak Lake, and there are petroleum resources in the Peace. Athabasca and Mackenzie river areas. Norman Wells (pop. est. 600) on the Mackenzie supplies the northwest. While the Mackenzie is one of the notable river routes of the world, most of the region is inaccessible except by air, making transportation too expensive for most needs. The western Boreal region is one of economic difficulty and, consequently, low population density. The total population is about 100,000 or about one-tenth that of its eastern counterpart. Agriculture has invaded the southern margin of the forest in central Saskatchewan and the Peace river area but it faces great climatic hazards.

8. Arctic Regions.—Although the arctic is supposed to be bounded by the Arctic circle, arctic conditions indicated by the tree line are encountered at least 500 mi. to the south along the shores of Hudson bay. Defined in this way, including both mainland and islands the area is more than 900,000 sq.mi. Most of the mainland is part of the Canadian shield, as are Baffin. Devon and some of the other islands. On Ellesmere Island the high folded mountains of the Innuition region have peaks up to 10,000 ft., and there are large areas of snow field and icecap. In the north, too, are areas of arctic coastal plain on disturbed Paleozoic rocks, where the structures indicate possibilities of petroleum. A wide continental shelf is also present.

Most of Canada's 11,500 Eskimos live in the southern part of this area. There are also a few thousand whites located in scattered stations. Frobisher Bay, on Baffin Island, is an administrative centre and air base; Rankin inlet, on the northwest shore of Hudson bay, is the site of a nickel mine; promising iron ore deposits are found on the shore of Ungava bay; it is probable that other mineral resources in many parts of the arctic region await development.

9. Geographical Pattern.—The pattern of population groups and geographical regions in Canada may be summarized rather briefly. In the south because of ease of access, surface conditions and favourable climate, there are four reasonably well-populated regions, the Atlantic provinces, the St. Lawrence-Great Lakes lowland, the Prairie region and the southern Cordilleran region. Making up one-fifth the area, they contain 90% of the people, the agriculture, the industry and the wealth. While all four regions are separated, it can be seen that there is an especially wide gap between east and west.

Immediately north of the populated regions, and in fact serving to separate east from west, lie the eastern and western Boreal regions and the northern Cordilleran region. From the standpoint of human geography they are fringe regions, with pioneer economies depending upon forestry and mining to a large extent, while the remnants of the fur trade still persist. Finally, north of the tree line lies the lonely land of the arctic tundra, empty save for a few Eskimos, administrators, weathermen and defense personnel. This is the simple, basic pattern of Canadian regions.

(D. F. Pu.)

III. NATIVE PEOPLES

1. General.—Anthropologically, as well as geographically, Canada is an integral part of the North American continent. The boundaries between Canada and the United States (including the boundary with Alaska) do not conform to ethnic divisions among the aborigines, nor is native culture significantly different on each side of the borders.

The early European explorers found the seacoast of Canada inhabited by people with brown complexions and lank hair. When it later became apparent that they were similar to the natives met

by Columbus in the West Indies, his term for them, "Indians," came into general use. Since Columbus had chosen this name in the belief that he was in the vicinity of India, a geographical error was thus perpetuated. In later years the same designation was given to the various tribes encountered by adventurers, French and English, as they penetrated westward across the continent. In the north, however, the hunters dwelling on the shores of the Arctic were so different both in appearance and culture that the term Indian was inapplicable, and Eskimo was used instead.

Certain physical characteristics are common to all Canadian Indians. The colour of the skin is dark brown—red is a misnomer and yellow an exaggeration; the black hair is smooth; the cheekbones are prominent; the face is broad in comparison with the breadth of the head; the nose is usually well developed, though not flattened; and the brow is somewhat low. But it must be emphasized that there is no absolute uniformity of type. On the coast of British Columbia the natives have relatively short stature, are of heavy build, with round heads, broad faces and a certain amount of facial hair. On the plains the stature is greater, the body more lithe and graceful, and facial hair is limited to an occasional sparse mustache. The eastern type generally resembles that of the plains, although several tribes have longer heads, and a few prehistoric dolichocephalic (distinctively long-headed) skulls have been found.

The Indians of Canada are part of the Mongoloid branch of mankind. A homogeneous stock does not exist in North America and the physical differences suggest that the migrations from Asia came in waves, comprising various Mongoloid groups. Furthermore, environmental factors have probably produced considerable variation within America itself.

The ancestors of the Indians and Eskimos came by the northwestern route across Bering strait. Even at the present time the passage occasionally freezes so solidly that it is possible to walk from Asia to America, while the Diomed Islands would have offered convenient steppingstones for sea voyagers. *Homo sapiens* undoubtedly developed in the old world, but he spread to the new at an early period—during the last interglacial period. Archaeological remains have been found beneath glacial deposits in Alaska, at Sheguindah in Ontario, and elsewhere. Culturally, artifacts from Cape Denbigh and other sites in Alaska and the northwest are related to the Eurasiatic Mesolithic Age culture of Lake Baikal in Siberia (see *ESKIMO: Eskimo Archaeology*). Even with the aid of carbon 14, it is impossible to put an accurate date on the coming of man to the new world. It was probably between 15,000 and 20,000 years ago.

The Eskimos (*q.v.*), who inhabit the shores of the Arctic from northwest Siberia to Greenland, are somewhat different from the Indians. Their hair is equally straight but the skin colour lacks the warm brown of their southern neighbours. The large, long head is high, somewhat keel-shaped in general form; the nose is narrow and inconspicuous, which, combined with prominent cheekbones and unusually broad face, gives a frontal appearance of flatness; the eyes are black with the epicanthic fold at the inner eye frequent; the hands and feet are even smaller than those of the Indians, and the stature usually less. It is clear, however, that the Eskimos, like the Indians, are part of the general Mongoloid stock, of which they may be regarded as a highly specialized offshoot. After spreading across the northern Canadian mainland and the coasts of the southern arctic islands, they probably reached Greenland over 2,000 years ago.

2. Culture.—Diversity characterizes the culture of the Indians of Canada. Some of this is due to differences in the background of different groups migrating from Asia at different periods. Furthermore, all immigrants to Canada had to move through a corner of Siberia and across Bering strait; this inevitably led to the loss of all culture elements which could not be practised under arctic conditions. These included, of course, horticulture, the domestication of animals except the dog, and the working of metals. In the new world man began life afresh with only a few heritages from the old. These were the polishing of stone implements, probably the domestication of the dog, the use of the spear thrower, certain religious beliefs and traditions, and language. Isolation

for centuries, geographical diversity and the sparseness of population in the new world facilitated the cultural diversity so characteristic of aboriginal Canada.

In the obtaining of food, for example, the Iroquois of southern Ontario were primarily farmers, the Indians of the northwest coast were fishermen, and those of the Prairies and the arctic were hunters. Villages varied from the relatively permanent settlements of the Iroquois and of coastal British Columbia to the mobile family units of northern Ontario and Quebec. So, likewise, in chieftainship there were all degrees from the aristocratic stratified government of the Haida of the northwest coast, or the matrilineal structure of the Iroquois, to the rugged individualism of the northern Athapaskans of the Northwest Territories. In religion, in warlike pursuits, in language, in social practices, in housing and in clothing, the tale was the same; that of diversity resulting from varied geographical surroundings as well as from the accidents of history. Only in deficiencies was there uniformity; nowhere in Canada was there use of the wheel, of iron, or of any system of writing.

3. Regional Distribution.—The culture of tribes living within regions of geographical and ecological similarity tended to conform to a type, irrespective of linguistic or physical classifications. On this basis the following areas can be distinguished:

Arctic Region.—About 11,500 Eskimos inhabit the coast of the arctic mainland and the adjacent islands. Before the period of European contact, and even in later times, they depended largely on seals for food, clothing and (from seal oil and blubber) warmth and light. Caribou, when available, are killed for meat and skins, while fish, birds and white whales are supplementary foods in the diet of these almost entirely carnivorous hunters. Before the acquisition of iron from white traders, their tools were made of stone, bone and ivory, and were characterized by great skill and ingenuity. The dog is used for drawing the sledges and for locating the breathing holes of seals, at which the animals are speared. The skin clothing is well tailored and admirably adapted to the extreme cold; equal ingenuity is shown in the manufacture of two types of skin boat (the kayak and the umiak) and the circular winter house of snow blocks, the igloo.

Eskimo political organization is limited to the simple band, comprising a number of related families. Such a group wanders over a vaguely defined area, returning year after year to the same camping grounds following the movements of game. The leader is the most skilful hunter, but he is entirely without authority, and hereditary chiefs with executive or judicial power are unknown. Shamans have much influence, especially with regard to the enforcement of multitudinous hunting taboos, but there are few communal religious rites.

The coming of the white man began to alter the Eskimo way of life in the 19th century, and the process of adjustment became more and more accelerated with mining developments and the building of the Distant Early Warning (DEW) line after World War II. The trapping of white foxes for their fur has grown into a major industry, and the Eskimo has become increasingly dependent upon the white man's economy. The Eskimo developed a unique style of stone and ivory carving. Most Eskimos have adopted some form of Christianity.

The North-Eastern Woodlands.—At the time of European contact Newfoundland, the maritime provinces and the wooded areas of northern Quebec and Ontario were sparsely inhabited by loosely organized hunting tribes. With the exception of the Beothuk of Newfoundland, who were exterminated before the close of the 19th century, languages of the Algonkian stock were spoken throughout this whole area. The Micmac occupied Nova Scotia, northern New Brunswick and Prince Edward Island; the Malecite and Abnaki lived in the river valleys of southern New Brunswick and southern Quebec; the Montagnais and Naskapi ranged over Labrador and Quebec north of the St. Lawrence; while northern Ontario and adjacent parts of Manitoba was the home of the Cree and the Ojibwa.

In every respect these Algonkian-speaking Indians are part of their environment. Skilled hunters of moose, caribou, bear, rabbit and beaver, they also utilize a wide range of wild plants, not only for food, but for medicines and dyes as well as for utilitarian

purposes. Birch bark was used for canoes and wigwams; basswood fibre for cordage; animal skins for clothing; and strips of woven rabbit fur for blankets. In former times there were seasonal movements in the never ending quest for meat, fish and berries. Political structure was weak, bands were loosely organized, and religion centred in the personal quest for power through vision experience.

By the 20th century much of the old life had disappeared, though its influence in religious beliefs and in the dependence on local ecology continued to be important. Most of the Indians lived in their old home areas; guns and metal tools entirely replaced implements of stone, and employment as guides, loggers and commercial trappers became the basis of life instead of subsistence economy.

Southern Ontario.—Very different from the hunters of the northern forests were the Indians of the north shore of Lake Erie and Lake Ontario. Though equipped only with stone tools, they cleared large fields in which they planted corn, beans, pumpkins and tobacco. Deer, fish, berries and nuts were hunted and collected, but as farmers they lived in relatively permanent villages of 1,000 or more inhabitants. Their houses were huge communal dwellings of saplings covered with bark, occupied by many families; pottery was made on a large scale and bone was utilized extensively. In fact, life was on a plane of comfort and security unknown further north.

The tribes of southern Ontario were the Huron, Tionontati (Petun) and Attiandaronk, or Neutrals, all speaking languages of the Iroquois stock. In the 1640s they were destroyed in war or incorporated by the Five Nations of the Iroquois from New York state; a century and a half later, after the American Revolution, many of the latter came to Ontario as royalist allies of the crown. Political organization was highly developed among all the Iroquois tribes, with chieftainship passing through the female line, and a complex system of religious rituals and an intertribal association, the League of the Iroquois. By the 19th century the military and political importance of the Iroquois had passed away, although memories of the past are proudly retained by those who have become essentially participants in the agricultural life of southern Ontario.

Plains Area.—The prairies of Manitoba, Saskatchewan and Alberta were inhabited by tribes having a general cultural uniformity, although speaking languages of three distinct stocks, Athapaskan, Siouan and Algonkian. The centre of life was the bison. The flesh was eaten in quantities, either fresh, or dried and pounded as pemmican; the skins provided clothing and covering for the movable tent, the tipi, or tepee; the bones were used for arrow points and scrapers; and the dung served as fuel. The dressing of bison, elk and deer skins reached a high development, and rawhide receptacles were used for storage vessels, basketry and pottery being unknown.

Martial achievement, in accordance with a strict code of behaviour, gave prestige, but not necessarily authority. The basis of all types of success, including war prowess, was attributed to the aid of a guardian spirit, acquired at adolescence. The collection of certain symbolic objects was sometimes recommended in a dream or vision, and these, carefully preserved, often for generations, served as tangible articles of religious veneration.

Socioreligious rites are extremely important on the plains, the scattered divisions of a tribe assembling annually for the performance of elaborate symbolic celebrations, of which the sun dance is the best known. An important place in all such rituals was played by the members of semisecret societies of men. Most of the Plains Indians now reside on reservations, and their life is patterned on that of the white settlers.

The Northwest.—This term may be used for the huge area occupied by the Dene, or Athapaskan-speaking peoples. It comprises two sections: (1) the Mackenzie and Yukon valleys and the scrubby forest west of Hudson bay, the home of the Hares, the Dogribs, the Kutchin, the Caribou-Eaters, the Yellowknives—so called because of their copper tools—the Slaves, the Chipewyan and the Beaver; and (2) the upland plateau of British Columbia, west of the Rocky mountains, inhabited by the Nahane, the Sekani,

the Carrier and the Tsilkotin (Chilcotin). Athapaskan languages extend even beyond this range. Political organization comprises only the simple band, a loosely knit patrilineal unit without definite leadership, and few regulations.

The staple food supply of this area is the caribou; deer, rabbits, wild fowl, fish and berries are eaten when obtainable, but, especially in the north! the roving hunting bands depend on the caribou. The toboggan simplifies transportation in winter, the canoe in summer. Material culture is scanty; baskets are plaited of spruce roots; clothing was formerly of skins; and one of the few distinctive traits of culture is the double lean-to. Though few white men have penetrated into these regions, metal tools and the fur-trading economy have modified much of the native life, although the aboriginal languages have been retained.

Interior Area of Southern British Columbia.—The wooded valleys of southern British Columbia were inhabited by the Kutenai and the Salish-speaking Ntlakyapamuk (Thompson), Shuswap and Lillooet. The rivers flowing westward were filled with salmon, which the natives caught in large numbers and smoked or pulverized for winter use. Deer and mountain goats were hunted and berries collected. Clothing was of deerskin, while blankets were made of rabbitskin. Pottery was lacking, but wood was used more extensively than on the plains and excellent basketry was produced, including watertight vessels. Rush-covered lean-tos served for shelter, replaced in winter by permanent semisubterranean houses.

Semiheditary leaders exercised considerable influence over local groups, but they lacked prestige based on martial prowess, as on the plains, or the respect dependent upon wealth as among the coast groups. Ceremonial rites were also weakly developed, although puberty ceremonies were performed, and the Kutenai held an elaborate ritual before departing to the plains on their annual bison hunt. In addition to guardian spirits, there was a belief, among the Kutenai at least, in the sun as a vague sky being of great power. The culture of this area is, in many respects, intermediate between that of the plains and the Pacific littoral.

Coastal Area of British Columbia.—This region had the most specialized and distinctive Indian culture in Canada. The northern part is occupied by the Haida of the Queen Charlotte Islands, the Tsimshian of the Skeena river, and the Tlingit of Alaska; the central, by the Kwakiutl of Vancouver Island and the Bella Coola; and the southern, by the Kootka and the Coast Salish, with many tribes of northern Washington.

In contrast to linguistic diversity, there was relative cultural uniformity. The chief food was salmon, which was smoked for storage; deep-sea fishing was practised by several tribes. Berries and shellfish were collected, deer and mountain goats were hunted, and the Nootka formerly captured whales at sea. These abundant sources of food supported a relatively dense population, living in permanent villages. The even-grained cedar was split into planks with which large, communal, rectangular houses were built; smaller boards were steamed and bent into serviceable watertight boxes; and large dugout canoes were hollowed from the trunks. Upright house posts were carved with elaborate designs of ancestral crests, from which developed the totem poles of the 19th century. Pottery was unknown, but baskets and mats of bark and roots were manufactured. Clothing was either made of skins or bark, or woven from mountain goat or dog hair. Nephrite, a jade stone, was extensively used and a little copper was pounded out from rich deposits in the north.

Political organization was marked by the importance of hereditary rank, with a stratified class society extending from aristocratic chiefs to slaves. In contrast to the principle of hereditary rank was that of the potlatch, whereby prestige was obtained by a lavish bestowal of goods to validate the assumption of prerogatives. The strongly organized northern tribes were matrilineal, the southern were patrilineal. Secret societies! employing masks and ingenious mechanical devices, complicated social life in the winter. There was a firm belief in supernatural beings, whom the Bella Coola organized into a pantheon dominated by a supreme deity.

By the middle of the 20th century, most of the old way of life had disappeared. Motor boats and power tools had replaced stone tools. The potlatch and native beliefs had largely passed away,

and the modern Indian operated his own fishing vessel or was a member of a trade union in the fishing or logging industries.

IV. HISTORY

About the year A.D. 1000 a Norse voyager, Leif Ericsson, on his way to Greenland, is said to have sighted land which may well have been some part of the east coast of Canada. The Norsemen had spread over the North Atlantic islands by a northern sailing route, and they apparently made some attempts to settle in America but they failed (*see* ERIC the Red).

There were still traces of the Norsemen in Greenland when the English explorer John Davis visited that island in the 1580s. But English and French seamen had followed the old northern route to Iceland and Greenland long before. In the 1490s an Italian navigator, John Cabot, led seamen of Bristol to a landfall somewhere on the Canadian coast, which he visited in 1497 and 1498, if not earlier. He also discovered the fishing banks off Newfoundland, and from 1500 on English, French, Portuguese and Spanish fishermen sailed every spring to the great cod fishery there.

A. NEW FRANCE

The shores of what are now the Bay of Fundy, Nova Scotia and Newfoundland were explored in the 1520s. Then in 1534 the French seaman Jacques Cartier entered the Gulf of St. Lawrence and took possession of "New France" for King Francis I. In succeeding years he ascended the St. Lawrence as far as the Lachine rapids, to where Montreal now stands, and attempted with the sieur de Roberval to found a colony near what is now Quebec. The colony failed, but out of these explorations and the fisheries the fur trade with Indians of the gulf and the river began. By 1600 it was well established and, because the Indians desired European goods, particularly metal knives and hatchets, already extended inland at least as far as the Great Lakes. Monopolies of the fur trade were granted to a succession of traders on condition that they begin colonization, but they either evaded the condition or failed to carry it out.

At the beginning of the 17th century appears the first great name in Canadian history. Samuel de Champlain (*q.v.*) was employed in the interests of successive fur-trading monopolies and sailed up the St. Lawrence in 1603. In the next year he was on the Bay of Fundy and had a share in founding the first permanent French colony in North America—that of Port Royal, now Annapolis Royal, N.S. In 1608 he began the settlement which was named Quebec, selecting a commanding site which controlled the narrowing of the St. Lawrence river estuary. From 1608 to his death in 1635 Champlain worked unceasingly to develop Canada as a colony, to promote the fur trade and to explore the interior. He passed southward from the St. Lawrence to the beautiful lake which still bears his name and also westward, up the St. Lawrence and the Ottawa, in the dim hope of reaching the shores of China. He reached Lake Huron and Lake Ontario, but not the Great Lakes that stretched still farther west. At his death, the fort at Quebec had only 85 adult residents.

1. The Company of One Hundred Associates. — This failure to build up the colony had led Cardinal Richelieu, the chief minister of France to found in 1627 the Company of New France, popularly known as the Company of One Hundred Associates. It was granted the colony of New France, then comprising the whole St. Lawrence valley, and for 15 years from 1629 it was to have complete monopoly of the fur trade. In return it was to take to New France 200 to 300 settlers a year. But war with England began, the company's first fleet was captured, and in 1629 Quebec itself surrendered to the English.

It was restored by the treaty of St. Germain-en-Laye in 1632, but the Company of New France never recovered from the blow, although it controlled New France until 1663. Colonization was slow for many years. The fur trade remained the chief concern of everyone except the missionaries. Jesuit fathers had begun missionary work in Acadia in 1611, and Récollect friars (Franciscans)

at Quebec in 1615. The main effort was made in 1625 when Jesuit missionaries advanced to the country of the Huron Indian; settled on Georgian bay. There the fathers returned in 1634 and built up their principal mission in the hope of establishing a Christian Indian community.

2. Iroquois Wars. — Their hope was destroyed by the beginning of the Iroquois wars of New France in 1640. Cartier had found Iroquois Indians at Quebec in 1535. The Algonkin (or Algonquin) tribes had driven them back into New York by 1600, where Champlain, with the Algonkin as allies had warred on them. After the founding of New Netherland by the Dutch in 1609, the Iroquois began to obtain knives and hatchets and in 1640 they got some firearms from Dutch traders. They began to raid the Algonkin and Huron trading parties, and soon they were attacking the French allies of these Indians. Finally they resolved to destroy the Huron confederacy which they did in 1648–50. Fathers Jean de Brébeuf and Gabriel Lalemant, now canonized, were tortured to death with many of their Huron people (*see* also HURON; BRÉBEUF, SAINT JEAN DE).

The destruction of "Huronnia" drove all the interior Indians friendly to the French west of Lake Michigan. The missionaries and the traders followed them, and there was a second great outburst of exploration. Two fur traders, Médard Chouart des Groseilliers and Pierre Radisson, pushed into the region of Lake Superior in the late 1650s and brought down furs from that new territory. Soon French missionaries and traders were to be found throughout the country which is now Wisconsin.

Radisson and Groseilliers were able to get their furs down to Montreal in 1660 only because of a heroic battle fought against the Iroquois by Adam Dollard and 16 companions at the Long Sault rapids (now covered by Lake St. Lawrence) in that year. So desperate was the plight of the colony of New France that an appeal was made to the French king for help. The Hundred Associates had failed to bring out colonists. So had most of the men, called seigneurs or seigneurs, to whom the company had made large grants of land on condition that they settle them with tenants. New France had only about 2,300 European inhabitants in 1660.

3. Royal Province. — The king responded to the colony's appeal by canceling the charter of the Hundred Associates and making New France a royal province with a governor, the ceremonial and military head of the colony, an intendant in charge of justice, finance, police, and the organization of the militia, a bishop and a superior council, which was a court of appeal.

The first bishop was François de Montmorency-Laval (*q.v.*), who arrived at Quebec in 1659. New France was then still a mission, but as population increased, parishes were formed and parish priests put in charge of them. To the Society of Jesus and the Franciscans the Ursuline nuns and the Sulpician fathers had been added. The church not only performed its ordinary duties, but provided the hospitals and schools of the colony as well.

In addition to creating a royal colony the king sent a military commander, Alexandre de Prouville, the marquis de Tracy, and a regiment of soldiers who in 1666 defeated the Iroquois and forced them to make peace.

It was then possible to proceed to populate and develop New France. Over 3,000 settlers, including girls of marriageable age, were sent out in the 1660s. Few followed thereafter, but by natural increase the population began to mount rapidly.

The first intendant, Jean Baptiste Talon (1665–68 and 1670–72), stimulated colonization and industry. He also pressed the exploration of the far west. Louis Jolliet explored the Mississippi until he was sure it flowed into the Gulf of Mexico, not into the Pacific ocean. In 1671 Simon François d'Aumont, or Daumont, sieur de St. Luson, at Sault Ste. Marie took possession of all the interior of the North American continent for France as an extension of New France.

Louis de Buade, comte de Frontenac et Palluau, became governor in 1672. There is little agreement on what kind of governor Frontenac was. But it does seem to be agreed that he used his office to enrich himself, and perhaps that he pursued policies which would help do so. New France was full of young men anxious to follow the profitable fur trade rather than to clear the land for

farming. Frontenac encouraged many of these *coureurs de bois* ("wood rangers"), as they were called, to follow leaders like Daniel Greysolon, sieur Dulhut (or Duluth), and René Cavalier, sieur de la Salle, into the far west to explore and trade. The result was a tremendous expansion of the French fur trade and La Salle's discovery of the mouth of the Mississippi in 1682.

Frontenac's policy of encouraging the fur trade led to a struggle with the Jesuits and Bishop Laval, who sought to protect the Indians from the ravages of brandy used in the fur trade. The missionaries were only partly successful in stopping the trade in brandy, but they did succeed in having Frontenac recalled in 1682. The expansion of the fur trade under Frontenac and La Salle, however, had aroused the jealousy of the Iroquois and led them to attack the Illinois Indians, who were friends of the French. Both missionaries and traders demanded that Joseph Antoine Lefebvre de la Barre, the new governor, attack the Iroquois. He did, but failed badly. He in turn was recalled and his successor, the marquis de Denonville, had to resume the attempt to curb the Iroquois. This he did with a measure of success in 1686.

4. War With England. — Not only the Iroquois but also English colonists and traders were menacing New France by that time. Since 1664, when the English took the colony of New Netherland from the Dutch, New York traders had supported the Iroquois. New England coveted Acadia (Nova Scotia) and its fisheries, which the English had captured in 1613 and again in 1654, only to restore it to New France in 1667. And in Hudson bay territory the Hudson's Bay company, founded in 1670 at the suggestion of Groseilliers and Radisson who had deserted New France, was drawing furs away from French traders. Now those traders and their governor thought the time had come to strike back.

In 1686–87 they captured the Hudson's Bay company posts in James bay and held them. Before this matter could be settled, war had broken out in Europe between England and France, and in New France the Iroquois had attacked the colony with even more than their old ferocity, massacring the people of the village of Lachine on Montreal Island in 1689.

The prospect of war had led to the reappointment of Frontenac. X New England fleet and army under Sir William Phips seized Acadia but Frontenac defied Phips's attempt to take Quebec in 1690. Then he began a series of border raids on New England, and finally marched into the Iroquois country. Meanwhile the brilliant young Canadian, Pierre le Moyne, sieur d'Iberville, had conquered Hudson bay, saved Acadia and overrun Newfoundland.

The war was ended by the treaty of Ryswick (1697) with New France holding Hudson bay (but not Newfoundland) as well as all its former possessions. This was the work of Canadians, with little help from France. D'Iberville then set off to found Louisiana, another part of New France, in 1699. And in 1700 and 1701 peace was made between the Iroquois and New France, and between the Iroquois and the Indian allies of New France. There were to be no more Iroquois wars, and New France stood at the height of its fortunes.

Its decline began almost at once. The English and their American colonists were to conquer all New France, but it was done in two stages. The first ended in 1713 with the end of the War of the Spanish Succession. In 1710 Acadia had been seized again by the British, but in the next year an English expedition under Sir Hovenden Walker suffered serious losses in the St. Lawrence river and returned home. Most of the fighting was done in Europe, however, and the English victories there enabled them: by the treaty of Utrecht that concluded the war, to recover Hudson bay, limit French rights in Newfoundland, force the cession of Acadia (without Cape Breton Island) and to get a foothold in the western fur trade.

5. Years of Peace. — These were serious losses, but 30 years of peace followed, which the French used to build the great fortress of Louisbourg on Cape Breton and to add to their empire of New France in the mid-continent.

This last was the work of Pierre Gaultier de Varennes, sieur de la Vérendrye, who obtained a licence to engage in the fur trade beyond Lake Superior on condition that he seek a route to the Western Sea. In 1730 he began his advance, and by 1738 reached

the Missouri by way of the Red river. He and his sons then turned their attention to the fur trade of the Saskatchewan river until their licence was revoked in 1744. They did not find the Western sea, or even the Rocky mountains, but they did take many furs from the Hudson's Bay company.

In these 30 years of peace New France flourished. Its population grew until in 1739 there were 42,000 people and in 1754 there were 55,000. Farming prospered and flour and wheat were exported to the West Indies. Lumbering, shipbuilding and even ironmaking were developed. Quebec and Montreal became flourishing towns, and schools, hospitals and convents increased in number. The seigniorial system of land grants had been reformed in 1711 to compel seigniors to settle their lands and to make tenants, or habitants, clear theirs. There were settlements with white houses and stone churches with tall spires along the St. Lawrence from below Quebec to Montreal Island and up the Richelieu river to Lake Champlain.

6. British Conquest. — In 1740 the War of the Austrian Succession began, pitting England against France once again, and the New Englanders attacked and captured Louisburg on Cape Breton Island. There was little other fighting in North America and by the treaty of Aix-la-Chapelle the war in Europe was ended in 1748 and Louisburg was recovered by New France. But both sides regarded the peace as a truce.

The truce was marked in North America by a struggle for control of the Ohio valley. Both English and French traders needed the friendship of the Indians. Virginian planters were planning to take up lands. The French laid claim to the Ohio valley in 1749 and in 1754 built Ft. Duquesne at the forks where the Monongahela and Allegheny rivers join to form the Ohio, and where Pittsburgh now stands. The young Virginian officer, George Washington, was sent to drive the French away but was defeated, and in the next year, 1755, the British general Ednard Braddock was defeated and killed in a similar attempt. That same year Ft. Beauséjour in Acadia was captured by British and New England forces and the Acadians, who had refused to swear allegiance to the British crown, were deported.

In 1756 the Seven Years' War in Europe began and the American phase of this conflict, the French and Indian War, was to settle the fate of New France. For two years the French troops and Canadian militia were victorious. Then the British and American strength, fed by British sea power, began to tell. In 1758 Louisburg fell; in 1759 James Wolfe captured Quebec; in 1760 Montreal surrendered and with it all of New France.

See also FRENCH AND INDIAN WAR.

B. CANADA AS QUEBEC

When the war was finally ended and peace was made by the treaty of Paris in 1763, all New France east of the Mississippi, outside the environs of New Orleans, was ceded to Great Britain. Only two little islands, St. Pierre and Miquelon near Newfoundland, and the French fishing rights in Newfoundland, were left to France. But in what now became the province of Quebec more than 60,000 French Canadians became British subjects. As it was expected they would soon be swamped by settlers from New England, Quebec was promised by the proclamation of 1763 a government like that of the other British colonies.

The New Englanders, however, went to Nova Scotia to take up the Acadians' lands. Since 1758 Nova Scotia had had its own assembly and was becoming a standard English colony. Prince Edward Island became a separate colony in 1769, but its lands were granted to absentee landlords who did little to settle them. Since the New Englanders did not go to Quebec, and when it became apparent Quebec would remain French, British policy changed. It was decided to give Quebec French civil law, which was established side by side with the English criminal law, to protect the position of the Roman Catholic Church and to allow Roman Catholics to hold public office; and to rest the government in a governor and council, without an elected assembly. All this was provided for by the Quebec act (*q.v.*) of 1774.

That act, however, while it became something the French Canadians valued, angered the Americans because it included in the

province of Quebec, or Canada, all the territory France had claimed south to the Ohio and west to the Mississippi. Thus it was one of the causes of the American Revolution by which Canada was once more separated from the old British colonies. These, of course, were recognized as the independent nation of the United States of America by the treaty of Versailles (1783).

By that treaty Nova Scotia, Newfoundland and Canada (now without the Ohio valley or the lands which later became Michigan, Wisconsin, and Minnesota) became what was known as British North America. To it came refugees from the United States, perhaps about 40,000 in number. These were the United Empire Loyalists, who had lost their lands and homes in the old colonies because they had opposed the revolution. They increased the population of Nova Scotia (*q.v.*), and added to the French population of Canada about 10,000 English-speaking people (see ONTARIO: History).

Their coming helped bring about a reorganization of the remaining British colonies. Nova Scotia was divided and the province of New Brunswick created in 1784. Then in 1791 Canada was given representative government by the Constitutional act (see CONSTITUTIONAL ACT, CANADIAN) which provided for an appointed legislative council and an elected legislative assembly. The governor had an executive council to assist him, and a revenue he controlled without vote by the assembly. The province was divided into the two provinces of Lower Canada (the future Quebec) and Upper Canada (the future Ontario). Lower Canada was almost wholly French. Upper Canada, like New Brunswick, was almost wholly British. Provision was made for the endowment of "a Protestant clergy."

During the years from 1763, British fur traders from Montreal, aided by French-Canadian voyageurs (frontiersmen who followed the wilderness rivers and portages trading: trapping and transporting furs), were carrying the fur trade of Canada into the far northwest. Alexander Mackenzie reached the Arctic ocean in 1789 and the Pacific in 1793. Canada, as explored by the fur traders following its long rivers, reached from sea to sea.

C. BRITISH NORTH AMERICA

The French Revolutionary and Napoleonic wars overshadowed British North America from 1792 to 1814. War created a demand for timber by which the colonies prospered. But out of the British blockade of France and similar war measures came a war between Great Britain and the United States, the War of 1812 (*q.v.*).

That war seemed to Americans to offer a new opportunity to liberate Canada and add it to the United States. To Canadians it was a war of defense against invasion and, if possible, to recover the lost lands of the west. The war ended in stalemate. If the Americans failed to conquer Canada, the British failed to force an alteration of the boundary of 1783. The treaty of Ghent, 1814, put things back as they were before.

The real results of the war came later. By the Rush-Bagot convention of 1817 the naval armaments of Great Britain and the United States on the Great Lakes were ended. By the convention of 1818 the Canadian-United States boundary was extended from the Lake of the Woods to the Rocky mountains, and the Oregon territory beyond the mountains was to be jointly occupied for ten years. The continent was peacefully partitioned.

1. Protest and Rebellion. — Up to this time there had been little political life in the Canadas, or indeed in British North America. The communities were too small, and the long years of war tended to silence political differences. Only in Lower Canada did some manifestations of French nationalism appear and some controversy arise with the government, notably when the first newspaper in French, *Le Canadien*, was begun in 1806.

This peacefulness ended after 1820. As the war years receded, and with the beginning of a large immigration from the British Isles to all parts of British North America, political agitation to change governments and persons which had become entrenched during the war years became vigorous in the two Canadas and Nova Scotia, and in the other colonies. The colonial governments lent themselves to rigidity. All officers except the governor held office for life. They could not be changed by popular wish, and neither

could their views nor policies. As liberal and democratic ideas spread in British North America, this situation became ever more irritating to liberal-minded men. And while most of the officials were honest and conscientious men who discharged their responsibilities justly, there were instances of corruption, injustice and, more often, of delay.

In Lower Canada, this friction of immovable officials and liberal ideas was intensified by the fact that nearly all the officials were English and nearly all—though not all—the opposition was French. Moreover, the English dominated the executive and the legislative councils, while the French dominated the assembly. Thus the conflict involved nationalities and institutions as well as politics.

In Nova Scotia and Upper Canada conflict between French and English was absent, but an edge was given to political controversy by the fact that many Nova Scotians and Upper Canadians were of nonloyalist American descent. They were regarded with suspicion by the official class as being potentially disloyal. As many were also Baptists or Methodists whose churches derived their ministers largely from seminaries in the United States, and also members of the political oppositions, or Reformers, the official class tended to equate political opposition with disloyalty.

The basic difficulty, however, was how to make the official class responsive to the needs and wishes of society. The Reformers put forward two suggestions. One was that the legislative council—and by implication even the governor and other officials—should be made elective. The leader of the French opposition, Louis Joseph Papineau (*q.v.*), endorsed this proposal, as did William Lyon Mackenzie, the most controversial of the Reform leaders in Upper Canada.

A second proposal was that the officials and advisers of the governor—his executive council—should be made responsible, or accountable, to the legislative assembly elected by the people. This proposal was first put forward by W. W. Baldwin and his son Robert, of Upper Canada, and was taken up by Joseph Howe (*q.v.*), the leader of the Nova Scotia Reformers (see BALDWIN, ROBERT).

Both suggestions had the disadvantage that they seemed to lead to full self-government, or independence. The supporters of responsible government therefore proposed that it should apply to local matters only.

These ideas were more vigorously agitated in the 1830s. The July Revolution in France, the victory of Jacksonian democracy in the United States and the fall of the Tories and the passing of the first Reform bill (1832) in the United Kingdom all stimulated political agitation in Canada. The Whig government of the United Kingdom tried to satisfy the Reformers but failed, and its failure led to the Canadian rebellions of 1837.

The rebellion in Lower Canada was partly planned by Papineau and his followers. It was also partly provoked by the official class and its partisans. But it was largely a spontaneous and despairing outburst caused by the collapse of wheat farming during the 1830s in the Montreal area, owing to soil exhaustion, and to the widespread commercial depression of 1837. There was some stiff fighting between the rebels and the British troops and militia around Montreal before the leaders fled to the United States or were captured.

In Upper Canada the uprising was unplanned. As all the troops had been sent to Lower Canada to deal with the serious situation there, Mackenzie seized the opportunity to try to take the capital, Toronto, by a sudden raid. His force was scattered by the local militia and he himself barely escaped over the border.

2. Union of Upper and Lower Canada. — Small as the insurrections were, they served to condemn the old system of government. An English statesman of the first rank, Lord Durham (*q.v.*), was sent out as governor general and royal commissioner to inquire into the causes of the rebellions and to make recommendations. His famous "Durham report" embodied two Canadian ideas and one English-Canadian fallacy. The ideas were that the Canadas should be reunited, as the Montreal businessmen wished, and that colonies should have responsible, or self, government in local matters, as the moderate Reformers like Baldwin and Howe wished. The fallacy was the idea that the French Canadians

could be swamped by English immigration and assimilated into an English population, a fallacy as old as the proclamation of 1763.

The British government still thought responsible government would lead to independence and did not explicitly grant it. But it did unite the Canadas by act of parliament in 1840, uniting Lower and Upper Canada as Canada East and Canada West. The rebellions had driven the radicals from Canadian politics and in the new assembly it was soon apparent that all moderates, whether Reformers or Tories, English or French, were prepared to accept, if not to demand, some measure of responsible government. Thus when the British government became convinced after 1846 that responsible government might be conceded safely, and sent Lord Elgin as governor general to Canada to govern as the queen governed in the United Kingdom, the last remaining obstacles were removed. In 1848 the principle was recognized in Nova Scotia and Canada, where in 1849 its significance was underlined by the riotous objections taken to the Rebellion Losses bill by the reactionary Montreal Tories and the Montreal mob. As the bill passed by the Canadian legislature proposed to compensate those, including French Canadians, who had suffered loss in the uprisings of 1837, it was viewed as payment to rebels. Elgin was petitioned to veto it, but refused on the ground that in domestic affairs the Canadian parliament was supreme. A Tory mob then pelted the governor and burned the parliament buildings.

Much of the anger of the Montreal Tories was caused by the repeal in 1846 of the British Corn laws, under which Canadian exports had a preference in the British market. The commercial shock Canada suffered was increased by the slump of 1847. So despairing were many of the Montreal businessmen that they saw a commercial future only in annexation to the United States.

Other remedies were found, however. One was reciprocal trade in natural products with the United States. This was finally arranged by the reciprocity treaty of 1854. Another was the beginning of railway construction in Canada. In 1849 there were only 66 mi. of railway in Canada; in 1860 there were 2,065. Much of this mileage was in the Grand Trunk railway, built from Sarnia on the Detroit river to Montreal and Portland, Me., in the 1850s. In consequence of these developments, and of the inflated demands for raw materials brought on by the Crimean War (1853–56), Canada enjoyed a boom until the slump of 1857.

Meantime, the British North American legislatures had been using the self-government won in the 1840s to remodel their laws and institutions. Primogeniture, for example, was removed from the law of inheritance. The French civil law was codified. Municipal government was made elective. The Clergy reserves, public lands granted for the support of the Church of England and the Church of Scotland, were abolished, and church and state separated in Canada. Seigneurial tenure was abolished. The French language was made an official language in Canada. Systems of public education were begun. The legislative council of Canada was made elective.

These advances, in which the other American colonies took part, ceased after 1858. The union was becoming unworkable. It had never been a complete union. Moreover, the representation in parliament had been fixed by the act of union at the same number for each section, Canada East and Canada West. Until 1851 Canada East (French Canada) was underrepresented. After that date Canada West was. A fierce protest built up against this alleged injustice, with a demand first for "representation by population" as advocated, for example, by George Brown (*q.v.*), then for a change in, or even a dissolution of, the union. The controversy became so fierce that parliamentary government by parties broke down. Attempts to govern by devices such as "the double majority"—a majority for a law in each section—also failed. By 1864 parliamentary government in Canada was deadlocked.

D. CONFEDERATION

For several years a proposal had been before the Canadian parliament to resolve the difficulties of the union by making it a federal rather than legislative union and by merging it in a confederation of all British North America. This was itself a very old idea, going back to before the French and Indian War, but it

had never entered practical politics until Alexander Galt of Montreal sponsored it in the Canadian parliament, and the governor general, Edmund Head (later Sir Edmund), urged it on the British government in 1858.

1. The Northwest.—The prospects of wider union had first become realistic in the 1850s. The northwest, once the preserve of Canadian fur traders, had been lost to the Hudson's Bay company in 1821. In that year the North-West Fur Company of Montreal and the Hudson's Bay company, after years of bitter rivalry which had threatened to destroy Lord Selkirk's colony on Red river, united under the name of the Hudson's Bay company. Thereafter the connection between Canada and the northwest became very slight. The great fur company traded in and governed all the north half of the continent from the Labrador coast on the east to the coasts of Oregon and Alaska on the west.

For two decades it was undisturbed and then two events began to threaten its remote and isolated monopoly. One was the advance of U.S. traders from St. Paul, Minn., to Pembina on the border in the 1840s. The result was that Red river settlers began to defy the company's monopoly and to trade with St. Paul. After the unsuccessful trial of a half-breed settler, Guillaume Sayer, for illegal trading, the company could no longer enforce its monopoly in the Red river country. The other was the beginning of U.S. settlement in the Oregon country, also in the 1840s. The coming of settlers ended the joint occupation of 1818, and by the Oregon treaty of 1846 the 49th parallel of latitude was extended to the Strait of Georgia. Vancouver Island was left to the Hudson's Bay company and made a crown colony in 1849. The American frontier was beginning to press on the great fur preserve of the north-east.

In the 1850s the pressure was greatly increased. Gold was discovered on the Fraser river in British Columbia and a rush of miners, mostly from the western United States, followed. Gov. James (later Sir James) Douglas of Vancouver Island acted to establish law and order on the mainland and to preserve British dominion of the area, and in 1858 the crown colony of British Columbia was created.

At the same time British Canadians began to take an interest in the Red and Saskatchewan valleys. A parliamentary inquiry was held in 1857 to determine whether the trading monopoly of the Hudson's Bay company should be renewed after it expired in 1859. The interest the inquiry aroused led Canada to dispatch an exploring expedition led by geologist Henry Youle Hind, who described the northwest as fit for settlement. The British government also sent an expedition. Its leader, geographer Capt. John Palliser, was much more skeptical of the agricultural possibilities of the western plains.

The result in Canada was an agitation in Canada West for the union of the northwest with Canada. French Canadians were somewhat doubtful of a proposition which would greatly increase the English majority. But in the early 1860s Canada West found an ally in Edward Watkin, an English financier sent out to report on the financial condition and future development of the Grand Trunk railway. He recommended that the railway be extended to the Pacific, which he thought a feasible enterprise, and for which purpose he organized the buying out of the Hudson's Bay company in 1863. Meanwhile, the continuing political deadlock between Canada East and Canada West and the slump of 1857 contributed to check the movement for the union of the northwest with Canada.

2. The Atlantic Colonies.—The events in the northwest which led Canada to think of a union extending to the Rocky mountains, if not to the Pacific, were matched by developments in the Atlantic colonies of British North America—Nova Scotia, New Brunswick, Prince Edward Island and Newfoundland. These also led to thoughts of political union, but a union of the Atlantic colonies, not of their union with Canada. All these colonies were now fully developed, with representative and responsible governments. Newfoundland, it is true, had been regarded for years as a fishery and not a colony. It had obtained resident law courts only in 1791 and an assembly only in 1832.

During the 1850s the trade and commerce of the Atlantic colonies had prospered as never before. The fisheries enjoyed good

markets, a particular necessity for Newfoundland. Lumber was in demand in the United States and Great Britain, and New Brunswick thrived. Farm produce flowed to New England, and Prince Edward Island and New Brunswick benefited. But beyond all these, the shipping of Nova Scotia flourished in the heyday of the clipper ships. That province was at the peak of its development, and its wealth may be gauged from the fact that two great business firms arose from its prosperity at that time, the Bank of Nova Scotia and the Cunard Steamship company.

Over this golden age of the Atlantic, or maritime, provinces a shadow began to pass in the 1860s. It was a realization that their further development would depend not only on their fisheries, shipping and overseas commerce, but also on their commercial and political relations with the rapidly developing continent behind them. One way to deal with the changes which seemed to be coming with the railway, the steamship and the probable end of the reciprocity treaty with the United States, was to end the political fragmentation of the Atlantic colonies by a union. This had been discussed in the late 1850s; now the discussion was renewed. A conference of governments was arranged for Sept. 1864 at Charlottetown in Prince Edward Island.

In Canada, meanwhile, the political deadlock had become so serious that the chief political leaders, John A. Macdonald and Georges Étienne Cartier of the Conservative party and George Brown of the Liberal, agreed to join in a coalition government to attempt to bring about a federal union of British North America. The Canadian government asked to join the Charlottetown conference, and it was agreed there to meet later at Quebec to discuss a union of all British North America.

3. The Quebec Conference and the Canadian State.—At the Quebec conference in October a scheme of federation was decided upon, which after few, if substantial, modifications was enacted by the parliament of the United Kingdom as the British North America act (1867). By this act four colonies, Nova Scotia, New Brunswick, and the Canadas, now named Quebec and Ontario, united federally. Newfoundland declined to come in, as did Prince Edward Island. The name of the new union was Canada, and it became in fact a subordinate and allied kingdom of the British crown. The Canadian request to call it the "Kingdom of Canada" was refused by the British government, as there had been some protest in the United States at the setting up of a monarchy in the new world. A substitute was found in the word "Dominion," and thus the true character of the Canadian state, which is a monarchy, was veiled until Queen Elizabeth II was proclaimed queen of Canada on Feb. 6, 1952.

The union was technically a federal union. The powers of government were assigned to the federal government, or to the provincial governments. General authority and the residue of power was given to the federal government in order, as it was thought, to avoid a weakness revealed in the government of the United States by the outbreak of the Civil War. The whole plan of government was modeled not so much on that of the United States as on that of the British empire from the 1840s, in which the imperial government had a supreme and overriding authority, but in which the colonies had wide and real powers of self-government.

Over and above legal technicalities, however, the act of confederation was a compact, not legal or political, but moral and constitutional, between French and British Canadians—French Canada was given freely what its leaders requested as necessary to ensure the life of the French community in Canada. This included the control of civil law and education by the provinces, the rights of the French language in Quebec and the federal parliament and the courts, and the guarantees given the educational rights of religious minorities in the provinces. On the observance or violation of these terms of the compact between French and English, the harmony of their relations and the strength of the Canadian union have depended since confederation.

E. THE DOMINION OF CANADA

The Dominion of Canada came into being on July 1, 1867, and July 1 has since been the national holiday of Canada. That date marked only the beginning, not the end, of the process of confed-

eration as the Conservative prime minister, Sir John Macdonald, knew. The rest of British North America had to be brought into the union, as the act of confederation provided.

Even before that work could be got well under way, the terms of confederation had to be revised to conciliate Nova Scotia. That province, led by Joseph Howe (*q.v.*), resented the way it had been brought into confederation without the question being submitted to the people in a general election. The anticonfederationists also argued, with much justice, that the financial terms of union given Nova Scotia were unfair. The dispute was adjusted and financial concessions were granted early in 1869. (See also *NOVA SCOTIA.*)

1. **First Riel Rebellion.**— Scarcely had Nova Scotia been pacified when trouble broke out in the Red river country. The transfer of the Hudson's Bay company territories of Rupert's Land and the North-Western Territory had been negotiated with the British government. For the nominal sum of £300,000, together with one-twentieth of the lands of the prairies as they were surveyed and about 45,000 ac. of land around its various posts, the company agreed to transfer its territories and rights of government to Canada.

In all this the people of the northwest had been neither consulted nor informed. More surprisingly, neither had the local officers of the Hudson's Bay company. In addition, the Canadian government had, with the best of intentions, and with the permission of the local Hudson's Bay company governor, William Mac-tavish, anticipated the transfers by sending into the territory a road-building party and a survey party. Both groups had alarmed and offended some of the local people.

Almost 12,000 people were settled in the Red river colony of Assiniboia. About one-half were French and one-half Scottish. The great majority had some Indian blood. They had been isolated for over half a century and had developed a distinctive way of life of their own. This was particularly true of the French-speaking people of mixed blood, known as the *métis*. They were mainly buffalo hunters and voyageurs, a proud people who thought of themselves as a "nation" with rights in the northwest. They now feared a threat to their French culture and their religion, and especially to the titles to their lands, in the prospect of a rush of Protestant farmers from Ontario. They resented not being consulted and they found a leader in one of their own people, an educated *métis*, Louis Riel.

Under Riel, the *métis* organized a council of war, and when the new lieutenant governor, William McDougall, whom the Canadian ministry had appointed, arrived at the border by way of the United States, he was not allowed to enter the territory. Riel seized Ft. Garry and set up a provisional government to negotiate terms of union with Canada. In the spring of 1870 these were agreed upon, and embodied in the Manitoba act, by which the province of Manitoba was established. But the rest of the northwest was made a territory, and Riel was driven into exile for ordering the execution of an Ontario man, Thomas Scott, in the course of the rebellion.

2. **Territorial Expansion.**— Canada then extended to the eastern boundary of British Columbia. That colony had been united with Vancouver Island in 1866, and a movement for union with Canada began. As the most important condition of union, British Columbia wanted a railway to the east. Early in 1870 delegates went to Ottawa and were granted generous terms of union. In particular, the Pacific railway was to be begun within two years of the union and completed within ten. The assumption of this enormous undertaking—one far greater than the building of the Union Pacific in the United States—was the measure of Canada's determination to bring the Pacific colony in and to extend from sea to sea. British Columbia entered confederation in 1871.

Despite high hopes held by Prime Minister Macdonald, Newfoundland refused to reconsider its decision to remain outside confederation. In 1873, however, Prince Edward Island won terms sufficiently generous to bring it in. The territorial expansion of Canada was greatly speeded when in 1880 the British government by order-in-council transferred to Canada jurisdiction over the Arctic archipelago. With that the territorial expansion of the

dominion was complete until the entrance of Newfoundland in 1949.

In 1871 the drawing of the boundary with the United States in the Gulf of Georgia was submitted to arbitration and the island of San Juan was awarded to the United States in 1872. That boundary was now defined from Atlantic to Pacific, but the boundary of the new U.S. possession of Alaska remained uncertain. Relations with the United States were also put on a new footing by the treaty of Washington, 1871, which ended the tension between the United States and Canada caused by the supposed sympathy of the Canadians with the Confederacy in the American Civil War. Canadians were aggrieved, however, that they obtained little compensation by the treaty either for rights granted to U.S. fishermen in Canadian waters, and none for the raids made on Canada by the Fenians (*q.v.*) from the United States.

3. **Transcontinental Railroad.**— This resentment made it difficult for the government of Prime Minister Macdonald to win the general election of 1872. To assist in a hard fought contest, he and his colleagues obtained large sums from Sir Hugh Allan (*q.v.*), a railway and steamship magnate who was interested in building the Pacific railway. Macdonald won the election, but a royal commission was appointed to investigate the transaction. Although Macdonald was acquitted of personal corruption, his government was overthrown by the "Pacific scandal," and a Liberal ministry came into office.

The Liberal government of Prime Minister Alexander Mackenzie tried to fulfill the terms of union with British Columbia and build the railway. But it thought the undertaking too big for Canada to assume alone, and in the depression that began in 1873 it could find no private interests to undertake the task. Then it attempted to negotiate a change in the time in which the railway was to be finished. In British Columbia there were angry charges of breach of faith, and there was talk of secession. But the Mackenzie government could only proceed with the railroad in sections, as the revenues of the country permitted.

4. **The "National Policy."**— Meantime the Conservative opposition had been looking for a policy on which to win the next election. There was a movement of national feeling, inspired by the annexation of the northwest and called "Canada First." At the same time there was the demand of Canadian industrialists for protection against the dumping of U.S. goods in Canada during the depression. Since the coming of the railway Canada had ceased to be a country producing only export staples like fish, fur, lumber and wheat. Daniel Massey had opened a foundry in 1847 and had begun to manufacture agricultural machinery, and other small industries had sprung up in the 1850s and 1860s.

These two things, national sentiment and industrial protection, Macdonald combined in what he called a "National Policy." The policy was a promise of protection for Canadian industry if the United States did not renew the reciprocity treaty which it had terminated after the Civil War, in 1866, as there was little likelihood of its doing. In 1878 the Conservatives returned to power on the National Policy platform and in the next year the Canadian tariff, hitherto a revenue tariff, was made in part a protective one.

The policy was one which strengthened the country, and with the return of prosperity enabled the Conservative government to push the building of the Pacific railway. A new company, the Canadian Pacific Railway company, was formed and was subsidized to the extent of 25,000,000 ac. of land in the west and \$25,000,000 to proceed with the completion of the railway. The task was finished in 1885 and by 1887 the Canadian Pacific railway extended from the Atlantic to the Pacific, a truly transcontinental railway system.

5. **Second Riel Rebellion.**— This triumph of nation-building had been marred by one outbreak of the old order in the northwest. On the Saskatchewan river the Indians and the *métis* were alarmed by the vanishing of the buffalo herds and the coming of white settlers. Also, some settlers were disappointed in their expectation that the railway would follow the Saskatchewan river to the Rocky mountains instead of crossing the southern plains. These stirred up the *métis* to send for Louis Riel to come from Montana and lead them in making new demands on the Canadian govern-

ment. In the spring of 1885 Riel formed a second provisional government and defied the authority of the Canadian government. Fortunately, only a few Indians joined Riel, and this rebellion was crushed by troops sent from eastern Canada and Manitoba. Riel was captured, as were the Indian leaders, Poundmaker and Big Bear.

The rebellion had two sets of consequences. One was the remedying of some of the grievances of the Indians and *métis* with respect to the issuing of rations and land titles, together with the granting of representation in parliament to the territories. The other was the trial and execution of Riel for treason, and the storm of protest which his death aroused in Quebec. (See RIEL, LOLIS.) The protest began a chain of events which was to destroy the Conservative government.

At the time, other things seemed more urgent than the fate of Riel. The National Policy had been put into effect but Canada, after a brief boom in the 1880s, settled down into a prolonged depression which lasted for a decade. The Canadian Pacific railway was built, but the northwest did not fill up with settlers. Emigrants from the British Isles and Europe still went mainly to the United States. Canadians were going there in large numbers, too, and the Liberal opposition added to their criticism of the National Policy and the Canadian Pacific railway sarcastic comments on the exodus of Canadians in which these measures, they alleged, had resulted.

Nonetheless, the Conservative party survived the next two elections, those of 1887 and 1891, in both of which the Canadian tariff and commercial relations with the United States were the leading issues. In 1891 the Conservatives won mainly by an appeal to patriotic sentiment against the Liberal policy of unrestricted reciprocity with the United States, the Conservatives holding that commercial union inevitably would lead to political unification. But Sir John Macdonald died immediately after the latter victory, and already the issue had arisen which was to break up his government and his party.

6. French-Canadian Nationalism.—The execution of Riel had cost ten seats federally. But in Quebec it had led to the rise of a strongly French-Canadian nationalist government led by Honoré Mercier. Mercier succeeded in passing the Jesuit Estates act to compensate the Society of Jesus for lands that had been confiscated at the dissolution of the order in 1773, and asked the pope to decide how the money should be awarded. This request gave offense in Protestant circles in Ontario and a brilliant young Conservative politician, D'Alton McCarthy, began an agitation against the act and papal intervention in Canadian affairs.

In 1889 he went to speak in Manitoba, where he found the new Liberal government of Thomas Greenway embarrassed by a railway scandal and concerned with the cost of extending schools to newly settled districts. The Manitoba schools were, by the Manitoba act of 1870, denominational schools. McCarthy's attack on the growing influence of Catholicism touched off an attack on the French language and the Catholic schools in Manitoba. French ceased to be an official language of the province and the school system was made nondenominational by the Manitoba School act of 1890.

The attack on the constitutional rights of the French and of Roman Catholics of Manitoba was contested in the courts. The right of the province to legislate as it had done was upheld. The Roman Catholics then sought remedial legislation under the British North America act of 1867, and in 1895 the courts held that parliament had the obligation to pass such legislation. But when the distracted Conservative government under its fourth prime minister since Macdonald's death introduced a remedial bill to restore Catholic schools, it failed to carry it before the life of that parliament ended.

In the ensuing election (1896) the Manitoba school question was a burning issue, especially in Quebec. Should the French voter support the Conservatives who had tried to impose remedial legislation on Manitoba, or the Liberals who held that education was a provincial subject and that the Manitoba government could be persuaded by a Liberal government to do justice to a minority? The Liberal plea was put by Wilfrid (later Sir Wilfrid) Laurier, a

French Canadian who in 1887 had succeeded Edward Blake as leader of the Liberal party.

The Liberals won a decisive victory partly because Quebec gave Laurier a large majority. The Manitoba school question was then compromised by Laurier and Greenway agreeing on legislation which allowed religious instruction under limited conditions and instruction on prescribed conditions in English and French "or such other language on the bilingual system."

7. Imperial Preference.—The problem of the tariff was urgent, for the Liberals had preached the doctrines of free trade. They had, however, to face the condition that many industries had grown up under protection and that to open the door to the more highly developed manufactures of the United States would involve disaster. The year 1897 was the 60th of the reign of Queen Victoria, and Laurier met his difficulties with a brilliant stroke. Though he made but slight changes in the tariff, he used the occasion of the jubilee to give Great Britain a reduction of 25%, later increased to 33 $\frac{1}{3}$ % of the tariff.

More important to Liberal success than these measures, however, was the fact that they came into power as the great depression of the 1880s and 1890s gave way to a prolonged boom. From 1896 to 1912 Canada prospered as never before, a prosperity which was advertised to the world by the last of the great gold rushes, the Yukon rush of 1897-98. With prosperity the west began to fill up at last. The last free land in the United States was gone, and emigrants from south of the border, from the British Isles and from Europe poured into Manitoba and the Northwest Territories in a last great land rush. To deal with it, and the rapidly swelling wheat crop of the prairies, two more transcontinental railways were built, the Canadian Northern, and the Grand Trunk Pacific in conjunction with the National Transcontinental. The two new provinces of Alberta and Saskatchewan were created in 1905 with self-government on the lines of the other seven provinces. This was done not without friction, for again the demand was made for the right to separate schools, supported by the state! in which should be taught the Roman Catholic faith. Minor compromise eased the friction and Regina and Edmonton, so recently little more than trading posts, soon had impressive parliament buildings as capitals respectively of Saskatchewan and Alberta. The political framework of Canada from the Atlantic to the Pacific was thus completed.

At the time that the farming frontier of the west was being taken up, a new mining frontier was being opened up on the Precambrian shield of northern Ontario and Quebec. The Cobalt strike of 1903 touched off a rush of prospectors in search of the precious and the base metals of the shield. The shield also began to yield the hydroelectric power of its many rivers, and the wood pulp of its spruce forests. A whole new complex of primary and secondary industries began to develop, and even while Canada's boom depended mostly on western wheat, the industrial development of the country was being rapidly advanced.

8. Support of the Empire.—Canada was not allowed to proceed in peace with its internal growth. In 1899 the South African War raised the question of Canadian participation in imperial wars. Laurier took his stand on the principle that only the Canadian parliament could decide to what extent Canada would participate. But the matter remained a live one. It recurred at successive imperial conferences from 1902 on, and especially in Quebec. There Canada's limited role in the South African War of recruiting Canadian contingents who were, however, paid by Great Britain had aroused the opposition of Henri Bourassa, a grandson of Papineau. Finally, the question became one of what contribution Canada should make to the imperial navy. Laurier's decision was to create a Canadian navy which might in war come under imperial command, but even this decision cost the government a by-election in Quebec in 1910.

9. Anti-American Feeling.—Then in 1911 the Laurier government fell before an outburst of anti-American feeling. The Yukon gold rush had made necessary a settlement of the vaguely drawn boundary of the Alaskan panhandle. It was settled in 1903 in favour of the United States claim by a joint tribunal, but Canadians felt the British representative had given in to American

pressure and yielded up Canada's right. The result was a feeling that Canada must handle its own affairs and that the United States had once more imposed its views in a boundary dispute. But when in 1911 the Canadian government was asked by the United States government to discuss a reciprocity agreement, and one was made, it supposed that Canada, which had wanted reciprocity since 1866, would approve and return the Liberals to power. The farmers of the Canadian west welcomed the proposal; it would give them wide markets and cheaper agricultural implements. But industry was naturally alarmed at any intrusion on a protected field; the railways feared diversion of traffic from the long lines running east and west to north-south lines to the United States; and banking interests were alarmed lest closer relations should lead to the financial dominance of New York city. These considerations were reinforced by the strong British sentiment in Canada, which resented giving the United States advantages in trade superior to those of Great Britain. Laurier dissolved parliament with confidence, but a violent campaign in defense of the national policy of tariffs and east-west railway traffic, aided by tactless American statements that Canadian union with the United States was only a matter of time, defeated the Liberals. (See also LAURIER, SIR WILFRID.)

10. World War I.—The Conservatives thus came to power under Robert (later Sir Robert) Laird Borden at the end of a great boom and on the eve of a great war. Canadian doubts about the degree of participation in wars to which Great Britain was committed were resolved by the German invasion of Belgium in World War I; Canada went to war united. At first Canadian troops were under British command, but by the end of 1916 four divisions had been built up, and were formed into a Canadian army corps under a Canadian commander, Gen. Sir Arthur Currie, in 1917. The war had stimulated national feeling, and the army became the symbol and expression of that feeling.

Canada also contributed food to the war effort and, on a rapidly increasing scale, munitions also. The war greatly accelerated the industrialization of the country. The demand for manpower led to a price inflation and a demand in 1917 for conscription. Prime Minister Borden proposed a coalition government to carry military conscription, but Laurier declined, largely because of opposition in Quebec. Conscription was enacted and a Union government formed which in Dec. 1917 won the general election. But the Liberal party was split and French Canada alienated.

Canada shared from 1917 in the conduct of the war through the imperial war cabinet, on which Prime Minister Borden sat. When the peace was made, Canada with the other dominions took a separate seat at the conference, signed the peace treaties as a nation of the British empire, and entered the League of Nations in its own right. Canada's share in the victory was thus recognition by its being accepted as an autonomous nation within the British empire, but the implications of the new status had yet to be worked out.

11. Postwar Unrest.—Within Canada war had less pleasing results. The Canadian Northern and Grand Trunk railways had gone bankrupt, and had to be taken over by the federal government and organized as the Canadian National railways between 1917 and 1923. By 1920 the slump from the prosperous war years had set in; wheat had fallen from its 1919 level of \$2.15 a bushel to 60 cents. The prairie farmer was hardest hit. Wheat farming had to be conducted on a large-scale basis and with machinery, necessitating a large capital outlay, which was usually found in the form of bank loans. Under these circumstances, forms of co-operation became popular. The most successful were the Grain Growers' associations, which originated in the Northwest Territories in 1901 and spread to Manitoba, and the United Farmers of Alberta, organized in 1909. Those associations had created the United Grain Growers' Grain company in 1907 and the Saskatchewan Co-operative Elevators company in 1911. These were joined after 1923 by the co-operative elevators companies of the wheat pools.

The period of postwar deflation presented a curious paradox. While the prices of primary products and wages fell, the prices of other commodities and services remained high. Protected by the tariff, or sustained by government subsidy, industry generally

weathered the difficult years between 1919 and 1924. There was no reduction of the tariff until 1923, when the reductions were offset by bonuses to favoured industries. Taxes, such as the sales tax, income tax and a variety of "nuisance" taxes which fell on individuals, rather than on corporations, remained.

Labour unrest was widespread, caused partly by the high cost of living, partly by the spread of industrial unionism in western Canada, partly by the revolutionary ferment of the times. This unrest flared up in strikes across the country. The chief was the Winnipeg strike of 1919. In that city a strike to force recognition of the right to bargain collectively in the metal trades became a general, sympathetic strike which involved the police and other public services. A bitter struggle followed, and after six weeks the strike was broken by the arrest of the strike leaders. This harsh and drastic action greatly strengthened the labour movement in Canada, which was henceforth a force to be reckoned with.

Agrarian unrest had also been building up since the defeat of reciprocity in 1911. In 1916 and 1919 the Canadian Council of Agriculture published "farmers' platforms." In 1920 and 1921 the unrest was greatly increased when the farmer was caught between falling agricultural prices and a still high cost of living. The farmers began to enter politics against the old political parties. They captured, or threatened to capture, several provincial governments, and then formed a farmers' federal political movement, which was called the National Progressive party.

In Quebec the French voters remained alienated from the Union government and the Conservative party. When the Liberal party elected a leader to succeed Laurier, he had to be a man acceptable to Quebec. He was found in William Lyon Mackenzie King, a grandson and namesake of the rebel, a young man of advanced ideas and a Liberal of rank.

All these forces determined the outcome of the election of 1921. The Union government of Prime Minister Arthur Meighen, who had succeeded Borden, was defeated. The Liberals elected the whole provincial representation of Quebec, 65 members, but only half the house of commons in all. Farmers and workers had revolted from both old parties to elect 65 Progressives. The new Liberal leader formed a minority government which could count on some support from the Progressives.

Domestically the decade of the 1920s was marked by a depression in the first half and a boom in the second. Improved conditions, which had been apparent as early as 1925, produced an unparalleled period of prosperity. A rise in the price of agricultural products helped the farmer, who was further assisted by the extension of branch lines of railway through the wheat-growing region of the west. Industry was stimulated by the influx of foreign capital. Another feature was the establishment of branch factories of United States or British origin. The government's steady reduction of taxation was popular, and the tariff was progressively scaled down, especially as it affected textiles. The Liberal party continued to hold the allegiance of Quebec and gradually reabsorbed all but the most militant of the Progressives. Some mild reform legislation and the building of the Hudson Bay railway alone distinguished these years.

12. External Affairs.—The major developments were in external affairs. A growing North American point of view was demonstrated in an emphatic fashion in 1921, when Canada was largely responsible for inducing Britain to abandon its alliance with Japan, chiefly in deference to United States opinion. Indicative of its increasing independence was Canada's refusal to be bound by imperial agreements unless formally engaged in by Canada. This was shown dramatically in 1922 when Prime Minister King refused to accede to Britain's request for troops in the impending crisis with Turkey until parliament had been consulted. In the various postwar European settlements, Canada had little part. It refused to ratify the treaty of Lausanne or the Locarno security pact, asserting that, not having been consulted and not having signed, it had no obligation. The right to separate diplomatic representation was successfully asserted as early as 1920, although it was not until 1927 that the first legation was opened at Washington, D.C. After that date Canada established legations at Paris and Tokyo. In 1923 treaty-making power was asserted in negotiating and signing the

Halibut treaty with the United States. Assertions of autonomy as sweeping as these demanded a restatement of Canada's relations to the British empire. The formula was found at the Imperial conference of 1926, which declared the dominions to be partner nations with Britain, equal in status! and bound together only by an allegiance to a common crown. In 1931 the Statute of Westminster (*q.v.*) gave legal effect to the declaration of the conference.

13. Economic Changes.— The 1930s found Canada sinking into the world-wide depression which was accompanied by prolonged drought on the prairies. The depression had been ushered in by the spectacular crash of the Montreal and Toronto stock markets on Oct. 29 and Nov. 13, 1929. Canada suffered severely, and the wheat economy and the government services of the prairie provinces were prostrated. Only heavy federal aid kept them going. Massive industrial unemployment plagued the cities and bankrupted municipal finances. The rise of the gold mining industry of Ontario and Quebec, which received an immense boost from the United States revaluation lam raising the price of gold from \$20 to \$35 an ounce, lightened the picture and helped the country to bear the public cost of the depression.

Economic distress so widespread had inevitable political repercussions. The Liberal party had been defeated in the general election of 1930, and the Conservatives under Prime Minister Richard B. Bennett governed the country until 1935. But their best endeavours failed to relieve the depression and they were swept from office by the Liberals in 1935. The depression also gave rise to a number of other parties. One was the Co-operative Commonwealth federation (C.C.F.), a farmer-labour party with a socialist intelligentsia. Another was the Social Credit party, which captured the province of Alberta in 1935 and attempted to end the depression by sweeping reform of the monetary system. The Social Credit party, which vocalized agrarian discontent, also appeared in British Columbia in 1952 and won control when the provincial Conservative party almost disappeared. Still another party was the Union Nationale which won power in Quebec in 1936. The political unity of Canada, slowly restored in the 1920s, was shattered once more.

It was more than apparent by 1935 that Canada was in serious trouble. Over the years the provinces had gained by judicial interpretation powers and responsibilities greater than their financial resources permitted them to exercise and discharge. This was particularly true of the poorer Atlantic and prairie provinces. The federal government had great financial resources but its powers had been progressively narrowed by the same process of interpretation. It seemed necessary to adjust the balance. An attempt to do so by constitutional amendment failed, and a royal commission on dominion-provincial financial relations was set up to study the problem and make recommendations. It recommended some transfer of responsibilities to the federal government, notably unemployment relief; and such financial transfers to the provinces as would maintain throughout Canada a minimum national standard of public services. It reported, however, in 1910, when Canada was already once more at war.

Canadian entrance into World War II was made deliberately a sovereign act of an independent nation by delaying it for one week after the declaration of the United Kingdom. Nonetheless, Canada was once more at war united with Great Britain. In Canada after World War I the ideals of the League of Nations had had a wide acceptance. Nevertheless, as a group, Canadians were unwilling to support League action, as witness their equivocal stand in 1932 in refusing to uphold sanctions against Japan at the beginning of the Sino-Japanese War, and the repudiation of the Canadian delegate to the League on the application of economic sanctions to Italy when it invaded Ethiopia in 1935. In British Commonwealth affairs Canada made full use of existing machinery, the imperial conference and the high commissionership, and seemed to have expected to be "informed" but not necessarily "consulted" on the various moves of British European policy. In its relations with the United States, Canada was much more forthright, thus indicating increasing commercial interdependence and an increasing American consciousness. Yet Canada's growing concern in the

Americas was not sufficient to carry it into the Pan American Union, in spite of substantial investments in Peru and Brazil. To the various world crises, Canada's response was by no means clear-cut. In official circles the Munich appeasement policy was tacitly accepted, and as late as the spring of 1939 the government refused to countenance any program which would involve Canada in war in defense of the smaller nations. Only the manifest menace of Hitler's aggression, made evident after Munich, united the nation and took it into war.

14. World War II and After.— The war at once pulled Canada out of the depression and drove its industrial development ahead at a furious pace. It restored the national morale after the sapping effect of the depression. Despite crises on the manpower (compulsory service) question in 1942 and 1944, unity between French and English Canadians, though strained, was maintained without an open breach like that of 1917. Canada came out of the war with greatly increased strength and greatly enhanced morale.

U.S.-Canadian relations reached a new high in co-operation during World War II and included agreements on defense, production and peace questions. From the summer of 1940, with the conference on defense of the northern half of the western hemisphere held at Ogdensburg, N.Y., at which the Permanent Joint Board On Defense was created, until a few months before the close of the war, when the two countries reached a wartime agreement on military transport routes, excellent relations existed. These extended into the postwar years during which the radar warning lines in Canada were built and a joint agreement for the air defense of North America was put into operation (1958).

The effects of the war shined themselves both in domestic and external affairs. At home the constitutional problem of ill-adjusted powers and resources was met by using the need to avoid a postwar slump to institute a number of social security measures, such as unemployment insurance and family allowances, which in fact established the welfare state in Canada. This was followed by instituting a system of federal payments to the provinces to enable even the weakest to maintain a minimum level of services. As all these measures came into effect, not in a postwar depression, but in the greatest boom Canada had ever known, they of course were successfully initiated.

In external affairs, Canada took an active part in founding the United Nations. While it pressed for the possession by the Security Council of a police power sufficient to maintain the peace, the Canadian government claimed for Canada the status of "middle power," and argued that power should be judged by the functions a nation could discharge. As Canada was relatively weak militarily, but strong economically, it hoped to exercise a decided influence in the economic and social, if not in the political, agencies of the United Nations. In fact, it exercised much political influence because of the personal confidence inspired by Lester B. Pearson, Canadian secretary of state for external affairs in the late 1940s and the 1950s.

Louis St. Laurent and Pearson were Canada's representatives in the creation of the North Atlantic Treaty organization. This body was of peculiar interest to Canada, because in the association of Atlantic powers it found an offset to Canadian isolation in America face to face with the United States.

15. National Sovereignty and Unity.— The exercise of full national sovereignty was accompanied by the removal of all but the last vestiges of the old imperial connection. Appeals to the privy council of the United Kingdom from Canada's supreme court were ended in 1949. But the ending of the formal ties perhaps only increased Canada's interest in the informal association of the commonwealth, particularly as the new Asian and African members transformed it into a multiracial grouping.

It was in this completion of the development of national status that the work of Prime Minister King terminated. In office from 1935 to 1948, and having served 20 years as prime minister, he stood down for St. Laurent. Under St. Laurent the boom continued, but the flow of reform legislation stopped. For almost a decade Canadian politics were lulled in a golden apathy and the opposition parties despaired of ever shaking the long rule of the Liberal party.

The boom was based partly on new resources, such as the oil of the prairie provinces and the uranium of the Pre-Cambrian shield. It was based still more on a roaring industrial development of central Canada. In 1921 Canada was still by a slight margin an agricultural and rural country. By 1951, it was overwhelmingly industrial and urban.

With the boom went an acceleration of the rate of population growth. A population of 3,689,257 in 1871 had become 8,787,949 in 1921; in 1956 it was 16,080,791 and by 1961 it exceeded 18,000,000 and was growing rapidly both by immigration and natural increase. About one-third was French, less than one-half British, and the remainder in the great majority European in origin.

In 1932 the St. Lawrence Deep Waterways treaty was signed with the United States providing for so widening and deepening the river and Great Lakes channels that ocean-going vessels could reach Port Arthur, Ont., or Chicago, Ill. The increased production of electric energy was another benefit that would flow from the agreement. The agreement was not ratified by the United States and construction of a seaway did not begin until 1955. The seaway was completed and opened to shipping in 1959. In 1960 a treaty was negotiated to control the development of hydroelectric power on the Canadian portion of the Columbia river.

Perhaps the most memorable developments of these years, however, were in the arts rather than in economic growth or political change. A royal commission on the arts, letters and sciences resulted in national aid to universities and, through the Canada council, to the arts and to scholarship in the humanities and social sciences. The Canadian Broadcasting corporation also greatly contributed to the development of the arts.

After the mid-1950s the boom began to slacken. At the same time, there was an outburst of criticism in parliament against the Liberal regime, to which the public responded. The Progressive Conservative party had just elected a new leader in John Diefenbaker and was able to turn the public reaction to its advantage. In 1957 the Liberal party was defeated after 22 years in power. A minority Conservative government came into office to grapple with a recession and to maneuver for advantage in a new election. St. Laurent retired and was succeeded by Lester B. Pearson as leader of the Liberal party. In the general election of 1958 the Conservatives won 208 seats out of 265 in the house of commons in the greatest electoral victory in Canadian history. Even in Quebec, the Liberal stronghold, it had a majority. The breach of 1917 had closed at last, and Canadian national unity was perhaps at its greatest pitch since confederation. (W. L. Mo.)

V. POPULATION: TRENDS AND DISTRIBUTION

1. Geographic Distribution.— The population of Canada reached 18,000,000 in 1960, having passed the 17,000,000 mark in 1958, 16,000,000 in 1956 and 15,000,000 in 1954. Growth has been rapid in the post-World War II period, but Canada is still a country of sparse settlement and vast area. The average density of population is about four and one-half persons per square mile, but this figure is misleading since most of the far northern area is barren and has never been settled except by Eskimos and a few Indians and whites. Canada's main area of settlement is a belt of 200 mi. along the United States border, and within that belt 90% of the Canadian people live.

TABLE III.—Population by Provinces, 1931-61

Provinces and territories	1931	1941	1951	1956	1961
Newfoundland	361,416	415,074	457,853
Prince Edward Island	88,038	95,047	98,429	99,285	104,629
Nova Scotia	512,846	577,962	642,584	694,717	737,007
New Brunswick	408,219	457,401	515,697	554,616	597,936
Quebec	2,874,662	3,331,882	4,055,681	4,628,378	5,259,211
Ontario	3,431,683	3,787,655	4,597,542	5,404,933	6,236,092
Manitoba	700,139	729,744	776,541	850,040	921,686
Saskatchewan	921,785	895,992	831,728	880,665	925,181
Alberta	731,605	796,169	939,501	1,123,116	1,331,944
British Columbia	694,263	817,861	1,165,210	1,398,464	1,629,082
Yukon	4,230	4,914	9,096	12,190	14,628
Northwest Territories					
Franklin

Ontario accounts for about one-third of Canada's population, and Quebec for more than one-quarter. British Columbia and Alberta are growing more rapidly than any other parts of the country and at the 1961 census together made up almost one-sixth of the Canadian total. The four Atlantic provinces together account for only 10% of the Canadian population. Saskatchewan's population declined from 1931 to 1951, but by 1961 had surpassed the 1931 level. Manitoba's growth has been steady, but well below the national average rate. The numerical distribution of the Canadian population by provinces in five census years, 1931 to 1961, is shown in Table III.

In three of the Atlantic provinces. Newfoundland, Nova Scotia and New Brunswick, settlement is mainly on the coasts, in fishing villages and port cities. Agriculture is confined to limited regions and most of the interior of these provinces is forested, rocky or marshy. Lumbering and pulp and paper manufacture support settlements in all three provinces. Mining, manufacturing, transportation and commercial and governmental services provide employment for the urban populations of the region, but none of the cities has a population of over 100,000. Unlike the other Atlantic provinces, Prince Edward Island, which has unusually fertile soil, is closely settled. Agriculture is the main support of its population, which remains just over 100,000, having grown very little for the past 100 years.

In Quebec, beginning in the 17th century, French-Canadian agricultural settlement spread back from the St. Lawrence river in long narrow farms and maintained the same distinctive linear pattern back from the early roads. English-speaking settlers established farms north of the Vermont border in the 19th century, but gradually this enclave of English-speaking persons has receded, as French-Canadians have taken over the farms and populated the urban centres. By the mid-1950s, 70% of the people of the province of Quebec lived in cities and towns of over 1,000 population, indicating that the formerly rural, agricultural Quebec had become one of the industrial and commercial centres of Canada. The rocky hills of the Pre-Cambrian shield, rising to the north of the St. Lawrence lowlands, have deterred settlement except for forestry camps, mining towns, power plants and railway divisional points. Agricultural settlement in northern Quebec is confined to the Lake St. John area and the clay belt adjoining Ontario near the upper Ottawa river. North of the railway lines, Quebec is largely uninhabited.

Ontario is the most populous province, having more than 6,200,000 people in 1961, but, as in Quebec, most of its people live in a small lowland area—constituting about 50,000 sq.mi. between Lakes Ontario, Erie and Huron, and along the St. Lawrence and Ottawa rivers. About one-third of the cities of more than 30,000 persons in Canada are located in southern Ontario, and they produce almost one-half of the manufactured wealth of Canada. To the north, again the Pre-Cambrian shield discourages agricultural settlement, though towns based on the mineral, forest and water power resources of the region were established there in the 1920s and 1930s, and still more rapidly in the 1940s and 1950s. In Ontario, as in Quebec, the region north of the transcontinental railway lines is virtually uninhabited.

The three prairie provinces have a wedge of population which broadens westward, following the widening plains and grasslands. Settlement expansion and railway building went together at the turn of the 20th century, until most of the grasslands had been plowed for grain. In Manitoba, farm settlement is mainly in the southern quarter of the province. In Saskatchewan it occupies the southern half, while in Alberta farming extends as far as the Peace river district, north of the 55th parallel. Population is fairly evenly distributed over the Prairie region and there are many small trading centres and market towns. In the second half of the 20th century urban population has been growing quite rapidly and rural population declining, owing to changes in farming methods which reduced the labour force needed to run the farms. The oil and natural gas resources of the region, particularly in Alberta, have stimulated the growth of industry and of the major cities. Alberta's population passed the 1,000,000 mark in 1953, and it has become Canada's fourth largest province.

TABLE IV.—Populations of Metropolitan Areas (1961 preliminary census)

Area—	Population	Area	Population
Calgary, Alta.	271,764	Saint John, N.B.	92,479

Quebec, Que.	351,448		

The mountainous western province of British Columbia has three-quarters of its 1,600,000 population concentrated into the small southwestern corner. British Columbia has a higher percentage of urban dwellers than any other province. Apart from the main population centres in the port city of Vancouver, the lower Fraser valley farming region, and southern Vancouver Island, settlement is principally in mining towns, forest industry settlements, transportation centres, the orchard district of the

Okanagan valley and the wheat farming area of the Peace river. Discoveries of natural gas in the latter region encouraged the forming of industrial settlements in the northern interior of British Columbia, while on the coast the aluminum smelting town of Kitimat, with a population exceeding 15,000, has been built entirely since 1950 to take advantage of the hydroelectric power of the inland rivers nearby.

2. Rural-Urban Distribution.—Canada's population has tended steadily to concentrate in cities and towns. In 1956 urban areas (meaning all cities, towns and villages of 1,000 persons or over, whether incorporated or not, as well as all parts of metropolitan areas) held 66.6% of the population. This reflected a major change since the beginning of the century; in 1901 only 37.5% of the population was classed as urban (*i.e.*, living in incorporated cities, towns and villages of 1,000 population and over) and in 1921 only 49.5% of the population was classed as urban. Since 1921 the urban growth has increased rapidly, from 4,400,000 in 1921 to 10,700,000 in 1956, while the rural population has grown very little, from 4,500,000 in 1921 to 5,400,000 in 1956. The part of the rural population living on farms has actually declined, from 3,200,000 in 1931 (the first year for which a figure on farm population became available) to 2,600,000 in 1956.

Table IV shows the populations of the major metropolitan areas in 1961. The populations of suburban communities, many of which are separately incorporated for municipal purposes, are included in these figures.

3. Natural Increase, Immigration and Emigration.—The rapid growth of Canada's population in the 20th century has been mainly because of natural increase, *i.e.*, the excess of births over deaths. Compared with natural increase, net migration, or the excess of immigration over emigration, has contributed relatively little to population

growth, except in the first decade of the century and again in the years after World War II. A population balance sheet for the years 1901-56 makes clear the relative importance of the sources of growth. (See Table V.)

The number of births has gone up substantially in each decade, except in the 1930s when it declined because of the depression. After 1945 the birth rate remained consistently between 27 and 29 per 1,000 per annum. Meanwhile the number of deaths had not increased by anything like the same amount as the number of births, because of steady improvements in public health and in particular the control of infant mortality. The death rate fell steadily after 1945 (when the rate was 9.4 per 1,000) and was as low as 7.9 per 1,000 in 1958.

Persons born outside Canada constituted, in 1951, approximately 15% of the population, and persons born in Canada constituted the remaining 85%. Canadians are made up of a wide range of racial or national stocks, but almost 50% of them are of British origin. The original French-speaking Canadians have had a high birth rate and have multiplied in southern Quebec and expanded into other provinces, particularly into northern New Brunswick and north-eastern Ontario. French-speaking Canadians thus number about 31% of the Canadian total.

Immigrants from mainland Europe came in increasing numbers after 1900 and helped greatly to settle the prairie farmlands or became workers in the industrial cities of Ontario. As a result, about 18% of Canadians have a European (non-British) national background. The largest numbers have been classified as from Germany, Scandinavia and the Ukraine. (See Table VI.) The native Indians in the late-1950s were steadily increasing in numbers and in 1959 totaled 179,126, of whom 37% lived in the prairie provinces. The other aboriginal inhabitants of Canada, the Eskimos, numbered about 11,500, and were widely scattered in small groups across arctic Canada. (See also *Native Peoples*, above.)

Immigration fluctuates greatly from year to year. The periods of rapid immigration correspond with periods of prosperity and rapid economic expansion. For example, in the first three decades of the 20th century rapid immigration was associated with the rapid agricultural settlement of the western prairies and the growth of industrial cities in eastern Canada. In the depression decade of the 1930s immigration virtually ceased, but after World War II there occurred both a remarkable revival in immigration and a spectacular economic expansion based on the exploitation of resources in hitherto undeveloped regions and on the continued growth of industrial cities. Immigration is both a result and a cause of this economic expansion: the immigrants have included a high proportion of young working-age men, of whom there was a shortage in the Canadian population owing to the low birth rates of the 1930s.

Emigration from Canada has been substantial in most periods when the United States has been prosperous. Canadian-born persons, as well as immigrants to Canada, have been attracted to the large cities south of the international border, and have contributed a disproportionately high share to the professions and skilled occu-

pations. At the 1950 census of the United States there were approximately 995,000 Canadian-born persons in that country. This equaled 8.3% of the Canadian-born population in Canada itself as reported in the 1951 census. In other words, for every 12 Canadian-born persons who have remained in Canada, one has emigrated to the United States. An interesting development, however, has been the gradual decline of emigration since 1930. It appears that the forces of attraction to the United States are diminishing. There were fewer Canadian-born persons in the United States in 1950 than in 1930, the peak year.

In the decade 1941-51, of the approximately 379,000 persons who emigrated from Canada to all countries, three-fifths were Canadian-born, and the remainder a-ere re-emigrants.

(D. C. C.)

VI. ADMINISTRATION AND SOCIAL CONDITIONS

A. GOVERNMENT

Canada is one of the self-governing nations of the Commonwealth of Nations. At the Imperial conference of 1926 Canada and the other dominions were declared to be "equal in status, in no way subordinate one to another in any aspect of their domestic or external affairs, though united by a common allegiance to the Crown and freely associated as members of the British Commonwealth of Nations." In 1931 the British parliament incorporated this principle into the Statute of Westminster, and in general removed any remaining disabilities from which legislatures in Canada had suffered. The governor general, as the representative of the queen, is appointed on the recommendation of the Canadian cabinet, although it seems to be customary to ascertain the queen's wishes by consultation previous to the appointment. Canada remained dependent on the British parliament for legislation only with respect to the amendment of the British North America act (*q.v.*), which was still beyond the legislative jurisdiction of either the federal or provincial parliaments, although this power was exercised only on Canadian request.

Both the Canadian and British parliaments passed the British North America act (no. 2), 1949, in which the Canadian parliament was given power to amend the constitution on matters lying solely within federal jurisdiction. There still remained for constitutional amendment, however, those areas which either belong to the provinces or directly affect the provinces, which are outside the jurisdiction of either the federal or provincial legislatures. The many unwritten conventions of the British constitution, such as the system of cabinet government and the office of prime minister, apply in Canada as in the United Kingdom. Canada also derives from the British constitution the structure of parliamentary monarchy and, generally, of British law based on parliamentary sovereignty (not on fundamental law, as in the United States).

The most important difference between the British and Canadian constitutions is that while the British is unitary (with power ultimately residing in one central organ, parliament), the Canadian is federal (the member provinces retaining in part their own organizations and individuality).

The federal principle was embodied in the British North America act which laid down the subjects of legislation assigned respectively to the federal government and the provinces, and the narrow area in which there was to be concurrent jurisdiction. The federal parliament has exclusive legislative authority in all matters relating to the regulation of trade and commerce, defense, navigation and shipping, banking and currency, etc. The federal government also has unlimited taxing powers and a broad residual power. The provinces have exclusive control over all matters relating to education, municipal government, property and civil rights within the province, licences, etc. The provinces' taxing power is limited to "Direct Taxation within the Province in order to the Raising of a Revenue for Provincial Purposes," and the residual power is limited to "Generally all Matters of a Merely local or private Nature in the Province." It seems to have been the original intention of the promoters of the constitution to invest the federal parliament with an overriding authority, but the judicial interpretation of the act to some extent nullified this in-

tion, and the provincial legislatures were pronounced to be sovereign within the sphere assigned to them.

The capital of Canada is Ottawa. The capitals of the provinces are: Alberta, Edmonton; British Columbia, Victoria; Manitoba, Winnipeg; New Brunswick, Fredericton; Newfoundland, St. John's; Nova Scotia, Halifax; Prince Edward Island, Charlottetown; Ontario, Toronto; Quebec, Quebec; and Saskatchewan, Regina.

1. Executive Power.—Formal executive power rests in the hands of the queen, who is represented by the governor general. He exercises such official authority as summoning and dissolving parliament, and giving royal assent to bills passed by parliament. The governor general, however, acts only on the advice of the Canadian prime minister and his colleagues in the cabinet, except on those rare occasions when there is doubt as to whether the prime minister commands the confidence of the house of commons. The active executive authority rests in the cabinet, which is selected by the prime minister from among his followers in the house of commons. The prime minister may select a member of the senate to hold a cabinet portfolio, but usually not more than one member is so chosen. The prime minister is normally the leader of the political party holding the most seats in parliament, and in all cases he must be able to command the support of a majority in the house.

Prime Ministers of Canada

Name	Party ^x	Term
Sir John A. Macdonald	(C)	July 1, 1867–Nov. 5, 1873
Alexander Mackenzie	(L)	Nov. 7, 1873–Oct. 16, 1878
Sir John A. Macdonald	(C)	Oct. 17, 1878–June 6, 1891
Sir John J. C. Abbott	(C)	June 16, 1891–Nov. 24, 1892
Sir John S. D. Thompson	(C)	Dec. 5, 1892–Dec. 12, 1894
Sir Mackenzie Bowell	(C)	Dec. 21, 1894–April 27, 1896
Sir Charles Tupper	(C)	May 1, 1896–July 8, 1896
Sir Wilfrid Laurier	(L)	July 11, 1896–Oct. 6, 1911
Sir Robert L. Borden	(C)	Oct. 10, 1911–Oct. 12, 1917
"	(U)	Oct. 12, 1917–July 10, 1920
Arthur Meighen	(U-N-C)	July 10, 1920–Dec. 29, 1921
William Lyon Mackenzie King	(L)	Dec. 29, 1921–June 28, 1926
Arthur Meighen	(C)	June 29, 1926–Sept. 25, 1926
William Lyon Mackenzie King	(L)	Sept. 25, 1926–Aug. 6, 1930
Richard Bedford Bennett	(C)	Aug. 7, 1930–Oct. 23, 1935
William Lyon Mackenzie King	(L)	Oct. 23, 1935–Nov. 15, 1948
Louis Stephen St. Laurent	(L)	Nov. 15, 1948–June 17, 1957
John George Diefenbaker	(P-C)	June 21, 1957–

* (C) Conservative; (L) Liberal; (U) Unionist; (U-N-C) Unionist-National and Conservative; (P-C) Progressive-Conservative.

2. Legislative Power.—The federal legislature is bicameral; in addition to the representative of the crown it is composed of a senate numbering, after the admission in 1949 of Newfoundland, 102 members, who are appointed for life by the governor general in council; and a house of commons numbering 265 members who are elected by the people for the duration of parliament, which may not be longer than five years. In the provinces, the crown is represented by a lieutenant governor, appointed by the federal government. He is advised by an executive council composed of a premier and a varying number of ministers, all of whom sit in the legislature. In nine of the ten provinces the legislature is unicameral, being composed of a legislative assembly elected by the people for a term of not more than five years. Only in Quebec is there a second chamber, styled a legislative council, composed of nominees (for life) of the provincial government.

3. Judicial Power.—Canada has a single system of courts to enforce both federal and provincial law. The administration of justice, including the constitution of the provincial courts, comes within the jurisdiction of the provincial legislatures with the exception that the criminal law comes under the jurisdiction of the federal parliament. The judges of the provincial courts are appointed, during good behaviour, for life, by the federal government, and are removable only by the governor general on address, or formal petition, by the senate and the house of commons. Canada's supreme court was established in 1375. Its justices are appointed in similar fashion, except that they must retire at age 75. Legislation in 1949 abolished the right of appeal to the judicial committee of the imperial privy council in England, and made an enlarged supreme court the nation's highest tribunal. Police

magistrates and the officials of some special courts, such as juvenile courts, are appointed by the provincial governments.

The Royal Canadian Mounted Police (*q.v.*) is a federal force charged with the enforcement of federal legislation. The provinces may maintain a provincial police force and Ontario and Quebec do so, but all the other provinces hire the services of the R.C.M.P. to carry out provincial police duties. Municipalities may also employ their own police force, and most of the larger cities do so, but in many of the smaller communities, outside of Ontario and Quebec, the R.C.M.P. are also employed to carry out municipal police duties.

4. Taxation.--The division of powers and responsibilities of government, including taxation, between the federal and provincial governments is set out in the British North America act. Responsibilities within various spheres of jurisdiction have changed greatly since 1567. By and large those responsibilities which were assigned to the provinces have expanded more rapidly than have the potential fields of taxation assigned to them. This has led to continued demands by the provinces for an increasing share of the tax dollar. Many conferences have been held to resolve this problem, particularly in the fields of personal and corporation income tax and succession duties, or estate and inheritance taxes (*q.v.*). A series of tax rental agreements under which the federal government rented, or took over, from the provinces the personal and corporation income taxes and succession duties and returned guaranteed minimum amounts ran from 1942 to 1957. The federal government passed the tax-sharing agreements act of 1956 which provided that the provinces could, by agreement, share in the revenues derived from the three standard taxes to the extent of 10% of the individual income tax, 9% of the corporation tax, and 50% of the succession duty. At the same time provision was made for an equalization payment by the federal government designed to bring the tax income, per capita, of each province up to the average of the two highest provinces. In 1958 the percentage of personal income tax allowed was raised from 10% to 13% in an effort to provide the provinces with sufficient revenues to meet their expanding operations. This agreement continued until March 1962 when it was replaced by a new agreement allowing the provinces more responsibility for levying their own income and corporation taxes.

There have been similar adjustments in revenue and responsibility between the provinces and the municipal authorities within their bounds. As the volume as well as the diversity of the public services and the sources and amount of the revenue required continue to change and expand, this problem must be constantly under review. Governments provide services and collect revenues unheard of in years past, but these accrue in ever changing proportions and while adjustments cannot be continuous, they must be sought periodically to maintain equity and efficiency within the federal system. So long as the provinces are limited to such sources of revenue as gasoline tax, general sales tax, liquor profits, licences and permits, many of the provinces have difficulty in meeting the ever increasing expenditures for highways, health and social welfare, education and the development of natural resources. The municipalities, depending as they do for a large portion of their revenue on real property taxation, find even greater difficulty in meeting the growing expenditures required in a modern industrial society.

B. POLITICAL PARTIES

Political parties, like so many Canadian institutions, reflect their British origin and the influence of North American environment. Party designation professes to be based on shades of opinion from right to left, as in Britain, but in practice there are frequently as marked differences in political thought within each of the major parties as there are between parties, as is the case in the United States.

There are two major parties in Canada which have alternated in power since confederation—Conservative (Progressive Conservative) and Liberal. The Conservatives took control of the house of commons from the Liberals in 1957. Quebec has been the Liberal stronghold and Ontario that of the Conservatives. A third

party, the Co-operative Commonwealth federation (C.C.F.), after its success in Saskatchewan in the 1940s, had a national organization, ran candidates in all sections of the country and polled an appreciable popular vote, but it was never the official opposition nor did it hold the balance of power between the major parties. The C.C.F. was more socialist than the older parties, and drew its chief support from the prairie grain farmers, especially in Saskatchewan, and from organized labour in the larger cities throughout the country.

In Aug. 1961, at a national convention, the C.C.F. was re-organized into the New Democratic party with a closer working arrangement with organized labour. T. C. Douglas, former premier of Saskatchewan, was elected national leader.

There are several smaller political parties whose support tends to lie in specific geographic regions. The Social Credit party centres in Alberta, but it has also shown strength in British Columbia. The Union Nationale is a potent factor in provincial politics in Quebec and it operates with some degree of co-operation with the federal Conservative party. The Labour Progressive (Communist) party has frequently put up candidates in the cities but with little or no success.

C. LIVING CONDITIONS

1. Working Conditions.—Canada's labour force has grown rapidly with the expansion of the country and the productive capacity of the economy has increased greatly. Technological improvements, higher wages, better working conditions, higher educational standards and greater emphasis on vocational training have helped to raise the standard of living for the whole community of workers. General improvement in working conditions has been retarded or interrupted on several occasions due to general economic conditions (see *History*, above). Unemployment caused by cold weather, and to some extent by consumer buying habits, results in serious annual loss to the Canadian economy. Though some winter slowdown is inevitable, it has been possible, by concerted effort, to reduce its extent.

Developments in the field of labour have been assisted by legislation at both federal and provincial levels. Laws have been enacted to set minimum standards for hours of work, wages and many other conditions of employment. Most Canadian workers, however, enjoy conditions of employment far better than those required by law. The right of workers to belong to labour unions of their own choosing is protected legally, and union membership has grown rapidly, particularly since 1940. By 1960 there were about 1,500,000 union members. The general average wage per hour was about \$1.70.

Legislation, which may be federal, provincial or in some instances municipal, plays an important part in securing safe and healthy working conditions. Under a Workmen's Compensation act in each province, the worker who is disabled by an industrial accident or a disease caused by the nature of his employment is entitled to compensation based on the amount of earnings and, if the disability is permanent, upon the extent of the disability. In fatal cases wives, children or other dependents are awarded fixed monthly sums. Compensation and medical aid are payable from an accident fund to which all employers are required to contribute and which provides a system of employee insurance. A compulsory scheme of employment insurance and a nationwide free employment service is in operation.

2. Housing.—Like most other countries, Canada faced a serious housing shortage at the close of World War II, but substantial improvements have been made. By 1960 there were 4,300,000 dwellings in the country, and they were being added to at a rate of over 100,000 a year. About one house in every three that was built after 1945 was financed with government assistance. The National Housing act provides for insurance of mortgage loans by private lenders and sets maximum rates of interest that may be charged. By reducing the risk to the lender it enables the borrower to get a larger loan on more favourable terms than would otherwise be the case. The National Housing act also authorizes the national government's agency, Central Mortgage and Housing corporation, to make direct housing loans for such special pur-

poses as the construction of low rental housing and the building of rental units for primary industries. The general shift of population to urban centres, and particularly to suburbs, has brought an increasing awareness of the need for community planning.

D. HEALTH AND WELFARE

1. **Health Services.**—The development of health and welfare services has provided a reasonable comprehensive network of assistance against most economic and health hazards. Health and rehabilitation services have been expanded and integrated to support the work of hospitals and the medical professions, although much remains to be accomplished before adequate facilities are available to deal with the problems of mental illness and the chronic degenerative diseases. There also continues to be variation between provinces in the type of service provided, and in the availability of the services to different groups in the population.

Canada has one of the world's healthiest populations, the death rate being less than 8 per 1,000 of population. This has been due chiefly to reducing the death rate from communicable disease. Public health is primarily the responsibility of the provinces. Federal participation in health matters is generally centred in the department of national health and welfare, although important treatment services are administered by the department of veterans' affairs and the department of national defence. The department of national health and welfare controls food and drugs, including narcotics, and quarantine and immigration medical services, and provides for Indians, Eskimos, sick mariners and other groups. In addition, it provides financial assistance to the provinces for the development of health and welfare services through the national health program, serves in an advisory and co-ordinating capacity, and makes grants to certain voluntary agencies.

Most health programs are administered by provincial health departments or by local health departments and units serving counties and municipalities. They include activities ranging from preventative and treatment services to the operation of public health laboratories. Health responsibilities of the municipalities, particularly the larger ones, generally cover such public health services as sanitation, communicable disease control, child, maternal, and school health, public health nursing, health education and vital statistics. Public mental health programs consist chiefly of treatment and custodial care of persons committed to mental institutions. Hospital facilities expanded rapidly in the second half of the 20th century. Growth has been stimulated by the hospital construction grant under which the federal and provincial governments contribute toward construction costs. By 1960 Canada had approximately 1,400 hospitals of all types with space for about 175,000 beds and cribs; that is, about 11 places for each 1,000 of the population.

By 1960 personal health care and public health services cost the Canadian public over \$1,000,000,000 a year, and about half of it was expended on hospital care. Prepaid hospital care was provided through public insurance programs in several of the provinces, and considerable progress had been made toward the development of the federal government's proposal for a federal-provincial system of prepaid hospital service.

2. **Welfare Services.**—Welfare needs in an increasingly industrialized society have led to an emphasis on social security problems which are beyond the financial resources of the municipalities or the provinces. Therefore the program of the federal government, proceeding either by constitutional amendment or by agreement with the provinces, has seen the greatest expansion. Family allowances and old-age security are the two most significant developments.

The federal government makes special provision for the welfare of veterans with payment of pensions through the Canadian pension commission.

Family Allowances.—All children under 16 years of age who are resident in Canada are eligible for family allowances. These allowances do not involve a means test and are not considered as income for taxation purposes. They are paid at the monthly rate of \$6 for each child under 10 years of age, and \$8 for each child

aged 10-15. In the 1950s allowances were paid annually for about 5,500,000 children in more than 2,000,000 families at an expenditure of more than \$400,000,000 a year.

Aid for the Aged, Blind and Disabled.—To provide old-age security a pension of \$55 a month is paid by the federal government to all persons 70 years of age or over who have been resident in Canada for at least 10 years. This amount is supplemented in some provinces on a means test basis. Old-age security is paid to about 800,000 persons at an annual expenditure of about \$420,000,000.

Old-age assistance of up to \$55 a month is paid to needy persons 65-69 years of age who have been resident in Canada for 10 years. The federal government reimburses the province for 50% of the \$55 per month or of the assistance paid, whichever is the lesser. The provinces administer the program and the shareable amount of assistance is sometimes supplemented. The total annual income including assistance cannot exceed \$960 for a single person, or \$1,620 for a married couple, although the latter may go to \$1,980 if a spouse is blind. In the 1950s about 90,000 persons, or almost 20% of the population 65-69 years of age, were in receipt of old-age assistance.

For needy blind persons 18 years of age or over, who have been resident in Canada for 10 years, an allowance of up to \$55 a month is paid. The federal government pays 75% of the allowance. The province administers the program and in some cases provinces or municipalities add a supplemental amount.

Needy persons who are totally and permanently disabled, over 18 years of age and resident in Canada for at least 10 years, receive allowances of up to \$55 a month. A means test the same as that for old-age assistance is applied.

Unemployment Assistance.—The Unemployment Assistance act of 1956 provides for federal aid to the provinces for unemployment assistance, subject to an agreement between the province and the federal government. The latter reimburses each participating province by one-half of the cost of assistance provided to needy persons in excess of 0.45% of the provincial population.

Provincial Programs.—The provinces on their own also make considerable provision for the needy. A mother's allowance on behalf of needy mothers and their dependent children is paid in all provinces, although the amounts so provided vary. Most of the provinces reimburse municipalities for a part of the cost of general assistance or relief that is provided for the needy, regardless of age. Child welfare legislation including child protection, child care and adoption, is administered in some provinces by the provincial child welfare authorities and in others by the Children's Aid societies. These services are financed by the municipalities or by voluntary organizations, although there are some provincial homes. The maintenance of indigent old people in homes for the aged is primarily a municipal responsibility, but most provincial governments share in the cost, either through subsidies to meet the cost of operation or through grants on behalf of the indigent residents.

E. EDUCATION

Education is the primary occupation of one-quarter of the population of Canada. In the second half of the 20th century there were more than 3,500,000 boys and girls in the public elementary and secondary schools and 145,000 in private schools, and an estimated 500,000 were taking vocational training, while there were 86,000 full-time students in the universities. They were taught by over 150,000 teachers, instructors and professors. Expenditure on education totaled almost \$1,000,000,000 annually, or approximately 3% of the gross national product.

The British North America act gave control of educational administration to the provinces. The nine English-speaking provinces operate English-Canadian schools, but in some areas the Roman Catholic Church maintains separate elementary schools. In Quebec the French-Canadian tradition is followed with Roman Catholic schools, but there are separate Protestant schools.

Education in each province except Quebec is administered by a department of education, headed by a cabinet minister responsible to the legislature. The deputy minister or superintendent is re-

sponsible for the administration of the provincial system, and in Newfoundland there is also provision for a chief executive officer for each of the leading religious denominations, namely Roman Catholic, Church of England, United Church, and Salvation Army. Each provincial department is concerned with the general administration and inspection of schools, the payment of provincial grants, teacher training, curriculum, schools for the blind and deaf, registration of private schools, provincial examinations, trade, vocational and technical schools, public and traveling libraries and correspondence courses.

The direct operation of schools is under local school boards composed of members usually elected for two or three year terms. The local boards employ teachers, maintain buildings and administer the revenue derived from provincial grants and municipal taxation.

In the English-speaking provinces the elementary schools usually have eight grades, with pupils beginning at the age of five or six years. Secondary schools continue for another four or five grades and provide entrance qualification for university courses of from three to seven years in various academic and professional fields. In a few provinces the elementary and secondary schools are organized on the basis of six years in elementary, three years in junior high school and three years in senior high school.

There are about 300 institutions offering courses of university standard in Canada. About 50 of these are active degree granting institutions to which most of the others are affiliated. All the provinces have provincial universities or their equivalent, giving courses in arts, science, engineering, medicine, theology, etc. The universities derive their revenues from student fees, provincial grants, endowments and the federal grant, the total amount of which is \$1.50 per capita of the total population of the country.

In the French-speaking schools of Quebec, boys and girls are taught separately, taking primary courses to grade seven. Pupils may then enter either the church-operated *collège classique* which provides an eight-year course leading to the *baccalauréat* and entry to a university professional course; or they may enroll in the secondary division of the public school which provides further training preparatory to certain technical fields, trades, arts or home economics; or, in a growing number of schools, the first four years of the classical course. Higher schools of applied science, commerce or agriculture, affiliated with universities, are available to graduates of the secondary courses. Trade school or regional agricultural school training is optional.

The federal government through the department of northern affairs and natural resources operates schools in the Northwest Territories, where it completely maintains some schools and assists others, operated by church missions, with grants. The Indian affairs branch of the federal government maintains schools for the Indians who are its wards. Some of these schools are operated as day schools on the reservations and others as residential schools under some religious denomination. In the residential schools, grants are paid for each Indian child attending.

Most provinces require elementary teachers to have had high school graduation or better, plus at least one year of professional training. High school teachers are required to have a university degree plus a year of professional study. In the post-World War II years, because of an acute teacher shortage, many provinces were unable to maintain these standards and had to accept lower teacher qualification to keep schools open.

There are very few institutions in Canada devoted exclusively to adult education. It is sponsored by a variety of universities, colleges, school boards, government departments and voluntary associations, each of which has some other function which is primary. Universities have extension departments, school boards offer night classes, and provincial governments have divisions of community programs, adult education or cultural activities. The Canadian Broadcasting Corporation, National Film Board, National Museum, National Gallery, and many provincial museums, art galleries and libraries engage in adult education as part of their work. The chief co-ordinating and documentation agencies in this field are the Canadian Association for Adult Education and the Institut Canadien d'Éducation des Adultes.

F. DEFENSE

The minister of national defense, a member of the cabinet, exercises control over and management of the Canadian armed forces, the defense research board and other matters relating to national defense. Under his direction the three chiefs of staff are responsible for the control and administration of their respective services, navy, army and air force, and the chairman of the defense research board is responsible for defense scientific service. The chairman of the chiefs of staff committee has, since 1951, been responsible to the minister for insuring that all matters of joint defense and defense policy in the widest sense are carefully examined and co-ordinated before decisions are made.

The civilian administration of the department is organized under the deputy minister, who maintains a continuing review and control over the financial aspects of operational policy, logistics, personnel and administration. A number of committees meet at regular intervals to consider and advise on joint issues. These include such boards as the defense council, chiefs of staff committee, etc. Liaison abroad is maintained through a representative in the North Atlantic Treaty organization (NATO), the Canadian joint staff in Washington and in London, the military mission in the far east, and through service attachés in various countries throughout the world. A number of defense matters of concern to both Canada and the United States are considered by the permanent joint board on defense which is composed of representatives from the two countries. Defense policy is based on active participation in the United Nations and membership in NATO, and in assuring continental defense through close co-operation with the United States (*see ARCTIC, THE: Military Aspects*).

The primary role of the Royal Canadian Navy in carrying out these policies is antisubmarine warfare in all its aspects. Because of the prospect of long-range submarines capable of launching nuclear missiles many miles offshore against coastal and inland targets, primary emphasis has been placed on the development of forward operational systems for locating and dealing with hostile submarines far out at sea. The strength of the Canadian navy in the second half of the 20th century was about 20,000 officers and men in the regular force, and about 5,000 in the reserve force. The two main components of the Canadian army are the regular and the reserve forces. The strength of the army was about 45,000 officers and men in the regular force, and about 40,000 in the reserve force. The Royal Canadian Air Force had a strength of about 50,000 officers and men in the regular force, and about 5,000 in the auxiliary air force. They were organized into 40 squadrons with over 3,000 aircraft in operation.

Civil defense planning is integrated with the over-all plan for national defense, with the aim of survival in the event of direct attack. A further role is the provision of aid to the civil power in times of national disaster. Canadian civil defense is organized at all levels of government. The federal government is responsible for planning, policy and financial assistance; the provincial governments for organization and implementation; and the municipal governments for execution of plans and policy. Training has been carried out at all levels. (R. O. MacF.)

VII. THE ECONOMY

Canada, occupying the northern half of the North American continent, possesses a variety of natural resources. Nevertheless, unfavourable environmental factors—the severe climate of the north, the natural aridity of the prairie plains, the steep high slopes of the mountain regions, the huge rocky expanse of the Pre-Cambrian shield—have presented formidable obstacles to easy and rapid exploitation of these resources. As a result, economic development is still represented, for the most part, by a narrow ribbon of settlement about 3,020 mi. long from east to west and seldom more, usually much less, than 200 mi. wide from south to north. The heavy burdens and persistent problems of transportation are readily apparent in such a country.

The initial primary industries, agriculture, fisheries and forestry, all remain of great importance to the various regional economies and to the economy as a whole. But at least part of the emphasis has shifted to utilization of the vast energy resources

TABLE VII.—*Area of Farmland (1956 Census)*

of water power, petroleum, natural gas and uranium, to increased exploration and development in every region of the rich variety of mineral resources, to increased production of pulp and paper and to a wide range of secondary industries, processing and manufactures. Development of Canada's natural resources to form the base of a modern, integrated economy and to achieve a high standard of living for the Canadian population has required heavy borrowings of capital and the application of every available technological improvement.

A. PRODUCTION

1. Agriculture. — Although the importance of both field crops and livestock production have declined relatively as other resources developed, agriculture in the second half of the 20th century still remained the most important of the primary industries in terms of number of persons employed. The census of 1956 showed that Canada had about 175,000,000 ac. of occupied farmland, of which almost 100,000,000 ac. were under cultivation. (See Table VII.)

There were 575,000 farm units, ranging from small vegetable farms outside the larger cities to the large wheat farms and larger cattle ranches of the prairie provinces. The number of persons engaged in agriculture has steadily declined, following the mechanization and enlargement of farms. As in the United States, greater production has come from fewer persons, owing to improved varieties, better tillage practices, chemical weed killers, more effective control of plant diseases and insect pests, and increased use of fertilizers.

Canada's agricultural area has not changed greatly since 1930; by that time most of the good lands were already occupied. The intensity of land use has increased in areas adjacent to metropolitan centres although this has probably been more than offset by land disappearing from agricultural uses to support urban housing and industrial development. The expansion of agriculture northward, however, faces environmental problems of poorer soils, shorter frost-free periods, poor drainage and high forest-clearing costs. As long as Canada produces a surplus of agricultural products, with problems of world marketing there will be little incentive to increase the total agricultural area.

Agricultural income in Canada is obtained chiefly from the sale of wheat, other grains, livestock and livestock products. Wheat, oats, barley, rye and flax are grown chiefly in the three prairie provinces. Wheat and the feed grains were the main crops of eastern Canada in the first major period of agricultural settlement in the 19th century, but when the western grasslands were opened up by the railroads, the east turned to more specialized crops and animal products to feed its growing cities.

In the west, limited by marginal precipitation and threatened by unseasonable frosts, grains were the only crops that grew well, and even they failed in some years. About 25,000,000 ac. under wheat and another 15,000,000 ac. in other grains was the average annual prairie crop acreage in the post-World War II period 1945–55, but the world surplus of wheat which developed after 1952, plus above-average crops, resulted in subsequent decreases in wheat acreage. Fluctuations in annual wheat production from 200,000,000 to 600,000,000 bu. have been more the result of environmental conditions than acreage changes. The hazards of wheat production include drought, frost, hail, plant rust and grasshoppers.

The spring wheat belt forms a crescent across the prairie provinces, coinciding for the most part with the dark brown soil zone; it extends from southern Manitoba across Saskatchewan including Regina and Saskatoon, into Alberta south of Edmonton and bends southward to the Calgary region. In this belt wheat usually constitutes about 70% of the cultivated acreage. South of this crescent wheat is also grown as the main crop, but because of low and variable precipitation most of the land remains in natural pasture with ranching as the main occupation. In these semiarid regions, between Calgary, Lethbridge and Medicine Hat, Alta., were also the main irrigated sections of Canada, by 1960 totaling about 1,000,000 ac. Water was diverted from several headwater tributaries of the South Saskatchewan river. Smaller

irrigation projects were located in southwestern Saskatchewan, using the streams rising in the Cypress hills. Irrigation agriculture produced specialized crops, notably sugar beets in southern Alberta, but also vegetables, alfalfa for livestock feeding, and even wheat when prices were high. Small irrigation projects, or "dugouts," were important for stock watering.

North of the wheat crescent oats and barley assume greater significance, although wheat remains the most important single crop. Surplus grain of this belt enters the export market, but most of the oats and barley is fed to livestock, particularly beef cattle, and also to dairy cattle for butter production. Swine and poultry are also part of this mixed farming-grain economy.

The agricultural lowlands of eastern Canada are classified as part of the hay and pasture, or dairying, belt of North America. In southern Quebec almost 90% of the cultivated land consists of hay, pasture and oats, used primarily to support the dairy industry. Cultivated hay, pasture crops and oats are also the dominant land use in southern Ontario, although the more favourable summer climate of this region encourages the production of other specialized crops as well.

Although grain, hay and pastureland uses constituted the largest areas of cultivated crops in Canada in the second half of the 20th century, there were sections where specialized production brought large cash returns from small acreages. Truck garden vegetables were grown close to most of the larger industrial centres, with a heavy concentration of canning crops in southwestern Ontario. Potatoes and other root crops were grown in nearly all agricultural areas, but specialized areas of potato production, particularly for seed and for export, were located on Prince Edward Island and in the valley of the St. John river in New Brunswick.

The tobacco industry, starting in Essex county of southwestern Ontario, moved eastward after 1920 to adjacent areas of sandy soils which were ideal for tobacco. By the 1960s about 90% of Canadian tobacco production centred on these soils north of the central section of Lake Erie and southwest of Brantford, Ont. Protected by a tariff, this area supplied the Canadian market and had a surplus for export.

Fruit production is dispersed across Canada but commercial production tends to be confined to a few areas where environmental conditions are favourable. The Annapolis valley of Nova Scotia was Canada's chief apple-producing area prior to 1940, but the loss of overseas markets resulted in sharply decreased production. By 1960 the Niagara peninsula, jutting eastward between Lakes Erie and Ontario, was the major centre of soft fruit production.

The lowland area facing Lake Ontario produces a large share of Canada's peaches, cherries, plums and pears, and in addition is the chief area of grape production. The other important fruit region is the irrigated Okanagan valley of south-central British Columbia. Aided by generally cloudless and hot summer days, the valley terraces produce the largest share of the Canadian apple crops, having a surplus for export. It is the centre of apricot production in Canada and sometimes equals Niagara for peaches, cherries and pears.

Other intensive and specialized crops produced in Canada are: soybeans in Essex and Kent counties of southwestern Ontario; sugar beets northeast of Lake St. Clair in Ontario and in the irrigated lands of southern Alberta; and hops, flower bulbs and seeds in southwestern British Columbia. Throughout much of

eastern Canada in particular an important source of farm income is from the sale of forest products off the farm; these may take the form of pulpwood or lumber logs, or maple sirup or maple sugar from the deciduous forest areas.

2. Forestry.—The forested area of Canada has been estimated at about 1,700,000 sq.mi. which is about 44% of Canada's area. Because of Canada's size these forests rank as the third largest in the world, although environmental conditions have prevented forest growth over more than half of the country. In the north the arctic and subarctic regions of almost 1,000,000 sq.mi. are treeless. In the mountain peaks and uplands of the Cordillera, forest growth is generally not found above 6,000 ft. in the south and 4,000 ft. in the north, depending on local site and exposure conditions. Other non-forested areas are the semiarid plains of the prairie provinces and the innumerable lakes, swamps and muskegs of the Canadian shield.

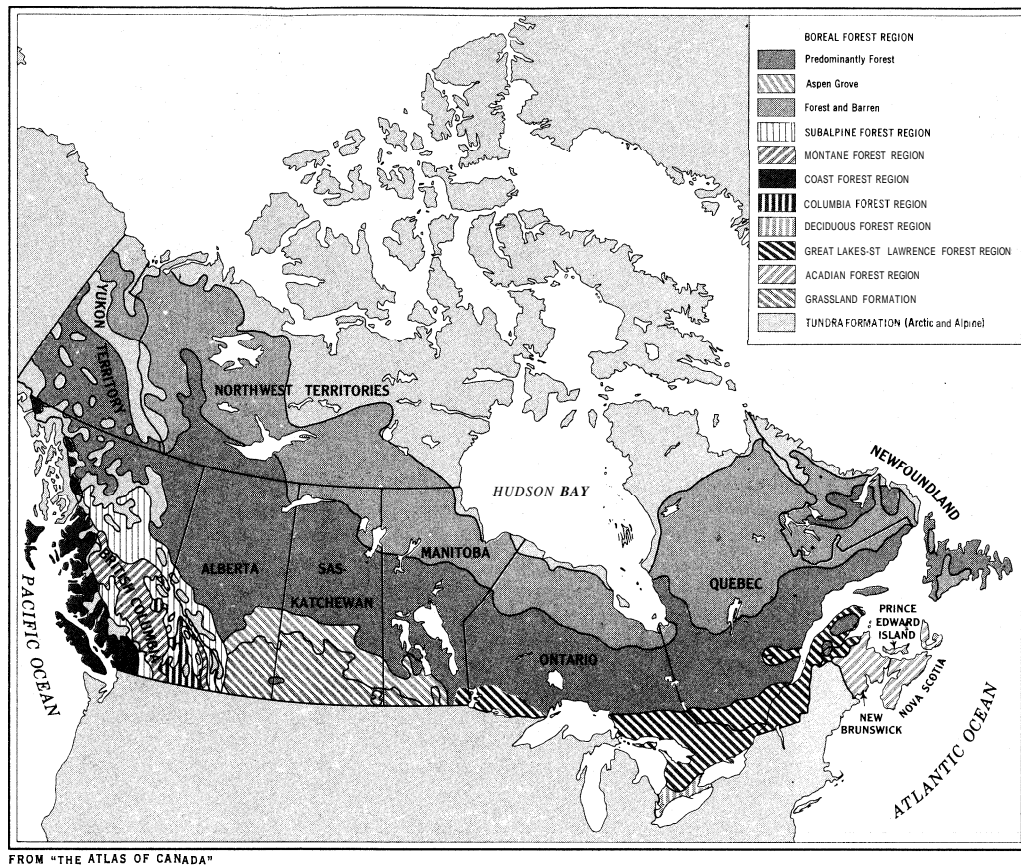

Within the total forested area of Canada there are large sections where cool climate or low precipitation results in slow growth rates and scattered or stunted trees which cannot be classed as commercial or productive forest. The productive forest area of Canada is estimated at about 950,000 sq.mi., which is about 25% of the country's land area.

About 95% of Canadian forests are owned by the government, primarily the provincial governments which have control of natural resources within their borders. The federal government has control of certain forest reserves, the timber in national parks, and the relatively small forest areas of the two northern territories.

The forest regions of Canada were described in the section on Vegetation. These regions, and the species of trees which are contained in them, are closely related to the climate of Canada. In all of Canada it is estimated that 63% of the productive forest is made up of softwood (generally coniferous) species. The most solid stands of these species for commercial use are located in the northern, boreal, forest region and along the Pacific coast. About 12% of the forest is classified as hardwood (generally deciduous), with the most extensive stands in southern Ontario, and across the parkland of the prairie provinces. The remaining 25% of the forest, which is classed as mixed, is found in the maritime provinces and along the southern edges of the Canadian shield.

The type of forestry production in Canada varies from region to region. The mixed forest of the Atlantic provinces was used for lumber, particularly for shipbuilding, in the 19th century; but in the 20th century the pulp and paper industry, using the softwoods, became of increasing importance. Pulp and paper mills were located at several river mouths in New Brunswick and Newfoundland, using the river and its tributaries as a means of transport to float logs to the mills during the summer, and also using the river water in the papermaking process. Partly because of the shorter rivers in peninsular Nova Scotia pulp production remained secondary to lumber.

Much of the area of hardwood forest in southern Quebec and Ontario was cleared in the 19th century to become agricultural land. At the end of that century the lumbering industry was moving into the mixed forest of the Canadian shield, following several rivers, notably the Ottawa, which drained to the urban

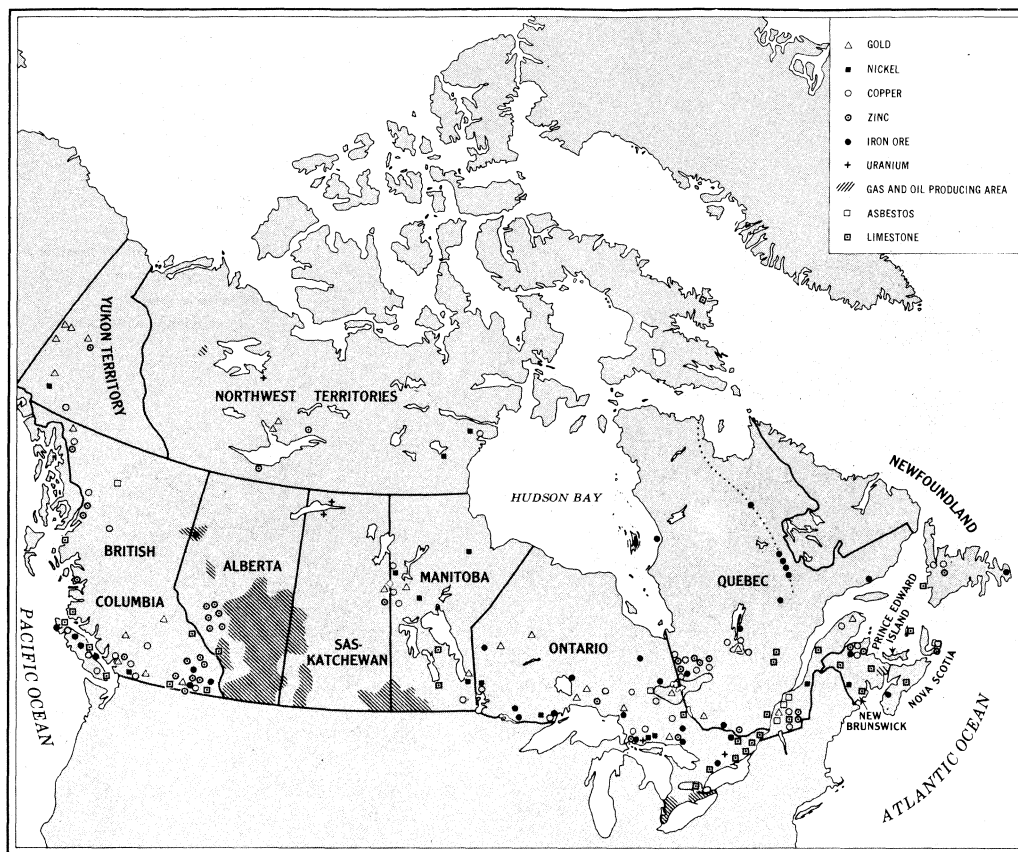

FROM "THE ATLAS OF CANADA"

FIG. 3. — FOREST REGIONS OF CANADA

and overseas markets of the lowlands. Lumbering is still carried on, but in the 20th century the pulp and paper industry expanded enormously along with the greatly increased world demand for newsprint. In the second half of the 20th century Quebec, which has a large share of the softwoods of the boreal forest, and the longest southward flowing rivers tapping this forest, produced nearly one-half of the pulp and paper of Canada. Ontario has a smaller forest area and shorter southward flowing rivers, but better rail transport, and produced about 30% of the pulp and paper. The largest share of Quebec pulp and paper mills were located at the mouths of shield rivers where they could use the rivers for log transport and the drop at the shield edge for power. In addition, their location along or near the St. Lawrence river gave the mills access to ocean shipping to export markets. Rivers such as the Saguenay, St. Maurice, Lièvre, Gatineau and Ottawa were important to the industry.

In Ontario the pulp mills had a distribution pattern similar to that of Quebec in that the plants were located along the edge of the shield, particularly along the shores of Georgian bay and Lake Superior. However, Ontario mills were also located on some of the northward flowing rivers, such as the Moose and its tributaries, where they were crossed by railroads. In Ontario and Quebec both pulp mills and pulp and paper mills were generally located within the forested regions, but paper mills were frequently built in industrial cities of the southern lowlands. The largest share of their production was for export, notably to the adjoining sections of the United States for newspapers.

The forestry industry is of lesser importance in the prairie provinces. Pulp and paper mills were located on the westward (and outward) flowing rivers of the shield in northwestern Ontario and eastern Manitoba, but the remainder of the western shield forest was untapped. Lumbering was of local importance in all three provinces, but did not supply the demand of the region. Good reserves of pulpwood across central Saskatchewan and northern Alberta could be developed if transport costs or market prices should permit them profitably to reach the large industrial centres of the Canadian and U.S. St. Lawrence and Great Lakes areas.

ADAPTED FROM "THE ATLAS OF CANADA"

FIG. 4.—PRINCIPAL MINERALS OF CANADA

The large and tall trees of British Columbia, particularly the Douglas fir, are Canada's chief source of lumber products, especially structural timbers. In the 1960s the west coast province produced more than one-half of the Canadian lumber, much of it shipped by rail or ocean transport to eastern Canada, but about half of it going for export. Timber cutters had difficulties in the 19th century because of lack of equipment to handle the big trees. Expansion came rapidly, however, after the building of the Panama canal opened up markets in the eastern industrial areas of the United States and Canada. Pacific coast tree growth is rapid, because of the year-round moderate and wet climate; exploitation is assisted by the numerous long fiords and inlets which penetrate into the forests; transportation in large rafts along the coast has the protection of the sheltered waters of the inside passage. Most of the large sawmills were located near the mouth of the Fraser river—in the Vancouver area and along the east coast of nearby Vancouver Island. After 1946 the coast forest industry began to produce increasing amounts of pulp and paper, in some instances based upon small growth and mill remnants once abandoned by the lumber industries. The coast forest industry appeared to be cutting at about the maximum in proportion to growth rates, and expansion in lumber production came from opening up new forest areas in the central interior and southeast of the province.

Canadian lumber production in the second half of the 20th century came from more than 7,000 sawmills, ranging from giant-sized ones in British Columbia which could cut almost 1,000,000 bd.ft. per day, to small portable mills producing a few thousand feet per day. Pulp and paper production was supplied by about 125 mills, most of them large and involving sizable capital expenditure; more than half of these mills were classified as combined pulp and paper mills, and about 20% were purely paper mills.

Canadian forestry production is an important item in Canada's balance of trade. In the 1960s newsprint usually ranked as the leading export by value from Canada, with the item planks and boards following wheat as the third export product. Wood pulp also ranked among the leading five exports in most years.

3. Mining and Minerals.—

The geological regions of Canada indicate the kinds of minerals that may be found. The flat-lying, geologically more recent sedimentary rocks of the interior plains and St. Lawrence lowlands may be the source of nonmetallic minerals such as petroleum, natural gas, coal, salt, potash and gypsum. The ancient, hard Precambrian rocks of the Canadian shield have yielded such metals as gold, silver, copper, lead, iron, nickel and uranium. On the periphery of Canada the complex geology of the Cordillera mountains and the Appalachian hills, as well as the arctic islands, contains combinations of both hard and soft rocks, and therefore may have both metallic and non-metallic minerals.

The expansion of the mining industry in Canada is a fairly recent development in Canadian history. Although the mining of coal and other minerals goes back to the French regime, more concentrated efforts in prospecting and discovery began around the turn of the 20th century. Many of the mines discovered at that time were still in production in the second half of the 20th century.

A further major expansion in the mining industry, however, came after 1946 and was still in progress in the 1960s, aided by transportation and power developments.

Because the Canadian shield section of Ontario was well served by transcontinental railway systems and feeder lines, mining developed there early, and throughout the 20th century Ontario has produced annually more than one-third of the value of Canadian mineral production. Quebec usually ranked second, having about 20%, chiefly from the shield but also from its Appalachian section. Of increasing importance was the nonmetallic production of Alberta, which also totaled about 20%. Next in importance, until supplanted by Saskatchewan in 1958, was British Columbia with 10% of the value of Canadian minerals.

The regional importance of minerals in the Canadian economy shows wide variations. The folded sedimentary rocks and crystalline cores of the Appalachian-Acadian system have not yielded any wide variety of important minerals. Iron ore was produced after the turn of the century on Bell Island in Conception bay of Newfoundland, and was transported over water to the extensive coal fields around Sydney on Cape Breton Island, N.S. The base metals, lead, zinc and copper, were mined in central Newfoundland and on the east coast of Nova Scotia, and production expanded following base metal discoveries in northeastern New Brunswick. In the second half of the 20th century Nova Scotia produced the largest share of Canadian gypsum, chiefly from the Minas basin area at the head of the Bay of Fundy. In the Quebec section of the Appalachians mineral resources were somewhat richer. More than one-half of the world's asbestos was mined in a belt of serpentine rocks extending through the eastern townships, including the main asbestos-producing centre of Thetford Mines. Short fibre asbestos was obtained in large open-pit mines, with crushing plants at the surface, near great piles of rock slag which scar the landscape. The Quebec Appalachians produced copper intermittently, the largest mine being operated in the central Gaspé peninsula.

The sedimentary rocks of the St. Lawrence lowlands underlie the chief industrial area of Canada but played a small part in

assisting the economic development of the area. Much of Canada's salt was produced near Windsor, Ont. Southeast of Sarnia, Ont., were some of the earliest oil wells in North America, but production was insignificant after about 1950. Small amounts of natural gas were also produced. Of greater importance was limestone, quarried particularly along the Niagara escarpment, which becomes an industrial raw material for the chemical and fertilizer industries. The widespread glacial deposits of the lowlands supplied important sources of sand and gravel used in great quantities by the construction industries.

The Canadian shield, the mineral storehouse of Canada, produced about 50% of the country's mineral wealth. In the second half of the 20th century there were about 100 mines producing in the shield region, almost one-half of them in the Ontario section. Although the shield covers almost 2,000,000 sq.mi. of the mainland of Canada, most of the mines were located on the outer edges of the region, suggesting greater development as more detailed geological information becomes available.

The geology of the eastern sections of the shield was little known until the exploration of large deposits of hematite iron ore along the Quebec-Newfoundland (Labrador) boundary during World War II. Reserves estimated in excess of 500,000,000 tons resulted in a railway being completed in 1954 from Seven Islands, on the estuary of the St. Lawrence river, to the ore fields. This was the first railway or land transport to penetrate into this section of Canada. Nearer the coast another post-World War II development was the opening of North America's largest ilmenite or titanite iron ore deposit, northeast of Mingan airfield.

The central section of the shield, across the Quebec-Ontario border, had some of the oldest mines of the shield and also some of the newest ones. In the second half of the 20th century the largest share of Canada's gold came from the Timmins and Kirkland Lake fields of Ontario, and the gold belt extended across the boundary through Noranda and Val d'Or in Quebec. The Quebec section of the gold belt also produced base metals. To the northeast, copper-gold discoveries near Chibougamau, Que., resulted in another new railway which pushed northward into previously unsettled regions.

One of the oldest of modern mining districts was the Sudbury basin in Ontario. Discovered as a copper deposit during the building of the Canadian Pacific railway in 1883, the area in the second half of the 20th century produced about 75% of the world's nickel, was the world's main source of platinum. Canada's chief source of copper and also produced selenium, tellurium, rhodium, gold, silver, cobalt and by-product iron ore. To the southwest, Blind River on Georgian bay was one of Canada's main uranium producers.

In the Lake Superior region of Ontario iron ore was mined at Michipicoten Harbour, on the northeast shore, and at Steep Rock lake, to the northwest. Other mines north and northwest of Lake Superior produced gold and copper.

Little was known of the mineral possibilities of the western sections of the shield prior to 1940. Remote from eastern mining centres and lacking transport, this development proceeded more slowly. On the southern fringe of the shield, and on the Manitoba-Saskatchewan border, Flin Flon was a well-established zinc-copper region. Northward at Lynn Lake, Man., Canada's second nickel deposit came into production in 1954, following the construction of a new railway. The Saskatchewan section of the shield lacked road or rail transport so that the large pitchblende deposits north of Lake Athabasca, around Uranium City, were supplied during the uranium boom of the late 1950s by air or water transport, largely from the Athabasca river in Alberta.

Mineral deposits rich enough to withstand the high costs of transportation in the Northwest Territories were discovered along the western edges of the shield. Gold was mined after 1937 at Yellowknife, on the northeast shore of Great Slave lake, and Canada's first pitchblende deposits were in production from 1933 to 1960 at Port Radium, on the rocky east side of Great Bear lake.

The interior plains are Canada's chief source of fuels. Nearly three-quarters of Canada's coal reserve of about 100,000,000,000 tons is located in Alberta and Saskatchewan; it is mainly bi-

tuminous, subbituminous and lignite quality. The coal belts parallel the folding of the Rocky mountains, being exposed in the foothills, and also eastward on the plains. Alberta was the leading coal-producing province prior to 1954, but mining declined with the expansion of petroleum and natural gas production.

Within a decade Canada rose from being an insignificant producer of petroleum (less than 8,000,000 bbl. in 1947), and a major importer, to become one of the world leaders in production, approaching 185,000,000 bbl. in 1957. Most of the production came from oil fields discovered in the Edmonton region—Leduc-Woodbend in 1947, Redwater in 1948 and Pembina in 1955—but after 1955 Saskatchewan emerged as an important producer and smaller discoveries were made in Manitoba. Oil pipelines were built eastward to Ontario, crossing through parts of the United States south of Lake Superior, and westward to southwestern British Columbia and adjoining Washington. Northeast of Edmonton, the Athabasca oil sands area had a reserve of petroleum estimated in excess of 100,000,000,000 bbl. Many of the oil fields, but not all, were also producers of natural gas, and in addition there were separate natural gas fields. After reserves proved large enough to supply all Alberta's requirements, the natural gas was piped eastward to Ontario and Quebec, following a Canadian route north of Lake Superior, and another pipeline was constructed from northern gas fields in the Peace river district to southern British Columbia and Washington.

In addition to the fuels, the interior plains also produced smaller quantities of sodium sulfate, salt, sulfur (obtained from cleaning natural gas), gypsum, clay and building stone. Production of potash began in central Saskatchewan in 1959 from deeply-buried deposits believed to be the largest and richest in the world.

In the Northwest Territories section of the plains, prospecting was hampered by the thick layer of glacial deposits across the Mackenzie river valley, and by the lake and muskeg cover which is almost impassable in summer. In the late 1950s a small oil field produced at Norman Wells, on the Mackenzie river. Development of a large lead-zinc deposit on the south side of Great Slave lake awaited transportation.

The Cordilleras of British Columbia and the Yukon contain minerals in several places, but prospecting is difficult on the steep and heavily forested slopes. The alluvial gold discovered around 1856 in the central Fraser river and tributaries brought the first settlers to interior British Columbia, and changed the political status of what had been a small British colony on the southern end of Vancouver Island. Many mines began production in the Kootenay region at the turn of the 20th century, only to become ghost towns in a few decades. In the second half of the 20th century mineral production was dominated by the lead-zinc mines at Kimberley in the southeast, which ranked among the world's largest. These and other mines shipped their ore concentrates to smelters at Trail, B.C., on the Columbia river. In addition to lead and zinc the Trail refinery yielded silver, gold, tungsten, bismuth, cadmium, tin, antimony and indium. British Columbia produced copper around the flanks of the Coast mountains, both at Britannia on the south coast, and near Stewart on the north coast. Alluvial gold was of minor importance but lode gold was produced from a few mines around the edges of the interior plateau. Alluvial gold was still produced from the Klondike region of the Yukon, although not in the quantities that created the colourful gold rush of 1897-98.

The Arctic islands have a variety of rock types but the detailed geology is not known. Low-grade coal is widespread throughout several of the islands, and the central islands of the Queen Elizabeth group have structural possibilities for petroleum. Any possible economic development would have to overcome transportation difficulties such as the short navigation season which ranges from about four months off southeastern Baffin Island to less than one month in the northwestern islands.

Value of the annual production of Canadian minerals varies each year depending on market prices and new mineral discoveries. Petroleum, which was unimportant in 1946, had risen to first place by 1956. Nickel, copper and gold have ranked among the leading minerals by value throughout the 20th century, followed by coal,

asbestos, zinc and lead. Silver is less significant than it was prior to 1925, whereas iron ore is of increasing importance. In terms of world importance Canada ranks first in the production of nickel and asbestos, is placed among the leading three or four producers of uranium, copper, lead, zinc and gold, and is probably the world's leading exporter of iron ore.

4. Fisheries.— Although Canada has a great number of inland lakes, many of them among the world's largest, most of the commercial fishing takes place off the Atlantic and Pacific coasts. British Columbia ranks as the leading producer, by value, with about one-third of the Canadian total, but the combined Atlantic provinces, plus the Gaspé coast of Quebec, constitute the main fishing region accounting for about 60% of total fish values. Fishing plays a less important part in Canadian economy than do the other leading primary industries, being about one-eighth the net value of either the forestry or mining industries. In local economies, however, the fisheries are vital to Newfoundland, and to a lesser degree Nova Scotia, and are important to communities around the shores of the Gulf of St. Lawrence and along the central and north coasts of British Columbia.

Canadian fishermen catch about 2,000,000,000 lb. of fish annually, but because Canadians are not particularly fish eaters and the main population concentrations are inland, away from the fisheries, much of the fish catch enters export markets. In some years Canada is the world's leading fish exporting nation, noted for its fresh, frozen or dried fish from the east coast, and for canned fish from the west coast.

On the Atlantic coast much of the catch is obtained from waters within a few miles of the shore; the day's haul is brought to the many small fishing villages in sheltered bays and harbours. With increased capital, however, more and more fishermen in the second half of the 20th century were obtaining bigger and better equipped boats, and were working out to sea in international waters above Sable Island, Banquereau and Grand Bank. At the same time fish processing was being centralized in larger settlements along the coasts in order to give a standardized and higher quality product. Cod, haddock and herring continued to be the most valuable fish, as they have been since the early history of settlement, but, beginning in the 1950s, other fish formerly of little value were processed into frozen fillets for the ready-cooked market. Along the coast lobsters ranked as the most valuable part of the fishing industry, most of the catch being exported to the eastern United States.

The west coast fishery is dominated by several species of Pacific salmon, the most valuable of Canadian fish. Salmon are netted off the river mouths when they appear in summer to begin their migrations to inland spawning waters. Most of the coastal rivers are salmon rivers but the largest, the Fraser and Skeena, have the greatest numbers caught off their mouths. The fish canning industry is concentrated in the Vancouver area, although other canneries are located northward on the coast. The halibut fishery ranks second in importance, being shared by international agreement with U.S. fishermen, and centres around the Queen Charlotte Islands. Prince Rupert is the port for the halibut fleet and for processing the product.

Inland fisheries in fresh-water lakes are relatively unimportant. Catches declined notably in the Great Lakes after the mid-1940s possibly because of overfishing, but certainly because of the destruction caused by the lamprey eel. A joint program has been launched with the United States to control the lamprey and the bulk of the Great Lakes catch has shifted from trout and whitefish to pickerel, perch, cisco (lake herring), silver bass and smelt. The great lakes of Manitoba (Manitoba, Winnipeg and Winnipegosis) support a fishery of local importance, part of the catch being exported to the midwest United States. Farther to the northwest the fishery established in Great Slave lake in 1945 made that water body one of the leading fish-producing lakes in Canada. The great body of water which is Hudson bay, in the centre of Canada, does not contain fish in commercial size or quantity. Although hair seals, white whales and decreasing number of walrus are obtained for food by the Eskimos in the north, there appear to be fewer fish in the Canadian arctic than along

the arctic coasts of west Greenland. The inland waters attract many sports fishermen from Canada and the United States, forming a basis for an increasingly important tourist industry.

5. Fur Production.— The trapping of furs, historically one of the incentives to explore Canada, was by mid-20th century no longer a major primary resource. Throughout the northern coniferous forest fur trapping remained a winter occupation for some inhabitants in areas away from the largest settlements, and it was the chief livelihood of many Indians and most Eskimos. Since most fur-bearing animals have natural cycles of abundance and scarcity, the annual production of furs varies and the catch by species changes from year to year. Since these cycles appear to move across Canada, there are also regional variations in the year's production. Wild furs usually constitute close to 60% of the total fur production.

Fur farms were started on Prince Edward Island in 1887 and spread across Canada until there were more than 10,000 fur farms prior to 1939. Changes in fashion and loss of European markets resulted in declines in the number of fur farms, particularly those being operated on a part-time basis. The original centres of fur farming are of minor importance, there being only about 5% of fur farm animals in the three maritime provinces as against nearly 50% in the three prairie provinces.

Among the wild fur bearers, mink are the most valuable in most years, followed by muskrat, beaver, squirrel, ermine and foxes. About 80% of the fur farm animals are mink; the only other notable fur bearers are chinchilla and foxes.

6. Water Power.— About 90% of Canada's electrical power is obtained from water. It supplies power to most of the industries of the St. Lawrence lowlands, and is essential to the great pulp and paper and mining industries of the Canadian shield. Water power supplies the base of industrial expansion in British Columbia, and on a smaller scale helps the industries of the Atlantic provinces. Since Canada lacks coal in its industrial heartland of southern Ontario and Quebec and, until the Alberta petroleum discoveries, also lacked oil for power, it turned to the abundant potential power of the southern shield region and the St. Lawrence river system.

Canadian hydroelectric installations are expanding each year, paralleling the country's industrial growth and increased resource production. Installed turbine capacity exceeded 26,000,000 h.p. in 1960 and Canada ranked second to the United States in hydroelectric power generation; its per capita power of slightly more than one horsepower was second to that of Norway. Canada's potential power resources had not yet been fully measured, especially on northern rivers, but they probably exceeded 60,000,000 h.p. at ordinary six-month flow averages. The nation was thus using less than one-third of its water-power potential.

The water-power potential of the Atlantic provinces is assisted by ample precipitation evenly distributed throughout the year, and by rough or rocky topography, but is limited in that many rivers are short and therefore lack volume. In addition, Nova Scotia has coal for power. The largest installations are located on the island of Newfoundland, where they are used mainly for the pulp and paper industry. New Brunswick is able to make use of the St. John river, one of the longer rivers in the region, but this use requires international agreement since the headwaters are in the United States.

In the second half of the 20th century the St. Lawrence lowland was the major consumer of hydroelectric power, but had only a few large power sites within its boundaries. Below Niagara falls on the Niagara river, and at Beauharnois dam, west of Montreal on the St. Lawrence river, large power plants each produced in excess of 1,500,000 h.p. The international power plant at Cornwall, constructed for the St. Lawrence seaway, generated more than 2,000,000 h.p. used both in Ontario and New York.

The Canadian shield produced about 60% of the water power of Canada, much of which was transported to cities and industries in the nearby lowlands. The innumerable lakes of the glaciated shield serve as natural storage basins, and potential power is found along the fall line where the rivers tumble through the shield escarpment above the St. Lawrence. Rivers such as the Bersimis,

Saguenay, St. Maurice and Ottawa produce about 2,000,000 h.p. each by utilizing several dams along the river course. The southward-flowing rivers of the shield in Ontario are shorter and produce less power. Ontario also has a northern fall line, where the northward flowing rivers drop over the shield to the flat-lying sedimentary rocks west of James bay. Except for the Abitibi river, however, this potential is poorly located for development. Waters flowing westward from the shield are utilized along the English and Winnipeg rivers as they drop toward Lake Manitoba.

Potential power sites are widely scattered throughout the shield, so that resource development nearly anywhere will be close to sources of power. The Nelson and Churchill rivers have falls and rapids as they tumble toward Hudson bay. In the east, the Hamilton river (*q.v.*) has one of the largest single sites at Grand falls in western Labrador (estimated potential more than 4,000,000 h.p.), and northward the Koksoak and other rivers have falls as they drop toward Ungava bay.

Water-power potential is relatively small in the shallow rivers of the interior plains, and is further limited by the scanty and seasonal precipitation. In addition, this region has Canada's main supply of coal, petroleum and natural gas, as cheaper competing sources of power.

The mountains and rivers of the western Cordilleras rank second to the shield as sources of potential power. The mountain slopes receive the heaviest precipitation in Canada, although there is a problem of seasonal distribution toward the south. Many of the coastal rivers are quite short. The longer rivers which rise in the interior cut down through the coast mountains while they were being uplifted geologically, and thus do not have many falls or rapids. Although power can be produced by dams across these rivers, they are the main source of salmon for the fishing industry which dams might destroy. The chief power development for aluminum production at Kitimat on the northern British Columbia coast is obtained by damming an interior tributary of the Fraser river and backing up the flow through a long tunnel in the Coast mountains to drop the water almost 2,000 ft. on to turbines located near tidewater. This same principle of diversion of interior plateau rivers through the mountains to potential coastal industries applies to other areas of western British Columbia. In northern British Columbia and southern Yukon such power developments are politically complicated since the coastal locations for industries are in the U.S. state of Alaska. Other power developments in British Columbia are located on smaller rivers of the southwestern region to serve the large urban market of Vancouver, and on the tributaries of the Columbia river, such as the Kootenay, in the southeast, primarily for the mining industry. The Peace river has a large power potential where it cuts through the Rocky mountains. Canada and the United States in Jan. 1961 signed a treaty making possible the integrated and basin-wide development of the water and power resources of the upper Columbia river with water-storage projects in British Columbia creating downstream flood protection in Washington and increased power production at all U.S. dams from Grand Coulee to Bonneville. The agreement was based on 50-50 sharing of added power output and payment by the U.S. to Canada for one-half the added flood control benefits.

7. Manufacturing.—Canadian manufacturing industries received their first major impetus during World War I, after which trends in the economy were toward further industrialization and away from a dominant agricultural base. Although the processing of agricultural products for a relatively small domestic market and for export remained a major activity, new industries came into prominence after 1920, led by pulp and paper, transportation equipment and farm implements. World War II resulted in rapid and far-reaching industrial expansion, and Canada emerged from the war among the six leading industrial nations of the world. By 1951 manufacturing employed more than 1,000,000 persons, and had replaced agriculture as Canada's leading industry. By 1960 manufacturing industries accounted for more than 30% of the value of all goods and services produced in the country, being valued in excess of \$22,000,000,000.

Manufacturing is concentrated in southern Ontario and Quebec.

These lowlands had the historical advantage of an early start and had, for Canada, a relatively large regional population as a market. When industrial expansion came in the 20th century, the region could call on a fairly wide range of domestic raw materials nearby, an excellent transportation system, including ocean transport to Montreal and cheap movement on the Great Lakes, established banking and financial support and, of major importance, a good supply of hydroelectric power. Ontario alone normally produces nearly 50% of Canada's manufactured goods, and Quebec about 30%. British Columbia, with about 9% of the value of manufactures, produces as much as the three prairie provinces together. The Atlantic provinces have a minor share in Canadian manufacturing.

Montreal is the leading industrial city. In the 1960s the value of its factory shipments was equal to the total production of the three western provinces (Saskatchewan, Alberta and British Columbia). Toronto's manufactures were almost as valuable as those of Montreal and increasing; they were worth more than twice the total value of all manufactures from the four Atlantic provinces. The next most important industrial city was Hamilton, Ont., with Windsor, Ont., and Vancouver, B.C., competing for fourth place.

The list of 15 leading industries did not change significantly between 1946 and 1960. The pulp and paper industry ranked in first place in the value of factory shipments. About 80% of its output moved abroad; it provided about half of the world's newsprint and led the world in pulp exported. The other major forest industry, sawmills, was about half as valuable as pulp and paper, but usually ranked among the leading six or seven industries.

The processing of Canadian minerals is an important part of the manufacturing economy. Led in value by nonferrous metal smelting and refining (aluminum, nickel, copper, lead, zinc), the list also includes the processing of petroleum products and the manufacture of primary iron and steel. The aluminum industry, based on imported bauxite ores and Canadian hydroelectric power, is ranked second in world importance only to that of the United States. The processing of petroleum products used less than 10% Canadian crude oil in 1946, but the industry was using more than 50% Canadian oil by 1960. Although Canada has large quantities of iron ore, most is for export because of the relatively small national market. By the 1960s Canada was producing about 4,000,000 tons of pig iron and more than 5,000,000 tons of steel ingots and castings.

Canadian agricultural products are processed for an increasing urban population and for export. Slaughtering and meat packing in the second half of the 20th century usually ranked fifth among the leading industries, followed somewhat further down the list by butter and cheese manufacturing, the preparation of miscellaneous food products, and the production of bread and baking products.

In a country of great distances the manufacturing of transportation equipment has been important throughout the 20th century, although the actual products have changed. By the 1960s the motor vehicle industry stood in fifth place among all industries, and was further important because of the large number of such small industries as motor vehicle parts that depend on it. The manufacture of railway rolling stock declined in value relative to others. The aircraft industry arose during World War II and maintained itself as a newcomer among Canada's most valuable industries. Other industries which usually appeared on the list of leading manufactures were: industrial machinery, rubber goods, furniture, men's and women's clothing, electrical apparatus, and flour and feed mills.

B. TRADE AND FINANCE

1. Foreign Trade.—Throughout the first half of the 20th century Canada became of increasing importance as a trading nation. After World War II it rose to third place among the trading countries of the world, following the United States and the United Kingdom. After 1954 Canada ranked in fourth place behind a revived western Germany. In per capita trade Canada by the 1960s stood far ahead of the other large trading nations.

About one-third of the value of Canadian exports was made up of forest products. Newsprint ranked as the leading export for many years; planks and boards and wood pulp usually appeared among the leading four export items.

Mineral resources were of increasing importance in the export trade after 1950, also supplying about one-third of the total value. Nickel, aluminum, iron ore, copper, petroleum and uranium were the most valuable of the mineral exports, and asbestos and zinc often ranked among the leading export products.

Agricultural products constituted about one-half of Canada's exports in the 1920s but their relative value had declined to less than 30% in the second half of the 20th century. Wheat maintained its position, however, usually in second place and sometimes displacing newsprint for top place among Canada's exports. Wheat flour and grains other than wheat, especially barley, were among the most valuable exports; for all these products Canada was among the leading world exporters.

Canadian exports are thus based primarily on the products of the farm, the forest and the mine. At one time these products were exported in the raw state, but as Canada became an industrial nation, more and more processing was done within the country prior to export.

Canadian imports are of a different type, and consist largely of machinery and other manufactured products which can be produced more cheaply by mass-production methods in the United States. In the early 1960s nonfarm machinery usually ranked as the most valuable import into Canada, but also on a list of the leading imports were automobile parts; electrical apparatus, tractors and parts; rolling-mill products; aircraft and parts; engines and boilers; and automobiles. Canada produced most if not all of these manufactures within its border, many by U.S. companies with Canadian branch plants, but additional large quantities were imported for the expanding economy.

Mineral imports into Canada include crude petroleum, such petroleum products as fuel oil and coal. These items may appear strange as imports when Canada ranks as a leading petroleum producer and has billions of tons of coal as reserves, but petroleum in western Canada is far from the industrial areas of Quebec and from the maritime provinces in particular and the Ontario market for coal is far from both Alberta and Nova Scotia coal mines.

Other imports into Canada are chiefly products which cannot be grown in the Canadian climate, such as citrus and other subtropical and tropical fruits, coffee, cotton and cane sugar.

Around the start of the 20th century Canada was part of a three-cornered trade movement with the United States and Great Britain, but steadily its economic ties became closer to its U.S. neighbour. About one-half of Canada's imports came from the United States around 1900, but by the 1950s this had risen above 70%, falling below that figure in the 1960s as trade with Great Britain, west Germany and Japan gained in relative importance. The United States took about 60% of Canadian exports, the United Kingdom less than 20%, and Europe less than 10%. Latin America received about 5% of Canadian exports, and supplied more than 5% of its imports.

Canadian trade within the commonwealth declined relative to the growing American trade dominance; commonwealth countries (other than the United Kingdom) accounted for about 5% of Canadian imports and exports.

2. Banking and Currency. — Commercial banking consists essentially of the Bank of Canada, a government-owned central bank, and eight privately owned commercial banks which have a total of about 5,000 branches in Canada. At confederation in 1867 there were 28 banks; the maximum number reached was 41 in 1886, but afterward the number was reduced, chiefly by amalgamations, to eight. Each commercial bank has a savings department but savings banks also exist, including post office savings banks run by the federal government, provincial savings banks operated by the provinces of Alberta, Ontario and Newfoundland, and two large private institutions operating under federal charters in the province of Quebec. More than 4,000 credit unions, with nearly 2,000,000 members in the ten provinces, accept savings deposits and serve as co-operative agencies for extending credit.

The incorporation of a commercial or chartered bank requires an act of parliament, and the conditions, including a minimum subscribed capital of \$1,000,000, to which the applicant for a charter must conform are laid down in the Bank act. Under the provisions of this act, all bank charters come up for renewal every ten years. The Bank act of 1871 was the original act and provided for a decennial revision of banking law; there was a major revision in 1954.

In 1934 the banking system of Canada was completed by the establishment of the Bank of Canada to perform all the usual functions of a central bank. The Bank of Canada, which began operations on March 11, 1935, was at first privately owned but in 1938 the government bought out the shareholders and nationalized the bank. Bank of Canada notes are the chief currency of the country. Before the bank was established both the federal government and the chartered banks issued notes, but the Canadian note issue was discontinued and the chartered banks had to reduce their issue gradually to 25% of their paid-up capital of March 1935; the Bank act cancelled the right of chartered banks to issue or re-issue notes after 1944. The Bank of Canada can issue notes to any aggregate amount and the condition that it maintain a gold reserve equal to one-quarter of its note and deposit liabilities in Canada was suspended in 1940. The chartered banks, which formerly were not required to keep any specific reserve against their deposit liabilities in Canada, later were required to keep 5% and, after 1954, not less than 8% of such deposits either on deposit with the Bank of Canada or in Bank of Canada notes. When the Canadian gold holdings were revalued in 1935, the government established an exchange fund for the purpose of aiding the stabilization of the foreign exchange.

3. National Finance. — The national debt of Canada was \$336,000,000 in 1914, but after World War II reached a peak of almost \$13,500,000,000. Budget surpluses gradually reduced the debt to less than \$11,008,000,000 by 1957. Budget deficits increased it again to \$11,678,589,860 in 1959. This debt, which in 1914 was almost entirely repayable in London, was after World War II more than 95% repayable in Canada.

Sources of federal revenue are, in order of importance, personal income tax, corporate income tax, sales taxes on commodities, excise taxes (spirits, tobaccos, etc.), customs duties and nontax revenue (post office, investments, etc.) and other receipts and credits.

Federal expenditures, in order of size, include defense forces, interest on public debt, family allowances, subsidies, special grants and tax rental payments to the provinces, veterans' pensions, old age security fund deficits and unemployment insurance fund contributions, and public works.

C. TRANSPORT AND COMMUNICATION

Canada has been primarily a new country with a small population exporting such bulky raw materials as wheat, lumber, pulp and paper, and minerals to densely populated industrial countries. Cheap water transportation has been fundamental. Canadian ports are seriously affected by geographic considerations and climatic conditions. Montreal is closed in the winter season, and Halifax and Saint John, N.B., although open through the winter, are too distant from the interior to compete effectively with U.S. Atlantic ports. Vancouver benefited as an export centre by the opening of the Panama canal.

The export of wheat from the prairie provinces intensified the transport problem since it produced a peak load in early autumn for Great Lakes shipping. The handling of great quantities of wheat during the rush season involved the use of specially constructed boats, "lakers," and of elaborate loading and unloading facilities at Port Arthur and Fort William, Ont., Port Colborne, Ont., Buffalo, N.Y., and the Georgian bay ports. The Canadian canal at Sault Ste. Marie has a depth of 19 ft. and the U.S. canal 30 ft. The locks in the Welland Ship canal are 30 ft. deep and permitted lake vessels to continue to the foot of Lake Ontario. Opening of the St. Lawrence seaway, begun in 1954 and completed in 1959 at a cost to Canada of about \$340,000,000, provides a deep waterway for oceangoing vessels extending about 2,200 mi.

from the Atlantic to the head of the Great Lakes.

Railway facilities were improved in relation to the export of wheat from the prairie provinces. Especially after 1900, railways were rapidly extended for the development of traffic in western Canada; the marked increase in the export of wheat led to the construction of new lines from Winnipeg to Fort William and Port Arthur and from Georgian bay ports to Montreal, as well as to the construction of a line from Winnipeg through Cochrane, Ont., to Quebec. An additional outlet for the trade of the prairie provinces was completed with a railway to Churchill on Hudson bay in 1929. The development of the mineral industry and of pulp and paper mills in the Canadian shield was followed by the construction of numerous lines in northern Ontario and in northern Quebec, including the Ontario Northland railway and lines to the Saguenay country, and in northern Manitoba.

Railway construction virtually ceased between 1930 and 1950. After that date new northern lines were built to tap mineral developments in the shield region and in British Columbia. As in the case of canals, railway construction involved heavy expenditures on the part of the federal and provincial governments. Land grants up to 1958 of the federal government totaled about 32,000,000 ac., of provincial governments almost 16,000,000 ac.

More than 95% of Canadian railway mileage (in excess of 59,000 mi. in 1960) was under the control of two great transcontinental systems, the Canadian National and the Canadian Pacific. The Canadian Pacific was incorporated in 1881 and the company built up a strong organization with low-fixed charges and a large proportion of capital in the form of common stock on which it paid 10% to 1930. The Canadian National is government-owned and the result of the amalgamation of several companies, including the Intercolonial, Canadian Northern, Grand Trunk, Grand Trunk Pacific and National Transcontinental, which found themselves in difficulties through dependence on government-guaranteed bonds and high costs of operation during World War I (see also *History*, above). Various units were joined and the organization rounded out as a system. Both systems have connections with U.S. roads and substantial mileage in the United States. The Ontario government owns a railway extending from North bay to James bay, and British Columbia operates the Pacific Great Eastern railway between Vancouver and Peace river area.

The east-west pattern of railways across southern Canada is supplemented by numerous branch lines, or feeders. In new territory further extension was made by gravel roads or with river steamboats, as on the Mackenzie and the Yukon, and with the organization of air transport systems in these and in newly opened mining districts.

Aircraft equipped with floats or skis were used in new districts, chiefly for passenger and mail service and in government work of surveying, mapping and prevention of forest fires. Government-owned Trans-Canada Air Lines (T.C.A.), established in 1937, was developed to provide continuous transcontinental service from the Atlantic to the Pacific, and east and south across the Atlantic. Canadian Pacific Airlines developed overseas services to Europe, the orient and Australia and to South America, but its domestic services were confined largely to the north and west until it obtained authority to operate a limited transcontinental service in competition with T.C.A. in 1959. Several smaller domestic airlines operated scheduled air services in Canada and a number of commonwealth and foreign air carriers held licences covering scheduled international services flying into Canada.

Railway rates were placed under the jurisdiction of the board of transport commissioners formed in 1903. It also regulates telephone, telegraph and express rates and deals with problems of location, construction and operation of the railways, of Great Lakes shipping and of interprovincial and international oil and natural gas pipelines. The air transport board, established in 1944, exercises jurisdiction in all matters related to civil aviation.

Transport facilities were vastly extended with the construction of roads. By 1960 there were more than 150,000 mi. of earth roads, chiefly in the prairie provinces, and about 270,000 mi. of surfaced roads of which much of the 45,000 mi. of bituminous

surface was in eastern Canada. The registration of more than 5,000,000 motor vehicles meant more than one vehicle for every four Canadians. The first paved highway across Canada, financed jointly by the federal and provincial governments, was completed in 1960. The Canadian northwest was given its first land transport route with the building of the Alaska highway during World War II, and a road from the Peace river to Great Slave lake in 1948. As in the United States, truck transport increased in importance after World War II.

Construction of transcontinental systems of oil and natural gas pipelines during the 1950s made significant contributions to transportation in Canada. There is a crude oil pipeline extending for 1,931 mi. from Edmonton, Alta., via Superior, Wis., to Sarnia and Toronto, Ont., gathering oil from the three prairie provinces and serving Canadian and U.S. refineries en route. The other main line transports oil from Edmonton to Vancouver, B.C. and the Puget Sound area of Washington. By 1960 Canada had a network of more than 8,000 mi. of oil pipelines linking oil fields with refineries and ports. A 650-mi., 30-in. gas pipeline was completed in 1957 to carry gas from the Peace river area of Alberta to Vancouver and the states of the Pacific northwest. Another pipeline, completed in 1959 at a cost of about \$375,000,000, carried Alberta gas 2,290 mi. across northern Ontario to Toronto and Montreal and other industrial areas in eastern Canada.

Canada is one of the world's leading trading nations and much of the exports and imports move by ocean transport. Several steamship lines run between Canada and Great Britain and Europe on the Atlantic and between Canada and Asia and Australia on the Pacific. The Canadian Pacific operates an important subsidiary ocean steamship company and the Canadian National has smaller steamship lines under its control.

Increase in transport facilities was accompanied by improved communications. In the second half of the 20th century telegraph mire mileage totaled more than 450,000 mi., about evenly divided between the Canadian National and Canadian Pacific telegraphs. Submarine cables connected with the province of Newfoundland, the French island of St. Pierre, and the east coast of the United States, nine crossed the Atlantic and two crossed the Pacific. Wireless and radio stations served as communication links with northern Canada. Commercial radio and television stations were operated chiefly by the government-owned Canadian Broadcasting corporation, but there were also more than 200 privately-owned stations. Telephone service was in almost every home, there being an average of one telephone for every four persons.

CANADA BALSAM, an exudation of the North American balsam fir, *Abies balsamea*; called also Canada turpentine and balsam of fir. It is strictly speaking a turpentine (*q.v.*) and not a balsam (*q.v.*), and at ordinary temperature is a yellow solid. It belongs to the class of oleoresins, which are natural products consisting of resin (*q.v.*) dissolved in a volatile oil. It contains 24% of essential oil. 60% of resin soluble in alcohol and 16% of resin soluble only in ether. Canada balsam is of importance in optics because of its refractive index, which is close to that of glass. Its chief uses are for mounting preparations for the microscope and as a cement for glass in optical work.

CANADA THISTLE, a deep-rooted, erect perennial (*Cirsium arvense*) of Europe, extensively naturalized throughout North America, where it is found in fields and waste grounds as an exceedingly pernicious weed. It is one foot to six feet high. The staminate (male) and pistillate (female) flowers are sometimes borne on separate plants. The grooved stems, somewhat branched above, bear deeply cut, exceedingly prickly leaves and numerous clustered purple or white flower heads about one inch broad. As the plant spreads by long, underground rootstocks as well as by wind-borne seeds, it is difficult to eradicate. Short rotation of crops, clipping of pastures, intense cultivation of field crops and rigorous cutting of the plant along roadsides and in waste grounds before the seeds mature are only partly effective. The best control is spraying young foliage with 2,4-D or other weed killer in full sunlight with an air temperature of 70° or higher. See THISTLE. (N. Tr.)

CANADIAN CONSTITUTIONAL ACT: see CONSTITUTIONAL ACT, CANADIAN.

CANADIAN LITERATURE (ENGLISH). The earliest Canadian literature in English was written at about the time of the American Revolution and was largely a result of that event. The 40,000 American loyalists who took refuge in the northern colonies which had not joined in the revolt were to determine the English-speaking character of Nova Scotia, New Brunswick and Upper Canada (Ontario), and to give them the slight beginnings of a literature. The Rev. Jonathan Odell (1737–1818), for example, has a minor place in the literary history of his two countries as the writer of convivial lyrics and of satire on Whig rebels. It is in the next generation, however, and among the sons of the loyalists that are found the clear beginnings of indigenous writing. Oliver Goldsmith (1794–1861), a grandnephew of the author of *The Deserted Village*, published an optimistic Nova Scotian imitation, *The Rising Village* (1825), which includes some interesting description but suffers at every point by comparison with the earlier poem. Joseph Howe (1804–73)—whose father, a proprietor of the *Boston News-Letter* at the time of the evacuation of the city, had taken the presses of that oldest of New England newspapers off to Halifax—was the most remarkable personality in the political life of Nova Scotia in his time, editor of the *Nova Scotian* (1828–41), and author of patriotic and narrative poems and of several volumes of travel sketches remarkable for their humour and shrewd observations. In the columns of the *Nova Scotian* in 1835–36 appeared the first Canadian literary work to gain international notice, *The Clockmaker, or the Sayings and Doings of Samuel Slick of Slickville*. The author, Thomas Chandler Haliburton (*q.v.*), member of the assembly and judge, was motivated in his public life by the pro-British, anti-American and antidemocratic prejudices of the Tory loyalist families. His fellow Nova Scotians, most of them the descendants of New Englanders, seemed to him to have acquired most of the faults and few of the dubious virtues of the republican Yankees. In *The Clockmaker*, Yankee shrewdness, energy and salesmanship make an easy victim of Nova Scotian gullibility and laziness, and Haliburton joins in the laughter. The sayings and doings of Sam Slick and the vivid little pictures of frontier life make this book a minor classic, in spite of its formless and sometimes repetitious arrangement.

These earliest writers all lived in the maritime provinces which had attracted a large part of the better educated loyalists of the northern Atlantic seaboard; the loyalists who settled in Quebec

and along the St. Lawrence and Niagara frontiers were of humbler stock, mostly farmers, and literary activity began later than down east. The first name in this region is John Richardson, a native of Queenston, whose background and military adventures were almost as romantic as his novels. His best book, *Wacousta* (1832), a story of the days of Pontiac's descent in 1763 on Michilimackinac and Detroit, draws on the experiences of Richardson's grandparents who included Scottish Jacobite exiles and an Indian grandmother who had witnessed the siege of Detroit. Richardson is best in graphic descriptions of scene and episode; his faults are stilted dialogue and frequent lapses into melodrama. Of the early immigrants to the Canadas (Quebec and Ontario) from Britain the most literary were two sisters, Catherine Parr Traill (1802–99) and Susanna Moodie (1803–85). Although they published novels, poems and stories for children, they are remembered mainly for their autobiographical volumes: *The Backwoods of Canada* (1836) by Mrs. Traill and *Roughing It in the Bush* (1852) by Mrs. Moodie, accurate and spirited social records of pioneer life. About contemporary with these two gentlewomen were two immigrant poets of the working class: Alexander McLachlan (1818–96), a tailor turned farmer, whose verses are compounded of memories of poverty and social inequality in Scotland and love for the new country where "Jack's as good's his master," and Charles Heavyside (1816–76), a Montreal cabinetmaker, whose dramatic poems *Saul* (1857), *Count Filippo* (1860) and *Jephthah's Daughter* (1865), though often commonplace or pompous in language, are bold in design and in their implied moral and religious skepticism.

From Federation to the 1920s.—In 1867 the separate colonies of British North America joined in a federal union to form the Dominion of Canada—except Prince Edward Island and the western territories (which joined within six years) and Newfoundland (which stayed out until 1949). A growing sense of national identity preceded the federal union and was cultivated by its accomplishment. The most national-minded poet in the decade before federation was Charles Sangster (1822–93), once regarded as the unofficial laureate of the Canadas but now remembered, if at all, for a few lines in his memorial verses on Gen. Sir Isaac Brock and for some description in "The St. Lawrence and the Saguenay" (1856). In the two decades after federation Charles Mair (1838–1927), who spent most of his life in the west, found themes for poetry on the new frontier and also in Canadian history, as in his verse drama *Tecumseh* (1886). Historical romance, always a popular form in Canada, is best represented in this period by *The Golden Dog*, (1877) by William Kirby (*q.v.*). Superficially, it is a costume romance of the struggle between the forces of honesty and corruption in New France; but Kirby's romantic Toryism informs the plot, characterization and description, giving the novel more depth and consistency than is found in any earlier Canadian example.

Meanwhile, a considerable number of semiliterary periodicals had appeared in Canada, the most notable being the *Literary Garland* (1838–51), the *Canadian Monthly* (1872–78) and the *Nation* (1874–76), the organ of the "Canada First" group. A little later (1883–96) appeared the best of these periodicals, *The Week*, founded by Goldwin Smith.

The first editor of *The Week* was Charles G. D. Roberts who, with Bliss Carman, Archibald Lampman (*qq.v.*), and Duncan Campbell Scott wrote the best poetry composed in Canada before the 1920s. Of these, Roberts and Carman had much in common. They were first cousins, brought up in New Brunswick, educated at the same school and at the provincial university, steeped in the poetry of English romanticism and in the transcendentalism of their distant kinsman Ralph Waldo Emerson; and both were to spend many years outside Canada. Roberts is most memorable as a regional poet but he also expresses the nationalistic optimism of the end of the century. He is best in his *Songs of the Common Day* (1893) and similar poems where he renders the appearances of the rural scene in the St. John valley and by the wide tidal flats of Tantramar and gives to field and barn or to the lonely wood chopper at his work a representative human significance. His religious and philosophic poetry seems less authentic, a pale reflec-

tion of romantic pantheism and transcendentalism. In the case of Carman these romantic and transcendental feelings are pervasive in his regional description and the outlines of objects are often blurred by the soft haze of the poet's mood. At his best in this manner in a few stanzas or brief poems, he is very fine; more often his pseudo-Keatsian beauties and languors are over-sentimental and cloying. Carman was a popular poet, even outside Canada, in part because he represented two thriving literary cults at the end of the 19th century, the cults of pagan aestheticism and of bohemian vagabondage, both having their North American temples in Greenwich Village, New York city. The other two poets of this so-called Confederation group, Lampman and Scott, were friends living in Ottawa as members of the civil service. Lampman learned to describe the countryside in the Ottawa region with affection and exact truthfulness; but the commercial and political life of the capital he regarded with distaste and foreboding. Both his poetry of natural description and of social comment are the expressions of a lonely and sensitive mind. Scott was also, in his way, an isolated and slightly austere figure, but of a more vigorous cast of mind. Like the others he was a regionalist, but of the remote and vast northern wilderness where the Indian lived, a region and a people that Scott knew intimately during his long career in the department of Indian affairs. Scott's narrative and descriptive poetry is commonly a poetry of conflict, of man against man or of the charged energies of nature against man, but the potentially realistic violence of the themes is subdued and often given suggestions of strangeness and fantasy.

During the years 1900-20 three of these poets were living and publishing, but the most characteristic writing of the period was more popular. This was the first age of the best seller; regional idylls and the tales of the frontier were popular types. The romances of Ralph Connor (*q.v.*) and the Yukon ballads of Robert W. Service (*q.v.*) sold by the millions. Tom MacInnes (1867-1951), who began as another rhymist of the gold rush, for 40 years chanted the joys of bohemian vagabondage, more plausibly than Carman, in ballade and villanelle. At the other extreme, Marjorie Pickthall (1883-1922), a much finer artist who also preferred exotic verse forms, combined religious feeling with end-of-the-century aestheticism in her beautiful but often cloying historical idylls. The comic-sentimental dialect poems of rural Quebec by William H. Drummond (*q.v.*), beginning with *The Habitant* (1897), and the feminine romances of Lucy M. Montgomery (1874-1942), author of *Anne of Green Gables* (1908) and numerous sequels, were very popular. The best book of the period, *Sunshine Sketches of a Little Town* (1912) by Stephen Leacock (*q.v.*), is predominantly a regional idyll, though the sentiment is laced with ironic satire and the author's affection for an Ontario town does not diminish his comic sense of the pettiness of its life. In the best of his other humorous volumes, in *Literary Lapses* (1910) and *Arcadian Adventures With the Idle Rich* (1914), beyond the fun and sheer nonsense one discerns the ambivalent attitude of the genial satirist.

Literature After 1920.—World War I had little immediate and direct influence on Canadian writing, but it fostered the growing nationalism and eventually an interest in Canadian cultural arts. The founding of the *Canadian Forum* (1920) which championed the painters of the Group of Seven, the little theatre movement and the new poets, and offered criticism of politics, society and the arts, was one sign of the times. The first of the new poets was E. J. Pratt (*q.v.*), who lived in Newfoundland until he was in his 20s and kept his connections with the island during his career as a professor of English in Toronto. Pratt's love of the sea: his fascinated interest in great sea monsters, his gusto and his impulse toward sheer fantasy are evident in *The Witches' Brew* (1925) and *The Titans* (1926). Later, most of his longer poems have been narratives of heroism: *The Titanic* (1935), *Brébeuf and His Brethren* (1940), *Behind the Log* (1947)—poems displaying exact historical and technical knowledge, a sense of the latent heroism in ordinary men and an Elizabethan delight in the vigour and splendour of words. Pratt is an isolated figure in poetry, without predecessors or followers, but his example of a complete break from the tradition of the Confederation poets was soon followed

in the late 1920s and early 1930s by younger men, mostly influenced to some degree by T. S. Eliot. Five of them, with Pratt, in 1936 produced an important joint volume of verse, *New Provinces*, and all later published volumes of their own. A. J. M. Smith (1902-), the critic of the group, and Leo Kennedy (1907-) show most clearly the influence of Eliot; Robert Finch (1900-) owes more to Eliot's French masters; F. R. Scott (1899-) is most effective in brief poems of social satire; much of the special quality of Abraham Klein (1909-) derives from his being a learned, sensitive Jew, steeped in the religion and history of his people and writing in Canada's most cosmopolitan city, Montreal.

Among those who began to publish during the depression of the 1930s and World War II, economics and politics were predominant concerns. They include Earle Birney (1904-), Dorothy Livesay (1909-), P. K. Page (1916-) and Louis Dudek (1918-). Of these, Birney has the widest range: social comment and satire, war verse, regional description of his native British Columbia and a fine narrative poem, "David." About contemporary with the younger poets listed above is Patrick Anderson (1915-) whose verbal exuberance often suggests Dylan Thomas. The aggressive naturalism of Irving Layton (1912-) may remind one of D. H. Lawrence or of the "angry young men." He is the castigator of puritanism and intellectualism which he apparently considers the bane of Canadian society and writing. His fellow Montrealer, Louis Dudek, as in *Laughing Stalks* (1958), has shown a similar attitude and temper. James Reaney (1927-) is also a satirist, of small town life in southern Ontario, beneath the often complex literary and archetypal allusiveness of his poems. A rather similar preoccupation with symbol and myth, Blake and Jung, informs the poetry of Jay Macpherson (1931-).

Meanwhile, after the 1920s some able writers of prose fiction appeared, though the art of the novel was never cultivated in Canada as carefully as the art of poetry. The early novels of Frederick Philip Grove (*q.v.*), from *Settlers of the Marsh* (1925) to *Fruits of the Earth* (1933), are powerful and sombre studies of pioneering on the prairies, though marred by a rather stiff formality of style. Two previous volumes of western sketches, *Over Prairie Trails* (1922) and *The Turn of the Year* (1923), are the most perfect of his writings. From *Jalna* (1927) to *Morning at Jalna* (1960), Mazo de la Roche (*q.v.*) published 16 novels about the turbulent Whiteoak family—the most massive achievement in Canadian fiction. Writers of historical fiction include Frederick Niven (1878-1944), who attempted an ambitious trilogy on the settlement of the west, and Will R. Bird (1891-) and Thomas Raddall (1903-), who wrote of 18th-century Nova Scotia.

Philip Child (1898-), who began with historical romance, turned later to contemporary realism of a clearly humanistic and humanitarian tendency, as in *Day of Wrath* (1945). Morley Callaghan (1903-) has been a humanitarian realist all his career, describing with compassion the lives of the misfits, the outcasts and the morally bewildered in urban society. W. O. Mitchell (1914-), in his short stories and novel *Who Has Seen the Wind* (1947), writes of small town life on the western prairies, with special sympathy for eccentric independents. Hugh MacLennan (1907-) was a realist of regional life in *Barometer Rising* (1941) and *Each Man's Son* (1951), stories of Nova Scotia society; more ambitiously, he attempted to be the interpreter of the Canadian national character in *Two Solitudes* (1945). Canadian mores, in small cities of southern Ontario, provide comic themes for Robertson Davies (1914-), the witty and versatile author of several plays, a fictional diary and collection of table talk, and satiric novels. Ethel Wilson, whose novels are set chiefly in Vancouver and adjoining countryside, writes with sensitivity and technical skill about the private world of emotion and conflict.

CANADIAN LITERATURE (FRENCH). The cultural history of Canada has been conditioned by the country's dual origin, resulting in a certain tension between French and English within the nation, and by a sensitivity in regard to the position Canada occupies in the company of France, Great Britain and the United States. The psychological problem is more acute in French Canada, however, and a strong urge to hold to the past long remained a prominent feature of the French-Canadian outlook. All these considerations are reflected in the literature and thought of French Canada.

History and Related Fields.—It was François X. Garneau (*q.v.*) who laid the foundation for the later blossoming of both historical studies and creative literature. His *Histoire du Canada* appeared in the years 1845 to 1848; it reawakened a dormant pride of nation and inspired poets, novelists, and other historians of the day. His successors have presented points of view ranging from the strictest nationalism to the broadest liberalism. The abbé Lionel Groulx (1878–) has, for instance, supported strong nationalist sentiments in an abundant work which is the result of a long scholarly career; perhaps his most important publication is his *Histoire du Canada français* (4 vol., 1950–52). A more partisan point of view is found in the work of Robert Rumilly; his *Histoire des Acadiens* (2 vol., 1955) interprets the 18th century deportation of the Acadian French population as a martyrdom. Rumilly is probably better known for his detailed *Histoire de la Province de Québec*, which reached volume 32 in 1960. The abbé Arthur Maheux (1884–) has striven, on the other hand, to eradicate prejudices; in *Ton histoire est une épopée* (1941) he showed that French Canadians had reasons to be grateful to Britain, even from the very beginning. Jean Bruchési's wealth of factual information, marshaled in an easily accessible form, makes pleasant reading of *Canada: réalités d'hier et d'aujourd'hui* (2nd ed., 1954). Pleasant reading is also found in Msgr. Albert Tessier's solid two-volume history entitled *Neuve-France* (1956) and *Québec-Canada* (1958).

Michel Brunet's *La Présence anglaise et les Canadiens* (1958) studies the thought, history, politics and economy of French Canada in the light of English-Canadian influences. It follows naturally after Edouard Montpetit's scrutiny of economic history, *La Conquête économique* (3 vol., 1938–42). Various aspects of French-Canadian society are examined in J. C. Falardeau's *Essais sur le Québec contemporain* (1953), Philippe Garigue's *Essais sur le Canada français* (1958), and Father P. Angers' *Problèmes de culture au Canada français* (1960). Among the many theologians and philosophers who have contributed to religious thought was Msgr. Louis Adolphe Paquet (1859–1942), who published a series of social and religious studies in the first two decades of the 20th century in which he developed the theme of *la mystique nationale*, the providential mission of the French in America. This theory cast strong reflections on regional literature earlier in the 20th century.

Poetry.—The first literary movement of French Canada, the Patriotic school of 1860, was inspired by F. X. Garneau and centred around Crémazie's bookshop in Quebec city. The authors of the day were imbued with a strong nationalism to which religious fervour, often sentimental in tone, was a natural adjunct. Literary inspiration was found principally in Victor Hugo and Alphonse de Lamartine. Later in the 19th century Baudelaire, the Parnassians and the Symbolists gradually replaced romantic models, and literary activity was oriented more around Montreal. In the 1930s Surrealist influences began to predominate; after World War II it was more difficult to trace lines of filiation, and one has the impression that poets felt and wrote with more independence than formerly. Young poets tended to form certain loose groups, such as the "Hexagone" in Montreal, which offered stimuli to their inspiration and outlets for their production.

Joseph Octave Crémazie (*q.v.*) was the first important poet of French Canada. His "Chant du vieux soldat canadien," "Le Drapeau de Carillon," "Les Morts," "Le Canada," were still popu-

lar poems early in the 20th century. Louis Fréchette (*q.v.*) won success with a collection of patriotic poems in the rhetorical style of Victor Hugo entitled *La Légende d'un peuple* (1887). Other followers of Crémazie who celebrated Canadian life, its picturesque customs and religious faith are Pamphile Lemay (1837–1918), William Chapman (1850–1917), Alfred Garneau (1836–1904) and Nérée Beauchemin (1850–1931). These poets were precursors of the *Terroir*, or regionalist, school of Quebec who recorded the humble aspects of French-Canadian life. Blanche Lamontagne, the best-known of the group, published *Par nos champs et nos rives* (1917), *La Vieille maison* (1920) and *Ma Gaspésie* (1928). Other poets of the *Terroir* school were Albert Ferland, Englebert Gailkze and Alphonse Désilets.

In 1895 Jean Charbonneau and Paul de Martigny founded the Montreal Literary school. Canadian life, Canadian landscape and patriotism did not inspire these poets. Symbolists and aesthetes, they wished to live in the presence of beauty. Charbonneau's *Sur la borne pensive* (1952) invites his readers into a garden of delights where life is a spectacle of Persian lilacs, pergolas, fountains and ruined temples. These poets liked to picture their souls as beautiful things, and Émile Nelligan (1879–1941) pictured his as a ship sculptured in massive gold and laden with treasures, "Le Vaisseau d'or." Paul Morin (1889–) reflects his European experience in the exotic and Parnassian poems of *Le Paon d'émail* (1911) and *Pobmes de cendre et d'or* (1922). Louis Dantin (pen name of Eugène Sears), the critical conscience of the group, contributed *Le Coffret de Crusoé* (1932). Another writer of Parnassian sonnets is Alfred DesRochers, author of *L'Offrande aux vierges folles* (1928) and *A l'ombre de l'Orford* (1929). The gusty spirit of the north country found expression in his grand "Hymne au vent du nord." Clément Marchand, poet and critic, sang of town and country in *Soirs rouges* (1939).

In 1934 Robert Charbonneau, François Hertel (pen name of Rodolphe Dubé) and St. Denis Garneau founded an important literary journal called *La Relève*. Charbonneau (1911–) made a name for himself as a novelist and editor; Hertel and Garneau were poets. For Garneau (1912–43), author of *Regards et jeux dans l'espace* (1937), poetry was a means of probing the despair within himself and touching the solitude of reality. His intense feeling and superior technique have exerted a strong influence on many poets who follow him. Hertel (1905–) as noted in such titles as *Axe et parrallaxes* (1941) and *Strophes et catastrophes* (1943), is a humorous man with a double vision. Torn between sensuous delights and the consciousness of sin, Hertel is the poet of religious inquietude and metaphysical rebellion (*Mes naufrages* and *Jeux de mer et de soleil*, 1951).

Alain Grandbois (1900–), world traveler and exquisite poet, translated the nightmare in his soul into cosmic images. Constellations of silence, worlds vanishing, black eyes in a dark night, ghostly, insubstantial things on a swift black river, are some of the visions he conjured up in the poems of *Les Iles de la nuit* (1944). Art of the very first order continued to appear in his subsequent works, *Rivages de l'homme* (1948) and *L'Étoile pourpre* (1957). Jean Guy Pilon (1930–), one of the most active of poets both in publishing and in encouraging others to publish, is the founder of the Hexagone group in Montreal (1954). In his *Fiancée du matin* (1953) passion is balanced by illusion; in *Les Cloîtres de l'été* (1954) he clothes passion in a spiritual veil. *La Mouette et le large* (1960) presents the eternal themes: woman, life and death. His art is brittle and brilliant, sometimes prosaic but often cutting and impressive. Roland Gigukre, publisher as well as poet, has produced a dozen titles in which Surrealist elements are evident; *Les Armes blanches* (1954) is among his best.

Rina Lasnier (1915–), a Christian poet looking for perfection, was inspired by the women of the Old Testament who anticipated the perfection of the Immaculate Virgin (*Le Chant de la montée*, 1947). In her *Escapes* (1950), the pagan myth of Danae was a vehicle of ironic, metaphysical ecstasy. *Pre'sence de l'absence* (1956) contains one of her best poems, "Malemer"; her latest collection is entitled *Mémoire sans jour* (1960). Anne Hébert (1916–) is possibly the most impressive of contemporary poets if not the most prolific. A sure poetic progress is seen

between her *Songes en équilibre* (1942) and *Pobmes* (1960) which is composed of "Le Tombeau des rois" (1953) and "Mystère de la parole." The same inspiration is seen in her volumes of poetic prose, *Le Torrent* (1950) and *Les Chambres de bois* (1958). She belongs doubly to the lineage of St. Denys Garneau, by blood relationship and the excellence of her art. Near at hand she finds symbols to express the tensions between a desire to inhabit a childhood world and the necessity of living today's existence, the "house" of the bondage of tradition and custom and the "torrent" of the essential life of the poet, the surge of impulses in which she is fated to lose herself.

A comprehensive view of French-Canadian poetry may be had by reference to four documents: Laure Rièss's collection *L'Ame de la poésie canadienne-française* (1955). Guy Sylvestre's *Anthologie de la poésie canadienne d'expression française* (2nd ed., 1958); G. R. Roy's book, *Twelve Modern French Canadian Poets* (1958), and the long-playing record *Voix de 8 poètes du Canada* which appeared the same year.

The Novel.—The history of fiction follows a course parallel to that of poetry. Romantic in mid-19th century, it lapsed into a long period of regionalism in which authors tended to illustrate the theses of *la mystique natorzale*, the sanctity of the land, and the virtue in remaining faithful to soil, language, race and religion. The social novel developed under naturalist influences providing an authentic picture of urban French-Canadian society.

According to its author, P. A. de Gaspé, Jr., *Le Chercheur de trésor* (1837), is the first Canadian novel. It is a story of adventure and black magic. The best-known 19th century novel is *Les Anciens Canadiens* (1863), the work of P. A. de Gaspé, Sr., (*q.v.*); it describes seigniorial life and the tragedy of divided loyalties caused by the conquest. *Charles Guérin* (1852) by P. J. O. Chauveau and *Jean Rivard* (1862) by Antoine Gérin-Lajoie (*q.v.*) depict pioneer life, intending to show that it is the duty of young Canadians to settle in Canada and not to emigrate to the industrial cities of New England. In this sense they anticipated *Maria Ckapdelaine* (1916) by Louis Hémon (*q.v.*) and the novels of pioneering in which young people choose to carve out new homes in the northern Quebec wilderness. This theme is the mainspring of the "deserter" novels of writers like Claude Henri Grignon, author of the ever popular *Un Homme et son péché* (1933) and *Le Déserteur* (1934), where the habitant who sells his farm and moves to the city is called a deserter.

The feeling for the sacred earth takes the form of Franciscan mysticism in two of the works of Léo Paul Desrosiers (1896–), *Sources* (1942) and *L'Ampoule d'or* (1951). Msgr. F. A. Savard (1896–) finds inspiration for his novels of national energy in the logging industry (*Menaud, maître-draveur*, 1937), and in pioneering (*L'Abatis*, 1943); *Minuit* (1948) is an idyllic picture of life in a parish isolated from the cities.

Germaine Guèvremont (1900–) dramatizes the progressive decadence of a pioneer family in her novels of peasant life (*Le Survenant*, 1945, and *Marie-Didace*, 1947), knowing how to clothe the bitter facts in a charming veil of poetry without distorting them. Ringuet (pen name of Philippe Panneton, 1895–1960) brought a clinical talent into fictional art and in *Trente arpents* (1938) viewed the migration from the farm with disarming frankness. In *Fausse Monnaie* (1947) he photographed the frustration of an insignificant life in the city for one whose heart remained in the country. The inner void assumes tragic proportions in *Le Poids du jour* (1949), where the protagonist is crushed by his environment.

Historical Fiction.—Works of historical fiction exploit the natural interest in past glories. *Les Habits rouges* (1923), by Robert de Roquebrune, revives memories of the rebellion of 1837. The same author's *Testament de mon enfance* (1952) pictured a golden age, a delightful civilization which flowered in the 1890s. Léo Paul Desrosiers went back to the early days of the colony for *Les Opiniâtres* (1941), and to the fur trade of 1800 for *Les Engagés du Grand Portage* (1939). These works on historical themes contrast with his later style as found in *Sources*, *L'Ampoule d'or*, or *Vous qui passez* (3 vol., 1958–60).

Gabrielle Roy (1909–), who caught the humour of the poly-

glot situation in her native Manitoba (*La Petite poule d'eau*, 1950), went east and recorded her observations of life in a working-class district of Montreal in a widely acclaimed novel, *Bonheur d'occasion* (1945). The purity of her objective art and her ironic treatment of wartime affluence gives her work a universal appeal. She continued her skilful revelation of the frustrating insignificance of modern city living in *Alexandre Chenevert* (1954) in which a humble cashier is burdened by the consciousness of his fellow man's sufferings. *Rue Deschambault* (1955) is autobiographical fiction. While Gabrielle Roy was portraying Montreal, Roger Lemelin (1919–) was depicting life in Quebec city. The hero of his three novels, *Au pied de la pente douce* (1944), *Les Plouffe* (1948) and *Pierre le Magnifique* (1952), chafes under the limitation of his modest place in a theocratic society, torn between a desire for grandeur and a paralyzing sense of impotence. Yves Thériault (1915–), a prolific novelist, dared to reach out beyond his own milieu for his subjects. *Aaron* (1954) is concerned with the strain on a Jewish family in a gentile world; *Agaguk* (1958), an Eskimo family faced with the white man's code of law; *Ashini* (1960), the Indian way of life. Thériault has examined other social phenomena also, bigotry in *Les Vendeurs du temple* (1951) and alcoholism in *Cul-de-sac* (1961). Gérard Bessette (1920–) is another keen observer of French-Canadian society, as in *La Bagarre* (1958), dealing with antagonistic social forces in a big city, and *Les Pe'dagogues* (1961), a revelation of how education functions on the local scene. Lemelin's humour is tinged with cynicism, but it is not as boisterous or bitter as that of Thériault in *Les Vendeurs du temple*, or that of Jean Simard in *Félix* (1947) and *Hôtel de la Reine* (1949), not to mention the racy quality of Rodolphe Girard's *Marie Calumet* (1904).

Certain novelists, variously feeling the impact of Mauriac, Gide, Camus, or others more distant such as Stendhal or Dostoevski, probed the depths of the individual soul. Robert Charbonneau located his psychological studies in a small fictional town which also provides the name of his novel *Fontile* (1945). In it and in *Ils posséderont la terre* (1941) and *Les Désirs et les jours* (1948) certain people find their souls withering away just when they should have been maturing. André Giroux (1916–) chose two extreme situations for his penetrating studies, a *crime passionnel* in *Au delà des visages* (1948), and a man near death from cancer in *Le Gouffre a toujours soif* (1953). Robert Elie (1915–) depicts at length the case of a manic-depressive who sees life revolving around him as in a dream (*La Fin des songes*, 1950), and he examines an unmotivated murder in *Il suffit d'un jour* (1959). Perhaps the ultimate on the theme of despair is reached by André Langevin (1927–) in his novels *Evade' de la nuit* (1951) and *Poussière sur la ville* (1953), one of the most artistic novels to come out of French Canada, and far superior in style to his later work *Le Temps des hommes* (1956).

Drama.—The theatre is the poor relation of French-Canadian literature. After Louis Fréchette's *Ve'ronica* (1908) there was a long void. Two excellent and successful troupes have nonetheless been founded, "Le Théâtre du Nouveau Monde" in 1951 and "La Comédie Canadienne" in 1956. Gratien Gélinas (1909–) won great popular acclaim as author and principal actor of *Tit-Coq* (1950) and *Bousille et les Justes* (1960). Eloi de Grandmont presented the deserter theme in the historical tragedy *Un Fils à tuer* (1950). Robert Elie offers in symbolist form the anguish felt in longing for lost purity (*L'Etrangère*, 1954). André Laurendeau gives an example of psychological drama in *Deux femmes terribles* (1961). Marcel Dubé (1930–) is sure of a wider audience with his accessible social themes in *Le Temps des lilas* (1958), *Un Simple soldat* (1958), *Florence* (1960). Even more popular is the appeal of certain *romans fleuves* or "soap operas" appearing on radio or television; for example, C. H. Grignon's rural drama *Un Homme et son péché*, Roger Lemelin's chronicle of the Plouffe family in Quebec city, or Robert Choquette's vision of Madame Velder's Montreal boardinghouse which reached literary maturity when the novel *Elise Velder* was published in 1958. Radio and television have, indeed, offered much scope to poets and novelists in French Canada, but especially to dramatists, and quite a number are engaged in writing specifically for this medium. Examples of

their art are found in the series *Ecrits du Canada français* (1958–).

Criticism.—Literary criticism appeared in 1903 with the study of the poet Émile Nelligan by Louis Dantin. Msgr. Camille Roy (1870–1943), however, made one of the first systematic studies; among the many works he published the most important is his *Manuel d'histoire de la littérature canadienne* (1918; 10th ed., 1945). The over-all presentation was brought up to date by Rev. Samuel Baillargeon's textbook *Littérature canadienne-fran-aise* (1957), which, however, was almost immediately rendered obsolete by Gérard Tougas' *Histoire de la littérature canadienne française* (1960). Available literary histories are often eclectic or sketchy, as are, for example, Berthelot Brunet's *Histoire de la littérature canadienne-fran-aise* (1946), Dostaler O'Leary's *Roman canadien-français* (1954), Laure Rièse's introduction to *L'Ame de la poésie canadienne-fran-aise* (1955), or the *Essais critiques* (1958) of the Académie Canadienne-Française. The presentation is thorough, on the other hand, in Jeanne Paul-Crouzet's *Poésie au Canada* (1946), Jean Béraud's *350 ans de théâtre au Canada français* (1958), and Séraphin Marion's 10-volume study of the 19th century, *Les Lettres canadiennes d'autrefois* (1939–59). *The University of Toronto Quarterly* has published an excellent annual review of French-Canadian letters since 1936.

Other important critics may be mentioned by name rather than by their various publications: Roger Duhamel, René Gameau, Guy Sylvestre, W. E. Collin and André Belleau.

CANADIAN RIVER. Rising in the mountains of north-eastern New Mexico and flowing southward across Las Vegas plains, the Canadian river cuts a gorge nearly 1,500 ft. deep in the Canadian escarpment before turning eastward. It continues its course through the Panhandle of Texas in a deep, narrow valley cut into reddish sandstones, the walls of which are known locally as "the breaks." Continuing eastward through Oklahoma, the Canadian joins the Arkansas at the western edge of the Boston mountains. During dry seasons, usually late summer and early fall, little or no flow exists, but spring snow melt or summer thunderstorms may raise the level to raging flood proportions. A crest of 24 ft. was recorded near Amarillo, Tex., in May 1914. Through most of its 960-mi. course, the Canadian is a braided stream with an interlacing system of channels.

The main tributary of the Canadian is the North Canadian with a drainage area of 14,290 sq.mi. It enters the Canadian below Eufaula, Okla. Its flow is partly controlled through Lake Overholser and Lake Hefner, storage reservoirs which supply domestic water for Oklahoma City. Other tributaries include Mora river and Ute creek (N.M.) and Mustang creek (Tex.).

Control works on the Canadian include Conchas dam and reservoir which irrigates about 33,000 ac. near Tucumcari, N.M. Above Conchas dam the Canadian irrigates about 57,000 ac. The total drainage area of the main Canadian is about 47,576 sq.mi.

"The breaks" and other deeply eroded indentations into the Llano Estacado (*q.v.*) and the high plains caused by the Canadian and its system occur in a semiarid climate where shrubs and low grasses predominate. Because of the rugged terrain and many deep box canyons, this area was a favourite hiding place for bandits and rustlers. The name may have come from early French traders and hunters from Canada who followed it west into Spanish territory. The southern route for early U.S. immigrants to California lay along the south bank to Santa Fe. (C. N. C.)

CANAKKALE, a town in Turkey and capital of an *il* (province) of the same name which includes the peninsula of Gallipoli and the island of Imroz, the ancient Troad and the adjoining islands. Pop. (1960) 19,484. The town lies at the mouth of the Koca river (anc. Rhodius) and at the narrowest part of the Dardanelles (*q.v.*) strait which is there only one mile wide. The pottery trade, from which the town derived its name (*canak* means "pot" in Turkish), has declined, but the town has become one of

the chief centres of the fish canning industry in Turkey. Because of its location, controlling the Dardanelles, it has always been of great importance strategically. The site of ancient Troy, near Hisarlik on the Aegean coast, is about 20 mi. S.W. from the town.

The *il* of Canakkale (area 3,845 sq.mi.) had a population of 338,395 at the 1960 census. Its eastern and southern parts are mountainous and forested. Mt. Ida (*q.v.*) (Turkish Kaz Dagi) in the southeast reaches 5,797 ft. The climate is Mediterranean, with warm summers and relatively mild winters. Cereals, cheese and valonia are the chief products of the *il*.

CANAL: see WATERWAYS, INLAND.

CANALEJAS Y MÉNDEZ, JOSÉ (1854–1912), Spanish statesman who was prime minister from 1910 to 1912, was born at El Ferrol on July 31, 1854. He graduated from Madrid university in 1872, took two doctorates the following year, and then worked for the railway company of which his father was a director. Beginning his political career in 1881, when he was elected to the *Cortes* for Soria, he gained rapid promotion: undersecretary in the prime minister's department in 1883, successively minister of public works and of justice in 1888, and minister of finance in 1894. Canalejas stood on the extreme left wing of the Spanish Liberal party and believed strongly in imposing restrictions upon the religious orders and in suppressing the latifundia. His ministry, which succeeded Segismundo Moret's government in Feb. 1910, undertook a great deal of social reform, but was especially concerned with three problems: Morocco, the religious orders and industrial unrest (see SPAIN: History). Canalejas displayed great energy in dealing with the series of strikes and civil and military disturbances which occurred during 1910–12, but his firmness meant forfeiting the support of the moderate republican left, and led to his assassination in Madrid on Nov. 12, 1912.

See José Francos Rodriguez, *La Vida de Canalejas* (1918); Duque de Canalejas, *Reflexiones sobre la vida de mi padre* (1928).

CANALETTO, the name commonly given to the Venetian painter and etcher Antonio Canal (1697–1768) and sometimes applied to Bernardo Bellotto (*q.v.*), his nephew and pupil.

Antonio Canal or Canale was born at Venice on Oct. 18, 1697, and received his early training there in the studio of his father, Bernardo, a painter of theatrical scenery in the style of the Bibienas. About 1719 he abandoned this career and, probably at the suggestion of the view painter Luca Carlevaris, went to Rome where he came under the influence of the Dutch painters of classical ruins and perhaps of Giovanni Pannini. On his return in 1720 he adopted a career of a painter of views of Venice for foreign visitors, a course in which his early training in architectural draftsmanship stood him in good stead. At first he probably collaborated with Carlevaris, but was already working independently by 1722 when he received his earliest commission from an English-

man. Thereafter English visitors to Venice were to play a pre-dominating role among his patrons, many of his commissions coming through Joseph Smith, merchant, art collector and later British consul at Venice, whose own magnificent collection of Canaletto's work was purchased for the British crown in 1763. In 1741-43 Canaletto painted a series of large views of Rome and may even have revisited the city. The outbreak of the War of the Austrian Succession perhaps deprived him of his English patrons and induced him to visit England in 1746. His scenes of London, of the country houses of his patrons and of provincial cities brought him success as great as had his Venetian work, and except for two short visits to Venice he resided in England more or less continuously until 1755. He was elected a member of the Venetian academy in 1763. He died in Venice on June 20, 1768.

Canaletto's early style is broad and impressionistic, but under the pressure of prodigious success he adopted an increasingly lucid, linear and firm manner suited to the demands of his clients for accurate views of the city and more readily taught to assistants; toward the end of his life, marked mannerisms tended to displace accurate observations of nature. Among his contemporaries he was renowned for his masterly use of the camera obscura in preparing his drawings. In addition to view painting he executed many *capricci* in which real buildings from different sites were combined in an imaginary setting; he was a skilled draftsman and produced many drawings for engravers, his last important commission in 1763 being for drawings for a set of engravings of the principal ceremonial functions performed by the doge. About 1742 he executed a series of etchings of great brilliancy. They show the same command of aerial perspective seen in his paintings. He utilized a simple system of shading in parallels but gave his lines a slight sinuosity which seemed to invest the atmosphere with a misty heat. He etched 31 plates. Except for his nephew Bellotto the names of none of his many pupils are known. It is possible, however, that Francesco Guardi (*q.v.*) worked in Canaletto's studio briefly between 1755 and 1765. He was widely imitated during his lifetime in Venice and England.

CANAR, a province of highland Ecuador, bounded north by Guayas and Chimborazo, east by Oriente, south and southwest by Azuay. Area 1,034 sq.mi.; pop. (1960 est.) 127,700.

Canar includes a part of the high cordillera, a part of the basin of Cuenca on the east and the valley of the Naranjal river on the northwest. The higher slopes of the mountains are used for the pasture of sheep. Around the capital, Azogues, the farms provide pasture for cattle and produce maize, wheat, barley, potatoes and fruit.

In the deeply cut valley of the Naranjal river there are plantations of sugar cane and coffee. There are small deposits of coal and ores of gold, silver, copper and mercury, none of much importance. Around Cuenca householders weave panama hats.

(P. E. J.)

CANARIS, WILHELM (1887-1945), German admiral remembered for his ambiguous role as head of military intelligence under the Nazi regime, was born at Aplerbeck, in Westphalia, on Jan. 1, 1887, the son of an industrialist. He served at sea and in naval intelligence in Madrid during World War I. A member of the military tribunal that sentenced the murderers of Rosa Luxemburg in 1919, he is alleged to have assisted the subsequent escape of one of the condemned officers. In Jan. 1935 he was appointed head of the *Abwehr* (the military intelligence branch of the high command of the German armed forces). In this position he played an important part in organizing German aid to Spain during the civil war, but he had little sympathy for the Nazi regime, which he considered destructive of traditional conservative values and dangerous to Germany by its foreign ambitions.

Canaris participated in the resistance to Hitler from 1938 to 1944, but his exact role is difficult to determine. He enlisted some of the conspirators into the *Abwehr* (although it was his subordinate, Gen. Hans Oster, who sponsored them) and enabled

them to work under its cover, but while he shielded and encouraged others he lacked enthusiasm for the cause or the power of decisive action. His task was made more difficult by the fact that the rival security office, the *Reichssicherheitshauptamt*, a department of the SS (*Schutzstaffel*) under Heinrich Himmler and Ernst Kaltnbrunner, sought to gain control over the *Abwehr* in order to extend the empire of the SS within the regime. He thus found himself carrying on genuine and active (though not always successful), intelligence work against the Allies; defending his own organization against his Nazi rivals; and at the same time shielding conspirators against the regime that employed him. Investigations by the SS into the *Abwehr* inevitably uncovered evidence of treason; but Himmler made no use of such knowledge when, in Feb. 1914, he persuaded Hitler to disband the *Abwehr*, on grounds of inefficiency, and to place it under his control. Canaris was transferred to the economic staff of the armed forces, where he remained until after the abortive plot of July 20, 1944, against Hitler. He was then arrested. He was executed at Flossenbiurg concentration camp on April 9, 1945. (W. K.P.)

CANARY, a finch (*q.v.*) best known as the yellow cage bird, descended from the wild canary *Serinus canarius canarius* of the Canary Islands, the Azores and Madeira. The serin, *S. c. serinus*, of Europe is a close relative.

The wild canary is about five inches long and is a streaked, greenish-brown bird with conspicuous yellow on the head, breast and rump in the male. It lives in small flocks, has an undulating flight, perches in trees, hops on the ground and eats seeds. The birds live in pairs; the female builds a cup-shaped nest in a tree or bush and lays three to six pale blue, brownish spotted eggs.

As a cage bird, the canary was introduced into Europe in the 16th century and quickly became popular and much changed under domestication. The common household canary is clear yellow, green, cinnamon or mottled in

JOHN MARKHAM
WILD CANARY (SERINUS CANARIUS
CANARIUS)

colour. Among the fancy breeds are some with pure white, orange or spangled plumage. Others have crests or caps of long, flat feathers, or frilled or recurved plumage. There are breeds of large size, up to eight inches long; and those that, when excited, adopt grotesque poses with the neck held at a strange angle; and those like the rollers that are bred for sweetness of song.

Canaries do well in cages that are about 12 in. in each dimension. They do not need space to fly, but need round perches to hop on for exercise. The bottom of the cage should be covered with clean sand that is changed frequently for cleanliness: the sand also supplies grit for the bird's gizzard. Canaries are hardy birds, but they need sunshine and fresh air, and protection against drafts and too-high temperatures. Canaries may catch cold if subjected to too much heat, for instance when they are placed too close to a radiator. Their food consists chiefly of small seeds, such as those of millet, rape, canary, poppy, etc.; these should be given in moderate amounts only, for overfeeding is the commonest cause of illness. They should be fed fresh green food such as chickweed or lettuce and the surplus removed before it wilts. Clean drinking water is essential, and also water in a shallow dish for frequent bathing. When the birds are molting, they are voiceless; at that time a diet supplement, or "voice restorer," is advisable. The supplement usually includes egg cake or zwieback, poppy and flaxseed, and cayenne pepper; the pepper intensifies the yellow of the growing feathers.

To breed canaries, a pair is placed together in a cage in early spring. The cage is about 15 in. high, 10 in. deep and 24 in. long; all sides are covered except for the wire front. Nest receptacles and soft materials for building the nest are provided, and sup-

plementary "egg food" of grated hard-boiled egg and bread is given. The female builds, lays and incubates, being fed by the male during this time. The young hatch in 13 days, are fed by both parents, and leave the nest in about 3 weeks. About a week later they learn to feed themselves, and then are separated from the parents. The female may quickly start another family. The young are gradually changed to the adult diet. When the adults begin to molt in midsummer, they are separated until molting is concluded.

(A. L. RD.)

CANARY ISLANDS (ISLAS CANARIAS), a Spanish archipelago in the Atlantic ocean, between 27° 49' and 29° 27' N. and 13° 20' and 18° 12' W. The minimum distance from the northwest African mainland is 67 mi. between Fuerteventura and Cape Juby. Area 2,807 sq mi.

Physical Geography.—Physically the Canaries fall into two groups. The western group includes Tenerife, Grand Canary, La Palma, Gomera (*qq.v.*) and Hierro (Ferro) and consists of mountain peaks, isolated and rising directly from a deep ocean floor. The eastern group comprises Fuerteventura, Lanzarote (*qq.v.*) and six islets, surmounting a single submarine plateau less than 4,500 ft. deep. After the researches of Christian Leopold von Buch (*q.v.*) in the early 19th century, the Canary Islands, which are geologically associated with Madeira and the Azores, became classical ground to the student of volcanism. They are merely cones of ejection, formed by volcanic eruptions during and after the Tertiary Age. The lavas consist chiefly of basalts and trachytes.

Climate.—The Canaries are situated most of the year within the northeast trade wind and at the eastern edge of a vast subtropical anticyclone. The trade wind blows strongly and steadily all the summer but in winter may be interrupted by winds from between southeast and west which occasionally bring hot dusty weather, and, very rarely, locusts, from the mainland. In winter the passage of shallow depressions causes most of the archipelago's scanty rainfall. The climate is warm and dry. On the lower parts, February, the coolest month, has a mean temperature of about 60° to 64° F. and August, the hottest month, of 74° to 76° F. except in the eastern islands, which can be very hot. Sunshine is abundant at all seasons and rainfall, except on more exposed parts of some of the western islands, small and variable. The more populous districts have mean annual rainfalls of between 5 and 15 in., with about 50 to 60 rain days, but most of this falls in a few short, heavy storms in winter. The lower, eastern islands experience long periods of drought. Snow does not fall below about 3,000 ft. and is unusual below 5,000 ft. The Pico de Teide on Tenerife is often snow-clad above 8,000 ft. from December to March. This grand peak was the scene of a remarkable step in the progress of meteorology when in Aug. 1856 Charles Piazzi Smyth made two ascents that demonstrated the layering of the atmosphere in trade-wind areas.

Animal Life.—There were probably no indigenous mammals on the Canaries at the time of their discovery by Europeans. The dog, swine, goat and sheep found there by the Spaniards had probably been introduced by earlier invading peoples from Africa. The ferret, rabbit, cat, rat, mouse and bat and various domestic

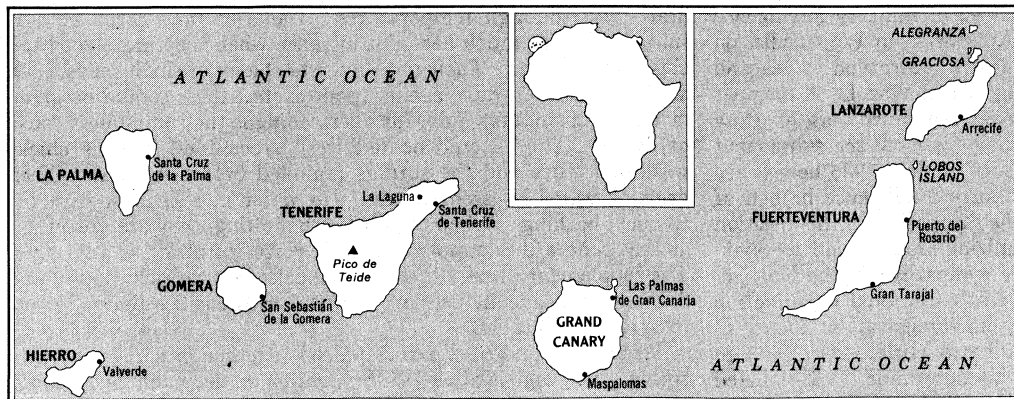

animals have become naturalized. The ornithology is more interesting. About 220 species have been recorded and of these, 75 breed locally and more than 40 are peculiar to this archipelago. Notable native birds include a large blue chaffinch, the houbara bustard, the black oyster catcher, the black-breasted sand grouse, the Canary chat, the greenish-brown wild canary (*Serinus canarius*) and the trumpeter bullfinch. There are no snakes but several species of lizard thrive.

Vegetation.—Of the 900 species of wild flowering plants found in the Canaries just over 300 are indigenous. The latter show strong affinities with the flora of the Mediterranean region and tropical east Africa and weak affinities with the vegetation of eastern Asia and the new world. The scanty rainfall and porous volcanic surfaces cause large tracts of the drier islands to be almost barren. Yet the xerophytic plant life is of great interest, especially the cactuslike *Euphorbia*, of which about 25 species occur, and the famous dragon tree (*Dracaena draco*). The considerable height of the western islands, all of which exceed 4,000 ft., allows a wide range of subtropical and temperate plants to flourish. The following scheme for Tenerife illustrates the general zonal arrangement of vegetation, wild and cultivated, with increase of altitude: (1) From sea level to about 1,300 ft. the climate resembles that of Egypt and the characteristic plants of arid tracts are *Euphorbia* and *Sempervivum*. The better-watered or irrigated lands yield crops such as bananas, oranges, coffee, dates, sugar cane and tobacco. (2) From 1,300 to about 2,400 ft. the climate resembles that of southern Italy and the chief crops are wheat, barley, maize (corn), potatoes and grapes. Where the rainfall suffices trees such as laurel, fig, walnut, almond and eucalyptus thrive. (3) Between 2,400 and 4,000 ft. is the main cloud layer and the climate becomes appreciably cooler except during southerly winds. Rather open formations and, in wetter places, quite dense stands of indigenous trees occur, including *Ardisia*, *Ilex*, *Rhamnus*, *Olea*, *Myrica* and various species of laurel. (4) From 4,000 to just about 6,000 ft., athwart the normal upper edge of the cloud layer, the Canary pine (*Pinus canariensis*) is dominant but tree heaths are fairly common and in some localities the faya (a beechlike shrub), Canary laurel and juniper. (5) Above about 6,000 ft., or above the cloud layer, the tree growth is replaced first by a narrow belt where escobdn (*Cytisus proliferus*) and the gorselike *codeso* (*Adenocarpus viscosus*) provide important fodder supplies, and then by a wide zone where the pumice-and-lava-strewn slopes are dotted with retama, a dark-green broom which bears white and pink flowers. (6) Above about 10,500 ft. snow lies for many months and vegetation is almost absent.

Population and Administration.—The Guanches (*q.v.*) who occupied the islands at the time of the Spanish invasion no longer exist as a separate race. The present inhabitants, or Canarios, are slightly darker than the people of Spain but otherwise are scarcely distinguishable from them. The men are of middle height, good physique and strong. Spanish is the only language in use and Spanish customs are stoutly maintained. Since 1900, when fully 80% of the Canarios could neither read nor write, education has progressed rapidly. Good schools are numerous and there is a university (founded 1701) at La Laguna, Tenerife. The staple diet of many of the poorer people is composed of fish, potatoes and *gofio*, which usually consists of maize or wheat roasted, salted, ground and kneaded with water or milk. Pop. (1960 est.) 918,068.

The archipelago formed one Spanish metropolitan province until 1927, when rivalry between the two chief ports, Las Palmas de Gran Canaria and Santa Cruz de Tenerife, caused it to be divided into two provinces. To the province of Las Palmas were allocated Grand Canary (Gran

Canary) and Tenerife. To the province of Santa Cruz de Tenerife were allocated Fuerteventura, Lanzarote, La Palma, Gomera, Hierro and the islets of Arrecife, Lobos Island, and Puerto del Rosario. The population of the archipelago in 1960 was estimated at 918,068.

CANARY ISLANDS. OFF COAST OF CAPE JUBY, AFRICA. SHOWING MAJOR TOWNS

Canaria), Fuerteventura and Lanzarote, together with three inhabited islets (Aleganza, Graciosa, Lobos) and several uninhabited rocky islets. Santa Cruz de Tenerife province comprises the islands of Tenerife, La Palma, Gomera and Hierro. Appropriate civil and military provincial officials reside in both capitals. In addition, each of the seven main islands of the archipelago has its own council (*cabildo insular*) under a deputy civil governor. Roman Catholicism is the official religion, and ecclesiastical law is the same as in other Spanish provinces. La Laguna and Las Palmas are episcopal sees in the archbishopric of Seville.

Economy.—Because of the mild temperatures and richness of the volcanic soils, agriculture in the Canaries is usually profitable and varied. Yet land values are extraordinarily high because the soil forms the only popular investment and relatively large areas are too dry, too rocky, too steep or inaccessible for cultivation. Land values vary with the amount of water available and with altitude and ease of access to ports. Until 1853 wine, largely from vines grown on unwatered slopes, formed the staple product and exports of it often exceeded £500,000 annually. In that year a grape disease caused by phylloxera (a plant louse) attacked the vineyards, and viticulture was soon largely replaced by cochineal production. The cochineal insect, introduced in 1825, thrived on a local cactus and yielded annual exports worth £750,000 by 1869. The boom imparted a lasting benefit to Canarian agriculture, as landowners undertook elaborate terracing and in places even broke up lava streams to expose the ancient soil buried beneath. The cochineal industry declined (because of competition from synthetic dyes) in the late 19th century in favour of the cultivation of sugar cane and later of bananas, tomatoes, potatoes and various other vegetables and fruits. By the early 1960s the banana, which occupied about 20,000 ac. of the lower areas, was the main cash crop. Fishing, especially of tunny, hake, sardine and mackerel, is important locally.

The Canaries lie athwart trade routes from Europe to South Africa and to Central and South America. The chief ports are Las Palmas de Gran Canaria and Santa Cruz de Tenerife (*q.v.*), which together are entered annually by about 8,000 vessels totaling 10,000,000 tons. The islands are interconnected by steamship services. The two capital cities are linked by airlines with Madrid and west Africa and maintain air services between each other and to the islands of Fuerteventura, Lanzarote and La Palma. The islands enjoy a popular reputation as a winter resort.

History.—The Romans learned of the Canaries through Juba, king of Mauretania, whose account of an expedition to the islands, made about 40 B.C., was preserved by Plutarch and the elder Pliny. The latter mentions "Canaria, so called from the multitude of dogs [canae] of great size." Ferro, then the most westerly place known, was chosen in about A.D. 150 by Ptolemy for the prime meridian of longitude, and until the late 18th century some navigators continued to reckon from this line. When the ideas of the early cosmographers were lost the Canaries became almost mythological (see ISLES OF THE BLEST), but as early as 999 the Arabs landed and traded on Grand Canary. During the 13th and 14th centuries Genoese, Majorcan, Portuguese and French navigators visited the islands. In 1402 Gadifer de la Salle and Jean de Béthencourt (*q.v.*) sailed from La Rochelle and soon occupied Lanzarote. Béthencourt went to Cadiz for reinforcements and returned in 1404 with the title of king, which he had secured from Henry III of Castile. Thereupon Gadifer, feeling slighted, departed. Béthencourt completed the conquest of Fuerteventura and Ferro and in Dec. 1406 returned to Europe, leaving his nephew Maciot in charge of the islands. Eight years of misrule followed before Queen Catherine of Castile intervened. At this, Maciot de Béthencourt sold his office first to the queen's envoy, then to Prince Henry of Portugal and finally to a Spanish count. Between 1420 and 1479 the Portuguese made attempts to establish a base in the archipelago, and a force sent by Prince Henry subdued Gomera. The various claims, still more tangled, were straightened in 1479 when the treaty of Alcáçovas between Portugal and Castile recognized Spanish sovereignty. The bitter conquest of the three more populous islands then began. In 1483 the few hundred surviving Guanche warriors on Grand Canary surrendered; La Palma was

finally conquered in 1491 and Tenerife in 1496. The islands were used by Columbus and became an indispensable Spanish base on sea routes to America. As such they were attacked sporadically by the Moors and by such English captains as Drake, Hawkins, Blake and Nelson.

In 1833–34 the islands were linked by submarine cable to Europe and America. In 1936 Gen. Francisco Franco used the Canaries as the first base of the nationalist revolution, going from there to Spanish Morocco.

CANASTA, a card game of the rummy (*q.v.*) family and itself the progenitor of a large group of games including notably samba, Bolivia, Cuban canasta, Italian canasta and others. The name canasta, which is the Spanish word for "basket," probably derives from the tray placed in the centre of the table to hold the undealt cards and discards.

The basic form of canasta originated in Uruguay in the late 1940s, probably about 1947. By 1948 it was the most popular game in the fashionable clubs of Argentina and in 1949 it was introduced in the U.S., where it had a vogue comparable only to those of mah-jongg in 1923–24 and contract bridge in 1930–32. By the end of 1951 the number of canasta players in the U.S. and Canada was estimated at more than 30,000,000, and for the first time since 1931 contract bridge had dropped from first place among the most popular games. Canasta's commercial record had never been matched or even approached by any other game in a similarly brief period; between 1949 and the end of 1952 canasta accounted for the sale of more than 5,000,000 books and about \$300,000,000 worth of playing cards, other equipment and accessories. By 1953 contract bridge had regained first place among card games in the U.S. but canasta in its various forms continued to be much played. In Great Britain and on the continent canasta never had more than moderate success. Throughout Latin America canasta remained the principal social card game after its North American vogue had ended.

The Game: Four-Hand Canasta.—This has usually been the most popular form of the game. The four players form two partnerships, partners facing each other across the table. A 108-card pack is used, two standard 52-card packs plus four jokers. All jokers and deuces are wild; *i.e.*, may represent any card. Eleven cards are dealt to each player, the undealt portion of the pack is placed on the table as the stock and the top card of the stock is turned up to start the discard pile. The player at the dealer's left has the first turn. Each player in turn must draw, may meld and must discard one card face up on the discard pile. The melds of partners are combined.

In drawing, a player may take the top card of the stock or—if he is able to use it immediately in a meld—the top card of the discard pile, in which case he takes also the entire discard pile. A meld consists of three or more cards of the same rank (sequences may not be melded), including at least two natural cards and not more than three wild cards. A meld of seven or more cards of the same rank is called a canasta and is a mixed canasta if it includes one or more wild cards and a natural or pure canasta if it contains no wild card. Having drawn and melded if he wishes, the player discards one card.

A player may add a card or cards to his side's previous meld of the same rank and a canasta may be completed in this way. The discard pile is said to be "frozen" for a side that has not melded and for both sides if it includes a red three or any wild card. When the discard pile is frozen, a player may take it only if he has in his hand a natural pair matching the top discard. The "official" laws of the game, made first (1950) by the Regency club of New York city and later (1951) revised by an international committee of U.S. and Argentine authorities, permit a

player to take the discard pile for a new meld if he can match its top card with one natural card and one wild card, or to add the top discard to a previous meld; but players in both North and South America have generally disregarded this provision and demand a natural matching pair to take the discard pile at any time. It is customary also to rule that no card may be added to a completed canasta.

Each card has a value in points: 50 for a joker, 20 for a deuce or ace, 10 for a card from king to eight, and 5 for a card from seven to three. A side's first meld in each deal must have a value of 15 if the side's score at the beginning of the deal was minus; 50 if its score was less than 1,500; 90 if its score was at least 1,500; and 120 if its score was at least 3,000. When a side's score at the end of a hand is 5,000 or more, the game ends. The side with the higher score wins the game.

A hand ends when a player goes out (melds his last card). A player may not go out unless his side has completed at least one canasta. At the end of a hand, each side scores the point value of each card it has melded, plus 300 for each mixed canasta, plus 500 for each natural canasta, plus 100 for going out, less the point value of all unmelded cards in the partners' hands.

Three-spots have special values and functions. Each player, at his first turn, must remove from his hand any red threes and lay them face upon the table, drawing from the stock to restore his hand. Thereafter, when a player draws a red three, he must immediately face it and draw a replacement card from the stock. At the end of a hand a side scores 100 for each red three it has obtained (800 for all four of them), provided it has made any meld; if it has not melded, these scores are charged against it. A black three when discarded stops the next opponent from taking the discard pile. Black threes may be melded only in the turn in which one goes out.

The object of the game is to score points by making as many melds, especially canastas, as possible. It is losing play to meld one's cards too rapidly or to go out too soon.

Two-Hand Canasta.—Canasta for two players differs only slightly from the above. Fifteen cards are dealt to each player. A player draws two cards from the stock but discards only one. To go out, a player must complete two canastas.

Three-Pack Canasta.—For three or six players (the latter in two partnerships of three each, or three partnerships of two each), three regular packs plus six jokers are used and 15 cards are dealt to each player. Other rules are as in four-hand canasta.

Samba.—Three 52-card packs plus six jokers are used. A sequence of three or more cards in the same suit may be melded and a seven-card sequence, or samba, ranks as a canasta (for the purpose of going out) and scores a bonus of 1,500 points. The top discard may never be taken without a natural matching pair. No meld may contain more than two wild cards. In each turn a player draws two cards from the stock (unless he takes the discard pile) and discards only one card. The discard pile may never be taken to add its top card to a sequence, and no wild card may be melded with a sequence. Game is 10,000, and the initial meld requirement for a side with 7,000 or more is 150.

Bolivia.—Three or more wild cards may be melded, the same as natural cards, and a canasta of wild cards pays a bonus of 2,500. Game is 15,000. A black three left in the hand when a player goes out counts 100 against the holder.

Other Variations.—There are many other variations of canasta, most of them permitting the melding of sequences or wild cards and paying special bonuses for designated melds.

See Oswald Jacoby, *Complete Canasta* (1951); Otilie Reilly, *Bolivia* (1954), *Brazilian Canasta* (1956). (O. J. Y.; A. H. M. D.)

CANBERRA, the national capital of the commonwealth of Australia, lies in the Australian Capital Territory (*q.v.*), 190 mi. S.W. of Sydney by road, 418 mi. N.E. of Melbourne, 760 mi. E. of Adelaide and about 70 mi. from the Pacific coast. Pop. (1954) 28,277.

Like Washington, D.C., and certain other federal cities, Canberra was deliberately chosen and planned as a capital, on a site formerly little occupied. The area was first entered by white men in 1820; it was reported as being "perfectly sound, well watered,

with extensive meadows of rich land on either side of the rivers" and having plentiful building materials. A small permanent settlement was made, probably in 1824, when stockmen squatted at "Canberry," or "Canbury," as it was called, which gradually expanded; in 1845 part of the church of St. John the Baptist was completed and in 1863 a post office established. By the end of the century the district had taken on the characteristics of a "contented, rather conservative world of great stations and prosperous, hard-working farmers . . . where life had changed little since the days of the pioneer settlers." (L. F. Fitzhardinge in Canberra, a *Nation's* Capital, ed. by H. L. White, Angus & Robertson, Sydney, N.S.W., 1954.)

As the demand for federation grew, suggestions were invited in 1899 for a site for the national capital. The commonwealth of Australia was inaugurated in 1901 and the Commonwealth Constitution act of 1900 provided for the establishment of a capital in the state of New South Wales, but not within 100 mi. of Sydney. After two royal commissions and much public debate, the commonwealth parliament in 1908 selected the Yass-Canberra district and in the following year the site for the new city was determined. On Jan. 1, 1911, an area of approximately 900 sq.mi. was transferred from New South Wales to the commonwealth, which then launched a world-wide competition for a design for the capital. The first prize was awarded to Walter B. Griffin (1876–1937) of Chicago, Ill. Construction was begun in 1913 but was delayed by World War I; from 1915 to 1920 Griffin was in charge of constructional work on the city.

After the war work was accelerated by the Federal Capital commission which assumed control over all constructional and administrative activities in the territory on Jan. 1, 1925. On May 9, 1927, the duke of York (later King George VI) opened the new parliament house and the transfer began of the central staffs of the administrative departments from Melbourne (hitherto the temporary seat of government of the commonwealth). Attractive houses, schools and other buildings for this garden city were built in the suburbs. In 1930 the Canberra University college was opened and in 1936 a wing of the National library. The depression and World War II curtailed progress, but the Australian war memorial and the patent office were opened in 1941 and an extensive new hospital in 1943. After World War II a great surge in the development of Canberra took place. More than 8,000 houses and flats were built, as well as administrative offices, extensive buildings for the Australian National university (founded in 1946), shops, schools and community facilities.

A resumption of transfers of central staffs from Melbourne began in 1959 with the movement of several hundred officers of the defense group. Further transfers were planned, with the object of making Canberra the headquarters of the whole commonwealth public service. This objective became the task of the National Capital Development commission, set up in 1958. Proposals of its five-year planning report were endorsed by the government; these included the erection of offices for the whole defense group and the construction of a system of ornamental lakes across the centre of the city. This feature, an important element of Griffin's plan, was aimed at unifying the city in a striking fashion.

Canberra has also developed as a centre of learning and research. In addition to the university, which provides for undergraduate studies as well as four schools devoted solely to postgraduate research in the fields of medical science, Pacific studies, physical and social sciences, there are such institutions as the Forestry and Timber bureau, Australian Institute of Anatomy, Mount Stromlo observatory, Bureau of Agricultural Economics, National library and several establishments of the Commonwealth Scientific and Industrial Research organization.

A short branch line links Canberra with the New South Wales railway system at Queanbeyan, eight miles distant. Road transport accounts for an important proportion of the inward movement of goods. Daily air services link the city with Sydney and Melbourne, and through them with the other state capitals.

CANCELLI, in architecture, screens or parapets, similar to those used by the Romans to divide off the judges' space in a basilica. From their resemblance to such Roman screens the

enclosures of the choir and chancel of a church are also known as cancelli.

See BASILICA; CHANCEL; CHOIR.

CANCER ("The Crab"), in astronomy, the fourth sign of the zodiac, denoted by the symbol ♋. The constellation contains a large loose cluster of stars known as Praesepe, or the Beehive. See CONSTELLATION.

CANCER, an abnormal and unrestrained new growth in cells and tissues that produces deleterious and often fatal effects. The basic cause of cancer is unknown. Cancer occurs in many different plants and animals, but this article deals primarily with cancer in man.

Cells and tissues are said to be cancerous when, for no known reason, they grow more rapidly than normal, assume abnormal shapes and sizes and cease functioning in a normal manner. If large numbers of cells in a vital organ, such as the heart, become cancerous then the organ is unable to function, and the cancer patient dies. Cancer, in contrast to benign neoplasms (tumours), tends to spread into contiguous cells and also to metastasize. In metastasis, cancerous cells break off from the original lesion and are carried in the blood or lymph systems to distant parts of the body where they set up new lesions. Cancer is said to be malignant because of its tendency to cause death if not treated. Benign tumours usually do not cause death, although they may if they interfere with a normal body function by virtue of their location or size. (See TUMOUR: True *Tumours*.)

Cancer cells grow and divide at a rate much higher than normal. When a cell changes from its normal to a cancerous condition, the growth restrainers present in the normal state apparently are removed or become neutralized. The ability of cancer cells to grow rapidly can best be shown in tissue cultures; in these cultures cancer cells have been kept alive and growing for as long as ten years by repeated transfers to fresh culture media. One such group of human uterine cancer cells, known as the HeLa strain, was still being used in laboratory studies a decade after the patient in whom they originated had died.

Cancer may not be so autonomous as once believed. The lesions probably are influenced by the host's susceptibility and immunity. Certain cancers of the breast and prostate, for example, are considered dependent on specific hormones for their existence; other cancers are dependent on the presence of specific viruses.

GENERAL

Classification.—There are two types of cancer according to the simplest method of classification—that of calling the cancer a carcinoma or sarcoma depending on whether the cancer originated in epithelial or nonepithelial tissue. The latter term refers chiefly to the structural framework of the body, including muscle, fat, connective tissue, bone cartilage, tendon, etc. It follows, therefore, that as many varieties of cancer exist as there are organs and tissues within the body. Each type and subtype of cancer has its own histological appearance and can be identified by microscopic study; the behaviour or natural history of each type has been well determined so that the pathologist can predict the manner of its growth.

Cancers also may be classified according to the stage of the disease; for example: (1) early, or localized, when still confined to the tissue of origin (frequently curable); (2) metastatic or spread to regional lymph nodes, or invading contiguous structures (sometimes curable); (3) widely disseminated throughout the body (usually incurable).

Cancers also can be classified into one of four grades on the basis of their degree of malignancy, as determined by microscopic examination. Grade one cancers (barely malignant) tend to differentiate toward and resemble the cells of the tissue of origin, whereas grade four cancers (highly malignant) are composed of cells extremely active in cell division. The other two grades represent intermediate degrees of differentiation and reproduction. It follows that grade four cancers as a rule grow more rapidly, metastasize earlier and more widely, pursue a more rapid course and have a lower rate of curability than the other three grades.

Prefixes are generally added to the basic designations of car-

cinoma and sarcoma to indicate the tissue of origin. Thus a sarcoma originating in bone and tending to reproduce osseous tissue is called osteogenic sarcoma; other examples of the use of prefixes include: liposarcoma primary in fat, rhabdomyosarcoma primary in skeletal muscle, fibrosarcoma primary in fibrous or connective tissue and synovial sarcoma primary in the synovial linings of bursa and joint. The word "primary" indicates the cancer originated in the tissue rather than having been established as a secondary site through metastasis from another lesion. The prefix "adeno-" connotes the persistence of ductal or glandular elements in the epithelial tumour, as in thyroid adenocarcinoma, gastric adenocarcinoma and uterine adenocarcinoma. Cancers of the pavement cell epithelium of the skin and of certain mucous membranes, such as cancers in the tongue, lip, larynx, urinary bladder, uterine cervix or penis, may be termed epidermoid or squamous cell carcinomas.

Distribution and Occurrence.—Cancer is widespread throughout the vegetable and animal kingdoms. Plant cancers occur in clover, sunflowers and other common plants. Malignant neoplasms in animals include cancer of the breast in dogs, melanoma of the anus in gray horses and epithelioma of the eyelids in cattle. Cancer occurs with great frequency in mice, and these rodents are used extensively for experimentation with transplantable cancer.

It is difficult to evaluate the relative influence, if any, of racial predisposition and environmental factors on the variation in racial distribution of human cancer. Cancers of the nasopharynx are notoriously frequent in the Chinese. Cancer of the liver occurs many times more frequently in Malay groups and west African Bantu than in Caucasian peoples. Kaposi's hemorrhagic sarcoma of the skin occurs almost exclusively in Chinese, Jews and peoples in the Mediterranean basin. Cancer of the breast is seldom seen in women who nurse their children. Malignant melanoma (black cancer of the skin), which develops from pre-existing moles, only rarely occurs in Negroes. Cancer of the stomach develops twice as frequently in the Japanese and Icelanders as in other peoples and occurs on an average of ten years earlier in Japanese and Negroes than in Caucasian people. Cancer of the uterine cervix is extremely rare in Jewish women. Cancer of the penis is infrequent in peoples who practise circumcision in childhood.

Until the 1950s it had been commonly assumed that the preponderance of certain cancers among specific peoples was due to racial transmission, implying a genetic background. Epidemiological surveys, however, have revealed extrinsic causes instead; for example, the frequency of stomach cancer in Iceland may be due to cancer-inducing hydrocarbons in the smoke that Icelanders employ to cure fish and meats. The cancer of the liver so common among the Bantu may be partly attributable to their severe nutritional deficiencies; the incidence of the disease drops sharply when the Bantu start eating nutritionally adequate diets.

Cancer occurs at a slightly greater frequency in women than in men because of the great susceptibility of the uterus and functional breast to this disease. Incidence differences between the sexes for certain cancers of the regional types cannot be explained. For example, 60% of the cases of cancer of the stomach occur in males. Kaposi's hemorrhagic sarcoma of the skin of the extremities occurs almost exclusively in males; cancers in the mucous membrane lining of the mouth, pharynx and larynx occur three to eight times more frequently in males than in females.

Cancer occurs at different rates in different age groups. In general it is pre-eminently a disease of middle and old age but may occur at any time of life. Certain varieties, such as glioma of the eye, embryonal adenocarcinoma of the kidney and neuroblastoma, are found more frequently in children than in any other age group, although children in the 5–14 age group have greater freedom from malignant tumours than any other age group. Cancer of the testicle, commonly known as teratoma, is a disease of young males, usually those under 30 years of age. Malignant tumours of epithelial structure are uncommon in adults under the age of 30, extremely rare in patients under 20 but increase in frequency after 30. Carcinomas of the breast and uterus have their greatest incidence in women between the ages of 45 to 65 and de-

crease in relative frequency after 65. Exceptions to the rule of unequal age distribution are connective tissue sarcomas, which occur at the same rate in all decades of life.

Effect of Heredity.— It has been possible through selective breeding, particularly inbreeding, to develop strains of mice in which cancer of different histological and regional types appear consistently in each generation. In humans, similar genetic tendencies are usually dissipated through marriage; a child may inherit the type of skin or the type of breast in which cancer is most prone to occur rather than inheriting the disease itself.

As a rule, two factors must be present for human cancer to develop: (1) the genetic background or susceptibility, which is not the same for every variety of cancer; and (2) an inciting or causal factor that precipitates the onset of the cancer in the predisposed tissue. Occasionally, through chance breeding in which the genetic factors are magnified, the hereditary tendency becomes manifest. For example, mothers, daughters and granddaughters in certain families acquire cancer of the breast, while in other families cancer of the stomach is a common ailment. This familial distribution has occurred too frequently to be considered coincidental. This conclusion has been supported by reports of cancers of similar type and regional distribution in identical twins.

Certain benign tumours are inherited, such as tumours of peripheral nerves, cartilaginous tumours (enchondromas), pigmented moles of the skin and polyps of the colon; some of these may eventually become malignant. Glioma of the eye in childhood is definitely inherited. Xeroderma pigmentosum is an inherited skin condition in which all protective resistance to the irritating action of actinic rays is lacking. For some unexplained reason, in this disease those portions of the skin exposed to sunlight, notably that on the hands and face, inevitably develop multiple lethal cancers; the only way for people with this condition to avoid cancer is to avoid sunlight or other radiation that includes rays beyond the violet end of the spectrum.

A genetic transmission theory based on the study of cancers in laboratory animals (mice, rabbits, fowls) gained credence in the early 1960s; this theory contended that the supposed heredity factor of cancer is not transmitted by the genes but by a parasitic virus present in the intracellular material of the egg or sperm that unite to begin the formation of the new individual.

Relation of Trauma to Cancer.— The origin of a cancer lesion can seldom be attributed to a single blow or trauma, even though this possible origin is a controversial medicolegal subject. In view of the thousands of serious injuries that occur in both war and peacetime and the rarity with which cancer follows such injuries, it is illogical to assume that a single trauma plays an important role in causing cancer. Before a single injury is accepted as the immediate cause of cancer, certain postulates should be fulfilled, namely, definite evidence of the injury, identical sites of the injury and the cancer that develops later, a logical time interval between the date of injury and the appearance of the cancer, the absence of a pre-existing tumour at the site and, finally, a type of malignant tumour consistent with this mode of origin, such as a sarcoma of the structural framework; *e.g.*, fibrosarcoma of connective tissue, liposarcoma and malignant synovioma arising from tendon sheaths. An injury such as an extensive laceration or burn may result in a scar that in future years becomes cancerous. But the mechanism of the genesis of cancer under these circumstances is different from its reputed onset immediately following a single injury.

Trauma does play a part in the development of some cancers of stratified epithelium in the skin or mucous membranes of the oral cavity and esophagus. But here the injury consists of a repetition of small traumas in the form of a chronic irritation, sometimes occurring daily for many years. Common examples are irritation of the tongue or mucosa of the cheek by ill-fitting dental plates, pressure of hot pipestems on the lip and daily irritation of the esophagus from swallowing hot soups or other liquids. A classic example of cancer that arises from chronic irritation is that which occurs in the cheeks of Hindus who are addicted to chewing a mixture of areca nut, betel nut and lime.

Occupational Cancers.— Occupational cancers can be defi-

nately traced to the patient's external environment. In the early 1960s many inorganic and organic compounds had been recognized as carcinogenic agents, *i.e.*, capable of causing cancers. The amount of an agent required to produce cancer may be so minute that it causes no apparent irritation at the time of exposure; but continued exposure gradually produces tissue changes that ultimately become cancerous. The precancerous change may be so permanent that a malignant tumour will develop many years after an occupation has been abandoned.

Examples of workers in whom cancer may develop if their occupational environment is not controlled properly include the following: roentgenologists and X-ray technicians; dentists who use X-rays without shielding themselves completely; orthopedic surgeons who overuse fluoroscopy for setting fractures; radium technicians. All of these persons, as a result of chronic overexposure to radiant energy, may develop radiation dermatitis and ultimately X-ray or radium cancer. Workers in the dyestuffs industry who are exposed to aniline, benzidine or beta-naphthylamine may later develop papillomas and even cancers of the urinary bladder; cancers of the respiratory tract occur in workers who inhale chrome salts, asbestos dust and nickel carbonyl. Leukemia, a malignant tumour of the tissues that form white blood cells, sometimes develops in workers who have been exposed to benzene. Workers exposed to coal tar, crude mineral oils, crude paraffins, pitch and arsenical compounds may develop multiple cancers of the skin, chiefly of the hands, arms and scrotum. Workers who prior to the mid-1920s painted radium numerals on watches and ingested the radioactive substance by moistening the brush tip on their tongues later developed bone sarcoma; this and similar hazardous practices were halted after the danger was discovered. (See CARCINOGENIC CHEMICALS.)

Precancerous Conditions.— Certain diseases have been recognized as potentially dangerous because they occasionally are followed by cancer. Malignant tumours do not develop inevitably but occur with such frequency that the term precancerous has been applied to these conditions.

An example is the presence of gallstones; the incidence of cancer in gall bladders is approximately 5% of the general population. But 98% of the persons who develop cancer of the gall bladder have or have had gallstones, which is a strong indication that the chronic irritation of the stones is a causative factor of the cancer.

Leukoplakia, another example, is a disease in which thick, white patches appear on the mucous membrane of the tongue, lip, cheek, floor of the mouth, palate, tonsil or other mucosa-lined organs such as the male and the female genitals and the esophagus. Cancer of the type known as epidermoid or squamous cell carcinoma develops with some frequency in these locations, probably because of pre-existing leukoplakia.

Syphilis of the tongue sometimes predisposes to the development of lingual cancer; in fact, 25% of all patients who have cancer within the oral cavity have had syphilis, which is a higher incidence by far than in the general population.

The neck of the womb (cervix uteri) may subsequently become cancerous if badly scarred, eroded or chronically infected, as sometimes occurs sequential to childbirth.

Certain benign tumours are precancerous in varying percentages; examples are benign adenomas of the thyroid gland, polyps of the colon, papillomas of the urinary bladder and the common pigmented mole of the skin.

Radiation dermatitis caused by overexposure of the skin to X-rays, as when improper dosages are used to treat acne or excess hair on the face, also may be precancerous.

Keratosis, which are warty overgrowths of the skin occurring in elderly persons or persons with oily skin, may degenerate over joints so that scar cancers develop. The scarred skin lacks the oil glands and elastic tissue that normally protect the skin against irritation. The early grafting of new skin in burns lessens the incidence of scar cancers later. Certain types of mastitis, when accompanied by overgrowth of the ductal elements, may, under certain conditions, become cancerous.

Incidence.— Statistics on the incidence of cancer by countries

must be based on the number of cancer deaths recorded, inasmuch as there is no national census of the number of cases or the number of cures. The significance attached to any figures must take into account the age composition of the population of each country, since cancer is predominantly a disease of middle and old age. The cancer death rate, per 100,000 population, in representative countries in the early 1960s was as follows: Switzerland 176, England and Wales 172.3, Germany 149, United States 146.9, Sweden 135, France 133, Italy 86 and Japan 71.

The percentages of cancer deaths in U.S. males, according to the most common sites of development, were as follows: stomach 18%, prostate 12%, intestines (including colon) 11%, lungs 11%, rectum and anus 6.4%, liver 5.4%, pancreas 4.4%, urinary bladder 4.2%, esophagus 3% and skin 2.4%. The corresponding percentages for U.S. women were: breasts 18.5%, uterus 18.5%, intestines (including colon) 12.8%, stomach 10.3%, liver 6.4%, ovary 5%, rectum and anus 4.6%, pancreas 3.2%, lungs 3.1%, urinary bladder 2.1% and skin 1.5%.

IDENTIFICATION OF CANCER

Diagnosis.—At least 50% of all cancers are visible on inspection or can be reached for palpation by an examining finger; at least 25% more can be seen with special examining instruments that are inserted within the orifices of the body.

The first of three steps in diagnosis is a careful elicitation of the history of the patient's complaints relating to abnormalities in the functioning of a specific organ. The symptom complex elaborated by most cancers is sufficiently characteristic to arouse the physician's suspicion when recited by the patient.

The second step is a careful physical examination that leads in most cases to the discovery of the malignant tumour and a recognition of its extent and character. By using special hollow instruments that are electrically illuminated and equipped with magnifying lenses, the examining physician is able to inspect the interior of such organs as the larynx, lungs, esophagus, stomach, lower colon, rectum and urinary bladder. This procedure is referred to generally as endoscopy and specifically, as they relate to the organs just listed, as laryngoscopy, bronchoscopy, esophagoscopy, gastroscopy, proctoscopy and cystoscopy. X-ray study, with or without the utilization of contrasting media, is important in the diagnosis of cancers within the nasal sinuses, lungs, esophagus, stomach, colon, intestines, kidneys, bladder, bone and brain. Chemical tests for cancer were generally discarded soon after being proposed, but a few for special types of cancers are valid, such as those for an increased acid phosphatase content of the blood in patients with cancer of the prostate and a quantitative increase of albumoses in the blood and urine of patients with myeloma of the bone.

The final step in establishing the diagnosis is the biopsy, in which a portion of the suspected cancerous tissue is removed for microscopic study and identification. The microscopic characteristics of various cancers are so definite and well known that this method serves as an accurate check on the diagnosis and usually enables the examiner to identify the tissue or organ of origin. Specimens for biopsy are removed by forceps or electric snare, or a plug of tissue is obtained by syringe aspiration, or cells may be obtained from body fluids, such as uterine, vaginal, gastric, bronchial or urinary secretions.

Symptoms and Course of Certain Common Cancers.—

Cancer of the skin may appear as a progressively enlarging ulcer with hard, elevated margins and no tendency to heal spontaneously. Pain is conspicuously absent in a great percentage of cases until the disease becomes advanced. It appears in other forms as a horny overgrowth of skin or as a fissure that degenerates into a scar. Between 75% and 95% of these cases can be cured with proper treatment. Half of the cases of malignant melanoma develop from pre-existing pigmented moles and the other half from apparently intact skin. It is the most malignant of all accessible cancers and soon metastasizes through both lymphatic and blood vessels to lymph nodes and internal organs. The cure rate is seldom higher than 20% to 25% of cases treated.

Oral Cavity.—Cancers of the lower lip develop as fissures, ele-

vated plaques of keratosis or hard ulcers situated on the vermilion border, usually of the lower lip. At least 90% of these cancers are cured if treated before metastases develop.

Cancer of the tongue appears as a fissure, chronic ulcer or indurated segment of the tongue, commonly on the lateral or posterior margins. It is one of the few cancers that is painful in its early stages and consequently is recognized early because of its tenderness and interference with the mobility of the tongue. Extension of the cancer to the lymph nodes in the neck occurs relatively early because of the high grade of malignancy of this type of cancer and the rich lymph drainage of the tongue. The cure rate is seldom above 22% to 30% of patients treated.

Cancer of the larynx may be detected early by an investigation of persistent hoarseness or changes in the voice. The development of stridor (difficult breathing) is an indication of an advanced stage of the disease. The prognosis of cancer of the larynx is good following radiological treatment or surgical removal of the larynx.

Cancer of the thyroid gland requires surgical removal of the gland and of the lymph nodes on the same side of the neck as the cancerous lesion. All nodular goitres, as distinguished from smooth enlargements and those associated with the toxic symptoms of hyperthyroidism, require immediate surgical removal because these nodules, even though painless, inconspicuous and without symptoms, are found on subsequent microscopic study to be cancerous in 8% to 20% of cases.

Cancer of the neck is more commonly secondary to a primary cancer either in the mouth, pharynx, larynx, hypopharynx, chest or abdomen than it is a primary site of origin within the structures of the neck. The appearance of a lump in the neck, if the thyroid gland is excluded from consideration, should arouse suspicion of a possible undetected and asymptomatic cancer within the mouth or adjacent structures, and it calls for careful investigation to discover the site of origin. When found, it requires treatment of the primary cancer and of the metastatic cancer within the cervical lymph nodes by radical surgical excision with or without irradiation by X-rays and radium.

Cancer of the lung was apparently increasing in frequency in the early 1960s, partly because of improvements in diagnosis and partly because of an increment in occurrence of the disease. Its presence is heralded by the onset of a cough that persists and may not be productive until later when expectoration of blood occurs. Its true character can be identified by X-ray study supplemented by bronchoscopic visualization and biopsy. The removal of the entire lung with dissection of those lymph nodes in the mediastinum that drain the lung offers opportunities for cure that formerly did not exist.

Cancer of the esophagus causes progressively increasing difficulty in swallowing, chiefly of coarse or solid foods. The patient voluntarily ingests a diet that is soft and liquid; diagnosis can be established by X-ray study, esophagoscopy and biopsy. The esophagus may be removed partially or completely; it can be replaced partially or completely by a joining together (anastomosis) in the chest of the remaining sections or by elevating the stomach and joining a remaining section to it or by interposing a section of colon between the remnants of the esophagus at the base of the neck.

Cancers of the stomach develop insidiously and are difficult to diagnose because of the absence of specific symptoms. Gradual onset of indigestion in a person of previously good health with symptoms occasionally suggesting peptic ulcer, associated with an unexplained loss of weight, anemia, loss of appetite and, in the advanced stages, vomiting and the presence of a mass that can be felt in the abdomen are common diagnostic features of the disease. The diagnosis is confirmed by X-ray study and gastroscopic visualization. Because of improved, more radical surgical technique, 60% of cancers of the stomach became resectable and of this group 35% of the patients were cured.

Cancers of the pancreas are seldom diagnosed early because of the absence of localized signs and symptoms. A radical operation was designed for successful treatment, but the end results were bad because of the delayed diagnosis. The presence of unex-

plained deep abdominal pain with backache, occasional diarrhea and later development of jaundice with the absence of gallstones are suspicious symptoms that indicate the possible presence of this disease.

Cancers of the rectum often are erroneously diagnosed as hemorrhoids in the early stages because of the frequent first symptom of repeated small hemorrhages with bowel movements. The usual indications of a rectal tumour are an incomplete sense of relief after defecation associated with some tenesmus or spasm, increased frequency of bowel movements, the passage of a mucous discharge with or without the stools and a change in the shape of the feces. Approximately 80% of the rectal cancers are resectable by radical operation, and about 50% of the operations produce permanent cures.

Cancer of the breast appears initially as a small, painless lump that grows in size: it subsequently may adhere to the skin, causing dimpling and later ulceration; the nipple sometimes becomes inverted. All lumps in the breast should be suspected of being cancerous until proved noncancerous. Although the disease develops more frequently in women of middle age than in any other age group, 17% of the cases occur in women under 40 years. One per cent of all breast cancer occurs in men, chiefly those of middle and old age. Cancer of the breast metastasizes or spreads most frequently to the lymph nodes in the armpit on the corresponding side of the body and sometimes to a chain of lymph nodes beneath the junction of the sternum and ribs; until it spreads beyond these nodes it is still operable and curable. In 78% of patients with cancer confined to the breast, a cure is obtained by removing the breast, muscles of the chest wall and the regional lymph nodes (radical mastectomy); 42% of patients who have cancer of the breast with metastases to the regional lymph nodes and without evidence of dissemination elsewhere are cured by the radical operation. Cancer of the breast may spread by lymph and blood vessels to other organs, such as the lungs, the brain or the bony skeleton, under which circumstances X-ray treatment and hormone therapy are excellent palliative measures. (See MAMMARY GLAND: Cancer.)

Uterine Cancer.—Cancer of the neck (cervix) of the uterus develops most frequently in women 30 to 50 years of age but may occur before 30 or after 50. Women who develop cancer of the uterine cervix often have sustained injury to the cervix during childbirth. The onset of the disease is heralded by excessive uterine bleeding either at the time of menstruation or in the intermenstrual phase or on sexual intercourse. The discharge may be brown and foul as well as bloody; actual hemorrhages may occur.

Cancer of the interior of the body of the uterus (endometrial cancer) is relatively more frequent in women who have not borne children; it occurs in a slightly older age group, usually postmenopausal. It is more difficult to diagnose than the cervical type since it is not visible. A diagnostic curettage of the uterus (obtaining a biopsy specimen with a scraping tool) may be done or secretions from the uterus may be studied for identification of cancer cells. By the proper application of X-ray and radium therapy or radical surgical excision, the curability of cancers of the uterus varies from 30% to 75%.

Cancers of the urinary bladder and kidney produce an initial symptom of hematuria (blood in the urine) that may be accompanied by frequent urination and pain. The exact location of the cancer may be determined by combined X-ray study and cystoscopic visualization of the urinary bladder. Cancers of the kidney may grow as silent tumours and may not be suspected until metastatic foci appear in distant parts, such as the bones, lungs or brain.

Cancer of the prostate in elderly men may provoke no symptoms other than occasional difficulty in micturition. Sometimes the first indication of the presence of this cancer is backache, which is caused by metastases of the prostatic cancer throughout the bones of the pelvis and vertebral column. Surgical treatment is employed only for the relief of obstruction to the urinary outflow and in rare cases for the extirpation of early cancers. The majority of prostatic cancers are in an advanced stage when diagnosed and

are treated palliatively by a combination of castration and the administration of female sex hormones or their synthetic chemical equivalents.

Cancer of the bone may occur in any age group, including children and young adolescents. The presence of pain and disability in an extremity, when associated with an enlargement of a bone, is a significant sign of an early bone sarcoma. Amputation, if performed early, may permit a curability in 10% to 15% of these patients.

TREATMENT

The therapy of cancer properly begins with prophylaxis. The recognition and discontinuance of cancer-inducing habits, the removal of environmental hazards and occupational predispositions to cancer, the treatment of precancerous diseases and the removal of benign tumours known to undergo malignant transformation are effective steps in prevention.

Surgical Excision.—This is the most generally applicable method of treatment. Cures are most readily obtained when the cancer is still confined to the organ or tissue in which it develops and before it becomes generally distributed throughout the body. The application of surgical excision is limited by the degree of usefulness of the organ that must be sacrificed.

Commonly employed operations for cancer are those for the removal of a segment of the lip, followed by plastic repair; the excision of a segment of the tongue, and a wide removal of skin with replacement by grafts. Hollow organs such as the esophagus, stomach and colon may be resected segmentally with anastomosis to restore the continuity of the intestinal canal. Cancer in one member of paired organs such as the eyes, testes, lungs or kidneys may be cured by removal of the diseased organ without interfering appreciably with the function of the patient. Internal organs, such as the larynx, esophagus, stomach, colon, rectum, pancreas and urinary bladder, may be totally removed for extensive cancers; the patient is able to lead a near-normal life by employing medications or devices that substitute for the removed organ.

Skin cancers, such as epitheliomas and melanomas on the hands and feet or other portions of the upper and lower extremities, may spread or metastasize to the lymph nodes in the armpit and groin, necessitating radical surgical dissections and in some instances complete amputation of the extremities. Malignant tumours that occur frequently in the bone and soft tissues of the upper and lower extremities may in some instances be removed segmentally, followed by grafting of bone and skin to preserve the arms and legs. In the majority of cases, however, amputation of the arm or leg to include the shoulder or hip joint may be necessary. Cancers that metastasize or spread via lymph vessels may require removal of the original site of the cancer together with regional lymph nodes secondarily involved; this is a well-recognized plan of surgical treatment and was first employed for cancer of the breast in which the breast was removed together with the lymph nodes in the corresponding axilla (armpit). For cancers involving the medial and central segments of the breast, this operation has been extended by some surgeons to include a segment of the breast bone and the cartilaginous ribs, which incorporate a chain of lymph nodes often involved by the cancer.

In the 1950s cancerous lobes of the liver were removed successfully for the first time; the patient can survive if only 20% to 25% of the liver remains. This organ is capable of amazing compensatory regenerative growth.

X-Ray and Radium Therapy.—The use of X-rays and radium (gamma) rays, at first empirical, became relatively standardized and most accurate in application. An immense body of knowledge accumulated concerning the radiation sensitivity of various cancers, and the dosages of radiant energy necessary to destroy or sterilize various cancers became well known. Cancers vary greatly in their known response to irradiation and, because of this variable response, both X-ray and radium therapy are not universally suitable for the treatment of all malignant tumours. In some cancers either X-ray or radium therapy produces better results than surgical excision; in other instances, surgery and irradiation may be equally suitable, and the choice of treatment will depend on the

experience and training of the therapist. In other instances, surgical treatment alone should be employed, and in some rare cases radiation therapy is used in conjunction with surgical excision either as a preoperative or postoperative supplement.

Examples of malignant tumours that are very responsive to irradiation are those originating in lymphoid tissue, such as lymphosarcomas, leukemia and Hodgkin's disease, and carcinomas of the palate, tonsil, base of the tongue and the larynx exclusive of vocal cords. X-rays of variable penetrating ability are employed, depending on the depth to which the X-rays must be delivered for absorption. Radiant energy must be absorbed before it can destroy human tissue, including cancer cells; cells through which the rays pass without being absorbed are not affected. Superficial cancers such as those in the skin may be treated with X-rays generated at low voltages of 50,000 to 120,000 v., whereas cancers in deep sites such as those in the uterus, esophagus and pancreas may be treated with X-rays generated at 1,000,000 v. The higher the voltage the greater is the penetration of the X-rays. The physical factors, such as filtration, intervening distance, milliamperage and voltage, are combined with spacing the treatments at proper intervals in order to allow maximum recuperation of normal tissues and maximum destruction of cancerous tissue.

Later innovations in X-ray therapy were the use of an X-ray bath (teleroentgen therapy), in which a patient with generalized radiosensitive cancer is placed in a special room with the X-ray beam emerging from the ceiling so that the entire body is irradiated at low intensity. Another mechanism employed in selected cases is a rotating chair or table in which the body of the patient rotates within the beam of X-rays so that the normal tissues are circumferentially and intermittently irradiated although the beam constantly impinges on cancers situated within the interior of the body. A beam of electrons (X-rays) emerging from an apparatus termed a betatron also has been used for treating deeply situated cancers. When properly controlled, an electron beam delivers a greater dose of radiant energy to the cancer than to the skin and normal tissues it traverses in reaching its objective.

Radium salts and their radiation equivalents, radon gas and radioactive cobalt, may be employed in several ways. Large quantities (4 to 500 g.) in a single applicator may be applied at a relatively great distance from the skin to treat deeply situated cancers. Plaques containing smaller amounts of radium are suitable for contact or short-distance radium therapy of superficial cancers involving the skin or mucous membranes of the mouth and nasal passages. Capsules containing radium may be inserted into cavities such as the uterus, esophagus and nasopharynx for the delivery of intracavitary irradiation. Radium salts or radon gas may be imprisoned in needles of variable lengths or in minute seeds for interstitial insertion. The radium or radon container is made of a heavy metal, such as platinum, gold, lead or mercury, to filter out the less-penetrating, caustic beta rays so that only the therapeutic gamma rays emerge. In some instances, a combination of X-ray and radium therapy is required for the successful treatment of cancer, notably in cancers of the uterine cervix.

(See RADIOLOGY: *Therapeutic Radiology*.)

Hormonal Treatment.—Certain cancers that originate in organs susceptible to influence by hormones may be temporarily controlled by withholding or administering certain hormones. Cancer of the prostate gland, even when widely disseminated to bone, may be controlled for one or more years either by castration or by administration of the female sex hormones (estrogens) or their chemical analogues such as stilbestrol. Cancer of the breast, when metastatic to bone, may be controlled with healing of the bone lesions, relief of pain and prolongation of life either by removal of the ovaries, by administration of testosterone (a male sex hormone), by removal of both adrenal glands or by hypophysectomy (removal of the pituitary gland). This radical ablative hormonal surgery is usually reserved for breast cancers that seem to require the presence of certain hormones for their continued growth.

Radioactive Isotopes.—Certain elements, when bombarded by neutrons or other nuclear particles from a nuclear accelerator,

start to disintegrate and in the process become radioactive. This radioactivity can be used to treat several kinds of cancer.

Radioactive phosphorus, for example, has been employed as a palliative measure in the treatment of malignant tumours of the lymphoid system; the phosphorus, when ingested, is concentrated within the tumour because cancerous lymphoid tissue absorbs two and one-half times as much phosphorus as does normal tissue.

Radioactive iodine, when administered to patients with certain types of thyroid cancer, will be selectively absorbed and concentrated within the cancerous thyroid cells; radioactive iodine destroys not only the lesion of origin in the thyroid but also the metastatic foci in bone or lung.

Radioactive gold, radioactive yttrium, radioactive chromium orthophosphate and other isotopes have been introduced into the pleural (chest) and peritoneal (abdominal) cavities to dry up accumulations of cancerous fluids. Radioactive isotopes, e.g., radioactive cobalt-60 and radioactive iridium, may also be used as radiation sources in surface application for superficial cancers and interstitially applied for deep invasive cancers.

Chemical and Biological Agents.—The majority of chemical and biological agents recommended in earlier years for the treatment of cancer, such as colloidal lead, Coley's toxin, etc., were largely abandoned as ineffective. During World War II a group of chemicals called nitrogen mustard was introduced in the treatment of Hodgkin's disease, and stilbamidine (stilbamidine isethionate) and urethan (ethyl carbamate) were later used with some beneficial results in the treatment of myeloma, a malignant tumour of bone. Thio-TEPA (triethylenethiophosphoramidate) and phenylalanine mustard have afforded relief in malignant melanoma, and certain antimetabolites, alkylating agents and cortisone have done the same in leukemia. After the introduction of chemotherapeutic agents, the number of infants and children suffering from acute leukemia who survived for one year increased from 5 to 50.

The increasing effectiveness of chemotherapy in cancer treatment is due to the synthesis of toxic radicals in chemical compounds (antimetabolites) that are required by the cancerous cell for its metabolism and division; when the cell ingests or absorbs these compounds, it tends to be killed by the toxic portion of the compound.

CANCER CONTROL

Great Britain, France, the Scandinavian countries and the United States early recognized the national need and opportunities for cancer control. These countries established disciplines for the special education of medical and nonmedical people, built institutions for the diagnosis and treatment of cancer and founded special societies and institutes for the organization and pursuit of cancer research. The movement spread throughout the world until many countries, including Canada, Mexico, India, Cuba, Peru, Venezuela, Chile, Argentina, Colombia, Brazil and Italy, operated cancer-control programs and special hospitals for the study and treatment of this disease.

The program for cancer control has involved several efforts, including the following:

1. Informing the public through private physicians and nurses, radio and television, and newspapers and magazines. The efforts, sponsored by lay cancer organizations, often included instructions to biology students in high schools and colleges.

2. Improved education of the medical profession through undergraduate instruction, postgraduate courses, special fellowships in cancer and allied diseases, and journals devoted largely to the subjects of cancer and cancer control.

3. Earlier diagnosis of cancer and allied diseases through the establishment of cancer-prevention and cancer-detection clinics, the organization of tumour-diagnostic groups in general hospitals, the enacting of laws by states and nations making cancer a reportable disease, and the increased availability of diagnostic aids such as endoscopic facilities, radiographic apparatus and competent pathologists. Cancer was reportable by law or by state health-department regulation in 30 of the 50 states and in one territory.

CANCER RESEARCH. Cancer is the generic term applied to a great host of diseases in man and animals, which, although different in their detailed manifestations, have a common basis and expression in the defectively controlled growth of one or other of the multitudinous types of living cell from which the body is constructed. From its origin in the fertilized egg by cell division, the body normally develops with utmost regulation and precision. At an early stage, the rapidly dividing cells differentiate one from another, that is, acquire individual properties of both structure and function, leading to the establishment of specialized tissues and organs in perfect integration. While at first the rate of growth is in general high, it gradually relents in the course of organogenesis and slowly declines in the adult organism. Even in the adult, however, very many cell types—as of the skin, the mucous membranes of the intestinal tract and the bone marrow—continuously multiply, so as exactly to repair an equal loss or wastage. Rapid cell growth also ensues in more abnormal situations, for example in the healing of wounds, or in the process of compensatory hypertrophy designed to offset the loss of parts of such organs as the kidneys or liver. In these cases, cell division comes to an end when repair or restoration has been completed, and all these mechanisms have the effect of ensuring the integrity of the body as a whole and the mutual and optimal functioning of all its parts. Considering the astronomical numbers of cells involved, and the high order of complexity, the system is one of great stability and freedom from error. On occasions, however, one or a few individual cells, either spontaneously or from the action of known causes such as are considered below, escape from normal regulation and, as cancer cells, embark on a course of unlimited division that has no relation to the physiological needs of the body but on the contrary leads to the development of rapidly growing tumour masses, which, either directly or by spreading by metastasis to other organs, interfere with structure and function and result in the death of the host.

In the space of this article it is clearly not possible to give a comprehensive account of every aspect of so formidable a problem. It is proposed, however, to outline briefly the historical development of the subject and to deal in turn with the properties of the cancer cell, the experimental reproduction of the disease by chemical, physical and viral agents, theories as to the mechanisms of carcinogenic action, treatment especially by chemotherapeutic means and, finally, the support and organization of cancer research.

There is ample evidence of the antiquity of cancer in records of the paleopathology of numerous species, many now extinct. This at once disposes of any suggestion that cancer is a product of civilization, although it is true that certain of the social, industrial and other appurtenances of civilization are capable of increasing the incidence of particular forms of the disease. Its zoological distribution appears to be universal and it is observed not only

throughout the whole of the animal kingdom but also very widely in plants: in this case its overt features are of necessity distinct from those in animals, but there is no question of the identity of biological principle that exists between them. Proceeding even further, analogous if not indeed equivalent phenomena are also encountered in many unicellular forms of life, especially in the field of bacterial variation and microbial genetics.

Hence it appears that cancer is not only a human disease but a profound alteration in growth properties to which any living and dividing cell is seemingly liable. This fundamental aspect is reflected in the structure of cancer research as an integral province of modern biology. The mainspring of the research effort is the desire and intention to ameliorate a medical and social ill involving a great amount of human suffering and approximately 5,000,000 deaths in the world population each year. Purely medical methods are not, however, in themselves sufficient, so that cancer research calls upon very wide resources of observational and experimental science, ranging from clinical medicine and surgery through the basic sciences of chemistry and physics, with biochemistry, physical chemistry and biophysics, to disciplines such as experimental pathology, cytogenetics and immunology and ultimately to the roots of the problem in molecular biology itself.

THE DEVELOPMENT OF RESEARCH TECHNIQUES

Observational.— Many classical observations of the features of cancer had of course been made throughout the whole of the history of medicine, but most notably in the 17th and 18th centuries, slowly accumulating to increase knowledge in terms of medicine, surgery and morbid anatomy. The origins of cancer research proper are, however, to be found in the historical development of the microscope, with which its own development is largely contemporaneous. This gradually led to the emergence of the cell theory. Although the theory had many precursors, it is remarkable that it only became finally established and accepted in the early part of the 19th century. Great developments immediately resulted, especially from Rudolf Virchow's application of the cell theory to pathology (*Die Cellularpathologie*, 1858), whereby he inaugurated several decades of investigation of the microscopic structure of cancer in man and animals, first in the medical schools of Germany and then the world over.

From this epoch of morphological description there gradually emerged certain key principles. First it became clear that the cancer cell is indeed a derivative of the normal, and second, that it is possible to classify tumour types not only according to the tissues from which they arise (e.g., such major groups as the sarcomas, carcinomas and endotheliomas derived from the connective, epithelial and endothelial tissues respectively) but also according to the extent to which individual tumours, over a wide and continuous spectrum of possibilities, lose the microscopic and other characteristics of their parent cell—that is, undergo a process of dedifferentiation. In general although not absolutely so, the extent of dedifferentiation is reflected in enhanced growth rate, autonomy and invasiveness and can proceed to extremes of virulent anaplasia in which the cell no longer retains any recognizable traits that might serve to reveal its origin. The earlier pathologists were impressed by the remarkable similarities between cancer cells and embryonic cells and it appears that malignant transformation may well involve an essentially regressive change, a more or less pronounced simplification, or atavistic reversion to a less specialized function. This conclusion, reached solely on the basis of microscopic observation, is one that is substantiated by the whole of modern research.

Many other essential facts have been, and continue to be, uncovered by the methods of clinical observation and recording, quite apart from experiment. The most central, and perhaps the oldest, is that the incidence of cancer for the most part increases steadily with age, and this relationship between cancer genesis and the aging process in cells and tissues is certainly of profound significance.

Demography and Statistics.— Again, major contributions have sprung from the fields of demography and geographical pathology. Pronounced differences in the incidence of cancer at

different geographic sites have long been known, as between the communities of North and South America, Europe, Africa and Asia, examples being the high rates of cancer of the liver in West Africa, Uganda, Portuguese East Africa, South Africa, Indonesia, Japan and Thailand (in contrast with western Europe and the United States), of neural and retinal tumours in African children, of cancer of the stomach in Japan, Norway and Iceland, of oral cancer in India, of multicentric tumours of the jaw in Uganda, of cancer of the penis in Jamaica and Paraguay, of nasopharyngeal cancer in China, Thailand, Malaya and Formosa and of cancer of the esophagus in almost epidemic proportions in the Transkei area of South Africa. Other disparities are the relatively lower incidence of leukemia and cancer of the blood-forming organs in Uganda and South Africa than in the United States, the infrequency of intracranial growths in African children, the marked differences throughout the world in the rates of occurrence of cancer of the uterus, the low incidence of cancer of the prostate in Japan and of cancer of the breast in Japan and in parts of Africa and in Deccanese Hindu women in India in contrast with the Parsees. It is evident that such variations are not merely of fascinating interest in their own right but also provide invaluable leads toward the understanding of both causation and prevention.

The power of the statistical method is also seen in its revelation of the close association between the incidence of cancer of the lung and tobacco smoking (and especially the cigarette habit). Finally, it is essential to the study of secular changes in the incidence of and mortality from particular forms of the disease. From evidence mainly in the United States and the United Kingdom, no very significant change appears to have occurred, over some decades, in mortality from cancer of the breast, prostate, intestine, esophagus and larynx. Types of cancer with an increasing trend in mortality include cancer of the lung, certain leukemias and related conditions and cancer of the ovary, bladder, pancreas and kidney; while sites for which mortality from cancer is decreasing are the stomach, tongue, lip, skin, rectum, uterus and liver. Obvious factors that may underlie all such trends are changes in classification, in accuracy of diagnosis and in efficiency of recording. Yet some of the trends, and outstandingly the increase in mortality from lung cancer and the decline in that from cancer of the stomach, are real and fundamental.

Experimental Method.—Immense as have been the advances in knowledge from observation and statistical analysis, cancer research, from the nature of the problem, is also heavily dependent upon the experimental method. Although this had early beginnings, its application on any scale dates only from the turn of the 19th century, when specialized research centres were established, particularly in the United Kingdom, the United States, Europe and Japan. Within 15 years, marked advances had taken place in understanding of the biological characteristics of the cancer cell (including its capacity to propagate indefinitely on grafting from one animal host to another in succession), the role of heredity had been defined and success had been attained in the artificial induction of cancer by ionizing radiations, by coal tar and by a virus.

The spread of cancer by metastasis arises from the dissemination of tumour cells from the primary growth, which then give rise to secondary growths in the organs in which they settle. Similarly, the artificial transfer of a tumour fragment to a fresh host can result in the continued proliferation of the neoplasm by cellular multiplication, a process that may then be extended indefinitely in serial transplantation. This capacity is the outstanding attribute of the cancer cell and the artificial propagation of animal tumours by such means in a variety of species, but especially the mouse, rat, rabbit, guinea pig and hamster, also affords a great wealth of material essential to research. The growth potential is also preserved—perhaps permanently—in cells carried into the frozen state by suitable techniques, as can be demonstrated when they are restored to normal temperatures and reimplanted, after periods certainly up to many years. During the course of transplantation, in most cases the cancer cell breeds true and may remain remarkably stable in its properties. In other

cases these properties may alter, either gradually or by a stepwise progression, a process usually involving further dedifferentiation and loss of function, with increased ease of transplantability and rapidity of growth. The first transplantation of a primary tumour to fresh hosts will on occasion only succeed when these are blood relations of the donor. But generally the conditions for success become less rigorous on repeated transfer, whereafter the tumour can be propagated in animals of the same species. In the overwhelming majority of instances, however, the limits of transplantability are the limits of species—or of hybridization between species where this is feasible—and are frequently even more closely restricted to a particular subline or strain. Where a tumour graft fails to be accepted (apart from accidental reasons), it does so from an immune reaction on the part of the host, which rejects it as foreign tissue; and when it is tolerated, it is then able to elicit from the tissues of the host the blood vessels and connective scaffolding on which its further growth depends.

Transplantation immunity is therefore directed against tumour grafts different in their genetical and immunological constitution from the tissues of the host, and they obey the laws that govern the transplantation of tissues of whatever kind. The capacity to develop such immunity does, however, vary with age and with transplantation site and can be diminished by various procedures. Thus, tumours of the mouse can be grown for short periods in the infant rat before immune responsiveness has wholly matured. Second, tumours of foreign species (including man) may persist or undergo varying degrees of growth when implanted in such sites as the cheek pouch of the golden hamster or the anterior chamber of the rabbit eye—sites in which the foreign graft appears to be shielded from the immune reaction that would otherwise destroy it. Last, successful transplantation to an alien host may be achieved by prior treatment of the host with various vital dyestuffs (*e.g.*, trypan blue), or other particulate material, both of which are taken up by the cells of the so-called reticulo-endothelial system on which transplantation immunity largely relies and lead to its temporary suspension; successful transplantation also may be achieved through a somewhat similar abrogation of immunity from the administration of cortisone, or following exposure to X-rays. Such technical modifications of the immune response permit the growth of tumours in circumstances in which it would not normally occur and are the basis of many experimental procedures invaluable for further research.

The propagation of tumours, so far considered, is dependent upon the transfer, from donor to host, of intact and living cancer cells. But a great revolution in cancer research occurred around 1910, with the discovery by Peyton Rous, at the Rockefeller Institute for Medical Research in New York, that certain fowl sarcomas could be transmitted not only by grafting tumour cells but also by injection of a submicroscopic agent extractable from them—the birth of the virus theory of cancer causation. The Rous and related agents are highly specific and immediate in their action, at once transforming the homologous normal cells of the fresh host into the replica of the tumour cells from which they were derived. Since that time, many other so-called oncogenic (tumour-causing) viruses have been revealed. In numerous ways heterogeneous in their properties and hence, perhaps, in their modes of action, it is, nevertheless, of much interest and significance that certain of them are also capable of transcending the species barrier and of inducing tumours in species alien to those from which they were derived.

The Study of Heredity.—A further early result of modern cancer research lay in the recognition of the importance, in the genesis of the disease, of hereditary constitution. As early as 1907 E. E. Tyzzer showed that the progeny of mice with mammary or lung cancer were more liable to develop these diseases than were the progeny of noncancerous animals. Similar conclusions were reached by Maud Slye (between 1913 and 1941) respecting other types of cancer in the mouse. The procedure of selective breeding was later developed by such pioneers as C. C. Little at the Roscoe B. Jackson Memorial laboratory at Bar Harbor, Me., and L. C. Strong. Selective breeding utilizes the principle that continued inbreeding of brother to sister, or of offspring

to parents, reduces the extent of variation in inheritance and increases the genetical uniformity of the resulting animals in succeeding generations. Thus from the selective breeding of the cancerous progeny of cancer-bearing mice can be evolved strains with a high natural incidence of cancer of the type shown by their ancestors. Contrariwise, by selection of the noncancerous progeny of noncancerous parents in successive generations, strains may be established with very low rates in their natural liability. It is patent that when selective inbreeding is utilized in experimental animals such as the mouse, heredity can be demonstrated as a powerful influence in cancer causation. However, since human society is based upon the deliberate exclusion of close inbreeding and since human breeding is to all intents random and nonselective, the hereditary factor is of little practical importance in man, unless in very exceptional circumstances.

THE STUDY OF THE CAUSES OF CANCER

For obvious reasons, a great part of cancer research is devoted to the study of causation. Here the experimental method is of paramount importance because it allows not only the artificial reproduction of the disease by a wide range of carcinogenic agents but also the investigation of their diverse mechanisms of action. When it becomes possible in chemical terms to elucidate the means by which carcinogens effect malignant transformation, this knowledge will have its corollary in a correspondingly precise understanding, on a biomolecular level, of the essential differences between normal and cancer cells and may also have its implications for rational treatment and control.

Physical Carcinogenesis.—*Ionizing Radiation.*—Known carcinogens fall into three major classes—physical, chemical and viral. Of the first, by far the most important are various electromagnetic and corpuscular radiations, and radiation as a carcinogenic agent can be considered as comprising ultraviolet, roentgen and gamma, alpha and beta radiation and protons and neutrons. For ionizing radiations, recognition of their carcinogenic hazard gradually developed in the early part of the 20th century, that is, not long after the discovery of roentgen rays (X-rays) and radium—partly from the experiences of the radiologist martyrs as a result of inadequate protection but also to some extent from experiment. Evidence in man has also accrued from such examples as the risk of bone sarcoma following the use of radium paints in industry, the sequelae to the use of a colloidal suspension of thorium dioxide in medical diagnosis, the occurrence of neoplasia in children treated with X-rays in infancy for enlargement of the thymus gland, the appearance of leukemia in a proportion of cases of ankylosing spondylitis treated with X-rays and the increased incidence of leukemia, and of other cancers, in the survivors of exposure to high levels of instantaneous radiation from the atomic explosions at Nagasaki and Hiroshima. Experimentally of great importance are the high-energy radiations associated with the uranium chain reaction and the range of radioactive elements and isotopes—especially including radiophosphorus, plutonium, radioactive strontium and iodine—made possible by the development of atomic physics. It is clear that this development, by rendering available radioactive isotopes in variety and abundance, has not merely stimulated the growth of radiobiology but has also added to the scientific and practical problems that the potential carcinogenicity of such substances creates.

Chemical Carcinogenesis.—As in the case of ionizing radiation, clinical observation played an essential part in the gradual development of knowledge of chemical carcinogenesis. The occurrence of cancer of the skin in chimney sweeps had been recognized by Percivall Pott as long ago as 1775 as attributable to soot. In the second half of the 19th century many other examples came to light of cancer as an industrial hazard—especially skin tumours among the workers in the German tar and paraffin industry, "paraffin cancer" found in workers in the Scottish oil shale deposits and the so-called "mule spinners' cancer" affecting workers in the Lancashire cotton-spinning industry and caused by contamination of the skin with lubricating oil.

These and many other similar observations indicated the presence of cancer-producing substances in soot, coal tar, pitch and

mineral oil and provided the stimulus toward the artificial reproduction of the disease by chemical means under experimental conditions. This was first attained by K. Yamagiwa and K. Ichikawa in 1915 by protracted application of coal tar to the skin of the rabbit ear, an achievement that in turn inaugurated the search for the agent responsible. In the 1920s the work of B. Bloch and W. Dreyfus in Ziirich and of E. L. Kennaway in London together indicated that this agent probably belonged to the class of cyclic hydrocarbons; and the following years in quick succession, by the contributions of E. L. Kennaway, J. W. Cook, W. V. Mayneord, I. Hieger and others, saw the discovery of the first pure chemical compound with pronounced carcinogenic properties (1,2,5,6-dibenzanthracene), recognition of the main carcinogen in coal tar and pitch (3,4-benzpyrene) and the production by synthesis of various series of carcinogenic polycyclic aromatic hydrocarbons. These advances were not merely of utmost importance in themselves but had immediate and lasting repercussions on every aspect of experimental cancer research throughout the world.

Carcinogenicity is not, however, restricted to the polynuclear aromatic hydrocarbons. Another occupational hazard had long been known in the incidence of cancer of the bladder in workers in the dyestuffs industry in England, Europe and Japan, from exposure to the intermediates alpha- and beta-naphthylamine and benzidine, and these substances were the forerunners of what was to prove a large class of carcinogenic amines. Further, the propensity to evoke cancer of the liver is a feature of many dyestuffs allied to aminoazobenzene. Of special interest are various associations between carcinogenesis and endocrine physiology, arising from the discovery by A. Lacassagne in 1932 that injection of the female sex hormones (estrogens) can produce cancer of the breast in male mice. The appearance of breast cancer in mice is known to be determined by a number of predisposing and conditioning factors. Also, the carcinogenic action of the estrogens is mainly confined to tissues that are highly responsive to the physiological action of the estrogens. Nevertheless, Lacassagne's experiment was the first in which cancer was produced by a naturally occurring compound and led to many other studies, including those of the induction of pituitary, mammary, uterine, testicular, adrenal, subcutaneous, leukotic and osseous tumours in mice and other species by both natural and synthetic estrogens. Among other types of chemical carcinogenesis may be listed the action of urethan in increasing the incidence of adenoma of the lung in mice; the induction of liver tumours by carbon tetrachloride, tannic acid and alkaloids derived from the plant genus *Senecio*, the appearance of sarcomas following implantation of many polymers and plastics; the production of a variety of proliferations of the reticulo-endothelial system after prolonged administration of such azo dyes as trypan blue or Evans blue, and the role of metals, metalloids or metal-containing substances (*e.g.*, arsenic, chromates, nickel carbonyl, asbestos, beryllium, selenium, cobalt and metal-dextran) in producing cancer, whether under occupational conditions or by experiment. Last but highly important is an extensive class of so-called alkylating carcinogens (*e.g.*, nitrogen mustards, bisepoxides, polyethylenimines) which because of their chemical simplicity and reactivity are specially advantageous in studying the mechanism of their action.

The Oncogenic Viruses.—Added to the growing knowledge of physical and chemical carcinogenesis, the mid-20th century also saw the beginnings of a revolution in opinion as to the causative role of oncogenic viruses. Much earlier, the discovery of the Rous sarcoma virus had been followed by recognition of similar agents recoverable from many avian leukemias. Later, J. J. Bittner demonstrated the contributory part in the etiology of breast cancer in mice of the so-called milk factor, a viral agent present in the tissues of certain strains of high susceptibility and transferred by the milk to suckling mice in which it can then determine an incidence of mammary cancer to which they would not otherwise be liable. In another direction, R. E. Shope described a virus capable of inducing, in the skin of the rabbit, rapidly growing papillomas, a proportion of which then transform into highly malignant cancers. By administration of extracts of mouse leu-

kemic tissue to day-old mice of strains not otherwise susceptible. L. Gross was able to generate a high incidence of leukemia and to demonstrate leukemogenic viruses in the mammal—a key discovery that led, through the application of similar methods by Sarah Stewart, and later by many others, to recognition of the polyoma (Stewart-Eddy) virus, capable of growth and enhancement in tissue culture and of evoking a wide range of tumours not only in the mouse but in other species. Apart from the unique biological properties of the polyoma viruses, remarkable advances were made by electron microscopy regarding their morphology and nucleic acid structure.

Mechanisms of Carcinogenesis.—A central problem concerns the mechanisms by which malignant transformation is effected and, in particular, what part (if any) is played in natural causation by processes of infection. It is clear that cancer can be induced by a great range of agents and from their diversity it is certain these must operate by different biochemical routes. It is, however, not improbable that these routes lead to a key alteration similar in principle in the different cases, notwithstanding the great diversities between the carcinogens themselves and even between many of the oncogenic viruses. The possibility of an eventual synthetic understanding is also seen in the fact that many physical, chemical and even viral carcinogens are capable of inducing chemical and biological mutation, of which carcinogenesis may be a specialized case. It is often said that the cancer cell has acquired the property of unlimited growth; but, as was earliest pointed out by J. A. Murray, this cannot be so since the same potentiality is inherent in the normal cell. Many studies, especially of such chemical carcinogens as the polycyclic hydrocarbons, the azo dyestuffs and the alkylating agents, strongly suggest an interference with protein synthesis, leading perhaps to the deletion of specific enzymes, either directly by chemical combination with protein or indirectly by damage to the chemical integrity of the nucleic acid structures, upon which both cellular heredity and protein synthesis depend. Hence it may well be that the action of all carcinogens, including the oncogenic viruses, is to deprive the cell, by various degrees of specificity of action, of growth-regulatory systems dependent upon the protein-nucleic acid association, and in this way to liberate permanently the growth potential all along present but normally controlled.

RESEARCH ORGANIZATION AND SUPPORT

In many countries cancer research is supported from both governmental and private sources. Examples of the former can be taken in the Medical Research Council of Great Britain, the department of health, education and welfare of the United States government and the French Centre National de la Recherche Scientifique. Examples of private support sources are seen in the British Empire Cancer campaign, the Imperial Cancer Research fund, the American Cancer society and the Damon Runyon Memorial Fund for Cancer Research; and a specially valuable function is performed by those—such as the Lady Tata Memorial fund (for research in leukemia) and the Jane Coffin Childs Memorial Fund for Medical Research and the Anna Fuller fund (both of New Haven, Conn.)—that distribute their help on an international scale.

In research itself, apart from its support, most countries have their scientific societies designed to bring together workers in the field, outstanding being the American Association for Cancer Research. On the international plane, it is a function of the Union Internationale contre le Cancer (founded in 1933) to organize a series of international cancer congresses, at four-year intervals, and to sponsor occasional international symposia. The Union was a founder member of the Council for International Organizations of Medical Sciences (C.I.O.M.S.) and is affiliated to the World Health organization.

CANDELABRUM, in architecture, is a decorative motif derived from the pedestal or shaft used to support a lamp or candle. The Romans, developing Hellenistic precedents, made candelabra of great decorative richness. Two Roman types are found: the simpler, consisting of a slender shaft, often fluted, supported on a spreading base of animals' feet and acanthus scrolls, and carrying a flat shelf with vaselike moldings. The multitude of such candelabra found in Pompeii proves them to have been a common form of household decoration. The more monumental type, either of marble or bronze, used in public buildings, had for the base a pedestal resembling a little altar which carried a heavy shaft, frequently decorated with row on row of acanthus leaves. The lavishness of such examples made a great impression on Renaissance artists, and the general form known as the candelabrum shaft was widely used in the late 15th century, especially for the centre of pilasters.

For candelabrum in the sense of a large branched candlestick, see **CANDLESTICK**.

CANDIA (ΕΡΑΚΛΕΙΟΝ): see **IRAKLION** (HERAKLION).

CANDLE, a cylinder of wax, tallow or similar material surrounding and saturating a fibrous wick.

Early Forms.—Candles were known to the peoples of the ancient world. Depicted in relief on ancient Egyptian tombs at Thebes are cone-shaped candles held aloft in dishlike holders. Dish-shaped candlesticks with a central socket, similar in design to the modern candlestick, were found at Crete and date from the first Minoan civilization, about 3000 B.C. The Romans had candles and tapers of tallow and wax, and a fragment of candle dating from the 1st century A.D. was found at Vaison, near Avignon, in France.

During the middle ages in Europe the familiar means of lighting of the poor was the rushlight, consisting of a reed stripped of the pith and dipped in oil. Both tallow and wax candles were commonly known, however, although wax candles were so costly that only the wealthy could afford them. Tallow candles were called "dips." Tallow was rendered from beef or mutton suet; strands of yarn were then dipped in the melted fat and allowed to cool. The dipping and cooling processes were repeated alternately until the candle reached a desired thickness. Wax candles were made by repeatedly pouring melted beeswax over a suspended wick and removing any unevenness in the finished candle by rolling it over a hard surface.

Candlemaking was exclusively a domestic pursuit for many years, but with the growth of medieval town life it became a specialized craft. In Paris in the 13th century members of a guild of tallow chandlers went from house to house making candles. A distinction was drawn between the making of tallow candles and the making of wax candles, as evidenced by the establishment in Paris of two separate guilds, the tallow chandlers and the wax chandlers. In London, also, two separate livery companies were incorporated. An interesting familiar feature of the middle ages was the tallow candle set in a lantern. It should be noted that candlemaking as a domestic art was never entirely lost. In some localities throughout the medieval period and on into much more modern times candles were still made in the home kitchen.

The candle mold did not appear until the 15th century. Its invention, attributed to the sieur de Brez of Paris, was of importance only to tallow chandling, since beeswax candles could not be molded satisfactorily.

Emergence of Modern Processes.—Few improvements in candlemaking were introduced until the 19th century, when chemistry exerted its impact on the industry. In the second decade of the century, a French chemist, M. E. Chevreul, proved that fats were composed of fatty acids and glycerin. He succeeded in separating these components by saturating fat with alkali and treating the resultant soap with sulfuric acid. The liquid oleic acid was expressed by pressure, leaving the solid combined palmitic and stearic acids, the stock of the superior stearin candle.

From this beginning, new processes for producing pure candle stock appeared in rapid succession. Fats were decomposed by treating them with concentrated sulfuric acid, by subjecting a mixture of fat and water to high temperatures under pressure in an autoclave or digester, and by distillation with superheated steam, a method that permitted recovery of pure glycerin. From these innovations developed the modern method of decomposing fats by hydrolysis; *i.e.*, breakdown through the addition of water. In this process, a mixture of fat and lime water (calcium hydroxide) is heated to a high temperature under pressure in a sealed, copper-lined steel digester, the material being agitated by a spirally turning paddle or by pumping. The products are lime soap, which is resolved into fatty acids, water and lime sulfate by treatment with dilute sulfuric acid and steam, and "sweet water," from which glycerin is recovered by purification with steam.

In addition to stearin, other important candle stocks were produced during the 19th century. Spermaceti, derived from the oil in the head cavity of the sperm whale, made a candle of superior illuminating power. Its tendency to brittleness was corrected by the addition of beeswax. The spermaceti candle, made to exact specifications, was established in England in 1860 as the

standard of photometric measure. Another bright-burning candle was made of ceresin, a wax obtained from the distillation of ozocerite, or earth wax.

The successful production of paraffin wax in 1850 was a development of first importance. By 1855 paraffin wax was being profitably produced in England, on the continent and to some extent in the United States by distillation of coal and oil shales. Discovery of petroleum in the United States in 1859 made possible the economical production of paraffin by redistilling the abundant residue left from the initial refining of crude petroleum. Purification of the resultant material yielded white, or bluish-white, translucent paraffin wax. Its single disadvantage of a low-melting point was overcome by combining it with stearic acid, and this composite material soon accounted for most of the candle production.

The plaited cotton wick, pickled in a dilute solution of a mineral salt such as borax, potassium nitrate or ammonium chloride, was introduced by W. Cambacères in 1825. Impregnation of the wick with a mineral salt causes it to curve when burning, thus facilitating oxidation. It also causes the ash to vitrify, eliminating the need for snuffing, or cutting away, the charred wick ends. Modern wicking is plaited by machines.

Production by Machine.—The modern candle-molding machine evolved from Joseph Morgan's machine of 1834, the first that permitted continuous wicking and ejection of molded candles by movable pistons. Molds of the modern machine are made of high-grade tin and are finely finished inside to give polish to the candles. The molds are arranged in parallel rows in a metal tank equipped for alternate heating and cooling. The amount of heat applied and the rate of cooling are carefully controlled to suit particular candle stocks. The upper, or butt, ends of the molds open into horizontal channels from which melted candle stock drains into the molds, which are preheated. The lower, or tip, ends of the molds are closed by inverted conical tip-molds, each of which is carried at the top of a hollow piston attached to a common bed. The tip-mold also serves to form the tapered end of the candle. After the filled molds have been cooled, the pistons are raised to eject the candles upward into a rack or clamp at the top of the machine. Spools of wicking are carried at the bottom of the machine, one for each mold; the wicking is threaded through the piston, entering a perforation in the tip-mold and passing up through the candle mold. As a charge of candles is ejected into the clamp the wicking is drawn up in preparation for the next charge. When a second charge of candles is ready for ejection, the wicks of the first are cut and the candles removed from the clamp. Such a machine can produce up to 500 candles at a single charge and can complete three charges an hour.

For certain specialized purposes, tallow "dips" are still made commercially. Beeswax candles continue to be made by basting a suspended wick with the melted wax, while tapers are made by drawing long strands of wicking through a bath of molten wax.

Nonlighting Uses.—Candles have been turned to interesting uses other than lighting. A millennium ago a candle marked off in 12 equal divisions was burned to time the passing of a day. Alfred the Great devised a thin horn shield that protected the time-candle's flame against disturbances by currents of air. In 17th-century England bidding at auctions opened with the lighting of an inch-high candle and closed when the candle guttered out.

Candles have exerted a perennial aesthetic and spiritual appeal. Through the centuries they have been lighted as sacramentals in Roman Catholic churches, and the lighting of candles has also been a part of Jewish religious and historic ceremonies. Where candles no longer fill the need for illumination: they are prized for the soft charm of their light. There is also a thriving interest in candlemaking as a creative art.

Y.)

CANDLEMAS, the church festival on Feb. 2 which commemorates the occasion when the Virgin Mary, in obedience to Jewish law, went to Jerusalem both to be purified 40 days after

giving birth to a son and to present Jesus to God as her first-born (Luke ii, 22–38). The festival is also known in the west as the Purification of the Virgin Mary and as the Presentation of the Child Jesus. In the Greek church it is called *Hypapante* ("meeting") because of their meeting in the Temple with the aged Simeon, who said the *Nunc dimittis* and prophesied to the Virgin Mary. The earliest reference to the festival comes from Jerusalem, where in the late 4th century the western pilgrim Etheria attended its celebration on Feb. 14, 40 days after Epiphany (then kept there as the nativity of Christ; see CHRISTMAS). It soon spread to other cities of the Byzantine empire, and in 542 Justinian I decreed that its date should be moved back to Feb. 2 (*i.e.*, 40 days after Christmas). By the middle of the 5th century the custom of keeping the festival with lighted candles had been introduced by a Jerusalem abbess; hence the name Candlemas. The festival is first heard of in the west when Pope Sergius I (687–701) instituted the procession for it in Rome. In the east it is primarily a festival of Christ, in the west of the Virgin Mary. (J. E. BH.)

CANDLE POWER (LUMINOUS INTENSITY), a term now technically obsolescent but still in commercial use, dating back to the candlelight era, when a standard candle was made of spermaceti wax and of such dimensions and wick length as to consume 120 gr. per hour. Later a specially made pentane lamp (Harcourt) was the standard candle for Great Britain and the United States; Germany meanwhile adopted the Hefner amyl-acetate lamp. In 1909 the international candle was defined in terms of groups of specially made and precisely operated carbon filament lamps kept at national standardization laboratories.

In 1939 the Commission Internationale de l'Eclairage in sessions at Scheveningen, Neth., recommended a new standard candle, to be of the luminous intensity per square centimetre of its surface equal to one-sixtieth of that of a black body (*q.v.*) (perfect) radiator held at the freezing point of pure platinum (1,773° C.). This was the accepted definition of the standard candle (see PHYSICAL UNITS).

The term candle power obviously referred intuitively to the rate of flow (flux) of luminous energy, as judged by the eye, from some source of light in comparison with that of a candle. The unit of flux is the lumen. This is defined as the rate of luminous output of energy, the flux, radially streaming outward through a unit of solid angle (steradian) from the standard candle located at the apex of this angle.

Thus in modern terms a standard candle's power sends a luminous intensity of 4π lumens out through any spherical surface centred on the candle.

For more technical details, see LIGHTING; PHOTOMETRY.

(H. B. LM.)

CANDLER, ASA GRIGGS (1851–1929), U.S. manufacturer of soft drinks, was born on a farm near Villa Rica, Ga., Dec. 30, 1851. He studied medicine, became a pharmacist and developed a prosperous wholesale drug business. In 1887 he purchased the formula for Coca-Cola, a soft drink, from a business associate. He improved the process of manufacture and developed Coca-Cola into one of the most prosperous businesses in the southern region of the United States. He sold the business in 1919 for \$25,000,000. Emory university in Atlanta, Ga., received many gifts from him and he constructed a teaching hospital adjacent to its medical school. He died March 12, 1929, in Atlanta, Ga. (H. J. SG.)

CANDLESTICK, a receptacle for holding a candle (*q.v.*). Candlesticks may range in size and complexity from the medieval block of wood holding an iron spike on which the candle was impaled, to the huge bronze altar candlesticks of the Italian Renaissance. In the most restricted sense, "candlestick" means a utensil for holding one candle, "candelabrum" a large, standing, branched candlestick for holding several candles; "candlestick" commonly is used in both senses. "Chandelier" is a branched candlestick (or lampstand) suspended from the ceiling.

Ancient Times.—In its earliest form, the candle was a torch made of slips of bark, vine tendrils or wood dipped in wax or tallow, tied together and held in the hand by the lower end. Candles of this type frequently figured on classical painted vases;

(LEFT) ENGLISH GILT BRONZE ALTAR CANDLESTICK, INSCRIBED AS HAVING BEEN GIVEN TO THE ABBEY OF ST. PETER, GLOUCESTER, BY THE ABBOT PETER, EARLY 12TH CENTURY; (RIGHT) ENGLISH CANDELABRA WITH BRISTOL GLASS STANDS MOUNTED IN GILT BRONZE, ABOUT 1800. BOTH IN THE VICTORIA AND ALBERT MUSEUM

subsequently a cup or discus was attached to the base to catch the dripping wax or tallow. The rushlight that was still used in 19th-century Europe was of similar construction.

Little is known of domestic candlesticks before the middle ages, but a number of references to ecclesiastical candlesticks are to be found in the Old Testament. Moses was commanded to make for the tabernacle a candlestick of hammered gold which was to weigh a talent and consist of a base with a shaft from which six arms sprang, supporting seven candles on the arms and central shaft. When Solomon built his temple, he placed in it ten golden candlesticks, five on each side of the Holy Place. After the period of captivity in Babylon the golden candlestick was again placed in the temple, as it had been formerly in the tabernacle by Moses, but on the destruction of Jerusalem it was carried with other spoils to Rome; representations of it can be seen on the Arch of Titus in Rome and in the catacombs.

Middle Ages.—The simplest form of domestic candlestick was a block of wood into the top of which an iron spike was driven vertically. The lower end of the candle was then impaled on this spike and the upper end lighted. This type of candlestick survived in rural areas into the early 19th century. It is found in various sizes. The earliest form had only a single spike, but subsequently the stem was wrought into two spikes, or a circular tray was attached to the top, on the upper side of which several spikes might be fixed. Candlesticks of this construction with several tiers of trays or rings for spikes (usually known as prickets) may be seen in use before shrines in Roman Catholic churches. The socket was introduced as an alternative to the pricket during the middle ages, but it did not replace it, and late medieval candlesticks are found with both prickets and sockets on one stem.

The bronze founders of Germany, the Low Countries and elsewhere produced splendid cast bronze candlesticks for both ecclesiastical and secular purposes from the 10th century onward. The most striking is the so-called Gloucester candlestick (in the Victoria and Albert museum, London), which is generally accepted as an English work dating from the early 12th century. The whole surface is pierced and modeled with nude human figures fighting dragons among foliate scrolls. There are also early bronze altar candlesticks in the Magdalenenkirche at Hildesheim and the Miinsterkirche at Essen, dating from the late 10th and early 11th centuries, respectively, but the most impressive examples are of later date. The most important is the Trivulzio candlestick in Milan cathedral. Six metres in height, it was executed about 1200,

but its place of manufacture is conjectural, suggestions varying between England, Lorraine and Milan itself. It is composed of floral scrolls inhabited by realistically modeled human beings and monsters. Incomplete candlesticks of similar type survive at Reims (in the museum) and Prague (in the cathedral). Alongside these huge paschal candlesticks, which usually had seven branches, smaller domestic ones were made, some of highly imaginative form. The German and Mosan bronze founders were fond of a type in which a pricket was attached to the back of a dragon or birdlike monster.

While the candlesticks from northern Europe were superbly modeled in the form of fantastic figures or animals, the enameling workshops of Limoges in central France produced altar candlesticks of various sizes in which the ornament was carried out in opaque *champlevé* enamel against a gilt copper ground. The Limoges workshops also specialized in small traveling candlesticks with folding legs; the secular nature of this type is shown by the shields of arms of noble French families with which they were usually enriched. Judging by surviving examples, candles were more popular than lamps during the middle ages.

The substitute in northern Europe for the hanging oil lamp used in eastern Europe was the chandelier. Hanging candleholders made of wood or iron of simple shape were used in Anglo-Saxon churches before the Conquest. In the 12th and 13th centuries huge coronas, openwork hoops of iron or bronze, supported numerous prickets for candles. Those made for royal palaces were of gold or silver, sometimes even set with jewels. Only in the cathedrals have such large Romanesque chandeliers survived, the most important being that in Aachen cathedral made for the emperor Frederick Barbarossa in 1168. A peculiar form of hanging chandelier for ecclesiastical purposes, produced in Spain, is known as a polycandelon; it consisted of a flat circular plate of bronze, the edge pierced with circular holes for the insertion of candles and the central area pierced with Christian symbols. Surviving examples date from the 8th to the 10th century.

The development of the brass-founding industry in the Meuse valley in and around Dinant, Belg., led to an important production there in the later middle ages of large altar candlesticks and smaller domestic ones of standardized form with circular molded stems and large spreading bases, often supported on three lion feet. Brass was also found to be a suitable material for the production of chandeliers, and a number of 15th-century examples survive, mostly in churches; among them is a 12-light chandelier arranged in two tiers in the Berkeley chapel at Bristol cathedral. These 15th- and 16th-century brass chandeliers were usually surmounted by a figure of the Virgin Mary, a saint or an angel, though some of the more magnificent examples, such as may be seen in Flemish 15th-century paintings, were enriched with much elaborate Gothic crocketing and tracery.

Candlesticks of silver gilt, enriched with enamel, decorated the altars of the great churches and rich chapels of the nobility in the later middle ages, but there is now little to show of such treasures. The treasury of Aachen cathedral includes silver altar candlesticks of the late 14th century, while a set of 15th-century Spanish altar plate in the British museum includes a pair of silver candlesticks enriched with translucent enamel. In England Henry VI owned a splendid pair of gold candlesticks set with 4 sapphires, 4 rubies, 4 emeralds and 24 pearls. Subsequently, in the 16th century, Henry VIII had a set of four golden candlesticks with his initials enameled on them in red and weighing 126 oz. The inventory of the plate of Queen Elizabeth I includes 148 candlesticks and chandeliers of silver or silver gilt, a great many of which were what would now be called candelabra. The houses of the wealthy must have contained a great quantity of candlesticks; the household inventory of Sir Thomas Ramsey, a former lord mayor of London, who died in 1590, included 58 brass candlesticks.

Instead of the elaborate chandelier with as many as 12 lights, a candlebeam was sometimes used. This was composed of two or three crossed beams of carved and gilded wood, fitted with sockets and drip pans. Chandelier and candlebeam alike were suspended by two or more chains to a rope passing over a pulley, so that the whole fitting could be lowered as required for snuffing. In the

larger houses the candlebeam was supplemented by wall lights or sconces of silver or brass fitted with reflectors behind the candles. These are described as plate candlesticks in the inventories of the time.

While the brass candlesticks were mostly imported into England, there was a considerable production of pewter ones, but the earliest-known English example, the Grainger candlestick (in the Victoria and Albert museum), dates from the beginning of the 17th century. The ordinary table candlestick of the 16th century had a high circular foot with its upper rim encircled by a deep molding to form a drip pan. The stem was of circular section and of cylindrical or baluster form. In Germany more ambitious types were made with the stem formed as a warrior or woodwose whose extended arms held the prickets or sockets.

Renaissance.—The Italian bronze founders produced superbly modeled candlesticks from small table examples to huge altar candlesticks with angel supporters of almost life size. The most magnificent examples were made of rock crystal mounted in precious metal enriched with translucent enamels; among these is the set of altar cross and pair of candlesticks (in the Victoria and Albert museum) with rock crystal panels mounted in enameled silver gilt, made in the mid-16th century by Valerio Belli. A late-16th-century silver pair in the Vatican was made by the goldsmith Antonio Gentili. A fine bronze candelabrum in the Church of S. Antonio, Padua, Italy, is about 11 ft. 6 in. high with many grotesques, garlands, figures and panels modeled in relief.

Renaissance artists pressed a great variety of materials into use for the production of candlesticks, including Limoges enamels, pottery such as Saint-Porchaire ware, amber and damascened iron. Among the more fantastic forms were the chandeliers called *Luster-Weibchen* made in German-speaking areas. A figure of a woman or a monster was carved in wood and painted in naturalistic colours and to the back was fixed a large pair of antlers to which in turn were attached prickets or sockets for candles. A design by Albrecht Dürer for a lustre of this type exists, and examples still survive in German castles and city council chambers. At the other end of the scale are the simple table candlesticks made in England from common earthenware covered with a greenish glaze. A few of these (in the Guildhall museum, London) were excavated in London; with their bell-shaped base surmounted by a wide drip pan, short stem and long, outward-tapering socket, they show English folk art at its best.

17th Century.—The few examples of English candlesticks of pre-Restoration date that have survived present considerable variety of form. The earliest, which probably dates from about 1600, is of crystal and silver gilt, with two sockets attached to a crystal crossbeam supported on a stem decorated with figures of eagles and satyrs. Other examples are less ambitious; a pair of 1618 have solid sockets and grease pans, but stems and triangular bases of wire, supported on three feet resembling pepper pots. A pair in the Fairfax inventory of 1624 described as "wyer silver candlesticks" were doubtless of this type. Fewer candlesticks were imported from the Low Countries in the 17th century, and one of the two main types in use in England at that time was of local origin. It had a trumpet base, hollow stem decorated with "sausage" turning and a wide drip pan set about a third of the way up from base to socket. The other type, which was much produced in the Netherlands, had a baluster stem of excellent proportions and form, spreading base and wide drip pan halfway between top and base.

The production of brass chandeliers, which became so important in the Netherlands during the 18th century, was started in the 17th. These had a boldly shaped baluster stem terminating beneath in a large burnished reflecting sphere; from the stem sprang a number of S-shaped branches ending in sockets. As a rule the chandelier was suspended from a chain, but in English churches it was sometimes attached to a wrought-iron suspension rod, which was lavishly ornamented with flowers, leaves and scrollwork, and enriched with painted colours and gilding. Simpler chandeliers were also made by village blacksmiths; these had a central sphere of wood from which sprang curved iron rods ending in prickets.

In accordance with the baroque style of the 17th century, silver

candlesticks were made with stems boldly modeled with human or animal figures. Very few of these survived, as they consumed a great deal of precious metal and were broken up for its sake when they ceased to be fashionable. The fashion for this type of figure ornament was widely spread in Europe and the few examples surviving are of German, English or Dutch origin.

Wall sconces were greatly favoured and were provided with reflector plates of great size, embossed with profuse ornament in high relief. The long dining halls of 17th-century houses had space for numbers of these sconces, and some of the German princely collections include large sets of them. The royal plate at Windsor castle, Berkshire, includes some very handsome sconces with elaborately embossed reflectors made for Charles II. It was soon realized that mirror plate made an even more effective reflector for candlelight than polished silver, and from the late 17th century it became usual to set the back of sconces with looking glasses, which were known as mirror sconces.

While in France the splendid silver furnishings of Louis XIV's palaces had to be sacrificed to contribute bullion to pay for his wars of conquest, much silver furniture survived in England, including several huge chandeliers made entirely of silver. The finest of these, made during the reign of William III for Hampton Court palace, Middlesex, is still in position there; others are found at Chatsworth in Derbyshire and Drumlanrig in Scotland. At the same time chandeliers of carved and gilded wood were made; one of those made for the Queen's gallery at Kensington palace during the reign of William III and now in the Victoria and Albert museum has 12 branches in two tiers of carved and gilded wood and is surmounted by a royal crown.

18th Century. — The 18th century was the great age of candlelight, and the salons of the nobility and gentry were lighted by many hundreds of candles from chandeliers, candelabra and wall sconces. In England silver and glass were used in the homes of the wealthy, while brass chandeliers were hung in churches and council chambers, these last being manufactured in England instead of being imported. As the century advanced, chandeliers became more massive in form and more elaborate in ornament. The earliest English glass chandeliers date from the 1720s and were of plain design with a heavy ball at the base of the shaft, like the contemporary brass chandeliers. Later they were decorated with numbers of pendants and the surface was given life by cutting. Another decisive change came in the 1770s when the ball was replaced by an urn form. At the same time pear drops were hung from the branches and glass spires set in the upper tiers in place of candles. The chandelier eventually became even more elaborate, icicles being suspended around the shaft and long cascades of pear drops suspended from the lustres.

In Europe rock crystal was used instead of glass on the finer chandeliers, but in the course of the 18th century the production of glass ones was greatly expanded in Venice and in Bohemia. The Venetian chandeliers were made of varicoloured glass with floral ornament and achieved a particularly decorative effect. Such was their popularity that the mid-18th-century design has been produced in Murano, Italy, ever since and can be purchased new in most European capitals. Magnificent porcelain chandeliers were produced at the larger European factories but, because of their extreme fragility, few have survived.

In 18th-century France some of the finest chandeliers were made of gilt bronze (*ormolu*). The richest and most splendid, dating from the mid-18th century, were cast and chased in bronze to highly rococo designs. Corresponding to the big chandeliers were candelabra and single candlesticks, which, designed by artists such as Juste Meissonier, rank as works of sculpture rather than as domestic accessories.

In the 18th century wall lights became more elaborate. Though the same materials — carved wood, silver gilt, bronze or brass — were used, they were made with many more candle sockets arranged in tiers or, in the case of those of the rococo period, growing asymmetrically out of a central stem. The reflector plate, which had played so important a part in the design of the 17th-century wall light, was abandoned in the course of the following century, the effect being gained by massing lights rather than by

reflection. The girandole was a particularly ornamental type of wall light made of gilt bronze or carved wood and having usually two branches. The great engravers and gilders of mid-18th-century Paris executed superb examples in gilt bronze.

Table candlesticks were made in great variety of design and material. The great houses contained many dozens of pairs of silver candlesticks, and consequently the candlestick is almost the commonest surviving article of English 18th-century plate. The rapid change of fashion in the 18th century from the plain Queen Anne style to the elaborate late baroque of early Georgian and subsequently to the rococo, neoclassical and regency or empire styles ensured variety in production. A similar evolution of design took place throughout Europe. Because of the greater wealth of the 18th century, the brass candlestick did not play so important a part, but toward the end of the century very elegant designs were executed in Sheffield plate at Matthew Boulton's works in Birmingham as well as in Sheffield itself.

19th Century. — The design of the candlestick in the early 19th century was influenced by the introduction of the tall glass open shade which kept the flame from flickering. The candlesticks were made of brass or bronze and decorated with Egyptian or classical motifs. An attractive type had a circle of branches below the nozzle from which were suspended cut-glass icicles. In large candelabra, figures of Atlas or of Egyptian slaves were popular, the latter especially in France. (J. F. H.)

In the latter part of the century, with the advent of the more convenient and efficient methods of gas and electric lighting, the real need for candlesticks diminished rapidly, although in remote districts their use continued in spite of the greater efficiency of acetylene, paraffin and other portable lamps. For use when moving about or going to bed, a candlestick was far lighter and simpler to use than these lamps, and the chamber type, with saucer-shaped base and small looped handle, continued to be manufactured in various metals, pottery or even kitchenware enamel. Designs retreated from decorative to purely utilitarian levels as candlesticks were relegated to humbler use.

20th Century. — A revival of purely decorative types of table candlestick or candleholder occurred in the middle decades of the 20th century, stimulated by fashions for candlelit dinner tables. Scandinavian designs popularized candlesticks of glass, both heavy polished glass and lighter blown or molded types. Wrought iron, copper and brass were used for designs in Italy, Spain, Yugoslavia and farther north, in some cases reverting to the spike or pricket method of fixing candles in position. Silver, pewter and wood also were employed.

Altar candlesticks continue to be used in churches, and although traditional "church plate" types persist widely, many individual designs have been commissioned in the modern style. Silver, gilt and, to a lesser extent, brass still remain favourite materials, but aluminum, stainless steel, enamel inlays and some forms of plastic have all been used successfully in both old and new churches. In general these designs are simple, based on pure or adapted geometric shapes that exploit the quality of the material. In contrast, the large bronze many-branched candelabra presented to Westminster abbey in 1939 and 1942 were designed by Benno Elkan with an elaborate symbolism and detail that owes much to historical sources. (E. C. D.)

CANDLISH, ROBERT SMITH (1806–1873), early leader of the Free Church of Scotland (*q.v.*), was born at Edinburgh on March 23, 1806, and spent his early years in Glasgow, where he graduated in 1823. In 1834 he was appointed minister of the important parish of St. George's, Edinburgh, and there he came to be regarded as one of the ablest preachers in Scotland. His first assembly speech, delivered in 1839, placed him at once among the leaders of the "nonintrusion" party, and his part in settling the problems created by the Disruption of 1843 was inferior only to that of Thomas Chalmers (*q.v.*). After Chalmers' death in 1847 Candlish was the most prominent leader in the Free Church. In 1862 he succeeded William Cunningham as the principal of New college, Edinburgh, while retaining his position at St. George's. His writings had a considerable influence on theological thought in Scotland and beyond. He died in Edinburgh on Oct. 19, 1873.

See W. Wilson, *Memorials of R. S. Candlish, D.D.* (1880).

CANDOLLE, (AUGUSTIN) PYRAME DE (1778–1841), Swiss botanist who played a prominent part in the establishment of a natural system of classification of flowering plants, was born at Geneva on Feb. 4, 1778. He studied at Geneva and settled in Paris in 1796. His *Plantarum succulentarum historia*, four volumes (1799–1829) and *Astragalogia* (1802), a work on the pea family, introduced him to the notice of G. Cuvier and to J. B. Lamarck, who confided to him the publication of the third edition of the *Flore française* (1805–15). The *Principes élémentaires de botanique*, printed as the introduction to this work, contained the first exposition of his principle of classification according to the natural as opposed to the Linnean or artificial method. In 1804 he published his *Essai sur les propriétés médicales des plantes*, etc., and soon after, in 1806, his *Synopsis plantarum in flora Gallica descriptarum*. At the desire of the French government he spent the summers of the following six years in making a botanical and agricultural survey of the whole kingdom, the results of which were published in 1813. He lectured on botany at Montpellier (1808–16) until he returned to Geneva to fill the chair of natural history there. The rest of his life was spent in elaborating and in trying to complete his "natural" system of botanical classification, embodied in his *Regni vegetabilis systema naturale*, of which two volumes only were completed (1818–21). In 1824 he began his most famous work, *Prodromus systematis naturalis regni vegetabilis* (1824–73), of which seven volumes were published during his lifetime. De Candolle died at Geneva on Sept. 9, 1841.

His son, ALPHONSE LOUIS PIERRE PYRAME DE CANDOLLE, famous for his formulation of the laws of botanical nomenclature and for his studies on the origin of cultivated plants, was born at Paris on Oct. 27, 1806. He succeeded to his father's chair at Geneva in 1842, and published the remaining nine volumes of the *Prodromus*, one of them in collaboration with his own son, (Anne) Casimir Pyrame de Candolle (1836–1918). Among numerous botanical works, Alphonse de Candolle published *Géographie botanique raisonnée* (1855); *Lois de la nomenclature botanique* (1867); *Origine des plantes cultivées* (1833; 2nd ed., *Origin of Cultivated Plants*, 1886). He died at Geneva on April 4, 1893.

See A. de Candolle, *Mémoires et souvenirs d'Augustin Pyrame de Candolle* (1862); A. Engler, *Alphonse de Candolle* (1893).

CANDY: see CONFECTIONERY MANUFACTURE.

CANDYTUFT, the name for any small annual or perennial herb of the genus *Iberis* belonging to the family Cruciferae and native to southern Europe (*Iberis* from Iberia, the old name for Spain) and western Asia. Of the approximately 30 species several are shrubby or evergreen garden perennials. The two outer petals of the flowers, which grow in round or elongated heads, are longer than the two inner ones. Their colours range from white to dark purple or red and some are fragrant.

The cultivated species are easily grown if they have plenty of sun and space. The commonest border kinds are: *I. amara* (rocket candytuft), an annual with white, scented flowers; *I. umbellata* (globe candytuft), an annual with unscented flowers in a variety of colours from purple to white; and *I. sempervirens*, an evergreen shrubby plant with white flowers, much used for edges and in rock gardens. *I. amara* is sometimes found in chalky cornfields in England.

CANE. Cane perhaps most generally refers to sugar cane, *Saccharum officinarum*, of the grass family. The related *Sorghum* cane is widely cultivated in warmer parts of the temperate zone to yield a sweet sorgho sirup, and selected varieties have been an important feed grain in drier climates. Cane also signifies the jointed, pithy stems of a number of other tall grasses such as *Phragmites* and bamboo, colonies of which may be termed cane brake. Stems of several oriental palms are especially well known

BY COURTESY OF BURPEE SEEDS
CANDYTUFT (*IBERIS SEMPERVIRENS*)

as rattan or rotan canes, a significant commercial export from the eastern tropics. In horticulture slender tough stems of almost any shrub may be termed canes, such as those of the raspberry and rose.

Sugar cane is probably native to the far east, but has been introduced throughout the tropics. It has become a mainstay in the agricultural economy of several Caribbean countries and Brazil. World production of sugar usually exceeds 25,000,000 tons. The spent canes, bagasse, are used as fuel for boilers and in making fibreboard.

Sugar cane is typically propagated by planting sections of stems. Modern machines have been used for planting and cutting. Often the plants are set afire to eliminate foliage on mature canes, facilitating harvest by cutting machines. Juice extracted from cut canes is concentrated to molasses by boiling, from which the sugar crystals are centrifuged out prior to refining (see SUGAR: *Sugar Cane*).

Bamboo, *Arundinaria*, canes have been used, like rattan, for construction in the orient; for the familiar fishing poles, porch furniture and plant supports; and (split) for weaving and binding. Bamboos are the largest members of the grass family, some species attaining heights of more than 100 ft. Bamboo cane has never attained the importance in the western world that it has in the orient (see also BAMBOO).

Rattan cane comes from the long trailing stems of climbing palms, especially species of *Daemonorops* and *Calamus*, exceedingly strong, tough and elastic. There are reports of stems reaching 600 ft., clinging to supporting jungle vegetation by hooklike spines on the petioles of the pinnate leaves. Canes are hand pulled from their lofty perches for harvest.

Stem sections have been used for walking canes (Malacca walking sticks), handles, in furniture and for basketry. Split, they are often woven into seats and backs, wickerwork, for garden type furniture.

Rattan is an important commercial item of Indonesia, exports from there reaching about 30,000 metric tons yearly. Rattan cane also finds native use for construction and binding. Plastics have supplanted canes for many industrial uses. (R. W. SY.)

CANEA (Gr. KHANIA), capital of Crete (since 1841) and of the *nomos* (prefecture) of Khania. The successor of the classical city Cydonia, it occupies the coast round the Bay of Canea (Kolpos Khanion) and the isthmus between that and Suda bay (Kolpos Soudhas). Pop. (1961) 38,268. The town returns five members to the assembly in Athens and is the seat of the governor general. As a port it has been largely superseded by Suda bay and Iraklion (Candia). It still exports, however, about a quarter of Crete's oil and wine and most of the island's citrus fruits. It is connected with Iraklion by a daily bus service and with Piraeus by regular boat services.

The Venetians fortified the town (which they named Canea) and built numerous churches, but the medieval buildings suffered severe damage during the German attack in 1941. The harbour and galley sheds, however, though originally far less inspiring than those of Iraklion, are now in much better condition. A Turkish bathhouse near the harbour is now an archaeological museum. Canea is the seat of a suffragan of the metropolitan of Iraklion and also has a Roman Catholic convent and a Jewish synagogue.

The city was captured from the Venetians by the Turks in 1646. After numerous revolutions the treaty of Khalepa (a suburb of Canea) was signed in 1878, granting various privileges to the Cretans. After the rebellion of 1897 Canea was occupied by detachments from the protecting powers. Eleutherios Venizelos was born at Mournies, a neighbouring village, and made Canea his headquarters during his rebellion in 1909. In 1941 the city was used first by the British and later by the Germans as their headquarters in Crete.

CANELONES, a department bordering Montevideo in southern Uruguay established in 1816; area 1,735 sq.mi., pop. (1954

est.) 224,446. The Montevideo market is the key to Canelones' flourishing economy. Its truck gardens, dairy and poultry farms, vineyards and cattle butchers supply products to the capital. Canelones' beach resorts Atlbntida and La Floresta, part of its 40-mi. coast line, and the racetrack at Las Piedras attract visitors from Montevideo. Proximity to the capital city has raised land values and encouraged land subdivision in Canelones, and loss of land fertility has been an indirect result. The departmental capital, Canelones (pop. [1954 est.] 24,900), is an agricultural trading centre with a flour milling industry: (M. I. V.)

CANEPHOROS (CANEPHORUS, CANEPHORA), one of the Athenian maidens of noble birth chosen annually to carry on their heads baskets with sacrificial implements at the Panathenaic and other festivals. The word (meaning "basket bearer") is applied in architecture to carved figures of either sex carrying baskets on their heads or shoulders and used either as caryatids (*see* CARYATID) or decoratively, as in many Italian Renaissance villas. A canephoros sometimes appears as a subsidiary figure in Italian 15th- and 16th-century paintings.

CANE RAT, a rodent of the hystricomorphic genus *Thryonomys*. The two species (long-tail, *T. swinderianus*; short-tail, *T. gregorianus*) occur in the warmer parts of central Africa. These "rats" (Boer *rietmuis*) have stocky bodies 12 to 20 in. long: short rounded ears; and coarse, spiny but flexible brown hair. The nipples, which are high on the sides, permit the young to suckle when the mother lies prone. They inhabit swamps and thicketed river banks, swimming and diving with ease. They are nocturnal and omnivorous. (K. R. KN.)

CANE SUGAR: *see* SUGAR.

CANES VENATICI (the Hounds or the Greyhounds), in astronomy, a constellation of the northern hemisphere named by Johannes Hevelius in a work posthumously published in 1690. He compiled it from the stars between the older asterisms *Ursa Major*, *Bootes* and *Coma Berenices*. The constellation contains a famous spiral nebula.

CANINE DISTEMPER: *see* DISTEMPER, CANINE.

CANISIUS, SAINT PETER (PETRUS KANIS) (1521–1597), Jesuit scholar and strong opponent of Protestantism, was born in Nijmegen, Holland, on May 8, 1521. He was educated at Cologne and, after becoming a Jesuit in 1543, taught successively at the universities of Cologne, Ingolstadt and Vienna, and himself founded colleges at Munich (1559), Innsbruck (1562), Dillingen (1563), Würzburg (1567), Augsburg and Vienna.

Perhaps more than any of his contemporaries, Canisius delayed the advance of Protestantism by his participation in the religious discussions at Worms (1557), at the Council of Trent and the diet of Augsburg (1559), by his friendship with the emperor and numerous magnates, by his zealot preaching in various German towns, by the extension of his own order and especially by his desire to provide worthy and scholarly priests. His most influential work was the triple catechism (1555–58), which contained a lucid exposition of Catholic dogma.

In 1580 he settled in Freiburg, Switz., where he had founded a Jesuit college, and died there on Dec. 21, 1597. He was canonized in 1925, and declared a doctor of the church. His feast is kept on April 27.

See J. Brodrick, *St. Peter Canisius* (1935). (J. P. BK)

CANIS MAJOR (the Greater Dog), in astronomy, a constellation southeast of Orion. It is situated across the Milky Way from *Canis Minor*, the Lesser Dog. The two Dogs are represented in old celestial picture books (*see* CONSTELLATION) as accompanying Orion in his conflict with *Taurus*. Some diversion of their interest is suggested, however, by the presence of *Lepus*, the Hare, immediately south of Orion.

Canis Major presents no distinctive geometrical figure; it consists of the brilliant *Sirius* (*q.v.*) and other stars generally to the south of it. *Sirius*, the Dog star, the brightest star in the heavens, appears in the south in the early evenings of late winter for observers in middle northern latitudes. It is situated nearly on the extension to the southeast of the line of the three stars of Orion's belt. *Sirius* occupies one vertex of a large equilateral triangle, of which the other two vertices are marked by *Procyon*, the Little

Dog star, and the red star *Betelgeuse* in *Orion*. For observers as far south as *St. Louis, Mo.*, *Sirius* comes up high enough in the south so that *Canopus*, in *Carina*, the second in brightness of all the stars, can be seen near the horizon below *Sirius*.

The Epsilon star of *Canis Major* ranks last in the list of 22 stars brighter than visual magnitude 15. *Beta Canis Majoris*, west of *Sirius*, gives its name to a class of variable stars that pulsate in periods of only a few hours (R. H. RR.)

CANITZ, FRIEDRICH RUDOLF LUDWIG, BARON VON (1654–1699). German poet and diplomat, one of a group of court poets who prepared the way for the ideas of the Enlightenment, was born at Berlin, Nov. 27, 1654. After traveling in Europe he was made a privy counselor by the elector Frederick III in 1697, and the emperor Leopold I created him a baron of the empire. Canitz died at Berlin, Aug. 11, 1699. His satires (*Nebenstunden unterschiedener Gedichte*, 1700) are dry and stilted imitations of French and Latin models, but helped to introduce classical standards of taste and style into German literature. He is also the author of a well-known hymn, translated as "Come My Soul, Thou Must Be Waking."

CANKAR, IVAN (1876–1918), an outstanding Slovene writer and patriot, was born at Vrhnika, May 10, 1876. After a childhood spent in poverty he went to Vienna to study engineering, but soon abandoned this to earn his living by his writings, which defended the oppressed and made satirical attacks upon those who exploited them. He returned to Slovenia in 1907. Cankar was a prolific writer of short stories, novels, articles, drama and verse; he was also a political speaker and was imprisoned for criticism of the Austrian regime. In spite of its tendentious nature his work has great artistic value and reveals an original style—simple, yet eloquent, subtle and melodious. He died at Ljubljana on Dec. 11, 1918.

Cankar's collected works were edited by Izidor Cankar in 20 volumes (1925–36). His *Hlapec Jernej in njegova pravica* was translated as *The Bailiff Jerney and His Rights* (1930). (V. J.)

CANKIRI (anc. GANGRA, also GERMANICAPOLIS after the emperor Claudius Germanicus) the chief town of the *il* (province) of Cankiri in northern Turkey, lies about 60 mi. N.E. of Ankara in the rich, well-watered valley of the *Ulu* river, a tributary of the *Kizil Irmak*. Pop. (1960) 20,009. The town contains modern buildings and the army school of infantry.

Gangra, the capital of the Paphlagonian kingdom of Deiotarus Philadelphus, son of *Castor*, was taken into the Roman province of *Galatia* on his death in 6–5 B.C. The earlier town was built behind the modern one on the hill, on which are the ruins of a late fortress; but the Roman city occupied the modern site. In early Christian times Gangra was the metropolitan see of Paphlagonia. At the synod of Gangra, held in about 350, the practices of *Eustathius* (of *Sebaste*?) and his followers (who contemned marriage, disparaged the offices of the church, held conventicles of their own, wore peculiar dress, denounced riches and affected especial sanctity) were condemned by 21 bishops. The 20 canons of Gangra were declared ecumenical by the Council of Chalcedon, 451.

The *il* of Cankiri is on the northern border of inner Anatolia. Pop. (1960) 241,953. Area 3,310 sq. mi. It is mostly a steppe, its undulating plains and low hills being devoted to cereals or stock raising (especially *Angora* goats), which provide the main occupations of the people. In the valleys, orchards, vineyards and rice fields are cultivated. Salt mines are worked near the town of Cankiri. (N. Tu.; S. Er.; E. Tu.)

CANNAE, an ancient village of *Xpulia* in Italy, on a hill above the right bank of the *Aufidus* (mod. *Ofanto*) river, 4 mi. S.W. of its mouth and about 6 mi. downstream from *Canusium* (mod. *Canosa di Puglia*), celebrated for *Hannibal's* victory over the Romans there on Aug. 2, 216 B.C. Later it became a municipium, and Roman remains survive on the hill of *Cannae* (Monte di *Canne*). In the middle ages it became a bishopric, but was destroyed in 1276.

The consuls of 216 B.C., *Lucius Aemilius Paulus* and *Gaius Terentius Varro*, acting in accordance with a senatorial decree, prepared to meet *Hannibal* in a pitched battle (for the military situa-

tion and for a plan of the battle *see* PUNIC WARS). They advanced to Cannae with perhaps 86,000 men; this is Polybius' figure, although Livy cites another tradition of 50,000–55,000. The Carthaginians had over 40,000 infantry and about 10,000 cavalry, of which a considerable proportion comprised Celtic recruits. The battle was fought on level ground beside the Aufidus near Cannae, but the precise position is uncertain. Attempts to place it either upstream from Cannae or near the hill of Cannae should be rejected. Two main theories prevail, placing the site (1) on the left (*i.e.*, north) bank, or (2) on the right (south) bank. The latter, which on balance seems more probable, is accepted here. Reports that the Romans were hampered by the rising sun and by a south-east wind have been used to help in establishing the position of the troops, but the former is denied by Polybius and the second is not decisive, any more than are suggestions about a possible change in the course of the Aufidus. Nor does the discovery in 1937 of large-scale burials help, since the date of the numerous skeletons remains uncertain but is probably medieval.

While Hannibal was encamped probably on the right bank near Cannae, the Romans camped on the other bank about three miles lower down, and then established a smaller camp as an outpost on the right bank. In order to provoke battle Hannibal then transferred camp to the left bank, but this challenge was refused, and the Romans in turn offered battle on the right bank. They faced southwest, with their right wing resting on the river, and with the sea about three miles in their rear. They placed their cavalry (about 6,000) on their wings, and massed their infantry in an exceptionally deep (and therefore narrow) formation in the centre in the hope of breaking the enemy centre by weight and push. To counter this, Hannibal relied on the elasticity of his formation. He stationed his Gallic and Spanish infantry in the centre, two groups of his African troops on their flanks, and the cavalry on the wings. But before engaging the enemy, his line adopted a crescent shape, the centre advancing with the African troops on their flanks *en échelon*. As he anticipated, his cavalry won the struggle on the wings, and some then swept round behind the enemy. Meanwhile the Roman infantry gradually forced back Hannibal's centre, and victory or defeat turned upon whether the latter held. It did: although it fell back, it did not break, and the Roman centre was gradually drawn forward into a trap. Hannibal's crescent had now become a circle: the African troops, past whom the Romans were now thrusting, turned inward against them, and the Carthaginian cavalry was in the rear. Massed together and unable properly to use their arms, the Romans were surrounded and cut to pieces. Only 14,000 men escaped, together with 10,000 who were captured. The dead included Aemilius Paulus, but his colleague survived: Varro has in fact been made the scapegoat for the defeat which the senatorial tradition attributed to the rashness of a "new man" (Varro's father had been a merchant). Much of central and southern Italy now went over to Hannibal, but Rome refused to admit final defeat, although it could not fight another pitched battle until it had eliminated the chief cause of the defeat, the rigidity of the legionary formation. Cannae has long been regarded by military historians as a classic example of victorious double envelopment.

CANNAN, EDWIN (1861–1935), British economist whose chief services to economic theory were on the theory of money, on questions of demography and in clarifying and modernizing the theory of supply and demand as laid down by Adam Smith. He was born at Funchal, Madeira, Feb. 3, 1861. After studying at Clifton college and Balliol college, Oxford, he became lecturer in political economy in London university in 1897. From 1907 until his retirement in 1926 he was professor of political economy. He died at Bournemouth on April 8, 1935.

Cannan's principal works were *History of the Theories of Pro-*

duction and Distribution (2nd ed., 1903); *History of Local Rates in England* (2nd ed., 1912); *Wealth* (3rd ed., 1928); *Money* (7th ed., 1932); and the standard edition of Adam Smith.

See his *An Economist's Protest* (1928); and an introduction by Hugh Dalton to *London Essays in Economics in Honour of Edwin Cannan* (1927).

CANNANORE, a town in Kerala, India, headquarters of Cannanore district, is on the west coast line of the Southern railway, 83 mi. S. of the line's terminus at Mangalore. Pop. (1961 est.) 46,100. It is a small roadstead port on the Arabian sea, exporting copra and coir. The town has large spinning, weaving and hosiery mills.

Cannanore was an important emporium of trade with Persia and Arabia in the 12th and 13th centuries A.D. Until most of the independent south Indian principalities disappeared in the 18th century Cannanore was the capital of the Kolattiri raja, the chief rival of the zamorin or ruler of Calicut. Vasco da Gama visited it in 1498 and a Portuguese fort was built there in 1505. The present fort was built by the Dutch in 1656 and sold to Ali Raja in 1771. In 1783 Cannanore was captured by the British and the ruler (then a princess) became tributary to the East India company. It was the British west coast military headquarters from 1709 to 1887 when these were moved inland to the Nilgiris (*q.v.*).

CANNANORE DISTRICT was formed in 1958 from six subdivisions of the former Kasaragod and Malabar districts. Pop. (1961) 1,779,852. Area 2,741 sq.mi. (G. R.N.)

CANNEL COAL, formerly called candle coal because of the appearance of the flame and because it can be lighted easily, is a massive, noncaking, fine-grained block coal with a conchoidal fracture found to a limited extent in Lancashire, Eng., and in Virginia, West Virginia, Tennessee, Kentucky and Pennsylvania in the United States. Cannel coal is used as a fuel in fireplaces; it has little industrial use. *See* COAL AND COAL MINING.

(M. D. Cr.)

CANNES, a fashionable resort and tourist centre of southern France, lies on the Mediterranean sea, 16 mi. S.W. of Nice, in the *dkpartement* of the Alpes-Maritimes. Pop. (1954) 40,540. Apart from its climate, that of the Côte d'Azur (French Riviera), the town has the advantage of being sheltered by hills. Its roadstead is a port of call for transatlantic liners and yachts. There are beaches of fine sand and luxuriant subtropical vegetation. The town has extended on both sides of the original village on the slopes of Mont Chevalier, where there still stand a 12th-century tower and a chapel. On the Promenade de la Croisette, which follows the curve of the coast, are the big hotels, and the Palais des Festivals in which the annual international film festival takes place. There are two casinos. The town is linked with Paris by the southeast highway, and by rail with Paris and with neighbouring countries. Most of the important airlines serve the Nice airport. The tourist industry is the principal occupation, but flowers, especially mimosa, are exported all over the world.

Little is known of the early history of Cannes before 1834, when Lord Brougham decided to settle there. It was probably founded in the 8th century B.C. by Ligurian tribesmen and occupied successively by Phocians, Celts (or Gauls) and Romans. In the 4th century A.D. it came under the protection of the monks of LCrins, whose abbots were lords of Cannes. In 1763 Tobias Smollett found it "a little fishing town, agreeably situated on the beach of the sea"; and Napoleon, on the first night of his return from Elba, bivouacked with his little army beneath the old village. There are numerous reminders of history in the offshore Lérins Islands: "the man in the iron mask" (possibly Count Mattioli or Eustache Dauger; *see* IRON MASK) and Marshal Bazaine, among others, were imprisoned in Ste. Marguerite; and in the smaller island of St. Honorat there are a Cistercian monastery and 5th-century chapel, and on a promontory a fortified tower facing to seaward.

CANNES, CONFERENCE OF (Jan. 6–13, 1922), a meeting of the supreme council of the Allies with the primary object of considering Anglo-French suggestions for World War I reparations, drafted at the preliminary conference of London, Dec. 18–22, 1921 (*see* LONDON, CONFERENCES OF; REPARATIONS).

The conference opened with a criticism of the Anglo-French sug-

gestions by the French minister of finance, who was supported by the Belgian representative. After long and complicated discussions this resulted in a modification of the London suggestions, and representatives of Germany, as well as the Reparation commission, were summoned to Cannes to make proposals on the basis of the agreement finally reached between the Allies.

But wider questions of security and reconstruction were broached by David Lloyd George in a memorandum submitted to Aristide Briand on Jan. 4, which declared that the three problems of reparations, security and reconstruction were interrelated, and that any general scheme for European reconstruction must include Russia; and in which he offered to conclude an agreement by which Great Britain would pledge itself to assist France with all its forces in the event of unprovoked German aggression upon French soil. Lloyd George warned Briand that the British empire would not be willing to incur military commitments in central and eastern Europe.

On Jan. 6 Lloyd George proposed the summoning of a general reconstruction conference to which both the U.S.S.R. and the U.S. were to be invited, and this proposal was adopted by the supreme council, together with an outline agenda. Meanwhile Briand had been making counterproposals respecting the Anglo-French pact. The guarantee must be reciprocal and supplemented by a technical military convention. This second condition would probably have proved an insuperable obstacle from the British point of view, but Briand was violently attacked in the French senate and chamber in the belief that he was giving way unduly to Lloyd George. As a consequence he resigned on Jan. 12, and therewith the conference came to a premature close. Its main results were the provision for the Genoa conference (*q.v.*) in April and the avoidance of a deadlock over reparations.

See British White Paper, *Resolutions Adopted by the Supreme Council at Cannes, Jan. 1922, as the Basis of the Genoa Conference*, Cmd. 1621 (1922); A. J. Toynbee, *Survey of International Affairs, 1920-23* (1925).

CANNIBALISM. The eating of human flesh by men is a widespread custom, going back into early human history and found among peoples on most of the continents. The term is derived from a Spanish form of *Carib*, a West Indies tribe who were famous cannibals; the Greek term "anthropophagy" is also used.

Many of the early accounts of cannibalism are undoubtedly exaggerated or in error, since many peoples attributed the practice to their enemies. But cannibalism is still practised in interior New Guinea and prevailed until recently in parts of west and central Africa, Melanesia (especially Fiji), Australia, among the Maori of New Zealand, in some of the islands of Polynesia, among tribes such as the Batak of Sumatra, and in various tribes of North and South America.

In some regions human flesh was looked upon as a form of food, sometimes equated with animal food as in the Melanesian pidgin term "long pig." Much of Melanesian cannibalism was apparently of this type, and Fijian chiefs sometimes kept count of the number of individuals consumed. The victorious Maori cut up the dead after a battle and used them for feasting. The Batak were reported to sell human flesh in the markets before full Dutch control.

In other cases, however, the consumption of particular portions or organs was a ritual means by which certain of the qualities of the person eaten might be obtained, or by which powers of witchcraft or sorcery might be employed. Ritual murders and cannibalism in portions of Africa are often related to the practice of sorcery. And head-hunters and others often consumed bits of the bodies or heads of deceased enemies as a means of absorbing their vitality or other qualities and reducing their powers of revenge. (See **HEAD-HUNTING**.)

In some cases a deceased individual is ritually eaten by his relatives, a form called endocannibalism. In portions of aboriginal Australia such practices occurred as an act of respect, the bones being kept for a period. In other cases ritual cannibalism occurs as a part of the drama of secret societies. In the famous Cannibal society of the Kwakiutl, the novice who is possessed by the cannibal spirit eats the flesh of a corpse or bites a piece out of the arm of a living person before being subdued and returned to a

normal state. But such dramas were carefully staged for their effect on the audience; both the Kwakiutl and their neighbours had an actual horror of eating human flesh.

In the interior of North America, where Indian tribes lived on the margins of subsistence, cannibalism was an ever-present possibility. Occasional individuals among the Ojibwa developed a psychosis involving the desire to eat human flesh, a condition greatly feared and thought to be brought about by the windigo, or cannibal giant, who was believed to reside in the woods.

Perhaps the most graphic account of cannibalism in existence is Hans Staden's 1557 account of his captivity among the Tupinamba Indians of eastern Brazil. There captives might be adopted and marry, until the day came when they were to be killed and eaten. They were fed and treated well, and even knowing their eventual fate they did not attempt to escape. On the appointed day the victim was killed with a club and the women participated in the preparation and the eating of the body.

The eating of human flesh, even where primarily for food, always involves special utensils or some ritual restrictions. There are no completely satisfactory explanations of cannibalism. Groups closely related often have radically different reactions, and a group may practise cannibalism at one period and view it with horror at another.

The practices of head-hunting, human sacrifice and ritual cannibalism seem to be linked in various areas, particularly in west Africa, Indonesia and South America. Often they are interchangeable or occur in adjacent groups; and frequently they have a general relation to fertility and group welfare.

The spread of western values and controls usually results in the prohibition of such practices before they are adequately studied. In modern society cannibalism occasionally occurs as the result of extreme necessity; the case of the Donner party crossing into California in the 19th century is such an instance.

(F. R. E.)

Lower Animals.—Cannibalism, in its broadest sense the eating of animals by other members of the same species, is common at all levels among the lower animals. The only necessary condition for cannibalism to occur is that some life stage of the organism fits within the range of food material of the species. Fertilized eggs or minute free-swimming larvae, for example, may fall prey to their own parents who subsist on minute organisms filtered out of the surrounding water. One of the more spectacular cases is the praying mantis, where the female devours the male during the mating process. Any carnivorous or omnivorous form is likely to be cannibalistic unless specific behaviour patterns contrary to cannibalism have evolved within the group. In some groups of birds and mammals which have evolved to what might be termed the family level of social behaviour, adverse conditions such as starvation or illness or injury of an animal may bring about a reversion to cannibalistic habit.

Under conditions of crowding, cannibalism is sometimes a powerful force for regulating the size of a population, a force that is greater when the population is relatively dense. In the flour beetle *Tribolium* the larvae and adults cannibalize the inactive stages, the egg and pupa. In a spatially limited environment at realistic densities of adult beetles, observations have shown that egg mortality caused by cannibalism alone can exceed 96% over a period of time equal to the duration of the egg stage. In this particular organism, this is the greatest single force regulating population growth, and thereby the degree to which the population exploits the environment. There have been no convincing data involving cannibalism as an important regulating force in a natural population. Rather it would appear that the event of an animal eating another member of its own species is largely a coincidence and, under suitable circumstances, not an unexpected one. The case of cannibalism as a specific behaviour pattern is a rather rare exception.

(E. R. R1.)

(F. R. E.)

CANNING, CHARLES JOHN CANNING, EARL (1812-1862), English statesman, who was governor general of India at

the time of the Indian Mutiny (*q.v.*), subsequently became the first viceroy of India and played an important part in the work of conciliation and reconstruction. He was born in London on Dec. 14, 1812, the youngest son of George Canning, succeeding in 1837 to the viscountcy created for his mother after his father's death. He served under Sir Robert Peel as undersecretary for foreign affairs and as commissioner of woods and forests, and under Lord Aberdeen as a successful reforming postmaster general (1853-55). Offered the governor generalship of India by Lord Palmerston in 1855, he took office in India in Feb. 1856.

His dispatch of an expedition to the Persian gulf in 1856 secured the Persian abandonment of Herat and the friendship of Dost Mohammed, ruler of Afghanistan. This friendship, consolidated by a treaty in 1857, proved invaluable when the Mutiny broke at Meerut in May 1857, for Canning, with small British forces eccentrically disposed, had soon to contend with rebels who held much of north India.

Canning was not an obvious leader: he combined great industry with an inability to delegate responsibility, his moral integrity involved him in overnice scruple. He lacked the dash, the feeling for public relations immediately required. But his stature grew with the danger. He was prompt to gather reinforcements, including troops on their way to China, and to hurry them up-country. He grasped the overriding importance of retaking Delhi and Lucknow, of not abandoning Peshamar. Above all he had the vision to look beyond the Mutiny—whence his insistence upon "deliberate justice and calm patient reason." He was severe. He brusquely rejected amnesty proposals made by John Colvin, John Lawrence and James Outram. But while in England people were "rabid with desire of indiscriminate vengeance" and in Calcutta British civilians were clamorous for wholesale punishment and wholesale distrust of all Indians, Canning convinced Indians that his purpose was conciliation, not vengeance. To him, the first viceroy, appropriately fell the task of announcing in Nov. 1858 the queen's offer of mercy, of impartial favour to all races, of respect for religion and hereditary title.

After the Mutiny Canning presided over the reorganization of the Indian government which had now passed from the British East India company to the crown. By the Councils act of 1861 he reorganized his executive council, substituting for collective action a departmental division of responsibilities. He enlarged his legislative council, making room for Indian nonofficial members. Though he restored legislative councils to the presidencies, he retained, through his law member and council, the right to legislate for all India and passed with their aid three great codes, including the remarkable penal code. He remodeled the Indian army, strengthening the European element and taming the sepoys by division. More Sikhs, Muslims and Gurkhas were recruited, and the Hindus were divided into caste companies. He pressed forward railway development. By his successful measures in 1861 he showed the possibility of famine relief. Education he encouraged: Calcutta, Bombay and Madras universities had been founded during the Mutiny, grants-in-aid followed for private colleges. By the Bengal rent act he protected tenants against eviction or undue rent enhancements, and he intervened to prevent their exploitation by European indigo planters.

Only in Oudh, where in 1858 he had alarmed everyone by declaring all land confiscated, did he introduce a land-revenue settlement unduly favourable to landlord interests. The motive was political, a wish to win over the influential landlords, to make them what the princes had proved to be, "breakwaters against the storm," junior partners under the crown in empire.

Lady Canning died in Nov. 1861. In March 1862 Canning left India, broken by overwork and grief. He died in London on June 17, 1862.

See Sir H. S. Cunningham, *Earl Canning* (1891). (J. B. HA.)

CANNING, GEORGE (1770-1827), British statesman, who was prime minister for a short time during 1827, is chiefly remembered for his liberal policy as foreign secretary from 1822 to 1827. He was born at London on April 11, 1770. His father, also named George, was the eldest son of a country gentleman with a large estate in County Londonderry, Ire. In May 1768, four years after

being called to the bar, Canning senior married a beautiful but penniless girl, Mary Ann Costello, against the wishes of his father, who disinherited him. He died on April 11, 1771, leaving his wife and year-old son entirely destitute. The widow became an actress to support herself and her son, and became the mistress of the actor Samuel Reddish, by whom she had five children. Later (Feb. 11, 1783) she married another actor, Richard Hunn, and by him too she had five children, but this new connection did nothing to rescue her from discredit and misfortune. From this unsatisfactory environment the boy was taken by a wealthy uncle, Stratford Canning, who brought him up with his own children.

Canning was educated at Hyde Abbey school near Winchester, at Eton and at Christ Church, Oxford. After graduating (1791) he entered himself at Lincoln's Inn, but soon decided on a political career. Hitherto his views had been distinctly Whiggish, under the influence of R. B. Sheridan and Devonshire house, but in July 1792 he came under the influence of William Pitt, who undertook to find him a seat in parliament. Moreover, the progress of the French Revolution toward anarchy and violence at home and aggression abroad cured him of his leanings toward constitutional change. He was elected for the pocket borough of Newtown, Isle of Wight, in July 1793, and he quickly became recognized as one of the rising men on the government side of the house. Pitt further procured for him the undersecretaryship of state for foreign affairs in 1796. Though the work was "pretty hard and constant" he found time to contribute to the *Anti-Jacobin* (1797-98), a weekly paper started to ridicule both English and French republicans. In 1799 he left the foreign office and was appointed a commissioner of the board of control. In May 1800 he was promoted to the office of joint paymaster of the forces and made a privy counselor. A few weeks later he married Joan Scott (with a fortune of £100,000), whose sister was the wife of the duke of Portland's son Lord Titchfield. By her he had four children, including Charles John, Earl Canning, a governor general of India. Mrs. Canning (d. 1837) was created Viscountess Canning in 1828.

When Pitt resigned in 1801 Canning too went out of office. Disapproving of Pitt's support of Henry Addington (later Lord Sidmouth) he made himself independent in 1802 by giving up Wendover, for which he had sat since 1796, and buying an Irish rotten borough, Tralee, "the freest seat that the market could afford." In 1803 Pitt began to turn against Addington, and Canning could then go into open opposition without forfeiting Pitt's friendship. On the formation of Pitt's last ministry (May 1804-Jan. 1806) Canning became treasurer of the navy, but his unpopularity (his biting wit made him many enemies) kept him out of the cabinet. Much to his disgust his colleagues resigned after Pitt's death because of the insecurity of their parliamentary position, but in March 1807 the king dismissed the "ministry of all the talents" on the Catholic question, and called upon "the friends of Mr. Pitt" again to form a government. Canning became foreign secretary but his rival, Spencer Perceval, was now leader of the house of commons.

Canning's first tenure of the foreign secretaryship witnessed the seizure of the Danish fleet (his own brilliant planning), the beginning of the Peninsular War and the unfortunate expedition to the Scheldt. Holding Viscount Castlereagh, the war secretary, responsible for the disasters that overtook British arms at Corunna, Spain, and Flushing (Holland), Canning, in 1809, insisted on his dismissal. They quarreled, and fought a duel on Sept. 21, Canning being wounded in the thigh. Both had already resigned, Canning because of the nonfulfillment by the duke of Portland, the dying prime minister, of his promise that Castlereagh should be removed from the war department. Canning offered to form a government, but the king called upon Perceval, and Canning remained out of office until 1816. Lord Liverpool, who succeeded to the premiership in 1812 on Perceval's assassination, tried hard to induce Canning to take office, the negotiations breaking down in July because Canning refused to allow his old rival Castlereagh (who generously offered to surrender the foreign secretaryship to him and to take the inferior office of chancellor of the exchequer) to retain the leadership of the house of commons. So Canning lost the chance of being the peacemaker of Europe in 1815, and he further

damaged his reputation in 1814 by accepting what was believed to be a rich sinecure, the Lisbon embassy.

Two years later he entered the cabinet as president of the board of control, and under his direction the marquess of Hastings extirpated the Pindaris and established British supremacy in central India by defeating the Marathas. Canning, disapproving the government's proceedings against Queen Caroline, resigned in Dec. 1820. In the hope of improving his financial position, and believing that advancement at home was blocked by the king's hostility to him, he accepted the governor generalship of Bengal in March 1822, with the additional prospect of a peerage on his return, but, before his ship was ready to sail, Castlereagh committed suicide (Aug. 12), and George IV reluctantly acquiesced in Canning's succession to the "whole inheritance"—the foreign secretaryship and the "lead" of the house of commons. He was now the most important member of the government. Afraid of becoming too deeply involved in continental politics, and disliking the great despotic sovereigns who were anxious to suppress liberal movements everywhere, he cut England adrift from the so-called Holy Alliance in 1823; prevented European intervention in South America on behalf of Ferdinand VII of Spain; recognized the independence of the rebellious Spanish American colonies (and so "called the New World into existence to redress the balance of the Old"); sent an army to Portugal to meet the threat of attack by Spain; gave diplomatic support to the Greeks in their struggle for freedom; and ensured the eventual creation of an independent Greek state.

Lord Liverpool's premiership came to an end on Feb. 17, 1827. He had long since marked out Canning as his successor, but it was far from obvious that he would be the king's choice. Although since 1822 he had gained a remarkable ascendancy at Windsor by the success of his foreign policy and by a judicious attention to the royal intimates there, Canning was the leading advocate of Catholic emancipation, and George IV had been persuaded that the cause of the monarchy was linked with that of the Established Church and resistance to the Catholic claims. Peel and Wellington, the leading opponents of Catholic relief, knew that no government could be formed without Canning, and Canning refused to serve under another anti-Catholic premier. Finally, on April 10, he was authorized to reconstruct the ministry on the understanding that the royal conscience was not to be forced. Moved partly by personal animosity, partly by dislike of Canning's advocacy of Catholic emancipation, half the cabinet refused to serve under him, and, in all, more than 40 ministers and placemen resigned, but the Whigs came to his assistance, and most of the independent members of parliament supported him with their votes. His ministry, however, lasted only four months; his health broke down under the strain, and he died on Aug. 8 at Chiswick in the house of the duke of Devonshire (but not in the same room, as is sometimes stated, as that in which Fox had breathed his last, 21 years earlier).

Character and Achievements.—Canning had all the irritability of the artistic temperament which he probably owed to his mother. To some, especially to his intellectual inferiors, he seemed arrogant and contemptuous. His wit and sarcasm were remembered by all who heard or read his speeches. Wellington thought him the finest speaker he had ever heard; he was probably, indeed, not inferior to Pitt. He was the most indefatigable of men, often working from breakfast until late at night without food, and this long-continued irregularity, his friends believed, rendered an irritable temperament still more uncontrollable. The world tended to misjudge his character from his defects, and overlooked his energy, patriotism and outstanding abilities. He could never forget his ambitions, but even his enemies like Metternich, who lamented the "mischief" he did as foreign secretary, had to admit that he was a great man. It was the fashion to say of him that he was no gentleman. The hatred and malignity with which he was assailed by the Tory aristocracy in 1827 showed what mountains of prejudice still existed against a prime minister born outside the purple of the governing class. Lord Grey declared that the son of an actress was incapacitated *de facto* for the premiership. Lord Londonderry spoke of him as a charlatan parvenu, "mother Hunn's

offspring." In choosing Canning as prime minister George IV found that he had to fight over again his father's battles against the pretensions of the great families to deprive the crown of its ancient and undoubted right to nominate its servants.

Contemporaries said that Canning's ministry was the most popular with the middle classes that had ever been known. As member for Liverpool (1812–22) he came fully to recognize the needs of the rising commercial and industrial interests. He and William Huskisson taught a large portion of the Tory party to take a more liberal view of many measures of domestic, colonial and foreign policy. Although the ablest and sincerest opponent of parliamentary reform, he largely contributed to the creation of that independent and liberal spirit among the younger members of the house of commons, without which the Reform bill could not have been carried without a revolution. Charles Greville thought Canning the only man capable of saving the unreformed parliament and the old order in general, but, far from recognizing him as their saviour, the Tory aristocrats hunted him to death "with their besotted and ignorant hostility." Some of his friends believed that, had he lived, he would have supported parliamentary reform in 1831, thereby taking the question out of the hands of those who were disposed to push reform as far as revolution. Lord Granville said that Canning "sought to avoid revolution, not by stubborn resistance to all movement and reformation, but by rendering the acts of the government conformable to the spirit of the times."

He put his country before personal or party interests. Nothing but a sense of public duty induced him to take the foreign secretaryship in 1822: "I take no joy, and I feel none. I have sacrificed my interests, my wishes, and I believe my happiness, but I hope I have done my duty." None of the party leaders of the time had more generous notions of the obligations that he owed to his supporters. He never thought he could do too much for his friends, but he never used his influence to secure undeserved promotion for them. They, for their part, were drawn to him by bonds of intense personal devotion, and, through his disciples, like William Huskisson and Lord Palmerston, he wielded an authority that endured beyond the grave. Like other public men of the day, he died much poorer than he would have been but for his long official career. His wife's fortune of £100,000 had shrunk to about £40,000 in 1827.

CANNING, COMMERCIAL. The history of canning goes back to 1795, when the French government offered a prize of 12,000 fr. for the discovery of a practical method of food preservation. France was in the grip of a revolution at home and at the same time was at war with several hostile European nations. Consequently, the need for adequate food supplies for its army and navy was acute. It was not until 1809 that Nicolas (François) Appert, a Parisian confectioner, succeeded in preserving certain foods in especially made glass bottles that had been kept in boiling water for varying lengths of time. Although there is one earlier reference in literature to the inadvertent preservation of food by heat sterilization (L. Spallanzani, 1765), credit for the discovery of the canning process is given to Appert. In the following year, 1810, his work was made known publicly in a treatise entitled *Art de conserver les substances animales et végétales*. The grateful government awarded Appert the prize.

The underlying principle of the various methods of food preservation is basically the same: the development of conditions within a food—temporary or sustained—that are unfavourable for the growth of spoilage organisms. Thus, for example, if a food be chilled, heated or desiccated, or if it be made excessively acid, it

immediately becomes an unfavourable medium for the development of microorganisms.

In commercial canning, carefully prepared raw food is placed in a sealed container, then is subjected to definite elevated temperatures for the proper period of time and finally is cooled. Heating the contents of the can produces an unfavourable temperature environment for spoilage organisms that may be present in the food; consequently such organisms are destroyed and their growth inhibited. Reinfection of the food by spoilage organisms in the air is prevented by the permanent seal of the can. This is the basic principle of commercial canning.

It was by patient trial and error in his experiments that Xpert was able to devise directions for conserving the many products listed in his treatise. He could give no logical explanations for the effects of canning. He believed, however, that the application of heat to a sealed container, together with the exclusion of air, combined to retard or eliminate the process of decomposition. Science was of little assistance, since chemistry was in its infancy and bacteriology was unknown. It was half a century later—about 1860—that the true causes of food spoilage came to be understood as a result of Pasteur's work.

Knowledge of the industry was taken to the United States from England, and by 1820 William Underwood and Thomas Kensett were engaged in the commercial production of canned foods, in Boston and New York respectively, using the Appert process. It was not until 1839, however, that tin-coated steel containers (tin cans) came into widespread use in America. Peter Durand, an Englishman, conceived and patented the idea of using tin cans instead of bottles.

In 1895 Samuel C. Prescott and William L. Underwood, working together at the Massachusetts Institute of Technology, first traced spoilage of certain lots of canned corn to imperfect sterilization (heat processing). This early work was followed by that of Harry L. Russell, Andrew Macphail, Bronson Barlow and others. Organized research into the problems of the industry was begun by the U.S. department of agriculture and several universities, followed by the inauguration of the long-range programs of the National Canners association and of the research departments of the leading can manufacturers.

The phenomenal growth of the industry in the United States and throughout the world may be attributed (aside from the scientific approach) to the development of (1) the art of container manufacture of both tin cans and glass jars and bottles; (2) the canning processes themselves; and (3) canning machinery. The United States became the greatest producer and consumer of canned foods in the world.

The modern tin can, which is 98.5% sheet steel with a thin coating of tin, is manufactured on wholly automatic lines of machinery at a rate in excess of 300 cans per minute. The improvement of the tin can as the cheapest and most serviceable container for mass production was marked by the advent of the sanitary, or open-top, can about 1905-08. This development answered many of the canner's practical problems by eliminating the use of solder in sealing the can, and a perfect closure was guaranteed by the double seamed top and bottom. Differential coated electrolytic tin plate was used beginning in 1951 to save tin and better resist interior corrosion and exterior rusting. In a typical year the industry uses about 25,000,000,000 tin cans and glass jars. Containers of aluminum and of plastic material had by 1960 been found commercially feasible for a restricted number of products.

By the 1960s the U.S. annual pack of canned goods approximated 700,000,000 cases (24 cans to the case, equivalent). The greater part was vegetables, fruits, juices and specialties; milk, meat and fish were also well represented. Annual packs of fruit, fruit juices and vegetables ran as high as 9,000,000 cases in Australia, 26,500,000 cases in Canada, 7,500,000 cases in South Africa and 42,500,000 cases (fruit and vegetables only) in the United Kingdom.

Perhaps the greatest early obstacle to volume production was the time necessary for processing the filled cans of food in boiling water. With the discovery in 1861, by Isaac Solomon of Baltimore, that calcium chloride added to boiling water raised the temperature of processing from 212° to 240° F. or higher, the time

necessary to ensure relative safety in the process was reduced from 4 to 5 hours to a mere 25 to 40 minutes. Thus the average production in a first-class cannery was increased from 2,500 cans to about 20,000 cans per day. This innovation, together with the impetus given by the American Civil War requirements, brought almost immediate prosperity to the young industry. In the next decade an advance that outdated the above method was the invention in 1874 of the closed, steam-pressure retort by A. K. Shriver of Baltimore. The resultant high temperatures shortened the time necessary for processing and reduced accidents and spoilage to a new minimum.

In the meantime, hand labour in the cannery was being largely supplanted by semiautomatic and later by wholly automatic machinery, thus increasing output, reducing costs and permitting wider use of canned products. It is necessary to mention only a few machines such as the washers, graders, peelers, corn huskers and cutters, bean snippers and filling machines. After World War II electronic devices were increasingly used for regulating and controlling various operations.

Products Used in Canning.—Products available for canning include almost every fruit, vegetable, meat or marine product. In addition many specialty products are packed in smaller quantities. The location of the canneries is largely dependent on the growing areas of the product to be packed. As a great fruit-growing area, California is heavily represented. Other geographical areas are noted for a specialty; *e.g.*, Hawaii for pineapple, Alaska for salmon, etc.

In practice the relationship between grower and canner is particularly close, and the growing of crops for canning has become a highly specialized branch of agriculture. As a result of the work conducted by the federal and state departments of agriculture, state universities and by the canners themselves, great advances were made in many aspects of crop production. In order to secure uniformity in growing conditions and to ensure uniformity in the raw product, the local canner contracts with the neighbouring farmers for an acreage sufficient for the normal capacity of his cannery and either supplies or specifies the seed to be used. Planting dates may be so spread that the harvest period will be prolonged, enabling the facilities to be used more efficiently. In this way the canner is able to turn out a superior product that is grown from one type of seed, supervised during the growing period by qualified fieldmen and harvested at proper maturity. The time elapsed between picking and canning is seldom more than three or four hours.

Operations Employed in Commercial Canning.—The operations employed in commercial canning procedures depend upon the nature of the product being packed. There are, however, certain operations that are included wholly or partially in canning procedures for fruits, vegetables, milk, fish, meat or the so-called specialty or formulated products (soups, pork and beans, spaghetti, etc.). These operations may be grouped as follows:

Cleaning.—All raw materials used in canning must be thoroughly cleaned. Cleaning is usually effected by automatic passage of the raw-food material through tanks of water or under high-pressure water sprays. For certain products, washing machinery of special design is used (flotation washers for whole kernel corn and peas). It is essential that only potable water be used. Some products (peas, spinach) receive a dry cleaning by subjecting them to air blasts or to a shaking that removes inedible or extraneous materials prior to water washing.

Preparatory Operations.—These operations are quite varied in character, but all aim at the removal of inedible or undesirable portions of the food and conversion of the food into the desired or necessary form for subsequent canning operations. Preparatory operations include sorting, trimming, vining (peas), husking, cutting, silking (corn), size or maturity grading (peas), sectioning (citrus fruits), slicing, dicing, peeling and coring (fruits), pitting (cherries), soaking (dry beans, cherries), straining or pureeing (infant foods), extraction (fruit and vegetable juices), homogenization (milk, some juices or pureed foods), evaporation (milk), etc. Many of these operations are performed by special machinery; in other instances hand operations are required. These

operations either precede or follow other canning operations such as cleaning or blanching.

Blanching.—Some products (beets, carrots, spinach, peas) require a blanching by immersion in hot water or steam to shrink or wilt the product in order to obtain desired or legal weight in the final container and also to inactivate enzymes and thereby improve the colour and flavour of the product. Electronic heating, sometimes called dielectric heating, was used to some extent in the post-World War II period. The blanching must sometimes precede certain preparatory operations (peeling, slicing, dicing). Occasionally the necessary shrink must be obtained by a precook rather than by blanching (certain meat products). In addition to its other functions, blanching in certain products serves as an additional cleansing operation, removing objectionable flavouring materials acquired by some raw foods from inedible portions of plants (the vine flavour of peas).

Filling and Exhausting.—Automatic filling machines, which are adaptable to specific products or to types of products (solid, semisolid or liquid products) and capable of high-speed operation, are employed to place the prepared food in the can. The washed, open cans are mechanically conveyed to and from the filling machines. With some products (certain fruits, tomatoes) hand filling methods are used.

After being filled, the open cans containing the food, especially that of nonhomogeneous type, are usually thermally "exhausted" by passing them automatically through a hot-water or steam bath in an exhaust box. Thermal exhausting heats and expands the food and releases gases (carbon dioxide and oxygen) from the cells. Air is also excluded by expansion of the food; thus, after sealing, heat sterilizing and cooling the can, the contraction of the contents produces a partial vacuum in the container. Thermal exhausting may also be effected by heating the food before it is put into the cans (cream-style corn). Certain products (corn on the cob, coffee, salmon) are largely packed by the vacuum-pack method in which the cans are mechanically exhausted by specially designed vacuum-can sealing machines. These machines withdraw air and other gases from the cans by a high vacuum and seal the cans while they are still under vacuum.

Can Sealing, Closing or Double Seaming.—Special automatic sealing (closing or double seaming) machines capable of operating at various speeds (from 10 to 250 cans per minute, depending upon the can size and the nature of the product) are used to seal or close the covers on the sanitary type of can. The cans are usually mechanically conveyed to and from the sealing machine, where the covers are placed on the can automatically and the sealing operation completed. The curl on the can cover and the flange on the can body are first rolled into position and then flattened together. The thin layer of gasket material or compound originally present in the rim of the cover is dispersed between the layers of metal to ensure a hermetic seal on the container. As previously described, some vacuum closing machines of special design mechanically exhaust the can just before the double seam is formed; other special types of closing machines seal cans in an atmosphere of an inert gas such as nitrogen, carbon dioxide or helium. The vent-hole types of cans (evaporated milk, certain meat products) are sealed on special tipping machines that close the vent hole with a small drop of solder.

Heat Sterilization or Thermal Processing.—This is one of the most important operations in the canning procedure and essentially consists of subjecting the food—usually contained in the sealed can—to a known temperature long enough to destroy spoilage and pathogenic organisms that might be present in or on the raw-food material. Canners follow time and temperature processing schedules established by laboratories associated with the canning industry. The heat treatments necessary to preserve canned foods are determined by a number of factors; important among these are the acidity, as expressed by pH, of the food or food product. The "acid foods"—with pH values of 4.5 or less—may be adequately processed by subjecting them to the temperature of boiling water (212° F. or 100° C.) for the proper length of time. The "nonacid foods"—with pH values higher than 4.5—must be processed at higher temperatures. Most commercial processing tem-

peratures for such foods fall in the range of 240° F. (116° C.) to 265° F. (130° C.). The processing temperature commonly employed, however, is 240° F. This temperature is attained by use of steam under pressure in a closed chest, or canner's "retort." Steam pressure of approximately 10 lb. corresponds to a processing temperature of 240° F.

Thermal processing equipment is of two general types: still retorts for batch operation and the so-called continuous cookers. Both types operate either at 212° F. for the acid foods or under steam pressure for the nonacid products; in either case the time of processing or "cooking" is regulated so as to subject the cans to the processing temperature for the proper length of time. Later processing installations included automatic retort controllers which regulate and record the process. In at least one U.S. state canners of nonacid products are required by law to equip their retorts in this manner. For specific products (such as evaporated milk) special processing equipment is available that either agitates or revolves the cans during the process cycle. The more acid type of foods and food products (e.g., berries and citrus fruits) may be sterilized by filling them into cans at certain temperatures and inverting the containers for a short period to sterilize the can covers while sterilizing the cans. This is also the underlying principle in the flash-sterilization method for preservation of acid food juices. For public health reasons antibiotics are not used in canning although extensive investigations have indicated that certain spoilage organisms are markedly affected by some antibiotics.

Cooling, Labeling, Casing and Storage.—Following thermal processing, the sealed cans are cooled in cold water or in air.

In water cooling, the hot cans are conveyed directly from thermal processing through tanks of cold water or through cold-water sprays; cans of large diameter must be pressure cooled by water under pressure. Pressure cooling prevents outward straining or buckling of the can ends during the time the internal pressure of the cans is being reduced through loss of the heat of sterilization. Water cooling is continued until the can contents have an average temperature of about 100° F. At this temperature the food usually contains sufficient heat to dry the cans and prevent external rusting of the tin containers.

In air cooling, the cans are stacked, or ricked, in rows to permit free air circulation. Many foods cannot be cooled suitably in air.

Cans are labeled by special labeling machines and may be placed in fibre or wooden cases by hand or by special machines designed for that purpose. Frequently, cans are stored—cased or uncased—without labeling, and the labeling operation is performed just prior to shipment. Canned foods are stored in cool dry warehouses which are not subject to wide variations of temperature or humidity.

Nutritive Values of Canned Foods.—A considerable amount of investigation has been devoted to the effects of commercial canning on foods. Canning procedures have no practical effect on proteins, carbohydrates, fats, etc. When sirups or brines containing sugars are added in canning, the natural carbohydrate contents of the foods are enhanced. Many researches have also established the effect of canning on the known vitamins.

In general, vitamin A and carotene (provitamin A), if protected from atmospheric oxygen, are not materially affected by the heat treatments given canned foods. Vitamin D and riboflavin appear to be unaffected by commercial canning. The stability of vitamin B₁ is dependent not only upon the heat treatment accorded it but also upon the acidity of the food in which it is contained. For the more acid foods there is practically no loss of this vitamin during canning; in the less acid foods, which require longer processing times at higher temperatures, the degree of retention is not so great. Vitamin C, which is generally considered to be the most labile of all the vitamins, is especially subject to destruction at elevated temperatures under conditions that permit free access to atmospheric oxygen. In canning, however, the food is protected to a large degree from contact with oxygen; consequently, vitamin C is well retained in canned foods.

CANNING, HOME: see FOOD PRESERVATION (IN THE HOME).

CANNIZZARO, STANISLAO (1826–1910), Italian chemist, was a pioneer in the development of modern atomic theory. He was born in Palermo on July 13, 1826. In 1845–46 he acted as assistant to Raffaele Piria (1813–65), known for his work on salicin and natural organic materials (e.g., glucosides), who was then professor of chemistry at Pisa and subsequently occupied the same position at Turin. Cannizzaro took part in the Sicilian revolution of 1848 and was condemned to death by the Bourbons. On the collapse of the insurgents he escaped to Marseilles and reached Paris in Oct. 1849.

In Paris he worked in the laboratory of M. E. Chevreul and, in conjunction with F. S. Cloëz (1817–83), prepared cyanamide by the action of ammonia on cyanogen chloride in ethereal solution (1851). In the same year he was appointed professor of physics and chemistry at the Technical institute of Alessandria (Piedmont), where he discovered that aromatic aldehydes are decomposed by alcoholic potash into a mixture of the corresponding acid and alcohol; e.g., benzaldehyde into benzoic acid and benzyl alcohol (Cannizzaro's reaction). In the autumn of 1855 he became professor of chemistry at Genoa university; six years later, after declining professorships at Pisa and Naples, he accepted the chair of inorganic and organic chemistry at Palermo. There he spent ten years, studying the aromatic compounds and continuing to work on the amines. In 1871 he was appointed to the chair of chemistry at Rome university.

Apart from his work on organic chemistry, which included also an investigation of santonin, he rendered great service to the philosophy of chemistry when in a memoir sketch of a course of chemical philosophy (1858) he insisted on the distinction, until then imperfectly realized, between molecular and atomic weights, and showed how the atomic weights of elements contained in volatile compounds can be deduced from the molecular weights of those compounds and how the atomic weights of elements of whose compounds the vapour densities are unknown can be ascertained from a knowledge of their specific heats. Copies of his pamphlet were distributed at the chemical congress held at Karlsruhe, Ger., in 1860. The significance of its contents was not realized until later, when the value of Avogadro's hypothesis in solving this problem became evident. For this achievement, of fundamental importance for the atomic theory in chemistry, Cannizzaro was awarded the Copley medal by the Royal society in 1891.

Entering the Italian senate in 1871 he became its vice-president and a member of the council of public instruction; and in other ways he rendered important services to the cause of scientific education in Italy. He died in Rome on May 10, 1910.

Cannizzaro's collected writings were published in 1925 by the Associazione Italiana di Chimica under the title, *Scritti Vari et Lettere*. The famous *Sketch of a Course of Chemical Philosophy* was no. 18 of the Alembic Club Reprints. For biographical details see W. Tilden, "Cannizzaro Memorial Lecture," *Journal of the Chemical Society* (1912); T. E. Thorpe, *Essays in Historical Chemistry*, 3rd ed. (1894); R. Vanzetti and M. Speter, essay in Günther Bugge's *Das Buch der grossen Chemiker* (1930). (R. E. O.)

CANNOCK, an urban district of Staffordshire, Eng., in the district known as Cannock Chase, is 10 mi. S.S.E. of Stafford and 9 mi. N.N.E. of Wolverhampton by road. Pop. (1961) 42,186. The church of St. Luke is Perpendicular; it was enlarged in modern times. The famous political preacher Henry Sacheverell held his first curacy there in the 18th century.

Cannock is the centre of the Cannock Chase coal field and also has metalworking and other industries. Cannock Chase, a tract generally exceeding 500 ft. in elevation, extends on an axis from Stafford in the northwest to Lichfield in the southeast over about 56.2 sq mi. It was a royal preserve, having been the hunting

forest of the Mercian kings, and contains, in addition to the coal field, woodland and open heath land. Castle Ring, a British hill fort covering 8½ ac. is owned by the council, which also holds 248 ac. of the Hednesford hills.

CANNON, ANNIE JUMP (1863–1941), U.S. astronomer and specialist in stellar spectra, was born at Dover, Del., on Dec. 11, 1862. She graduated from Wellesley college, Wellesley, Mass., in 1884, and did special work in astronomy at Radcliffe college, Cambridge, Mass. Miss Cannon was an assistant at the Harvard college observatory, Cambridge, Mass., 1897–1911, and after 1911 the curator of astronomical photographs. In 1938 she was named William Cranch Bond astronomer, a post established in honour of the founder of the college observatory.

The monumental *Henry Draper Catalogue* of stellar spectra which was published in sections between 1918–24, together with the catalogue of the *Henry Draper Extension*, comprise her principal contribution to astronomy. The importance of this work to all problems of modern stellar astronomy cannot be over-emphasized. In addition to the catalogues of stellar spectra, she discovered many new variable stars and five novae.

Miss Cannon died in Cambridge, Mass., April 13, 1941.

CANNON, JAMES (1864–1944), U.S. clergyman, was born Nov. 13, 1864, in Salisbury, Md. He graduated from Randolph-Macon college, Ashland, Va., in 1884, and received his bachelor of divinity degree from Princeton Theological seminary, Princeton, N.J., in 1888 and a master of arts degree from Princeton university, Princeton, N.J., the same year.

He entered the ministry of the Methodist Episcopal Church, South, in 1888, was elected bishop in 1918, and retired in 1938.

A fiery prohibitionist, Bishop Cannon was a foremost Anti-Saloon leaguer and head of the World League Against Alcoholism. During the 1928 presidential campaign, he delivered violent tirades against the Democratic candidate, Alfred E. Smith.

In 1930 Bishop Cannon was summoned to appear before a body of high Methodists to answer charges of stock speculation in "bucket shops." The bishop admitted his "error," begged for forgiveness and was not tried. Shortly afterward, he was called to appear before a senate lobby committee to explain what he did with \$48,300 given him for use in Virginia during the 1928 campaign. The bishop defied the committee and refused to answer questions. He was later acquitted in federal court of violating the Corrupt Practices act. With the repeal of prohibition his influence waned, although he continued his temperance crusade.

He died in Chicago, Ill., on Sept. 6, 1944.

See Virginius Dabney, *Dry Messiah: the Life of Bishop Cannon* (1949); James Cannon, Jr., *Bishop Cannon's Own Story: Lifer As I Have Seen It*, ed. by Richard L. Watson, Jr. (1955). (V. DA.)

CANNON, JOSEPH GURNEY (1836–1926), U.S. politician, a member of the house of representatives for 46 years and speaker from 1903 to 1911, was born in Guilford, N.C., on May 7, 1836. In 1858 he was admitted to the Illinois bar, and from 1861 to 1868 he was a state's attorney. He settled at Danville, Ill., entered politics and was elected Republican representative in congress for the periods 1873–91, 1893–1913 and 1915–23, retiring at the age of 87. On questions of national policy, Cannon usually aligned himself with the more conservative groups, and during his tenure as speaker of the house his partisan use of the powers of that office became known as "Cannonism." Rebellious against his control, the house in March 1910 passed a resolution making the speaker ineligible for membership in the committee on rules, thereby curtailing his prerogatives. Cannon was, however, personally liked by the members of the house and was popularly known as "Uncle Joe" Cannon. He died at Danville, Ill., on Nov. 12, 1926.

See I. White Busbey, *Uncle Joe Cannon* (1927); E. B. Bolles, *Tyrant From Illinois* (1951).

CANNON, WALTER BRADFORD (1871–1945), one of the greatest of U.S. physiologists, was born in Prairie du Chien, Wis., Oct. 19, 1871 and received his medical degree from Harvard in 1900. He was George Higginson professor of physiology at Harvard from 1906 to 1942, when he retired. He died on Oct. 1, 1945.

Cannon was the first to utilize X-rays in physiological studies. These studies led to the publication of *The Mechanical Factors of Digestion* (1911). His investigations on hemorrhagic and traumatic shock during World War I were summarized in *Traumatic Shock* (1923). His work on the emergency functions of the sympathetic nervous system and on homeostasis are reported in *Bodily Changes in Pain, Hunger, Fear and Rage* (2nd ed., 1929) and in *The Wisdom of the Body* (1932). His important contributions to the knowledge of the chemical mediation of nerve impulses were published (with A. Rosenblueth) in *Autonomic Neuro-effector Systems* (1937) and *The Supersensitivity of Denervated Structures* (1949).

These books, and over 200 original papers that appeared in physiological journals, bear testimony to Cannon's greatness as an investigator: his numerous students, scattered throughout the world, attest his teaching ability; and his continuous interest in human and public affairs, in his own and in other countries, reveals his rich and multifaceted personal quality. Some of his nonscientific activities are narrated in his autobiographical book, *The Way of an Investigator* (1945). (A. S. R.)

CANNON, a big gun or piece of ordnance as distinguished from a musket, rifle or other small arm. The term is used loosely to include guns, howitzers and mortars. It is derived from the Latin *canna* ("cane," "reed" or "tube"), and was sometimes spelled "canon" in the 16th century. The French use the term to refer to the barrel or tube of any firearm, large or small. In U.S. army usage it may denote only the tube, breechblock and firing mechanism as distinguished from the carriage or mount. Modern cannons are complex mechanisms cast from high-grade steel and carefully machined to exacting tolerances. They characteristically have rifled bores. (See ARTILLERY.)

Huge artillery pieces, to which a variety of names applied, appeared during the 15th century. A notable example was "Dulle Griete" of Ghent that weighed 13 tons. But during the later years of the century and indeed up until about 1670 the word "cannon" was applied only to special types of guns. These were the short battering pieces used in sieges, and they were usually divided, at least among the English, into the cannon-royal or double cannon, which weighed 8,000 lb. and fired a ball weighing 60-63 lb.; the whole cannon, which weighed 7,000 lb. and fired a 38- to 40-lb. ball; and the demicannon of 6,000 lb., which shot a 28- to 30-lb. ball. Weights vary from one early listing to another; these are average figures. Other pieces of ordnance had their own distinctive names—culverin, minion, saker, falcon and the like—to indicate their size and function. Cannon became ornate creations during the 1500s and were covered with scrolls, royal escutcheons and inscriptions.

During the third quarter of the 17th century it became the practice to designate pieces of ordnance by the weight of the projectile they threw and secondarily by their other characteristics; *i.e.*, whether field or siege, light or heavy, short or long. England adopted a series of cannon known as 6-, 9-, 12-, 18-, 24-, 32- and 42-pounders. With this streamlining of terminology the complex system of individual names disappeared, and the term "cannon" gradually came to be applied to every gun that was fired from a

carriage or fixed mount and had a bore larger than one inch. In the 20th century, artillery pieces mounted in aircraft were referred to as aircraft cannon; and the U.S. army's first atomic gun, announced in 1952, was generally referred to as the atomic cannon.

CANNON-BALL TREE (*Coirouputa guianensis*), a native of tropical South America (French Guiana), which bears large spherical woody fruits, containing numerous seeds, as in the allied genus *Bertholletia* (Brazil nut). The timber is of value.

CANO, ALONSO (1601-1667), was one of the few Spanish artists to practise painting, sculpture and architecture, and to produce numerous drawings. Baptized in Granada on March 19, 1601, he went as a youth to Seville where he was apprenticed in 1616 to Francisco Pacheco, master of Velázquez. He probably learned figure sculpture from Juan Martínez Montañés and architecture from his father! a maker of retables. In 1638 he moved to Madrid where he worked for the court and church. Influenced by Renaissance paintings in the royal collections and by contemporary baroque art, his style became increasingly eclectic. In 1652 he returned to Granada as prebendary of the cathedral. There he quarreled with the canons and was ejected, but after taking holy orders in Madrid was reinstated and appointed chief architect of the cathedral. His design for the façade was finished shortly before his death on Sept. 3, 1667.

Cano was chiefly a religious artist who created compositions and idealized types in painting and sculpture which were imitated by several followers.

See H. E. Wethey's monograph *Alonso Cano* (1955). (E. Hs.)

CANO, JUAN SEBASTIÁN DEL (d. 1526), Spanish navigator, the first to circumnavigate the globe, was born in Guetaria. He commanded one of the five vessels in the famous expedition of Magellan, and in 1521, on Magellan's death, became chief. He visited the Moluccas and returned to Spain on Sept. 8, 1522, having been around the world. He died at sea in Aug. 1526, while on an expedition to the Moluccas.

CANO, MELCHOR (MELCHIOR) (c. 1509-1560), Spanish theologian who upheld the rights of the Spanish crown against the claims of the papacy, was born at Tarancón, New Castile. He joined the Dominican order in 1523 and became professor of theology in Salamanca. In 1546 he defended the right of the Indians in America. He was strongly opposed to the influence of his fellow Dominican Bartolomé de Carranza (*q.v.*) and in 1558 accused him of Lutheran opinions. Charles V sent him to the Council of Trent (1551-52), where he participated actively in the discussions on the Eucharist and on penance. His close association with the ecclesiastical policies of Philip II incurred the enmity of Pope Paul IV. Cano's reputation as a theologian rests on his *De locis theologicis* (posthumously published in 1563), an analysis of the scientific value of theological statements which led him to evaluate the sources of theology. He also wrote commentaries on the Pauline epistles. He died at Toledo on Sept. 30, 1560.

CANOE, a lightweight boat pointed at both ends, originally designed for propulsion by one or more paddles (not oars) held without a fixed fulcrum, the paddler facing the bow. The name is applied to boats that are open within from end to end (the modern Canadian canoe is of this type) and also to craft covered with a deck except for a well, or cockpit, where the paddler sits (the kayak). The class includes the cruising canoe, combining the use of paddle and sails, and the sailing canoe, designed for racing and equipped with sails only. For paddling and sailing racing canoes and events see *Organized Canoeing*, below.

The primitive canoes were light frames of wood over which skins, as in the old British coracle or in the Eskimo canoe or kayak, or the bark of trees, as in the North American Indians' birchbark, were tightly stretched. The canvas-covered canoe, built on Indian lines, was a natural development of this idea. The structural parts of both the birchbark and the kayak were curved or bow-shaped, which gave them the resilient quality of strength

of a drawn bow. This construction not only imparted great strength in relation to weight but was streamlined, making it possible for even heavily loaded craft to be paddled through the water with a minimum of effort and a maximum of efficiency.

Primitive peoples also used and still use the dugout, made from a log hollowed out by chopping or fire or a combination of both. Many of these are wonderfully carved and ornamented with inlay and are of considerable size and carrying capacity; one in the American Museum of Natural History in New York city, from Queen Charlotte Island, B.C., is 63 ft. long, 8 ft. 3 in. wide and 5 ft. deep, cut from a single log. The war canoe of paddling races is its modern successor.

In the islands of the Pacific and elsewhere dugout canoes, mostly of the outrigger type and sometimes of a twin-hull, or catamaran, design, are handled with great skill by the natives, who make long sea voyages in them. In New Zealand the Maoris were masters of the art of dugout canoe construction, some of their ancient war canoes being of huge size. Along the coast of west Africa fishermen still use large dugout canoes for fishing at sea, remaining out of sight of land for days. (See also BOAT.)

Modern canoes evolved out of the two basic types, the birchbark, propelled by one or more single-bladed paddles, and the kayak, propelled by one or more double-bladed paddles. The open Canadian canoe is the direct descendant of the birchbark. The early explorers in North America promptly adopted it. Being indigenous, it enjoyed a wider range of use than any other small boat. Modern versions of this canoe are made of wood (ash frame and spruce ribs covered with thin cedar planking), canvas (wood frame, ribs and thin planking covered with canvas), aluminum, magnesium, molded plywood, plastic and glass fibres. The all-wood canoe is the favourite in Canada, while canvas-covered and aluminum canoes of the popular sportsman type are more commonly used in the United States for hunting, fishing, camping, cruising and pleasure paddling.

Canoes are built in almost any size from 10 ft. up, but the usual size is 17 ft. long and 34 in. wide. The depth ranges from 12 to 14 in., the ends rising 4 to 6 in. higher. This size was gradually accepted as canoeists found few lengthy portages in their usual waters and discovered that it was still within the limits that one man could conveniently handle. In Canada, where long portages militate against the weight of the larger canoe, the general size is 15 to 16 ft. with 30 to 35 in. beam. Sometimes exceptionally light guide canoes are used as are, under some circumstances, 22-ft. freighters capable of carrying 23 tons. The aluminum canoe became popular about 1942, and especially after 1945. It runs in length from 13 to 18 ft., the 17-ft. length being the standard size. This canoe has a beam of 36 in., a depth of 13 in. and a carrying capacity of 1,050 lb. It weighs 68 lb. and is extremely strong, withstanding a lot of abuse in rapids. It is easily repaired. It sails well with leeboards taking 65 sq.ft. of Dacron or nylon sail. With an outboard motor bracket it takes a 2½- to 3½-h.p. motor easily. Some canoes are designed with a square stern to accommodate an outboard.

The parts of the canoe—whether open, kayak or sailing—are identified by the terminology of old-time sailing ships, since the early explorers naturally applied the seafaring terms of the time to the craft they found among the Indians and the Eskimos. Hence a canoe has a bow and a stern, a keel, gunwales (or gunnels), a port side and a starboard side, the cover of a kayak is the "deck," etc.

The other basic design for canoes that are propelled by paddles is that of the kayak, in which the paddler sits on the bottom or on a low seat, using a double-bladed paddle. The modern kayak was developed largely in Great Britain, where it was known as a "canoe." In the early part of the 19th century it was popularly used for short river practice but the sport of boating in this type of craft dates from 1865, when Scottish canoeist and traveler John MacGregor designed the "Rob Roy" for long journeys by water, using both double-bladed paddle and sails, yet light enough (about 70 lb.) to be carried over portages. MacGregor's accounts of his cruises in the "Rob Roy" helped to popularize the sport and also popularized the Rob Roy as a type of craft. This was

FIG. 1.—MODERN CANOES: (TOP) OPEN CANADIAN CANOE; (BOTTOM) K-1, ONE-MAN OLYMPIC RACING KAYAK

generally built of oak with a cedar deck, from 12 to 15 ft. in length with a beam of 26 to 30 in. and a depth of 10 to 16 in. The paddle was 7 ft. long with a 6 in. wide blade at each end. Decked, and with the canoeist's weight low in the cockpit, it was exceptionally seaworthy. The type gained many adherents in the United States, as well as in Great Britain and in Europe. The Royal Canoe club was founded in England in 1866 and its members made sea voyages in their tiny craft and explored many previously inaccessible waters, including the Jordan river, the Sea of Galilee and the Abana and Pharpar at Damascus.

Modern canoes of the kayak type are made of a variety of materials, perhaps the most popular being a rubberized fabric over a light wood frame. Easily portable collapsible or folding versions of this type, called foldboats, or faltboats (Ger. *faltboot*), have been especially popular in Europe; such boats have been sailed across the Atlantic.

Sailing canoes, modifications of the Rob Roy design, were constructed by Royal Canoe club members W. Baden-Powell and E. B. Tredwen, who introduced the centreboard and two-masted yawl rig. Paul Butler of Lowell, Mass., did much to develop the out-and-out sailing canoe used for racing. He added the sliding outrigger seat, allowing the canoeist to slide out to windward as shifting ballast. Butler also developed clutch cleats and reefing gears; built hollow spars and other accessories; and introduced the sliding tiller, watertight compartments and self-bailing cockpits. This type of canoe was adopted for class racing in the United States, and was universal in Great Britain until, under the influence of Linton Hope's designs, the Royal Canoe club developed the B class canoe which replaced it. The B canoe was 17 ft. long, 3 ft. 6 in. wide and 1 ft. deep, decked, with the exception of the steering well, and divided into three compartments by two watertight bulkheads. Outboard seats were barred. The rig was sloop with sliding gunter or Bermuda mainsail and roller foresail, the total sail area being 150 sq.ft.

In the United States canoes derived from Butler's designs remained popular and customarily were 16 by 30s (16 ft. long by 30 in. beam). A 1909 rule limiting the sail area to 90 sq.ft. effectively blocked the building of larger craft until a sliding scale permitting sail area in proportion to boat dimensions was adopted in 1917, after which several canoes based on designs by Hilding Froling appeared with dimensions varying from 17 ft. by 34 in. to 18 ft. by 42 in. (see also *Organized Canoeing*, below). While the decked sailing canoe was recognized as the finest type of canoe sailing machine, it was frequently outnumbered at regattas by open or cruising canoes rigged with sails and leeboards.

The canoe is usually paddled by two persons, the helmsman doing most of the steering. Most of the canoes have two seats and two or three thwarts. However, the experienced canoeist ordinarily paddles his canoe without using the seats. Kneeling with his buttocks against a thwart allows him to apply greater power to his paddle and is much safer, the centre of gravity being lower. The canoe is often paddled by one person with a single paddle used continuously on one side. At the end of each stroke the canoeist steers his boat by an overhand twist of the paddle. The hand holding the upper end of the paddle and the paddle are so placed that the back of the hand is turned out toward the water on the same side of the canoe on which the canoeist is paddling. The blade of the paddle is kept in the water long enough to bring the canoe back on its course after each thrust of the paddle. The blade is always feathered on the recovery stroke. It is much

better to paddle a canoe on the side opposite to that on which the mind strikes the hull, for the thrust of the paddle offsets the thrust of the wind.

The major strokes of the canoe are divided into cruising strokes, draw or turning strokes, and jamming or stopping strokes.

Cruising Strokes.— These are the strokes used in going forward in a straight line. The bowsman strokes back straight to his hip (bow or forward bow stroke), while the sternman pulls the canoe back in at the end of the stroke by making a hook outward just enough to bring the canoe back on a straight course. This stern stroke is known as a cruising hook, or "J" stroke.

Draw or Turning Strokes.— These strokes are attained by reaching out at an angle and pulling to the canoe (draw stroke) or by placing the paddle by the canoe and shoving outward (pushover stroke), making the canoe turn or move to the angle of draw and opposite of the push or thrust. The same effect is obtained by an outward arc or an inward arc of the paddle. The latter draw strokes are called sweep strokes.

Jamming or Stopping Strokes.— These strokes are for stopping a canoe by placing the blade at right angles to the forward movement of the canoe, and locking it tight by holding it to the gunwale of the canoe. When done by both bow and stern paddler this can stop the canoe quickly, even with a heavy load. Locking or holding the blade tight to the gunwale, but turning the blade parallel to the centre beam of the canoe, is known as a keel lock. This gives stability to the craft, especially in heavy waves, acting like the centreboard in a sailing boat.

A properly trimmed canoe for ease in paddling has the bow slightly higher out of the water than the stern. In rapids a canoe

should be bow-light going upstream when propelled by either pole or paddle. Going downstream it should be bow-heavy. Going ashore through the surf the canoe should be bow-heavy. Going out through the surf it should be bow-light. The single paddler, unless the bow end of the canoe is heavily loaded, kneels in the canoe about one-third of the way forward.

Paddles are classified as soft or hard wood. The best paddles are made of spruce (soft wood) or maple or ash (hard wood). They should be in length equal to the height of the paddler.

If a canoe tips over, the occupants can hang on to it until it floats ashore or until picked up; they should never try to climb up on an overturned canoe. The water can be emptied out of an upset canoe even in deep water by "shaking out" the water, by splashing out the water or, if there is another canoe present, it can be pulled bottom side up over the other canoe to empty the water.

(L. W. J.; C. W. HA.)

Organized Canoeing.— All organized canoeing in the United States is headed by the American Canoe association (A.C.A.). This body, founded in 1880, is divided into nine geographic divisions. Each division holds paddling and sailing races and there is an annual national meet, held at a different site each year according to the best interests of the association. The first local organization in the U.S., the New York Canoe club, dates from 1871. In Canada the sport is supervised by the Canadian Canoe association (1900) and in Great Britain by the British Canoe union (1936). The leading English local organization is the Royal Canoe club (1866).

The world governing body is the International Canoe federation (I.C.F.), formed in 1945 as the successor to the Internationale Representationschaft des Kanusport (I.R.R.; 1924), which was dissolved during World War II. The I.R.K. was responsible for canoeing becoming an Olympic sport. The first competition took place at the 1936 games in Berlin with 19 nations entering teams. Canoeing has remained on the Olympic program since that time. (See OLYMPIC GAMES.)

The annual national races in the United States include one-man single- and double-blade competition, tandem single- and double-blade competition and four-man single- and double-blade competition in the paddling events; and open-cruising and decked-canoe competition in the sailing races.

Olympic competition consists of events for single and double kayaks and single and double Canadian canoes over distances from 1,000 to 10,000 m. for men. Olympic canoe competition for women at 500 m. was inaugurated at the 1948 games in London. Canoes and kayaks used in all racing events must conform to specific measurements agreed upon by the A.C.A. and other national governing bodies.

I.C.F. specifications cover a V-bottom cedar Canadian canoe, 17 ft. by 29½ in. for either one-man (C-1) or two-man (C-2) crews; the single kayak (K-1), 17 ft. by 20 in.; the double kayak (K-2), 21 ft. by 21½ in.; and the four-man kayak (K-4), 36 ft. by 23½ in.

International class sailing canoes must conform to a 10-m. rule (see YACHTING: The Linear and International Rating Rules). The A.C.X. also recognizes a cruising class with a 40 sq.ft. lateen cruising rig; a racing class with decked, self-bailing hulls, centreboards, sliding outrigger seats and upward of 90 sq.ft. of sail area; and A, B and C classes of standard canvas canoes with racing rigs of three sizes.

One of the oldest trophies still in contention in international competition is the International Challenge cup, first offered in 1885 by the New York Canoe club as a perpetual prize for decked sailing canoe racing.

Other types of canoe activities include "white water" running, or "shooting" the rapids of certain rivers (usually in aluminum canoes), and slalom racing over marked courses of fast-running water, marathon racing events over long distances, in laps lasting several days, as the classic race from Devizes to Westminster held at Easter in England, and ocean crossing or round-the-world trips in what are basically sailing canoes.

Canoeing instruction and safety demonstrations are part of American Red Cross chapter programs.

CANON, a musical device in counterpoint (*q.v.*), from the Greek *kanon*, a "law" or "rule," consisting of a theme played or sung as a single part but imitated during its course by other parts either at a specified distance in time or at a specified interval in pitch. The opening part of a canon is called *dux* ("leader") and the following parts come ("companion").

Different forms of canon include exact repetition of the theme after a given time interval (as in the round); a canon at the unison (*i.e.*, at the same pitch) or at an interval of the second, third or fourth, etc.; a canon in augmentation or diminution (the note values being lengthened or shortened); a canon "mirror" in which the ascending intervals become descending in the imitating parts, and vice versa; and a *canonizans* or "crab" canon, in which the theme is played backwards by the imitating part.

The principle of the canon underlies the form of the round: the medieval English six-part round "Sumer is icumen in" is in the form of a canon for four voices accompanied by a double canon. Many intellectual devices of canon were practised by Jakob Obrecht, Jean d'Okeghem and other composers of the 15th-century Netherlands school. In the 18th century devices of canon were incorporated in the fugue (*q.v.*), notably in J. S. Bach's *The Art of Fugue* and *Goldberg Variations*. Similar devices were revived in the 20th century by Schonberg and his followers, who made a wide use of the canon in 12-note music.

For clerical and religious usage of the word, see **AUGUSTINIAN CANONS**; **BIBLE**; **CANONIZATION**; **CANON LAW**; **CONSTITUTIONS**, **APOSTOLIC**; **KANON**; **MASS**.

CANONESS, a title that first occurs in the 8th century, applied to communities of women vowed to obedience and chastity, though not to poverty, and generally under a rule less strict than that of nuns. A distinction grew up between regular (*i.e.*, living under rule) and secular canonesses, very few of the second of which survive. There are several congregations of regular canonesses, the best known of which are those of St. Augustine, of the Lateran and of the Holy Sepulchre. See **WOMEN'S RELIGIOUS ORDERS**.

CANONIZATION, the official act of a Christian church declaring one of its deceased members worthy of public cult and entering his name in the Canon, the authorized list of recognized saints (see **SAINT**).

History.—There was no formal canonization in the early church, though the cult of martyrs was widespread in the Christian world, being local in character and regulated by the bishop of the diocese. The bishop, having examined the circumstances of the martyrdom and the miracles attributed to the martyr's intercession, passed judgment on the legality of his cult. The translation of the martyr's remains from his place of burial to a church was equivalent to canonization.

In the 4th century the age of martyrs was followed by that of confessors, especially with St. Martin of Tours, who died in 397 (see **CONFESSOR**). A widening of authority began to be the custom in matters of canonization and synodal intervention often was required. By the 10th century appeals were made to the pope in causes of canonization. The first saint canonized by a pope was Ulrich, bishop of Augsburg, who died in 973 and was canonized by Pope John XV in the Lateran council of 993. Pope Alexander III (1159–81) began to reserve the cases of canonization to the Apostolic See, and this became a general law under Gregory IX (1227–41).

The method of canonization during the 12th and 13th centuries was rather summary. Thomas a Becket, who died in 1170, was canonized in 1173, and Francis of Assisi, who died in 1226, was canonized in 1228. At this period there was no marked difference

between beatification and canonization.

Pope Sixtus V (1585–90) assigned to the Sacred Congregation of Rites—a department of the Holy See consisting of cardinals and subordinate officers—among other duties that of conducting the processes of beatification and canonization. In the following century Pope Urban VIII, in *Coelestis Hierusalem* (1634), forbade the public cult of any servant of God not as yet beatified or canonized by the church. Exception was made only for those who were in possession of public cult from time immemorial or for at least 100 years. Thus two different canonization procedures came to be adopted, one by way of cult and one by way of non-cult.

The legislation of Pope Urban VIII, together with later legislation by Pope Benedict XIV, formed the basis of the procedures for beatification and canonization found today in the Code of Canon Law (canons 1999–2141), which contains the universal ecclesiastical law of the Roman Catholic Church.

Roman Catholic Code of Canon Law.—Two types of beatification are distinguished by the Code of Canon Law: ordinary or formal and extraordinary or equivalent.

Formal.—Formal beatification, the commoner procedure, entails four general steps: an informative process, introduction of the cause, the apostolic process and four definite judgments. The first of these steps is under the jurisdiction of the bishop in whose diocese it takes place, the other three being directly under the jurisdiction of the Sacred Congregation of Rites and the pope.

In the first step, the informative process, an ecclesiastical court gathers together the following: (1) all material pertaining to the candidate's reputation for sanctity or heroic virtue; (2) the writings of the candidate; and (3) information about miracles wrought by the candidate either during his life or after death. The bishop appoints a person, called postulator of the cause, to promote the cause, and also a promoter of the faith, commonly known as the "devil's advocate," whose task it is to see that the entire truth is made known about the candidate. An investigation is made into any public worship prematurely existing; if such unlawful veneration does exist, more extensive investigation is required and the cause is delayed.

At Rome, after the findings of the first court and the writings of the candidate are received, the introduction of the cause begins with an examination of the candidate's writings to determine if there is anything in them against faith or morals. This action is conducted under the surveillance of another "devil's advocate," the general promoter of the faith. If the writings are free of objectionable material, or if the pope gives his approval to something that could be objected to, the cardinals of the Sacred Congregation of Rites examine the material gathered in the informative process and state whether or not they judge the case as worthy of official introduction at Rome. If the pontiff approves the cardinals' recommendation, he issues the *litterae remissoriales* by which five judges from the diocese submitting the cause are appointed to begin the apostolic process.

This process is concerned with two points, although the first point may be considered unnecessary for investigation: (1) the candidate's reputation for sanctity and (2) the virtue and miracles attributed to him. The first is the point of great importance. Usually two miracles occurring after the death of the candidate are required for beatification.

The fourth step then follows, namely, four judgments by the Sacred Congregation of Rites with approval by the pontiff, concerning: (1) the validity of the apostolic process; (2) the virtue of the candidate to an heroic degree; (3) the authenticity of the miracles attributed to the person; and (4) whether it is safe to proceed with the beatification itself. The most important decision, again, is that concerning the heroic sanctity of the candidate; for heroic sanctity practised throughout life or by martyrdom at death is of the essence of sainthood.

If at the completion of the process the pope orders the beatification, it is in the form of a solemn proclamation, read usually in St. Peter's basilica, with a solemn mass. Veneration then may be carried on in specified localities according to certain restrictions, and efforts may be made to have the *beatus* elevated to the position of a saint. The canonization process is a repetition of

the beatification procedure, except that the three congregations concerned with heroic virtue are omitted, this point being considered sufficiently established by the decision already rendered in the process of beatification. However, at least two authentic miracles obtained through invocation after beatification must occur before the cause for canonization may be introduced. The pope takes personal part in the ceremony of canonization, with a pontifical mass of extraordinary pomp and splendour at St. Peter's basilica.

The first formal papal canonization, as noted above, was that of Ulrich, bishop of Augsburg, by Pope John XV in 993; the first formal beatification is considered to be that of Francis of Sales, in 1661.

Extraordinary.—The other process for beatification and canonization, by way of cult—called extraordinary or equivalent canonization—is simply a papal confirmation that a person is a saint. It is applied only in the case of persons whose worship was immemorial at the time of the publication of *Coelestis Hierusalem* by Pope Urban VIII. Since beatification precedes canonization in the discipline of the modern Roman Catholic Church, equivalent beatification, according to canon 2125, can take place only in the case of servants of God who had been publicly venerated prior to the constitution of Pope Urban VIII and after the pontificate of Pope Alexander III. For canonization after equivalent beatification, three miracles are required instead of two. However, there is no difference in honour accorded saints canonized by either process, and many well-known saints were elevated by equivalent canonization: King Stephen of Hungary, Queen Margaret of Scotland, Pope Gregory VII, Cyril of Alexandria, Wenceslas of Bohemia, Cyril of Jerusalem, John of Matha, Bruno, Norbert, Peter Nolasco, Anselm, etc.

Eastern Orthodox Church.—The process of canonization in the Eastern Orthodox Church is less juridical, being a solemn proclamation rather than a process. Such canonizations are not always ecumenical, for the bishop of a particular locality has the authority to canonize. Spontaneous worship toward an individual on the part of the faithful establishes the usual basis for raising a holy person to the honour of sainthood. The bishop accepts the petition, examines it and delivers it over to a commission that will render a final decision. It is necessary that the person to be canonized possess moral perfection and holiness; moreover, the candidate must have worked miracles while on earth, or miracles must have taken place in connection with his relics after death.

Anglican Communion.—In 1950 the Anglican Church appointed a commission to study the question of canonization for eventual adoption in favour of deserving members of its own communion.

CANON LAW (*jus canonicum*), strictly speaking is the body of laws made by lawful ecclesiastical authority for the government of the whole church or of some part thereof. In the wider sense the term includes precepts of divine law, natural or positive, incorporated in the canonical collections and codes. The canon law concerns the constitution of the church, the relations between it and other bodies, and matters of internal discipline. It is not per se a formulation of dogma, although statements of the divine positive and natural law contained in the canons may be doctrinal in nature. Canon law has developed to the greatest extent in ecclesiastical bodies of the hierarchical type, and especially in the Roman Catholic Church.

ROMAN CATHOLIC CHURCH HISTORY

The historical evolution of canon law may be divided into four epochs: (1) up to the Decretum of Gratian; (2) thence to the

Council of Trent; (3) from Trent to the codification of 1917; and (4) under the *Codex juris canonici*.

From the Beginning to the Decretum of Gratian.—At no time, and least of all during the first centuries, was there any attempt to enact uniform legislation for the whole church. Each community was ruled by its own customs and traditions, with, however, a certain uniformity indicating a common origin. Such compilations of canon law as exist contain occasional decisions given by councils or by certain great bishops.

These compilations began in the east, the first appearing in the province of Pontus. This contained 20 canons of Nicaea (325), together with others from the Councils of Ancyra (314) and Neocaesarea (early 4th century). The collection later grew to more than 150 canons, so well known that they were referred to by number at the Council of Chalcedon (451). It was further augmented by canons from that council and from the Council of Constantinople and by placing the so-called Apostolic Canons at the head of the collection (see CONSTITUTIONS, APOSTOLIC). This was the Greek collection as first translated and introduced into the west. During the 6th century other documents were added, and from the Latin collection of Dionysius Exiguus (see below) were borrowed canons of the Councils of Sardica (342 or 343) and Carthage (419), the latter including most of the canons of the African councils. The Council in Trullo (692) enacted 102 canons and officially accepted the Greek collection above mentioned. The collection thus formed, together with 22 canons of the Council of Nicaea (787), became the official canon law of the Greek and subsequently of the Russian church (see below).

In the west, even local collections are not mentioned until the 5th century, and not until the 8th and 9th centuries are there found traces of unification as a result of exchange of these collections among various regions. The most ancient and homogeneous of these is the African collection deriving from the almost annual plenary meetings of the African episcopate. This survives only in the collection called the *Hispana* (see below) and in that of Dionysius Exiguus. The latter reproduces more or less fully almost all the synods of the African collection; this is the *Concilium Africanum*, so often quoted in the middle ages and also recognized by the Greeks.

The Roman church, even more than the others, governed itself by its own customs and traditions. Until the end of the 5th century the only non-Roman canonical document officially recognized there was the collection of the canons of Nicaea, including those of Sardica. The local law was founded on usage and on the papal decretals—letters addressed to bishops of the ecclesiastical province immediately subject to the pope, and others in reply to questions addressed to the pope from various quarters. At the beginning of the 6th century the Roman church adopted the collection by the monk called Dionysius Exiguus (*q.v.*). This was partly a new translation of the first 50 of the Apostolic Canons, which thus entered the law of the west. The second part contained 39 decretals of the popes from Siricius (384–399) to Anastasius II (496–498). Further decretals were added to this collection as they appeared. In 774 Pope Adrian I gave the augmented collection to Charlemagne as the canonical book of the Roman church (the *Dionysio-Hadriana*). It was officially received by the Frankish church, imposed by the Council of Aix-la-Chapelle (802), and thenceforward was recognized and quoted as the *liber canonum*, thus marking an important stage in the centralization of canon law.

In the Spanish church, which was strongly centralized around the see of Toledo, canon law was embodied in a collection that, though unofficial, was received everywhere; this was the *Hispana*. The first part is composed of the canons of the councils, arranged according to regions: Greek, African, Gallican and Spanish councils. Nearly all the latter were held at Toledo, beginning with the great council of 589 and continuing until interrupted by the Moorish invasion. The second part of the *Hispana* contains the papal decretals, as in the collection of Dionysius. It was this second part that later served as the basis for the collection of the *False Decretals*.

The British and Irish churches remained still longer outside

the centralizing movement. Their main contribution to the later system of canon law was in the influence of the Penitentials, collections for the guidance of confessors in imposing penances for various sins (see *PENITENTIAL*). The otherwise unimportant Irish collection introduced the canonists to the practice of quoting from Scripture and the Fathers.

In the middle of the 9th century an enlarged edition of the *Hispana* began to circulate in France, where it was falsely attributed to St. Isidore of Seville (and hence today is called the *Pseudo-Isidoriana*). Besides many genuine additions to the *Hispana*, this collection included 60 spurious decretals from popes prior to Siricius in its first part, and in the third part of the collection at least 104 out of some 120 documents are today considered to be fictitious. For the historical questions connected with the False Decretals, see *DECRETALS, FALSE*; here we are concerned only with their influence on the development of canon law. Despite some doubts and hesitation, it is safe to say that the False Decretals were fairly generally accepted until the 15th century, and all later collections used them extensively.

The False Decretals did not greatly modify or corrupt canon law. The collection in general introduced little new legislation, but rather gave a new formulation to existing practices and tried to give the authority of law to what was already accepted in fact. They did contribute much, however, to the progress of canon law toward unity. For they were the last of the chronological collections. Thereafter, canonists began to arrange their collections according to a preconceived order, leading to the development of a common canon law and, ultimately, to the *Decretum* of Gratian. From the end of the 9th to the middle of the 12th century, there were about 40 systematic collections, containing both texts of the law and the authors' comments and discussion of controversies.

From the *Decretum* of Gratian to the Council of Trent.—

It was against this background that Gratian, a Camaldolese monk, published, somewhere between 1139 and about 1150, his monumental treatise, called at first *Concordantia discordantium canonum* but soon known simply as the *Decretum* Gratiani, or *Decretum* (see *GRATIAN*). This immense work consists of three parts. (1) The first, treating of the sources of canon law and of ecclesiastical persons and offices, is divided according to the method of his pupil Paucapalea into 101 distinctiones, which are subdivided into 3,945 *canones*. (2) The second part consists of 36 *causae* (cases proposed for solution), subdivided into *quaestiones* (questions raised by the case), under which are arranged the various *canones* (canons, decretals, etc.) bearing on the question. (3) The third part gives, in five distinctiones, the law bearing on church ritual and the sacraments. The work is not a mere collection of texts but also a treatise giving the opinions and teaching of Gratian. He drew his materials from the existing collections and included the canons of recent councils and recently published decretals, up to and including the Lateran council (1139). When necessary, he had recourse to the Roman law and made extensive use of the Fathers and ecclesiastical writers. The apparent discordance of texts he explained away, or indicated the more authoritative.

From the viewpoint of its official authority, the *Decretum* occupies an intermediate position difficult to define. It is not an official code in which every text has the force of law: there was as yet no idea of producing an official compilation. It remains a work of private authority, and the texts contained in it have only that legal force they possess in themselves. On the other hand, it actually enjoys a public authority that is unique: for centuries it has been the text on which has been based the teaching of canon law in all the universities; it has been glossed and commented on by the most illustrious canonists; it became, without being a body of laws, the first part of the *Corpus juris canonici*, and as such it has been cited, corrected and edited by the popes. It thus, by usage, obtained an authority perfectly recognized and accepted by the church and served as an important source for the official codification of canon law in 1917.

Subsequent to the *Decretum*, the collections of texts were clearly separated from the commentaries in which the canonists continued the formation and interpretation of the law. Thus the

way was prepared for official collections. New decretals as they appeared were collected in five large *Compilationes*, which soon contained a mass of materials greater than that of the *Decretum*. In 1234 the contents of these compilations were edited, together with later decretals, and promulgated officially as *Decretals* by Gregory IX. This first official code forms the second part of the *Corpus juris canonici*. While it was intended to supersede the *Compilationes*, it was not meant to supersede the *Decretum*: there was no thought of codifying the whole of canon law. A supplementary collection, called the *Liber Sextus* (because it was in addition to the five books of the *Decretals* of Gregory IX), was officially promulgated by Boniface VIII in 1298 and became the third part of the *Corpus*. An additional collection was prepared under the direction of Clement V and was even promulgated by him in consistory in 1314; but, owing to his death, it was not sent to the universities until 1317. It is known as the *Clementinae* and forms the fourth part of the *Corpus juris canonici*.

At this point the official collections stop. The two last, which have found a place in the editions of the *Corpus*, are collections of private authority. The *Extravagantes* (*i.e.*, *extra collectiones publicas*) of John XXII number 20 and are divided into 14 titles. The *Extravagantes communes* (*i.e.*, coming from several popes) number 73, from Boniface VIII to Sixtus IV (1484), and are classified in books and titles. These two collections were included in the edition of Jean Chappuis in 1500; they passed into later editions and are considered as forming part of the *Corpus juris canonici* (parts 5 and 6). As such, and without receiving any complementary authority, they have been corrected and re-edited, like the others, by the *Correctores romani*.

Thus was closed, as the canonists say, the *Corpus juris canonici*; but this familiar expression is only a bibliographical term. Though the expression *corpus juris* is found, for example, at the Council of Basel, not even the official edition of Gregory XIII has as its title the words *Corpus juris canonici*, and this title is not used until the Lyons edition of 1671. Though there were no further collections, the sources of canon law were not dried up; decisions of councils and popes continued to appear; but no attempt was made to collect them. Canonists obtained the recent texts as best they could. The era of the Great Schism of the west, to be followed by the Reformation, was not a period favourable to the reorganization of ecclesiastical law.

After the Council of Trent.—The third epoch in the development of the canon law starts from the disciplinary decrees of the Council of Trent (1545–63), made in the second part of its sessions, called *de reformatione*. During this period there was a marked move toward centralization in the Roman Catholic Church and an increased tendency toward uniformity of legislation emanating from the Holy See.

At the same time, however, the dispersed condition of the canonical documents was not remedied; on the contrary, the large number of pontifical constitutions and of decrees from the Roman congregations even aggravated the situation. The constitutions were published in the *Bullarium*; but this was a collection of private authority, except that officially published by Benedict XIV in 1747; further, this compilation is in chronological order and rather unwieldy. The various Roman congregations published official collections of their decrees; the decrees of others were published by private authority. It is no surprise, therefore, to find that Catholic bishops from all quarters of the world petitioned for a codification of the canon law at the time of the Vatican council (1869–70). The position was thus stated by several French bishops:

It is absolutely clear, and has for a long time past been universally acknowledged and asserted, that a revision and reform of the canon law is necessary and most urgent. As matters now stand, in consequence of the many and grave changes in human affairs and in society, many laws have become useless, others difficult or impossible to obey. With regard to a great number of canons, it is a matter of dispute whether they are still in force or abrogated. Finally, in the course of so many centuries, the number of ecclesiastical laws has increased to such an extent, and these laws have accumulated in such immense collections, that in a certain sense we can well say: We are crushed beneath the laws, *obruimur legibus*. Hence arise infinite and inextricable difficulties which obstruct the study of canon law; an immense

field for controversy and litigation; a thousand perplexities of conscience; and finally contempt for the laws.

The Vatican council was forced to dissolve without dealing with the question of canonical reform, but on March 19, 1904, Pope Pius X issued a motu *proprio* decreeing the revision and codification of the canon law of the Latin church. A commission of cardinals was appointed for this purpose, under the direction of Pietro Cardinal Gasparri, together with a body of consultants. A circular letter was issued to all archbishops throughout the world requiring them, after consultations with their suffragan bishops, to set forth to the Holy See within four months the changes in canon law that were deemed advisable; at the beginning of April 1904 the universities also were asked to collaborate. After years of concerted labour, the new *Codex juris canonici* was officially promulgated on May 27, 1917, and, with the exception of a few provisions effective immediately, went into force throughout the Latin church on May 19, 1918. This date therefore ushered in the fourth epoch in the development of canon law in the Roman Catholic Church.

CODE OF CANON LAW

Like the Code Napoléon, which was the prototype for most of the modern civil codes, the Code of Canon Law (*Codex juris canonici*) is a systematic arrangement of the ecclesiastical law in force. The code itself consists of five books, which, with the exception of the first, are divided into parts, and the parts at times into sections. The parts are also subdivided into titles; some of the titles into chapters; and some chapters into articles. The canons are the ultimate subdivision and are numbered consecutively throughout the code into 2,414 canons. Citation to the code is simply by the number of the canon.

Book I.—Book i is concerned with general norms for interpreting the code—on ecclesiastical laws, the force of custom, methods of computing time, rescripts, privileges and dispensations from ecclesiastical laws (canons 1–86).

Book II.—Book ii (can. 87–725) deals with three classes of persons in the church—clerics, religious and the laity. The Roman pontiff has the supreme power of jurisdiction within the church (can. 218), as does also an ecumenical council consisting of the Roman pontiff and the bishops of the whole church (can. 228). This power of the Roman pontiff is at the same time legislative, judicial and administrative. The administration of the church is ordinarily conducted through the Roman congregations (can. 246–257), and the judicial power through the tribunals of the Roman curia, consisting of the Sacred Penitentiary for the internal forum, the Rota for the external forum and the Apostolic *Signatura* as the supreme tribunal of the church (can. 258–259).

At the local level, the local ordinary (residential bishop) is the sole legislator for the diocese, and the diocesan synod has only a consultative role (can. 362). Provincial councils are composed of the ordinaries of the ecclesiastical province, and their decrees are binding within the dioceses of that province; such councils are to be held every 20 years (can. 283). Plenary councils are composed of the ordinaries of more than one province (usually on a national scale), convoked with the permission of the Holy See, and may enact legislation binding within those provinces to be promulgated after approval by the Sacred Congregation of the Council (can. 281). Plenary or provincial councils, as well as diocesan synods, may supplement the common canon law to meet local needs, but they cannot derogate from that law without the express approval of the Holy See. (The annual meetings of the bishops of the United States are an informal conference, not a plenary council, and the conference has no power to enact legislation binding upon the member bishops.)

Book III.—Book iii of the code, entitled "De Rebus," legislates concerning things—the discipline for the administration of the sacraments (can. 731–1153), sacred places such as churches and chapels (can. 1154–1242) and sacred seasons (can. 1243–54), divine worship (can. 1255–1321), the teaching authority of the church, including the qualification of preachers and the censorship of books on religion (can. 1322–1408), the rules governing ecclesiastical benefices (can. 1409–94) and the temporal goods of

the church (can. 1495–1551). Of particular interest in this book are the canons establishing the impediments to marriage (can. 1035–80), the canonical formalities required for the validity of marriage of a Catholic (can. 1094–96, 1098–99), and the power of the church to dissolve a valid marriage (can. 1118–27).

Book IV.—Book iv of the code (can. 1552–2194) establishes the various tribunals or courts in the judicial system of the church, sets forth rules for the conduct of trials and the offering of evidence. The second part of this book establishes the procedure to be followed for beatification and canonization (can. 1999–2141).

Book V.—Book v, "On Crimes and Penalties," contains the criminal law of the church (can. 2195–2414). It establishes the mental and moral responsibility required for a criminal violation of canon law, defines the effect of the various penalties—such as excommunication or interdict—and then sets forth the particular laws, the violation of which is punished by such penalties.

Since its codification in 1917 the canon law of the Roman Catholic Church has not remained static. Thus, in 1948 a change was made in the formalities for marriage (cf. can. 1099, sec. 2); in 1950 the penalty of excommunication was added to the law forbidding clerics to engage in certain forms of commercial enterprises (cf. can. 142); and in 1953 and 1957 radical changes were made in the law of fasting before communion (cf. can. 858).

EASTERN CHURCHES

The development of canon law in the eastern churches was even more haphazard than that in the west, largely because of the strongly autonomous character of the great eastern patriarchates. After the final break with Rome in 1054, the eastern churches were cut off from the centralizing movement in the canon law of the west and came predominantly under the influence of Constantinople.

Orthodox.—The early Greek collections are referred to above. As adopted and augmented by the Council in *Trullo* (692) and subsequently supplemented by 22 canons of the Council of Nicaea (787), this collection became the official canon law of the Greek and later of the Russian church. Toward the end of the 6th century, a new type of collection began to appear in the east, composed of both ecclesiastical canons and imperial laws. Of these collections, called *nomocanones*, the most influential was the *Nomocanon* of Photius, patriarch of Constantinople in the latter part of the 9th century. This, together with the commentaries of the 12th-century monk John Zonaras, the scholia of Theodore Balsamon, patriarch of Antioch, and the compendium of Matthew Blastares (14th century), is considered to be the chief authentic source of law in the Orthodox Church. This nucleus has been further supplemented through the centuries by legislation of synods held in the various patriarchates of the east; but, while there has been a certain amount of mutual borrowing, there has not developed in the eastern churches a common canon law in the way that such a body of law developed in the western church.

Uniate.—In the Roman Catholic eastern churches that follow non-Roman rites the prevailing canon law did not differ radically from that of the Orthodox counterpart of each church, except, of course, for their recognition of the primacy and jurisdiction of the Holy See. In their case, the local patriarchal law is supplemented by a large body of legislation by the Holy See for the individual eastern rites of the church, but there was little or no attempt to make any systematic collection of this legislation or to codify it. The diversity of legislation was considerably augmented by the multiplicity of rites.

The success of the Latin Code of Canon Law, however, led Pope Pius XI in 1929 to establish a commission of cardinals for the codification of the law of the eastern churches and to invite the eastern bishops to submit their suggestions; and in 1930 a committee of consultants from each of the rites was put to work. The proposed eastern code was to be modeled on the Latin code. The resulting canons are in Latin and follow the text of the Latin code where possible, but many of these canons provide for supplementation by the local or customary law of the various rites, thus preserving many of the cherished traditions of the individual eastern churches.

Unlike the Latin code, the code for the eastern churches was not published as a whole, but various sections were promulgated as they were completed. The first section to be promulgated was that containing the 131 canons on marriage, which came into force on May 2, 1949, and correspond closely to the 132 canons of the Latin code. The greatest differences affect the impediments of consanguinity and affinity and the very wide powers of dispensation possessed by the eastern patriarchs. The procedural law, corresponding to book iv of the Latin code, became effective on Jan. 6, 1951. Another section, dealing with the law of religious and temporal goods, with a definition of the terms used in the eastern code, went into effect on Nov. 21, 1952. The section on the law of persons, corresponding to book ii of the Latin code, raised problems of the utmost delicacy, since it would concern the juridical status of the eastern patriarchs and bishops, the scope of their jurisdiction and the method of their selection. When finally promulgated in 1957, this part of the codification was found to preserve most of the traditional prerogatives and powers of the eastern prelates, and provided for the continuance of their selection by means of election with subsequent confirmation by the Holy See. A pontifical commission was created to give authentic interpretations of the eastern codification, and the gigantic task of collecting and publishing the fontes, or sources, of the eastern law was begun in 1930. (Jo. M. S.)

ANGLICAN COMMUNION

England.—The English courts, both temporal and spiritual, have since the Reformation consistently maintained that the Church of England is and has always been the national and independent branch of the Catholic Church operating in England. Though the Reformation severed the connection with Rome, so that thereafter further developments of the Roman canon law left England unaffected, the canon law of pre-Reformation England continued into the post-Reformation period. While the theory has been advanced and disputed that the pre-Reformation canon law of the western church was binding in England only insofar as it had been "received" into England, there can be no doubt that the vast bulk of pre-Reformation canon law remained and is still part of the law of the Church of England except insofar as it has been lawfully abrogated or varied by or since the Reformation.

The church remained, as before, established, so that the law of the church and the law of the state together make up the one law of England, which is the law of both church and state. This is so, even where there is an apparent conflict, as, for example, over marriage; while the state recognizes the validity of a secular divorce, no minister of the Church of England need perform the marriage ceremony for a divorced person whose former partner is still living. At the Reformation the papal claim to supremacy was decisively rejected and the royal supremacy as decisively enthroned, with the result that the church, with the rest of the nation, was equally affected by subsequent constitutional developments and the royal supremacy has effectively become a parliamentary supremacy. The church courts survived and became the king's courts. The two convocations of the two provinces of Canterbury and York survived with their limited powers of making canons, which, when they have received the royal assent, are binding on the clergy, and in 1603 and 1604 they supplemented the existing canon law with a further body of purely Anglican canons; they also from time to time pass resolutions, known as acts of convocation, which, though without legislative effect, carry considerable weight as considered pronouncements of the church's view. The bishops, too, retained their seats in the house of lords, though their number there is limited to 26.

From the time of the Reformation until 1919 the only source of new legislation (apart from the canons of convocation) was parliament, and there are many acts of parliament, varying in importance from the Act of Uniformity (giving statutory authority to the Book of Common Prayer) down to acts regulating the burial of the dead, all of which go toward the making of English ecclesiastical law. In 1919, however, parliament passed an Enabling act (the Church of England Assembly [Powers] act) that gave statu-

tory recognition to the already existing church assembly. This body consists of three houses, namely, a house of bishops (consisting of the upper houses of the two convocations), a house of clergy (consisting of the lower houses of the two convocations) and a house of laity (elected by the diocesan conferences). It passes measures which, with the consent of parliament, may be presented to the sovereign and which, when they have received the royal assent, have the full force of an act of parliament. After 1919 much legislation was effected by measures of the church assembly that, before that date, could have been done only by parliament.

The canon law of the Church of England consists, therefore, primarily of the pre-Reformation canon law of the western church, except insofar as it has been rejected or varied; acts of parliament; measures of the church assembly; legislation passed by virtue of powers delegated by parliament or the assembly; canons passed by the convocations; and, so far as it is applicable, the general law of England. As in the case of every other branch of English law the interpretation of the canon law rests with the courts of the land, both spiritual and temporal. (See also ECCLESIASTICAL LAW [ENGLISH] .) (E. G. Mo.)

Ireland.—The Church of Ireland was disestablished in 1869 by act of parliament, and that church thus was freed from the prohibition against holding synods and legislating for itself. Under this authority, the bishops met with representatives of the clergy and laity in a general convention in 1870. This convention declared that a general synod of the bishops, with representatives of the clergy and laity, should have supreme legislative authority in the Church of Ireland, together with certain administrative powers not inconsistent with the episcopal constitution of the church. The synod was to consist of two houses—the house of bishops and the house of clerical and lay representatives. To carry any measure there was required a majority of the clerical and lay representatives, voting either conjointly or by orders, and also a majority of the house of bishops, if the latter wished to vote. For any alteration of "articles, doctrines, rites or rubrics," a two-thirds majority of each order of the representative house was required, with a year's delay for consultation of diocesan synods, in which provision also was made for lay representation.

Scotland.—The canon law of the Anglican communion in Scotland prior to the 16th century was generally that of the continent. The usages of the church were similar to those in France and had not the insular character of those in England and Ireland. The canon law regulating marriage, legitimacy and succession was taken over by the Scottish secular courts and survived almost unimpaired as part of the common law of the land. In the post-Reformation period no canon law was recognized as being authoritative in Scotland unless it emanated from a national council or was adopted by such a council. The general canon law, except where acknowledged by act of parliament, or a decision of the courts, or sanctioned by the canons of a provincial council, is regarded in Scotland as having only persuasive force according to the rules of equity and comity, and is not per se binding.

United States.—The Protestant Episcopal Church in the United States of America is the successor of the Anglican Church as it existed in the American colonies before the Revolution. The Anglican body in the colonies was subject to "all the laws of the Church of England applicable to its situation," and this body of law was inherited by the Protestant Episcopal Church. It was recognized, however, that not all the canon law of the established English church could be applied in the United States; and in 1789 a general convention, consisting of clerical and lay representatives as well as of bishops, assumed for itself and its successors supreme legislative authority. The constitution adopted by the first general convention, with subsequent amendments, forms the organic law for the Protestant Episcopal Church in the United States of America. The general convention consists of a house of bishops and a house of deputies, the latter being composed of four presbyters and four laymen elected by each diocese. Voting in the house of deputies may be required to be by orders, and in such case the concurrence of both orders, clerical and lay, is required for the passage of any measure. The house of bishops

may propose measures to the house of deputies and also may veto acts of that house provided certain formalities are observed. Similar constitutions providing for representation of the laity have been adopted by the various dioceses. Standing committees composed of both clergy and laity are responsible for the government of the dioceses in the interim between diocesan conventions. A great body of canonical legislation has been enacted and amended by these bodies, and this was codified in 66 canons by the general convention of 1943. Although the Protestant Episcopal Church, except for a brief period immediately after the Revolution, has maintained cordial and more or less close relations with the parent Church of England, it is both de jure and de facto completely independent of that body. Together with other bodies in communion with the Church of England, the Protestant Episcopal Church participates in the decennial Lambeth conferences headed by the archbishop of Canterbury, but the conference has no legislative authority.

South Africa.—After 1870 the Church of the Province of South Africa secured autonomy while remaining a part of the Anglican communion. By its constitution of that year the English Church in South Africa adopted the laws and usages of the Church of England, insofar as they were applicable to an unestablished church. It disclaimed the right to alter doctrinal standards, except in agreement with such doctrinal alterations as might be adopted by a general synod of the Anglican communion. But in interpreting these standards of faith and doctrine, and even more so in interpreting disciplinary canons, the Church of the Province of South Africa was bound only by the decisions of its own ecclesiastical courts. (Jo. M. S.)

CHURCH OF SOUTH INDIA

This church provides an important and interesting example of a current attempt at the reunion of severed portions of Christendom. It consists of what were formerly four dioceses of the Anglican Church of India. Burma and Ceylon; the former Methodist province of South India; and the former South India United Church, consisting of Presbyterians and Congregationalists and members of the Dutch Reformed Church together with other European Protestant bodies. All these, after nearly 30 years of preparation, joined together in 1947 to form the Church of South India. The basis of this reunion includes the continuation of the ministries of the ministers of the constituent bodies under a constitutional version of the historic episcopate, with the intention that eventually every minister will have been episcopally ordained. The constitution is, of course, a written one in which care was taken both to avoid too close a definition in respect of points of theological difference and also to safeguard various aspects of the traditions of the constituent bodies. The governmental system is pyramidal, having at its head the synod, consisting of the bishops (one of whose number is moderator), together with representatives of the presbyterate and laity. Below the synod are the diocesan councils, consisting of the bishop, presbyters with charge of pastorates and lay representatives; they frame their own differing constitutions, subject to the general oversight of the synod. Below the diocesan councils come the pastorates; each has a pastorate committee, consisting of the pastor-in-charge and elected representatives of the congregations which form the pastorate. There are spiritual courts at three levels, the members of which are clerical and lay rather than legal. The marriage law of the church, while aiming at the Orthodox Christian ideal, is somewhat complicated and endeavours to take account of the complicating factors that the mission field provides. Since the constitution envisaged an interim period of 30 years, a more mature system of canon law may perhaps be expected to evolve at the end of that period; one that will, no doubt, bear the marks of its own interesting and unusual genesis.

See ECCLESIASTICAL LAW; see also references under "Canon Law" in the Index volume. (E. G. Mo.)

BIBLIOGRAPHY.—The literature on the subject in all its branches is very elaborate, and this is particularly true of the canon law of the Roman Catholic Church. The articles "Law (Christian, Western)" and "Law (Christian, Eastern)" by A. Fortescue and "Law (Christian, Anglican)" by A. J. Maclean in *J. Hastings, Encyclopedia of Religion*

and *Ethics*, give concise statements of information with references for further study. For an extended study of the history of western canon law, see A. G. Cicognani, *Canon Law*, authorized English version (1934). A fine discussion of legislation in the Roman Catholic Church is contained in R. Metz, *What Is Canon Law?* (1960); brief surveys of the current *Codex juris canonici* will be found in T. L. Bouscaren and A. C. Ellis, *Canon Law: a Text and Commentary*, 2nd ed. (1951), and in J. A. Abbo and J. D. Hannan, *The Sacred Canons*, 2 vol. (1952); while the post-code legislation and interpretation is collected by T. L. Bouscaren, *Canon Law Digest*, 4 vol. (1934–58), which is kept up to date by annual loose-leaf supplements. The Catholic University of America has published, under the general title of "Canon Law Studies," numerous doctoral theses dealing with particular canons. The sources used in drafting the Latin code have been published by the Vatican Press under the title *Fontes juris canonici*; publication of the *Fontes, juris canonici orientalis* was begun in 1930. (Jo. M. S.)

CANONS REGULAR, a body of canons bound by religious vows and living in community under a rule, as opposed to secular (collegiate and cathedral) canons, who take no vows and do not live under rule. See AUGUSTINIAN CANONS; CATHEDRAL; PREMONSTRATIENS.

CANOPUS (CANOBUS), an ancient city on the western coast of the Nile delta of Egypt, on a site 15 mi. N.E. of Alexandria, near the modern village of Abu Qir. Known to the Greeks as Kanopos, its Egyptian name was PeGewat. The Canopic branch of the Nile, which entered the Mediterranean in the Bay of Abu Qir, is entirely silted up, but on the shore at Towfiqiyya, about 2 mi. from Abu Qir, there are extensive remains including those of the temple of the Greco-Egyptian god Sarapis, which was a place of pilgrimage from Hellenistic times until its destruction in the 4th century A.D. Canopus was a centre of the unguent industry and a pleasure resort for the people of Alexandria and was notorious for its dissoluteness in the Roman epoch. On March 7, 238 B.C., an assemblage of priests from all Egypt passed a decree honouring Ptolemy Euergetes and his consort Berenice; copies of this decree were set up in the principal temples of Egypt and fragments of several have been found. The emperor Hadrian gave the name Canopus to part of his villa at Tivoli where he had gathered together Egyptian antiquities.

Osiris was worshiped at Canopus under the curious form of a human-headed vessel. The name "canopic jars" was therefore mistakenly applied by early archaeologists to the jars with human and animal heads in which the viscera were placed by the ancient Egyptians after mummification, and is still often applied to Egyptian and other jars, including Etruscan, with lids of this type.

CELESTIAL BALDACHIN CANOPY OVER
VIRGIN AND CHILD; CARVED IVORY.
6TH CENTURY. IN THE JOHN RYLANDS LIBRARY, MANCHESTER, ENG.

CANOPUS, the second brightest star in the sky, situated in the constellation Carina. It is in south declination 53° and therefore invisible from latitudes above 37° N. Canopus is a supergiant star situated about 160 light-years from the sun.

CANOPY, a hood or cover, supported or suspended above an object. In modern usage, canopies serve the primarily functional purpose of providing protection from the weather, as awnings, or canopy hoods above doors. Originally, however, the canopy was a variant of the reversed domical shape, which symbolized a divine and royal presence (see DOME); it probably derived ultimately from the cosmic audience tent of the Achaemenid kings of Persia. Used by

Roman and Byzantine emperors in their state appearances as supreme beings, it passed into the middle ages as a symbol of the divine presence, as in the small canopies placed over statues of saints on medieval church façades; in baldachins (*q.v.*); in testers (*i.e.*, canopies suspended from the ceiling or bracketed from a wall) placed above altars; and in the embroidered hangings supported on poles and carried over officiating priests in religious processions.

The canopy as a symbol of a royal presence also passed into the middle ages and beyond: beneath this mark of their divine right to rule, monarchs gave audience and dispensed justice down to modern times. Typical surviving examples are the canopies above the audience beds of

French kings; the elaborate canopied thrones erected for Napoleon in the Luxembourg palace and elsewhere; and the canopies used in British coronation ceremonies. (AN. G.)

CANOSA DI PUGLIA (anc. CANUSIUM), a town in the province of Bari, Italy, is 24 km. (15 mi.) S.W. of Barletta, dominating the tableland of Puglia, on the right bank of the Ofanto (Aufidus). Pop. (1957 est.) 35,910 (commune). There are a number of Roman remains, including an arch dedicated to Trajan.

Ancient Canusium stood about 12 mi. from the mouth of the Aufidus. It was said to have been founded by the legendary Diomedes (*q.v.*), and its people spoke both Greek and Latin in the time of Horace (*Sat.* i, 10, 30). A large number of Greek relics have been found, including fine polychrome vases made there (3rd century B.C.). Canusium came voluntarily under Roman sovereignty and remained loyal throughout the Punic Wars, but revolted in the Social War, in which it appears to have suffered (Strabo vi, 283). It stood on the Via Traiana and had a trade in agricultural products and in Apulian wool (cleaned and dyed there). Under the early empire it was a municipium, and later became a *colonia*. In the 6th century it was still the most important city in Apulia. The Normans rebuilt the town after its destruction by the Saracens (9th century); a medieval castle crowns the hill above the town. The southern Romanesque former cathedral of S. Sabino (bishop of Canosa, 514–566; the bishopric passed to Andria in 1818) was consecrated in 1801, and contains interesting Byzantine relics. To the south of it is the detached mausoleum of Bohemund, son of Robert Guiscard, who captured Antioch during the first crusade (1096). It is entirely faced with *cipollino* (Carystian) marble, and has fine bronze doors with long inscriptions.

The Barletta-Melfi and Cerignola-Andria roads intersect there, and the station is on the Barletta-Spinazzola railway, by which agricultural products are sent to Barletta port. Early in the 20th century large-scale emigration, principally to the Americas, depleted the population. Those who remained were chiefly farmers engaged in stock breeding. The rich yield of dairy produce is supplemented by cereals and herbs, grown on the banks of the Ofanto, and by almonds and olives; olive oil and wine are manufactured. A chalky, porous stone is also quarried for building.

See T. Ashby and R. Gardner in *Papers of the British School at Rome*, vol. viii, pp. 154 ff.; G. Jacobone, *Canusium* (1925). (M. T. A. N.)

CANOSSA, a ruined castle, 1,890 ft. above sea level, 12 mi. S.W. of Reggio nell'Emilia in Italy, famous as the seat of a powerful feudal family. The stronghold was built by Atto Adalbert (d. 988), the founder of the house of the Attoni, which derived the title of counts of Canossa from it. Adelaide, the widowed queen of Italy and future empress, is said to have taken refuge there in 951. Atto Adalbert acquired the counties of Modena, Reggio and

Mantua, his son Tedald (d. 1012) those of Brescia and Ferrara. Tedald's son Boniface (d. 1052) received the march of Tuscany c. 1027 from the emperor Conrad II and acquired Upper Lorraine through his marriage with Beatrice of Lorraine (d. 1076). The well-known countess Matilda (*q.v.*) was their daughter.

In 1077 Pope Gregory VII stayed at Canossa on his way to preside over the diet at Augsburg convened to determine whether the excommunicated emperor Henry IV (*q.v.*) was fit to rule. To forestall this, Henry journeyed to Canossa as a simple penitent and, on Jan. 28, after waiting for three days, received absolution. The castle was destroyed in 1255 by the people of Reggio.

CANOVA, ANTONIO (1777–1822), marquis of Ischia, Italian sculptor, the first great exponent of the neoclassic style in sculpture, was born at Possagno, a little village near Treviso, on Nov. 1, 1777, of a family of stonemasons. His work very early became the fashion, the way having been well prepared by Johann Winckelmann, in theory, and Anton Raphael Mengs, in painting, as well as by the excavations at Pompeii and Herculaneum. According to tradition, the boy's genius was discovered through a lion he had modeled in butter. He served under unimportant Venetian masters. In Venice he executed several groups, among them one of Daedalus and Icarus, and at 23 he went, with a pension from the Venetian senate, to Rome, where he found many patrons, among them Pope Clement XIV. He opened a studio in the Via del Babuino, and there spent two years on a monument to the pope in the church of the Holy Apostles, completed in 1787. Then followed the monument of Clement XIII in St. Peter's, on which he was engaged for five years. In 1798 he visited Vienna and Berlin; in 1802 he went to Paris to make studies for a statue of Napoleon, and he visited London in 1815. After the fall of Bonaparte, Canova was named head of the commission appointed to restore to their various Italian owners the works of art which had been sent to Paris. He received from the pope the titles of marquis of Ischia, and "prefect of the fine arts." From time to time he returned to his native village. He died in Venice on Oct. 13, 1822. His remains were deposited in a temple at Possagno which he had himself designed.

Among Canova's more celebrated works may be mentioned "Amor and Psyche" (Louvre, Paris); "Perseus With the Head of Medusa" (Vatican); "Napoleon I" (Brera palace, Milan); the monument of Alfieri (Santa Croce, Florence); the princess Pauline Borghese as Venus (Villa Borghese, Rome); and "The Three Graces" (Hermitage, Leningrad). In 1821 his statue of George Washington, in a tunic, was erected at Raleigh, N.C. Canova's work was compared by his contemporaries to the great works of antiquity, after which, in externals, it was modeled. His reputation since has declined.

See Elena Bassi, *Canova* (1943).

(A. K. McC.)

CÁNOVAS DEL CASTILLO, ANTONIO (1828–1897), Spanish statesman, who was the architect of the restoration of the Bourbon monarchy in Dec. 1874 and of the system of government thereafter established, was born at Málaga on Feb. 8, 1828. He studied law at Madrid university and earned his living by writing and journalism. He entered the *Cortes* in 1854, and held various offices in Liberal cabinets between 1860 and 1868. After the abdication of King Amadeo and the proclamation of the federal republic (1873), Cánovas advocated the return of the Bourbons and it was he who drew up the manifesto issued in 1874 by Alfonso XII. But he opposed the method of the *pronunciamiento*. After Alfonso had been proclaimed king, Cánovas formed a ministry and held office, with two brief interruptions, for six years. He had to construct a Conservative party out of the least reactionary parties of the reign of Isabella II and out of the more moderate elements of the revolution. With such followers he made the constitution of 1876 (see SPAIN: *History*). Cánovas was guided by two principles: the exclusion of the army from politics and the undesirability of free elections. Holding the latter view because of the insecure position of the monarchy, he instituted the system of

"made" elections, which was crowned when he permitted the creation of a Liberal party under P. M. Sagasta, who took office in 1881 and with whom Cánovas thenceforward alternated as prime minister. However necessary the faking of elections may have been in the years immediately after the restoration, the practice begun by Cánovas proved ineradicable and ultimately harmed the monarchy by associating it with a discredited political system. Cánovas became prime minister for the fourth time in March 1895 immediately after the outbreak of the Cuban insurrection, and prepared to send 200,000 men to the West Indies to carry his policy of no surrender. The Cuban question was still undecided when he was assassinated at Santa Agueda (Guipúzcoa) on Aug. 8, 1897.

Cánovas was a cultured and intelligent man. He continues to enjoy a considerable reputation as a historian, especially for his studies of 17th-century Spanish decadence, on which *Estudios del reinado de Felipe IV*, two volumes (1888-89), is his most notable work.

See M. Fernández Almagro, *Cánovas, su vida y su política* (1951).

CANROBERT, FRANÇOIS CERTAIN (1809-1895), marshal of France, whose early service in north Africa led to his appointment as French commander in chief in the Crimean War, was born at St. Céré, Lot, on June 27, 1809. After study at St. Cyr, he was commissioned sublieutenant in 1828. Sent to Algeria in 1835, he distinguished himself at the taking of Constantine. He was recalled to Paris in 1839 to organize a battalion of the Foreign Legion, but returned to Africa in 1841. As a colonel in 1847, he won renown with the Zouaves at the siege of Zaatcha. Summoned to Paris in 1850, he was made brigadier general and aide-de-camp to the prince-president Louis Napoleon and took part in the coup *d'état* of Dec. 2, 1851. He was promoted general of division in 1853. The Crimean War (1854-56), while confirming his merits, also exposed his limitations. Courageous, a magnificent leader of men and a good speaker, he feared responsibility and showed himself irresolute when he became commander in chief on the death of the marshal de Saint-Arnaud (Sept. 1854). He was aware of his own limitations and, on the pretext of ill-health and of a disagreement with the British, asked the emperor to appoint a new commander in chief (May 16, 1855) but to leave him the command of a division. Recalled to Paris in July 1855, he was made a marshal of France. He took part in the campaign of 1859 in Lombardy, distinguishing himself at the battles of Solferino and Magenta. On the outbreak of the Franco-German War, his fear of responsibility led him to serve under the junior marshal, A. F. Bazaine. In command in the battle of St. Privat, he at first withstood the Prussians but eventually had to retreat when his ammunition ran out and reinforcements failed to arrive. He was taken prisoner at Metz. Resuming his military career after the war, he became a member of the superior council of war. Elected senator for Lot (1876) and for Charente (1879 and 1885), he represented Bonapartist ideas under the third republic. In 1856 he married Lelia Flora de Macdonald, who bore him two children and died in 1889. He died in Paris on Jan. 28, 1895.

See L. Bapst, *Le Maréchal Canrobert*, 3 vol. (1898-1913). (L. G.)

CANTABRI, an Iberian tribe with a strong celtic element which occupied the centre of the northern coast of Spain and lived in the Cantabrian mountains situated parallel to the coast in the modern province of Santander. They occupied the territory now comprised by the modern province of Oviedo on the west as far as the Salia (Sella) river, beyond which lay the Astures tribe. They were bounded on the east by the Autrigones and on the south by the Vaccaei and Celtiberi. The Cantabri were little mentioned before they were incorporated by the emperor Augustus after protracted campaigns (29-19 B.C.) into the Roman province of Hispania Tarraconensis and were governed from Roman Clunia (mod. Peñalba de Castro) in Celtiberia.

Unlike the other Iberian tribes of Spain, the Cantabri were divided into distinct clans: Orgenomesci on the coast from the Sella to the Namnasa (Nansa) river, the Aurini to the east, Conisci in the area behind Santander, Vadinienses in the southeast, Concani round modern Potes, Tamarici round Velilla del Río Carrión, Velegienses in the Alto Pisuerga, Morecani in the region of Sedano, and Juliobrigenses about the Cantabrian capital of Juliobriga

near the origin of the Ebro river (perhaps Retortillo south of Reinosa).

The Cantabri were regarded as the fiercest people in the peninsula. They were subjugated by the Roman emperor Augustus in 25 B.C. but he, Tiberius and M. Vipsanius Agrippa were forced to keep them in check by a series of wars lasting until 19 B.C. which almost annihilated them.

Under the Romans, according to Pliny the Elder (1st century A.D.), Cantabria was made up of seven tribal groups, some retaining their old names while other names such as the Pleutauroi and Barduetai appear, but no details of this regrouping are known.

See P. Bosch-Gimpera, "El problema de los Cantabros y de su origen," *Boletín de la Biblioteca Menéndez Pelayo* (1933); A. Schulten, *Los Cantabros y Astures y su guerra con Roma* (1943). (Wm. C.)

CANTABRIAN MOUNTAINS (CORDILLERA CANTÁBRICA), a mountain chain loosely defined as extending along the north coast of Spain, more specifically defined as the series of high ridges rising inland from Torrelavega in Santander province and extending westward for 150 mi. toward Foz near the Galician border. Fractures have sharply demarcated the range from the Castilian plateau in the south and from the Cantabrian coastlands, but the eastern and western limits are indistinct. Between the valleys of the Navia and the Lesaya the mountain chain lies in the Asturias, sharing geological affinities with the hercynian structures of Galicia. East of the Lesaya, the eastern Cantabrians of Santander share features characteristic of the Basque mountains. As far west as the pass of Leitariegos, the ranges run nearly parallel with the coast: lower and near the coast and the main ridge to the interior. The eastern foothills south of Santander rise abruptly into the gigantic limestone mountains of the Picos de Europa (8,786 ft.) and the Peña Labra (6,566 ft.). The main ridge continues westward, usually less than 60 mi. wide but with altitudes of 5,000-7,000 ft. Compared with the Pyrenees, these chains are a more impressive barrier, and the Oviedo-Léon railway crosses the Puerto de Pajares at 4,524 ft., one of the most difficult railway passes in Europe. Most of the highest summits are along this main ridge: Espigüete (8,040 ft.), Prieta (8,300 ft.), Peña Vieja (8,573 ft.), Mampodre (7,185 ft.), Ubiña (7,929 ft.) and farther west Rubia (6,332 ft.). Locally, sedimentary rocks may be weathered into wild, serrated pinnacles but more characteristic are the isolated mountain blocks (*parameras*) whose desolate plateaulike summits are surrounded by steep or vertical cliffs. West of the Narcea valley, the ranges change their east-west trend and the Sas de Rañadoiro runs almost north-south. The main ridge bifurcates into the Sas de Picos and Caurel to the northwest and the Sas de Jistredo and Montafias de León, to enclose the basin of El Bierzo, drained by the upper Sil. On the Atlantic slopes, gradients on the rivers are steep but gentler on the southern valleys. The zone is rich in minerals. See SPAIN: ECONOMICS.

See M. de Terán (ed.), L. Solé Sabaris (author) and others, *Geografía de España y Portugal*, vol. i (1952). (J. M. Ho.)

CANTACUZINO, a Phanariote family prominent in Rumanian history, descended from the Byzantine Cantacuzeni, one of whom was Byzantine emperor as John VI (*q.v.*) from 1341 to 1354. After the fall of Constantinople (1453) the Cantacuzeni entered the Turkish service and rose to eminence in the Ottoman court. The Moldavian and Walachian Cantacuzinos are descended from the five sons of ANDRONIC CANTACUZINO (c. 1553-c. 1600) who settled in Moldavia late in life.

Andronic's youngest son, CONSTANTIN CANTACUZINO, called Postelnicul, moved to Walachia in the 1620s, where he became marshal of the court (*postelnic*) and married Elena, daughter of the ruler Radu Șerban Basarab. He was murdered by Grigore Ghica in 1663. Constantin's second son, ȘERBAN CANTACUZINO (c. 1640-1688), was ruler of Walachia from 1679 to 1688. He introduced maize (corn), now the staple diet, and encouraged the printing of books (including the Bible of 1688, named after him). He planned to drive the Turks out of the Balkans and secretly helped the Austrians in the siege of Vienna (1683). He died suddenly, apparently from poison. Șerban's younger brother CONSTANTIN CANTACUZINO, called Stolnicul or the Steward, was a historian, geographer and diplomat who conducted foreign affairs

under three rulers: his brother Șerban, Constantin Brancovan and his own son. STEFAN CANTACUZINO, who took Brancovan's place in 1714. In 1716, however, both Constantin Stolnicul and Stefan were executed by the Turks.

DUMITRAȘCU CANTACUZINO (1648–85), a nephew of Constantin Postelnicul, was prince of Moldavia from 1673 to 1675 and from 1684 to 1685. He was hated for his heavy taxation and incompetence.

Of the later generations of the family the most notable were: MIHAIL CANTACUZINO (born 1723; d. between 1790 and 1793), the historian of Walachia who went to Russia in 1776 and became a general; CONSTANTIN CANTACUZINO (1793–1877), who tried, with Turkish support, to make himself prince of Walachia in 1849; and GHEORGHE GRIGORE CANTACUZINO (1837–1913), leader of the Conservative party in Rumania from 1899 and prime minister from 1905 to 1907.

CANTAL, a *département* of central France, lies in the higher, southern portion of the ancient province of Auvergne. It is bounded north by Puy-de-Dôme, east by Haute-Loire, southeast by Lozire, south by Aveyron and west by Corrèze and Lot. Pop. (1954) 177,065. Area 2,231 sq.mi. It extends eastward into the heart of the Massif Central and consists largely of ancient granites and schists that form high plateaus, with extensive cappings of young, volcanic rocks. Such a volcanic superstructure are the Monts du Cantal that occupy the centre of the *département*. They form an imposing, symmetrical volcanic mass, culminating at 1,858 m. (6,096 ft.) in the Plomb du Cantal. Beyond the central core of ash and breccia are great tongues of lava that form tablelike plateaus, notably the *planèzes* of St. Flour and Aubrac, extending southeastward, and that of Cézalier, which links the Cantal massif with the similar Mont-Dore to the north. Streams radiate from the Cantal to the Allier, Dordogne and Truyilre. Beneath the volcanic heights the valley of the Cbre river opens westward into the fertile little basin of Aurillac. The radiating streams have vigorously eroded the heterogeneous volcanic rocks in the centre of the Cantal, and there are easy passes at the valley heads. Such is the Col de Lioran leading from the Cère valley to that of the Alagnon. The upper portion of the Truyère represents a diversion from the Allier drainage to that of the Lot, brought about by a lava flow that blocked the old valley.

Winters are wet and severe, with snow covering the ground for a long period. On the higher parts an alpine type of pastoral economy has developed, with seasonal use of the high pastures (*chaumes*) by cattle. The herdsmen occupy seasonal shelters (*burons*) associated with a dairy, where the large Cantal cheeses are made. At lower levels, permanent pasture is combined with some arable cultivation, and formerly a shifting type of cultivation, known as *écobuage*, was extensively practised. In modern times, however, the rural economy has become increasingly specialized upon cattle. Fodder crops and potatoes have largely replaced rye and buckwheat, and sheep have declined in importance. There is little manufacturing or mineral wealth, but there are numerous thermal springs, notably at Chaudesaigues. The population is sparse and there is a tradition of temporary migration, both short-term, as to lowland areas at harvest time, and for longer periods, Auvergnats being well known in the catering trades in Paris. Permanent migration greatly reduced the population after the 1860s.

Cantal is divided into three *arrondissements*, based upon Aurillac (*g.v.*), the capital, Mauriac and St. Flour. The last is the centre of the bishopric, which comes under the archbishop of Bourges. Cantal lies within the educational division of Clermont-Ferrand, and its court of appeal is at Riom.

For the history of the region, see AUVERGNE. (AR. E. S.)

CANTALOUPE is a common name for a botanical variety of muskmelon whose fruit has a hard warty rind without netting. The name comes from the castle Cantalupo in Italy where this kind of melon was early grown. In the United States the name is most often applied to small netted kinds, but sometimes to muskmelons in general. See MUSKMELON.

CANTATA, a musical term derived from the Italian *cantare*, "to sing"; it indicates primarily a composition intended to be

sung, in contradistinction to a sonata, which is one to be played instrumentally. The term is now loosely used to describe any work for voices and instruments; it may take almost any form, as is seen in application of the title to works by Bartók, Stravinsky and Schönberg, who have adapted new techniques to the old form.

In its earliest form the word appears in Alessandro Grandi's *Cantade et arie a voce sola* (1620), in which the individual items are constructed on much the same pattern as the strophic arias of Giulio Caccini and Jacopo Peri (see ARIA). The *Lettera amorosa* and *Partenza amorosa* of Monteverdi (1567–1643) are also regarded as forerunners of the cantata. The true chamber cantata (*cantata da camera*), which became one of the most important forms of the late 17th and early 18th centuries, consisted of a sequence of movements following a *recitative-aria-recitative-aria* pattern, sometimes with only a figured bass accompaniment, sometimes with an orchestral one. The pattern could be extended to include an overture, duets, trios and even choruses, though the apparently choral items were often sung by the soloists. Early composers of chamber cantatas were Francesco Rasi, Giovanni Berti, Giovanni Sances and Benedetto Ferrari; and, more famous, Luigi Rossi, Giacomo Carissimi and Pietro Antonio Cesti. Later the cantata form was taken over by the great Neapolitans, Alessandro Stradella and Alessandro Scarlatti; the latter is credited with over 600 cantatas, and in his hands the form became one of the most thoughtful and expressive of musical mediums. Handel, Leonardo Leo, Leonardo Vinci and Johann Hasse later contributed to the enormous repertory of chamber cantatas, Handel writing a large number, of which *Apollo e Dafne*, almost a miniature opera, is perhaps his best known. Although the chamber cantata died out among Italian composers of the later 18th century, an amusing late example is *Il Maestro di Cappella* by Domenico Cimarosa (1749–1801), in which the basic cantata pattern is still apparent, the whole forming a spackling satire on contemporary operatic rehearsal methods.

In England the cantata appeared in the late 17th century as a forerunner of the strong Italian influence of the 18th century; the extended songs of Henry Purcell are claimed as early examples. Many cantatas were composed and published in England during the 18th century by both English and foreign musicians, some as satires on the prevailing Italian operatic fashions; e.g., James Oswald's *Dustcart* Cantata (1753) and James Hook's *Musical Courtship* (c. 1787).

Italian influence was also strong in 18th-century France, where the Italian type of cantata with French texts was introduced about 1700. Jean Baptiste Lully's rival, Marc Antoine Charpentier (1634–1704), was one of the first to enter the field, but the next generation with André Campra, Nicolas Bernier, Michel Montclair, Jean Baptiste Morin, Jean Joseph Mouret and, especially distinguished, Louis N. Clérambault and Jean (Philippe) Rameau represented the greatest period of cantata composition.

In the German Protestant states the development of the cantata took a religious turn, and the most noteworthy contributions to the form were the church cantatas, which were serious in style and purpose. Franz Tunder, Matthias Weckmann, Dietrich Buxtehude and members of the Bach family all composed numerous church cantatas, especially "chorale" cantatas in which a well-known chorale-melody was used as the basis for at least part of the composition. Johann Krieger, Philipp Erlebach, G. P. Telemann and above all J. S. Bach are the most celebrated names in the history of the German church cantata; their texts frequently were provided by the highly dramatic religious poems of Erdmann Neumeister (1671–1756). A typical Bach church cantata opens with a more or less extended chorus, followed by a group of recitatives and arias, and ends with a chorale for chorus and orchestra, in which the congregation probably joined. Cantata and service were closely interwoven, an aspect that is lost when Bach's cantatas are performed away from the Lutheran service. Some German composers, Telemann in particular, wrote large numbers of church cantatas for solo voice with varying instrumental accompaniment.

North German composers also produced many secular cantatas as birthday or congratulatory odes; J. S. Bach composed several,

including the *Coffee Cantata* (c. 1732) and the *Peasant Cantata* (1742)—titles conferred by a later generation. Telemann's Schoolmaster cantata is another example of the secular type, of which there were both comic and serious versions. In the Roman Catholic provinces of south Germany and Austria, cantatas were more often secular than sacred, for church music consisted mainly of settings of Latin texts, but in Czechoslovakia strong local patriotism produced a thriving religious music that used vernacular texts; the charming Bohemian Christmas pastorales form a special type of church cantata. The great Viennese composers also wrote occasional secular cantatas to German words; e.g., Haydn's *Esterhazy Festkantate* (1763–64) and Mozart's Masonic cantata *Die Maurerfreude* (1785).

From about 1800 the style of the cantata became increasingly free, and the term was generally applied to any fairly large work for solo voice or voices, chorus and orchestra from Beethoven's *Der glorreiche Augenblick* (1814) onward, though the word cantata may not appear in the title. Mendelssohn's *Die erste Walpurgisnacht* (final version, 1843) and Brahms's *Rinaldo* (1869) are two 19th-century examples. Mendelssohn even combined the cantata with the symphony in the so-called symphony-cantata *Lobgesang* ("Hymn of Praise") (1840), while Benjamin Britten on the other hand called what is actually a cantata *Spring Symphony* (1949). Numerous English examples are provided in the works of Sir Arthur Sullivan, Sir Charles Stanford, Sir Hubert Parry, Ralph Vaughan Williams, Herbert Howells and Britten.

(Cs. CH.)

CANTEEN, a soldier's or sailor's combined clubroom, reading and writing room, recreation hall or place where refreshments are available. By an extension of meaning, it also denotes the place where meals are provided for their employees by large business and industrial organizations. It is also the naval or military equivalent of a universal store for the sale of a wide range of foodstuffs, dry goods, clothing and equipment. The term is of long standing in both British and U.S. armed services.

In the days of the duke of Marlborough the British army was accompanied by a swarm of sutlers peddling foodstuffs, liquor and tobacco at prices strictly controlled by the authorities. When the marching column halted for the night, a booth contrived of the sutler's tilt cart and a tarpaulin served as an elementary canteen. One of the most notorious of these sutlers was the former Scots Grey trooper "Mother" Ross. (See Daniel Defoe, *The Life and Adventures of . . . Mother Ross*.) The armies of the French Directory were also accompanied by many *cantinières*—motherly, capable women, usually married to one of the non-commissioned officers. With the expansion of permanent barrack accommodations in the early 19th century, canteens were included in the new buildings. Rented from the board of ordnance by contractors intent on speedily recouping the considerable "privilege money" demanded for the right to trade, these canteens became little more than sordid drinking dens, although the duke of York sought to provide a counterattraction by reserving space within the barrack confines for bowling alleys.

Much-needed reform came with the foundation, by three regimental officers, of the Canteen and Mess Co-operative society in 1894, a movement which paved the way for the establishment in 1915 of the officially sponsored but privately operated Expeditionary Force canteens (E.F.C.). Their activities were supplemented by the Church army, the Y.M.C.A. and other bodies, while the work of the "Sailors' Homes," founded by Agnes Weston, was greatly expanded. The responsibilities of the E.F.C. became so great that in 1921 the enterprise was taken over by the Navy, Army and Air Force institutes (N.A.A.F.I.), controlled by a council and a board representative of both service and catering interests, profits being "plowed back" or devoted to the provision of amenities for the serviceman.

The British "dry" canteen, for the sale of groceries and the like, has its counterpart in the U.S. "post exchange" and commissary. The lineal descendant of the elementary canteen stores organized for Washington's Continental forces, the trading scope of the PX, as it is called, is that of the supermarket. Presided over by a council, with the post commander as ex officio chairman,

its profits are devoted to the general interests of the serviceman, and it is to be found wherever U.S. forces are established.

A soldier's water bottle is called a canteen. In the days of antiquity the canteen as a water container was fashioned of leather. Then came wood, pewter, tin and subsequently aluminum canteens, partly insulated from heat or cold by a jacket of cloth or felt.

See Hon. Sir J. W. Fortescue, *A Short Account of Canteens in the Britzh Army* (1928).
(R. C. H.)

CANTELUPE (CANTILUPE), **SAINT THOMAS DE** (c. 1218–1282), bishop of Hereford, known for his ascetic life, strict discipline and martial spirit, was the son of William, 2nd baron Cantelupe. Educated at Paris and Orléans, he taught canon law at Paris and at Oxford and in 1262 became chancellor of Oxford. He held a dispensation from the pope for a plurality of benefices. During the Barons' War he favoured Simon de Montfort and represented the barons at the court of St. Louis IX of France.

Cantelupe became chancellor of the realm in 1265 but lost the post the same year, after Montfort's death; whereupon he returned to Paris as a teacher. He returned to Oxford shortly for a second term as chancellor. In 1274 he attended the second council of Lyons and in the following year was made bishop of Hereford. He was also a counselor of Edward I and a friend of Archbishop Robert Kilwardby. But on the accession of John Peckham to the primacy in 1279, succeeding Kilwardby, Cantelupe became involved in a number of jurisdictional disputes, and in 1282 he was excommunicated.

He went to Italy to plead his cause but died at Orvieto on Aug. 25, 1282. He was buried at Hereford. His canonization took place in 1320, and his feast day is Oct. 3.

See Richard Strange, *Life and Gestis of Thomas of Cantilupe* (1674).
(T. L. C.)

CANTELUPE (CANTILUPE), **WALTER DE** (d. 1266), bishop of Worcester, uncle of St. Thomas de Cantelupe (*q.v.*), was the son of William, 1st baron Cantelupe, a partisan of King John. Educated at Rome for a time, he was named bishop of Worcester while still a subdeacon and was consecrated (1237) at Viterbo by Pope Gregory IX.

Cantelupe was known in Worcester for his energetic administration and for his numerous reforms. He identified himself with the nationalist clergy led by the bishops Edmund Rich and Robert Grosseteste, and opposed the visitation policies of Archbishop Boniface of Savoy and the attempted suppression of plural holding of benefices by the papal legate Otho.

At the parliament of Oxford (1258) Cantelupe was chosen one of the 24 who virtually ruled the kingdom, and in 1259 he became a member of the council which ruled in the king's absence. He sided with Simon de Montfort in the Barons' War and acted as an arbiter in the baronial party's internal disputes. He was also sent on a number of diplomatic missions abroad. For his continued support of the barons Cantelupe was suspended from his see and summoned to Rome, but he died on Feb. 12, 1266, before making the journey.
(T. L. C.)

CANTEMIR (Russ. KANTEMIR), a family distinguished first in the principality of Moldavia, then in Russia, where its importance was chiefly in the field of literature. Of Tatar origin, the Cantemirs came from the Crimea in the 17th century and settled in Moldavia.

CONSTANTIN CANTEMIR was prince of Moldavia from 1685 to 1693. A conscientious ruler, he brought peace to the country. He was succeeded by his son ANTIOCH, who ruled twice (1696–1700 and 1705–07) in a period of great instability, during which Turkish influence was paramount.

Antioch's youngest brother DIMITRIE, born on Nov. 5 (new style; Oct. 26, old style), 1673, was made ruler of Moldavia in 1710. Ready to acknowledge Russian suzerainty instead of Turkish, he concluded an alliance with Peter the Great at Lutsk on April 24 (N.S.; 13, O.S.), 1711. After the Russian defeat at the battle of Stanilești on the Pruth, Dimitrie fled to Russia, where he settled and wrote the greater part of his work. Peter the Great appointed him imperial chancellor.

Dimitrie Cantemir was one of the greatest linguists of his time, speaking and writing 11 languages. He was interested in scientific matters and was elected to the Berlin Academy in 1714 for his work in this field. The best known of his works is his *Historia incrementorum atque decrezentorum aulæ Othomanicæ* (1716; Eng. trans., *History of the Growth and Decay of the Othman Empire*, two parts, 1734-35). His other works include *Hronicul vechimii a Romano-Moldo-Vlahilor*, the first critical history of Moldo-Walachia; *Descriptio Moldaviae*, the first geographical, ethnographical and economic description of Moldavia; *Historia hieroglyphica*, a Rumanian equivalent of the story of Reynard the Fox; a history of the two ruling houses of Brancovan and Cantacuzino; and the *Divan*, a philosophical treatise in the guise of a disputation between body and soul. There is an edition of his works by the Rumanian Academy, *Operele principelui D. Cantemir* (1872-1901). He died at Kharkov on Sept. 1 (N.S.; Aug. 21. O.S.), 1723.

Dimitrie's younger son ANTIOCH (RUSS. ANTIOKH DIMITRIEVICH KANTEMIR; 1708-44) was educated at St. Petersburg and was elected a member of the academy there when still quite young. Between 1729 and 1731 he wrote a number of poems, the most important being two satires, "To His Own Mind: On Those Who Blame Education" and "On the Envy and Pride of Evil-Minded Courtiers." These denounced the opposition to Peter the Great's reforms and enjoyed great success when circulated in manuscript (they were not printed until 1762). Russian ambassador in England from 1732 to 1736, Cantemir brought to London the manuscript of his father's history of the Ottoman empire and furnished the biography of the author that appeared with the English translation (*see above*). From 1736 until his death he was minister plenipotentiary in Paris.

As well as Russian translations from several classical and modern authors, including one of Fontenelle's *Entretiens sur la pluralité des mondes* (1740), which was suppressed as heretical, Cantemir also wrote a philosophical work, *Letters on Nature and Man* (1742), and a *Letter* on the old syllabic system of Russian verse composition (1742).

CANTERBURY, CHARLES MANNERS-SUTTON, 1ST VISCOUNT (1780-1845). English lawyer and a notable speaker of the house of commons, was born on Jan. 29, 1780, the elder son of Charles Manners-Sutton (1755-1828), who afterward became archbishop of Canterbury. Educated at Eton and at Trinity college, Cambridge, in 1806 he was called to the bar and entered parliament as Tory member for Scarborough. He became judge advocate general in 1809. He was elected speaker in June 1817. His strong voice, dignified presence and even temper fitted him well for this post, to which he was seven times re-elected. He refused to exchange it for the home secretaryship in April 1827, or for the premiership in the crisis over the Reform bill in May 1832. He was persuaded to remain speaker by the Whig government of 1832, but outside parliament made no secret of his Tory leanings. This led to resentment and complaints from radicals and extreme Whigs. When a new parliament met in Feb. 1835, a sharp contest for the speakership ensued and Manners-Sutton was defeated by ten votes. He was made a viscount in March 1835. He died in London on July 21, 1845. (M. R. D. F.)

CANTERBURY, a provincial district in the east central part of South Island, New Zealand. Pop. (1961) 339,883. Area 13,940 sq.mi. It extends from the Conway river to the Waitaki river and includes Banks peninsula, the Canterbury plains, the enclosing foothills, inland basins, alpine ranges and valleys, together with part of South Canterbury and of the Waitaki valley. Population is confined to a narrow coastal strip and largely to Christchurch and its port, Lyttelton. The wealth of Canterbury derives from the mixed farming of the plains and the fine-wooled sheep of the alpine grazing lands. Ashburton is the chief town of mid-Canterbury; the port of Timaru serves South Canterbury and is also a tourist resort. Canterbury is famous for its alpine scenery and the mountaineering and skiing in the Mt. Cook area. (K. B. C.)

CANTERBURY, a city and county borough, metropolis of an archdiocese of the Church of England, in the Canterbury par-

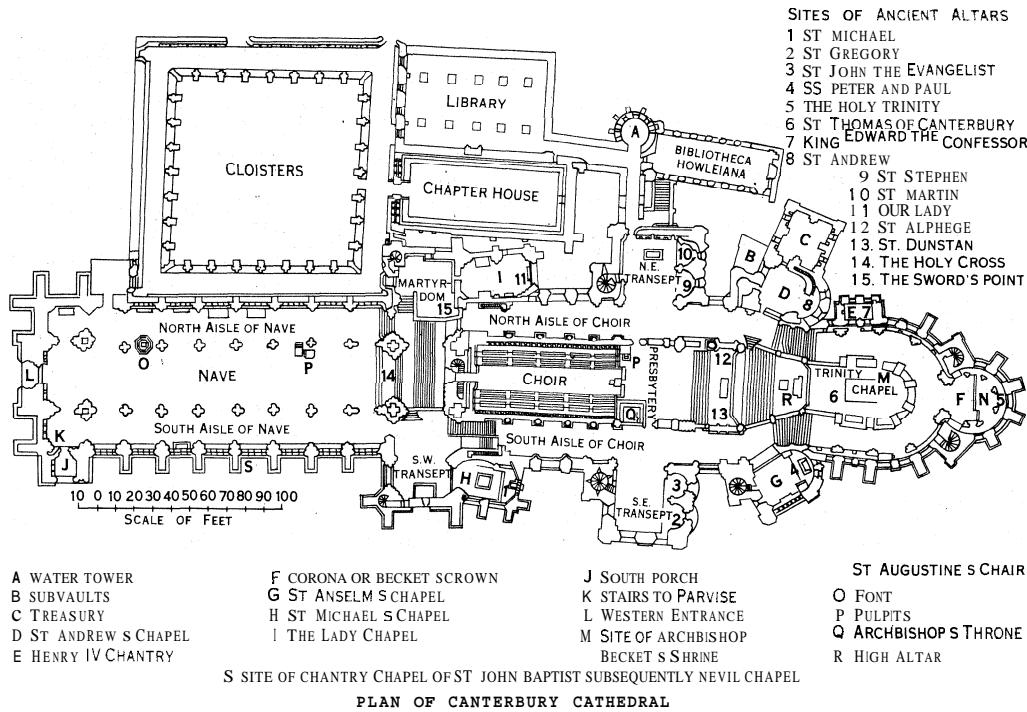

liamentary division of Kent, Eng., 55 mi. E.S.E. of London by road, 16 mi. N.W. of Dover and 27 mi. E. of Maidstone. Pop. (1961) 30,376. It is a picturesque city, dominated by the magnificent cathedral, and lies on the Kentish Stour, which there debouches from a narrow valley into a broadening marshy plain, representing a one-time creek running from the belt of water that separated the Isle of Thanet from the mainland.

History.—Canterbury seems originally to have been a settlement at the head of this creek, at an ancient mouth of the Stour. The site was occupied long before the Roman period. Excavations have shown that as early as 200 B.C. there was a heavily stockaded and ditched settlement with at least one complex gateway in what is now the southeastern quadrant of the city walls. Julius Caesar stormed Bigbury camp (two miles west) in 55 B.C. and was again near Canterbury on his second campaign (like the first, abortive) in 54 B.C. After the invasion of the emperor Claudius (A.D. 43), the Romans immediately established a community called Durovernum (a Latinized version of the native name). The town, though with no great population, must have been of some cultural significance, judging from the remains of the vast Roman theatre, greater than anything in this class yet found in Roman Britain, of which the foundations were identified (1950) in the Watling street area. A wall, built around the city (c. A.D. 200), and still partly standing, was heightened in medieval times.

After the collapse of Roman rule, Canterbury emerged in the late 6th century as the capital of Aethelberht (Ethelbert), fifth Jutish king of Kent and overlord of Britain. The place acquired the name Cantwaraburh or Cantwarabyrig, "the borough of the men of Kent." Aethelberht married the Frankish Christian princess Berta, a fact that made the way easy for the mission from Rome (597) dispatched by Pope Gregory I and headed by St. Augustine (*q.v.*). Augustine founded a Benedictine monastery, converted Aethelberht and many of his subjects, and upon his later return as bishop of the English set up a cathedral in a building said to have been used as a church by Romans of Christian belief. Canterbury thus became established as the prime see of England, a position maintained ever after. With Christ Church cathedral and St. Augustine's abbey, the city was an outstanding religious and cultural centre during the whole Saxon period. It suffered badly in Danish raids, notably in 1011, and surrendered to William the Conqueror in 1066 just after the battle of Hastings. Archbishop Thomas Becket was murdered in the cathedral, on Dec. 29, 1170. Some phase, or side issue at least, of most of the major struggles and political events of medieval English history was enacted at Canterbury, as of the Peasants' Revolt or of the Wars of the Roses. In the 12th century it appeared among the dozen or so economically most important boroughs in England, when the most outstanding local activity was minting, in which Canterbury surpassed every other centre except London. In the 14th century there was a flourishing tourist industry, based on the pilgrimage to the shrine of St. Thomas. This aspect was immortalized by Geoffrey Chaucer in *The Canterbury Tales*.

During the Reformation all the monastic houses were dissolved, the cathedral alone surviving, when a dean and chapter took the place of the monks (1541). The greatest holocaust of Protestant martyrs outside London took place at Canterbury under Mary I (1553-58) when 41 persons were burned at the stake. In the 16th century there was a state of decay, as in other boroughs, though a great influx of Walloon and Huguenot Protestant refugees (nearly all weavers) from France and the Low Countries brought in a vigorous textile industry. There were periodic disturbances during the English Civil War, especially in 1647-48. Charles II entered Canterbury at the Restoration (1660). A garrison was established in Canterbury in the later 18th century, bringing in new life.

Half the circuit of the city walls still survives, with fine stretches at the Dane John and in Broad street. Westgate alone (1380) of the six gates remains. The Dane John mound, a great tumulus, is a survivor of a group of such mounds, probably Roman burial mounds. Of the Norman castle the battered shell of the keep alone stands (in Castle street, by the gasworks which were once housed inside it).

tower. The southwestern tower is an original Perpendicular structure finished about 1465, while the northwestern was copied from it in 1834-40, replacing a Norman tower of Lanfranc which had become unsafe. The cathedral plan is characterized by double cross aisles. The choir is flanked by projecting chapels (of SS. Andrew and Anselm). The building terminates at the east in a circular tower known as the Corona or Becket's crown. The principal dimensions of the cathedral are: length (outside) 522 ft., nave 178 ft., choir 180 ft. The nave is 71 ft. in breadth and 80 ft. in height. The main entrance is by the South porch (1400).

Interior. — An unusual feature of the interior is its separation into two parts which represent the two main periods of building. In most English cathedrals the choir is separated from the nave by a screen; at Canterbury the separation is further marked by a

Local government can be traced from an early date. Several old English reeves are named. By the 14th century the ancient borough moot had divided into court and council, the latter consisting in 1350 of 2 provosts or bailiffs, 6 aldermen, 12 jurats, and 36 councilors. This constitution was modified from time to time. In 1448 the two bailiffs were superseded by a mayor, and in 1461 a sheriff was added when the city was promoted to county status. In modern times there are a mayor and a sheriff, and a council having 6 aldermen and 18 councilors.

Since the end of the 19th century there has been an ever increasing influx of tourists. Among the industries are tanning, brick-making, and light metalwork. The city is a natural centre for the agricultural industry of east Kent as well as being the main shopping and educational centre.

THE CATHEDRAL

The original cathedral was reconstructed several times. Archbishop Lanfranc (*q.v.*) undertook the building (1070-89) of an entirely new church. Early in the 12th century the choir of the new building was demolished and extended, this new work, the "glorious choir" of Prior Conrad, being dedicated with great ceremony in 1130. Fire destroyed the choir in 1174, and thenceforward the rebuilding was conducted by the French master-mason William of Sens until he was crippled by a fall in 1178, when another William, commonly distinguished as the Englishman, carried on the work and completed it in 1184. In 1376 Archbishop Simon of Sudbury entered upon the construction of a new nave, and Prior Chillenden continued this under Archbishop William Courtenay while additional chapels were added. The building of the central tower was undertaken between 1495 and 1503 by Prior Thomas Goldstone.

Canterbury was severely damaged in World War II, principally in the air raid of June 1, 1942. The cathedral received superficial damage, the chapter library was blown up and large numbers of buildings throughout the city were destroyed. The chapter library was rebuilt in 1954 and houses extensive collections of early capitular and diocesan archives.

Exterior. — The Perpendicular central tower is the most notable feature of the exterior. It rises in two stories to a height of 235 ft. and is known variously as Bell Harry or as the Angel steeple from the gilded figure of an angel which formerly adorned the summit. The Perpendicular nave is flanked at the west front by towers, whose massive buttresses, rising in tiers, enhance by contrast the beautiful effect of the straight lines of Bell Harry

broad flight of steps leading up to the screen, the choir floor (but not its roof) being much higher than that of the nave. Chillenden, in rebuilding the nave, retained only the lower parts of some of the early Norman walls of Lanfranc and the piers of the central tower arches. These piers were encased or altered on Perpendicular lines. In the choir (the late 12th-century work of the two Williams), the notable features are its great length, the fine ornamentation and the use of arches both round and pointed, a remarkable illustration of the transition between the Norman and Early English styles; the prolific use of dark marble in the shafts and moldings strongly contrasting with the prevailing light stone; and, finally, the graceful incurve of the main arcades and walls at the eastern end of the choir where it joins the Trinity chapel. From the altar eastward the floor of the church is raised again above that of the choir. The choir screen was built by Prior Eastry, about 1300. There are several tombs of archbishops in the choir.

Next to the site of Becket's shrine (*see* below) is the tomb of Edward the Black Prince (d. 1376) with a remarkable portrait effigy and in a cabinet, close by, his helmet, shield, scabbard and surcoat. Near at hand is the tomb of Henry IV (d. 1413) and Queen Joan of Navarre. In the Corona is the so-called chair of St. Augustine, a marble throne of undetermined date.

The western crypt dates from the early 12th century, and the eastern, most lofty portion, from 1181. The capitals of the western crypt bear a remarkable series of grotesque carvings. St. Gabriel's chapel contains an important group of mid-12th-century paintings depicting the birth of St. John the Baptist. The crypt was granted to the Huguenot refugees as their church in the 16th century, and weekly services in French are still held.

Becket's Shrine and the Pilgrimages. — The priory owed its chief fame to the murder of Archbishop Becket, his canonization and the pilgrimages to his tomb. St. Thomas Becket was credited with a vast number of miraculous cures. Henry II performed his famous penance in 1174, walking barefoot into Canterbury and undergoing a flogging at the tomb. The fact that the king of Scotland, who was invading England, was captured at the moment of the completion of the penance was attributed to St. Thomas' intercession, and henceforth the popularity of the pilgrimages was well established. In 1220 the body was removed from the old tomb in the crypt to a magnificent new shrine in the Trinity chapel behind the high altar, visited by a constant stream of pilgrims. Great inns for accommodation of pilgrims were erected, such as the Chequers (c. 1400, part of which still stands).

Chaucer's *The Canterbury Tales* recount the journey of a typical group of pilgrims setting out from London about 1390.

The English language embodies two expressions originating in the pilgrimage—"Canterbury bell," a flower resembling the little bells bought as souvenirs at Canterbury, and "canter," the easy trot to which pilgrims set their horses. In 1538 Henry VIII decreed the destruction of the shrine, and every effort was made to obliterate the cult, though the 13th-century windows (depicting anecdotes from the miracles of St. Thomas) around the shrine were largely spared.

Province and Diocese.—The archbishop of Canterbury is primate of all England; the ecclesiastical province of Canterbury covers England south of Cheshire and Yorkshire; and the diocese covers a great part of Kent. The archbishop has a seat at Lambeth palace, London. In Canterbury there are fragments in Palace street of the old archbishop's palace which have been incorporated into a modern palace.

The following is a list of archbishops of Canterbury:

1. St. Augustine, 597–c. 607.
2. St. Laurentius, c. 607–619.
3. St. Mellitus, 619–624.
4. St. Justus, 624–627.
5. St. Honorius, 627–653.
6. St. Deusdedit, 655–664.
7. St. Theodore, 668–690.
8. Beorhtweald, 692–731.
9. Tatwine, 731–734.
10. St. Nothhelm, 735–739.
11. Cuthbeorht (or Cuthbert), 740–760.
12. Breguwine, 761–764.
13. Jaenbeorht, 765–792.
14. Aethelheard, 793–805.
15. Wulfred, 805–832.
16. Feolgilð, 832.
17. Ceolnoth, 833–870.
18. Aethelred, 870–889.
19. Plegmund, 890–914.
20. Aethelhelm, 914–923.
21. Wulfhelm, 923–942.
22. St. Odo (or Oda), 942–958.
23. Aelfsige, 959.
24. Beorhthelm, 959.
25. St. Dunstan, 960–988.
26. Aethelgar, 988–990.
27. Sigeric Serio, 990–994.
28. Aelfric, 995–1005.
29. St. Alphege (Aelfheah), 1005–1012.
30. Lyfing, 1013–20.
31. St. Aethelnoth (Ethelnoth or Egelnodus), 1020–38.
32. St. Eadsige, 1038–50.
33. Robert of Jumièges, 1051–52.
34. Stigand, 1052–70.
35. Lanfranc, 1070–89.
36. St. Anselm, 1093–1109.
37. Ralph d'Escures (or de Turbine), 1114–22.
38. William of Corbeil, 1123–36.
39. Theobald, 1138–61.
40. St. Thomas Becket, 1162–70.
41. Richard (of Dover), 1174–84.
42. Baldwin, 1185–90.
43. Hubert Walter, 1193–1205.
44. Stephen Langton, 1207–28.
45. Richard le Grant (of Wetharshed), 1229–31.
46. St. Edmund (Edmund Rich), 1233–40.
47. Boniface of Savoy, 1245–70.
48. Robert Kilwardby, 1273–78.
49. John Pecham (Peckham), 1279–92.
50. Robert de Winchelsea, 1293–1313.
51. Walter Reynolds, 1313–27.
52. Simon Mepeham (or Meopham), 1328–33.
53. John de Stratford, 1333–48.
54. Thomas Bradwardine, 1349.
55. Simon Islip, 1349–66.
56. Simon Langham, 1366–68.
57. William Whittlesey, 1368–74.
58. Simon of Sudbury, 1375–81.

Monastic Buildings.—Ornate Christ Church gate (1517) gives entrance from the southwest. The northern side of the precincts is covered by the remains of the monastic buildings. The Great cloister (144 ft. square) was built in the early 15th

century, but embodies Norman and 13th-century work. The vaulting is enriched by more than 800 shields of arms. The chapter house (c. 1300 in the lower stages, early 15th century in the upper) is covered by a vast roof of oak. The great Norman dormitory (90 by 155 ft.), flanking the chapter house, is now in ruins. Important among the many architectural features of the precincts is the Norman staircase (c. 1160) built by Prior Wibert which leads to the hall of the King's school, founded in the early middle ages and refounded by Henry VIII in 1541.

Other Ecclesiastical Foundations.—The most important of these was the abbey of SS. Peter and Paul (St. Augustine's) outside the walls, founded by Augustine about 600. Substantial remains survive of the abbey church (11th century). The Great gate (c. 1300) now gives access to St. Augustine's theological college. Outside the city Northgate was a house of canons (St. Gregory's) founded by Archbishop Lanfranc about 1080. The Austin friars, the Dominicans and the Franciscans had houses at Canterbury.

There are several almshouses, some of early date, such as St. John's (c. 1080), Maynard's (c. 1200) established by Mainer the Rich, a moneyer, and St. Thomas's of Eastbridge (c. 1175). In the 12th century there were 22 parish churches, though the number diminished as time went on. St. Martin's, still in use, was a Christian chapel where Queen Berta worshiped even before the arrival of St. Augustine. None of the local churches is of any great size, though many contain architectural features of interest, such as the nave arcades of St. Alphege and St. Dunstan. The head of Sir Thomas More is interred at the last-mentioned church. At Harbledown, where the traveler first comes in full view of the cathedral, stands the leper hospital, now an almshouse, founded about 1080. It still enjoys the pension of 20 silver marks (£13 6s. 8d.) a year, assigned by Henry II on the day of his great penance, which started at this point.

CANTERBURY BELLS: see CAMPANULA.

CANTH, MINNA (ULRIKA VILHELMINA CANTH, née JOHNSON) (1844–1897), Finnish novelist and dramatist, a leader of the revival of the vernacular and of the realist movement in Finland in the latter part of the 19th century. Born at Tampere (March 19, 1844) she went to school at Kuopio, Finland, and in 1863 entered the new seminary at Jyväskylä, where she married her teacher, J. F. Canth, in 1865. Widowed in 1879, with seven children, she went into business at Kuopio, but still found time to produce literary works that had a powerful impact on her time. In her early short stories *Novelleja ja Xertomuksia* (1878) she was somewhat influenced by Bjørnson's idealistic descriptions of country life, but in later novels and plays she turned to the realistic treatment of urban social problems, as in *Työmiehen Vaimo* (1885), a feminist play which, like *Sylvi* (1893), shows the influence of Henrik Ibsen. Among her best works are the short story *Kauppa-Lopo* (1889) and the play *Anna-Liisa* (1895), the latter influenced by Leo Tolstoy. As a dramatist she long ranked second only to Aleksis Kivi, and as a personality she was in the front rank of notable Finnish women. She died at Kuopio, May 12, 1897. (Ko. S.)

CANTICLES is one of the names of the biblical book also known as the Song of Songs and the Song of Solomon (*q.v.*). The word further denotes those biblical and nonbiblical "songs" or "odes" other than the Psalms that are used in church worship. At matins in the Orthodox Church there are nine canticles (on which are based the nine odes of the Kanon; *q.v.*): the two songs of Moses (Ex. xv, 1–19; Deut. xxxii, 1–43), the prayers of Hannah (I Sam. ii, 1–10), Habbakuk (Hab. iii, 2–19), Isaiah (Isa. xxvi, 9–20) and Jonah (Jonah ii, 2–9), the Song of the Three Holy Children (Dan. iii, 52–88 in the Septuagint), the Magnificat (Luke i, 46–55) and the Benedictus (Luke i, 68–79). The *Nunc dimittis* (Luke ii, 29–32) is sung at vespers. In the Roman breviary, Old

Testament canticles and the *Benedictus* are used at lauds, the *Magnificat* at vespers and the *Nunc dimittis* at compline (see BREVIARY). On Sundays the *Te deum* is used at matins and the Athanasian creed at prime.

CANTILEVER, a beam supported at one end and carrying a load at the free extremity or distributed evenly all along the exposed portion. The upper half of the thickness of such a beam is subjected to tensile stress, tending to elongate the fibres; the lower half to compressive stress, tending to crush them. Cantilevers are employed extensively in building, steel constructional work and machines. In the first specified any sort of wood or steel or masonry or concrete beam built into a wall and with free end projecting forms a cantilever; brackets of braced type are also used in small and large dimensions. The longer cantilevers have to be incorporated in a building when clear space is required below, the cantilevers carrying a gallery, roof, canopy, part of the building above or a runway for an overhead traveling crane. A good example of a cantilever sustaining a portion of a workshop out over a yard appears in fig. 1.

FIG. 1.—LONG CANTILEVER

This type is used in sustaining a portion of a workshop built over a yard

In bridge building a cantilever construction is employed for large spans, the classic type being that of the Forth bridge (see fig. 2), having girders connecting up the ends of the huge cantilevers. The clear span between the piers is nearly one-third of a mile. Cantilever cranes are necessary when a considerable area has to be served, as in steel stockyards, and shipbuilding berths. In the lighter types a central traveling toner sustains the cantilever girders on either side, the big hammerhead cranes (made in capacities up to 300 tons) for fitting-out basins have a fixed tower and revolving pivot reaching down therein, to rotate the cantilever in a circle. Block-setting Titan cranes have a very large reach of the cantilever, besides being mounted on a traveling carriage, to move out to sea as the block setting proceeds.

FIG. 2.—THE CANTILEVER IN BRIDGE BUILDING AND IN CRANES

Upper drawing shows the cantilever Forth bridge, Scot.; the span between the piers is nearly $\frac{1}{3}$ mi. Lower drawings show the cantilever principle applied to large cranes used in steel stockyards and shipbuilding berths

In motor car construction a cantilever spring was formerly much used for rear suspensions. Such a spring was anchored to the frame at the centre and at the forward end, the rear end being supported by the axle housing.

CANTON (KWANGCHOW; KCANG-CHOU), the great commercial metropolis of south China, is the capital of Kwangtung province and the historic vestibule of western influences from the late 17th century. The city had a population of 1,598,000 in 1953, including thousands of families living on small boats. It lies largely on the north bank of the Pearl (or Canton) river (Chu Chiang) in the northeast corner of the delta of the Hsi Chiang (or West river) and between the mouths of the Pei (North) river and of the Tung (East) river. The whole delta covers 2,900 sq.mi., and is one of the most crowded areas of China, containing an estimated 10,000,000 persons. It is a maze of streams and canals between small rice paddies constantly being expanded and

dotted with isolated hills that were once coastal islands. A 12-month growing season permits two rice crops and often a third dry crop each year, while ample water ensures rich returns from fish farming, and the marketing of tropical fruits, vegetables, sugar and firewood; silk, hogs and poultry also supplement farm income in the delta. The area is not self-sufficient, drawing rice and firewood from the upper reaches of its major stream valleys, as well as rice from central Hunan via the Che-ling pass, central Kiangsi over the Mei-ling pass, and from the Yangtze delta, Bangkok and Saigon by sea.

Ocean ships cannot enter the city but must anchor 12 mi. downstream at the port of Whampoa (Huang-pu), where dredging is steadily carried on to prevent silting. River craft bypass the port farther south by sailing up the Hsi to Wuchow, on the eastern border of Kwangsi, 230 mi. upstream. The two main railways of Canton lead south to Hong Kong, 111 mi. away, and north over the Yangtze river bridge between Wu-ch'ang and Hankow to Peking, 1,428 mi. away. Many bus and truck routes, and the 32-mi.-long railway to San-shui (Samshui) on the Hsi river are used for local passengers and freight. Traveling by water, ancient roads over the northern passes, and later by rail and air, the merchants of Canton spread over south China and into southeast Asia.

Because of the relatively late advance of the Chinese to the South China sea, the Canton delta was for long an outpost in a barbarian region. It was brought into the empire by the Ch'in dynasty (221–207 B.C.), and from the time of the Han dynasty (202 B.C.–A.D. 221) the city was known as Kuang-chou, its modern official name. The people of the delta, the Cantonese, are known as "the sons of T'ang," presumably because of large migrations from the north in the T'ang period (A.D. 618–906) and also because the Cantonese dialect is believed to be much closer to the spoken language of antiquity prior to the strong influences of later peoples in north China. Also, there are persistent culture traits from southeast Asia that have helped to distinguish Cantonese from other Chinese. One of the major differences may be explained by the close contact over many centuries with foreigners: Hindus, Arabs, Malaysians and Europeans, both abroad and in Canton itself.

Canton was the first Chinese port regularly visited by European traders, for there was the main outlet of tea, silk, spices, rhubarb and handcrafted articles. After more than a century of efforts by these traders to establish permanent stations along the south China coast, the British East India company began regular ship sailings in 1699, followed by the French in 1721 and the Dutch in 1762, and their trading agents or factors set up office-residence-warehouses or "factories" in a small area known as Shameen along the Pearl river. Canton became the pivot of official Chinese policy toward western trade whereby the foreigners were confined to a special area and compelled to deal only with a small group of Chinese merchants (Co-hong) directly responsible to the imperial government (imperial decree of 1757). This system, plus the rise of opium imports from India, led to increasing friction that erupted in the first of the so-called opium wars between Great Britain and China, 1839–42. The treaty of Nanking, signed Aug. 29, 1842, ended the war and replaced the Chinese merchants' monopoly or Hong system by five treaty ports where foreigners could live and work outside of Chinese legal jurisdiction. Although Canton was one of these ports, the British also gained Hong Kong, 80 mi. S., and built it into one of the greatest commercial bases in the far east. This realization spurred Chinese plans to develop Whampoa into a deepwater port able to handle 8,000–10,000-ton ships and eventually to reduce Hong Kong's dominance in the interport and foreign trade of south China.

In common with the other south China ports and reflecting its southward aspect, Canton long was a centre of overseas emigration to southeast Asia and other parts of the world. This carried a Cantonese version of Chinese culture abroad in the form of Cantonese foods and restaurants, handicrafts, dialects, by merchant and labouring classes rather than by scholars and families tied to the area. Remittances and visits from overseas family

members helped to maintain the interest of those abroad in conditions back home, while many Cantonese educated abroad returned to introduce new ideas and new methods to the city as well as to their native villages, particularly in the San-shui, T'ai-shan and Chung-shan districts. Christian missionaries in Canton founded China's first modern newspaper and established at an early date a printing plant, a hospital and a medical school; they founded Lingnan university and its well-known school of agriculture in 1916. Thus, Canton has played a conspicuous part in changing China, bearing out the saying that "Everything new begins in Canton."

Always restive under the imperial regime and a source of anxiety to the emperors of the Ch'ing (Manchu) dynasty, Canton became the centre of the revolutionary propaganda which led to the downfall of that dynasty in 1912. Many of the active parts were played by Cantonese, several of whom had lived in, or had been influenced by the examples of, western countries. Such men as Sun Yat-sen (*q.v.*), Wang Ch'ung-hui, Liao Chung-k'ai, Huang Hsing and Hu Han-min, as well as many of the 72 "martyrs" killed in the abortive uprising at Canton in April 1911, were of this region and background.

In the subsequent civil wars, Canton became the centre of opposition to the northern militarists. It was there that the Kuomintang or Nationalist party before Sun's death in 1925 began, under Soviet advisers, to develop into an all-inclusive one-party apparatus. For support against regional warlords, Sun set up the Whampoa Military academy in 1924, under the direction of Chiang Kai-shek to train a corps of officers loyal to the Kuomintang as the leader of a revived China.

It was from Canton that the Nationalist armies in 1926-27, including some of the later Communist leaders, advanced north over the Che-ling pass to the capture of Hankow and the lower Yangtze. The government set up in Nanking in 1927 as the national government of China proclaimed itself based on the "Three Principles of the People" expounded by Sun in Canton during 1923-24.

Beginning in 1919 a great program of street widening, razing of city walls, transfer of old graves, creation of public parks and a pleasant water front, building a bridge across the Pearl and dredging the harbour were all undertaken entirely through local initiative. In 1924 Sun promoted a university, later renamed the National Sun Yat-sen university, 10 mi. E. of the city.

An early attraction for foreign trade was in the handcrafted articles, much in demand in Europe at the end of the 18th century. When the fashion was at its height, thousands of artisans of all ages toiled in making porcelain, silks, embroidery, lacquered furniture, ivory carvings, enamels, paper umbrellas, fans and sundry toys. Declining demand in Europe and less skilled workers in China, plus the classical revival, broke this trade until the end of the 19th century when handicraft exports from Canton rose in other wares (palm-leaf fans, firecrackers, woven matting and fine paper) mainly for an expanded overseas Chinese market.

Powered industry came early, beginning with a steam-powered silk filature in Nanhai, 10 mi. W. of Canton, in 1880. From that time, more filatures for raw silk exports rather than to furnish thread for local weavers were the rule. Other kinds of light industry (rather than heavy industry) were developed, reflecting the lack of political stability that would attract large capital investment. The absence of sufficient coal also influenced this trend. Coal occurs around Chiu-chiang on the upper Pei river, but its high sulfur content and poor transportation in rugged mountain areas, as well as the constant political upheavals, inhibited extraction in sizable quantity. The city long obtained its coal by sea from north China and elsewhere. In and around Canton were located 9 of the 11 industries wholly or partially financed and operated by the provincial government from the late 1920s. These were a cement mill, two sugar refineries, a spinning and weaving factory, a paper mill, a machinery works, a communications equipment factory, a sulfuric acid plant, a fertilizer plant and a beverage plant. With the Japanese occupation of Canton (1938-45) much of the equipment was destroyed or removed, while inflation and easy imports from Hong Kong after

PETER SCHMID—PIX FROM PUBLIX

STREET SCENE, CANTON

A vendor uses a replica of a rooster to attract attention

World War II discouraged speedy industrial rehabilitation.

Compared with other areas, the Chinese People's Republic did not announce any extensive plans for industrial growth in Canton. Plans emphasized previous trends in linking industry with local agriculture by the opening of plants for sugar refining, manufacture of insecticides, fertilizers, jute for rice sacks, farm tools and the stimulation of light skilled industries for making sewing machines and small internal-combustion engines. The government enlarged the Canton paper mill, China's largest newspaper factory. Surveys were in progress in the early 1960s for hydroelectric development along the nearby tributaries of the Pearl river, which has an estimated potential of 8,400,000 kw.

Under the Nationalists' coastal blockade and the United States embargo of the latter 1950s, Canton served as a funnel for goods and persons moving in and out via Hong Kong. Thus, it maintained its old function reminiscent of the century before the opening of the original treaty ports.

See also CHINA.

(TE. H.)

CANTON, a city of northeastern Ohio, U.S., 60 mi. S.E. of Cleveland and the seat of Stark county. Corporate limits have lagged behind population, which in 1960 was 113,631 in the city itself, and 340,345 in the standard metropolitan statistical area—which includes all of Stark county. (For comparative population figures see table in OHIO: Population.)

Canton is a leading producer of electric furnace alloy steel and a major producer of tapered roller bearings. Brick and ceramics, in many varieties, form another important group of industries. Other leading products are safes, vaults and office equipment, shelving, lockers, voting machines, heavy steel presses, water softeners and cleansers, forgings, gasoline and diesel internal-combustion engines, street lighting standards, foundation piles, rubber gloves and titanium steel.

Canton was the permanent home of Pres. William McKinley from 1867 until his death in 1901. He and Mrs. McKinley are buried in a granite memorial in Monument park, since 1943 a state memorial administered by the Ohio Historical society.

Canton was laid out in 1805. The name probably derives from Canton, China, via Baltimore, where Canton's founder, Bezaleel Wells, had been a neighbour to the Canton estate, a private home founded on the profits of a famous shipload of goods from China. It became the county seat in 1808 and was incorporated as a village in 1822, as a town in 1838 and as a city in 1854. Its period of fastest growth was from 1900 to 1920, when the population increased from 30,667 to 87,094. This period brought in a large immigration of central, southern and eastern Europeans and of Negroes. There is also a large Jewish community. Among the original settlers Germans predominated, followed by Irish, French and Swiss.

Malone college, a four-year Quaker liberal arts college founded in 1892, was moved in 1957 to Canton from Cleveland, where it was known as Bible college. Kent State university, Kent, O., founded in 1910, conducts night school classes in Canton. Walsh college, a Roman Catholic institution, moved from Maine to Canton in 1960. Brunnerdale, a Roman Catholic seminary operated by the Society of the Precious Blood, was opened in 1931. Sancta Clara monastery is a monastery of the Perpetual Adoration of the Blessed Sacrament.

Canton is known to the sports world as the cradle of U.S. professional football, the American Professional Football association having been formed there in 1920 with Jim Thorpe (*q.v.*) of the Canton team ("Bulldogs") as its first president.

Cultural organizations include the Canton Art institute, the Players guild, the Canton Symphony orchestra, Canton Civic opera, Civic Music, Canton Poetry society and the Stark County Historical society. (E. T. HE.)

CANTON, a word used for certain divisions of some European countries. In France, the canton, a subdivision of the *arrondissement*, was a territorial rather than an administrative unit. The cantons were created by the law Dec. 22, 1789, but their administrative character was taken away by the consular constitution of the year VIII (Dec. 24, 1799). The canton, the seat of a justice of the peace, returned a member to the *conseil d'arrondissement*. In Switzerland, canton is the name given to each of the 22 states comprising the Swiss confederation. (See also FRANCE; SWITZERLAND; LOCAL GOVERNMENT.)

In heraldry (*q.v.*), a canton is a corner or square division on a shield, occupying the upper corner (usually the dexter). It is in area two-thirds of the quarter.

CANTON ISLAND, the largest and northernmost of the Phoenix group in the South Pacific, 1,630 mi. S.W. of Honolulu, Hawaii (lat. 2° 50' S., long. 171° 43' W.). A coral atoll, its narrow fringe of land encloses a lagoon 7 mi. by 3 mi. Several ships visited it before 1820 and it was named for a New Bedford whaler wrecked there in 1854. U.S. guano companies claimed Canton in 1856; later British interests worked its guano deposits and Great Britain annexed it in 1889-92. The British again asserted sovereignty in 1936 and the United States in 1938: the rival claims were settled by an agreement on April 6, 1939, in which Canton and Enderbury Island (32 mi. S.E.) were to be jointly administered for 50 years. Pan American Airways built facilities there and began using Canton for stops on transpacific flights in 1940. During World War II it was an important U.S. air base. U.S. and British airlines resumed using Canton after the war and in 1951 it gained some importance for commercial fishing.

Pop. (1960) 320.

CANTONMENT: see CAMP.

CANTOR, GEORG FERDINAND LUDWIG PHILIP (1845-1918), German mathematician, renowned for his contributions to the theories of analysis, topology and mathematical logic, was born of Danish parents on March 3, 1845, at St. Petersburg (Leningrad), Russia. The family moved to Germany in Cantor's boyhood, and he was educated at Frankfurt, Zurich, Berlin and Göttingen. Most of his academic career was spent at the University of Halle (Wittenberg), where he became extraordinary

professor (1872) and ordinary professor (1879) of mathematics. His hope of becoming professor at the University of Berlin was disappointed, and his work gained little recognition during his lifetime.

Cantor's early work was on the Fourier series (*q.v.*), and in extending the results obtained he developed a theory of irrational numbers that became classical. He also developed an arithmetic of the infinite and a new branch of mathematics—the theory of sets, which underlies modern mathematical analysis. This theory had a profound influence on subsequent work in the foundations of mathematics and mathematical logic.

In 1895-97 he published his famous work *Beiträge zur Begründung der transfiniten Mengenlehre*, Eng. trans., *Contributions to the Founding of the Theory of Transfinite Numbers*, by P. E. B. Jourdain (1915). Cantor suffered from nervous breakdowns in his later years, and died on Jan. 6, 1918 in a mental hospital at Halle.

See also references under "Cantor, Georg Ferdinand Ludwig Philip" in the Index volume.

See *Gesammelte Abhandlungen*, ed. by Ernst Zermelo, with biography by Xdolf Fraenkel (1932); E. T. Bell, *Men of Mathematics* (1937).

CANTOR, MORITZ BENEDIKT (1829-1920), German mathematician, who wrote a classic history of mathematics, was born at Mannheim on Aug. 23, 1829. He studied at Heidelberg, Göttingen and Berlin. In 1853 he became a tutor and in 1863 professor of mathematics at Heidelberg. His first important book was *Mathematische Beiträge zum Kulturleben der Völker* (1863); this was followed by his well-known *Vorlesungen über die Geschichte der Mathematik*, the first volume of which was published in 1880, the second in 1892 and the third in successive parts between 1894 and 1898. By this time Cantor was too old to undertake the fourth volume; consequently the work was divided among nine men, under the editorship of Cantor. This work gives an account of the history of mathematics from earliest times up to 1799.

Between 1856 and 1898 Cantor wrote a number of papers that were published chiefly in the *Zeitschrift für Mathematik und Physik*, of which he was an editor, among them being "Euclid und seiner Jahrhundert" (1867) and "Die Romischen Xgrimensoren" (1875). Cantor's eyesight failed him toward the end of his life. He died on April 10, 1920, at Heidelberg.

CANTOR, a Latin term used in the middle ages for the ecclesiastical official in charge of music at a cathedral, known also as the chanter or precentor. His duty, later undertaken by the organist, was to supervise the singing of the choir, particularly in the psalms and canticles. The term was also used for the head of a college of church music, such as the Roman Schola Cantorum of the early middle ages, and the singing schools founded by Charlemagne. In Germany in the 17th and 18th centuries the cantor (or *Kantor*) was the choirmaster and organist of a school or college subordinate to the rector; J. S. Bach held this post at the Thomasschule in Leipzig. The duties of the German cantor corresponded to those of the French *maître de chapelle* and of the Italian *nzaestro di capella*. In the synagogue the cantor is the minister (*hazan*) who chants the service, accompanied by the choir, and who leads the congregation in prayer.

CANTUS FIRMUS, in Italian *canto fermo*, a form of chant deriving from plainsong melodies, generally of equal note values; and serving as a fixed theme around which a polyphonic structure is woven. In motets of the 13th and 14th centuries the part of the *cantus firmus* was usually given to the tenor. Later it was used as a contrapuntal device in instrumental works, notably the organ works of Antonio de Cabezón and Jean Titelouze, which were constructed on the principle of the embroidered *cantus firmus*. In organ works by Johann Sebastian Bach, such as *Wachet auf, ruft uns die Stimme* ("Sleepers, wake!"), the *cantus firmus* derives from a Protestant chorale (*q.v.*), while in the masses by Guillaume Dufay, Jakob Obrecht, Jean d'Okeghem and others it is based on a folk-song tune. "L'Homme armé," a 15th-century folk song, served as a *cantus firmus* for over 30 masses. The practice of building an ornamental texture around a given theme has persisted in the improvised chorale preludes and variations played by or-

ganists. The principle of the *cantus firmus* is not confined to European music. It is characteristic of certain eastern music, notably the contrapuntal system used in the music of the Javanese gamelan. See also COUNTERPOINT.

CANUSIUM: see CANOSA DI PUGLIA.

CANUTE (CNUT or KNUT) (d. 1035), king of Denmark, England and Norway, son of Sweyn, king of Denmark, as a very young man accompanied his father on the expedition of 1013 by which he gained control of all England. On the death of Sweyn (Feb. 3, 1014), the English invited the native king, Aethelred II, to return. Canute was declared king by his crews at Gainsborough, but when Aethelred appeared in the district, he fled, mutilating and putting ashore at Sandwich the hostages given to his father. In Denmark he was probably recognized as joint king with his brother Harald; in any event he was permitted to fit out an expedition for the reconquest of England, which reached Sandwich in the autumn of 1015. England was riven by treachery and internal quarrels, yet the opposition to Canute was long and bitter. Aethelred died on April 23, 1016, but the struggle was continued by his son Edmund Ironside. Despite the great Danish victory of Ashingdon (Oct. 18, 1016), a peace was ultimately concluded which gave Wessex to Edmund and Mercia to Canute. Northumbria had already submitted to Canute, who had appointed Earl Eric of Hlathir to govern it. Edmund died on Nov. 30, 1016, and Canute was accepted in 1017 as king by all England. His brother Harald appears to have died in 1018 or 1019, so Canute became sole king of Denmark also. He sought to strengthen his position in England by a marriage with Emma of Normandy, the widow of Aethelred.

Canute's attempt to govern England as a fourfold state proved short-lived. Having already appointed Eric as earl of Northumbria, he placed in Mercia Eadric Streona, a treacherous English thegn, and in East Anglia Thorkel the Tall, a Danish invader who had entered Aethelred's service; he kept Wessex in his personal control. But Eric's premature death (c. 1023) led to utter confusion in Northumbria, Canute himself had second thoughts and allowed or authorized the murder of Eadric (1017), while Thorkel was relegated to Denmark (1023) as the guardian of the king's son Hardicanute. Soon also the rise (c. 1019) of Earl Godwin weakened the direct rule of Wessex by the crown. But despite the resurgence of a multiplicity of earldoms, Canute's reign was a period of good rule, conducted within the framework of native institutions, lay and clerical. His code of laws derives mainly from earlier English codes. He made no effort to approximate the English to the Danish constitution. He seems to have felt that he was the head of a number of separate kingdoms, which would ultimately fall apart, rather than of an empire. The king was a strong supporter and benefactor of the church; he undertook at least one pilgrimage to Rome (1026–27), and was seen at St. Omer, on his way there, extravagantly repenting his sins, by a monk or cleric who later wrote at his widow's request the *Encomium Emmae reginae* in his honour. After his visit to Denmark in 1019–20, and once when in Rome, he addressed to his subjects an explanation of his absence. The former of these documents incorporates an interesting statement of legal policy, especially relating to the church.

In foreign affairs Canute's main aim was to add Norway to his empire and to maintain peace elsewhere. His relationship with Normandy was satisfactory till his wife's brother, Richard II, died (1026) and was succeeded by his sons Richard III and Robert. The marriage of Canute's widowed sister Estrith to Robert seems to have ended in divorce, and Robert planned an invasion of England on behalf of Aethelred's sons who were sheltering with him; but it did not eventuate. The ascendancy of the Scots on his northern borders consequent upon the weakness and confusion of the government of Northumbria roused Canute in 1031. He led an expedition in person and received the homage of the Scots without striking a blow.

Friendly relations with the emperor Conrad II were sealed by the engagement of Canute's daughter Gunhild to Conrad's son Henry and led to a peaceful settlement of the Dano-German frontier by the return to the Danes of Schleswig, an old Danish

area which had been subject to gradual German encroachments.

Canute had continuous trouble with Norway which in 1015 was being ruled in the Danish interest by the brothers Eric and Sweyn, earls of Hlathir. Eric accompanied Canute to England, and Olaf II (Haraldsson), an exile of the native royal house, easily conquered the kingdom, expelling Sweyn and Eric's son Haakon. Canute worked to destroy Olaf by fomenting treachery. His only open attack (1027) was foiled at the battle of the Holy river, but Olaf was forced by his rebellious subjects to withdraw to Russia (1028) and on attempting to return he was killed at the battle of Stiklestad (1030). Canute then ruled Norway through his mistress Aelfgifu (of Northampton) and Sweyn, his son by her, until 1035, when Magnus, the son of Olaf II, established himself as king of Norway and Sweyn fled to Denmark and died.

Canute died on Nov. 12, 1035, at Shaftesbury, Dorset. Harold I, who was also his son by Aelfgifu, became king of England, but Hardicanute, his son by Emma, who had been sent to Denmark as viceroy by his father, continued to rule there. On Harold's death (1040) Hardicanute became king of England also.

CANUTE VI (CNUT or KNUT) (1163–1202), king of Denmark, the eldest son of Valdemar I, was crowned as his father's coregent on June 25, 1170, and succeeded to the throne in 1182. As a ruler he was overshadowed by his closest associates— at first by the archbishop Absalon (*q.v.*), later by his younger brother Valdemar, duke of Schleswig (afterward king as Valdemar II), but during his reign the kingdom asserted its independence of the Holy Roman empire and began the establishment of its own authority along the Baltic coast. Absalon won a crushing victory over the Pomeranian duke Bogislav's fleet at Strela (Stralsund) in 1184. Immediately afterward the German frontier princes began to submit to Danish supremacy, and in 1185 Bogislav swore fealty for Pomorze, followed in 1186 by two Obodrite princes for territories covering modern Mecklenburg. Canute then added the words *Slavorumque rex* ("and king of the Slavs") to his regal title. Thus Denmark entered into European high politics—an event clearly marked when, in 1193, Canute's sister Ingeborg married Philip II Augustus of France—and became increasingly active and influential in German internal disputes. A conspiracy against the reigning house by Valdemar, bishop of Schleswig, a member of a branch of the royal family, in concert with the emperor Henry VI, was crushed in 1192 by Duke Valdemar, who thenceforward conducted Danish policy toward the south: during 1200–01 the whole of Holstein as far as the Elbe was conquered and incorporated in the Danish realm under the name of North Albingia. At the same time Lübeck acknowledged Danish sovereignty, so that Denmark dominated all the eastern Baltic territories to beyond the Oder. Canute died, childless, on Nov. 12, 1202. (A. E. CN.)

CANVAS, a stout cloth that probably derives its name from *cannabis*, the Latin word for hemp. This would appear to indicate that canvas was originally made from yarns of hemp fibre, and there is some ground for the assumption. Hemp fibre and that of flax have been used for ages to produce cloth for sails; for certain classes of cloth used for this purpose the terms sailcloth and canvas are synonymous. The manufacture of sailcloth was established in England in 1590, but a similar cloth with the same name had been used centuries before by the Egyptians and Phoenicians. After the introduction of the power loom the cloth underwent several modifications, and it was later made from flax, hemp, tow, jute and cotton or a mixture of these. Flax canvas is essentially of double warp, for it is invariably intended to withstand pressure or rough usage.

The structure of canvas is similar to jute tarpaulin; bagging, tarpaulin and canvas form an ascending series of cloths as regards fineness, although the finest tarpaulins are finer than some of the lower canvases. Canvas may be natural colour, bleached or dyed, a very common colour being tan.

Among the articles made from canvas in addition to sailcloth are: carrying devices for photographic and other apparatus; bags

for fishing, shooting, golf and other sporting equipment; shoes for cricket and other games, and for yachting; tents; mail bags; tire casings; traveling cases and holdalls, letter bags, schoolbags and nose bags for horses. Large quantities of flax and cotton canvases are tarred and then used for covering goods on railways, wharves, docks, etc.

Sail canvas, since it is of a strong build, is quite different from art canvas, the canvas cloth used for embroidery purposes. The latter is similar in structure to cheesecloths and strainers, the chief difference being that the yarns for art canvas are, in general, of a superior nature.

The chief vegetable fibres used to produce canvas are cotton, flax and jute. The yarns are almost invariably two or more ply. an arrangement that tends to produce a uniform thickness—a desirable element in open-built fabrics. A plain weave is extensively used for these fabrics, but in many cases special weaves are used that leave the open spaces well defined.

Artists' canvas, a single-warp variety, is used, as its name implies, for painting in oils. It is much lighter than sail canvas, but must, of necessity, be made of level yarns. The best qualities are made of cream or bleached flax line, although it is not unusual to find an admixture of tow and even of cotton in the commoner kinds. When the cloth comes from the loom it is treated to prepare the surface for the paint.

CANVASBACK, a diving duck related to the pochard (*q.v.*), but larger. The canvasback (*Aythya valisineria*), an American bird much esteemed for the table, takes its name from the light colour of the back. The head is chestnut, the beak long and narrow. The canvasback is found in the whole of North America, and breeds from Great Slave lake south to eastern Oregon, northern New Mexico and central Minnesota; wintering from southern British Columbia and Chesapeake bay to the Gulf states and Mexico. Feeding on wild celery in winter was supposed to give its

CANZONA (**CANZONE**), a term derived from the Provençal *canço* (French *chanson*), and used at different times to describe various musical forms, both vocal and instrumental. It was applied in the early 16th century in Italy to an important song form preceding the madrigal, and later in the century to secular pieces in a lighter vein than the madrigal (*e.g.*, *canzoni villanesche*, the first collection of which was published in 1537); though works in this style were more commonly called by the diminutive form *canzonetta*. In the 18th and 19th centuries the term was used occasionally for lyrical songs (sometimes in opera) and for instrumental pieces of a songlike nature.

In the above cases the word is loosely used in its original meaning to denote a type of song. A more precise, specialized and important use occurs in reference to instrumental music of the 16th and 17th centuries, though here too the form of the *canzona* derives from the French *chanson* for voices, known in Italy as *canzon(a) francese*. Instrumental canzonas are usually fairly light and lively pieces, in common time, beginning, like chansons, with three repeated notes in dactylic rhythm and consisting of alternating polyphonic and homophonic sections. At first they were composed mainly by Italians, who did not distinguish initially between those for the keyboard and those for instrumental ensemble. Gradually the form spread to other countries, notably Germany, though Italy remained its principal home, and with the emergence in the later 16th century of idiosyncratic instrumental styles, canzonas written for the two different media began to grow apart. Keyboard canzonas became more concentratedly polyphonic and prepared the way for the fugue, though more than one subject was often still treated in succession, while those for an instrumental group led to the trio sonata of the 17th century. Of the former the important composers are, first, Girolamo Cavazzoni

(c. 1540) and later his fellow countrymen Claudio Merulo (1533–1604), Andrea Gabrieli (c. 1520–86), Giovanni Maria Trabaci (d. 1647) and Girolamo Frescobaldi (1583–1643), with J. J. Froberger (1600–67) in Germany, where quite early in the 17th century the term "fugue" was used synonymously with "canzona." Some canzonas for instrumental ensemble continued to resemble those for keyboard, but the most distinctive are those that, unlike keyboard canzonas, emphasize diversity rather than unity of texture. From the clearly defined sections of the canzonas of Giovanni Gabrieli (1557–1612) and Frescobaldi, with their contrasting tempi, metres and rhythms, the movements of the trio sonata emerged. When, toward the middle of the 17th century, the movements were reduced to four and became longer, the terms "trio sonata" (more especially *sonata da chiesa*) and "canzona" became synonymous. Italian composers such as Biagio Marini (d. 1665) and Giovanni Legrenzi (1626–90) clearly illustrate the new tendencies. By the time sonatas were habitually called sonatas, the word "canzona" was still sometimes applied (*e.g.*, by Purcell) to a fugal movement in a sonata.

See G. S. Bedbrook, *Keyboard Music From the Middle Agec to the Beginnings of the Baroque* (1949); G. Reese, *Music in the Renaissance* (1954). (N. Fo.)

CANZONE, the oldest metrical form of verse in Italian literature. The word is believed to derive from the Provençal *canço*, a song, and according to Dante and Boccaccio the early Italian literary forms of the canzone were accompanied by music.

The canzone strophe consists of two parts, the opening one being distinguished by Dante as the *fronte*, the closing one as the *sirma*. These parts are connected by rhyme, it being usual to make the rhyme of the last line of the *fronte* identical with that of the first line of the *sirma*. In other respects the canzone shows great liberty in regard to number and length of lines, arrangement of rhymes and structure. The best Italian model of 14 lines resembles an irregular sonnet. The form reached a high development in Dante's *Vita Nuova* which contains many examples, with explanations of their use. Petrarch's *Canzoniere* similarly shows a classical use of the form. Canzone on the models of Petrarch were later written by Alfieri, Ugo Foscolo, Manzoni, Carducci and d'Annunzio. Though the form was essentially Italian it was introduced into England at the end of the 16th century by William Grummond who left some beautiful examples. In German poetry it was cultivated by A. W. von Schlegel and other poets of the romantic period.

See H. Wilkins, "The Derivation of the Canzone," in *Modern Philology*, xii, 9 (1915).

CAOUTCHOUC, the principal constituent of natural rubber and therefore sometimes called pure rubber. It occurs as a vegetable gum, mixed with from $\frac{1}{10}$ to 8 times its own weight of other substances. Caoutchouc is a white resilient solid; at 0–10° C. it is hard and opaque, but it becomes soft and translucent above 20° C. It contains carbon and hydrogen only, and, chemically, belongs to the terpenes (*q.v.*). By polymerization isoprene can be converted to a product resembling caoutchouc but inferior to that synthesized by the plant. Mineral caoutchouc is one of the names of elaterite (*q.v.*), or elastic bitumen. See also RUBBER.

CAPACITANCE is the modern term for what was formerly called "capacity" in electrical circuits. It may relate to an isolated conductor when it is defined as the constant ratio of the charge Q on the conductor to the potential, V , to which that charge raises the conductor, *i.e.*, $C = Q/V$. If the conductor is an isolated sphere in vacuo the potential $V = Q/r$ where r is the radius of the sphere. Hence the capacitance of an isolated sphere equals its radius.

Capacitance is often concentrated in electrical condensers (see CAPACITOR) and in many such cases may be simply calculated. On the other hand in many electrical circuits the capacitance is distributed throughout the circuit and more technical methods are required to find its value.

The capacitance of conductors or electrical circuits in general depends on the presence of neighbouring charges or conductors, also on the medium between them. See ELECTRICITY: Electrostatics: Condensers; see also references under "Capacitance" in the Index volume. (H. B. Lm.)

CAPACITOR, a fundamental electric circuit element sometimes called a condenser, to perform many functions in electric and electronic circuits. It was discovered by E. G von Kleist in 1745 and independently by P. van Musschenbroek of the University of Leyden at about the same time, while in the process of investigating electrostatic phenomena. They discovered that electricity obtained from an electrostatic machine could be stored for a period of time and then released. The device, which came to be known as the Leyden jar, consisted of a stoppered glass vial or jar filled with water, with a nail piercing the stopper and dipping into the water. By holding the jar in the hand and touching the nail to the conductor of an electrostatic machine they found that a shock could be obtained from the nail after disconnecting it, by touching it with the free hand. This reaction showed that some of the electricity from the machine had been stored.

A simple but fundamental step in the evolution of the capacitor was taken by John Bevis in 1746 when he replaced the water by metal foil forming a lining on the inside surface of the glass and another covering the outside surface. This form of the capacitor with a conductor projecting from the mouth of the jar and touching the lining had, as its principal physical features, two conductors of extended area kept nearly equally separated by an insulating or dielectric layer made as thin as practicable. These features have been retained in every modern form of capacitor.

Capacitors differ only in the size and geometrical arrangement of the metal foils or plates (as they are more generally called) and, most important of all, in the kind of dielectric material used. The dielectric is the heart of the capacitor and has been the subject of much scientific and engineering investigation in the past. A great deal of progress has been made possible by the rapid advances in the chemistry of dielectric materials, which has revealed the intimate relation between molecular structure and dielectric properties.

Fundamental Properties.—The electricity stored by a capacitor when electrified by a direct current voltage is in the form of discrete electrical charges held on the surface of the plates. One plate has positive charges and the other an equal number of negative charges. The charge, which it is possible to store, is dependent on the voltage applied between the plates. The theory of electrostatics provides a mathematical formula, given by equation 1, relating the voltage V , the charge Q and the capacitance C that together characterize a capacitor electrically. These are expressed in practical electrostatic units of volts, coulombs and farads respectively.

$$C = Q/V \quad (1)$$

The capacitance C depends only on the geometrical area of the plates, their separation and the type of dielectric. For a capacitor with two parallel plates of equal area electrostatic theory gives equation 2:

$$C = K \frac{A}{4\pi d} \quad (2)$$

where A is the area in centimetres squared, d the separation of the plates in centimetres and K is a numerical constant called the dielectric constant or specific inductive capacity. This constant is, by definition, equal to 1 when the space between the plates is a perfect vacuum. But for any dielectric substance the value is greater than 1 and is characteristic of the substance when measured under well-defined conditions of frequency, voltage and temperature. The value was first measured by Henry Cavendish between 1770 and 1780. Modern values for K for several technically important dielectrics are shown in Table I. The technical

TABLE I.—Dielectric Constants of Various Dielectric Materials Used in Modern Capacitors

Dielectric	K	Dielectric	K
Vacuum	1	Polytetrafluorethylene	2.0
Air	1.00059	Polyethylene terephthalate	3.1
Glass	4-8	Polyethylene	2.2
Mica	5.4	Mineral oil	2.2
Titanium dioxide	125	Chlorinated diphenyl	6.5
Barium titanate	6,000	Aluminium oxide	8.7
Kraft paper	2.2	Tantalum pentoxide	22.0
Polystyrene	2.6		

importance of the dielectric constant is evident from equation 2. The capacity of a capacitor is increased by a factor of K relative to that of vacuum when the space between the plates is filled with a dielectric or, conversely, the size of the capacitor plates is decreased by the same factor for the same capacitance; e.g., replacing a vacuum by barium titanate increases the capacity by 6,000 times. This material was discovered by E. Wainier in 1942 and has led to a host of combinations of titanate ceramic dielectrics. Similar efforts have been made to find liquid dielectrics of high K for use as impregnants for kraft paper and led to the discovery of chlorinated diphenyl in the early 1930s. The dielectric increases the capacity because under the action of the voltage the electrical charges of which it is composed are slightly displaced from their position of equilibrium. In this condition it is said to be polarized, and the degree of polarization attainable is determined by the molecular structure of the dielectric.

The capacitance of a capacitor cannot be made indefinitely large by decreasing the thickness of the dielectric as equation 2 might suggest, because the dielectric strength comes into play. If too high a voltage is applied to a capacitor an electric arc will pierce the dielectric and destroy its insulating properties. This reaction is known as dielectric breakdown and each dielectric is characterized by a maximum ratio of voltage to thickness called the dielectric strength and expressed in volts/centimetres. It varies from 10^7 v./cm. to a few hundred.

Another important characteristic of the dielectric is its resistivity. This determines how much current continues to flow through it after the capacitor has been charged. This residual current is known as the leakage current, and may vary as much as 1,000,000 to 1 for different dielectrics. It is also referred to as leakage resistance since by Ohm's law an equivalent resistance can be derived. The leakage resistance decreases rapidly with increasing temperature and voltage. In some cases the heating resulting from the leakage current may be sufficient to degrade the dielectric by thermochemical changes.

Cavendish discovered that it takes time to charge a capacitor with a dielectric compared to one in which the plates are separated by air. This phenomenon is due to the finite time required to displace the charges in the dielectric and may vary from a few seconds to months.

For this reason a capacitor charged on direct current (D.C.) will discharge repeatedly with decreasing intensity after being charged only once. This phenomenon is known as dielectric absorption. When alternating current (A.C.) voltage is applied to a capacitor new phenomena arise on this account.

A capacitor connected to an A.C. voltage source is alternately charged and discharged each half-cycle. The time for charging or discharging is thus limited by the period of the A.C. and if the time required to polarize the dielectric is greater, the polarization is not complete. This condition makes the dielectric constant appear to be less than it really is and results in its variation with frequency. The constant is thus lower the higher the frequency. During the alternation of polarity of the plates the charges in the dielectric must be displaced first in one direction and then in the other and the friction which they encounter internally leads to a production of heat which is known as dielectric loss and which has a great technical importance in modern electrical engineering. These dielectric losses are dependent on frequency and temperature.

Another phenomenon not observed on D.C., which A.C. produces, is the flow of current through a capacitor. Except for the residual leakage current, no current flows through a capacitor on D.C. voltage after it is charged. A.C. will pass readily, however, and is called a displacement current because unlike D.C. in which actual charges move through the dielectric, in this case charges are only displaced. This discrimination between D.C. and A.C. and the dependence of the A.C. capacitance on frequency makes the capacitor so important in modern radio, television and communication circuits.

Some dielectrics exhibit maximum dielectric losses in certain frequency bands and, correspondingly, the dielectric constant changes rapidly in this range. In 1912, P. J. Debye developed a

theory based on quantum theory to explain this phenomenon and showed that this may be explained by presence of groups of unlike atoms in a molecule in which a permanent internal displacement of charges is localized. In an alternating electric field these molecular groups are aligned by the field, oscillate as it changes direction and give rise to an additional polarization superimposed on that produced by the direct displacement of charges in the dielectric. This additional polarization gives polar substances a higher dielectric constant. The motion of such groups gives rise to additional dielectric losses and so these materials also have greater losses.

Kinds and Uses of Capacitors.—Electric circuit theory deals with ideal capacitors that have no dielectric or ohmic losses, have infinite resistance, no residual inductance and a capacity that is independent of frequency and temperature. To a great extent the engineering problems encountered in their application have to do with the deviation of the real device from the ideal one. The large variety and complexity of modern electronic equipment has led to the development of many kinds of capacitors from which those best suited to the electrical requirements and the physical environment may be chosen. These differ mainly in physical design and type of dielectric and fall into two broad classifications, A.C. and D.C.

A.C. Capacitors.—This classification is further divided into low (or power) frequency and radio-frequency types. At power frequencies, paper capacitors impregnated with chlorinated diphenyl and mineral oil are used and vary in size from a few to 1,000 cu in. An example of this type of capacitor used to improve the efficiency of motors and fluorescent lamps is shown in Figure 1. These capacitors improve the transmission efficiency of power lines and are economically important in conserving generating equipment at the power stations. Large mica, ceramic and vacuum capacitors are used at radio frequencies because of their low dielectric losses. This characteristic is of special importance in high-

BY COURTESY OF GENERAL ELECTRIC CO

FIG. 1.—SMALL A.C. CAPACITOR (CUTAWAY SHOWS CONSTRUCTION)

power radio, television and loran transmitters and industrial equipment for dielectric heating.

Small capacitors find use in radio and television receivers, telephone and telegraphic equipment, electronic instruments and mobile and airborne communication equipment. Some of the small ones are made variable to allow an adjustment to be made after they are connected in a circuit. These are called trimmers and when a variable dielectric is used are called variable capacitors. The variation in capacitance in these cases is affected by the effective plate area.

Vacuum capacitors (see fig. 2) find special use in high-frequency high-voltage A.C. applications because of their very low losses.

D.C. Capacitors.—These capacitors are more varied in form and size and use many more dielectrics in addition to those used for A.C.

The sizes range from .001 cu in. for a 2-v. tantalum electrolytic to several thousand cubic inches for a 100,000-v. paper capacitor. The most widely used paper capacitors (see fig. 3) for electronic

BY COURTESY OF JENNINGS RADIO MFG CO

FIG. 2.—VACUUM CAPACITOR

This capacitor, housed in a glass envelope and made of tubular shaped plates that nest into each other, is used in high-frequency high-voltage A.C. applications

circuits are tubular types encased in metal or plastic tubes sealed against the atmosphere and impregnated with dielectric liquids such as chlorinated diphenyl, chlorinated naphthalene, mineral oil, castor oil and synthetic polyisobutylene. Other polymers introduced between 1940 and 1950 include polyvinyl carbazole, polyesters and polystyrene. Usually these are introduced as liquids into the paper and polymerized *in situ*.

Developments in the manufacture of thin plastic films have led to the development of plastic film capacitors using polystyrene, polyethylene, polytetrafluorethylene and polyethylene terephthalate films in which no paper is used. These polymers are among the best organic dielectrics known. Polytetrafluorethylene films retain good properties even at 200° C. Capacitors made of high and medium dielectric constant titanate ceramics are also used in large numbers. They are usually disc or tubular in shape and are smaller than the corresponding rating in paper, consequently where the electrical application permits these replace the paper.

Their main limitation is that the capacitance varies steeply with frequency, voltage and temperature.

The paper, plastic and ceramic capacitors which make up the bulk of D.C. capacitors used in modern electronic equipment are all of the electrostatic (also called nonpolar) type. They operate equally well, whether one plate or the other is the positive one. However, there is a special D.C. type known as an electrolytic capacitor which functions as a capacitor only when the proper plate is made positive. This type was discovered in Germany about 1880, but assumed technical importance only with the advent of A.C.-powered radios in the late 1920s. This created a need for capacitors of reasonable size having capacitances several thousand times greater than a Leyden jar. The electrolytic filled this need and its continued development has made it practically indispensable in modern radio, television and communication equipment of all types.

The merit of the electrolytic lies in concentrating a large capacity in a small space, a virtue made possible by the extremely thin dielectric layer (only a few millionths of an inch thick) between the plates. The layer consists of an oxide film formed electrolytically on the surface of one plate which is usually a foil of high-purity aluminum or tantalum. Such thin films of dielectrics are impossible to make without flaws, but in the electrolytic this difficulty is overcome by the presence of the electrolyte in contact with the oxide which heals up any flaws, by the action of the leakage current.

The capacitor gets its name from the fact that the other plate

BY COURTESY OF GENERAL ELECTRIC CO

FIG. 3.—D.C. TUBULAR PAPER CAPACITOR ENCASED IN MOLDED PHENOLIC (CUTAWAY SHOWS CONSTRUCTION)

The two plates of the capacitor are foils wound spirally with paper interleaved to insulate them. Electrical contact to the foils is made on the ends of the roll

is an electrolytic solution similar to that used initially to produce the oxide layer. It is necessary to use specific salts in it and their concentration must be controlled. One reason the polarity is important is that the aluminum will not oxidize in the solution unless it is positive. But the most important reason is that if it is negative, current flows freely and the oxide layer loses its insulating properties. This one property the electrolytic capacitor has in common with a rectifier, and it is in fact possible to use these capacitors as rectifiers in special circuits.

The presence of a liquid electrolyte-cathode makes it possible to increase the surface area of the anode by etching it and still have the cathode follow the microscopic undulations of the surface. This condition allows the capacitance to be increased by almost an order of magnitude and use is made of it in etched plate electrolytics which have almost entirely supplanted the plain plate type.

Another development introduced in the 1930s is an electrode of sintered tantalum metal powder with a high surface-to-weight ratio. These capacitors are even smaller than the etched plate type. A more recent development in electrolytic capacitors is the use of a semiconductor in place of a solution and tantalum electrolytic using manganese dioxide, a semiconductor, were first made commercially in 1955 using sintered tantalum anodes. These capacitors are known as tantalum solid electrolytics. They retain the preferred polarity so that a rectifying junction is still present but they lose the self-healing properties.

D.C. capacitors are used in radio and television receivers, telephone carrier and central office equipment, airborne and mobile communication equipment, electronic instruments and radar equipment.

Electrolytic capacitors function mainly as filter and by-pass capacitors to keep undesired A.C. voltages out of certain parts of the circuit. In radios, for example, the A.C. line frequency causes undesirable hum in the loudspeaker and the large capacitances of electrolytics filter this out, thus the name filter capacitors. The electrostatic capacitors perform other functions of coupling, blocking, integrating and timing.

The increasing use of electronic equipment in military planes, land and sea military craft, rocket-powered guided missiles and ballistic missiles created a demand for capacitors of the smallest possible weight and capable of operating up to 200° C.

Tantalum electrolytic capacitors have found wide application in the guidance systems of guided missiles because of their small size. These complement the small size of transistors which are replacing vacuum tubes in the trend toward the miniaturization of electronic equipment.

See LEYDEN JAR; ELECTRICITY; DIELECTRIC; ELECTROLYTE; see also references under "Capacitor" in the Index volume.

BIBLIOGRAPHY.—Philip R. Coursey, *Electrical Condenser* (1927); M. Brotherton, *Capacitors* (1955); G. W. A. Dummer, *Fixed Capacitors* (1956); Georg Straimer, *Der Kondensator in der Fernmeldetechnik* (1939); A. von Hippel (ed.), *Dielectric Materials and Applications* (1954). (J. B.M.)

CAPACITY, the ability to contain a definite quantity. Cubical capacity is measured in units of volume. Electrical capacity or capacitance (*q.v.*) is denoted, by the charge *Q* (see ELECTRICITY: Electrostatics: Condensers), which a system will hold on the application of a given voltage *V*, and is given by the ratio *Q/V*. (See CAPACITOR.)

Thermal capacity measures the capability of a body for absorbing heat, and numerically is the product of its specific heat and its density.

CAP DE LA MADELEINE, industrial city and site of a famous shrine in Quebec, Can., on the north shore of the St. Lawrence river, 80 mi. above the city of Quebec and near Three Rivers. Population (1961) 26,530. It was named after Jacques de la Ferté, abbot of Ste, Marie Madeleine de Chateaudun, France, to whom Louis XIV ceded a fief in 1636. It was settled during the 17th century but development really began only after 1900, when sawmills and woodpulp mills were established, making the place a large centre for the production of newsprint. A shrine to the Virgin of the Rosary was dedicated in 1888 and was taken over by the Oblates of Mary the Immaculate in 1902. A large basilica has

been erected in honour of "Our Lady of the Cape" and Cap de la Madeleine has become an important place of pilgrimage, receiving around 1,000,000 pilgrims each year.

See James G. Shaw, *Our Lady of the Cape* (1961). (J.-C. B.)

CAPE BRETON HIGHLANDS NATIONAL PARK, in the highlands of Cape Breton Island, northern Nova Scotia, is reminiscent of the Scottish Highlands and has a peculiar charm and atmosphere that distinguishes it from other Canadian national parks. Established in 1936 when almost 400 sq.mi. of the northern section of the island were set apart for public use, it lies between the Atlantic ocean and the Gulf of St. Lawrence and is more than 1,700 ft. above sea level.

Adjacent to the park are a number of picturesque fishing villages and small settlements inhabited mainly by people of Highland Scottish and French ancestry. Many of them are skilled homecraft workers, noted for their hooked rugs and other distinctive handicrafts.

Around the park runs a spectacular scenic highway known as the Cabot trail, named after the Cabots, who in 1497 made their first landfall on the North American continent along the shores of Cape Breton Island. The Cabot trail is linked with the main provincial highway system of Nova Scotia. In 1955 a causeway was built across the Strait of Canso, connecting the island with the remainder of the province.

Park headquarters are at Ingonish on the Atlantic side of the park and in that area are most of the accommodations for tourists, including the widely known Keltic Lodge operated by the government of Nova Scotia. There are also various campgrounds, especially along the coastal region. (J. G. P.)

CAPE BRETON ISLAND, the northeast portion of Nova Scotia province, Canada, separated from the mainland by a narrow strait known as the Gut of Canso; length (north to south) 110 mi., greatest breadth about 75 mi., land area 3,970 sq.mi. A headland on the east coast is also known as Cape Breton, and is said by some to be the first land visited by John Cabot on his voyage in 1497-98. The surface of the island is hilly and the northern part is a tableland 1,000 ft. high. Valuable seams of coal are worked, and the lumber, agricultural products and fisheries are also important. The island's population of 162,859 (1956) is largely concentrated in the east coast mining and steel centres of Sydney and Glace Bay. After 1955 a causeway provided direct road and rail connections with the mainland.

See NOVA SCOTIA.

CAPE COAST, a town in the centre of the seaboard of Ghana (formerly Gold Coast). 90 mi. W. of Accra by the new coast road. Pop. (1957 est.) 30,000. The name is a corruption of the Portuguese *Cabo Corso*, but the local people call it Gua or Oegua. The town stands on a low promontory dominated by a castle partly built on and incorporating a large rock. This rock is referred to as Tarbir by the natives, who venerate it as one of the 77 tutelary gods of the town. To its east and sheltered by it is a landing beach for surfboats and the canoes of a large fishing community. The castle was built in 1652 on land granted to the Swedes by the king of Fetu (as the state was called) and passed through several hands before coming finally into British possession in 1664. The town, which grew up around the castle, was the chief port of the Gold Coast and the commercial and administrative headquarters of the British settlements until 1877 when Accra became the capital. Following the construction of railways leading inland from Sekondi-Takoradi and from Accra, Cape Coast declined in importance as a port and trading centre. Notable buildings in Cape Coast include Christ church (1865), the first Anglican church in the country, the cathedral of St. Francis, seat of the Roman Catholic archbishop of Ghana, and the Wesley chapel founded by missionaries in 1838. A bust of Queen Victoria stands in Victoria park. The town has long been the educational centre of the country and is well endowed with secondary schools. Cape Coast is linked by tarred roads to Accra, Sekondi-Takoradi and Kumasi, and vessels of various shipping lines call regularly at the port. The principal imports include building materials, provisions and hardware and the chief exports are cocoa and citrus products. The town, which is the seat

of the regional administration. is governed by a fully elected municipal council. (W. S. K. J.)

CAPE COD CANAL, an artificial waterway which joins Cape Cod bay, Mass., with the waters of Buzzards bay, an inlet of Long Island sound, and traverses the narrow isthmus of Cape Cod. It is 17.5 mi. long including its dredged approaches. It has a controlling width of 450 ft. and a minimum depth of 30 ft. There are no locks. Put into operation in 1914 by private capital. The canal cut the distance for water-borne traffic between New York and Boston, via the East river, Long Island sound and the canal, by more than 75 mi. The Cape Cod canal was purchased by the U.S. government in the late 1920s and is operated toll free as the northernmost section of the Atlantic Intracoastal waterway (*qv*). See also WATERWAYS, INLAND.

CAPE COLONY: see CAPE OF GOOD HOPE.

CAPE COLOUREDS, the largest of the racially mixed peoples of South Africa. In 1960 they numbered 1,488,267, living mostly in Cape Town, its suburbs, Port Elizabeth and rural areas of western Cape of Good Hope province. Total population of Cape Coloureds in Cape of Good Hope province in 1960 was 1,314,392.

The Cape Coloureds originated from interbreeding between slaves (from Madagascar, the Malayan archipelago, Ceylon and India. who were originally held in Cape Town by the Dutch East India Co. during the 17th and 18th centuries), Hottentots, Bushmen and Europeans, the latter mostly from the Low Countries. The majority of unions were illicit and almost invariably between men of higher and women of lower social groups, for instance, between European men and slave or Hottentot women, and between slave men and Hottentot or Bushmen women. The Bantu (Negro) element has been small until recent years.

The Cape Coloureds form a group socially intermediate between Europeans and Negroes. They speak Afrikaans and English. are Christians, live in a European manner and regard themselves as affiliated to the Europeans. There is a minority of about 60,000 Muslims, the so-called Cape Malays, who are mainly artisans and traders; they live mostly in separate communities and marry among themselves for religious reasons. Although the Cape Coloureds are racially mixed, they have a strong sense of community as a consequence of the Europeans' refusal to accept them as equals and their own refusal to be classed socially with the Negroes. Until recently there was considerable intermarriage between lighter-skinned Cape Coloureds and Europeans, and many Coloureds were absorbed into the white community. Also, the offspring of Coloureds and Negroes have been frequently accepted as Coloureds.

Cape Coloureds living outside the towns are mostly labourers on European-owned farms. In the ports of Cape Town and Port Elizabeth their communities are divided into several classes: teachers and salaried workers; shopkeepers, artisans and other skilled norkers; and casual labourers and factory workers, which are the biggest group.

Under the Nationalist government, from 1948 onward, there was more rigid separation of occupation, the common franchise was removed, and intermarriage and sexual relations were prohibited; the social status of Cape Coloureds tended to be grouped more and more with that of the Negro community as "nonwhite." See also SOUTH AFRICA, UNION OF.

BIBLIOGRAPHY.—S. Patterson, *Colour and Culture in South Africa* (1953); J. S. Marais, *The Cape Coloured People, 1652-1937* (1939); W. M. Macmillan, *The Cape Coloured Question: a Historical Survey* (1927). (J. F. M. M.)

CAPE GIRARDEAU, a city of Missouri, U.S., is on the west bank of the Mississippi river at the southeast edge of the Ozark plateau. Established prior to 1793 by French-Canadian Louis Lorimier, its name derives from an even earlier trader. Sieur Jean B. Girardot (1704?). One of five seats of administration in Upper Louisiana during the Spanish regime, it was incorporated as a town in 1806 and as a city in 1843. Cape Girardeau during the American Civil War was a Union stronghold. River traffic and trade from a rich hinterland, largely funneled to the river there because of swamps to the south and hilly terrain to the

north, made it the largest community in southeast Missouri; in the 20th century it remained the cultural, scientific, educational and commercial centre of the area.

Manufactures include shoes and clothing; cement, concrete, crushed stone, gravel and sand; timber; beverages and foods; surgical dressings; printed materials; and towboats, barges, pressure tanks and electrical items. Southeast Missouri State college (founded 1873) is in Cape Girardeau. The Trail of Tears state park is nearby. For comparative population figures see table in MISSOURI: *Population*. (F. E. SN.)

CAPE HUNTING DOG,

Lycaon pictus, an African wild dog that differs from the rest of the canine family in having only four toes on each foot. Its coat is dark brown with blotches of yellow, black and white. The species is nearly as large as a mastiff, with long limbs, broad flat head, short muzzle and large erect ears. These wild dogs hunt in packs of 15 to 60 or more and are found in nearly the whole of Africa south and east of the Sahara. They prey usually on

BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

WILD AFRICAN HUNTING DOG
(LYCAON PICTUS)

small antelopes and occasionally on larger game such as harte-

beest. Sometimes the dogs do great damage to domestic animals, such as sheep.

CAPE JASMINE: see GARDENIA.

CAPEK, KAREL (1890-1938), Czech writer who gained an international reputation as playwright, novelist and essayist. He was born at Malé Svatoňovice, northeast Bohemia, on Jan. 9, 1890, and after studying philosophy in Prague, Berlin and Paris he settled in Prague as a writer and journalist. He died there on Dec. 25, 1938. His early essays and plays were written in collaboration with his brother, Josef Čapek (1887-1945).

Čapek's most successful plays exposed the problems of the centralized, machine-dominated society of the 20th century. These were *R.U.R.*, in which the word "robot" was introduced into English, and *The Insect Play* (both 1920; Eng. trans. by P. Selver, 1923). At the end of his life, in *Bílá nemoc* ("The White Disease," 1937; Eng. trans. by P. Selver and R. Neale, *Power and Glory*, 1938) and *Matka* (1938; trans. by P. Selver, *The Mother*, 1939) his pacifism gave way to an acceptance of patriotic duty. His novels reach a higher artistic level, especially in the trilogy *Hordubal, Povětroň and Obyčejný život* (1933-34; Eng. trans. by M. and R. Weatherall, 1934; *The Meteor*, 1935; *An Ordinary Life*, 1936). These illustrate both Čapek's skepticism and his sensitive sympathy for his fellow beings. Other novels. *Krakatit* (1924; Eng. trans. by L. Hyde, 1925) and *Vulka s mloky* (1936; Eng. trans. by M. and R. Weatherall, *War with The Newts*, 1937) deal with subjects similar to those of the plays. Čapek was particularly successful also with his travel books, among them *Letters from England* (trans. by P. Selver, 1925), and with such whimsical essays as *The Gardener's Year* (1931). (R. AY.)

CAPEL (OF HADHAM), ARTHUR CAPEL, 1ST BARON (1604-1649), English royalist, son of Sir Henry Capel of Rayne Hall, Essex, was elected a member for Hertfordshire of the Short and Long Parliaments (1640). He at first supported the opposition, but went over to the king's party and was raised to the peerage on Aug. 5, 1641. In 1643 he was appointed lieutenant general of Shropshire, Cheshire and North Wales, and was a commissioner at the negotiations at Uxbridge in 1645. He attended the queen in her flight to France in 1646, but disapproved of Prince Charles's journey thither and retired to Jersey, subsequently aiding in the king's escape to the Isle of Wight. He was one of the chief leaders in the second Civil War. On Aug. 27, 1648, together with Lord Norwich, he surrendered to Fairfax at Colchester on promise of quarter for life, an assurance which the civil authorities declared not to be binding on themselves. He succeeded in escaping from the Tower, but was again captured, was condemned to

death by the new "high court of justice" on March 8, 1649. and was beheaded, with the duke of Hamilton and Lord Holland, the next day.

His son ARTHUR CAPELL was created earl of Essex in 1661. See ESSEX, EARLS OF.

CAPELL, EDWARD (1713-1781), English Shakespearean scholar, who aimed at an accurate text and collated thoroughly the folio and quarto texts, was born at Throston, Suffolk, on June 11, 1713. His *Prolusions, or Select Pieces of Ancient Poetry*, with its tentative ascription to Shakespeare of the anonymous *Edward III*, appeared in 1760, to be followed by the ten-volume Shakespeare (1768). He died on Feb. 24, 1781.

A separate glossary and commentary was published posthumously in three volumes: *Notes and Various Readings to Shakespeare* (1783). Lack of appreciation for this (especially important for its collection of extracts from Elizabethan books in the third volume, *The School of Shakespeare*) was shared by scholars, though it was said that George Steevens had filched from it matter for his own edition by bribing a printer's servant. Dr. Johnson granted Capell ability sufficient only "to select the black hairs from the white for the use of the periwig makers." but he has come to be linked with Lewis Theobald and Edmund Malone as a sound 18th-century scholar. (G. A. O.)

CAPELLA, MARTIANUS MINNEUS FELIX (fl. late 4th and early 5th century A.D.), was a native of north Africa and an advocate at Carthage who mixed prose and poetry in an introduction to the liberal arts written perhaps c. A.D. 400 and certainly before 439. It was a work of his old age and dedicated to his son. His title for the whole work is not known. Manuscripts give the title *De nuptiis Philologiae et Mercurii* to the first two books and entitle the remaining seven *De arte grammatica, De arte dialectica, De arte rhetorica, De geometrica, De arithmetica, De astrologia* and *De harmonia*. Mercury gives his bride, who is made divine, seven maidens, and each declaims on that one of the seven liberal arts which she represents. The prose style is often dry, but in parts it is influenced by the style of the *Metamorphoses* of Apuleius and is even more mannered and bizarre. The verse is mostly competent.

Martianus Capella seems to have indirect knowledge of Varro's *Disciplinarum libri IX* and of his theological works. Pliny, Solinus, Aquila Romanus and perhaps Xristides Quintilianus are among his immediate sources. Fulgentius owes something to him, and the cultural influence of his encyclopaedia was immense down to the late middle ages. Numerous manuscripts survive: there are commentaries by Iohannes Scotus, Dunchad and Remigius of Auxerre.

BIBLIOGRAPHY.—A. Dick (ed.), *Martianus Capella*, "Teubner Series" (1925); H. W. Fischer, *Untersuchungen über die Quellen der Rhetorik des Martianus Capella* (1936); F. May, *De sermone Martiani Capellae—ex libris I and II—quaestiones selectae* (1936). (G. B. A. F.)

CAPELLA, the sixth brightest star in the sky and the brightest star in the constellation Xuriga (*q.v.*), hence its alternative name α Aurigae. It was found to be a spectroscopic binary, and the separation of its two components was first directly measured in 1919 with A. A. Michelson's interferometer (*q.v.*) in conjunction with the 100-in. telescope on Mt. Wilson. Its approximate distance from the sun is 45 light-years. The spectrum (see SPECTROSCOPY, ASTRONOMICAL) of Capella closely resembles that of the sun.

CAPELLO (CAPPELLO). BIANCA (1548-1587), the beautiful and unscrupulous mistress of Francesco de' Medici, who by marrying her made her grand duchess of Tuscany, was born of a rich and patrician family of Venice. After a runaway marriage (Dec. 1563) with Pietro Bonaventuri, a poor Florentine clerk, she promptly became the mistress of Francesco, the grand duke Cosimo de' Medici's son and heir, who in Dec. 1564 was married to the Austrian archduchess Joanna. Bonaventuri was murdered in Florence in Aug. 1572. Francesco, meanwhile, who succeeded to the grand duchy in 1574, remained with no male heir, and in 1576 Bianca simulated pregnancy and foisted on him a child, son of a woman of the people, whom the duke named Antonio. Joanna having died in 1578, Bianca was married to Francesco, the wed-

ding being publicly announced on June 10, 1579. Bianca's fraud was discovered and Antonio was not made Francesco's successor. In Oct. 1587 both she and her husband died within a few days of each other in circumstances that gave rise to suspicions of poisoning. Both deaths, however, would seem to have been from natural causes.

CAPE MAY, a city of New Jersey, U.S., located at the southern tip of the state, was named for the Dutch explorer, Cornelius Mey who visited there in 1623. Tradition indicates it to be the oldest beach resort in the nation, although authorities disagree as to the date the tourist trade began. In the 1850s the Mount Vernon, accommodating 2,000 guests, was the largest hotel of its kind in the U.S. It was later destroyed by fire. Cape May clientele, mainly from the south, included Stephen Decatur, Henry Clay, Franklin Pierce and Abraham Lincoln. Henry Ford raced on the beach in 1903 and sold a car to Daniel Focer, a local resident, who later received the nation's first franchise for a Ford agency.

Cape May is very much a family-type resort, with many tree-lined streets reminiscent of a rural village. On the boardwalk is Convention Hall where free concerts and dances are held during the summer season. The famed Cape May lighthouse, a plant which extracts magnesite from sea water and a U.S. coast guard base are outside the city. Bird lovers frequent the dunes to observe migrations along the Atlantic flyway. The permanent population in the 1960s was about 4,000.

Under the name Cape Island the settlement was incorporated as a borough in 1848 and chartered as a city in 1851. The name was changed in 1869. (E. R. D.)

CAPE OF GOOD HOPE (CAPE PROVINCE, KAAPROVINSIE) is the largest of the four provinces of the Republic of South Africa, its area being 278,465 sq.mi. or 59% of that of the republic. Its coast line forms the western, southern and eastern boundaries. The northern boundary lies along the Orange river in the west and the Nossob and Molopo rivers in the middle. In the northeast the province is divided rather irregularly from the Transvaal, the Orange Free State, Basutoland and Natal.

Physical Features.—Physiographically the major part of the province lies on the South African plateau (see SOUTH AFRICA, UNION OF: *Physiography*), the Great Escarpment being most prominent along the Cape-Basutoland border where the Drakensberg range rises to over 9,000 ft. Farther west the highest part of the escarpment is the northern part of the Sneeuwberge ("snow mountains") where the Compass Berg, a dolerite peak, rises to 8,215 ft. In the southern and southwestern part of the province is some of the finest scenery in the continent, for although the highest parts of the folded mountains in the south do not reach 7,700 ft., the valleys are deeply cut between the ranges and the topography is extremely rugged. In the river valleys of the Little Karroo intensive cultivation is practised under irrigation. In the Great Karroo basin, which lies between the folded mountains and the Great Escarpment, the main areas of cultivation are the irrigated valleys of the Sundays and Great Fish rivers in the eastern part of the basin, to the south of Graaff-Reinet and Cradock.

In the coastal zone of the south and southwest two comparatively flat areas have a winter rainfall sufficient for wheat growing. To the east of the folded zone and the Great Karroo basin, the eastern Cape Province is a moderately dissected part of the marginal zone between the plateau and the coast. The many rivers rising in the plateau edge provide narrow striplike alluvial terraces suitable for cultivation but, especially in the Transkei (the marginal zone northeast of the Great Kei river), these valleys are generally too steep and rugged for more than strip cultivation.

In the north of the province the course of the Orange river forms the main feature. Above the Aughrabies falls the valley is wide and open and fairly large tracts can be irrigated; below the falls the course of the river is for the most part troughlike and little irrigation is possible.

Climate.—The outstanding climatic features are associated with the great range of temperature and the seasonal variation of rainfall. Mean January temperatures vary from below 65° F. in the west coastal zone to between 65° and 70° in the south coastal

area and on the higher parts of the plateau, over 75° in the Great Karroo basin and more than 85° in the lower Orange river basin. Mean July temperatures vary from less than 45° on the southern part of the plateau to over 60° in the southeastern coastal zone. The average duration of frost ranges from more than 180 days in the southern part of the plateau to an almost complete absence in the coastal areas. The highest mean absolute range of temperature (over 80°) is found on the west central part of the plateau.

Rainfall varies from the summer rainfall of the eastern areas of the province to the winter rainfall of the west and southwest. Along the south coast is an area of all-season rainfall with monthly averages of two to three inches, and in the interior a narrow corridor of rainfall with no special seasonal incidence separates the winter and summer types. Mean annual rainfall totals vary from probably over 100 in. in some parts of the Cape ranges (e.g., Wemmers Hoek) to less than 4 in. in the west coastal zone and in the lower Orange river basin. In the summer-rainfall area the highest averages (above 40 in.) occur on the Drakensberg and Amatola mountains and in the eastern coastal zone. The greatest contrasts occur in the folded mountains where it is common for the ranges to have an annual rainfall exceeding 60 in. and the adjacent valleys in the rain shadow less than 10 in.

In the summer the reliability of the rainfall is highest in the southeast of the province (75%) and lowest in the west (30%); in the winter the reliability is greatest in the south coastal zone (60%) and least in the northeast (30%).

Vegetation.—The climatic features are closely related to the vegetation. In the winter-rainfall area the vegetation is sclerophyllous, the bushes having leaves protected in some way against the intense dryness of the hot summer months. There is little tree growth except in very moist localities, although some exotic pines do well when nursed over the early stages. In the summer-rainfall region the area of lowest rainfall (below five inches) is desert with only succulent vegetation or other types specially protected against the continual aridity. The area with 5 to 15 in. of rain is largely occupied by karroo shrubs which have root systems and fine leaves adapted to withstand long periods of drought. Many of these bushes provide excellent browsing for sheep and goats. In areas having over 15 in. of rainfall the karroo vegetation tends to give place to grass which in the lower parts of the province is associated with tree growth, forming savanna. In the few humid areas, such as the eastern part of the south coastal zone and on the Hogsback and Amatola mountains, there are considerable areas of natural forest.

Animal Life.—After European occupation the fauna changed greatly. Formerly the larger antelopes and quaggas roamed the plains in countless thousands and the large carnivores were numerous. The lion appears to have been found everywhere except in the south coastal zone. The elephant, rhinoceros and hippopotamus were almost universally present, as the farm names testify, but now it is only in the mountains and the unoccupied areas that leopards (sometimes called tigers in South Africa) and baboons may be found. Jackals are common in most areas and are hunted continually by the sheep farmers. Small buck are found wild in some localities, but the larger buck are confined to the reserves.

A few of the Knysna elephants still roam the southern forests where they are protected, but lions, rhinoceroses and giraffes no longer exist in the province.

Game Reserves.—Four national parks are situated in the province: the Kalahari Gemsbok National park in the north; the Addo Elephant National park in the southeast; the Bontebok National park in the extreme south and the Mountain Zebra National park near Cradock. A department of nature conservation was established for conserving the flora and fauna and many nature reserves have been proclaimed.

Population and Administration.—When the Union was formed (1910), the population of the province was about 2,500,000. At the 1951 census it was 4,426,726, comprising 935,085 whites, 981,802 Coloureds, 17,818 Asians and 2,492,021 Bantu. Census results in 1960 were: total 5,308,839; whites 997,377; Coloureds 1,314,392; Asians 20,243; Bantu 2,976,827. (See also SOUTH

AFRICA, UNION OF: Population, and AFRICA: Ethnography (Anthropology): Southern Africa.)

The chief towns are on the coast, including the provincial capital, Cape Town, and the ports of Port Elizabeth and East London (*qq.v.*). Goodwood is a large residential town just east of the capital, and the largest inland centre is Kimberley (*q.v.*). Uitenhage, Paarl, Worcester and Queenstown (*qq.v.*) are other towns with populations exceeding 25,000. The remaining towns are small and are mostly market centres, railway junctions or pleasure or health resorts. Most of the smaller towns have a rectangular layout with a central square or market place. Streams directed into channels along the streets, which may be lined with trees, assist in keeping them cool in summer.

Administration.—An account of the relations of the provinces to the central government, and of the judicial system, is given under SOUTH AFRICA, UNION OF. In 1960 the province was divided into 108 magisterial districts. For local government there were 95 divisions, each with a divisional council; 155 municipalities; and a number of village management boards and local boards. These local government bodies are under the legislative control of the provincial council and their local responsibilities are defined by provincial ordinances. The annual expenditure of the province in the early 1960s was more than £45,000,000, the main items being education, hospital services and public health, and roads and bridges. The main items of taxation included provincial income tax, licences, companies tax and tax on persons. There was a sizable subsidy from the government.

Education.—For whites in the province in the early 1960s there were more than 200 high schools, about 60 secondary schools, about 850 primary schools and about 30 farm and other schools with, altogether, around 200,000 scholars. For Asians and Coloureds, there were about 1,200 primary schools, about 15 intermediate and approximately 45 secondary and high schools. For Bantu education there were about 2,700 schools of which all but 120 were government or government-aided. The enrollment of about 420,000 included 285,000 lower primary pupils, 105,000 higher primary, 13,000 secondary and 2,500 teacher-training and vocational-training students. In the nongovernment schools there were about 12,000 pupils. The whole Bantu educational system was transferred in 1958 from the ministry of Bantu administration and development to the ministry of Bantu education.

Three universities are situated in the province: the University of Cape Town for white (mainly English-speaking) students; the University of Stellenbosch with mainly Afrikaans-speaking students; and Rhodes university at Grahamstown (English-speaking). The University College of Fort Hare at Alice for Xhosa-speaking students is affiliated with Rhodes university.

ECONOMY

Agriculture.—In western Cape Province the main crop is wheat, grown under natural conditions of winter rainfall. The two most important areas are the Swartland, lying between the folded mountains and the coastal sand veld from Bellville in the south to Het Kruis in the north, a distance of about 90 mi., and a second area known as the Rûens ("ridge lands") west of Bredasdorp. The annual wheat production of the province is between 4,000,000 and 5,000,000 bags (of 200 lb.). Oats and barley are subsidiary crops. In the eastern part of the province the main crop is maize ("mealies"), which is grown where the summer rainfall exceeds about 20 in. and yields about 2,000,000 bags annually.

The province produces grapes, deciduous tree fruits and citrus fruits. Grapes are grown mainly in the southwest, both under natural conditions of rainfall and under irrigation. Wine grapes form the bulk of the crop; table grapes are grown mainly for export. The chief deciduous tree fruits, grown mainly in the winter-rainfall areas within a 100-mi. radius of Cape Town and Mossel bay, are apples, pears, plums, peaches, nectarines and apricots. Citrus fruits are grown mainly in the Olifants river valley in the west and in the Sundays river valley in the east. Both deciduous and citrus fruits are important export crops.

Virginia tobacco of the Orinoco type is grown in the Oudtshoorn and Gamtoos regions and relatively small quantities of Turkish

tobacco in the southwestern winter-rainfall area. The production of chicory in the coastal regions between Port Elizabeth and Komgha (near East London) varies between 7,000,000 and 24,000,000 lb. annually, fluctuating greatly with the rainfall.

Excluding the well-watered southwest, the areas of most intensive cultivation in the province are irrigated lands. In the early 1960s the largest schemes (of over 20,000 ac.) were the Vaal-Hartz scheme to the north of Kimberley where about 55,000 ac. were irrigated by water from the Vaal river; the Orange river valley (from Buchberg dam to Kakamas) where about 48,000 ac. were under irrigation; the Great Fish river, where numerous small schemes had a total area of about 44,000 ac.; the Kammanassie river near Oudtshoorn with 23,000 ac.; the Sundays river scheme below Lake Mentz dam with 23,000 ac.; and the Olifants river scheme in the west with 21,000 ac. In most of these areas the main crops were fruit and lucerne (alfalfa), but cotton growing was increasing in the Orange river valley.

Forestry is important in the southwestern and southern coastal areas and in the adjacent ranges. State-owned natural forests extend to nearly 500,000 ac. but are strictly protected because of former overexploitation. The rapid development of afforestation in the mid-20th century resulted in plantations exceeding 300,000 ac., of which approximately 90,000 ac. were of hardwoods (mostly eucalyptus and wattles) and about 230,000 ac. were of softwoods (conifers). The annual volume increment of wood was between 80 and 280 cu.ft. per acre.

In the southwestern part of the province there is little livestock except for dairy herds. In the eastern summer-rainfall area the veld is suitable for cattle and most of the 4,000,000 head of cattle in the province in the early 1960s were located there. In the drier middle interior, where the karroo type of vegetation flourishes, were most of the 24,000,000 sheep and 4,000,000 goats of the province. Of the sheep about 20,000,000 were of the woolled type, mainly merinos; about 1,500,000 were karakuls. A few ostriches were still bred on some of the farms of the Oudtshoorn area.

Fisheries. — About nine-tenths of the fish caught and marketed in South Africa come from Cape waters. The main shoal fish are the pilchard (*Sardinops ocellata*) and the maasbanker or horse mackerel (*Trachurus trachurus*), the catches being about 300,000 tons annually. Trawled fish include the Cape hake (*Merluccius capensis*)—about 60,000 tons a year—and much smaller catches of other fish! including the Agulhas sole (*Austroglossus pectoralis*). Line fisheries land annually about 30,000 tons, by far the most important item being the snoek (*Thyrsites atun*). An important inshore catch is the crayfish or rock lobster (*Jesus lalandii*). Annual exports of fish and fish products from the province in the early 1960s were valued at about £(S.A.)8,000,000. Whaling is carried on from Saldanha bay. Annual catches were about 1,500 whales (sperm and baleen) and the value of oil and other products about £(S.A.)600,000.

Mining. — The most valuable mineral found in the province is the diamond which occurs in the volcanic pipes of the Kimberley area and as alluvial stones in river terraces. To 1960 the value of diamonds produced in the province was over £(S.A.)394,000,000, with an average annual output in the 1960s of about £(S.A.)12,000,000. Among the base minerals the most valuable is the "Cape blue" (crocidolite) asbestos found to the north of Prieska, the annual output being about 70,000 tons valued at about £(S.A.)5,000,000. Manganese from the Gamagara hills near Postmasburg realizes about £(S.A.)4,000,000 annually for 700,000 tons of ore. Copper is mined in the Okiep area in Little Namaqualand, the annual output of blister copper being about 60,000 tons. Other minerals are of small value.

Manufactures and Trade. — Manufacturing is concentrated in the Cape western and Port Elizabeth areas, which together account for approximately four-fifths of the net value of manufacturing output. The East London area is a distant third. Power stations in the province are in the Cape western and East London areas. Industries include foundries, engineering works, saw- and grain mills, distilleries and wineries and the manufacture of many kinds of consumer goods.

The principal exports from Cape Town are maize and fruit. Cargoes landed are mainly fuel oil, timber and railway material, besides general cargoes. From Port Elizabeth the more important cargoes shipped are wool, citrus fruit, ores and other minerals.

HISTORY

The Dutch East India Company. — In 1652 Jan van Riebeeck or Riebeek landed at De Kaap (Cape Town) with instructions from the Dutch East India company to organize a refreshment station for ships en route between Holland and Batavia. He was directed to build a fort, to plant a garden and to keep on good terms with the natives (Hottentots and Bushmen) so that they would barter cattle. Throughout its rule, the company clung to its primary objective, namely, the development of the Cape as a supply depot. Any colonial development was subordinate to company policy, and the diffusion of pioneer farmers eastward to the Great Fish river and beyond took place in spite of official plans. The company never outgrew the mercantilist spirit of the 17th century. To the end of its rule, navigation laws were enforced, local industries prohibited and freedom of trade proscribed. Up to a point the interests of the Cape and those of the company coincided. The company gave reasonable security, provided ammunition and basic necessities, fostered the production of wine and corn, encouraged first the barter, then the farming of cattle and sheep and periodically sponsored experimental crops. But the net result was that economic enterprise in the Cape was tied to the fortunes of a monopolistic and, in the 18th century, corrupt and declining company. When the company abandoned Mauritius to the French (1710) and failed to consolidate the move to seize Delagoa bay from the Portuguese (1721–30), the Dutch lost the opportunity to command the western shores of the Indian ocean.

The duel between England and France for domination in India emphasized the strategic importance of the Cape. During the American Revolution the English were forestalled and the French occupied the Cape between 1781 and 1784. During the French Revolutionary Wars the position was reversed. In 1794 the company, which had declared no dividend since 1782, went bankrupt, while the Netherlands, torn between pro-French and pro-Orangist factions, were attacked by the armies of republican France. The exiled prince of Orange authorized the British occupation of the Cape under a treaty made in 1788. In reality the occupation was a legitimate piece of naval strategy effected with political discretion.

The century and a half of company rule (1652–1795) left a permanent impress on South Africa. Granted its handicaps, its achievements were considerable. By 1795 Cape Town was an attractive garrison town, with an estimated population of 5,000 Europeans and 10,000 of other races. It was the centre of government and the hub of society and commerce. Beyond the Cape flats, the garden province of the western Cape was only beginning to take shape. Stellenbosch had been made the centre of a new district by Simon van der Stel (1679–99). In the Breede valley Swellendam, on the advice of Baron van Imhoff, had become a third district for local government in 1746. The Berg valley was fairly thickly settled, and the company had supervised the granting of freeholds, often with conditional clauses stipulating in some cases one-tenth of the corn grown, in others the planting of trees. The most decisive venture in this area had been launched when, on Dec. 31, 1687, the first shipload of Huguenot refugees had sailed from Holland to be settled in the new Stellenbosch district. Their total number is estimated at less than 200, roughly one-sixth of the free burgher (*i.e.*, nonofficial) European population in the Cape at the end of the 17th century. They proved industrious agriculturalists and laid the foundations of Cape viticulture, though the first good wines seem to have been made at Constantia by Willelm Adriaan van der Stel (1699–1707). There were the Groote Kerk in Cape Town, a church at Stellenbosch, another at Swellendam. In the 18th century new churches were built at Paarl, Roodezand (Tulbagh) and at Zwartland (Malmesbury).

It has been argued that the policy of close settlement exemplified by Stellenbosch should have been adhered to and enforced.

With its local government could have been effectively developed, cultural contacts would have been richer, a school system other than that in the lee of the churches would have been practicable. By contrast, in 1795 about 20,000 Europeans were scattered over a vast area, stretching at least 300 mi. N. of Cape Town and 600 mi. E. In 1786 Graaff Reinet was founded, as J. van Plettenberg (governor 1771–85) had fixed a frontier at the Great Fish river. But in 1795, though there was a church at Graaff Reinet, the buildings were still rough mud and thatch. There was no effective control of the Boers (estimated population 4,262 in 1795) in and beyond this new colonial outpost. In brief, north and east of Swellendam there were colonists but no colony. To the north there was no defined frontier. Bushmen contested every water hole and spring (from 1774 onward ruthless commandos slaughtered them by the hundreds); Hottentots and Griquas, where not serving in the colony, were retreating; but detribalized marauders, often provided with firearms and sometimes guided by renegades, raided from a no man's land. To the east the Trek-Boers (*trek-boeren*), isolated physically by poor communications and intellectually by lack of schools, lived the life of pastoralists, bound together by common hardships, a common faith and resentment of all official interference. Frontier life was precarious and made harsher by the ease with which slaves and apprentices could be acquired and discarded. At his best the frontier Boer developed stamina, courage and dignity, a love of the land and a habit of local co-operation on commando and on trek, liable to turn as quickly against a government as against an enemy. As the Xhosa peoples were moving southward, and as their society also depended on land and cattle, it seems probable that, but for the Trek-Boer, the frontiers of some future Bantu confederacy might have marched with Swellendam.

Whether or not the policy of close settlement with commercial apartheid, which the company vigorously reiterated in decrees against the cattle barter in 1677, 1727, 1739, 1770, 1774, 1780 and 1794, was sound in theory, in practice it was impossible. Many things militated against it. A limited and erratic market, where good crops caused a glut and poor harvests acute hardships, discouraged intensive agriculture in a country whose climate and soil remain a challenge. By contrast, as the Hottentots broke up, withdrew and were shattered by the smallpox epidemics of 1713 and 1755, cattle farming was a safer venture. The company needed fresh meat, and though the farmers had to move far in quest of grazing, the animals could be driven back to market on the hoof. A policy of monopoly excluded the burghers from commerce or industry; geography largely dictated the alternative lines of expansion. The company, it would seem, unwittingly fostered this slow-motion trek by the systematizing of loan-place tenure in 1714. Large farms, of which the average size was 6,000 ac., could be "rented" on annual renewable licence. Though tenure was insecure, land was plentiful, and the company checked the licences rather than the leases. Farmers moved from one pasturage to another, and every adult male came to regard a loan-place farm as his right, as well as to confuse possession with legal title. Thus, by decree, the company sought to prevent clashes with the natives; by its land tenure, it facilitated the trek to the east; by its failure to construct effective frontier control or local government, it continued to command but ceased to direct.

Throughout, the company had been frustrated in part by its own economic policy and often by the ambiguous conduct of its own officials. Burgher opposition to its policy, until the last quarter of the 18th century, had been mainly economic in impulse, isolated and not sustained in impetus. However, the American Revolution in 1776 (the first ship flying the Stars and Stripes entered Table bay in 1784) and the speculation which preceded the French Revolution, as well as the party struggles of the 1780s in the Netherlands, gave a new emphasis to burgher demands. The burgher petition of 1779 was sent over the heads of company officials direct to the states-general in Amsterdam. It demanded not merely economic relief but a share in the making and administering of known laws—in brief, a constitution. Characteristically, the burghers demanded also liberty to flog their own slaves. Since the governorship of M. P. de Chavonnes (1714–24) the

policy of assisted white settlement had been abandoned and the importing of slaves, restrained in the 17th century, had increased. As the number of slaves increased in proportion to the white population, not only was the slave code stiffened, but social instinct recoiled from the miscegenation hitherto, though prohibited, not uncommon. It seems also that the large numbers of detribalized Hottentots and free persons of colour in the western Cape suffered a reflex diminution of status, though the company recruited Hottentots to defend the colony in 1793.

What is significant is that the generation which was to experience first the British occupation and then, in 1814, formal cession by Holland to England had begun to formulate a claim to share in the government. This was not the rural nihilism of the Trek-Boer but the active political consciousness of a people who, as far back as 1706, had coined the word "Afrikaner" to distinguish the South African burgher, born in the land, from the alien official class. The officials of the Castle still wrote High Dutch and the services of the church were conducted in that language; but the average burgher spoke a local variant from which Afrikaans was to develop. The seeds of Afrikaner nationalism, though slow to germinate, are to be sought in the generation that preceded the British occupation.

This was true in the western Cape. It was true also in the frontier areas of the east, and though the life of the Trek-Boer was very different from that of the western farmer, traditions were common and families interrelated. In the western areas the challenge to white occupation had come from the Bushmen and the Hottentots. By 1795 neither Bushmen nor Hottentots were a serious military danger; on the contrary, 90% of the Hottentot population of the Cape lived in the three western districts of Cape Town, Stellenbosch and Swellendam. There was a social but no longer a military frontier. In the late 18th century, however, as the Trek-Boers pushed eastward seeking new land and immunity from company control, they encountered the forward drift of the Xhosas. Bantq social customs were based on cattle, their tribal structure on land. In the last quarter of the 18th century, at a time when the death of their paramount chief Palo had exposed them to internal confusion, the Xhosas crossed the Great Fish river along its entire length and two societies, one white, one black, alike in that each was a cattle-farming community, clashed on a frontier that neither respected. Van Plettenberg toured all the eastern districts as far north as modern Colesberg and agreed with some petty chiefs that the Great Fish river should be the boundary. The treaty was ignored by both sides. In 1779 armed clash developed into a major war (the first so-called Kaffir war) and forced the Xhosas back beyond the Great Fish. In 1789 (in the second Kaffir war) Chief Ndhambi crossed the Great Fish river again and diffused his men over the Zuurveld, to the fury of the Boers. Fury was impotent since H. C. Maynier, secretary at Graaff Reinet, disapproved of the Trek-Boers and oversimplified the native question. He allowed Ndhambi to stay but, in bland ignorance of native custom and society, reserved the property rights of Europeans.

While the Cape government evacuated Swellendam to concentrate on peninsular defense and turned its back on the eastern frontier, the Xhosas plagued one another, some Boers crossed the Great Fish and a few dabbled in intratribal conflicts. Finally the Xhosas united to rend the Boers and made a desert of the farms between the Kowie and Zwartkops rivers. Again partly from conviction, partly from impotence, Maynier, now officially landdrost but with no armed support from the Cape, came to terms with the Xhosas after an abortive campaign. The sequel was significant. First Graaff Reinet (led by A. van Jaarsveld and J. C. Trigardt) and then Swellendam revolted against the company. They elected their own officials and adopted the tricolour flag. In June 1795 Swellendam summoned a national assembly to cover a frontier secession. In the same month British warships anchored off Table bay.

With rebellion on a chaotic frontier, pro-Orangist sentiment strong in the Castle and inadequate manpower, A. J. Sluysken (1793–95) could put up no strong resistance. In Sept. 1795 he signed a favourable capitulation and the British, in view of the

recent alliance between Holland and France, took possession.

The First British Occupation. 1795–1803.—From 1795 to 1803 Great Britain was interested in the Cape only as a naval base and maritime junction. Few changes were made in the structure of government and Roman-Dutch law was recognized. Monopolies were abolished, whaling encouraged, trade to the east thrown open and, so far as war allowed, British goods freely imported. Adequate salaries were paid to officials and judges and though the highest posts were held by the British administration, there was no official purge. But colonial problems were thrust on the administration by the confusion in Graaff Reinet which, having submitted in Nov. 1795, revolted when Van Jaarsveld was arrested for forgery and again in 1801 because the third Kaffir war terminated on the basis of the unsatisfactory *status quo*. The establishment of a garrison point at Fort Frederick (Port Elizabeth) was directed to secure Algoa bay rather than to police the Zuurveld. In Feb. 1803, under the treaty of Amiens, the Cape was retroceded to Holland, now styled and organized as the Batavian republic.

The Cape Under the Batavian Republic, 1803–06.—The Batavian administration thrust its policy on the colony, which was to be reformed in accordance with French revolutionary ideals. The ideas of the governor, Gen. J. W. Janssens, and of Commissary J. A. de Mist were humane and their approach methodical. Several effective steps were taken. New districts were created at Tulbagh and Uitenhage; the Moravians at Genadendal were encouraged; the missionary J. T. van der Kemp was established at Bethelsdorp, in the hinterland of Algoa bay, to rally and civilize the Hottentot remnants in the eastern districts. Hottentot labour was to be registered and contracts observed by both parties. The frontier was defined and expanded in the northwest. Clearly the Batavians meant to govern as benevolent despots. They proposed religious toleration and secular education. Above all they meant to control frontiers and frontier folk. This, with sustained crisis on the eastern frontier and the truculent self-sufficiency of Graaff Reinet, which wanted gunpowder rather than government, brought the colony to the edge of revolt. From this attempt to revolutionize society, the Cape was reprieved by the second British occupation in Jan. 1806. Throughout the Napoleonic Wars Holland was the ally of France, and in their course the British conquered the entire Dutch colonial empire. Under the general settlement at Vienna in 1814 Great Britain relinquished most of its colonial conquests but retained the Cape and part of Guiana.

British Colonization and the Great Trek.—Theoretically the British might have evacuated the Cape in 1814. In practice, from 1806 administration was handled on the assumption that the "conquest" of that year would probably be permanent. The slave trade, legally abolished in 1807, was progressively suppressed. In 1834 slaves, as elsewhere, were emancipated subject to a period of apprenticeship. Free settlers were encouraged, frontiers were held and expanded, while even before the discovery of diamonds in 1867 the successful introduction of wool farming, of crossbred Angora goats, which launched the mohair industry, and the improvement in horse breeding (the company had exported horses to India as early as 1769) had led to steady economic expansion. The improvement in road communications (Montagu pass, Mitchell's pass, Bain's Kloof, 1848–53), the expansion of shipping in Cape Town, Port Elizabeth and Durban, the removal of commercial restrictions and, after 1854, the promise of railways made, in spite of financial depression in the late 1820s and the shock of frontier wars, for a general leavening of prosperity and fostered the growth of urban life. The Cape offered a career open to talent and enterprise. There was virtually free emigration from the European continent as well as from Great Britain.

During 1836 and 1837, Boer farmers, mainly from the eastern districts, launched the Great Trek and systematic emigration by ox wagon across the Orange river, away from British rule. It is estimated that in the decade after 1836 about 14,000 farmers abandoned the Cape to become the Pilgrim Fathers of the high veld and to found republics in the Free State and the Transvaal. The trek is the axial point in South African history, an exodus remarkable less for its size than for its significance. In part it

was the acceleration of leisurely progress toward the open veld. In part it was the fulfillment of dreams that had crystallized in the abortive republics of Graaff Reinet and Swellendam in 1795. But in the main it had a coherence and spontaneity arising from revulsion from British rule. Though frontier Boers and frontier British settlers made common cause in criticizing frontier policy, only a few British abandoned the colony. Though each trekker family had its private goal, the trek was a quasi-nationalist move out of what threatened to become a house of bondage.

British rule at the Cape had begun cautiously but systematically. In structure the administration, subject to veto from the home government, was autocratic. It was not until 1825, when the unpopularity of Lord Charles Somerset (1814–26) forced the issue, that an advisory council was associated with the governor; a nominated legislative council and executive council followed in 1834. From the beginning local affairs were more closely supervised, and frontier posts and magistracies multiplied even in the first decade. In 1811 Alexander Du Pré, earl of Caledon, instituted circuit courts. These, among other things, could hear Hottentot as well as European complaints against the violation of Caledon's ordinance of 1809 as amended by Sir John Francis Cradock (1811–14) in 1811, which had sought to enforce master-and-servant contracts. The first circuit in 1812 acquired notoriety, partly because some frivolous charges were brought, chiefly because legal protection was effectively extended to Hottentots. In 1815, at Slachter's Nek, F. Bezuidenhout, having defied a summons for two years, was shot while defending himself from arrest by a European officer and Hottentot soldiers. His brother and friends launched a republican revolt, sought, in vain, the armed assistance of Chief Gaika and tried, also in vain, to raise the frontier. The rebellion was suppressed. 32 rebels were banished from the frontier and 5 executed. Legally Somerset's action was correct and politically it was in accord with current practice, but the fact remains that Slachter's Nek stands in Boer legend as an example of British tyranny and *lèse-majesté* against the white man.

The early governors strove to face problems frankly. In the western Cape schools were sponsored and new churches opened. The Dutch Reformed Church alone opened ten new churches between 1824 and 1829 and built up its synodal structure. Currency reform in 1826 caused considerable hardship, but with the development of banking and credit facilities this necessary preliminary laid the basis of future stability. The coincidence of currency reform and the progressive loss of preference for Cape wines in the home market (1825, 1831) meant that the emancipation of the slaves, against whom (as a species of property) mortgages were held, hit the Western province severely in 1834. Compensation was inadequate, and payable only in London. Many, even if admitting the wisdom of the measure, resented the penalty which resulted, as also the incorrect analogies drawn from West Indian conditions. In the main though, adjustment was easier in the western Cape, where closer settlement made for closer contact, and, after 1828, a free press provided a safety valve. The main difficulties lay on the frontier. To the north, annexation up to the Orange between Ramah and Bethulie in 1824 gave some stability, as did also the settlement of Bastards and Griqua in missionary-sponsored communities round Klaarwater, Campbell and Philippolis. Missionary enterprise, begun in the 18th century under the company at Genadendal, founded settlements for Bushmen, for Hottentots and among the Bantu. Most denominations and most countries were represented in a fumbling drive to civilize the coloured races, and what co-ordination the movement had it received from John Philip, the general superintendent of the London Missionary society. The missionaries' objectives were sound, their methods uncertain, their resources inadequate and, in the colony, their critics legion. Of their devotion, there is little doubt. They were, moreover, welcome. Their approach to frontier questions coincided in the main, especially between 1825 and 1842, with that of the colonial office and with underinformed opinion in Great Britain.

The crux of the issue lay mainly in eastern frontier districts. Cattle farming on primitive lines, with poor grazing and erratic rainfall, demands vast cattle runs and elastic tenure, whether the

farmers are European or Bantu. The economy of both groups was primitive. There was no scientific breeding, no fencing, no adequate herding. The company had sought in vain to hold the Great Fish river as a frontier in its last 20 years. Neither in 1789 nor in 1799 had the Xhosa been cleared from the Zuurveld. In 1812 (fourth Kaffir war) Cradock with ruthless efficiency drove Ndlhambi and 20,000 followers over the Great Fish. Forts at Cradock and Grahamstown, as well as the older one on Algoa bay, were planned to hold this line. As a solution, it was faulty. The Great Fish often dries up, making a highway instead of a barrier, and in its lower reaches it is covered on both banks by thick bush. It became increasingly an imaginary line. When Ndlhambi was driven back he came into conflict with Gaika and, in 1820, defeated him in a bloody battle at Amalinde Flats (near King William's Town). Aided then by the prophet Makana, he launched a counteroffensive to recover his land. In this, the fifth Kaffir war, Grahamstown bore the brunt, and the Great Fish frontier was restored, with the difference that the land between the Great Fish and the Keiskama was to be a neutral belt, with a military station and fort at Fort Willshire. This was trespassed upon by both sides! especially inland in the Tyumie valley, where Gaika settled.

It was partly to hold the Zuurveld that about 4,000 settlers were assisted by the British government to settle in what later became the district of Albany. After great hardships, accentuated by official ineptitude, they established themselves in the Zuurveld, though many craftsmen gravitated to the new towns at Grahamstown and Port Elizabeth (formerly Fort Frederick). Their paper, the *Grahamstown Journal*, became the acknowledged mouthpiece of frontier opinion, both Boer and British. Both groups demanded security from cattle raids on the frontiers and the European settlement of the neutral belt into which the overcrowded Xhosa cautiously expanded. When, in 1828, ordinance 50 ended the pass system for Hottentots built up on the regulations of Caledon and Cradock, there was a general outcry. Henceforward no special regulations governed free persons of colour, and the Hottentots drifted from the farms six years before the mooted emancipation of the slaves in 1833.

Between 1828 and 1838 the whole trend of British policy in the Cape was often unpopular with the settlers and anathema to the

Boers. After 1831, in accordance with E. G. Wakefield's theories, crown land would be put up for auction. Expansion to the east was barred, expansion to the north was growing more difficult, labour was scarce and the price of new farms was rising. A series of droughts meant stock losses and also stimulated Xhosa cattle-raiding parties. The establishment of a new supreme court in 1827 had been associated with the use of English instead of Dutch as the official language. The familiar jurisdiction of landdrost and heemraden gave place after 1828 to magistrates and civil commissioners. Thus to frustration was added a sense of alienation. True, some autonomy was given to the east by the appointment of a lieutenant governor, but the first holder, Andries Stokenstrom, an administrator of vigour and imagination, was dubbed a negrophilist and the label stuck. The emancipation of the slaves in 1833 hit the Eastern province as a psychological rather than an economic shock, which became more profound when, in

1834, a proposed vagrancy law to check the Hottentot drift was disallowed by Britain. Already in 1834 *commis*ie treks went ahead, one northwest, one north, one northeast to spy out prospects of escape. The sixth Kaffir war (1835) delayed action on their reports; and the Boers, Piet Retief conspicuous among them, helped to save the frontier. Victory seemed to offer the prospect of new farms in the ceded territory between the Great Fish and the Great Kei. But when the governor, Sir Benjamin D'Urban (1834-38), failed to convince the colonial secretary, Lord Glenelg, either of the legitimacy or of the advisability of annexing the territory to the Cape, the Boer felt he had everything to lose, including his whole standard of values, if he remained in the colony. The reversal of D'Urban's frontier policy was not the cause, but the final incident, which provoked the Boers resolutely to abandon the colony and everything associated with it. Fifty-seven years old, Retief had experienced the whole gamut of change. He saw no life that he cared to live save in a new land, and his departure (Feb. 1837) was the signal for the main exodus. With the trekkers went the whole complex of ideas of the traditional Trek-Boer, hardened by antagonism to the ideas and practices of the new era. The British: accustomed to a society where equality of legal rights in no sense connoted social equality, failed to appreciate that the different structure of Boer society, where all white men were peers, made it impossible for them to conceive legal equality for "free people of colour" apart from the nightmare of social equality.

The Colony From 1837 to 1854.—Within a few years the Great Trek had revolutionized the political structure of southern Africa. Natal was annexed by Great Britain in 1843 and was administered from the Cape until 1856. By the terms of the Cape of Good Hope Punishment act (1836) criminal jurisdiction extended to latitude 25° S., but failing either civil or military apparatus of government, it was a dead letter. In 1852 the independence of the Transvaal (*q.v.*) was recognized; in 1854, after six years of experimental control, the independence of the Orange Free State (*q.v.*) was recognized, and Great Britain's direct political responsibilities in southern Africa were limited to the Cape and to Natal. Nevertheless, from 1847 the governor of the Cape was also high commissioner for South Africa, for nothing could alter the political and military fact that Great Britain was *de facto* the paramount power. The Cape and Natal controlled

the markets for republican goods, so that isolationism would in any event have been impracticable. Moreover, however shakily, the new republics had turned the flank of the Bantu. Events in the Free State were always likely to have repercussions across the Drakensberg in Natal and in the no man's land between the Cape and Natal, as the European states mere like the walls of a dam encompassing a series of potential Bantu floods. Theoretically the Bantu tribes were all separate; in practice news passed freely between, for instance, Pondoland and Basutoland, and they were informed of the attitude of the frontier press. The risk of a concerted native convulsion was always within the bounds of possibility. Shrewd observers saw that the economic and political interests of the four South African communities could not be completely severed. It was therefore unfortunate that doctrinaire theorists in Great Britain, reinforced by an understandable clamour in parliament for economy, led Great Britain in 1852 and 1854 to abdicate from the legal power that should legitimately have gone with paramountcy by recognizing the independence of the republics.

In the Cape, the trek left no obvious vacuum. The European population of the Cape in 1832 is estimated to have numbered 66,000. In 1854, partly by natural increase, partly by immigration, it had increased to 140,000. Systematic colonization from Great Britain was encouraged and many soldiers, having completed their service, settled in the colony. The territory of the colony was substantially enlarged when Sir Harry Smith (1847-52) completed annexation up to the Orange river. After the War of the Ax (1846) he also annexed Victoria East and the land between the Great Fish and the Keiskama.

Three things characterized the development of the Cape during this period: the rapid growth of sheep farming and wool production as a new staple; the new approach to frontier issues marked by the crown's annexation of Kaffraria after the War of the Ax; and the successful demand for a representative assembly. Sporadic but unsuccessful attempts had been made by the company in the 18th century to breed sheep for wool and isolated experiments had been made by individual farmers for some time, but sheep farming for wool first became general in the eastern province, mainly because of the enterprise of British settlers.

The practice of enumerating a series of Kaffir wars, 1779, 1789, 1799, 1812, 1819, 1835, 1846, 1850, 1858, 1877, though sanctioned by convention, to some extent hides the problems which they indicate. The fact that the Xhosas many times outnumbered the Europeans, although the latter had superior military resources, together with the clash of race, has obscured the fundamental nature of the dispute. Many perished on both sides, and tension was almost as great in time of peace as in time of war. The colonists were embittered by repeated losses; others, speculators as well as farmers, were covetous of land. To peaceful settlement, however benevolent, by the colonial authorities in London, there were two handicaps: first, the length of the frontier and the nature of the terrain, which made it impossible to patrol (the Xhosas used the tactics that the commandos were to adopt later); second, ignorance of Xhosa tribal institutions and land tenure, which every European onslaught made more chaotic. Until about 1846 the object was to exclude the Xhosas from the colony, leaving the task of civilization to missionaries. With this went the experiment, based on misleading Indian analogies, of concluding *status quo* treaties with the miscalled states beyond the frontier. The prototype was the treaty with Andries Waterboer (1834; see GRIQUALAND EAST AND GRIQUALAND WEST). Similar treaties were concluded with the Gaikas, the Ndhlabis, etc., immediately after the war of 1835; with Adam Kok and Moshesh in 1843; and with Pondoland in 1844. In the case of states on the immediate frontier, the treaties thrust duties on the chief which tribal structure made it impossible to perform. After the war of 1835 the treaties gave eight years of uneasy peace. Both sides settled between the Great Fish and the Great Kei, and Fort Victoria in 1844 was established in the heart of native territory. Twice the treaties were somewhat arbitrarily revised, and there were constant clashes of patrols before the War of the Ax. The Xhosas then launched a counterrevolution which swept missionaries, traders, farmers and soldiers over the frontier. The government's counterattack was

terrible, but even so it proved physically impossible to drive the Xhosas behind the Great Kei. The chiefs were therefore dispossessed and planted on locations interlaced with white settlement, and Kaffraria was annexed to the crown. Reaction came in 1850, when even the Hottentots of the Kat River settlement (hitherto a buffer settlement south of the Winterberg) as well as the Xhosas attacked the colony, starting with massacre on an unprecedented scale in the Tyumie valley. Three years of fighting saw the Xhosas stripped of most of their cattle (at least 55,000 head mere taken) and metaphorically penned into congested locations. There was one last flash when, in 1857, Nonquase the prophetess persuaded the tribes to burn their crops and kill their stock as a sacrificial preparation for the destruction of the white people. Though Sir George Grey (*q.v.*) took remedial steps, Sandile's tribe dropped, by famine and dispersal, from 105,000 to 37,000 in a few months. The way was thus cleared by race suicide for the planting first of the so-called German legion in Kaffraria and then of German peasants on the coastward side. By 1860 there were approximately 6,000 Europeans and 53,063 natives. Their interspersal and the initial overcrowding of the locations, in spite of the benevolent intentions of Grey, who wanted to civilize through the tribal structure, made this Ciskei area a rural slum and handicapped the working of native institutions.

Parallel with economic development and with new ventures in frontier stabilization had gone considerable political development. A representative element was introduced into local government. In 1837 Beaufort West became the first town to elect a board of commissioners. Others rapidly followed. Churches developed greater institutional autonomy. The Dutch Reformed Church was emancipated from political control in 1843. The Anglican Church developed rapidly after the creation of the bishopric of Cape Town in 1848, to be followed by new sees at Pietermaritzburg (Natal) and Grahamstown in 1853. A free press and a growing though still inadequate school system helped to make informed public opinion, which, if undisciplined, was strong enough to avert the proposed introduction of convict labour in 1849. The Eastern province, which had its own lieutenant governor, demanded administrative autonomy and clamoured for separate representation. Great Britain was chary of granting representative government, lest the sequel be the revocation of the principle of legal equality or even an irresponsible frontier policy. But in 1853, with the latest Kaffir war over, Kaffraria annexed to the crown and the Orange River sovereignty abandoned, the legitimate demands were met. The Cape Constitution ordinance of 1853 set up a bicameral legislature. In the legislative council (the upper house) there were eight members for the Western and seven for the Eastern province. In the legislative assembly (lower house) no attempt was made to balance the voting strength of the provinces, but as the electoral districts were then arranged, the Western could outvote the Eastern by two. High property qualifications were demanded for membership of either house, but the franchise for the lower house, based on property rather than colour, though it favoured the Europeans, did not exclude free persons of colour.

The Advent of Responsible Government. — In 1854 Great Britain had sought to cut its liabilities by giving up the Orange River sovereignty and concentrating on Natal and the Cape. Although some officials at the colonial office saw southern Africa as a unit, public policy toward the colonies inclined to the ideas of the Manchester school. Like the Wakefield Radicals: this group of theorists believed sincerely in the educative discipline of self-government wherein the Cape, which now had representative but not responsible government, lagged behind the other colonies. Unlike the Radicals, the Manchester school did not believe in imperial co-ordination. They emphasized that Great Britain's colonies, especially South Africa and New Zealand, were the cause of heavy expenditure, whereas their economic significance was slight. Thus they favoured the acceleration of constitutional and fiscal responsibility, the reduction of military expenditure and, to that end, a conservative imperial policy. In April 1859 Great Britain therefore rejected the federative proposals of Sir George Grey and ignored the fact that the fragmentary structure of southern Africa was an economic handicap and a political danger.

When, in 1856, Natal was constituted as a crown colony, there were eight political units in southern Africa: in diminishing order of stability, the Cape, Natal, Kaffraria, the Orange Free State, the South African Republic, Zoutpansberg, Lydenburg and Utrecht. That the Transvaal coalesced and survived under M. W. Pretorius was hardly the result of imagination or forethought on Great Britain's part. In Basutoland and Griqualand West, however, in the interests alike of the Cape and of Natal, Sir Philip E. Wodehouse (1862-70) was compelled to act. The clash between Moshesh and the Orange Free State was dangerous in two ways. Already Nehemiah, son of Moshesh, was on the eastern side of the Quathlamba mountains, while Molapo and Moshesh commanded the main passes over the Drakensberg into Natal. An overwhelming Basuto defeat would lead to their dispersal either into Natal, always harassed by fear of the Zulu, or into the Cape, where the colonial Xhosas, as in the early 19th century, would be caught between two pressures. Furthermore, Kreli, paramount chief of the eastern Xhosas, held the strategic key to the native territories between Kaffraria and Natal. Kreli was in touch with Moshesh, with the Ponds and with the Tembus around Umata. Any victory secured or any defeat sustained by Moshesh would have repercussions in the Cape and in Natal. Because of this, Wodehouse, while refusing to arbitrate in the Klip river dispute (see TRANSVAAL), promised Pretorius to arbitrate the Basuto line if requested by Moshesh. In 1864 he modified the first treaty of Aliwal North (1858), arbitrating at J. H. Brand's request. In 1868, when after three years of war the Free State had won a victory which Brand could not consolidate and Moshesh dared not accept, Wodehouse annexed Basutoland and in 1869 the Free State *volksraad*, with only one dissident, ratified the second treaty of Aliwal North. In 1871 Basutoland was annexed to the Cape, to revert to crown protection in 1884. Thus British policy was once again committed to responsibility north of the Orange and west of the Drakensberg.

Much the same issues were involved in the disputes beyond the Cape boundary north of the Cape and west of the Orange Free State. The claims of Pretorius in 1868 threatened to disrupt the Batlaping and Barolong, hitherto intact under British missionary guidance, and what was vitally important, to cut across the trader-missionary road to the interior. Seven years earlier, in the Vaal-Hartz-Orange area, the migration of Adam Kok from Philippolis to Griqualand East had left behind a tangle of claims north of the Vetberg line and on both sides of the Vaal. The chief disputants were Waterboer, coached by David Arnot, and the Orange Free State, which in 1861 had purchased the lands of Adam Kok (see ORANGE FREE STATE; GRIQUALAND EAST AND GRIQUALAND WEST).

Confusion threatened chaos when diamonds were discovered first at Hopetown in 1868, then in the dry diggings (site of the future Kimberley) in 1870. Disorder and conflicting jurisdictions were of more than local significance because the traffic in spirits and guns now available to migrant native labourers threatened to kindle and arm native unrest. It was clear that control of diamond areas would restore the waning economy of the Cape, but neither that nor the treaty links with Waterboer were so decisive as the threat to security. In 1871 the Keate award resolved the Transvaal boundary dispute. In the same year Sir Henry Barkly (1870-77) annexed Griqualand West, which the Cape, however, declined to accept until 1880.

Piecemeal annexation added to difficulties in the Cape, where the granting of representative institutions imposed on the high commissioner in his capacity of governor the ambiguity of a double role. For his actions as high commissioner he was answerable to the colonial office; yet such steps as Grey's policy in Kaffraria and the subsequent annexation of Kaffraria to the Cape (1865), the dispatch of Cape police to Basutoland and the fate of Griqualand West could not be determined without the connivance of the Cape assembly, and there was the risk of deadlock between the upper and lower houses and between the two houses and the irresponsible official executive, as well as between either or both and the colonial office. Grey's tenure of office coincided with a period of relative prosperity when the home government was prepared to spend fairly lavishly both on the imperial garrison and on the development of Kaffraria; and Grey himself did much to

enrich the cultural life of the colony.

In the 1860s the threat of the diversion of shipping routes when the Suez canal should be opened hung over a colony hit by drought, by changes in the wool market and by the general tightening of credit that followed the American Civil War and the outbreaks of war in Europe. Economic stagnation retarded the development of railways and telegraphs; government debt increased (it stood at £1,420,000 in 1870) and Great Britain was with difficulty dissuaded from hasty garrison withdrawals like those in New Zealand. Depression was accentuated by awareness of frontier threats, further advance in the Transkei was prohibited (1865) and Kaffraria—the heyday of imperial grants departed—was incorporated in the Cape (1865). Within the colony, the Eastern province clamoured for separation on the analogy of Natal. With wool as the staple and the traffic at Port Elizabeth expanding, it claimed that it could be self-supporting; and it hoped to increase its own weight by the inclusion of Kaffraria (which however the Kaffrians, headed by J. G. Sprigg, opposed).

Tension was such that Wodehouse, who met the parliament of 1864 in Grahamstown and established there a two-judge court for the Eastern province, toyed with instituting "Jamaica" reforms and restoring official autocracy. Even such enthusiasts as J. C. Molteno (Beaufort West) hesitated to urge full responsible government on a fractious, stagnant and well-nigh bankrupt colony. Sir Henry Barkly took advantage of returning prosperity to encourage Molteno's move for responsible government. The move failed in 1871, but in 1872 a bill to institute responsible government was introduced with a parallel measure to equalize representation of the two provinces. In Dec. 1872 Molteno built up the first cabinet government in the Cape and wisely sought to make it truly representative in the major provincial groups.

The Cape From 1872 to 1902.—Between 1854 and 1872 there had been more than a little danger that parties in the Cape would follow a territorial alignment of the Western province versus the Eastern province, with the Kaffrarian group under Sprigg holding a balance of power. Molteno, the first premier of the colony (1872-78), did much to avert this by the electoral law of 1874, which divided the colony into electoral circles. Molteno also worked to give the Cape full responsibility for its own affairs. Two complementary factors made this difficult to achieve: in the first place the governor of the Cape was also, until 1901, high commissioner, and his actions as such were determined mainly by the home government; in the second place, as Sir Michael Hicks Beach (secretary of state for colonies, 1878-80) was to explain, "the peculiar conditions of the Colony" as well as the political structure of southern Africa were held to make responsible government subject to special limitations. Molteno raised both issues. He was critical of the federation dispatch of the 4th earl of Carnarvon which, when it arrived in June 1875, included without official consultation the proposed separate representation of the Eastern province. He further claimed that the Cape should control its own forces on the Cape side of the Great Kei in the Kaffir mar of 1877. On the other hand, the high commissioner, Sir Bartle Frere (1877-80), treated the war as part of a native resurgence that constituted an imperial problem, not solely a Cape frontier question. Molteno was dismissed and the dismissal was endorsed by the Cape parliament. His successor, Sprigg (1878-81), was prepared to work for federation with a colonial initiative. By 1880, however, Zululand had been conquered and the Transvaal was preparing armed resistance against the annexation of 1877. Sprigg's federation motion was defeated, though his government managed to hold out a few months longer.

The whole picture of Cape politics had altered, substantially because British annexation of the Transvaal had roused the antagonism of the Afrikaner groups in the Cape. A revival of journalism, the formation of farmers' associations from 1873 onward, the founding of the Genootskap van Regte Afrikaners in 1875—all signs of a cultural renaissance of Afrikaner tradition—assumed a political significance with the formation of the Afrikaner Bond in 1879. This movement was a popular political muster of democratic and race-conscious nationalism. Its object was to unite the Afrikaans-speaking people throughout southern

Africa in a national republic. It helped to determine the Cape elections of 1879, to defeat Sprigg's federation motion, to drive him from office and to replace him successively by T. Scanlen (1881-84) and T. Upington (1884-86). The cleavage in the Cape had been widened by British policy in the Transvaal and by S. J. P. Kruger's propaganda, but three factors served to conceal it.

First, the convention of London in 1884, while suppressing overt mention of suzerainty, defined the external relations of the Transvaal, so that for about a decade, though there was often acrimonious dispute, fundamental issues of principle were avoided. Second, J. H. Hofmeyr weaned the bond from its extremism and converted it into a party structure for purely Cape ends. Situations reminiscent of the Italian techniques of *trasformismo* resulted, from the moment when C. J. Rhodes (*q.v.*) and Hofmeyr first co-operated to drive Sprigg from office in 1881. Governments ruled by grace of the bond even when Hofmeyr was not in office. In 1882 Dutch as well as English was allowed in addressing either house, and Dutch was permitted as the medium of instruction in certain grades of Cape schools; two years later it was enacted that parliamentary bills and papers should be in both languages, and Dutch was given parity with English in the magisterial courts. The retrocession of Basutoland to crown government was the main reason for Scanlen's fall, and the imperial—as distinct from colonial—annexation of Bechuanaland was the operative reason for the more formal alignment between Hofmeyr and Rhodes. The third factor that helped the growth of a moderate but enterprising colonial party was the governorship of Sir Hercules Robinson (1881-89), who, not yet caught up in Rhodes's financial undertakings, understood the colonial point of view more clearly than anyone else since Grey.

In the Cape there were three main political groups. On the extreme right was a section of the British, organized in the Imperial league and kindred groups, which favoured the imperial connection as necessary and, in patches, were not averse to open conflict with the Transvaal and revenge for the British defeat by the Transvaal Boers at Majuba. On the extreme left was that section of the Afrikaners who saw in the Transvaal their spiritual home and in Kruger their Moses. In the centre were grouped Rhodes and Hofmeyr. Rhodes, when he was not representing his own ideas and the financial projects which could translate dreams into reality, stood avowedly for something nearer to Cape imperialism than to colonialism (he introduced the Glen-Grey act as a "Bill for Africa"). He wanted the Cape to fit itself to lead South Africa by closing its ranks within and taking a wider view of its potentialities. This side of his policy was closely related to that of Hofmeyr, who deprecated accentuating differences between two European races confronted with a common future and sought to secure the maximum of colonial self-determination by federal co-operation with other South African states under the necessary protection of the British crown.

Meanwhile the diamond fields had made possible the rapid expansion of railways and telegraphs (the existing 63 mi. had been bought from private ownership for the colony by Molteno). This in its turn put the colony in a favourable position to profit from the quickening of commerce that was to follow the opening of the Rand gold fields in 1886. At that time the colony already had three trunk lines: one to Colesberg, one to Kimberley and one to Aliwal North. Unwisely it rebuffed Kruger's proposal for customs negotiation, but it concluded a customs agreement with the Orange Free State in 1888 and a railway agreement in 1889.

In 1891 the Cape line reached Bloemfontein from Colesberg (extended to Pretoria in 1892), while the Kimberley line, sponsored by Rhodes, reached Vryburg. Once the extension thence to Mafeking was completed, two routes lay open if the Cape was to be linked by rail with the territories of Rhodes's newly chartered British-South Africa company (1889) in the north. One lay along the western margin of the Bechuanaland protectorate where Rhodes eventually, in 1895, negotiated with Joseph Chamberlain, the new secretary of state for the colonies, the purchase of the ill-fated railway strip, outside but nevertheless contiguous to the western frontier of the Transvaal. The better route lay across the Transvaal. But Kruger wished to have an independent rail-

way system through Portuguese East Africa to Delagoa bay. This was the nearest port and had the unique advantage of being free from British control. In 1889 he concluded with the Free State political and economic alliances which threatened the balance of power in South Africa. By 1895 his railway policy, which culminated in the drifts crisis (Aug.-Nov. 1895; see TRANSVAAL) had alienated what was almost a national body of opinion, and the Cape sponsored and endorsed the protest of the imperial government. On Nov. 7 Kruger reopened the drifts.

At the same time fear of foreign intervention (and the evidence is clear that this was contemplated after the German annexation of South-West Africa) led to successive annexations of territory, both by the crown and by the colony. Though Basutoland was returned to crown control in 1884, Griqualand West was incorporated in the Cape in 1880; and in 1895 the Cape, at the instigation of Rhodes, took over the crown colony (as distinct from the protectorate) of Bechuanaland. For Rhodes, this kept the path to Rhodesia open; for the colony, it brought back under its rule the many farmers who had trekked to farm there. Even more decisive were annexations on the east coast, over which the crown proclaimed a coastal protectorate in 1885. The native territories between Natal and the Great Kei river were progressively absorbed in the Cape. Griqualand East was annexed in 1879, followed by the Pondoland coast in 1884, by Tembuland and Galekaland in 1885 and by the rest of Pondoland in 1894. This confronted the Cape with a challenge, since its social frontiers were now within its political borders, and the proportion of native to European population was greatly increased. In spite of some agitation the established principle of equal franchisal qualification for all races was not touched, but steps were taken to avert premature swamping by blanket voters.

In 1887 the franchise was extended to newly annexed areas with the proviso that communal tenure of property could not qualify individuals for the vote. In 1892 qualifications for the franchise were raised and a simple education test was imposed. Parallel with this compromise between Cape realism and Cape liberalism went a constructive attempt to work out administrative policy for native territories. The Transkei was rather simpler to face than the Ciskei, where European and native settlement had been deliberately interspersed and tribal structure weakened by war. In 1883 it was decided that native civil law should be recognized. This put magisterial authority behind tribal tenure and marriage customs. In the Glen-Grey act Rhodes made a comprehensive attack on the Transkei problem. Detailed for one area, the act was designed on lines which might apply throughout a hypothetical union and beyond. Individual tenure, subject to quit-rent and inalienable without the consent of the governor of the Cape, was instituted, and provision was made for the natives to share in local self-government. This was not only the greatest legislative achievement of Rhodes, but the most constructive invention in native administration in a century of conflict.

More could have been done but for the Jameson raid (see JAMESON, SIR LEANDER STAKR) at the end of 1895, which not only split the Rhodes-Hofmeyr grouping but fanned extremism on both sides. The congratulatory telegram sent by the German emperor William II to Kruger alarmed the British foreign office far more than Rhodes's complicity in the raid shocked Chamberlain—who, it would seem, came near to being accessory before the fact. The Transvaal Boers were now convinced that Great Britain had deliberately surrounded the Transvaal as a prelude to annexation on the pattern of 1887, and that British insistence on the integrity of Swaziland, even if under a Transvaal protectorate, was part of the same design. Afrikaners everywhere saw in the Transvaal the only hope for the survival of Afrikaner ideals. In the Cape, while many of the bond were critical of Krugerism on points of detail, and many, after the arrival of Alfred Milner (*q.v.*) in 1897, strove to avert conflict as tension mounted over the "Uitlanders" in the Transvaal, it was nevertheless clear that armed conflict would have serious repercussions in the colony. Sprigg, prime minister since Rhodes's resignation (Jan. 1896), hoped that federation could still be brought about by the nebulous Progressive party, which counted itself heir to the best in Rhodes's program.

But Sprigg could do no more than fight a losing rearguard action in the assembly. In the election of 1898, conducted in mounting tension, although Rhodes returned to the field, the bond and its allies carried the day. Sprigg resigned on a vote of censure and was succeeded by W. P. Schreiner (1898–1900), the parliamentary leader—but not the puppet—of the bond.

Schreiner faced a difficult role with imperturbable integrity and, in the most bitter of all Cape parliaments, was loyal to his obligations as a minister of the crown. His hopes of keeping the colony out of the war were as futile as his repeated attempts to avert by compromise the outbreak of war between Great Britain and the Transvaal. When war began, the fact that revolts against the British were mainly limited to the north and west of the Cape districts was chiefly due to Schreiner, who was, however, overthrown by a schism in his own cabinet when he accepted the British demand that rebels should be disfranchised. His fall made way for another Sprigg cabinet, which passed emergency legislation before parliament was prorogued sine die. Except when J. C. Smuts's commandos swept within 30 mi. of Cape Town, the heart of the colony was relatively untouched by war; but refugees from both sides flocked to the Cape and most families had relatives fighting. (See further SOUTH AFRICA. UNION OF; SOUTH AFRICAN WAR.)

From **Vereeniging** to the Union.—Through all the vicissitudes of his administration Milner had clung to his initial purpose of bringing about a closer union of the southern African countries—if necessary, by asserting British paramountcy beyond challenge. With the occupation of Bloemfontein and Pretoria in 1900 he counted the war as won, though in fact the period of the commandos was still to come. He seriously considered suspending the Cape constitution rather than face in the Cape the possible obstruction of those whose compatriots he had defeated in the north. This plan of reducing the Cape to the status of the defeated republics was rebuffed by Chamberlain, contested by Sprigg and snuffed out by the colonial conference in London.

The parliament therefore met in Aug. 1902 and duly passed the necessary act of indemnity, but Sprigg's hold on the assembly was slight and, after defeat on a motion to examine sentences passed when the colony had been under martial law, he dissolved it. In the 1904 election, partly because the former rebels had not yet worked out their five-year disfranchisement, the Progressives under Jameson won a slender and illusive victory. This Jameson hoped to consolidate by a necessary redistribution of seats (effected in 1906) on a more systematic population basis that would not sacrifice the voting strength of the towns to that of the rural areas. This was regarded by some as sharp practice, since, they said, the British parties were stronger in the towns and the bond stronger in the country. This was broadly true but not the whole picture. Many of the bond were liberals, and many Afrikaners had business interests which gave them a stake in the economic integration of southern Africa. Conversely, many British farmers shared the rural demand for the protection of farming interests, and not all mere either liberal or enlightened. The Cape parties could thus rise above cutthroat politics, which might have been fatal to intercolonial co-operation. Moreover, whereas many Afrikaners had been hard hit by the war, all alike felt the slump which saw Cape revenues shrink, in spite of Jameson's efforts, from £12,000,000 in 1904 to £7,000,000 in 1908.

In Sept. 1907 the Progressives were defeated in the first post-war election in which former rebels could vote. Jameson's government had offered assistance to Natal during the Bambata rebellion and had co-operated fully in the customs and railway conventions and in the intercolonial Native Affairs commission. The axis of political power, however, lay on the Rand; the grant of responsible self-government to the Transvaal and to the Orange River colony had shifted the fulcrum of political initiative beyond the Orange river; and the moderation of such men as Smuts could not conceal the fact that the leaders of the former republics were Afrikaner in social and political outlook. As federation of any kind could only become practical with the connivance of the north, the defeat of the Progressives in the Cape paved the way for the only kind of political integration that the Transvaal was prepared to accept. It swung the pendulum from federation to union.

Jameson was succeeded in Feb. 1908 by J. X. Merriman (1908–10), whose South African party was the old bond in a new guise, calculated to secure the support of the moderates among the British colonials but unlikely to make the general acceptance of the Cape franchise a condition of co-operation with the Transvaal, which had already adopted an all-white franchise. Merriman favoured union rather than federation—and the closer the better. He was persuaded by Sir John Henry de Villiers (chief justice of Cape colony) to leave tactics to Smuts, who moved resolutions of procedure to be followed at the intercolonial railways and customs conference of 1908. The ensuing National convention met successively at Durban, at Cape Town and at Bloemfontein. The absence of Hofmeyr and Schreiner, both keen federalists, made it fairly easy to override Natal prejudice against union, and the proposal of the high commissioner, Sir Walter Hely-Hutchinson (1901–10), that in the Union property, not race, should, as in the Cape, determine the franchise, was neither firmly pressed nor generally acceptable. The one thing that the Cape delegates would not abandon was the nonracial franchise within the Cape. This, together with equal language rights throughout the Union, was entrenched by the safeguarding clause that it could be altered only by a two-thirds majority of both houses, assembly and senate, sitting in joint session. In 1910 the Cape had 51 members in the lower house; and though the provision for periodical redistribution of seats after census meant that the relative preponderance of the Cape in the lower house was to shrink, if the Cape remained solid for the franchise, the entrenched clause could not be touched without violating the constitution.

The provincial status of the Cape was identical with that of other provinces, and the sovereignty of the Union parliament over provincial activities, even though they lay within the provincial sphere allotted by the constitution, was clearly established. Federal union had long been the thesis of Cape journalists and politicians of divergent views on other issues, although union at the time and in the manner in which it came was very substantially the architecture of the northern colonies. That the parliament of the Union should meet in Cape Town was fitting acknowledgment that the Cape, more than any other colony, had forged the parliamentary traditions of the subcontinent.

The history of the Cape Province from 1910 is merged in that of the Union of South Africa (from 1961 Republic of South Africa). Two of the Union's major problems, however, the preservation of the structure of Bantu society and the non-European franchise, were especially serious in the Cape (see SOUTH AFRICA, UNION OF: History).

CAPE PROVINCE: see CAPE OF GOOD HOPE.

CAPERCAILLIE (CAPERCAILLIE), a name derived from the Gaelic and applied to the largest of the old-world grouse (*q.v.*), *Tetrao urogallus*. The species is widely, though intermittently, distributed on the continent of Europe, from Lapland to the northern parts of Spain to Turkistan, but is always restricted to pine forests, which alone afford it food in winter. It has long been a source of food for man, its bones having been found in the kitchen middens of Denmark and the caves of Aquitaine.

The male, known as the mountain cock or cock of the woods, is remarkable for his large size, often reaching 34 in. in length and 12 lb. or more in weight; dark glossy plumage; shaggy metallic green breast; and rounded tail. The hen is much smaller, with mottled-brown upperparts and a reddish-brown breast. During the characteristic courtship ceremonies in the spring, the polygamous cock performs for the assembled hens: he struts about the clearing, spreading his wings and voicing a peculiar cry; frequently he mounts to the topmost bough of a tall tree and challenges all rivals by extraordinary sounds and gestures; the combat takes place on the ground in the presence of the waiting hens. In earlier times the capercaillie population suffered great losses because of

the unsportsmanlike behaviour of hunters who shot them while they were absorbed in courtship.

The hen nests on the ground, laying from seven to nine or more yellowish eggs. Soon after they are hatched, the young are able to fly; toward the end of summer, from feeding on the fruit and leaves of the bilberries and other plants, they are of a size and flavour fit for the table. With the first heavy snowfalls they resort to the trees where they feed on the pine leaves. The capercaillies' flesh, under this diet, rapidly acquires a distasteful flavour of turpentine.

The Siberian capercaillie (*T. parvirostris*), a darker species with a longer, more graduated tail, lives in northeast Asia. Hybrids are frequently produced between the capercaillie and related birds—the black grouse (*Lyrurus tetrix*), red grouse (*Lagopus scoticus*) and pheasant (*Phasianus colchicus*). (G. F. Ss.; X.)

CAPERNAUM (in the Douai version of the Bible, **CAPHARNAUM**), an ancient city on the northwestern shore of the Sea of Galilee in Israel, identified with the ruined site at Tell Hum, was Jesus' second home and, during the period of his life, a garrison town (Matt. viii, 5 ff.), an administrative centre (John iv, 46) and a customs station (Matt. ix, 9). Jesus chose his disciples Peter, Andrew and Matthew from Capernaum. It was the scene of many of his miracles, and in its synagogue he delivered many of his discourses. Its fame did not prevent the complete disappearance of the name and a long dispute over its location. Two identifications were advanced—Tell Hum, about 2½ mi. W. of the Jordan river's entry into the lake, and Khirbet al-Minyeh, 2 mi. W. of Tell Hum. Excavations were begun at Tell Hum in 1905 by Heinrich Kohl and Carl Watzinger; they were completed by the Franciscans, who established its identification with Capernaum beyond doubt. Minyeh has also been excavated and has proved to be of the early Arabic (Omayyad) period.

The remains of a synagogue have been uncovered and partially restored. It was a rectangular building (57 x 75 ft.), oriented to the north. It was entered by three doors from a platform on the south side. Built of white limestone, its walls were ornamented outside with pilasters. An open court with covered porticoes on three sides extended the entire length of the east side. In the interior a stylobate, 1 yd. wide, raised 2½ in. from the floor and based on the south wall, ran parallel to the walls and divided the synagogue into a nave, two aisles and a transept. It supported seven columns with Corinthian capitals on each of its long sides with two additional columns between nave and transept, 16 in all. Above the aisle and transept was a gallery of Doric columns. Above each set of columns was a richly ornamented entablature. The lintels of the door had been surmounted by a frieze from which the figures forming part of the design have been obliterated. This synagogue, though an early example of its type, dates from the 3rd century A.D., but an older synagogue dating from the time of Christ may well be buried beneath its foundations.

CAPERS, the unexpanded flower buds of *Capparis spinosa* (family Capparidaceae), prepared with vinegar for use as a pickle. The caper plant is a trailing shrub, belonging to the Mediterranean region, having handsome flowers of a pinkish white, with four petals, and numerous long, tassellike stamens. The leaves are simple and ovate, with spiny stipules. The plant is cultivated in Sicily and the south of France. Capers are valued according to the period at which the buds are gathered and preserved. The finest are the young tender buds called "nonpareil." Other species of *Capparis* are similarly employed in various localities.

CAPET, the name—derived from the specific designation of Hugh Capet (*q.v.*)—not only of the French royal house "of the third race" (the first being the Xerovingian dynasty, the second the Carolingian) but also of the many other sovereign princes of Europe descended in the male line from the Capetian kings of France. The founder of the house was Robert the Strong (*q.v.*), count of Anjou and Blois, whose two sons were both crowned king of the Franks: Eudes in 888 and Robert I in 922. Robert I's son, Hugh the Great, effected a restoration of the Carolingians in 936,

but in 987 the claim of the next Carolingian heir was ignored, and Hugh the Great's son Hugh Capet was elected king.

In France the 13 kings from Hugh Capet to the infant John I, who succeeded one another from father to son, and John I's two uncles, Philip V and Charles IV (d. 1328), are designated as the Capetians "of the direct line." They were followed by the 13 Capetian kings of the house of Valois. Of these, seven kings (from Philip VI to Charles VIII) succeeded from father to son; after whom Louis XII began the house of Valois-Orléans, continued in the branch of Valois-Orléans-Angoulême (five kings from Francis I to Henry III) until 1589. Then the Capetians of Bourbon succeeded. For these and for the house's subsequent accession to other sovereignties, see **BOURBON**. (See also **FRANCE: History**.)

The duchy of Burgundy (*q.v.*) was also held by branches of Capetians separate from the French royal line: first, until 1002, by two sons of Hugh the Great; then, from 1032 to 1361, by 12 dukes (from Robert I, brother of Henry I of France, to Philip of Rouvre); and finally: from 1363 to 1477, by four Valois dukes (from Philip the Bold, a son of John II of France, to Charles the Bold; who left only a daughter, the duchess Mary).

Three Capetians were emperors of Constantinople between 1216 and 1261: Peter of Courtenay, grandson of Louis VI of France, and his sons Robert and Baldwin II.

Capetians of the first Angevin line were descended from Charles of Anjou, a brother of Louis IX of France. Charles in 1266 won the kingdom of Naples (*q.v.*), in which he was succeeded by four kings and two queens of his blood (from Charles II to Joan II) until 1435. His great-grandson Charles Robert (Caroberti, more-over, was crowned king of Hungary (*q.v.*) in 1310 as Charles I, but the latter's successor Louis (d. 1382) left only daughters.

The second separate Angevin (Valois) line of Capetians furnished five counts of Provence (*q.v.*) from Louis I, brother of Charles V of France and count from 1382, to Charles (d. 1481).

Apart from its periods of union with France or with the Bourbon titles, Navarre (*q.v.*) had three Capetian kings from 1328 to 1425, of the house of Evreux: Philip III, grandson of Philip III of France and count of Evreux, Charles II and Charles III.

Capetians descended from Louis VI's son Robert, count of Dreux, furnished not only a line of counts of Dreux (1132-1377) but also 11 dukes of Brittany (*q.v.*), from Peter Mauclerc to Francis II, between 1213 and 1488. See also **ALençon**, **Ducs d'**; **Artois**; **Orléans**, **Ducs d'**.

CAPE TOWN (**KAAPSTAD**), the legislative capital of the Republic of South Africa, and capital of the Cape of Good Hope province, is situated at the northern end of the Cape peninsula, a narrow strip of land 32 mi. long whose southernmost point is the Cape of Good Hope on the South Atlantic. The metropolitan population in 1951 was 577,648 (city 411,209) and in 1960 was 731,484 (279,404 Europeans, fairly evenly divided between those of Dutch and British descent, and 452,080 Africans, Cape Coloureds and Asians). Civic affairs are administered by the Cape Town city council of 45 members and a wide range of municipal services is provided.

The city consists of a central business area with a chain of suburbs stretching out in three directions. The central area is bounded to the south by the flat-topped Table mountain (*q.v.*), 2 mi. long and rising to about 3,500 ft., and to the east by subsidiary peaks. Reclamation from Table bay carried out between 1935 and 1945 added another 360 ac. known as Roggebaai ("the Foreshore") to the central area. This work also provided for the 290-ac. Duncan dock and the Sturrock graving dock (completed in 1945); this is one of the largest in the southern hemisphere, being 1,119 ft. long with a width of 156 ft. and an entrance depth of 10 ft. at low water. These docks, together with the older Victoria basin, provide harbour facilities comparable to other international ports.

The main street is Adderley street (named for C. B. Xdderley, an English member of parliament, who in 1849 successfully opposed the establishment of a convict settlement on the Cape), to which was added an extension known as the Heerengracht running seaward across the reclaimed area. Running south from Adderley street is Government avenue, a splendid thoroughfare lined by oak

trees and closed to vehicular traffic. Greenmarket square, the original centre of the town, is to the west of Adderley street, and a little farther west is Riebeeck square, originally an outspan, or place where oxen were unyoked. A large rectangular space known as the Grand parade, used as a parking lot and for market stalls, lies east of Adderley street.

The suburbs fall into three groups. The marine suburbs stretch along the coast to the west and south of the city to Bakoven; those to the south extend southward along the eastern side of Table mountain to Kalk bay. 17 mi. from the city; the northern suburbs lie along the main route inland. There are a number of other large separate municipalities outside the city limits.

Public Buildings and Amenities.— The oldest building in Cape Town is the castle. Situated near the Grand parade, it dates from 1666 and replaced the original wood and mud fort begun in 1652, soon after the arrival of Jan van Riebeeck. Most of its bricks were imported from the Netherlands; the stone comes from Table mountain. The castle was formally inaugurated by Gov. Johan Bax on Nov. 25, 1677. At that time, the waters of Table bay came almost to the ramparts.

The Dutch Reformed church (Groote Kerk) in Adderley street is the oldest and largest church of the denomination in South Africa. It was begun in 1699 but all that remains of the original building is the bell tower. Eight former Dutch governors of the Cape are buried in the church. There are Anglican (St. George's, still incomplete) and Roman Catholic (St. Mary's) cathedrals.

The city hall (1905) is situated on Darling street but after 1960 it was replaced by a modern municipal centre on Roggebaai. The general post office, a tall building completed in 1942, occupies an entire block.

Opposite the public gardens on Government avenue are Government house, internally one of the handsomest buildings in South

Africa, the houses of parliament, and the South African National gallery. On the western side is the South African Public library, founded in 1818 as a free government-supported institution. Its nucleus was a collection of 5,000 books left by Joachim von Dessin in 1761. At the top of the botanical gardens is the South African museum, the oldest in the country, dating from 1825. Its collection of Bushmen figures is unique, casts having been taken from living bodies.

In Greenmarket square the Michaelis collection of 17th-century Flemish and Dutch paintings is exhibited in the Old Town house, originally the Burgher Watch house (1755), a fine example of colonial Dutch architecture. Other well-preserved buildings are the 18th-century Koopmans de Wet house in Strand street, which contains furniture, china and glassware of the same period, and the Martin Melck house. The old supreme court building, originally a slave market, adjoins the Groote Kerk, at the top of Adderley street. After the abolition of slavery in 1835, it housed the supreme court and is now used as government offices.

About three miles east of the city centre stands the observatory (1827-28), one of the most important in the southern hemisphere. South of the observatory, in the suburb of Rondebosch, the Groote Schuur estate of several thousand acres, was permanently reserved for the nation by Cecil Rhodes. The name literally means "great barn." for the early settlers of the Dutch East India company established a cattle station there in 1657. On this site on the slopes of Devil's peak, Groote Schuur, the official residence of the prime minister, was rebuilt in the Dutch colonial style after a fire in 1896.

Higher up the hill lies the University of Cape Town which achieved its present status in 1918, having been known as the South African college from its beginning in 1829. Student enrollment exceeds 5,000; there are faculties in arts, science, commerce, edu-

BY COURTESY OF THE INFORMATION SERVICE OF SOUTH AFRICA

cation, engineering, architecture, law, medicine, music (including ballet) and social science. Three other features of note on or near the Groote Schuur estate are the Rhodes memorial; Mostert's mill, a perfectly restored example of 18th-century Dutch work dating from 1796; and the national botanical gardens at Kirstenbosch. These gardens, founded in 1913 and reserved for the native flora of South Africa, are situated on the eastern slopes of Table mountain and cover about 1,200 ac. extending to the summit.

The municipal public gardens, which occupy 14 ac. of the site of the 17th-century vegetable gardens of the Dutch East India company, are situated west of Government avenue and contain 8,000 kinds of trees, flowers and plants. The Claremont public gardens are noted for exotic trees and shrubs. Other open spaces are Wynberg park, on the slopes of Wynberg hill, the Green Point common, the Rondebosch common and de Waal park.

Transport. — Two main transport systems serve the city and its suburbs. The government-owned suburban electric railway runs from Cape Town station, Adderley street, through the southern suburbs to Simonstown, with branches to the Cape Flats areas. Buses and trolley buses serve the metropolitan area. A feature of the city is the Table mountain cableway which takes visitors to the summit and provides a magnificent view of the city and its surroundings.

Cape Town is the southern terminus of the national railway system. Through train services connect with all parts of South Africa, Rhodesia and its neighbouring territories. In the early 1960s a new station was erected on Roggebaai. The D. F. Malan airport near Bellville, 12 mi. E S E. of the city, though not an international airport, is the southern terminus for South African air services.

Cape Town is the chief passenger and mail port of the nation and the nearest to Great Britain. It is the principal port of shipment for gold, diamonds and citrus and deciduous fruit.

Industries and Trade. — Situated near fertile farm lands, Cape Town has as its leading industry the processing of foodstuffs, such as jams, tinned fruit and vegetables, fish and its by-products (vitamin oil and fertilizer), dried fruit and processed cereals. There is an extensive export trade in these goods, as well as in wine and spirits. Second is the clothing industry which provides employment to about 18,000 workers (mainly Coloured). There is also an increasing development in the manufacture of plastics and leather goods. The city is the second largest industrial area in South Africa. Its chief imports are raw materials for the country's industry and manufactured articles.

As a tourist resort Cape Town is popular with visitors from both inland and overseas, its Mediterranean type of climate and scenic beauty being the chief attractions.

History.—Ever since Bartolomeu Dias in 1488 and Vasco da Gama in 1497 rounded the Cape of Good Hope, Table bay has been a place of call for ships passing to India and beyond. Water and food could be obtained and mail left under marked "post office" stones, to be picked up by ships bound for Europe. The first permanent white settlement was begun in April 1652 by Jan van Riebeeck who had been sent by the Dutch East India company to build a fort and establish vegetable gardens for ships bound for the East Indies. By the end of the 17th century, the town had already taken shape. The gardens and the castle which replaced the fort were surrounded by streets lined with warehouses, taverns and the houses of officials of the company. The style of living was similar to that of the Netherlands, then at the height of its prosperity, but the climate caused the Dutch architecture to be considerably modified.

As a result of the Napoleonic Wars, the British were in control of the Cape from 1795–1803, when it was returned to the Netherlands. It was, however, again annexed by the British in 1806. The emancipation of the slaves in 1833 and the opening of the Suez canal in 1869 were severe blows to the town's prosperity. However, the discovery of diamonds in 1867 and of gold in 1886 had a revitalizing influence. It became the capital of South Africa in 1910. See also the History section of CAPE OF GOOD HOPE and SOUTH AFRICA, UNION OF; and references under "Cape Town" in the Index volume.

(M. E. H.)

CAPE VERDE ISLANDS (ILHAS DE CABO VERDE), a Portu-

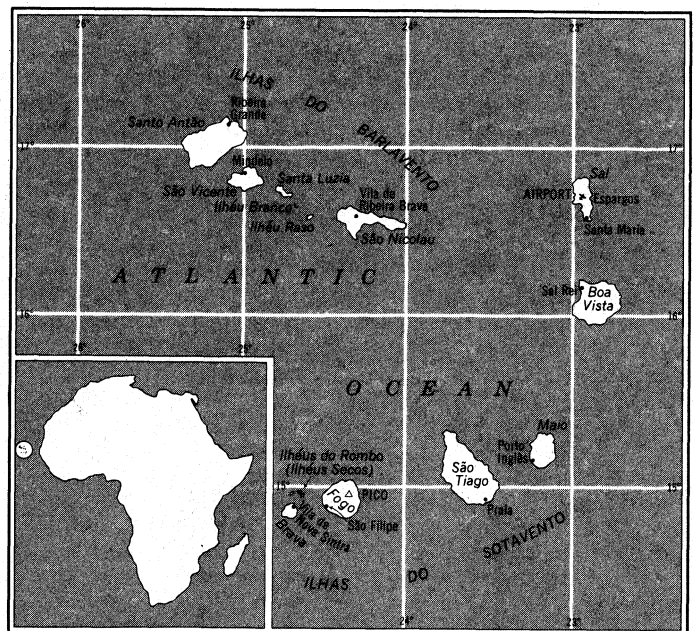

guese overseas province, forming a crescent-shaped archipelago off the west African coast about 280 mi. W.S.W. of Cape Verde. There are 14 islands, with a total area of 1,552 sq.mi. They fall into two groups: the northern or windward islands (Ilhas do Barlavento), Boa Vista, Sal, São Nicolau, Santa Luzia, São Vicente and Santo Antão, with the islets of Branco and Raso, and the southern or leeward islands (Ilhas do Sotavento), Maio, São Tiago, Fogo, Brava and Ilhéus do Rombo (Ilhéus Secos).

Physical Geography. — The islands are volcanic in origin, and mostly mountainous and rocky. Sal, Boa Vista and Maio, the islands nearest Africa, are flat except for a few sandy and saline hills. The highest mountain is Pico (9,251 ft.) on Fogo Island. Its volcano has frequently in eruption in the 16th and 17th centuries, but was quiescent from 1857 to 1951. Earthquakes have been recorded, the last severe eruption being in 1847. The coast lines are mostly rocky and dangerous, and Boa Vista has reefs and sandbanks, and dunes on the east coast. Santo Antão, the largest island in the northern group, has no adequate harbour. The finest natural harbour is Mindelo (or Porto Grande) on São Vicente; the crater of an old volcano, it is completely circular. There are good harbours on Brava, the most densely populated of the islands, which has no lowlands but is steeply terraced.

Drought is the perennial problem and is increasing, partly because of the gradual drying out of the whole area and partly because of deforestation by early settlers and by the goats they introduced. The climate is hot and dry: the range of temperature at Mindelo is 63.1° to 86.7° F. and at Praia, São Tiago, 62.1° to 91.8° F. The prevailing wind is the northeast trade, which somewhat abates during the rainy season between August and October.

The plants of the islands are mainly African, though there are said to be about 70 species peculiar to the islands. The dry areas carry little vegetation except the American aloe or agave, but the fertile valleys or *ribeiras* have a luxuriant tropical vegetation, including mangoes, palms, sugar cane, manioc and tamarisks. A few trees such as the baobab have been introduced, but the forested area is small. Economic crops brought in by the Portuguese include coffee, maize (corn), tobacco, cotton, sugar cane and oranges and other semitropical fruits. There are relatively few animals and no indigenous mammals. Several varieties of birds are found only on the islands, including frigate birds and shearwaters.

The People. — When discovered in 1456 or 1460, the islands were uninhabited. The first Portuguese *donatários* brought in Negroes to work their plantations, and after the discovery of America the

CAPE VERDE ISLANDS OFF WEST AFRICAN COAST. SHOWING MAJOR CITIES AND SETTLED AREAS

islands became a collecting point for the slave trade. Mulatto strains predominate, and there is a Cape Verdean language known as *lingua crioula*, which is basically a Negro simplification of Portuguese. In 1950 the population was 148,331, of whom 103,251 were of mixed ancestry, 42,092 Negro and 2,913 white. The population decreased significantly after 1940, through droughts and emigration. Emigration since the 19th century was mainly to the United States (Massachusetts, Rhode Island, Hawaii), Senegal and other Portuguese territories in Africa.

Because the islands that constitute the Cape Verde archipelago are separated from each other by rough seas, their inhabitants developed their own dialects, customs and individuality. Although Roman Catholicism is the official religion, a shortage of priests has meant the survival of largely pagan customs. The islands have a native song and dance called the *morna* and described as "a Negro spiritual without the religion."

The area and population of the principal islands are shown in the table:

Island	Area (sq. mi.)	Population (1950 census)	Chief town
Santo Antão	301	27,947	Ribeira Grande
São Vicente	88	19,158	Mindelo
Santa Luzia	13	—	
São Nicolau	132	10,316	Vila de Ribeira Brava
Sal	83	1,813	Santa Maria
Boa Vista	239	2,903	Sal Rei
Maio	104	1,879	Porto Inglês
São Tiago	383	58,893	Praia
Fogo	184	17,520	São Filipe
Brava	25	7,903	Vila de Nova Sintra

History.—The date of the islands' discovery has been much disputed; it is possible that they were visited in 1456 by the Venetian captain Alvise Ca Da Mosto. In 1460, however, it is certain that Diogo Gomes and António da Nola sighted and named Maio and visited São Tiago. The archipelago was granted by Alphonso V of Portugal to his brother, Prince Ferdinand, and in 1466 its inhabitants received the monopoly of the Guinea slave traffic. In 1470 on Prince Ferdinand's death his privileges reverted to the crown and were bestowed by John II on Prince Manuel, by whose accession to the throne in 1495 the archipelago finally became part of the royal dominions. Its importance and wealth grew with the development of the slave trade. Slaves were brought in to cultivate the land, Portuguese settlers increased; in 1532 the first bishop was consecrated and in 1595 the first governor general was appointed. The wealth of Ribeira Grande, the former capital, caused it to be attacked twice by Sir Francis Drake (1585 and 1592) and later, unsuccessfully, by the Dutch. With the decay of the slave trade (finally abolished in 1876) and the increase in drought, the history of the islands became one of recurrent drought and famine, a situation made worse by corruption and maladministration. The end of the 19th century saw some improvement; the islands' position on the great trade routes between Europe and South America and South Africa led to the opening, first of a coaling station at Mindelo and later of a submarine cable station (1875). Also, the islanders began to emigrate to the United States, particularly from Brava. The money they sent home played a large part in the islands' economy. After World War I, however, reduction in shipping and the introduction of a quota policy for immigration into the United States caused a further decline in prosperity, somewhat arrested by loans from the Portuguese government for relief and development.

Administration and Social Conditions.—The islands form a single overseas province of Portugal, administered by a governor assisted by a government council. The capital is at Praia on São Tiago. The old capital, Ribeira Grande, founded in 1462, sacked by the French in 1712 and abandoned in 1770, is a few miles to the west and almost uninhabited. The chief town in the northern group is the port of Mindelo on São Vicente. The islands are divided for administrative purposes into 12 *concelhos* (districts) and 31 *freguesias* (parishes). They form a diocese, the seat of which is Vila de Ribeira Brava on São Nicolau.

In culture, social life, local administration and the tax system, the Cape Verdes resemble mainland Portugal. In the early 1960s

there were more than 120 primary schools, 1 lyceum (Gil Eanes, on São Vicente) and 1 technical school (at Mindelo) on the islands.

The Economy.—Agriculture, mainly subsistence, forms the livelihood of more than 70% of the islanders. Cape Verde is constantly threatened by the scarcity of water, though in the rainy years the land shows high productivity. After 1948 considerable development was made in water research and irrigation. The forested area of the archipelago only comprises 2% to 3% of the total area, but reforestation was intensive during the 1950s, partly to increase the water supply. The main crops are coffee (*arabica*), grown at an elevation of 1,000 to 4,000 ft., maize (corn), the basic food crop of most of the inhabitants, *purgueira* or physic nut, sugar cane, castor beans, broad beans and potatoes. Some islands are particularly suitable for fruit growing, especially for tropical and Mediterranean varieties, but lack of transport prevents their commercial development. Fisheries are little exploited. There are a few small factories which produce canned fish, sugar, biscuits and other foodstuffs, hats, shoes, cotton goods, soaps, dyestuffs and tobacco. Salt is an important product in Sal, Maio and Boa Vista.

In addition to the normal trade of the imports for local consumption and the exports of goods locally produced, there is a considerable import of coal and liquid fuels to be supplied to ships. Canned fish (albicore), coffee beans, *purgueira* and salt are the chief exports.

Communications are poor. There are about 340 mi. of road. Espargos, on Sal, is the most important airport in the archipelago. Mindelo, in spite of the competition from Las Palmas de Gran Canaria and Dakar, is frequently visited by large ships, because of its excellent position in the Atlantic. Improvements are being carried out in the harbours. Telegraphic communications are by submarine cables and radiotelegraph stations.

CAPGRAVE, JOHN (1393–1464), English chronicler, theologian and hagiologist, whose life of St. Katharine deserves more praise than it has received, was born at Lynn, in Norfolk, on April 21, 1393. He became a priest, took the degree of D.D. at Oxford, where he lectured on theology, and subsequently joined the order of Augustinian hermits. Most of his life he spent in the house of the order at Lynn, of which he probably became prior; he was certainly provincial of his order in England, which involved visits to other friaries, and he made at least one journey to Rome, the wonders of which are described in *The Solace of Pilgrims* (ed. by C. Mills, 1911). He died on Aug. 12, 1464.

Capgrave was an industrious writer, though his works seem to have been mainly compilations from other authors or free translations. The majority are theological works in Latin—biblical commentaries, lectures, sermons, treatises and lives of saints, mostly lost. He also wrote a history in honour of Henry VI, of little historical value. In English he wrote a *Chronicle of England* (from the creation to 1417, cut short by his death) of which the latter part has some independent value; the *Lives* of St. Augustine and of St. Gilbert of Sempringham in prose; an unprinted life of St. Norbert and the life of St. Katharine, both in rhyme royal. This last work is didactic but with some dramatic energy of debate, and in vigorous verse. Much of Capgrave's work was produced for patrons, from kings and Humphrey, duke of Gloucester, to abbots and ordinary gentlewomen, and illustrates the literary tastes and circumstances of the time.

The huge Latin collection of the lives of English saints, the *Nova Legenda Angliae* (printed 1516 and 1527; ed. C. Horstman, 1901), attributed to him in the 16th century, was at most rearranged by him at one stage of its development.

BIBLIOGRAPHY.—F. C. Hingeston edited the *Chronicle* and the *Liber de Illustribus Henricis* for the "Rolls Series" (1858) and published an English translation of the latter. *The Life of St. Katharine* was pub-

lished by the Early English Text Society in 1893 and *The Lives of St. Augustine and St. Gilbert* in 1910.

(D. S. B.)

CAP-HAÏTIEN (locally **LE CAP**), called Cap Français when Haiti was a French colony and the town gained renown as the "Paris of the Islands." is the capital of Nord *département*. Pop. (1950) 24,423. United States ships used its excellent harbour during the dispute with France. 1798-1800, and during the American Civil War. Haitian and French troops razed it in 1802. Henri Christophe rebuilt much of it, but an earthquake in 1842 and a hurricane in 1928 destroyed many historic buildings. The modernization of its harbour enabled it to handle about 11% of Haiti's imports and exports. It is the trade centre for the Plaine du Nord (mainly bananas, pineapples, coffee, sugar cane, cacao). Many tourists use the adjacent airport and the paved road from Port-au-Prince for excursions from Le Cap to the palace of Sans-Souci and the fortress La Citadelle. Cap-Haitien is the most picturesque city in Haiti (*q.v.*).

(R. W. LN.)

CAPHARNAUM: see **CAPERNAUM**.

CAPILLARY ACTION: see **CIRCULATION OF BLOOD**; **PLANTS AND PLANT SCIENCE**; **SURFACE TENSION**.

CAPILLARY TUBE, a tube of small dimensions in which the effects of surface tension (*q.v.*) in liquids become conspicuous and may be approximately measured. When a small-bore glass tube is inserted in a vessel of water which wets the glass, the surface tension of the water film adhering to the glass on the inside of the tube draws water up in the tube above the level of the surrounding liquid outside. If the liquid be mercury, which does not wet but tends to draw away from a glass surface, the mercury is depressed within the tube a very definite distance below the level at which it stands in the outside vessel. Various porous solids whose structure consists of small-bore tubes show these phenomena in varying degrees. In anatomy, the capillaries are the most minute blood vessels. See **CIRCULATION OF BLOOD**: *The Capillaries*.

(H. B. LM.)

CAPITAL, in architecture, is the crowning member of a column, pier, anta, pilaster or other columnar form. It marks the top of the vertical rise of the shaft and provides a transition to

the horizontal or arched members above. Usually wider at the top than the bottom, it provides better bearing for the superstructure as well as a visual accent. In the classical styles the capital is the part that most readily distinguished the order.

In simple form a capital may be no more than a wooden block placed on the top of a post. Square in plan, this form is called an abacus (*q.v.*) and is an important part of many capitals. An oblong block or billet, placed with its greatest dimension parallel to the beam above, is another simple form. Shaping the ends of such a block has produced laterally spreading forms of capital. These primary shapes have been elaborated by multiplication of parts, addition of moldings (*q.v.*), and the use of ornament of floral, zoomorphic or other inspiration.

In many early buildings in which the plans indicate that columns were used, the employment of capitals can only be surmised. Secondary evidence derived from representations on small objects and persistent traditions in vernacular architecture, however, is sufficient to indicate their use at an early date in Egypt and Mesopotamia. Primitive abacus capitals were known in both places. Small huts shown in reliefs from Ur, from the third millennium B.C., show decorated impostes and it is likely that similar ornaments were used on columns, the bases and shafts of which have been found. Two kinds of stone capital have been found in the stepped-pyramid complex at Sakkara (c. 2780-2680 B.C.); both apparently followed prototypes in perishable material. One was a saddlelike shape suggesting bent reeds or leaves; the other an upturned bell derived from the papyrus plant. Later Egyptian architecture used capitals derived from other plant forms such as the palm and lotus, as well as simple abacus capitals. Anthropomorphic and aedicular designs also appeared on Egyptian capitals. In Mesopotamia there is evidence of the use of capitals with paired volutes or spirals. Capitals with volutes rising vertically from the centre appear on a stele of Nabupaliddina, 870 B.C., and in a relief from Khorsabad, c. 742-705 B.C. Volute capitals seem to have been known in Hittite architecture in Anatolia. In Achaemenid Persia very elaborate capitals combining multiple volutes, plant forms and zoomorphic elements were created. Minoan civilization in

REPRESENTATIVE CAPITALS

(TOP row) Greek Ionic (restored), Temple of Artemis, Ephesus, Greece, 4th century B.C.; Roman Doric, Arch of Augustus, Roman Forum, originating in the 6th century B.C.; Greek Corinthian, Temple of Athena Aiea, Tegea, Greece, 4th century B.C.; (bottom row) Indian Saracenic, Agra Fort, India, 17th century; Persian double bulls (restored), Persepolis, Iran, early 5th century B.C.; Italian Romanesque, Cathedral of Santa Maria, Nardo, Italy, 13th century

Crete used principally capitals composed of an abacus above a bulbous ring, suggesting the Greek Doric. Others had rectangular boxlike forms with decorated faces.

The Greeks in their systematic development of columnar architecture created some of the best known forms. The Doric capital consisted of a square abacus surmounting a round form with an egg-shaped profile, called the echinus; it was usually related to the shaft below by several narrow ridgelike moldings. The Ionic, probably related to the volute capitals of western Asia, had a pair of horizontally connected volutes inserted between the abacus and echinus. The Corinthian was basically an abacus supported on an inverted bell surrounded by rows of stylized acanthus leaves. Roman capitals were generally similar to the Greek. In addition to standardizing Greek forms, the Romans added the Tuscan, a modified form of the Doric, and they created the Composite by combining Ionic volutes with the Corinthian bell shape. More elaborate Roman capitals sometimes included representational elements with the conventionalized foliage.

Islamic capitals for the most part followed late classical and Persian types. The nonrepresentational bias of Muslim art encouraged development of abstract forms derived from repetition of small moldings and multiplication of miniature squinches. In India, China and Japan some form of bracketed capital was used most frequently. Bell shapes, either upright or inverted, often decorated with lotus motifs, were employed, especially in India. A combination of these types with additional ornamental features characterized the most elaborate Indian capitals.

Capital design in medieval Europe generally stemmed from Roman sources. More massive forms were used as they more frequently carried arched rather than trabeated construction. Byzantine capitals in general had less relief and showed a tendency toward closed or basketlike form. The simplest transition from round base to square top produced cubiform or cushion capitals, sometimes with scalloped faces. This type was used in the Romanesque period along with others derived from simplified treatment of the Roman Corinthian. Grottesque animals, birds and other figurative elements were added. Historiated capitals with religious themes were frequent, especially in French Romanesque. At the beginning of the Gothic period exotic features tended to disappear in favour of simple stylized foliage and crockets. Greater naturalism marked 13th-century capitals, particularly in France. A combination of geometric moldings was characteristic of English Gothic. In the later middle ages the importance of the capital tended to decrease because of a reduction in scale and emphasis.

Classical forms were revived in the Renaissance. While variation in detail appeared in the early Renaissance, the High Renaissance achieved a standard of correctness close to the best examples of antiquity. The baroque saw some further efforts toward variety, but in general the ancient model was followed, with a preference for the Corinthian. Attempts to invent new orders during the Renaissance and the succeeding classic revival met with little success.

The revival styles of the 19th century encouraged the use of many older forms of capital with varying degrees of archaeological correctness. Near the close of this period new techniques of construction in steel and reinforced concrete were developed. The framed nature of this construction differed radically from the bearing relationship of the past and made visible capitals redundant. The feeling that capitals were structurally false led to a conscious effort to avoid their use in much 20th-century design. In some designs in reinforced concrete, however, the top of the column is spread to provide better integration with the floor slab, producing a mushroom column in which the funnellike shape has both the appearance of a capital and real structural purpose.

CAPITAL, EXPORT OF. An export of capital is a transfer of funds from one country to another. It need not entail a physical transfer of currency or of capital goods. What is transferred is command over purchasing power, which residents of the capital-exporting country put at the disposal of residents of the capital-importing country. The funds may be provided by private individuals, companies, banks, governments or international organizations, and may be put at the disposal of any of these. The motives for such movements include: provision of temporary credit to finance international trade; speculation (*i.e.*, the purchase or sale of a currency in anticipation of a rise or fall in its price); the safeguarding of interest or dividends in excess of those which can be earned at home; support or influence of a foreign country or government, and the like. The gain to owners of the capital exported may include any of those enumerated; an important gain for the capital-importing country is often command over goods or services not otherwise available to it.

Various attempts have been made to categorize capital movements. They have been divided, for example, into stabilizing and destabilizing, depending upon whether they tend to restore or move away from equilibrium in a country's balance of payments; autonomous or induced, depending upon whether they initiate or follow changes in other items in a country's balance of payments; and normal or abnormal, depending upon whether they run from a capital-rich to a capital-poor country, or vice versa. The most usual division, however, is between short- and long-term movements.

Short-term capital movements are those embodied in credit instruments maturing in less than one year. The most significant of these instruments prior to 1914 was the sterling bill of exchange, used to finance international trade. After the 1920s, the bulk of short-term capital movements occurred through changes in bank deposits, often effected through cabled orders. Long-term capital movements are those embodied in credit instruments without maturity, or which mature in a period longer than one year, and normally include newly issued foreign bonds, existing securities, government loans and direct investment, where ownership of equity securities in a foreign corporation carries with it control of the company. The most important instrument among these prior to 1929 was the foreign bond.

Apart from repayments, there was little long-term movement during the 1930s. After 1945 the major movements were through government loans, with direct investment the leading private form of capital movement. It should be noted, however, that the division of capital movements into short- and long-term, by instrument, does not really indicate whether a movement is temporary or semipermanent. Bank deposits are often held for more than a year, while a purchase of securities by a foreigner may be liquidated again in a few days.

SHORT-TERM CAPITAL MOVEMENTS

The most constructive purpose served by short-term capital movements is the finance of international trade. A considerable period elapses between the time monies must be paid out for the production of goods sold in international trade and the time the ultimate consumer pays for them. During the interval, finance is needed and may be provided at home or from abroad. Short-term capital movements may also be speculative and stabilizing: speculators may buy sterling in the autumn, when it is weak because of harvest payments, and sell it in the spring, when it is normally strong. In so doing, they have evened out the movements of the exchange rate and loaned Great Britain foreign exchange to pay for seasonal harvest purchases. But short-term capital movements may also be destabilizing and lead to the selling of a currency when it is weak or buying it when it is strong.

Before 1914 trade was largely financed in London through the sterling bill of exchange, an instrument normally payable in three months. Exporters all over the world collected payment for sales to Great Britain and to third countries by drawing sterling bills

on their customers and discounting them in London. A bill is an order drawn by an exporter instructing the importer to pay the bearer of the bill, and to discount it means to get the face amount less interest to the maturity date. If an exporter discounts a bill on a third country in London and repatriates the proceeds, there is a short-term capital export from Britain. If the foreign exporter holds the proceeds of the bill on deposit in London, or if he does not discount it but holds it to maturity, an export of capital takes place from the exporting country to England. And if British exporters draw sterling bills on foreign customers and discount them in London, the increase in British claims on foreigners constitutes a short-term capital export.

The Bank of England was in a position before 1914 to regulate the movement of short-term capital by means of changes in its discount rate. The higher the rate, the less money a bill holder received upon discounting. Thus an increase in the rate gave foreigners a reduced return and encouraged them to hold bills to maturity so as to earn the interest. It also made it expensive for British holders of sterling to finance the export of capital themselves, either through borrowing in London or through the sale of long-term assets. A high rate accordingly encouraged the import of capital into and discouraged the export of capital from Great Britain. Conversely a reduction in the rate stimulated capital exports and slowed down capital imports.

In time, merchants and banks throughout the world found the sterling bill of exchange the least expensive and most reliable means of financing trade. They became indifferent as between assets in sterling and their own currency, for sterling was freely convertible into other currencies and into gold. As long as foreigners were willing to hold sterling and to regard it as good as gold, Britain financed a large portion of world trade, and short-term capital movements to and from Britain were regulated by changes in the discount rate.

In the 1920s changes in Great Britain and elsewhere altered this system. Many European countries, including Great Britain and France, found it impossible to maintain the level of their currencies against gold and the United States dollar. Rate fluctuations encouraged speculative movements of short-term capital. Initially such movements tended to stabilize exchange rates, as speculators bought currencies when their prices fell in the expectation of a rise. As time passed further exchange depreciation belied these expectations. Speculators then sold currencies when their prices fell, and added destabilizing pressure from short-term capital movements to the underlying inflationary forces.

A second new condition was the increase in the volume of liquid funds. In France in the 1920s, for example, the national debt was financed to a large extent through short-term bills, continuously coming due. If the money market took fright, it was able to obtain cash without discounting as bills matured and to export capital in large amounts.

The financial structure dependent upon these large-scale speculative capital movements was not secure. When the franc depreciated in 1922 and 1926, and the pound sterling was restored to par, a heavy volume of French private funds depressed the French franc and held up the pound. After the stabilization of the franc in July 1926, these funds returned to France. For a time, pressure against the pound and pushing up the franc was offset by Bank of France purchases of sterling. In the 1931 crisis, however, the conversion of this sterling into gold and other withdrawals from London forced the Bank of England to suspend convertibility and caused the pound to depreciate.

During the 1930s large-scale movements of liquid funds took place from country to country in search of safety and unaffected by rates of discount. In particular, so-called "hot money" move-

ments from Europe to the United States after the establishment of a new lower rate for the dollar in terms of gold in 1934 evaded exchange controls in central Europe, pushed the liberal gold bloc off parity in 1936, picked up in the spring of 1937 when there was a gold scare that the United States might lower the price of gold (raised in 1934), and reached flood proportions in the Munich crisis in 1938 and after the Stalin-Hitler pact in 1939.

At the 1944 monetary conference held at Bretton Woods, N.H., to formulate monetary rules for the postwar financial world, it was agreed that while trade restrictions should be avoided, there was no objection to controls to prevent movements of destabilizing short-term capital or "hot money." These movements, however, have been difficult to regulate. Laws can be evaded; for example, capital exports can occur through underinvoicing exports and the retention abroad of the difference between the true value and the stated one. Or foreigners can withdraw capital from a country, contrary to its wishes, by ordering goods and then "shunting" them to a third country with a hard currency. Of most significance is the fact that no country has been willing to dictate the credit terms on which its exporters and importers operate, and systematic changes in these credit terms can bring about sizable capital movements. In 1947, 1949, 1951 and again in 1956, when sterling underwent recurring crises, foreign exporters sped up the collection of their claims on Britain, and foreign importers delayed their payments to produce a sizable adverse movement. A London weekly, the *Economist*, estimated in 1956 that this source, known as changes in the "leads and lags" of trade finance, can produce a capital movement as large as £400,000,000.

A significant long-term capital import into Britain in World War II took short-term form. This was the increase in sterling balances of the commonwealth and the Allied powers in the middle east. These balances, owned by the sterling area and owed by the United Kingdom, rose from less than £1,000,000,000 in 1939 to more than £3,000,000,000 in 1945. After that time, the total changed slightly, but large changes occurred within it. British liabilities to the commonwealth and to the middle eastern allies were drawn down, while those to the crown colonies rose substantially. Some part of this capital flow from the colonies to the United Kingdom, it should be noted, was offset by an opposite movement through the long-term sale of colonial securities in London.

United States short-term capital movements, shown in Table I along with other selected items from the United States balance of payments since World War I, have varied substantially. U.S. capital was exported in the 1920s and again in the decade after World War II. Foreign funds, however, consistently moved to the United States, except for the brief period before the revaluation of the dollar in terms of gold. The substantial movement during the 1950s, which reached more than \$12,000,000,000, reflects governmental assistance to other countries substantially in excess of their balance-of-payments deficits. The bulk of this capital inflow represents the reconstitution of official exchange reserves.

During 1960-61 the United States experienced a temporary gold reserve crisis and immediately took steps to protect its reserves.

LONG-TERM CAPITAL MOVEMENTS

Reparations.—The transfer of reparations (*q.v.*) from one country to another constitutes a particular type of capital export which has been increasingly excluded from the category. Since the claim on the paying country arises from a peace treaty rather than from economic transactions, the discharge of the liability is sometimes regarded as a transfer of income, like a private gift or government grant, rather than a capital movement which gives rise to or extinguishes a claim. Nevertheless, reparation payments have loomed large in practice and in the development of the theory of capital movements. The most striking contrast lies between the French indemnity of 5,000,000,000 marks successfully paid to Germany after the Franco-German War, and the reparations exacted from Germany after World War I at the treaty of Versailles in 1919, which that country was unable to pay despite two reductions (the Dawes plan of 1924 and the Young plan in 1930), with the result that they were abandoned after the Hoover moratorium of June 1931. The causes of this inability or unwillingness of Germany to transfer reparations were widely debated in the 1920s and 1930s.

After World War II, reparation was exacted from Germany in the form of transfer of its foreign assets and removals of capital equipment in excess of its peacetime needs. Disagreement with the Soviet Union over the zonal treatment of reparation removals, and emphasis on the role that Germany might play in European recovery, brought western attempts to exact reparation from Germany to a halt shortly after 1948.

Bonds.—The principal instrument for long-term lending in the period from the Napoleonic Wars to 1928 was the foreign bond. Until 1914 London was the world's leading capital market and the sterling bond the leading long-term investment instrument. In a single year, unrepresentative since it was the peak. Great Britain saved 15% of its national income and invested 56% of this amount abroad. If the United States were to lend abroad in this relation to national income, the private export in 1958 would have amounted to \$35,600,000,000 instead of only \$4,000,000,000. Bonds were sold in London largely for the accounts of the dominions, the United States and the countries of Latin America especially Argentina. Loans were made both to governments and to private companies engaged in building railroads, public utilities, operating mines, etc. In 1913 British capital publicly invested amounted to £3,700,000,000, of which two-thirds consisted of the securities of foreign governments and companies, largely bonds. Income from public and privately floated investments was estimated at almost £200,000,000 and paid for virtually one-third of British merchandise imports.

In the period up to 1870 London provided the continent with both capital and British engineers to build railroads and other works. Thereafter, Paris and Berlin became lesser lending capitals, and London switched its investment to other overseas countries. France and Germany, however, directed the flow of capital in ways deemed politically important. In particular, French investment bankers floated tsarist and Balkan bonds which were subsequently defaulted in World War I. Switzerland, Belgium and the Netherlands became small-scale lenders on bond account in the 1920s. During and after the war the Allies incurred large debts to the United States, to certain overseas governments such as Canada, and to each other. Despite the attempt of the United States to separate the question of debts from that of reparations, the major Allied governments regarded them as intermingled. The moratorium on reparations in 1931 was quickly followed by default on debts, except on the part of Finland, whose small annual debt payments were finally completed.

After World War I London sought to regain its status as an international lender, but new loans were limited and were in part offset by the import of capital on short-term account. The 1920s were characterized by the shift of the world lending capital from London to New York.

Major borrowers in New York during the 1920s consisted of German provincial and municipal governments and German industry. So long as these borrowers had access to the New York market, reparation payments could be made. In addition, bonds

were sold for Scandinavian and dominion governments which had previously borrowed in London and for a variety of governmental and private undertakings in Latin America. At its peak in 1927, \$1,100,000,000 of new issues were sold in the United States for the account of foreign borrowers.

The foreign bond market faltered in 1929, when investor interest was diverted to stocks and call money, and collapsed in the world depression after 1930. A wide number of government debtors defaulted because the fall of commodity prices and the low level of trade made it impossible to maintain debt service. In retrospect, it seemed clear that the New York investment community had floated many bond issues of dubious quality. The private U.S. investor, badly hurt in the foreign bond market, turned his attention to other forms of investment and was not interested in foreign bonds thereafter. The one exception was Canadian bonds, which sold in substantial amounts to institutional investors since they were regarded as not really "foreign." But it proved impossible up to 1958 to float new issues for many other countries. In 1958 the foreign bond market picked up, however, and by 1960 signs of a comeback appeared.

In London, redemptions of foreign loans continued on balance through 1952, before any substantial net new investment occurred, exclusively directed to the sterling area. For the postwar period as a whole, capital exports were equally divided between the sterling area and other nondollar regions. Capital exports to the nondollar world were financed entirely in 1946 to 1949 and mainly from 1950 to 1952 by capital imports from the United States and Canada. Only after 1953 did the United Kingdom export its own savings. Capital exports outside the sterling area, and to a degree within, consisted mainly of withdrawals of sterling assets by foreigners rather than voluntary investments undertaken by British savers.

Outside New York and London, a few foreign issues were floated in Brussels, Amsterdam and Zurich. Most Swiss capital exports in the postwar period, however, consisted in the purchase of United States securities in New York.

Direct Investment.—The major channel for private capital export in the period after World War II was direct investment. As shown in Table II, direct investments which represent ownership accompanied by control over the direction of a company increased in the United States by \$19,800,000,000 from the end of 1946 through 1958, whereas portfolio investment where control is lacking gained by only \$5,100,000,000. Direct investment figures are in book values which understate by as much as half the market value of U.S. holdings abroad. The degree of understatement of foreign investments in the United States is smaller. Portfolio investment estimates, on the other hand, are adjusted for market fluctuation.

In the first years after World War II, the major source of overseas investment was the oil industry, in which U.S. companies

expanded both production and distribution facilities abroad. In addition to oil, substantial investments were made in the automobile and chemical industries. In manufacturing, the major foreign country for U.S. investment was Canada.

A number of policy issues have arisen with respect to direct investment. It is claimed for it that it imposes less strain on the balance of payments of the country where the investment takes place than do bonds bearing fixed interest. This is because much direct investment occurs in export industries abroad and earns the foreign exchange necessary to transmit profits, or is in import-competing industry and hence saves exchange. In addition, direct investment is said to combine with capital technology which is also needed abroad.

The U.S. government has taken the position in international conferences that private business through direct investment can provide most of the foreign capital needed by countries for economic development. A number of points are made in opposition to primary reliance on direct investment. It is claimed that the rate of profit on direct investments tends to be exorbitant; that direct investment in such lines as plantations may after its initial impact prevent changes in technology rather than provide continuous training; and that direct investment fails to furnish developing countries with social overhead capital—roads, schools, public utilities, etc., for which capital is needed but which are generally not private undertakings. Foreign borrowings for these purposes must be for the account of the government.

Governmental Lending.—During and immediately after World War I, intergovernmental loans were made to assist in the prosecution of the war and in economic recovery after the hostilities. The impossibility of collecting on these war debts after the default on German reparations has been mentioned. In the depression, when inconvertible exchange rates increased the risk of financing trade, various countries undertook to guarantee foreign credits or to extend them directly, as through the Export-Import Bank of Washington, in an effort to stimulate employment through the expansion of exports. But the major growth of governmental lending occurred after World War II as a response to the unwillingness of private investors to buy foreign government bonds. (See INTER-ALLIED DEBTS.)

The development of lend-lease and mutual aid during World War II prevented a large-scale repetition of the war-debt difficulties. The United States undertook to procure matériel for its Allies in the United States, against a book entry, while in turn the Allies furnished United States forces abroad with supplies and facilities against counterentries. Gross lend-lease from the United States to the Allies amounted to \$49,100,000,000, offsetting mutual aid amounting to \$8,000,000,000.

With the victory over Japan, lend-lease by the United States was abruptly shut off, and countries receiving items of civilian use were required to contract loans for them. Surplus matériel and ships were made available to foreign countries at favourable prices and on long-term credits. Supplies furnished to liberated Allies and to defeated countries through military appropriations were also funded into loans. To a limited extent, therefore, some war debts were created.

In the early postwar planning, it was decided to establish the United Nations Relief and Rehabilitation administration (UNRRA) to meet the immediate postwar needs of liberated countries. Supplies were furnished as grants rather than loans. It was contemplated that after the rehabilitation phase had been completed, the International Bank for Reconstruction and Development, established at Bretton Woods in 1944, would assist in meeting the long-term reconstruction needs of the belligerents as well as provide capital to countries engaged in economic development. Finally, the International Monetary fund was created, simultaneously with the bank, to provide a pool of liquid funds to meet short-run balance-of-payments difficulties. UNRRA, the bank and the fund were each to be built out of governmental contributions, based on the capacities of the various countries. In addition, the bank undertook to sell its securities to private investors. In contrast with UNRRA, the bank and fund were expected to operate on a businesslike basis.

Pending the organization of the bank and fund, the U.S. government in 1945 enlarged the capital of the Export-Import bank by \$3,000,000,000 to assist European reconstruction. In addition, under the Anglo-U.S. financial agreement of July 1946, \$3,750,000,000 was loaned to the United Kingdom to assist it in making sterling convertible and thereby to speed the recovery of the world as a whole in which the pound was a key currency. Under the terms of this agreement, the pound was made convertible in July 1947. After a month, however, pressure of foreign capital withdrawals obliged the authorities to suspend convertibility.

Despite military procurement. UNRRA, loans of the Export-Import bank, the Anglo-U.S. loan and some reconstruction loans to Europe of the International bank, it became clear in 1947 that European recovery was not complete. In June of that year, Secretary of State George C. Marshall proposed that Europe devise an over-all recovery program. Pending its formulation and enactment, the U.S. government undertook to make interim aid available to some European countries. Under the so-called Marshall plan, \$9,700,000,000 was devoted to European recovery from April 1948 to June 1951, of which \$8,600,000,000 was granted without obligation and \$1,100,000,000 was scheduled to be repaid as loans. (See FOREIGN AID PROGRAMS.)

The outbreak of war in Korea in June 1950 shifted the emphasis from reconstruction to defense. Military support was offered by the United States to its Allies, entirely on a grant basis.

A third objective of United States assistance to foreign countries was support of their efforts to raise their levels of living in the long run. Initial steps in this direction, apart from support of the bank, focused on the provision of technical assistance, largely as grants. Subsequently, economic assistance outside Europe was extended to include some provision of funds largely as grants. In a speech in April 1953 Pres. Dwight D. Eisenhower asserted that the United States would assist in furnishing the capital needs of developing countries when it became possible to cut down expenditure for armament.

Under the Marshall plan, 5% of the local-currency counterparts (&., the proceeds of the sale of commodities procured with U.S. aid) was turned over to the United States for its use. To this extent, the transaction could be said to be not aid but a sale against local currency. From this beginning, a number of devices arose involving local currencies, including particularly the sale of surplus U.S. agricultural products for local currency, where the local-currency proceeds were donated to some purpose (making the transaction a grant), or held (which constituted an export of capital in surplus commodities). Ultimately, the United States provided special surplus-commodity loans on a substantial scale, including a \$350,000,000 loan to India in 1956.

It is not always possible in some of these transactions to distinguish loans from grants, and a category of so-called "fuzzy loans" appears to have grown up.

An insistent demand has been expressed in the United Nations for more government-to-government lending on terms less onerous and businesslike than those of the International bank. Experts have proposed a special United Nations fund for economic development and similar arrangements, but the United States as the largest potential contributor has been opposed. The International Finance corporation, however, was established by the United Nations to provide equity capital to foreign entrepreneurs.

In 1955 and 1956 the Soviet Union entered as a provider of capital to underdeveloped areas. Special credits were extended to India, Burma, Egypt and one or two other countries, partly on trade account and partly to finance the construction of capital equipment.

Control Over Private Long-Term Lending.—In the 1920s investment bankers in New York contemplating foreign loans were required informally to advise the department of state to give the latter an opportunity to object on the grounds of foreign policy. Objection rarely occurred. This mild political restraint may be compared with the pre-World War I practice in France and Germany, where loans were made by bankers on the advice of the foreign office in the national interest. During the depression, Britain developed a system of restraint related to

the balance-of-payments position. The capital issues committee, established largely to limit pressure on capital markets, undertook to ration foreign borrowers in the interest of the foreign exchanges.

The major problem in capital-exporting countries, however, was not restraint but stimulation. The revival of the foreign-bond market was slow in coming after World War II. The issues of the International bank sell at a discount from those of the U.S. government despite what is a virtual government guarantee and despite legislation in most states, passed after a campaign by the bank, which makes the bank's bonds trustee investments for savings banks, insurance companies and other fiduciaries.

It is possible to remove certain restraints, such as double taxation. A major stimulus to direct investment in the United States is the tax credit on dividends from foreign subsidiaries to the amount of income taxes paid to governments where the subsidiaries are located. A special measure under which dividends from Latin-American subsidiaries were taxed at a rate of 14% below the normal tax was not effective in expanding investment in Latin America. This result occurred largely because of legal and technical reasons which disqualified many of the corporations for which it was intended and admitted others.

Under the European Recovery program (ERP), certain guarantees were provided by the government against confiscation of United States-owned property or blocking of remittances of dividends. These guarantees were issued on insurance principles against payment of premiums. No substantial interest in the guarantees has been shown, either because of objection in principle or because the premiums have been too high.

A number of countries attempted to regulate the import of capital, with varying degrees of success. In the early period after World War II, the major object of such legislation was to prevent undue exploitation of domestic resources or labour by foreign capital and to ensure the maximum benefit in terms of training. Limits were set to the remittance abroad of dividends accruing to foreign investors and to the repatriation of capital. Companies undertaking direct investment were required to share ownership and direction of their enterprises with local capital and to employ native labour. In particular cases, discriminatory requirements were enacted requiring foreign capital to adhere to higher standards of health, safety, wages, etc., than domestic enterprise.

After about 1950, however, the pendulum in the regulation of foreign investment swung in the opposite direction, and previous oppressive enactments in many instances were modified or eliminated. A number of countries found that they needed foreign capital more than foreign capital needed them. This was less true in oil and similar extractive industries than in manufacturing, but even in oil some reaction occurred after the confiscation by the Iranian government of the assets of the Anglo-Iranian Oil company (see PERSIA). Nevertheless, a rampant spirit of nationalism produced the confiscation of the international Suez Canal company by Egypt in July 1956. One area, Puerto Rico, went to the opposite extreme of discriminating substantially in favour of foreign capital. It was assisted in this by peculiarly favourable circumstances under which a United States company may be exempted from all Puerto Rican and U.S. taxes for a period of ten years. To a considerable extent, however, institutions of international lending, such as the London money bond markets before World War I, cannot be created by legislation but must evolve slowly with developing public confidence.

CAPITAL AND INTEREST. Capital is a word of many meanings. All its meanings, however, have something in common. They all imply that capital is a "stock" by contrast with income, which is a "flow." Capital may be broadly defined, therefore, as the set of economically significant elements in existence at a moment of time. The various concepts and definitions of capital revolve around the question of defining what is economically significant. In its broadest possible sense capital includes the human population; nonmaterial elements such as skills, abilities and education; land, buildings, machines, equipment of all kinds; and all stocks of goods—finished or unfinished—in the hands of both firms and households.

In economics the word capital is generally confined to "real" as opposed to merely "financial" assets. In the business world, the word usually refers to an item in the balance sheet which represents that part of the net worth of an enterprise that has not accrued through the operations of the enterprise. Different as the two concepts may seem, they are not unrelated. If all balance sheets were consolidated in a closed economic system all debts would be cancelled out, because every debt is an asset in one balance sheet and a liability in another. What is left, therefore, in the consolidated balance sheet, is a value of all the real assets of a society on one side, and its total net worth on the other. This is the economist's concept of capital.

Within the all-inclusive set of economically significant elements many useful subsets can be defined, and some authors have given the name capital to one or another of these subsets. There is, for instance, a distinction between goods in the hands of firms and goods in the hands of households, and attempts have been made to confine the term capital to the former. There is also a distinction between goods that have been produced and goods that are gifts of nature; attempts have been made to confine the term capital to the former, though the distinction is very hard to draw in practice. Another important distinction is between the stock of human beings (and their abilities) and the stock of nonhuman elements. In a slave society, of course, human beings are counted as capital in the same way as livestock or machines, and the value of slaves appears as an asset in the balance sheets of the slaveowners and is therefore part of the net worth of the nonslave element in society. In a free society each man is his own slave—the value of his body and mind is not, therefore, an article of commerce and does not get into the accounting system. In strict logic, persons should continue to be regarded as part of the capital of a society, but in practice the distinction between the part of the total stock that enters into the accounting system and the part that does not is so important that it is not surprising that many writers have excluded persons from the capital stock.

Another distinction, which has some historical importance, is that between circulating and fixed capital. Fixed capital is usually defined as that which does not change its form in the course of the process of production, such as land, buildings and machines. Circulating capital consists of goods in process, raw materials and stocks of finished goods waiting to be sold; these goods must either be transformed, as when wheat is ground into flour, or they must change ownership, as when a stock of goods is sold. This distinction, like many others, is not always easy to maintain. Nevertheless, it represents a rough approach to an important problem of the relative structure of capital; that is, of the proportions in which goods of various kinds are found. The stock of real capital exhibits strong complementarities. A machine is of no use without a skilled operator and without raw materials for it to work on.

Historical Background.—Although ancient and medieval

writers were interested in the ethics of interest and usury, the concept of capital as such did not rise to prominence in economic thought before the classical economists (Adam Smith, David Ricardo, Nassau William Senior and John Stuart Mill). Adam Smith laid great stress on the role played by the accumulation of a stock of capital in facilitating the division of labour and in increasing the productivity of labour in general. He recognized clearly that accumulation proceeds from an excess of production over consumption. He distinguished between productive labour, which creates objects of capital, and unproductive labour (services), the fruits of which are enjoyed immediately. His thought was strongly coloured by observation of the annual agricultural cycle. The end of the harvest saw society with a given stock of grain. This stock was in the possession of the capitalists. A certain portion of it they reserved for their own consumption and for the consumption of their menial servants, the rest was used to feed "productive labourers" during the ensuing year. As a result, by the end of the next harvest the barns were full again and the stock had replaced itself, perhaps with something left over. The stock that the capitalists did not reserve for their own use was the "wages fund"—the more grain there was in the barn in October the sharper the competition of capitalists for workers, and the higher real wages would be in the year to come. The picture is a crude one, of course, and does not indicate the complexity of the relationship between stocks and flows in an industrial society. The last of the classical economists, John Stuart Mill, was forced to abandon the wages fund theory. Nevertheless, the wages fund is a crude representation of some real but complex relationships, and the theory reappears in a more sophisticated form in later writers.

The classical economists made a sharp distinction between three categories of income—wages, profit and rent; and identified these with three factors of production—labour, capital and land. Ricardo especially made a sharp distinction between capital as "produced means of production" and land as the "original and indestructible powers of the soil." In modern economics this distinction has become blurred. About 1870 a new school of economics developed, sometimes called the Austrian school from the fact that many of its principal members taught in Vienna, but better perhaps called the Marginalist school. The movement itself was thoroughly international, and included such figures as William Stanley Jevons in England and Léon Walras in France. The so-called "Austrian theory of capital" is mainly based on the work of Eugen Böhm-Bawerk (*q.v.*). His *Positive Theory of Capital* (1884) set off a controversy that has not yet subsided. In the Austrian view the economic process consisted of the embodiment of "original factors of production" in capital goods of greater or lesser length of life which then yielded value or utility as they were consumed. Between the original embodiment of the factor and the final fruition in consumption lay an interval of time known as the period of production. In an equilibrium population it can easily be shown that the total population (capital stock) equals the annual number of births or deaths (income) multiplied by the average length of life (period of production). The longer the period of production, therefore, the more capital goods there will be per unit of income. If the period of production is constant, income depends directly on the amount of capital previously accumulated. Here is the wages fund in a new form. Unfortunately, the usefulness of Böhm-Bawerk's theory is much impaired by the fact that it is confined to equilibrium states. The great problems of capital theory are dynamic in character and comparative statics throws only a dim light on them.

In many ways the marginalist school culminated in the work of three men—Philip H. Wicksteed in England, Knut Wicksell in Sweden and Irving Fisher in the United States. The last two especially gave the Austrian theory clear mathematical expression. Perhaps the greatest contribution of the Austrian theory was its clear recognition of the importance of the valuation problem in the relation of capital to interest. From the mere fact that physical capital produces an income stream there is no explanation of the phenomenon of interest, for the question is why the value of a piece of physical capital should be less than the total of future values that are expected to accrue from it. The theory also makes

a contribution to the problem of rational choice in situations involving waiting or maturing. The best example is that of slowly maturing goods such as wines or timber. There is a problem here of the best time to draw wine or to cut down a tree. According to the marginal theory this is at the time when the rate of net value growth of the item is just equal to the rate of interest, or the rate of return in alternative investments. Thus, if a tree or a wine is increasing in value at the rate of 7% per annum when the rate of interest is 6% it still pays to be patient and let it grow or mature. The longer it grows, however, the less the rate of value growth, and when the rate of value growth has fallen to the rate of interest, then is the time to reap the fruits of patience.

The contributions of John Maynard (Lord) Keynes to capital theory are incidental rather than fundamental. Nevertheless, the "Keynesian revolution" had an impact on this area as on most others. The great contribution of Keynes is the recognition that the attempt to save does not automatically result in the accumulation of capital. A decision to restrict consumption is only a decision to accumulate capital if the volume of production is constant. If abstention from consumption itself results in a diminution of production, then accumulation (production minus consumption) is correspondingly reduced.

Theoretical Problems.—The theory of capital was not a matter of primary concern to economists in the mid-20th century, though some revival of interest was apparent in the late 1950s. Nevertheless, certain problems remain of perennial interest. They may be grouped as follows:

1. Problems involved in the measurement of a heterogeneous aggregate of goods. Real capital is a set of very heterogeneous items. The measurement of the total volume of real capital, therefore, involves a serious index number problem. A single measure of total real capital can be achieved only if there is an assumption of constant co-efficients of valuation by which each item can be expressed in a common denominator such as dollars. The problem is particularly complicated in periods of rapid technical change when there is change not only in the relative values of items but in the nature of the list itself. Only approximate solutions can be found to this problem and no completely satisfactory measure is possible. Nevertheless, approximate solutions are better than none. A related problem which has aroused considerable interest among accountants is that of accommodating the valuation of assets in balance sheets to changing price levels. In the conventional balance sheet the value of some items is based on their cost at an earlier period than that of others. When the general level of prices is changing this means that different items are valued in dollars of different purchasing power.

The problem is particularly acute in the valuation of inventory. Under the more conventional "FIFO" (First In, First Out) system, inventory is valued at the cost (purchase price) of the latest purchases. This leads to an inflation of inventory values, and therefore of accounting profits, in time of rising prices (and a corresponding deflation under falling prices) which may be an exaggeration of the long-run position of the firm. This may be partially avoided by a competing system of valuation known as "LIFO" (Last In, First Out), in which inventory is valued at the purchase price of the earliest purchases. This avoids the fluctuations caused by short-run price level changes, but it fails to record changes in real long-run values. There seems to be no completely satisfactory solution to this problem, and it seems wise to admit the fact that any single figure of capital value that purports to represent a complex, many-dimensional reality will need careful interpretation.

2. The second theoretical problem relates to the determinants of the rate of accumulation of capital; that is, of investment. It has been seen that investment in real terms is the difference between production and consumption. The classical economist laid great stress on frugality as the principal source of capital accumulation. If production is constant it is true that the only way to increase accumulation is by the reduction of consumption. Keynes shifted the emphasis from the reduction of consumption to the increase of production and regarded the decision to produce investment goods as the principal factor determining the rate of

growth of capital. In modern theories of economic development great stress is laid on the problem of the structure of production—the relative proportions of different kinds of activity. The advocates of "balanced growth" lay stress on the necessity for investment in a wide range of related and co-operative enterprises, public as well as private. There is no point in building factories and machines if the educational system does not provide a labour force capable of using them. There is also, however, a case to be made for "unbalanced growth," in the sense that growth in one part of the economy frequently stimulates growth in other parts. A big investment in mining or in hydroelectric power, for example, creates strains on the whole society which result in growth responses in the complementary sectors. The relation of inflation to economic growth and investment is an important though difficult problem. There seems to be little doubt that deflation, mainly because it shifts the distribution of income away from the profit-maker toward the rentier and bondholder, has a deleterious effect on investment and the growth of capital. In 1932, for instance: real investment had practically ceased in the United States. It is less clear at what point inflation becomes harmful to investment. In countries where there has been long continuing inflation there seems to be some evidence that the structure of investment is distorted. Too much goes into apartment houses and factories and not enough into schools and communications.

3. A third problem of the theory of capital is that of the period of production and the time structure of the economic process. This is a complex problem which cannot be solved by the simple formulas of the Austrian school. Nevertheless, the problem is a real one and there is still a need for more useful theoretical formulations of it. Decisions that are taken today have results extending far into the future. Similarly, the data of today's decisions are the result of decisions taken long in the past. The incompatibility of decisions is frequently not discovered at the time they are made because of the lapse of time between the decision and its consequences. The existing capital structure is the embodiment of past decisions and the raw material of present decisions. It is tempting to regard the cyclical structure of human history, whether the business cycle or the war cycle, as a process by which the consequences of bad decisions accumulate until some kind of crisis point is reached. The crisis (war or depression) redistributes power in the society, and so leads to a new period of accumulating, but hidden, stress. In this process, distortion in the capital structure is of great importance.

4. The fourth theoretical problem is that of the relation between the stocks and the flows of a society, or in a narrower sense the relation between capital and income. Income! like capital, is a concept capable of many definitions; a useful approach to the concept of income is to regard it as the gross addition to capital in a given period. In real terms this is practically identical with the concept of production. For any economic unit, whether a firm or an individual, income may be measured by that hypothetical amount of consumption that would leave capital intact. It should be observed that all the difficulties that arise in the measurement of a heterogeneous aggregate of capital arise also in the measurement of real income. Money income is the value of production at current prices. The total flow of income is closely related to both the quantity and structure of capital; the total real income of a society depends on the size and skills of its population, and on the nature and extent of the equipment with which they have to work. The most important single measure of economic well-being is per capita real income; this is closely related to the productivity of labour, and this in turn is closely related to per capita capital, especially if the results of investment in human resources, skills and education in the capital stock are included.

INTEREST

Historically, the concept of capital has been so closely bound to the concept of interest that it seems wise to take these two topics together, even though in the modern view it is capital and income rather than capital and interest that are the related concepts.

Definition and Concepts.—Interest as a form of income may

be defined as income received as a result of the possession of contractual obligations for payment on the part of another. Interest, that is, is income received as a result of the ownership of a bond, a promissory note or some other instrument that represents a promise on the part of some other party to pay sums in the future. The obligations may take many forms. In the case of the perpetuity, the undertaking is to pay a certain sum each year or other interval of time for the indefinite future. A bond with a date of maturity usually involves a promise to pay a certain sum each year for a given number of years, and then a larger sum on the terminal date. A promissory note frequently consists of a promise to pay a single sum at a date some time in the future.

Rate of Interest.—If a_1, a_2, \dots, a_n , are the sums received by the bondholder in years 1, 2, . . . n , and if P_0 is the present value in year 0, or the sum for which the bond is purchased, the rate of interest r in the whole transaction is given by the equation

$$P_0 = a_1(1+r)^{-1} + a_2(1+r)^{-2} + \dots + a_n(1+r)^{-n}$$

There is no general solution for this equation, though in practice it can be solved easily by successive approximation, and in special cases the equation reduces to much simpler forms. In the case of a promissory note, for instance, the equation reduces to the form

$$P_0 = a_n(1+r)^{-n}, \text{ or } \log(1+r) = \frac{\log a_n - \log P_0}{n}$$

where a_n is the single promised payment. In the case of a perpetuity with an annual payment of a , the formula reduces to

$$P_0 = a[(1+r)^{-1} + (1+r)^{-2} + \dots \text{ to inf.}] = \frac{a}{r}$$

whence $r = \frac{a}{P_0}$

Thus if we had to pay \$200 to purchase a perpetual annuity of \$5 per annum, the rate of interest would be $2\frac{1}{2}\%$.

It should be observed that the dimensions of the rate of interest are those of a rate of growth. The rate of interest is not a price or ratio of exchange; it is not itself determined in the market. What is determined in the market is the price of contractual obligations or "bonds." The higher the price of a given contractual obligation, the lower the rate of interest on it. Suppose, for instance, I have a promissory note that is a promise to pay me \$100 in one year's time. If I buy this for \$100 now, the rate of interest is zero; if I buy it for \$95 now the rate of interest is a little over 5%; if I buy it for \$90 now, the rate of interest is about 11%. The rate of interest may be defined as the gross rate of growth of capital in a contractual obligation.

A distinction is usually made between interest and profit as forms of income. In ordinary speech, profit usually refers to income derived from the ownership of aggregates or assets of all kinds organized in an enterprise. This aggregate is described by a balance sheet. In the course of the operations of the enterprise, the net worth grows, and profit is the gross growth of net worth. Stocks, as opposed to bonds, usually imply a claim on the profits of some enterprise.

Changing Attitudes.—In ancient and medieval times the main focus of inquiry into the theory of interest was ethical, and the principal question was the moral justification of interest. On the whole, the taking of interest was regarded unfavourably by both classical and medieval writers. Aristotle regarded money as "barren" and the medieval schoolmen were hostile to usury. Nevertheless, there developed elaborate defenses for the taking of interest where it fulfilled a useful social function. Among the classical economists the focus of attention shifted away from ethical justification toward the problem of mechanical equilibrium. The question then became this: Is there any equilibrium rate of interest or rate of profit in the sense that where actual rates are above or below this, forces are brought into play, tending to change them toward the equilibrium? The classical economists did not provide any clear solution for this problem. They believed that the rate of interest simply followed the rate of profit, for people would not borrow or incur contractual obligations unless they could earn

something more than the cost of the borrowing by investing the proceeds in enterprises or aggregates of real capital. They believed that the growth of capital itself would tend to reduce the rate of profit because of the competition of the capitalists. This doctrine is important in the Marxian dynamics in which the struggle of capital to avoid a falling rate of profit is an important factor, leading, for instance, to unemployment, foreign investment and imperialism.

Within the general framework of classical economics the work of Nassau William Senior (*q.v.*) deserves mention. He raised the question of whether profit or interest were "paid for" anything; that is, whether there was any identifiable contribution to the general product of society that would not be forthcoming if this form of income were not paid. He identified such a function and called it "abstinence." Karl Marx denied the existence of any such function, and argued that the social product must be attributed entirely to acts of labour, capital being merely the embodied labour of the past. On this view, profit and interest are the result of pure exploitation in the sense that they consist of an income derived from the power position of the capitalist and not from the performance of any service. Non-Marxist economists have generally followed Senior in finding some function in society that corresponds to these forms of income.

The marginalist school generally took the view that profit and interest were related to the marginal productivity of the extension of the period of production. Bohm-Bawerk assumed that "roundabout" processes of production, would generally be more productive than processes with shorter periods of production; there is, that is to say, a productivity of "waiting" (to use the term of Alfred Marshall), and the rate of interest can then be seen as an inducement to the capitalist to extend the period of production. A low rate of interest leads to concentration on longer, more roundabout processes, and a high rate of interest on shorter, less roundabout processes. There is a limit, however, on the period of production imposed by the existing stock of accumulated capital. If we embark on a long process with insufficient capital, we will find that we have exhausted our resources before the end of the process and before the fruits can be gathered. It is the business of the rate of interest to prevent this, and to adjust the roundaboutness of the processes used to the capital resources available. The marginalists' theory of interest reached its clearest expression in the work of Irving Fisher. He saw an equilibrium rate of interest as determined by the interaction of two sets of forces: the impatience of consumers on the one hand, and the productivity of extending the period of production on the other.

J. M. Keynes brought a new approach to the whole problem. His liquidity preference theory of interest is a short-run theory of the price of contractual obligations ("bonds"), and it is essentially an application of the general theory of market price. If people as a whole decide that they want to hold a large proportion of their assets in the form of money, and if new money is not created to satisfy this desire, there will be a net desire to sell securities and the price of securities will fall. This is the same thing as a rise in the rate of interest. Conversely, if people want to get rid of money the price of securities will rise and the rate of interest will fall. This, then, is the theory of the "market" rate of interest, by contrast with the marginalists' theory, which concerns itself with whether or not there is a long-run equilibrium rate of interest. The controversy, therefore, between the liquidity preference theory which regards interest as a "bribe" to prevent people holding money rather than bonds, and the time preference theory which regards interest as a bribe to persuade people to postpone enjoyments to the future, can be resolved by placing the former in the short run and the latter in the long run.

Theoretical Problems.—The middle of the 20th century saw a considerable shift in the focus of concern relating to the theory of interest. Economists seemed to lose interest in the equilibrium theory and their main concern was with the effect of rates of interest as a part of monetary policy in the control of inflation. It was recognized that the monetary authority could control the rate of interest in the short run within wide limits. The controversy lay mainly between the advocates of "monetary policy" and the

advocates of "fiscal policy." If inflation is regarded as a symptom of a desire on the part of a society to consume and invest more in total than its resources permit, it is clear that the problem can be attacked either by diminishing investment or by diminishing consumption. On the whole, the attack of the advocates of monetary policy is on the side of diminishing investment, through raising rates of interest and making it harder to obtain loans, though the possibility that high rates of interest may restrict consumption is not overlooked. The alternative would seem to be to restrict consumption by raising taxes. This has the disadvantage of being politically unpopular. The mounting concern with economic growth, however, has raised considerable doubts about the use of high rates of interest as an instrument to control inflation. There is some doubt whether high interest rates in fact restrict investment; if they do not, they are ineffective, and if they do, they may be harmful to economic growth. This is a serious dilemma for the advocates of monetary policy. On the other hand, it must be admitted that the type of fiscal policy that might be most desirable theoretically has received neither public support nor a political acceptability.

The problem of the ethics of interest is still unresolved in spite of many centuries of discussion; as long as we accept the institution of private property, the institution of securities, loans and a security market can hardly be denied usefulness. In the long historic process of inheritance, widowhood, gain and loss, by which the distribution of the ownership of capital is determined, there is no reason to suppose that the actual ownership of capital falls into the hands of those best able to administer it. Much of the capital of an advanced society, in fact, tends to be owned by elderly widows, simply because of the greater longevity of the female. There must, therefore, be some machinery in society for separating the control of capital from its ownership. Financial instruments and financial markets are the principal agency to perform this function. It might be argued that we could get along without contractual obligations (bonds), and therefore without interest as a form of income, if all securities took the form of stocks or equities. The case for bonds and interest, however, is the case for specialization. There is a demand for many different degrees of ownership and responsibility, and interest-bearing obligations tap a market that would be hard to reach with equity securities; they are also peculiarly well adapted to the obligations of governments. The principal justification for interest and interest-bearing securities, therefore, is that they provide an easy and convenient way whereby skilled administrators can control capital that they do not own, and the owners of capital can relinquish its control. Society has to pay a price for this arrangement and the price is interest.

There has been very little discussion of the problem of the socially optimum rate of interest. It could be argued that while interest has to be paid for a certain convenience there is no point in paying any higher price than we need to, and that hence the rate of interest should be as low as is consistent with the performance of the function of the financial markets. This position, of course, would place all the burden of control of economic fluctuations on the fiscal system, and perhaps we are not ready for this politically.

The ancient problem of "usury," in the form of the exploitation of the ignorant poor by moneylenders, is still important in many parts of the world. The remedy would seem to be the development of adequate financial institutions appropriate to all classes rather than the attempt to prohibit or even limit the taking of interest. The complex structure of lending institutions in a developed society—banks, building societies, land banks, co-operative banks, credit unions, and so on—is a tribute to the reality of the service that the lender provides and that interest pays for. The democratization of credit—that is, the extension of the power of borrowing to all classes in society—is one of the important social movements of the 20th century.

CAPITAL GAINS, TAXATION OF. Strictly speaking, capital gains are gains realized from the sale or exchange of capital assets. Under federal income tax law in the United States all properties are, with certain exceptions, classed as capital assets. Personal securities, private residences and other properties held to yield income or for personal use are types of capital assets under the tax law. The main exceptions are properties used in the taxpayer's business, including stock in trade, depreciable property and land. However, if certain of the excepted properties are sold or exchanged with a resulting gain, the gain is treated by law as though it were truly a capital gain. The term is therefore used commonly to include any gain that is treated by law as a capital gain.

Capital gains have been taxed in the United States since the advent of federal income taxation, but after 1921 certain capital gains were afforded preferential treatment. There are several reasons for this special treatment. One is that it encourages the investment of risk capital. Another is the unfairness of taxing in a single year the full value of several years' appreciation. Accordingly, tax benefits are limited to long term gains; *i.e.*, those involving assets that the taxpayer has held for a specified period (after 1942 this period was six months). Other capital gains are short term, and, with some exceptions, are treated the same as ordinary income.

To compute the amount of a capital gain two things must be known: the value received for the asset and the taxpayer's adjusted basis therein. When a taxpayer acquires an asset he obtains a basis therein. Generally, if the acquisition is by purchase, the basis is cost; if by transmission at death, it is fair market value; if by gift, it is the donor's basis. This original basis may be adjusted upward to account for capital improvements or may be lowered to take depreciation into account. Thus, if a taxpayer buys a hotel for \$1,000,000, adds capital improvements of \$200,000 and over the years has had allowable depreciation of \$300,000, his adjusted basis is \$900,000. The amount of the capital gain is computed by subtracting the adjusted basis from the value received for the asset. In the example given, if the taxpayer sells the hotel for \$1,500,000, the capital gain is \$600,000.

If the taxpayer has held the hotel for more than six months and is an individual, only 50% of the gain, or \$300,000, is subject to taxation. Furthermore, the maximum tax on the total gain cannot exceed a specified percentage, which for several years has been 25%. To individual taxpayers whose effective rates are below this maximum percentage, this ceiling is unimportant. But for taxpayers in higher brackets this limitation may effect substantial savings. Thus, in the example given, the maximum possible tax is 25% of \$600,000, or \$150,000.

By contrast, if the gain were ordinary income, the tax thereon to a single person, with no other income and no special deduc-

tions, would be approximately \$170,000 at current rates.

CAPITALISM, a term used to denote the economic system that has been dominant in the western world since the breakup of feudalism. Fundamental to any system called capitalist are the relations between private owners of nonpersonal means of production (land, mines, industrial plants, etc., collectively known as capital) and free but capital-less workers, who sell their labour services to employers. Under capitalism, decisions concerning production are made by private businessmen operating for private profit. Labourers are free in the sense that they cannot legally be compelled to work for the owners of the means of production. However, since labourers do not possess the means of production required for self-employment, they must, of economic necessity, offer their services on some terms to employers who do control the means of production. The resulting wage bargains determine the proportion in which the total product of society will be shared between the class of labourers and the class of capitalist entrepreneurs.

After penetrating the resisting framework of feudal society, the capitalist process gradually permeated the fabric of economic life and attained its classical form in the 19th century. Internal and external forces in the 20th century have transferred an increasing range of economic decisions from the private (capitalist) to the public (government) sector, and the resulting economic system is quite different from capitalism in either its early or its classical form. This article is organized according to the following outline of topics:

- I. Historical Development
 1. Origins of Capitalism
 2. Early Capitalism (1500-1750)
 3. Classical Capitalism (1750-1914)
 4. The Later Phase (Since 1914)
- II. Criticisms and Problems
 1. Allocation of Resources
 2. Employment of Resources
 3. Unemployment and Waste
 3. Exploitation and Inequality
 5. Concentration of Private Economic Power
 6. Public *v.* Private Sector
 7. The Future of Capitalism

I. HISTORICAL DEVELOPMENT

1. Origins of Capitalism.—Although the continuous development of capitalism as a system dates only from the 16th century, antecedents of capitalist institutions existed in the ancient world, and flourishing pockets of capitalism were present during the later middle ages. One strategic external force contributing to the breakup of medieval economic institutions was the growing volume of long-distance trade between capitalist centres, carried on with capitalist techniques in a capitalist spirit. Specialized industries grew up to serve long-distance trade, and the resulting commercial and industrial towns gradually exerted pressures which weakened the internal structure of agriculture based on serfdom, the hallmark of the feudal regime. Changes in trade, industry and agriculture were taking place simultaneously and interacting with one another in highly complex actual relations, but it was chiefly long-distance trade which set in motion changes that spread throughout the medieval economy and finally transformed it into a new type of economic society.

Flanders in the 13th century and Florence in the 14th century were two capitalist pockets of special interest. Their histories shed light on the conditions that were essential to the development of capitalism in England. The great enterprise of late medieval and early modern Europe was the woolen industry, and most of the business arrangements that later characterized capitalism developed in connection with long-distance trade in wool and cloth.

In Flanders revolutionary conflict raged between plebeian craftsmen and patrician merchant-manufacturers. The workers succeeded in destroying the concentration of economic and political

power in the hands of cloth magnates, only to be crushed in turn by a violent counterrevolution that destroyed the woolen industry and brought ruin to both groups. A similar performance was repeated in Florence, which became one of the great industrial cities of Europe during the 14th century. Restless, revolutionary urban workers overthrew the ruling hierarchy of merchants, manufacturers and bankers, and were in turn crushed in a bloody counterrevolution. Thus both Flanders and Florence failed to perpetuate their great industries because they failed to solve the social problem arising from conflicting claims of small numbers of rich capitalists and large numbers of poor workers.

2. Early Capitalism (1500-1750).—By the end of the middle ages the English cloth industry had become the greatest in Europe. Because of the domestic availability of raw wool and the innovation of simple mechanical fulling mills, the English cloth industry had established itself in certain rural areas where it avoided the violent social strife that had destroyed the urban industries of Flanders and Florence. Although it was subject to many problems and difficulties, the English rural cloth industry continued to grow at a rapid rate during the 16th, 17th and 18th centuries. Hence, it was the woolen industry that spearheaded capitalism as a social and economic system and rooted it for the first time in English soil.

Productive use of the "social surplus" was the special virtue that enabled capitalism to outstrip all prior economic systems. Instead of building pyramids and cathedrals, those in command of the social surplus chose to invest in ships, warehouses, raw materials, finished goods and other material forms of wealth. The social surplus was thus converted into enlarged productive capacity. Among the historical events and circumstances that significantly influenced capital formation in western Europe in the early stage of capitalist development, three merit special attention: (1) religious sanction for hard work and frugality; (2) the impact of precious metals from the new world on the relative shares of income going to wages, profits and rents; and (3) the role of national states in fostering and directly providing capital formation in the form of general-purpose capital goods.

Capitalist Spirit.—The economic ethics taught by medieval Catholicism presented obstacles to capitalist ideology and development. Hostility to material wealth carried forward the teachings of the Christian fathers against mammonism. Saint Jerome said, "A rich man is either a thief or the son of a thief." Saint Augustine felt that trade was bad because it turned men away from the search for God. Down through the middle ages commerce and banking were viewed, at best, as necessary evils. Moneylending was for a time confined to non-Christians because it was considered unworthy of Christians. Interest on loans was unlawful under the anti-usury laws of both church and secular authorities. Speculation and profiteering violated the central medieval economic doctrine of just price.

Expansion of commerce in the later middle ages stirred controversies and led to attempts to reconcile theological doctrines with economic realities. In Venice, Florence, Augsburg and Antwerp—all Catholic cities—capitalists violated the spirit and circumvented the letter of the prohibitions against interest. On the eve of the Protestant Reformation capitalists, who still laboured under the shadow of the sin of avarice, had by their deeds become indispensable to lay rulers and to large numbers of people who were dependent upon them for employment.

The Protestant Reformation of the 16th and 17th centuries developed alongside economic changes which resulted in the spread of capitalism in northern Europe, especially in the Netherlands and England. This chronological and geographical correlation between the new religion and economic development has led to the suggestion that Protestantism had causal significance for the rise of modern capitalism. Without in any sense being the "cause" of capitalism, which already existed on a wide and expanding horizon, the Protestant ethic proved a bracing stimulant to the new economic order. Doctrinal revision or interpretation seemed not only to exonerate capitalists from the sin of avarice but even to give divine sanction to their way of life. In the ordinary conduct of life, a new type of worldly asceticism emerged, one that meant

hard work, frugality, sobriety and 'efficiency in one's calling in the market place similar to that of the monastery. Applied in the environment of expanding trade and industry, the Protestant creed taught that accumulated wealth should be used to produce more wealth.

Acceptance of the Protestant ethic also eased the way to systematic organization of free labour. By definition, free labourers could not be compelled by force to work in the service of others. Moreover, the use of force would have violated the freedom of one's calling. Psychological compulsion arising from religious belief was the answer to the paradox. Every occupation was said to be noble in God's eyes. For those with limited talents, Christian conscience demanded unstinting labour even at low wages in the service of God—and, incidentally, of employers. It was an easy step to justify economic inequality because it would hasten the accumulation of wealth by placing it under the guardianship of the most virtuous (who were, incidentally, the wealthiest) and remove temptation from weaker persons who could not withstand the allurements associated with wealth. After all, it did not much matter who held legal title to wealth, for it was not for enjoyment. The rich like the poor were to live frugally all the days of their lives. Thus the capitalist system found a justification that was intended to make inequality tolerable to the working classes.

The Price Revolution.—Meanwhile treasure from the new world had a profound impact on European capitalism, on economic classes and on the distribution of income in Europe. Gold and silver from the mines of Mexico, Peru and Bolivia increased Europe's supply of precious metals sevenfold and raised prices two- or threefold between 1540 and 1640. The significance of the increased supply of money lay not so much in the rise in prices as in its effect on the social and economic classes of Europe. Landlords, the older ruling class, suffered because money rents failed to rise as rapidly as the cost of living. The more aggressive landlords raised rents and introduced capitalistic practices into agriculture. In England the enclosure movement, which developed with ever increasing momentum and vigour during the 17th and 18th centuries, encouraged sheep raising to supply wool to the expanding woolen industry. Among labourers, money wages failed to keep pace with the cost of living, causing real wages to fall during the price revolution. The chief beneficiaries of this century-long inflation were capitalists, including merchants, manufacturers and other employers. High prices and low wages resulted in profit inflation, which in turn contributed to larger savings and capital accumulation. Profit inflation and wage deflation created a more unequal distribution of income. Wage earners got less and capitalists got more of the total product than they would have received in the absence of inflation. Had the new increments of wealth gone to wage earners instead of to capitalists, most of it would have been consumed rather than invested, and hence the working classes of the 16th century would have eaten better, but the future would have inherited less accumulated wealth.

Mercantilism.—Early capitalism (1500-1750) also witnessed in western Europe the rise of strong national states pursuing mercantilist policies. (See MERCANTILE SYSTEM.) Critics have tended to identify mercantilism with amassing silver and gold by having a so-called favourable balance of exports over imports in trading relations with other nations and communities, but the positive contribution and historic significance of mercantilism lay in the creation of conditions necessary for rapid and cumulative economic change in the countries of western Europe. At the end of the middle ages western Europe stood about where many underdeveloped countries stand in the 20th century. In underdeveloped economies the difficult task of statesmanship is to get under way a cumulative process of economic development, for once a certain momentum is attained, further advances appear to follow more or less automatically. Achieving such sustained growth requires virtually a social revolution.

Power must be transferred from reactionary to progressive classes; new energies must be released, often by uprooting the old order; the prevailing religious outlook may constitute a barrier to material advancement. A new social and political frame-

work must be created within which cumulative economic change can take place.

Among the tasks which private capitalists were either unable or unwilling to perform were the creation of a domestic market free of tolls and other barriers to trade within the nation's borders; a uniform monetary system; a legal code appropriate to capitalistic progress; a skilled and disciplined labour force; safeguards against internal violence; national defense against attack; sufficient literacy and education among business classes to use credit instruments, contracts and other documents required of a commercial civilization; basic facilities for communication and transportation and harbour installations. A strong government and an adequate supply of economic resources were required to create most of these conditions, which constitute the "social overhead capital" needed in a productive economy. Because the returns from them, however great, cannot be narrowly channeled for private gain, such investments must normally be made by the government and must be paid for out of public revenues.

Preoccupation with productive use of the social surplus led mercantilist commentators to advocate low wages and long hours for labour. Consumption in excess of bare subsistence was viewed as a tax on progress and therefore contrary to the national interest. Mercantilist society was not a welfare state; it could not afford to be. Luxury consumption was condemned as a dissipation of the social surplus. Restrictions on imports were directed especially at luxury consumption.

Opportunities for profitable private investment multiplied rapidly as mercantilist policy succeeded in providing the basic social overhead capital. Rather paradoxically, it was because the state had made such an important contribution to economic development that the ideology of *laissez-faire* could later crystallize. When that occurred, dedication to capital accumulation remained a basic principle of capitalism, but the shift from public to private initiative marked the passage from the early state of capitalism and the beginning of the next stage, the classical period.

3. Classical Capitalism (1750–1914).—In England, beginning in the 18th century, the focus of capitalist development shifted from commerce to industry. The Industrial Revolution (*q.v.*) may be defined as the period of transition from a dominance of commercial over industrial capital to a dominance of industrial over commercial capital. Preparation for this shift began long before the invention of the flying shuttle, the water frame and the steam engine, but the technological changes of the 18th century made the transition dramatically evident.

The rural and household character of the English textile industry continued only as long as the amount of fixed capital required for efficient production remained relatively small. Changes in technology and organization shifted industry again to urban centres in the course of the Industrial Revolution, although not to the old commercial urban centres. Two or three centuries of steady capital accumulation began to pay off handsomely in the 18th century. Now it became feasible to make practical use of technical knowledge which had been accumulating over the centuries. Capitalism became a powerful promoter of technological change because the accumulation of capital made possible the use of inventions which poorer societies could not have afforded. Inventors and innovators like James Watt (*q.v.*) found business partners who were able to finance their inventions through lean years of experimentation and discouragement to ultimate commercial success. Aggressive entrepreneurs like Richard Arkwright (*q.v.*) found capital to finance the factory type of organization required for the utilization of new machines. Wealthy societies had existed before capitalism, but none had managed their wealth in a manner that enabled them to take advantage of the more efficient methods of production which an increasing mastery over nature made physically possible.

Adam Smith's great *Inquiry Into the Nature and Causes of the Wealth of Nations* (1776) expressed the ideology of classical capitalism. Smith recommended dismantling the state bureaucracy and leaving economic decisions to the free play of self-regulating market forces. While Smith recognized the faults of businessmen, he contended they could do little harm in a world of freely

competitive enterprise. In Smith's opinion, private profit and public welfare would become reconciled through impersonal forces of market competition. After the French Revolution and the Napoleonic wars had swept the remnants of feudalism into oblivion and rapidly undermined mercantilist fetters, Smith's policies were put into practice. *Laissez-faire* policies of 19th-century political liberalism included free trade, sound money (the gold standard), balanced budgets, minimum poor relief—in brief, the principle of leaving individuals to themselves and of trusting that their unregulated interactions would produce socially desirable results. No new conceptions of society arose immediately to challenge seriously what had become, in fact, a capitalist civilization.

This system, though well-defined and logically coherent, must be understood as a system of tendencies only. The heritage of the past and other obstructions prevented any full realization of the principles except in a few cases of which the English free trade movement, crystallised by the repeal of the Corn Laws in 1846, is the most important. Such as they were, however, both tendencies and realizations bear the unmistakable stamp of the businessman's interests and still more the businessman's type of mind. Moreover, it was not only policy but the philosophy of national and individual life, the scheme of cultural values, that bore that stamp. Its materialistic utilitarianism, its naive confidence in progress of a certain type, its actual achievements in the field of pure and applied science, the temper of its artistic creations, may all be traced to the spirit of rationalism that emanates from the businessman's office. For much of the time and in many countries the businessman did not rule politically. But even non-capitalist rulers espoused his interests and adopted his views. They were what they had not been before, his agents.

More definitely than in any other historical epoch these developments can be explained by purely economic causes. It was the success of capitalist enterprise that raised the bourgeoisie to its position of temporary ascendancy. Economic success produced political power, which in turn produced policies congenial to the capitalist process. Thus the English industrialists obtained free trade, and free trade in turn was a major factor in a period of unprecedented economic expansion.

The partition of Africa and the carving out of spheres of influence in Asia by European powers in the decades preceding World War I led critics of capitalism to develop, on a Marxist basis, a theory of economic imperialism. According to this doctrine, competition among capitalist firms tends to eliminate all but a small number of giant concerns. Because of the inadequate purchasing power of the masses, these concerns find themselves unable to use the productive capacity they have built. They are, therefore, driven to invade foreign markets and to exclude foreign products from their own markets through protective tariffs. This situation produces aggressive colonial and foreign policies and "imperialist" wars, which the proletariat, if organized, turn into civil wars for socialist revolution. Like other doctrines of such sweeping character, this theory of imperialism is probably not capable of either exact proof or disproof. Three points, however, may be recorded in its favour; first, it does attempt what no other theory has attempted, namely, to subject the whole of the economic, political and cultural patterns of the epoch that began during the long depression (1873–96) to comprehensive analysis by means of a clear-cut plan; second, on the surface at least, it seems to be confirmed by some of the outstanding manifestations of this pattern and some of the greatest events of this epoch; third, whatever may be wrong with its interpretations, it certainly starts from a fact that is beyond challenge—the capitalist tendency toward industrial combination and the emergence of giant firms. Though cartels (*q.v.*) and trusts antedate the epoch, at least so far as the United States is concerned, the role of what is popularly called "big business" has increased so much as to constitute one of the outstanding characteristics of recent capitalism.

4. The Later Phase (Since 1914).—World War I marked a turning point in the development of capitalism in general and of European capitalism in particular. The period since 1914 has witnessed a reversal of the public attitude toward capitalism and of almost all the tendencies of the liberal epoch which preceded

the war. In the prewar decades, European capitalism exercised vigorous leadership in the international economic community. World markets expanded, the gold standard became almost universal, Europe served as the world's banker, Africa became a European colony, Asia was divided into spheres of influence under the domination of European powers, and Europe remained the centre of a growing volume of international trade.

After World War I, however, these trends were reversed. International markets shrank, the gold standard was abandoned in favour of managed national currencies, banking hegemony passed from Europe to the United States, African and Asian peoples began successful revolts against European colonialism, and trade barriers multiplied. Western Europe as an entity declined, and in eastern Europe capitalism began to disintegrate. The Russian Revolution, a result of the war, uprooted over a vast area not only the basic capitalist institution of private property in the means of production, but the class structure, the traditional forms of government, and the established religion. Moreover, the juggernaut unleashed by the Russian Revolution was destined to challenge the historic superiority of capitalist organization as a system of production within less than half a century. Meanwhile, the inner structure of west European economies was tending away from the traditional forms of capitalism. Above all, *laissez-faire*, the accepted policy of the 19th century, was discredited by the war and postwar experience.

Statesmen and businessmen in capitalist nations were slow to appreciate the turn of events precipitated by World War I and consequently they misdirected their efforts during the 1920s by seeking a "return to prewar normalcy." Among major capitalist countries, the United Kingdom failed conspicuously to achieve prosperity at any time during the interwar period. Other capitalist nations enjoyed a brief prosperity in the 1920s only to be confronted in the 1930s with the great depression, which rocked the capitalist system to its foundations. *Laissez-faire* received a crushing blow from Pres. Franklin D. Roosevelt's New Deal in the United States. The gold standard collapsed completely. Free trade was abandoned in its classic home, Great Britain. Even the classical principle of sound finance, the annually balanced governmental budget, gave way in both practice and theory to planned deficits during periods of depressed economic activity. Retreat from the free market philosophy was nearly complete in Mussolini's Italy and Hitler's Germany. When World War II opened in 1939, the future of capitalism looked bleak indeed. This trend seemed confirmed at the end of the war when the British Labour party won a decisive victory at the polls and proceeded to nationalize basic industries, including coal, transportation, communication, public utilities, and the Bank of England. Yet a judgment that capitalism had at last run its course would have been premature. Capitalist enterprise managed to survive in Great Britain, the United States, western Germany, Japan and other nations. Its remarkable show of vitality in the postwar world calls for a closer look at its long-range achievements and the internal working of the system.

Perhaps the most useful index of economic development is the increase in real output per capita (allowing for population growth and for price changes). In the United States over the 120-year period from 1839 to 1959, real gross national product per head increased, on an average, at 1 $\frac{3}{4}$ % per year. At this rate, annual real income doubles every, 40 years and increases sixfold in a century. In Great Britain the annual rate of increase of real output per head was slower than in the United States; from 1839 to 1959 it averaged approximately 1 $\frac{1}{8}$ % per year. Assuming the relatively constant share of national income to labour which has prevailed in the past, a steady increase of from 1% to 2% in per capita real income would eventually eliminate poverty.

II. CRITICISMS AND PROBLEMS

Few observers are inclined to find fault with capitalism as an engine of production. Criticism usually proceeds either from moral or cultural disapproval of certain features of the capitalist system, or from the short-run vicissitudes (crises and depressions) with which long-run improvement is interspersed. What-

ever its faults, historically the capitalist system has led the way from an age of scarcity to an age of potential abundance. Karl Marx, capitalism's most formidable critic, wrote in 1848 that capitalism "... in scarce 100 years has created more massive and more colossal productive forces than have all preceding generations together."

1. Allocation of Resources.—Leaving aside the moral and cultural aspects, we may approach the problems usually discussed in connection with capitalism through the economics of resource allocation and the economics of employment. Economic analysis of resource allocation within the private sector typically assumes a high degree of competition among firms in the same industry. In an industry with many buyers and sellers who are free to enter and to leave the industry, producers will tend to expand output to a point at which current price just covers the cost of producing an additional increment of output, and profits will tend toward a minimum. This hypothesis of pure competition with many buyers and sellers free to enter and to leave an industry suggests the best possible allocation of scarce resources resulting in maximum welfare.

Unfortunately, the conditions required for pure competition are seldom realized, except perhaps in the case of some agricultural commodities of a homogeneous nature produced by large numbers of farmers selling in national and world markets without government regulation. Since the latter part of the 19th century technological innovations have rendered progressively obsolete the assumption of pure competition in industry. Monopolistic competition and oligopoly are typical of a majority of markets in advanced capitalist countries, and in this context the allocation of resources departs from the optimum of pure competition. Government intervention aimed at restoring competition (antitrust policies) has proved generally ineffective for the simple reason that the potentialities of mass production can be fully realized only by firms that are beyond the size compatible with pure competition. (See COMPETITION, ECONOMIC.)

2. Employment of Resources.—Employment of resources, as distinguished from their allocation, is the second major division of economic analysis. According to the Keynesian theory of employment (see KEYNES, JOHN MAYNARD KEYNES), capitalist prosperity requires that current production exceed current consumption by substantial amounts because a sizable part of current income is saved, that is, not spent for current consumption. Because of this withheld income (saving) everyone cannot be employed to produce consumer goods because there would not be enough demand to buy back all the consumer goods produced at full employment. The gap between total income and total expenditure on consumption must be filled by production which is not for current consumption, *i.e.*, by some form of capital formation.

There exists, however, an organic connection between capital formation (production in excess of current consumption) and consumption because the ultimate purpose of capital formation is to increase consumption in the future. This connection imposes definite limitations on the amount of capital formation. Current levels of consumption output can be maintained indefinitely with no net capital formation, that is, with production equal to current consumption. Production can exceed current consumption only if consumption is expected to increase in the future. Moreover, today's success may contribute to tomorrow's failure—greater capital formation today lessens the need for it tomorrow. Abundance of wealth becomes a barrier to abundance of current production. A major boom like that of the 1920s is followed logically, within the capitalist framework, by a major depression like that of the 1930s. Further, the provision of current consumption out of past accumulations of wealth compounds the difficulties because it means that current consumption is in excess of current production, which is the opposite of the condition required for prosperity. Cyclical fluctuations in business since the Industrial Revolution, according to this theory, have resulted from periods of high capital formation and prosperity, followed by periods of low or negative capital formation and depression.

3. Unemployment and Waste.—In view of the foregoing analysis there exists no mechanism within the capitalist process to

insure full employment. The strategic determinant of the volume of employment is the volume of capital formation, which in turn depends on expanding consumption and on fortuitous and historical conditions (such as inventions which lead to major new industries like railways in the 19th century and automobiles in the 20th century). New investment (capital formation) is important in the short run because it disperses income into the hands of consumers whose spending is necessary in order to keep existing productive capacity operating. In other words, a capitalist economy must always be adding new productive capacity if it is to keep its existing capacity in operation. This is another way of stating the accepted proposition that capitalism cannot stand still. It must either move forward or collapse. Stationary socialism would still be socialism, but stationary capitalism is a contradiction in terms. In the absence of a high rate of capital investment, unemployment mounts until the potentially rich community becomes so poor that all the income it produces is currently consumed.

Losses attributable to underutilization of labour and plant capacity are the most serious element in the indictment of capitalism on the score of waste. In the United States even during the prosperous 1920s unemployment ranged from 5% to 15% of the nonfarm labour force, according to W. C. Mitchell: during the 1930s unemployment ranged from 15% to 30% of the total labour force; and after World War II unemployment was often above 5% of the total labour force. In the United Kingdom unemployment in the years 1920 to 1939 was roughly parallel with that in the United States. After World War II, however, when Great Britain developed a "mixed" economy, unemployment did not exceed 5% and generally averaged much less.

4. Exploitation and Inequality. — Since the development of capitalism had profound cultural effects, to evaluate capitalism is to evaluate a civilization in all its aspects. The complexity of such a task is one reason why agreement is not to be expected. Another is that moral and cultural judgments presuppose moral and cultural standards that are matters of individual preference and beyond the range of scientific proof or disproof. All that can be done from a scientific standpoint is to establish the truth or falsity of such statements of fact as may enter into those judgments, and to point out the economic and cultural consequences to be expected from giving effect to them.

The role of exploitation in Karl Marx's assessment of capitalism is somewhat paradoxical (*see* MARX, KARL; SOCIALISM: PRINCIPLES AND OUTLOOK). Eager to set his "scientific" socialism apart from the "utopian" socialism of his predecessors, Marx appears to exonerate the capitalists of exploitation in the sense that workers are said to be cheated through underpayment for their services. Equivalents always exchange for equivalents in Marx's analysis. Wages received by workers are equal to the value of the labour power purchased by capitalists, and commodities are sold by capitalists at their value. The value of all commodities, including labour power, is determined by the socially necessary labour time required for their production. Labour power, however, is a unique commodity in that it is capable of producing values in excess of its own value. Hence, when the capitalist purchases labour power at its value, he appropriates to himself all the surplus value the worker is capable of producing by working longer than is required to produce his subsistence (wage).

What Marx really meant was that the labour market is a power market in which capitalists, possessing a monopoly of the means of production, have a power advantage over capital-less wage earners and therefore are able to appropriate the entire social surplus. While the notion of exploitation is clearly conveyed without being formally incorporated into the analysis, the theory of value and surplus value find their meaning in relation to Marx's leading proposition (which lends itself to empirical verification or refutation depending on the course of history) that capitalism as a system will break down because of contradictions associated, among other things, with the tendency for production capacity to outstrip consumption capacity. With the entire surplus value accruing to capitalists and being converted into expanding productive capacity and with the incomes of workers narrowly restricted by low wages, the stage is set for a falling rate of profit

and for a deficiency of demand to keep the system operating. Consequently, cyclical movements of increasing extent will finally result in a crisis so severe that the capitalist system will collapse. Since exploitation of workers calls forth nothing but ethical disapproval, Marx makes it the basis for the inequality which disrupts the continuity of production and, according to him, results in ultimate breakdown.

Classical economists justified economic inequality on the ground that capital accumulation depended on the savings of the rich out of their wealth. However repugnant inequality was on moral grounds to liberal economists like John Stuart Mill, they were so greatly concerned for economic progress that they accepted inequality as a lesser evil. The ultra-liberal Mill opposed the personal income tax on grounds that it is a tax on savings and therefore an impediment to capital accumulation, which he considered necessary for economic progress.

Modern economic analysis, in keeping with its rejection of some capitalist preconceptions, does not accept so unreservedly as did classical economics the virtue or necessity of individual thrift. In conditions of unemployment, an increase in thrift has a depressing effect on demand and thus leads to a decrease rather than an increase in capital formation. If it is true that under modern conditions thrift frequently impedes rather than fosters the growth of wealth, the chief justification for inequality is open to question. While there may be social and psychological reasons for favouring some degree of inequality in income and wealth, in democratic societies the presumption would seem to favour limited inequalities. This democratic presumption finds expression in highly progressive death duties and income taxes. Death duties have gone far toward eliminating large family fortunes, which formerly could be passed intact from generation to generation. Despite numerous loopholes in tax laws, highly progressive income taxes have gone far toward socializing income without socializing income-earning property.

5. Concentration of Private Economic Power. — The evolution of economic collectivism, which was the fundamental premise of Marx and the basis of his theoretical and practical position, has accelerated in the 20th century under the stimulus of industrial technology and corporate organization. Accompanying the evolution of economic collectivism has been a revolution in the fundamental institution of capitalism — private ownership of the means of production. The prevailing but obsolete theory of private property stems from John Locke (*q.v.*), who justified private ownership of land and other means of production on the right of every man to the "labor of his body and the work of his hands." Locke said a man acquires property in land when "he hath mixed his labor with it." Locke's conception asserts active, functional control as a condition of property ownership.

With the growth of the modern corporation, ownership has become progressively separated from management of the means of production. In 20th-century America, characteristically, the owners of corporate shares are not managers and the managers are not owners. Separation of ownership from management has led to great concentration of power in the hands of nonowning managers, and has reduced nonmanaging shareholders to a functionless status similar to that of bondholders. Although the forms of private ownership remain, its substance has been revolutionized. Locke's concept of property represented the extension of the owner's personality into land or other objects, but there is nothing personal about giant corporations and the pieces of paper which represent shares of ownership in them. Nominal voting rights attach to common stock, but these rights have little meaning to the vast majority of shareholders. Managers rather than shareholders control corporation property, determine its use, and decide how much, if any, of the profits shall be paid out to the "owners."

Since World War II the rapid growth of pension funds, mutual investment funds, and insurance companies has led to further concentration of economic power and, in many instances, to the virtual disappearance of ownership in any meaningful sense. Pension funds, for example, invest heavily for income purposes, in common stock of industrial corporations. Managers of pension funds with large blocks of voting shares in industrial corpora-

tions are in a position to exercise control over the policies of the industrial corporation. In one sense this development has reversed the early 20th-century trend toward de-concentration of share ownership, but it has done so only by rendering meaningless the concept of "ownership." For no one really owns the assets of a pension fund. Industrial workers have contingent claims to the income from pension funds after retirement, but they do not own the assets of the fund any more than do the shareholders or the managers of the corporation which places the assets in the pension fund. Pension fund trustees—mostly large banks in financial centres like New York—control the voting shares held in the pension fund, but the trustees are in no sense the owners of the industrial corporations whose policies they are in a position to control. What has emerged in the pension fund arrangement is a system of power without property, a system beyond property in the means of production, a "paraproprietary society," as one writer labeled it. Changes in property relations affecting capitalist means of production have been so fundamental as to raise the question whether the resulting system should continue to be called "capitalist."

Power without property has long been characteristic of political office, but it is a relatively recent phenomenon for economic management. In assuming some of the characteristics of political leaders, capitalist managers under big business parallel the position of managers of trusts and factories in the Soviet Union. Both hold power by virtue of office rather than of ownership. That power should follow management rather than ownership is perhaps inescapable in the conditions of modern large-scale technology and organization, whether the collectivism be of a private (American) or public (Russian) type. Nevertheless, in a democratic society massive concentration of power in the hands of a self-perpetuating oligarchy of corporation managers raises a host of questions, including how this power can be circumscribed and directed into channels where it will serve rather than threaten the general welfare.

By replacing market prices with administered prices of a monopolistic character, giant corporations have undermined the freely competitive market in numerous industries. Despite the creation of government agencies and other countervailing forces designed to curb extortionate practices, modern industrial capitalism operates in an altogether different world from that of the "sovereign consumer" of classical economics. Almost by definition the major decisions concerning production and distribution in a capitalist economy are made in the private sector, yet in the absence of strong competition there are no effective curbs on the power of corporate management. A. A. Berle described these corporation managers as "non-statist civil servants" and has suggested that a major abuse of power will bring government into the picture to remedy abuses, since the ultimate recourse of democratic society is to make all holders of power accountable to the people and their elected representatives. Thus far governments in capitalist countries have not attacked directly the greatest abuse of power by private management, the withdrawal from use of the socially necessary means of production in periods of depression. Probably the survival of capitalism lies in preventing, by indirect means such as monetary and fiscal policies, the conditions which lead to serious depression. A direct attack by government on this major abuse probably would mean the end of capitalism and the establishment of some form of government collectivism.

6. Public v. Private Sector.—The rationale of resource allocation under capitalism is that the people decide what should be produced (1) through the market forces of supply and demand operating within the private sector; and (2) by allocating from the private to the public sector, through taxes and bond issues, the resources the public believe should be in the public sector for schools, roads, defense, hospitals, urban renewal, public health, welfare and other public needs. The market theory of resource allocation within the private sector is the central theme of classical economics. The criterion for allocation between public and private sectors is formally the same as in any other resource allocation, namely, that the community should receive equal satisfaction from a marginal increment of resources used in the public and

private spheres. Unfortunately, investment in the public sector yields no capturable monetary return similar to profit from private investment. As a result, the formal requirement of equal returns at the margin for private and public investment does not lend itself readily to operational testing. Nevertheless, many economists have asserted that there is substantial, perhaps overwhelming, evidence that total welfare in capitalist United States, for example, would be increased by a reallocation of resources to the public sector—more schoolrooms and fewer shopping centres, more public libraries and fewer automobiles, more hospitals and fewer bowling alleys. Affluence in the private sector, in this view, contrasts with parsimoniousness in the public sector.

Capitalism has a bias against the public sector for two reasons. First, all products and income accrue initially to the private sector while resources reach the public sector through the painful process of taxation. Public needs are met only by sufferance of consumers in their role as taxpayers, whose political representatives are acutely conscious of their constituents' tender feelings about taxation. That people know better than governments what to do with their income is a notion more appealing than the contrary one, that people get more for their tax money than for other types of spending. Only in acute national emergencies are public outlays likely to increase substantially.

Second, the pressure of private business to sell leads to the formidable array of devices of modern salesmanship which influence consumer choice and bias consumer values toward private consumption, whereas no similar pressures are marshaled on behalf of public needs. Under opulent capitalism, advertisers contrive all manner of means to sell gadgets that will satisfy the wants thus created. Hence, much private expenditure goes for wants that are not very urgent in any fundamental sense. The corollary is that many public needs are neglected because these superficial private wants, artificially generated, compete successfully for the same resources. Capitalist society, some argue, would be enriched by converting some of its persuasive salesmen into gifted school teachers.

A comparison of resource allocation to the public and private sectors under capitalism and under socialist collectivism is illuminating. In a collective economy all resources operate in the public sector and are available for education, defense, health, welfare and other public needs without any transfer through taxation. Private consumption is restricted to the claims that are permitted against the social product, much as public services in a capitalist economy are limited to the claims permitted against the private sector. In a collective economy public needs enjoy the same sort of built-in priority that private consumption enjoys in a capitalist economy. In the Soviet Union teachers are plentiful, but automobiles are scarce, whereas the opposite condition prevails in the United States. The percentage of national product going to education in the Soviet Union during the 1950s was twice that in the United States. Within this more generous Soviet allocation to education, a much higher proportion was devoted to mathematics, science and engineering in keeping with Soviet emphasis on rapid economic and scientific development.

Different resource allocations to private and public sectors reflect different economic structures. They also are major determinants of rates of economic growth. In the short run, resources withheld from private consumption can be allocated to capital formation. Under collective economic planning in the Soviet Union one-fifth to one-fourth of the total national product was invested in capital formation, with emphasis on heavy industry. After World War II, Soviet rates of industrial growth were from two to three times greater than in the United States, a more highly industrialized nation where capital formation constituted a much lower proportion of total national product. The strong arm of dictatorship is, of course, able to maintain high rates of investment at the expense of low levels of consumption. Yet with each succeeding year that heavy industry is expanded, the possibility of simultaneously increasing both consumption and heavy industry is enhanced. Thus consumption levels in the Soviet Union gradually rose even though they remained below the standards in advanced capitalist nations.

Many economists maintain that, in the long run, larger resource allocation to the public sector, especially in education, basic research, and investment in people generally, heightens the prospects for sustaining high rates of economic growth. Historically, changes in technology arising from scientific discovery and innovations have been much more important for economic growth than successive additions to existing types of capital assets. Scientific and technological advances in turn are functionally related to investment in human capital, which falls almost entirely within the public sector. Hence, the argument runs, an economy that is generous in its allocations to the public sector, wisely managed, has the potentiality of outstripping an economy that is sparing in its allocations to the public sector. In 1957 the dramatic Russian sputnik episode, which opened the space age, shocked the capitalist world. Economists pointed out that Soviet achievements in launching earth satellites and intercontinental ballistic missiles arose from the same source as its high rate of economic growth—a generous allocation of resources to the public sector. Capitalism's public poverty in the midst of private plenty, it was argued, created a social imbalance that impeded economic growth.

7. The Future of Capitalism.—Karl Marx was the first to formulate correctly the fundamental scientific question, namely, whether or not there are observable tendencies, inherent in the capitalist process as we know it, which, if allowed to work themselves out fully, would destroy the capitalist and produce the socialist system. The coexistence of capitalism and communism in the 20th century places the issue of the future of capitalism in a somewhat different perspective from that of Marx. Even if the apparent contradictions of capitalism have been overcome through fiscal, monetary and other anticyclical stabilization policies, the spectre of collectivism still hovers over the capitalist world both in terms of strong collectivist tendencies within contemporary capitalism and also in the high rates of economic growth in communist countries. The relative strength of the two systems in the latter decades of the 20th century may well turn on which type of economic system is capable of faster growth, with victory to the swifter. As noted above, communist Russia grew two or three times faster than capitalist America following World War II. Soviet successes in economic development, space exploration and military prowess were too impressive and persistent to be dismissed lightly and they made a strong impression on the uncommitted peoples in the populous underdeveloped areas of the world. The growing economic power of the Soviet Union enabled it to provide economic aid and technical assistance—items clearly in the public sector—to underdeveloped countries. Capitalism may continue to grow at 3% per year, but, some observers declared, if Soviet growth continues at 7%, the uncommitted peoples may prefer the collectivist to the capitalist type of economic organization. In this event, relative but not absolute decline would characterize the future of capitalism.

Predictions concerning the survival of capitalism are, in part, a matter of definition. One sees everywhere in capitalist countries a shifting of economic activity from the private to the public sphere. None of the five great events of the first half of the 20th century—World War I, the Russian Revolution, the great depression, World War II, and the Chinese revolution—were favourable to the future of capitalism. By the 1960s the process of transformation had gone so far that capitalist economies bore little resemblance to classical capitalism of the 19th century. Exigencies of technology, organization and development had suggested to many economists that in the future the public sector would occupy an expanding role in the mixed private-public economies still called capitalist. At the same time private consumption appeared destined to increase in communist countries. The two economic systems seemed to be drawing closer together by changes converging from both directions. Yet significant differences in the economic structures still existed. It seemed reasonable to assume that the society which invested more in people would advance more rapidly and inherit the future. In this important respect capitalism, in the eyes of some economists, labours under a fundamental but not inescapable disadvantage in competition with collectivism.

(D. D.)

CAPITAL LEVY. The strict meaning of this term is a direct tax assessed simultaneously on the capital resources of all persons possessing taxable wealth in excess of a minimum value and paid at least partly out of capital resources. This definition excludes death duties because in any given year they are necessarily limited in application. Various taxes have been popularly included under the capital levy term, even though they were assessed on current incomes or though their burden did not exceed the taxpayers' capacity to pay out of current income. Thus the "special contribution" introduced by Sir Stafford Cripps in Great Britain in his 1948 budget was assessed on the basis of current incomes, but was popularly called a capital levy because in the case of higher incomes its burden, together with that of income tax and surtax, was in excess of 20s. in the pound, so that a number of taxpayers had to pay it out of capital. On the other hand, in a large number of instances during the interwar period and also after World War II the annual installments of taxes levied on capital assets were well within the taxpayers' capacity to pay them out of current incomes, because the payment was spread over long periods.

British Experience.—Interpreted in the sense of being simply a tax assessed on capital assets, capital levy has a very long history. In England some of the earliest-known taxes were assessed on capital assets. The Danegeld during the 10th and 11th centuries and the land tax raised in the kingdom of Wessex in the 7th century were assessed according to the area of land, regardless of its yield. For a long time, until the 17th century, a tax on movable goods was assessed on the taxpayers' possessions. On many occasions parliament voted several "tenths" or "fifteenths" of movable goods, payable in a single year, for financing wars. The burden of this tax in such years may well have exceeded the taxpayers' current incomes, so that it constituted a capital levy in the strict sense.

In its narrowest sense capital levy aims at achieving the surrender of a relatively substantial proportion of the taxpayers' wealth, to enable the government to cope with some nonrecurrent major emergency, or to bring about with one stroke a major redistribution of wealth, or a major reduction of the note circulation or of the national debt. It is in this latter sense that the idea gained popularity in Great Britain during and after World War I.

The first suggestion for a capital levy of this type in Great Britain was made by W. Watson Rutherford in the house of commons on Nov. 19, 1914. He advocated this tax as an alternative to an increase of the income tax. The idea received much support from all parties and also from academic economists. In his evidence before the Colwyn Committee on National Debt and Taxation, John Maynard Keynes (*q.v.*) declared that he would prefer even a capital levy to an income tax in excess of 6s. in the pound, even though he was fully aware of its grave disadvantages. A. C. Pigou also favoured the levy during the early postwar period. Labour politicians—Philip Snowden among others—advocated it originally as a convenient way of reducing the national debt. It was only gradually that the anticapitalist character of the proposal gained prominence, as the postwar slump materially weakened the economic argument in favour of such a tax, because a large propor-

tion of the wealth created during the war and the postwar boom was wiped out, and inflation was a matter of the past. The device provided, however, a popular political slogan during the general elections of the 1920s, and eventually it became almost entirely identified with the Labour party.

Because the first Labour government did not have a majority in the house of commons it did not emphasize the political and social aspects of capital levy. It appointed the Colwyn committee with the object of considering the question of such a levy in relation to national debt and taxation in general. The report of the committee, issued in 1927, emphatically rejected the idea, largely because it anticipated strong resistance on the part of the taxpayers. The report concluded that "unless a levy were accepted with more goodwill than it would be possible to anticipate on the present conditions it would be highly injurious to the social and industrial life of the community." Even if the levy were well received "the relief from debt which it offers would be insufficient to justify an experiment so large, difficult and full of hazard."

There was a minority report in favour of the levy, subject to reservations. Capital levy disappeared from the official program of the Labour party after the publication of this report and there was no attempt to introduce it under the second Labour government of 1929-31. Individual Socialist politicians continued to press for it, however.

The idea was revived after World War II, and was put into practice on a modest scale by Sir Stafford Cripps in 1948, presumably in order to make his policy of wage restraint and austerity more acceptable to government supporters. As there was no time for the highly involved operation of a valuation of capital assets, it was levied in the form of an additional income tax assessed on incomes of more than £2,000 a year, the rates charged being 2s. for the first £250, 4s. for the next £500, 6s. for the next £1,000, 8s. for the next 13,000 and 10s. on incomes in excess of £6,750. For most of those taxpayers already paying surtax this meant a tax of more than 20s. in the pound so that part of the levy at any rate had to be paid out of capital. Throughout the budget debate government spokesmen emphasized that this tax would not be repeated. The yield of this levy was £79,400,000 during the first fiscal year. Up to March 1959 it produced £110,400,000.

Other Countries. — Capital levies were introduced in a number of European countries both after World War I and after World War II. During 1919-20 the device was adopted in Germany, Czechoslovakia, Austria, Hungary, Italy, Poland and Greece. In all these countries economic conditions were so chaotic that the majority of the taxpayers concerned were prepared to accept a capital levy as a lesser evil, for the sake of achieving financial stability.

In Germany there was already in 1913 a tax on capital called a defense levy. In 1920 a more substantial levy called the National Distress contribution was adopted. Its effect was completely wiped out, however, by the rapid progress of inflation. Italy, after toying with the idea of a forced loan assessed on capital, adopted an extraordinary tax on capital in 1920. Its rate varied from 4½% to 50% payable in 20 years. This meant that even at its highest rate the majority of taxpayers were able to pay it out of income, even though it was assessed on their capital. In 1936 Italy introduced a rearmament levy representing 5% of capital values. The schedule relating to real property yielded some 7,000,000,000 lire by March 1936, against an estimate of 8,700,000,000 lire. Hungary adopted a levy in 1938 partly to finance rearmament and partly to effect social improvement. It was called an investment contribution and was payable within five to six years.

During and after World War II several continental countries introduced taxes on capital the extent of which came, however, well within the annual income of most taxpayers. The Swiss federation introduced a defense tax in 1941 which continued till 1959. The Swiss cantons have capital taxes, the basic rate of which is under 1%. After World War II the German Federal Republic adopted an equalization of burden levy at a rate of 50%, payable over 30 years. Austria, too, adopted a similar levy the rate of

which varied from 12% to 33% payable within 8 to 22 years. Smaller taxes of a similar nature were adopted by Finland, which first introduced a levy on the conclusion of the war with Russia in 1940. Belgium, and the Scandinavian and other countries. In Italy there is a capital element in the corporation tax.

Outside Europe, Ceylon introduced in 1959 a tax assessed on capital at rates varying from ½% to 2% per annum and India in the same year adopted a similar tax of 1% to 2% per annum. In both these countries this tax is additional to very high taxes on current incomes, so that many taxpayers have to pay it out of capital.

Arguments Pro and Con.—It is a matter for argument whether capital taxes at a sufficiently low rate to constitute a more or less permanent source of revenue are preferable to income taxes. In most instances the device was chosen in preference to income tax as a gesture to satisfy the clamour for social justice rather than for fiscal or economic considerations. The economic argument usually put forward in their support is that a tax levied on capital penalizes idle wealth and is therefore an incentive for the productive employment of wealth. The most popular argument is that capital taxes are directed mainly against classes which seek to avoid the effect of high current taxation on their standard of living by living on capital.

There are strong arguments against capital taxes, even if their rate is low, on the ground of the difficulty of making a fair valuation of capital assets. It would be necessary to make frequent revisions of the assessment in order to avoid grave injustices resulting from substantial changes in capital values. Yet in a number of the above instances the levy was assessed on the basis of capital values as of a given date and continued to be collected over a period of years regardless of the fluctuations of those values. The main argument against any tax on accumulated wealth is that it tends to discourage saving.

When it comes to the case for and against a substantial capital levy which has to be paid out of capital, the balance of argument is now considered to be overwhelmingly against it. Unless the payment is spread over a number of years it necessitates large-scale realizations of assets, leading to a disastrous slump of their prices and spelling ruin not necessarily confined to those directly affected. It is bound to cause grave dislocation in the national economy. From a purely fiscal point of view such a levy amounts to killing the goose that lays the golden eggs. The receipt of an abnormally large sum is bound to be followed by a substantial decline in the current yield of taxation during the following years. The argument that was so popular during and immediately after World War I, that it would be worthwhile to make sacrifices for the sake of a drastic reduction of the national debt, has long lost its popularity because in the meantime the inevitability of a gradual increase of the debt has come to be accepted. Nor does the argument presenting capital levy as an alternative to higher taxation of current incomes carry any conviction since it was found possible during and after World War II to maintain very high direct taxation of current incomes. The redistribution of wealth effected by such prolonged high taxation, combined with high death duties, has gone a long way toward weakening also the argument in favour of capital levy as a means of social justice.

The social argument formerly used in favour of a capital levy is now used in support of a capital gains tax. Such a tax is in operation in the United States, in the Scandinavian countries and in some other continental countries, but in every instance it is levied on realized profits only and not on increases of capital values, and so cannot be regarded as a capital tax proper. In Great Britain, too, the government decided in 1961 to introduce a capital gains tax confined to profits on stock exchange speculation and on certain transactions in real property.

The fact that capital levy in the sense of a heavy tax on capital assets that is expected to yield a substantial amount is no longer advocated by any responsible political party should not be regarded as proof that the idea is now dead and buried. It is likely to be revived in case of major emergencies or in countries where left-wing governments gain power. Once the taxation of current incomes and even of realized capital gains has reached its limits it would be tempting for such governments to impose a capital levy,

or even a series of capital levies, as a form of expropriation in stages. The temptation is likely to be particularly strong where a considerable proportion of capital assets is owned by foreign investors.

CAPITAL PUNISHMENT is the execution of a criminal pursuant to a sentence of death imposed by a competent court. In Roman law the term had a wider significance and meant, besides the *summum supplicium* (death), those punishments that affected the *caput* (status) of the citizen, namely, banishment (*acquā et igni interdictio*) under the republic or *deportatio* under the empire, and condemnation *in opus perpetuum* (a life sentence to hard labour).

Capital punishment was once a common penalty throughout the world. It was inflicted for a large number of crimes, especially during the middle ages and the early modern period, and was often aggravated by torture. Burning at the stake, breaking on the wheel and slow strangulation were methods commonly used. The attitude of legislative authorities toward human life is reflected in the frequent application of the penalty to even petty property offenses. In England during the 18th century death was decreed for several hundred specific offenses, mostly against property.

The turning point came in that century, when the rise of a democratic political philosophy led to political struggles against the old regimes. The writings of Montesquieu and Voltaire and, especially, C. B. Beccaria's (*q.v.*) *Essay on Crimes and Punishments* (1764) proved to be a powerful stimulus to reform. The growing strength of the industrial working class and the humanitarian movement also played important roles. The number of offenses punishable by death was reduced in all leading countries. In the United States, where during colonial times a dozen or more crimes had been punishable by death, Pennsylvania limited such punishment to murder in the first degree in 1794, and other northern states adopted the same principle. In England, under the influences of Jeremy Bentham and Samuel Romilly (*qq.v.*), the number of capital crimes was reduced to 15 by 1834, and in 1861 to 4. Penalties involving torture disappeared and the principle that the punishment should aim solely at the swift deprivation of life, whether by the guillotine (in France, from 1792), the garrote (in Spain), the headsman's axe (in Germany) or by fracturing the neck by hanging (in England), was firmly established. Where formerly the penalty was generally mandatory upon conviction, a trend began to develop toward making an alternative punishment, usually life imprisonment, available to the court. By the middle of the 20th century, mandatory death sentences were relatively rare in most countries; in the United States they were required only in the state of New York and in the District of Columbia in the case of premeditated murder. Since 1835, when New York abolished public executions (England did so in 1868), these spectacles have disappeared in more advanced countries in favour of executions within a prison that are attended only by certain officials and perhaps by witnesses required by law.

Extent.—In the early 1960s capital punishment could be inflicted on a criminal for certain crimes in a majority of jurisdictions throughout the world. Even where it had been abolished as a penalty for crimes committed during peacetime it was retained for treasonable crimes occurring in times of war or emergency, or for crimes in military law. Since discussions about the death penalty usually centre about its use in peacetime, this article will focus on that aspect of the problem.

In the early 1960s death was a possible punishment in Canada and in the United States under the federal code as well as all the states of the union except the following: Michigan (abolished in 1847 except for treason); Rhode Island (1852, except for murder by a prisoner serving a life sentence); Wisconsin (1853); Maine

(1876; 1887); Minnesota (1911); North Dakota (1915, except for treason or murder by a prisoner sentenced for life); Alaska (1957); Hawaii (1957); and Delaware (1958; restored, 1961). Puerto Rico abolished it in 1929, and the Virgin Islands in 1957. In Latin America it existed in Bolivia, Chile, Cuba, Guatemala, Haiti, Honduras, Nicaragua, Paraguay, Peru and El Salvador, but had been abolished in Costa Rica (1880), Colombia (1910), Panamá (1903), Uruguay (1907), Venezuela (1863), Ecuador (1897), Argentina (1922), Brazil (1891), Dominican Republic (1924), the federal code of Mexico (1928), and in all but eight states of the Mexican federation.

In Europe the death penalty was found in all communist states, the Balkans, the United Kingdom, Ireland, France and Spain. It had been eliminated in Sweden (1921; last execution, 1910); Finland (1949; last execution, 1822, except during the civil war of 1918 and World War II); Norway (1905; last execution, 1876, except for "quislings"); Denmark (1933; last execution, 1892; same exception); Netherlands (1870; last execution, 1860; same exception); German Federal Republic (1949); Iceland (1944); Austria (1950); Italy (1944); Portugal (1867); and Switzerland (1942; last execution, 1940). Belgium and Luxembourg kept the penalty and occasionally imposed it, but Belgium's only execution after 1863 occurred in 1918 until numerous executions of enemy collaborators took place shortly after World War II; Luxembourg's last execution occurred in 1822.

All African and Asian countries retained capital punishment except Israel (abolished in 1954 except for treason and Nazi collaborators) and Nepal (1931); in Australia, only Queensland had abandoned it (1922; last execution, 1911). New Zealand abolished it in 1961, having previously done so during 1941–50.

Crimes Punishable by Death.—Certain homicides are capital offenses in all countries that have retained the death penalty, but there are numerous variations in the definition of capital homicide. In the United States it ordinarily means murder in the first degree, *i.e.*, the premeditated and willful killing of a person, and (except in federal law) homicide in connection with certain serious crimes, usually arson, robbery, rape or burglary. In England and Wales, from 1957, capital murder included a homicide in furtherance of a theft; by shooting or by causing an explosion; while resisting, avoiding or preventing a lawful arrest, or while effecting or assisting escape or rescue from legal custody; murder of a police officer, or murder by a prisoner of a prison officer or of someone assisting him in the execution of his duties; and a murder committed by a person with a previous conviction for the same offense. In France it covered assassination; parricide; poisoning; perjury resulting in a death sentence; ill-treatment or kidnapping of a child under 15 years resulting in its death; premeditated infanticide by someone not the mother; homicide connected with another serious crime; and intentional arson leading to another's death. In Yugoslavia it included murder; the killing of an official or public employee in order to undermine the republic or socialist progress; and the killing of several people by intentional use of fire, inundation, explosives, poison, poisonous gases, motor power, electric or other energy, by an act dangerous to the public, by a dangerous instrument, or by destruction or injury to industrial safety devices. In Japan it included murder and parricide, and in the U.S.S.R., from 1954, ordinary murder.

As regards other than capital crimes there were considerable variations among the many jurisdictions in the early 1960s. In the United States, federal law made treason, espionage and rape capital offenses. Kidnapping, usually associated with a demand for ransom or harm to the victim, had been made capital in 30 states, mostly from the early 1930s. Treason was capital in 24 states; rape, variously defined, in 21; robbery in 9; arson in 5; burglary in 4; train wrecking in 4; perjury in a capital case in 4; bombing and the use of machine guns in crime in 4; and assault by a prisoner serving a life sentence in 3. A few other crimes were also occasionally threatened with death in some states. In England and Wales, high treason, piracy and the destruction of public arsenals and dockyards were punishable by death. In France, those committing treason or espionage; recidivists, twice previously sentenced to life imprisonment; those who illegally re-

strained and physically tortured a person; and those who committed armed robbery or carried a weapon in the vehicle used in perpetrating the crime could be sentenced to death. The situation in communist countries could be inferred from the law of Yugoslavia, which provided a nonmandatory death penalty for robbery when the victim was killed or seriously injured; plunder of public property, by an organized group or when it could have serious consequences for the economy; counterrevolutionary activity undermining defense; armed insurrection; espionage; service in an enemy army; organizing armed bands, terrorists, weapons or propaganda in the republic; destruction of important economic installations or injury to means of production in order to undermine the government: sabotage, including failure to work or delaying work; violence against a member of a representative body, military official or public employee to hinder him in the exercise of official or political duties; burning or destroying a building or the property of such a person for the same purpose; organizing gangs, conspiracies or groups to commit any of the above offenses, or committing acts preparatory to doing so; failure by a responsible person to observe regulations governing construction work; endangering public circulation on bridges and streets by reckless driving, use of unlit vehicles, placing obstructions, etc.; endangering railroad, ship or air travel; and failure by a responsible person to keep public transport facilities in order. The laws of all countries governing the conduct of military personnel provided the death penalty, at least for serious offenses in wartime such as treason, espionage, desertion, looting, etc.

Lack of mental responsibility, however defined, was generally a bar to a sentence of death. Many jurisdictions also forbade a death sentence to be passed on a child, usually under 14, 16 or 18 years of age, and some countries excluded women.

Executions.—The fact that the death penalty is provided by law does not mean that it is generally imposed or executed. It is a rare punishment! either because the crimes involved are relatively uncommon or because alternative penalties are chosen by the courts. The best way to disclose the characteristics and trends of capital punishment is by examining the data on executions.

In the United States such data have been systematically compiled since 1930. During 1930–60, 3,724 persons were executed—3,225 for murder, 434 for rape, 23 for armed robbery, 18 for kidnapping, 11 for burglary, 8 for espionage, and 5 for aggravated assault. Only 31 were women; all but two (kidnapping, espionage) of these were sentenced for murder. Fifty per cent of those executed for murder, 90% of the rapists and 46% of the rest were nonwhite. Only 31 were executed under federal law: 15 for murder, 2 for rape, 1 for armed robbery, 5 for kidnapping and 8 for espionage. Sixty per cent of the executions took place in the 17 southern states, including all but two of those for rape, and all of those for burglary. The unequal application of the penalty, greatly out of proportion to the relative criminality of racial groups in the south, is seen from the fact that 9 out of 10 rapists, all burglars and 3 out of 4 robbers were Negroes. No death-penalty state was free from executions, but the total number ranged from 1 in New Hampshire and South Dakota to 358 in Georgia. In addition, the army and air force carried out 159 executions, 148 of them during 1942–50. Of the total, 106 were for murder, 52 for rape and 1 for desertion. The navy had executed no one since 1842.

There has been a decline in the annual number of executions in the U.S. Comparing the period 1930–34 with that of 1956–60, the annual average dropped in the northeastern states from 31 to 7, in the north central states from 21 to 3, in the southern states from 84 to 36, and in the western states from 19 to 11, in spite of a tremendous population increase, especially in the west. A part of the reason may be the decline in murder rates, but their decline has been much less than the fall in executions.

Shifts in the method of execution also occurred, prompted by a desire to find the most expeditious and "painless" method. Traditional hanging, used before the invention of the electric chair in 1888 (New York), was still used in 1930 by 19 states and the federal government, but 19 states and the District of Columbia had adopted electrocution and Nevada (1924) the gas chamber; Utah permitted the victim to elect shooting or hanging. By 1961

only 6 states used the gallows, 11 gas. Utah its old system of choice, and the federal government whatever method was employed in the state where the prisoner was executed; the rest used electrocution.

During 1900–49, 632 persons were executed in England and Wales for murder; of these, 11 were 19-omen. During the same period, 1,210 persons were sentenced to death, including 130 women. The percentage of death sentences executed each decade varied for men from 64% in 1920–29 to 47% in 1930–39, and for women from zero in 1910–19 to 18.5% the previous decade. From 1900 to 1913, in France, 5,388 convictions occurred for capital homicide, but death sentences were imposed in only 6.3% of the cases, and of these 338 only 78, or 23%, were executed. Between the two world wars, 1919–38, 555 (8%) of the 6,960 convictions resulted in death sentences, of which 176 (32%) were executed. During 1945–56, 431 sentences were pronounced and 155 executed, or 36%.

The postwar settlement with enemy collaborators resulted in a great number of executions in the occupied countries. From Aug. 1944 to Oct. 1946, 4,783 persons were executed in France; in Norway there were 37 executions, the last in 1948. In Denmark, Belgium and the Netherlands there were also large numbers of cases.

Arguments Pro and Con.—Arguments for or against the death penalty are of two kinds. Some are categorical assertions based on traditional sentiments and beliefs. The claims that man's innate sense of justice requires that a murderer should lose his life, or that man has no right to take life, which the Creator alone may dispose of, fall into this class; yet it is obvious that the "innate sense of justice" is a variable thing, since the world is sharply divided between countries that have abolished the death penalty and those that have retained it. Furthermore, many countries that once thought it "just" to burn witches, to bury adulterous women alive and to break robbers on the wheel now find it "just" to execute only traitors and murderers. As for man's right to take life, the need for national defense has caused no nation to refuse to send its sons to death against an enemy, and those who regard some criminals as dangerous to the community find little difficulty in advocating the use of capital punishment.

There is another class of arguments, which are utilitarian or empirical in nature. Those who use them claim that capital punishment produces certain demonstrable effects or serves some demonstrable purpose. They mainly focus on the belief that it has a unique power to deter people from committing crimes. Life imprisonment, it is said, would not be equally effective; furthermore, it would expose prison staffs and fellow prisoners to dangerous murderers; and the risk later extends to the community, since such persons may escape or be pardoned or paroled; further, as long as life terms are in prison they are an economic burden on the state. The death penalty, it is said, even has eugenic value; and without it, lynchings and vendettas might occur.

Opponents challenge the validity of these arguments. They say that there is no proof that capital punishment is more deterrent or protects the community better than does life imprisonment. Errors of justice could lead to the execution of innocent people, which would be intolerable. Sterilization would effectively prevent procreation. In well organized prisons, prisoners would be economic assets. The discriminatory or unequal use of the death penalty causes it to be applied mostly to the poor and defenseless. Its existence complicates the administration of justice, lengthens trials, may lead to unjustified verdicts and greatly increases the burden on appellate courts and pardon authorities.

Regarding deterrence, it is well established by statistical studies that (1) when comparisons are made between contiguous states with similar populations and similar social, economic and political conditions—some of these states lacking and others retaining capital punishment—homicide rates are the same and follow the same trend over a long period of time, regardless of the use or nonuse of capital punishment; (2) the abolition, introduction or reintroduction of this penalty is not accompanied by the effect on homicide rates that is postulated by the advocates of capital punishment; (3) even in communities where the deterrent effect

should be greatest because the offender and his victim lived there and trial and execution were well publicized, homicide rates are not affected by the execution; (4) the rate of policemen killed by criminals is no higher in abolition states than in comparable death-penalty states. Capital punishment, then, does not appear to have a specific influence on the amount or trend of the kind of crime it is supposed to deter people from committing.

It is evident from statistical studies and the reports of prison officials that imprisoned murderers are among the best behaved prisoners and that they rarely commit new crimes—almost never a new homicide—if released. Though very rare, homicides in prison by murderers, whose death sentences were commuted, have been known, but the vast majority of such crimes are committed by prisoners serving sentences for crimes other than homicide, and when prisoners serving sentences for robbery, burglary or theft are paroled they are later convicted of new crimes 10 to 15 times more often than are paroled murderers.

Executions of innocent persons have undoubtedly occurred, even though rarely, and with the decline in the number of executions and the increasing substitution of imprisonment, the likelihood of such errors is small. That the existence of the penalty may induce a person to seek execution as a devious method of suicide is apparently an accepted fact, rare as such cases may be. The fear that abolition of the death penalty may cause people to take the law into their own hands is unfounded; lynchings have been most frequent in states that have most often employed execution, and the vendetta, still practised in various parts of the world, is mostly confined to countries that have capital punishment.

The Abolition Movement.—Rare and short-lived experiments with abolition occurred in ancient and medieval times, but an effective movement can be said to date from the time of Beccaria. Thirteen of the jurisdictions that had abolished capital punishment by 1960 had previously ceased to apply it for peacetime offenses in the 19th century, and 20 more since 1900. Sporadic returns to the penalty had occurred in some of these states after an earlier experiment with abolition, just as sporadic experiments with abolition had occurred in several jurisdictions that had the penalty in 1960. Restoration was usually due to alarm over some brutal crime or an increase in criminality; its beneficial effects have never been demonstrated. All in all, the trend toward abolition has continued to grow in the peacetime codes of many nations.

CAPITAL STRUCTURE, a term used to indicate the total amount and type of permanent capital invested in a business concern. Capital structure is not the same as a firm's financial plan, which shows the source of all assets used in a going concern and thus includes short-term as well as long-term borrowings.

A business firm's capital structure includes all outstanding capital stock and surplus, together known as net worth, as well as long-term creditor capital. All classes of capital stock are included in net worth, plus all classes of surplus accounts and certain reserve accounts, minus all operating or capital deficits. Other items included in the capital structure are pension fund liabilities, deferred income tax arising out of the use of accelerated depreciation, and intermediate-term loans. Some analysts also include a money figure representing an estimate of the capitalized value of long-term leases. Valuation reserves, such as a reserve for depreciation, would not be included. (O. R. G.)

Differences in Terminology.—There are, of course, varia-

tions in the detail of approach, not only as between different investment analysts but as between Great Britain and the United States. In the latter country some analysts would regard financial facilities as permanent if committed for more than one year. In Britain, any period from 1 to 5 years would be considered short term; 5 to 15 years would be medium term; and over 15 years, long term. The distinction is of importance particularly concerning the issue of loans of whatever type. Some analysts would be prepared to include short-term borrowing in the capital structure, while others would take a contrary view. Again, in the United States, some analysts would include in the capital structure a figure, admittedly estimated, representing the capitalized value of long-term leases when property has been the subject of sale-cum-lease back arrangements. In that country, too, some would exclude depreciation, while in Britain such a reserve would be admitted.

There are differences in terminology between the two countries which merit noting at this stage. Bonds in the United States are the debentures of Great Britain. Although the word bond is often used in Britain, it frequently refers to foreign government issues or is used indiscriminately to mean a debenture. On the other hand, debenture, when used in the United States, corresponds to what is known in Britain as an unsecured loan note. It is the practice in the United States to refer to bonds and preference stocks obviously ranking before the equity as senior securities or charges. Senior, in this context, is not used in Britain, but a recognized and accepted term is prior charges and capital.

By reason of the very nature of business growth, capital structure must fluctuate continually, although the nominal capital of a company may be relatively constant. Additional resources are generated from profitable trading operations and profits are "combed back" or "plowed back" into the business, appearing in the balance sheet as reserves or cash, or some form of investment such as (in Great Britain) tax reserve certificates or treasury bills. Sometimes, however, the dynamic expansion of a firm is insufficient to provide all its capital requirements from its own profit-making capacity. In such cases, further capital can be raised by means of a rights issue. The essentials of capital structure are, therefore, loans and prior charges, equity and reserves. (GA. S.)

Variations in Practice.—The capital structures of different firms and industries vary widely. Financial managers consider industry capital structure patterns in evaluating and designing a plan for a specific company, taking into consideration the financial and operating characteristics of the firm. Executives differ in their attitude toward risk, and exercise considerable discretion when adding to business risks through using leveraged capital structures. The ideal capital structure is one that provides sufficient capital to provide for efficient and profitable operations, a maximum rate of return with a minimum of financial risk, and a minimum dilution of control.

In the period following World War II, financial managers showed a greater willingness to use debt as a means of offsetting the effects of inflation. Another influence working in the same direction was the widespread belief in a growing economy. At the same time, tax rates and regulations had the effect of easing the burden of meeting income and capital maturities.

The use of borrowed funds or preferred stock is known in the U.S. as "trading on the equity." The term is not commonly used in Great Britain, but the practice is common. The extent of trading on the equity can be measured by the proportion of fixed income capital to total capital structure or can be measured by the leverage (or gearing as it is known in Britain); *i.e.*, the ratio of debt plus preferred stock to equity capital. The customary reason for trading on the equity, when the company is not obliged to do so, is in the hope of employing the senior funds at a rate of return higher than their cost in order to increase the return on the investment of the residual owners. The investment of the common stockholders serves as a protection to both the income and principal of the bondholders. Stockholders thus "trade" on the strength of their "equity." If earnings are high, they profit by the transaction; if earnings are poor, they lose by having to pay more in interest than the added investment earns. In a capital

structure of \$100,000, \$50,000 of which represents bondholders' investment at an interest rate of 5%, and \$50,000 representing equity, total earnings of \$10,000, before interest but after taxes, would represent a 10% rate of return on the capital structure. The bondholders would receive 5% and the equity would earn 15%, reflecting the different nature of their earnings claims and the effect of leverage. Stockholders also risk partial or complete loss of their own investment if conditions grow so bad that the corporation is unable to fulfill its contractual obligations to bondholders.

The use of financial leverage involves a compromise between the liquidity function and the profit function of the financial manager. Cash flows must be arranged to meet fixed payments on debt; the more sales and profits fluctuate, the more difficult is the task of the financial manager in meeting the cash outflow for interest and debt repayments. One therefore finds a much greater willingness on the part of companies with stable sales and profits, such as U.S. electric utilities, to use higher degrees of leverage, resulting in capital structures carrying 50%–70% in senior capital. Before nationalization, the position of British electric companies was similar.

On the other hand, manufacturing and retailing have volatile earnings and sales and use a much lower degree of financial leverage, when possible. Net profit contributions through a capital structure design which emphasizes financial leverage would be minor, ordinarily, when compared to the net profit contribution of such factors as operating and financial efficiency, and would add substantial nonoperating risks to the business operation. One cannot create, only potentially improve, profit by financial design since the company must be profitable before it can gain an advantage by trading on the equity. Management should consider availability, suitability, maneuverability, risk, control and income among the major factors affecting the character of the capital structure. Therefore, the demands of essential capital contributors for a creditor relationship, the nature of the assets employed, the desire of the managers to increase the return to the equity holders by trading on the equity, and the ability of the company to generate and plow back earnings are important. The reluctance to share control, the relative costs of new financing, the utilization of available short-term credit and governmental actions in the areas of stability, inflation, regulation and taxes are also significant.

Managerial decisions on the extent of the use of credit in business operations and the availability of creditor capital for private and public enterprise directly affect the vitality of the economic system. An increased use of credit allows a greater utilization of available entrepreneurial, or risk, capital and results in an increase in productivity and in rate of economic growth. The economic risk created by the increased use of credit is one of greater instability and uncertainty in the course of the business cycle due to possible changes in the attitudes and demands of creditors. CAPITO (KÖPFEL), WOLFGANG FABRICIUS (1478–1541), a leading reformer at Strasbourg, the son of a distinguished senator and master smith (hence "Fabricius"), was born at Hagenau in Alsace. His father was opposed to church vocations, so Wolfgang studied at Ingolstadt and Freiburg, becoming doctor in medicine and in law. After his father's death, he took a doctorate in theology at Freiburg and in 1512 became diocesan preacher in Bruchsal. There he came to know the future reformers John Oecolampadius and Conrad Pellicanus. When called to Basel in 1515 as cathedral preacher he lectured also at the university, became a friend of Erasmus and Zwingli, a correspondent of Luther, and a diligent biblical scholar, editing the psalter in Hebrew (1516). Somewhat to his dismay, the elector archbishop Albrecht

of Mainz summoned him (1519) to Mainz as cathedral preacher, and later as chancellor. Badly torn in conscience, he twice visited Wittenberg, met Luther, and, despite an imperial patent ennobling him, finally (1523) left the service of Xibrecht to settle upon a post at Strasbourg that had been given him by the pope (without cure) in 1521. Shortly, he was second only to Martin Bucer (*q.v.*) in the reform activities of Strasbourg and southern Germany. Though usually guided theologically by Bucer, he remained friendly to the Anabaptists and other dissenters until 1534. With Bucer he drafted the *Confessio Tetrapolitana* (1530). His most important work, on church discipline, was the *Berner Synodus* (1530). He was a participant in several important church councils. He died at Strasbourg in Nov. 1541.

CAPITULARY (Lat. *capitulare*), the name given to certain acts of legislation, regulation or administration promulgated by the Carolingian sovereigns of western Europe. They are so called because they are divided into articles (*capitula*). The word *capitulare* is in fact first found in 779, in the reign of Charlemagne, but similar acts (*edicta* and *decreta*) were promulgated by the Merovingian kings.

As no capitularies are extant in their original form, their texts can be studied only through copies. In the manuscripts in which they have been transcribed, the capitularies are usually arranged in groups or classifications. In most cases this does not destroy their individuality, but in two collections compiled in the 9th century their individuality is considerably obscured. The first of these two, dating from 827, is the work of Ansegius, abbot of the monastery of Saint Wandrille (Fontenelle). In it the contents of 26 capitularies are distributed in four books, the *capitula* being numbered consecutively in each book. The second such collection, made 20 or 25 years later by Benedictus Levita (Benedict the Deacon), purports to be a continuation of Ansegius' collection by three further books. In reality, however, though it contains some articles lifted from genuine capitularies, it also contains material that has been recast, or expanded by interpolation, or even taken from documents which had nothing to do with Carolingian legislation. Hence this collection is usually designated as the *False Capitularies*.

In 1677 the French scholar Étienne Baluze published the text of most of the capitularies in two folio volumes, *Capitularia regum Francorum*, but the first critical edition was that by G. H. Pertz (1835), the first volume of the folio section of the *Leges* in the collection *Monumenta Germaniae historica*. The later edition by A. Boretius and V. Krause, two volumes (1883–97), the quarto series of the same collection, is that usually quoted by scholars.

As early as the Carolingian period those capitularies which dealt with ecclesiastical matters, *capitula ecclesiastica*, ad ordinem ecclesiasticum pertinentia, came to be set apart from those dealing with secular affairs, *capitula ad mundanam pertinentia legem*. Further distinctions were made between (1) *capitula legibus addenda*, (2) *capitula per se scribenda* and (3) *capitula missorum*. The *capitula legibus addenda* were those intended to supplement or to modify the national laws of the peoples of the Carolingian empire. They were therefore concerned, as were the laws themselves, with the penal law, with rules of procedure or with private law; e.g., the *capitulary* added to the Riparian law (803), the *capitula* added to the Bavarian law (also probably 803), and the *capitula* added to the Salic law (819–820). The *capitula missorum* were instructions for the king's *Missi* or envoys (see *MISSI DOMINICI*), who were sent in pairs to a group of countries to supervise the local administrations, to stop abuses and to ensure obedience to the royal commands. The *capitula per se scribenda* are more difficult to characterize. Whereas the *capitula missorum* were issued to individuals, the *capitula per se scribenda* applied to a territory and contained provisions of a more general and permanent character. Finally, a distinction was made between Frankish and Italian capitularies, the latter valid only for the kingdom of Italy (corresponding to the former Lombard kingdom).

For the most part these distinctions are only approximate. Many capitularies deal both with ecclesiastical and with secular matters, and, as F. L. Ganshof has pointed out, several capitularies drawn up for *missi dominici* contain articles of general application, while *capitula per se scribenda* sometimes contain articles modifying national law or laws or even include instructions to *missi*. The Carolingians did not legislate according to a fixed system, and although certain capitularies are confined to one subject (such as the noted capitulary *De villis*, by which Charlemagne regulated the administration and the exploitation of the royal domains), most of them contain measures unrelated to each other. Even from the point of view of diplomatic they are not uniform.

Most of the capitularies were submitted to the *placitum* (assembly) of the notables for their *consensus*, but many historians believe that, at least up to the last years of the reign of Louis I the Pious, their force of law was derived from the royal authority alone and that the *consensus* was not a genuine vote of approval that the assembly could, if it wished, withhold.

After Louis I's death the Carolingians of Germany ceased to promulgate capitularies. Charles II the Bald, however, issued many. The last capitularies to be issued by a Carolingian are two of the French king Carloman and belong to the years 883 and 884.

CAPITULATIONS, treaties by which one state conferred upon another state the privilege of exercising extraterritorial jurisdiction within its boundaries over nationals of the latter state (see **EXTRATERRITORIALITY**). The term arose because treaties of this type with Turkey were divided into chapters (*capitula*), and is to be distinguished from the military term "capitulation," an agreement for surrender. There was no element of surrender in the early capitulations made by European rulers with the powerful Turkish sultans who were motivated by a desire to avoid the burden of administering justice to foreign merchants. Later, ideas of exclusive territorial sovereignty penetrated to the eastern states, and capitulations, which in the case of China and other Asian states had resulted from military pressure by European states, came to be regarded as humiliating derogations from the sovereignty and equality of these states.

The legal explanation of the practice is to be found in conflicting conceptions of sovereignty and of law. In contrast to the modern conception, which relates sovereignty to territory, early conceptions related it to persons. The sovereignty of the state was held to apply only to its nationals. The privilege of citizenship was too precious to be extended to the alien, who was long practically an outlaw and his state sought to protect him and exercise jurisdiction over him even when he was living abroad. Therefore, when the numbers, wealth and power of foreigners residing within a state became such that it was felt politic to subject them to some law, it was naturally held that this law should be their own. This was particularly the case when people from Christian countries were living in countries where the principles of justice were based on non-Christian traditions. Thus, Christians living in Turkey would have been bound under Muslim law by the maxim that the oath of a Christian could not be accepted against a Muslim, and foreigners in China would have had to accept such alien ideas of justice as that of collective criminal responsibility, and indifference to any distinction between accidental and willful homicide.

Early examples of extraterritorial rights are to be found in the privileges enjoyed by the Phoenicians in Memphis in the 13th century B.C., the guarantees and commercial facilities accorded by Harun al-Rashid to the Franks in the 9th century A.D., and the concessions made to certain Italian city-states by the prince of Antioch and the king of Jerusalem in 1098 and 1123. The Byzantine emperors followed this example, and by the end of the 12th century Genoa, Pisa and Venice had all obtained capitulations. The system was continued under the Ottoman sultans, and capitulation treaties were signed with Genoa in 1453 and with Venice in 1454. In 1536 a capitulation treaty was signed between Francis I

of France and Suleiman I of Turkey which became the model for later treaties with other powers. It allowed the establishment of French merchants in Turkey, granted them individual and religious liberty and provided that consuls appointed by the French king should judge the civil and criminal affairs of French subjects in Turkey according to French law, with the right of appeal to officers of the sultan for help in carrying out their sentences. Until 1583, when England obtained its first capitulation, France was the official protector of all Europeans in Turkey. Later, England claimed to protect the subjects of other nations, but in 1607 it was laid down that the subjects of all nations not represented at Constantinople by an ambassador should be under French protection. At first capitulations were for the sultan's lifetime only, but in 1740, after France's friendship had secured for Turkey a successful negotiation of the peace of Belgrade, a capitulation in perpetuity, which could not be modified without French consent, was granted. During the 18th century nearly every European power obtained capitulations in Turkey, and in the 19th century such newly established countries as the United States, Belgium and Greece followed suit.

The capitulation system spread widely in the 17th, 18th and early 19th centuries, when traders from the west were spreading western influence by a process of infiltration rather than by annexation. An interesting case was that of China. The first commercial treaties concluded with foreign powers, e.g., that with Russia in 1689, granted special rights and privileges to nationals of both countries when living on one another's soil. Later, the system of "unequal treaties" was developed, and such treaties as the Sino-British supplementary treaty, 1843, and its later modifying enactments, set up a system of provincial courts and a British supreme court in China to try all civil and criminal cases involving British subjects, but granted no corresponding rights to Chinese residents in Britain. Capitulations in China were obtained by 17 other European powers, by the United States, and by Japan; Japan also obtained such rights in other countries.

Another country in which the system was of special interest was Egypt, which continued to grant capitulations to foreigners even after it ceased to be part of the Ottoman empire. In 1875, however, mixed courts were set up to decide civil and commercial cases between Egyptians and foreigners and between foreigners of different nationalities. Three district courts were established, at Cairo, Alexandria and El Mansura, each with one Egyptian and two foreign judges, with a court of appeals composed of six Egyptian and ten foreign judges, at Alexandria. Modifications introduced in 1889 and 1911 gave the court of appeals the right to approve legislation to be applied to foreigners.

Other countries where capitulations were in force during the 19th and early 20th centuries were Japan, Persia, Siam, Iraq, Abyssinia (despite the fact that it was a Christian country), Morocco, Albania, Crete, Tripolitania, Muscat and Bahrain.

The evils to which the system gave rise were exemplified particularly in Turkey and China. The fact that a foreign consul had jurisdiction in all matters concerning foreign nationals early led to encroachments on Turkish rights of sovereignty, and it was possible for foreign governments to levy duties on goods sold in Turkish ports; e.g., the 2% duty established on Venetian goods by the treaty of Adrianople in 1454. Foreign powers were also able to set up banks, post offices and commercial houses on Turkish soil which were exempt from Turkish taxes and were able to compete with local firms. In both Turkey and China the existence of capitulations led to the development of a class immune from local jurisdiction—protégés of a foreign power, who, because they were employed by foreigners, claimed partial immunity from their own laws and were particularly useful as pawns in diplomatic intrigue. In China, especially, it was possible for fugitives from Chinese justice to seek sanctuary with foreigners. Then, inevitably, foreigners misused their privileges; their own law was sometimes badly administered, their courts tended to favour their own nationals at the expense of the natives of the countries in which they were living (particularly in China, where there were no mixed courts) and the way was opened for bribery and corruption. In the Chinese treaty ports, a multiplicity of territorial

settlements and concessions, practically exempt from local jurisdiction, led inevitably to administrative confusion; each foreign legation had its own, sometimes conflicting, rights. A special political development arose when Manchuria, which was Chinese territory, was penetrated by Koreans who claimed exemption from Chinese law under the capitulations granted by China to Japan.

One positive effect of the system, however, was to be found in the example offered by the western ideas of justice. These, particularly in Turkey, became the basis for the development of a sound administrative and judicial system.

Inevitably, as the eastern countries became more conscious of their own sovereignty rights and more resentful of western domination, agitation began for the ending of capitulatory rights. At the same time improvements in the administration of justice made the western powers more willing to relinquish these rights. Turkey first raised the question of their abrogation in 1856, and in 1914 served notice on the Allies and on the central European powers that all capitulatory rights should cease. The United States denied the validity of unilateral abrogation, but the Central Powers formally relinquished their rights in 1919, Soviet Russia spontaneously renounced all such rights in 1921, and at the peace treaty between the Allies and Turkey signed at Lausanne in 1923 the capitulations were brought to an end. The first country to conclude treaties ending capitulations had been Japan (1899); they were ended in Tripolitania in 1911, in the Ottoman territories acquired by Greece and in Crete in 1914, in Morocco in 1920, in Siam in 1927, in Persia in 1928, in Iraq in 1931, in Abyssinia in 1936 and in Egypt (subject to a 12 years' modified transitional period) in 1937.

In China, agitation against capitulations led representatives of the powers concerned to provide, at the Washington conference of 1922, for a commission to make recommendations on the subject. The commission met in Peking in 1926, and recommended gradual abrogation. Treaties were concluded by China in 1928 with Belgium, Italy, Portugal, Spain and Denmark which conditionally abolished capitulations. In 1929 the Chinese government declared that all remaining rights should be at an end, but it was not until 1943 that Great Britain and the United States formally relinquished their rights in China. With that, except for certain arrangements in Muscat and Bahrain, capitulations ceased to exist and the equality of states, long recognized in the theory of international law, was recognized also in practice. See CONSUL: EX-TERRITORIALITY.

CAPIZ, a province of northern Panay Island, Republic of the Philippines. Land area 965 sq.mi. Pop. (1960) 314,834. Rice and sugar cane are the chief crops grown in the eastern section, where pond raising of fish and coastal fishing also are important. Rice, coconuts and abaci (Manila hemp) are the chief crops of the Aklan valley. The eastern area ships its surplus rice to nearby islands, whereas Aklan valley rice surpluses go to towns on the west coast of Panay.

The capital, Roxas city (formerly Capiz), received its new name and charter in 1951 (pop., 1948, 32,353; 1958 est., 38,893). The city is located on the Capiz river, 4 mi. from the sea, with port facilities at the river mouth, at which interisland ships call regularly. Roxas city is the northern terminus of the transisland railway running to Iloilo. In 1957 about half of Capiz province was created into Aklan (*q.v.*) province. (J. E. SR.)

CAPMANY Y MONTPALAU, ANTONIO DE (1742–1813), Spanish scholar and politician, was born at Barcelona. Nov. 24, 1742, and died at Cádiz, Nov. 14, 1813. He became secretary of the Real Academia de la Historia and, during the Napoleonic invasion, represented Catalonia in the nationalist *Cortes* of Cádiz. Among his best works are *Memorias históricas sobre la marina, comercio y artes de la antigua ciudad de Barcelona* (1779–92) and *Teatro histórico-crítico de la elocuencia española*

(1786–94), a critical anthology designed to prove to foreign critics who judged Spain's past by its present decadence, that its language and literature are among the finest in Europe. Later he entered into controversy with the nationalist poet Manuel Quintana.

CAPO D'ISTRIA, GIOVANNI ANTONIO: see KAPO-DISTRIAS, IOANNES ANTONIOS. COUNT.

CAPQRETTO, BATTLE OF, the successful Austrian-German offensive against Italy in 1917, during World War I. After the Italians' offensive on their northeastern front in August and September, known as the eleventh battle of the Isonzo, the Austrian and German staffs began organizing a counteroffensive. The Austrians assembled 25 divisions, the Germans 7. The attack began on Oct. 24, 1917, in the area of Caporetto (Kobarid in Slovenia; Ger. Karfreit), on a sector of the front occupied by only four Italian divisions. The initial blow was made by the 14th German army (Gen. Otto von Below), consisting of the seven German and four Austrian divisions. Gas was used and this caused panic among the inadequately protected Italians. The attackers advanced rapidly. By Nov. 10 the Italian chief of staff, Luigi Cadorna (*q.v.*), had withdrawn his defeated forces about 65 mi. behind the formidable Piave river, and further retreat was avoided.

The Italian defeat so alarmed the British and French staffs that they despatched six French divisions and five British to Italy. Their arrival was completed by Nov. 22. Italian casualties were about 305,000—of whom about 275,000 were prisoners. Cadorna was replaced as chief of staff by Gen. Armando Diaz.

See V Coda, *Dalla Bainsizza al Piave* (1919); J. E. Edmonds, *A Short History of World War I* (1951). (C N B.)

CAPPADOCIA, the ancient name of a district in eastern Asia Minor, stretching from the Taurus mountains in the south to the Black sea in the north, and bounded on the west by the great central salt desert and Lake Tatta (mod. Tuz Gölü), and on the east by Armenia and the Euphrates river. Originally a whole, it was divided for administrative purposes by the Persian kings into two satrapies, Pontic Cappadocia, the northern region (see PONTUS) and Cappadocia proper or Greater Cappadocia, which comprised the central and southern districts, the subject of the present article. Its area has been estimated at 33,000 sq mi.

The country forms a rugged tableland, with extremes of temperature and a poor soil. Mountain barriers cut it off from both the Mediterranean and the Black sea. For a long time there were no cities and little intercourse with neighbouring lands. The rearing of horses was one of the few things for which the wild terrain was suitable. The yearly tribute to the Persian kings consisted of 1,500 horses, 2,000 mules and 50,000 sheep. The ancient temple state of Comana (*q.v.*) in southern Cappadocia where the great nature mother-goddess Ma was worshiped, and the similar temple of Zeus at Venasa in western Cappadocia, with their high priests and thousands of temple slaves, survived into the 1st century AD.

When Cappadocia became part of the Persian empire in the 6th century B.C., it attracted settlers from Iran, some of whom were priests or magi of the fire worship of Zoroaster (*q.v.*), who introduced their cult, while others became local dynasts, living in strongholds from which they dominated the countryside, ruling the native population who became their serfs. This feudal system, which had no doubt prevailed before the Persian conquest, continued until the country became a Roman province in the 1st century AD.

During his campaigns in Asia (334–323) Alexander the Great did not find time to conquer Cappadocia, but in 322 Perdikkas (*q.v.*) subdued it and installed Eumenes (*q.v.*) as satrap. Macedonian control under Antigonos I and later under the Seleucid kings (see SELEUCID DYNASTY) was slack. A native dynasty exercised power in the country after the death of Antigonos at the battle of Ipsus in Phrygia (301) as it had done earlier under the Persians and Alexander. These rulers were nominally vassals of the Seleucid king. About 255, however, Ariarathes III proclaimed his independence by taking the royal title. This king and his successor Ariarathes IV married daughters of ruling Seleucids, and Ariarathes IV supported Antiochus III till his defeat by the Romans at Magnesia in 190 whereupon Cappadocia became a client kingdom of Rome. Ariarathes V, reigning from about 165

to 130 followed a policy of unflinching loyalty to Rome. Educated at Athens, he was Greek in outlook and sympathies. Under him Hellenization, hitherto very slow, was speeded up. His sister became the wife of Eumenes II of Pergamum. But in 130 he was killed while fighting alongside the Romans against the Pergamene pretender Aristonicus, and Cappadocia entered a long period of chaos. The two following kings Ariarathes VI (d. 111) and VII (d. c. 100) were assassinated, and by 96 Mithradates VI, king of Pontus, was in control. This foreign occupation was resisted by the Cappadocian nobles. They invited Roman intervention, and one of their own number, Ariobarzanes I Philoromaos, was appointed king and recognized at Rome (c. 95).

After the overthrow of Mithradates (63) and Pompeius' reorganization of the east, Cappadocia was bound even more closely to Rome as a client kingdom. Ariobarzanes III (q.v.) was succeeded in 42 by his brother Ariarathes who was deposed by Antony in favour of Archelaus (q.v.) in 36 B.C., who ruled until the emperor Tiberius called him to Rome about A.D. 14. After his death (A.D. 17) the kingdom was annexed by Tiberius as a Roman province governed by a procurator. It came to be an important military district because of its strategic position on the Roman frontier with Armenia, and later it had the large garrison of two legions. Two cities only were important, Mazaca, the royal capital (later Caesarea, mod. Kayseri), and Tyana (10 mi. S.W. of mod. Sigde). The population was distributed under the kings into ten *strategiae* (generalships), and these administrative divisions were retained by the Romans. Before the Roman annexation Cappadocia had developed very gradually into an area of Greek civilization and language, the native and Iranian elements being overcome. The Roman occupation ensured that Hellenism retained its dominance, and through improving communications and facilitating the exploitation of natural resources it brought a greater prosperity to the region.

See D. Magie, *Roman Rule in Asia Minor* (1950). (R. H. St.)

CAPPARIDACEAE, the caper family, mainly tropical plants with strong drought resistant tendencies. It includes herbs, shrubs or trees, with simple or palmately compound alternate leaves, and mostly bisexual, somewhat irregular flowers, with usually four separate sepals and petals, six to many stamens, a superior one-celled ovary and fruit that may be sessile but is more characteristically stalked. The family is closely related to the more temperate (mostly northern) mustard family (Cruciferae).

The Capparidaceae has been divided into two major subfamilies. The woody Capparidoideae have indehiscent, rather fleshy berries or pods and usually many stamens. The pantropical, simple-leaved genus *Capparis* (300 species) includes *Capparis spinosa*, the caper-bush, grown for its flower buds, which, when pickled are sold as capers (q.v.). Some species of *Capparis* are characteristic desert shrubs of South America, Africa and Asia; others are trees of tropical rain forests of the Amazon region, and jungle climbers of southeastern Asia. Two species occur in the Florida keys. Other genera include the tropical garlic pear, *Crataeva religiosa*, and the African desert genera *Maerua* (about 40 species) and *Boscia* (30 species).

The mainly herbaceous subfamily *Cleomoideae* have dry capsules dehiscent by two valves, which fall from a hoop-shaped placenta releasing the seeds; usually six stamens; and palmately compound, rarely simple, leaves. The large, mainly annual, genus *Cleome* (200 species) is nearly world-wide in tropical to temperate-arid regions. *Cleome houtteana* (*C. spinosa*), native from southeastern Brazil to northeastern Argentina, is the commonly cultivated, pink spiderflower; *C. speciosa* is frequently cultivated in the tropics. *Cleome serrulata*, Rocky Mountain bee plant, is widespread in the western mountains. *C. isomeris*, burro-fat, is characteristic of California deserts. *C. viscosa* and *C. gynandra* are pantropical weeds. *Polanisia* (6 species) is clammyweed, common in North America. (H. H. I.)

CAPPEL, LOUIS (LUDOVICUS CAPELLUS) (1585–1658), French Huguenot theologian and Hebrew scholar, was born Oct. 15, 1585, at St. Elier, near Sedan. He studied theology at Sedan and Saumur, and Arabic at Oxford, where he spent two years. In 1613 he accepted the chair of Hebrew at Saumur, and in 1633 became

professor of theology. It was Cappel who first concluded that vowel points and accents were not an original part of Hebrew but were inserted by the Masoretic Jews of Tiberias, not earlier than the 5th century A.D., and that the primitive Hebrew characters are those now known as Samaritan, while the square characters are Aramaic and were substituted for the more ancient at the time of the captivity. Cappel's important *Critica Sacra* (1634) met with such theological opposition that he was not able to print it until 1650, at Paris, and then only by the aid of a son who had turned Roman Catholic. The various readings in the Old Testament text and the differences between the ancient versions and the Masoretic text convinced him that the integrity of the Hebrew text, as held by Protestants, was untenable. This amounted to an attack on the verbal inspiration of Scripture. Bitter as was the opposition, however, it was not long before his results were accepted by scholars.

CAPPONI, GINO, MARCHESE (1792–1876), Italian historian and statesman whose writings contributed to the inspiration of the Risorgimento, was born in Florence on Sept. 13, 1792, of an ancient Florentine family. After the restoration of the Habsburgs to the grand duchy of Tuscany in 1814, Capponi began a long period of travel that brought him into touch with the most notable intellects of his day in England (where he formed a lasting friendship with Lord John Russell), in Scotland, the Netherlands, Germany and Switzerland. Returning to Florence in 1820, he devoted himself to historical studies and to promoting the economic and educational welfare of Tuscany. The periodical *Antologia* that he founded in 1821 was modeled on the *Edinburgh Review* (as a result of his meeting with Francis Jeffrey in Scotland), and he was also one of the founders of the periodical *Archivio storico*. By 1844, however, he had become completely blind. Nevertheless, in 1848, when the grand duke Leopold II decided to grant his people a constitution, Capponi, whose writings had gained him a reputation as a liberal, was appointed prime minister (Aug. 17–Oct. 27). Having voted for the union of Tuscany with the kingdom of Sardinia in 1859, he was made a senator in 1860.

Capponi's *Pensieri sull'educazione* appeared in 1845, and in 1848, despite his blindness, he began his great work, the *Storia della repubblica di Firenze* (1875). He died in Florence on Feb. 3, 1876. A large number of his miscellaneous writings were published under the title of *Scritti inediti* (1877); there are also selections, *Le più belle pagine*, ed. by G. Gentile (1926).

CAPPS, EDWARD (1866–1950), U.S. classical scholar, noted as an authority on the Greek theatre, was born in Jacksonville, Ill., on Dec. 21, 1866. He graduated from Illinois college, Jacksonville, in 1887 and received the degree of Ph.D. from Yale university in 1891. In 1890 he was appointed tutor at Yale. He was professor of Greek language and literature at The University of Chicago from 1892 to 1907. In 1903 he was special lecturer at Harvard and during the next two years studied in Europe at Athens and Halle. During 1906–07 he was managing editor of *Classical Philology* and in 1907 was called to Princeton university as professor of classics. In 1914 he was president of the American Philological association and in 1917 was Turnbull lecturer on poetry at Johns Hopkins university, Baltimore, Md. In 1918 he was appointed head of the American Red Cross commission to Greece and became also chairman of the managing committee of the American School of Classical Studies at Athens. In 1920 he was appointed minister to Greece, resigning in March 1921 and returning to Princeton. He was editor in chief of The University of Chicago decennial publications, 29 volumes, and became the U.S. editor of the Loeb Classical Library. His works include *The Greek Stage According to the Extant Dramas* (1891); *From Homer to Theocritus* (1901); *The Introduction of Comedy Into the City Dionysia* (1903); and *Four Plays of Menander* (1910).

CAPRAIA (Lat. CAPRARIA, from *capra*, "wild goat"), an Italian island between the mainland of Italy and the north point of Corsica, lies 50 mi. S.S.W. of Leghorn. Pop. (1957 est.) 348. Area 7.4 sq.mi. Belonging to Leghorn province, the island is volcanic and rises to about 1,467 ft. It produces wine and is a centre of the anchovy fishery. It became Genoese in 1527 and was strongly fortified. About 24 mi. N. is Gorgona island (2 sq.mi.)

also famous for its anchovies. Both islands have penal colonies. (G. KH.)

CAPRARA, GIOVANNI BATTISTA (1733-1810), Italian ecclesiastic and diplomat, who negotiated between the Vatican and Napoleon, was born at Bologna on May 29, 1733. After service at Ravenna he became nuncio at Cologne in 1767, at Lucerne in 1775 and at Vienna from 1785 to 1792, in which year he was created cardinal. Despite his long diplomatic career Caprara was too timid and pliant to be an effective defender of papal interests in a period of exceptional difficulty. It was doubtless knowing this that Napoleon requested that Caprara be appointed legate in France to implement the terms of the concordat and that in Feb. 1802 he procured for him the archbishopric of Milan. At his formal reception in Paris on April 9, 1802, Caprara appeared to commit himself to respect the Gallican liberties, and in the issues of the institution of former "constitutional" bishops and the retracting of their errors by "constitutional" clergy, as in other matters, he accepted compromises unpalatable to the Vatican. He assisted in the negotiations leading to Napoleon's coronation by Pius VII in 1804 and himself crowned him king of Italy in 1805. Caprara died in Paris on June 21, 1810.

See V. Bindel, *Histoire religieuse de Napoléon* (1940).

(J. P. T. B.)

CAPRERA (ISOLA CAPRERA), an island 4 mi. in length off northeast Sardinia, in Sassari province, Italy, is connected by causeway with the adjacent island of Maddalena. Pop. (1951) 114. The Italian patriot Giuseppe Garibaldi (*q.v.*) established himself there in 1856 and died there on June 2, 1882. His house and tomb are national monuments.

CAPRI (ISOLA DI CAPRI), an island in the Bay of Naples in Napoli province, Campania, Italy, 6.25 km. (3.9 mi.) long with a maximum width of 3 km. (1.8 mi.) and an area of 10.36 sq.km. (4 sq.mi.). Its highest point is Monte Solaro, 589 m. (1,932 ft.), in the west, above a group of cliffs rising 274 m. (899 ft.) sheer from the sea. The island is a single block of limestone, consisting of a western high portion, where the town of Anacapri, 275 m. (902 ft.), is located, and an eastern lower portion upon which stands the capital, Capri, 138 m. (453 ft.). Two small indentations on the coast serve as landing places: Marina Grande, on the north shore, is protected by a breakwater, while Marina Piccola on the south shore, which is open, is used when the north wind is particularly strong. Until a carriage road was built in the late 19th century between Capri and Anacapri, the latter could only be reached from the sea by a flight of 800 steps (now there are less) called the "Phoenician stairs." Although there is a general lack of water, vineyards, olive groves and gardens are highly productive, as the climate is exceptionally mild. The flora is among the most varied in Italy and large numbers of migratory birds often rest there for days. The name of the island may have two possible origins: either *capra* (goat) or *kapros* (wild boar). Stone age artifacts have been found in one of the caves with which the rocky shores of Capri abound; the most notable of which, the Blue Grotto (Grotta Azzurra), on the north coast, can only be reached by boat. Its entrance, shaped roughly like a keyhole with much the greater part below the water line, is barely 4 ft. high and sunlight entering through the water gives to it an extraordinary blue light. Although known in Roman times, this cave was rediscovered in 1826.

Capri, at one time joined to the mainland, was inhabited in prehistoric times and later became a Greek colony and then a resort (Capreae) of emperors in the early years of the Roman empire. Augustus resided there and Tiberius built several villas, one of which, the Villa Iovis on the northeastern tip of the island, was excavated. Its view of Naples and the Sorrento peninsula is exceptionally fine. To the northeast of Anacapri rise the ruins of the Castello di Barbarossa, destroyed in 1535, and in the same neighbourhood is the Villa San Michele, built by the Swedish writer, Axel Munthe, on the site of a Tiberian villa. The oldest church (10th-11th centuries) is that of S. Costanzo, the island's patron saint.

During the 10th century the population, fearing pirate raids, moved from seaside settlements to the present towns high above

the shore. In the middle ages Capri belonged to the abbey of Monte Cassino, and later to the republic of Amalfi. In the course of the Napoleonic wars it changed hands several times, and in 1806 was captured by the British fleet under Sir William Sidney Smith. Although strongly fortified by the governor, Sir Hudson Lowe, it fell again to the French, led by Maximilien Lamarque, in 1808, and was returned to the kingdom of the Two Sicilies in 1813. Since the second half of the 19th century, Capri has gradually become one of the most popular resorts of southern Italy. There are numerous hotels in Capri and Anacapri, and villas scattered throughout the island. A frequent steamer service connects Capri with Naples and Sorrento. Capri had a population of 9,292 in 1951.

See Norman Douglas, *Siren Land* (1911); Axel Munthe, *The Story of San Michele* (1929).

(G. KH.)

CAPRICCIO, an Italian name, in English and French caprice, given to various types of musical compositions, usually implying a vivacity of rhythm and a freedom of construction. In the 16th century the term was synonymous with the vocal *canzone* and the instrumental *fantasia* and *ricercare*. In the 17th century Girolamo Frescobaldi wrote fugal capriccios on themes of arias or to illustrate devices of counterpoint, and Domenico Scarlatti gave the title Capriccio to one of his one-movement sonatas. The term was widely applied in German 18th-century keyboard music, notably by J. S. Bach. Nineteenth-century examples include the 24 capriccios, in the form of studies, for violin solo by Paganini, and the brilliantly scored Capriccio *italien* by Tchaikovsky and the Capriccio espagnol by Rimski-Korsakov. The term capriccioso was used by Weber and Mendelssohn to convey a fleeting sense of fantasy.

In the 20th century the title Capriccio was used by Igor Stravinsky for his three-movement piano concerto (1929) and by Richard Strauss for his one-act opera (1942).

CAPRICORNUS (the Goat), in astronomy, a constellation and sign of the zodiac. The word is derived from Lat. *caper*, "goat," and *cornu*, "horn." The constellation was sometimes pictured as a goat with the tail of a fish. Its stars, which are generally faint, outline the figure of an inverted cocked hat. The sign Capricornus, which has shifted to the west of the constellation, gives its name to the tropic of Capricorn. When the sun, about Dec. 22, arrives at the winter solstice and enters the sign, it is directly above this important circle of the earth. (R. H. BR.)

CAPRIFOLIACEAE, the honeysuckle family, dicotyledonous plants of the order Rubiales, most closely related to the Rubiaceae (madder family). They are shrubs, rarely vines (*Lonicera*) or herbs (*Triosteum*, *Sambucus ebulus*); the leaves are opposite, simple (pinnate in *Sambucus*) and without stipules (except *Sambucus*); the flowers are bisexual and clustered (in two's in *Linnaea*, *Lonicera*); the calyx tube is united with the ovary (ovary inferior); the petals are united into a tubular or open, five-lobed, regular or two-lipped corolla; the stamens are five (rarely only four) and borne on the corolla tube alternate with the lobes; the ovary is one-eight-celled; the fruits are fleshy or dry.

The family contains about 13 genera and 400 species, many of which are important in horticulture. They are propagated by seeds, layering or by cuttings. Since they are mostly native in northern parts of Eurasia and America they are usually rather hardy. The largest genus is honeysuckle (*Lonicera*), with 175 species, about 50 of which are in cultivation, among them the woodbine (*L. periclymenum*), a twining European plant, and the Japanese honeysuckle (*L. japonica*). The latter escaped from cultivation to become one of the worst weeds of the eastern United States, scrambling over the native vegetation and smothering it;

J. HORACE McFARLAND CO.

FIG. 1.—FRUIT OF VIBURNUM

control has been difficult. The tubular, often highly coloured flowers of honeysuckles are pollinated by moths or hummingbirds. The arrowwood (*Viburnum*) includes about 40 ornamental species in cultivation, especially the wayfaring tree (*V. lantana*) and the cranberry bush or guelder-rose (*V. opulus*), in which many of the flowers become enlarged and sterile, forming large, white inflorescences, whence the name snowball bush. Plants of this

J. HORACE MCFARLAND CO.

FIG. 2.—FLOWER CLUSTERS OF VIBURNUM

genus are mostly deciduous, and the foliage assumes a handsome fall colouring. The snowberry (*Symphoricarpos*), a North American plant of hedges and thickets with clusters of white berries, is common in cultivation. *Weigela* includes a number of prized garden shrubs with clusters of large pink or white flowers in the spring, and *Abelia*, *Kolkwitzia* (beauty bush) and *Levcosteria* (Himalayan honeysuckle) are other important ornamentals. The fruits of the wild elder (*Sambucus*) were formerly much used to make elderberry wine. The remaining genera of the family are all rare except the twinflower (*Linnaea*, named for the celebrated Carolus Linnaeus, the "father" of systematic botany), a small trailing plant of northern woods in Europe and North America; the whitish or pinkish flowers are borne in pairs on erect stalks.

(C. V. M.)

CAPRIMULGIDAE, a family of nocturnal birds with large mouths and a jarring song. See NIGHTJAR; NIGHTHAWK; WHIPPOORWILL.

CAPRIVI, LEO, GRAF VON (1831–1899). German statesman, a soldier who came to be chancellor from 1890 to 1894, was born in Berlin-Charlottenburg on Feb. 24, 1831, the son of a member of the Prussian upper house. His family, originally from Gorizia, had been ennobled during the Austro-Turkish wars and had come to Prussia via Silesia about 1700. Joining the army in 1849, Caprivi became a member of the general staff in 1860 and distinguished himself in the Franco-German War as chief of staff of the X (Hanover) corps. In 1883, against his will, he was appointed head of the German admiralty as successor to A. von Stosch. Doubting the wisdom of Germany's colonial policy, Caprivi was also skeptical about the building of a high sea fleet and advocated the development of the torpedo boat arm in which the young Alfred von Tirpitz began his career. Unlike Tirpitz, he emphasized the need for coastal defenses in view of possible war on two fronts against France and Russia. When, in 1888, the young emperor William II prepared to separate the command and the administration of the fleet, Caprivi raised strong objections and resigned, since he could not force his will on the chancellor Bismarck and William II.

Caprivi now became commander of the X corps and was in Bismarck's opinion the "best horse in the army stable." In March 1890, moreover, Bismarck proposed Caprivi to the emperor as his successor in the post of prime minister of Prussia—not knowing that already, in February, William II had prepared Caprivi to succeed him not only in that but in all his offices. On Bismarck's resignation, therefore, Caprivi became chancellor.

Caprivi took office regretfully, realizing that his military career was finished and not confident in his political abilities. An example of his sense of inadequacy might be seen in his deference to his advisers in the foreign office, who persuaded him to allow the "Reinsurance" treaty with Russia to lapse in 1890. On the other hand this much criticized decision was in keeping with Caprivi's own conviction that a war on two fronts against France and Russia was inevitable and that for this reason alliance with Austria-Hungary was indispensable for Germany. Caprivi did not necessarily wish to jettison Bismarck's foreign policy, but in fact he became the representative of the "new course" in German foreign policy. He concluded the treaty of 1890 granting Zanzibar to Great Britain in exchange for Heligoland for which he was immoderately attacked by the "Pan-Germans"; he maintained a dis-

couraging reserve toward Russia; and, in 1891 he was responsible for the ostentatious renewal of the Triple alliance of Germany, Austria-Hungary and Italy. The new policy did not deliberately break the link with St. Petersburg, but in the event surrendered it and thus smoothed the way to the Franco-Russian alliance of 1893, finally ratified by Russia in March 1894.

Nevertheless Caprivi tried, with the Russian trade treaty of Feb. 9, 1894, to restore better relations with the great eastern power and thus produced that uncertain situation the consequences of which seriously affected German policy right up to 1907. His attempt to continue the policy of the "free hand" between Russia and Great Britain prepared the way for the mistakes that Friedrich von Holstein and Bernhard von Bülow (*q.v.*) were to make at the turn of the century. Nevertheless the Triple alliance acquired a considerable weight in the European balance of power between Great Britain on the one hand and Russia and France on the other.

Caprivi's conscientiousness expressed itself in a domestic policy which, if not free from weaknesses and mistakes, was nevertheless worked out from personal convictions. His main achievement was a series of trade treaties. These, beginning with the lowering of the corn duties in 1891, aroused the bitter opposition of the great landowners east of the Elbe river and provoked the founding, in 1893, of the Agrarian league. Caprivi succeeded in his aim of finding more markets for the industrial produce of the Reich, especially in Europe, but his firm adherence to the tradition of a supra-party administration in the constitutional monarchy meant that he could not rely even on the Liberals for constant support. It was the Liberals, in fact, who in 1892, with the emperor's backing, secured the rejection of his elementary schools bill for Prussia, with its favourable provisions for church schools. Caprivi thereupon resigned the prime ministership of Prussia to the Conservatives in the person of Botho von Eulenburg, confining himself to the imperial chancellorship. The result was that during his last years in office the dangerous dualism between the Reich and Prussia once again made itself felt.

Added to his other difficulties, Bismarck's passionate criticism weighed heavily on Caprivi, and its consequences were intensified by the fear of his colleagues Holstein, Adolf von Marschall and Eulenburg that the Bismarcks might return to power. Out of loyalty to the monarchy Caprivi took the responsibility for the notorious order of June 1892 forbidding the German embassy in Vienna to attend Herbert Bismarck's wedding so as to divert the anger that it aroused from William II's person to himself. He was thus all the more compromised by the apparent reconciliation between the emperor and Bismarck which occurred soon afterward.

Caprivi's brittle, rather rigid and often pedagogic nature became yearly more irksome to the emperor. His elevation to the rank of count in 1891 marked the zenith of his favour, and his standing at court diminished from then on. His strong monarchism did not prevent him from seeing that the government of the modern German Reich could not be indefinitely conducted against the wishes of the majority in the Reichstag. In the empire he could not dispense with the help of the Centre and liberal elements, to the indignation of the court and the Conservatives, while in Prussia he had to meet increasing pressure from the Conservatives, who were supreme thanks to the Prussian three-class suffrage laws. He foundered on this dilemma. His greatest success as a legislator, the great bill of 1893 which raised the strength of the army by 84,000 men, could be achieved only at the price of reducing the period of conscription to two years instead of the three years traditional since William I's time. William II, who gave his assent to the measure most unwillingly and against military opinion, held Caprivi responsible for this capitulation.

The end came in 1894. The emperor, disappointed at the slight success of his "new course" in social policy, angrily demanded a return to repressive measures against the growing Social Democratic party and let Eulenburg persuade him into considering a coup d'état against the system of universal suffrage for the Reichstag. Caprivi showed a true sense of responsibility and political maturity in resolutely opposing these plans. After a crisis rich in intrigue, Caprivi and Eulenburg were simultaneously dismissed on Oct. 28, 1894.

Caprivi spent his last years in strict retirement. His reticence sharply distinguishes him from Bismarck, and historians are still sadly lacking in material for his personal history. He died at Skyren, near Crossen-an-der-Oder, on Feb. 6, 1899.

CAPSICUM (red pepper, cayenne pepper), a genus of perennial woody plants of the nightshade family (Solanaceae; *q.v.*), best known in northern vegetable gardens as herbaceous annuals.

The genus appears to be native in Central and South America, with one anomalous species in Japan; American species are one to several, depending on the authority. Most authors, however, include all the cultivated forms of the genus under a single species, *Capsicum frutescens* (including those formerly classified as *C. annuum* and *C. baccatum*), with several varieties, such as var. *abbreviatum*, the ornamental bush pepper; var. *cerasiforme*, cherry pepper; var. *conoides*, Tabasco and coral gem peppers; var. *fasticulatum*, cluster pepper; var. *grossum*, bell or sweet pepper; var. *longum*, long, cayenne, chilli, yellow peppers; and var. *typicum*, the bird pepper.

JOHN H. GERARD

CHILI PEPPER (CAPSICUM FRUTESCENS LONGUM)

An oleoresin, used as a counterirritant, is obtained from red pepper. The active principle, considered to be capsaicin, when applied to the skin causes a feeling of warmth followed by an almost intolerable burning. Taken internally in small doses it stimulates gastric secretions but if used in excess causes inflammation. See CAYENNE PEPPER. (F. L. A.; J. M. BL.)

CAPSTAN, an appliance used chiefly on board ships or in shipyards for mechanical power to move or lift heavy weights, consisting primarily of a barrel-sized, spool-shaped, cast-iron drum which is mounted vertically. Power is supplied either manually or by steam or electricity; when operating, the whole capstan revolves and winds in a line that has been wrapped around it.

The term "capstan" is also used to denote a shaft that rotates with constant angular velocity so as to maintain constant speed in the tape drive system of a magnetic tape recorder (see TAPE RECORDING, MAGNETIC).

Prior to the advent of anchor chain both the capstan and the windlass could be used to haul in the anchor cable, but since the capstan was mounted vertically while the windlass was mounted horizontally it was much easier to "walk the capstan around" than to "pry" or "crank over" the windlass. With the introduction of anchor chain and auxiliary power on the forecastle (the donkey engine), shipbuilders developed a recessed drum which would fit around the links of the anchor chain and prevent slippage around the drum. This "wildcat" drum operated originally with better control when used on a horizontal axis, and consequently the term windlass became so popular that modern usage tends to call all anchor-handling machinery by that name. However, some modern equipment uses a low vertically mounted wildcat above the deck, but locates the power machinery below. If this vertical drum has sockets for capstan bars and can be operated manually, then technically it should be termed a capstan.

The basic parts of the capstan are the base plate, the spindle, the barrel with pawls, the drumhead and the capstan bars. The base plate bolts to the deck and supports the barrel and drumhead by the spindle and a roller path. The pawls attached to the bottom rim of the barrel ride over a notched track in the base plate and operate in much the same way as a ratchet to prevent backward

motion. The spool shape of the barrel keeps the turns of line sliding toward its middle rather than working off the top. "Whelps" or ridges fitted vertically around the barrel prevent wet lines from slipping. The "pigeonholes" in the drumhead hold and support the capstan bars, which radiate out from the rim when inserted for use. These bars vary from 5 to 6½ ft. in length, and are notched at their outer end to receive a rope "swifter" to confine them to their pigeonholes when the ship is rolling. In operation, men push against these bars as they walk around the capstan, and as it revolves the rope wrapped around the barrel is put under tension and tends to move any object to which it is attached.

The crank capstan and the geared capstan are modifications which multiply manual power through use of gears in the drumhead. (M. H. I.)

CAPTAIN, in its general application refers to the leader, master, chief or person of similar status in any walk of life. Captains are chosen for teams in sports, and the expression "captain of industry" has become hackneyed. It is in the military and maritime services, however, that the word applies to a definite rank, distinguished for its antiquity. In most armies and some air forces, a captain is the commander of the largest group of soldiers that an officer can be expected to know personally—a company in the infantry, a battery in the artillery, a flight in the air force and a troop in the cavalry when that arm flourished. In the U.S. coast guard the captain of the port supervises anchorage, the loading and unloading of explosives and the movement of shipping.

On the sea a captain is usually the commander of a large warship—a cruiser, battleship or aircraft carrier in the navy, and any sizable ship in the mercantile marine service. Because of his isolation, he has traditionally exercised powers and privileges far beyond those granted to an officer of equivalent station on land. He can perform marriages and conduct burial services; he has life and death powers of decision in matters affecting the safety of his ship or the welfare of its crew or passengers.

In the British and U.S. navies the rank corresponds to the army rank of colonel, as does the term group captain in the Royal Air Force. It is customary to give an officer of lower rank the courtesy title of captain when he is in command of a ship, but this does not allow him the right to claim the rank or to be so addressed in writing. The term is also generally applied to the officer in charge of an aircraft or group of aircraft, whether in military or civilian service. See INSIGNIA, MILITARY. (L.N. MS.)

CAPTIVE: see LAWS OF WAR; PRISONERS OF WAR.

CAPTURE AT SEA: see BLOCKADE; CONTRABAND; NEUTRALITY; PRIZE; VISIT AND SEARCH.

CAPUA (mod. SANTA MARIA CAPUA VETERE), the chief ancient city of Campania in Italy, was situated 16 mi. N. of Neapolis (Naples). The site is that of modern Santa Maria Capua Vetere, not modern Capua (which was ancient Casilinum). Occupying the northeastern edge of a plain, it lacked natural defenses and depended on the produce of the plain. It was founded about 600 B.C., probably by the Etruscans, and its name was applied to the whole surrounding plain, *ager campanus* (*Capuanus*) or Campania. It controlled neighbouring communities (Casilinum, Calatia, Atella) but not all Campanian cities such as Teanum (Teano), Nola, Neapolis and Cumae, which were independent. With the weakening of Etruscan power in the south after 474 B.C., the Etruscan period at Capua ended when it was captured by Samnites (*q.v.*), Sabellian tribes from the mountains, about 440; the city adopted the Oscan language and customs (see OSCAN). Whether or not the Campani of Capua had made an alliance with Rome in 343 against new Samnite invaders, they at first supported the revolt of the Latins and other allies against Rome in 340. In 338 Rome confiscated their *ager Falernus* on the

CAPSTAN SHOWING: (A) BASE PLATE; (B) BARREL WITH PAWLS; (C) DRUMHEAD; (D) CAPSTAN BAR

right bank of the Volturnus (Volturno) river and distributed it to Roman citizens who were enrolled in a new tribe, the *Falerna*, but the Campani were given *civitas sine suffragio* (a limited form of Roman franchise); the aristocracy probably did not receive full Roman citizenship. Thus Capua became a municipium (*q.v.*), but it kept its local Oscan language and its magistrates (*meddices*); from 318 it had to receive Roman prefects (but probably not regularly). Its connection with Rome was reinforced by the construction of the Appian way in 312 which linked the two cities. Its prosperity increased and it became the second city in Italy, famous for its bronzes and perfumes. After the battle of Cannae (216 B.C.) during the Second Punic War its loyalty to Rome was shaken and it revolted to Hannibal, whose troops wintered there. During the revolt Capua issued a series of independent coins. It was recaptured by Rome after a short siege (212–11) and severely punished: its citizens were deprived of political rights, and their local magistrates were replaced by regular Roman prefects. The territory was confiscated: part was used for Roman colonies (Volturnum [Castel Volturno] and Linternum [Villa Literno] in 194 B.C.), but most was rented to small farmers until Julius Caesar redistributed it to 20,000 colonists in 59 B.C. Further colonists were sent, in 44 B.C. by M. Antonius, in 36 B.C. by Octavian (Augustus) and later by Nero. In 90 B.C. it had recovered municipal status, and although it suffered during the civil wars at the end of the republican period, it prospered as a *colonia* during the empire. In the 4th century it was the seat of the *consularis Campaniae* (see CAMPANIA). It was sacked by the Vandal Gaiseric in 456 and was finally destroyed by the Saracens in 840; only the church of Santa Maria survived. It has given its name to the late medieval village and the modern town.

Early tombs and traces of two 6th-century temples survive. Roman monuments include a grand amphitheatre, baths, a theatre and a fine Mithraeum. The amphitheatre recalls Capua's addiction to gladiatorial shows: here Spartacus and his fellow gladiators escaped in 73 B.C. This darker side of Capuan society is offset by the ribaldry of the Atellan farces (see ATELLANA FABULA) and the gaiety of the Oscan paintings that survive.

CAPUA (anc. CASILINUM), a town and episcopal see of Campania, Italy, in Caserta province, lies 11.26 km. (7 mi.) W. of Caserta, on the Volturno river and the ancient Appian way. Pop. (1957 est.) 17,054 (commune). The modern town is 4.8 km. (3 mi.) N.W. of the ancient Capua (now Santa Maria Capua Vetere), and was founded in A.D. 856 by the citizens of ancient Capua on the site of the old city of Casilinum. Capua has the appearance of a medieval town. The cathedral (856) was largely destroyed in 1943 and rebuilt, though the original tower (861) survived. Among other buildings are the churches of S. Salvatore ad Curtim (960) and Sta. Caterina (1383); the Norman castle (1050); the towers of Frederick II's castle (1239) and several palaces. The Campanian museum contains important pre-Roman and Roman collections. Capua has good rail and road connections. Industry includes munitions, chemical and sugar factories.

Ancient Capua (*q.v.*) was an Etruscan and then a Samnite stronghold and became a Roman colony in 59 B.C. It was destroyed about A.D. 840 by the Saracens. Ancient Casilinum, where Capua now stands, was a strategic road junction and was contended for by Hannibal and the Romans from 217 to 214 B.C., during the Second Punic War; it lost its importance to ancient Capua. Modern Capua changed hands frequently in the middle ages and was part of the kingdom of Naples until 1860.

(J. B. W.-P.; S. G. V.; X.)

CAPUANA, LUIGI (1839–1915), Italian novelist whose works showed pathological and occult tendencies, was born at Mineo, Sicily, May 28, 1839. His psychological novel *Giacinta* (1879) is one of the earliest Italian examples of this genre. In-

fluenced by Hegel and looking forward to Verga and Pirandello, he was also one of the early realists in Italian literature. Other novels have serious psychological themes, among them *Il Profumo* (1890) and the Sicilian story *Il marchese di Roccaverdina* (1901), though some of his works have been accused of being merely pseudoscientific. Detached in outlook but highly imaginative, he wrote successful fairy tales as well as some literary criticism. He died at Catania, Nov. 29, 1915.

CAPUCHIN MONKEY, a tropical American monkey. *Cebus capucinus*; the name is often extended to embrace all species of the same genus, whose range extends from Nicaragua to Paraguay. These monkeys, among the most intelligent in the new world, are

BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

CAPUCHIN MONKEY (*CEBUS CAPUCINUS*)

the typical representatives of the family Cebidae, and belong to a subfamily (Cebinae) in which the tail is generally prehensile. From the other genera of that group with prehensile tails, capuchins are distinguished by the comparative shortness of that appendage and the absence of a naked area on the undersurface of its extremity. The hair is not woolly, the general build is that of a house cat and the limbs are of moderate length and slenderness. The name capuchin is derived from the cowl-like form assumed by the thick hair on the crown. These monkeys go about in troops, frequenting the summits of tall forest trees. In addition to fruits, they consume tender shoots and buds, insects, eggs and young birds. Many of the species are difficult to distinguish, and little is known of their habits in a wild state. Capuchins are easily trained; they are gentle and good-natured, traits which make them valued as pets and performers. See PRIMATES.

CAPUCHINS (ORDO FRATRUM MINORUM CAPUCINORUM; O.F.M. CAP.), an order of friars, chief among the permanent offshoots of the Franciscans. It arose about the year 1525, when Matteo di Bassi (1495–1552), an Observant Franciscan, became possessed of the idea that the habit worn by the Franciscans was not the one that St. Francis had worn; accordingly he made himself a pointed or pyramidal hood and also allowed his beard to grow and went, about barefooted. Matteo was soon joined by others and a recognized order grew out of the movement. Their life was to be one of extreme austerity, simplicity and poverty—in all things as near an approach to St. Francis' idea as was practicable—and though this has been to some extent mitigated they remain very strict. In 1619 they were constituted into an independent order, with a general of their own. Their chief work is missionary, and they number around 15,000. Like the Franciscans the Capuchins wear a brown habit. The general motherhouse is at Rome. See also FRANCISCANS.

CAPYBARA (CARPINCHO), *Hydrochoerus* species, the largest living rodent, belonging to the guinea pig family (Caviidae). It is characterized by its partially webbed toes, of which there are four in front and three behind, hooflike nails, sparse hair, short ears, cleft upper lip and the absence of a tail. When full grown the length of the animal is about four feet, the girth three feet

BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

SOUTH AMERICAN CAPYBARA (*HYDROCHOERUS HYDROCHOERUS*)

and the weight up to 100 lb. Capybaras are aquatic, frequenting the banks of lakes and rivers in South America from Panamá to Uruguay. They associate in herds, spending most of the day under cover along the banks and most of the evening and morning feeding on water plants and bark; in cultivated areas they do much harm to crops. Capybaras are shy, gentle animals, which voice a low, abrupt grunt when pleased, and which at the slightest sign of danger resort to the water. They swim and dive with expertness, often remaining below the surface for several minutes. One litter, comprising usually five to eight young, is borne yearly. Although only a few species survive in modern times, many extinct species occur in the Tertiary deposits (from 70,000,000 to 1,000,000 years ago) of Argentina, some considerably larger than the living forms. See **RODENTIA**.

CARABINIERS, originally 16th-century light cavalry armed with "large pistols called carabins having barrels 3 ft. long." English carabiniers are mentioned as early as 1597 at the battle of Turnhout under Sir Francis Vere. The early practice in England and France was to attach a proportion of men armed with carabins to each regiment, and it was not until the 17th century that regiments of carabiniers were formed. The original duties of carabiniers were analogous to those of grenadiers of the infantry, in fact they were mounted infantry. In 1660 the life guards were equipped with carabins (or carbines) while the other cavalry regiments had swords and pistols until 1678. As a reward for its services in Ireland in 1692, William III designated the ninth horse "the Carabiniers" (later the 6th dragoon guards or the Carabiniers), and although the term "carabiniers" was more common in France than in England it was not until 1693 that Louis XIV constituted his companies of carabiniers into a corps with the distinct title of royal carabiniers. He had, however, regimented them for tactical purposes at Neerwinden in that year. In Italy the gendarmerie are called carabinieri.

CARABOBO, a state located in north central Venezuela with a Caribbean coast line of 46 mi. It has an area of 1,795 sq.mi. and a population (1961) of 377,854. Principal cities are Valencia, the capital (pop. [1961] 161,413), and Puerto Cabello (pop. [1959 est.] 46,166), one of the busiest ports in the nation. Other cities of importance are Guacara (pop. [1959 est.] 7,445) and Güigüe (pop. [1959 est.] 7,483). Lake Valencia, area 92 sq.mi., is situated almost entirely within the state. Carabobo has relatively good communications. In the 1950s it had 256 mi. of highways, including the Transandine, which provides excellent connections with Caracas. The Caracas-Valencia railroad extends for 62 mi. within the state and there is a 34-mi. line from Valencia (which has an airport) to Puerto Cabello.

Carabobo is important both agriculturally and industrially. Rice, cotton, corn, tobacco, coffee, cocoa and sugar are produced. The state has an expanding dairying industry which supplies, in part, the requirements of Caracas. Cattle from the llanos are fattened on the pastures surrounding Lake Valencia. One of the nation's main experiments in planned agricultural communities is carried on at Chirgua, where Venezuelans and immigrants work together. Cement, powdered milk, textiles and shoes are manufactures produced within the state, primarily in Valencia. There is a major petroleum-chemical plant between Valencia and Puerto Cabello. The state was named in commemoration of the battle which proved decisive in the Venezuelan independence movement. At the time the Spaniards conquered Venezuela, there were Indians known as the Carabobos. (J. J. J.)

CARACAL (*Lynx caracal*), sometimes called Persian lynx, an animal widely distributed throughout southwestern Asia and a large portion of Africa. It is somewhat larger than a fox, uniformly reddish brown above and whitish beneath, with two white spots above each of the eyes and a tuft of long black hair at the tip of the ears. It dwells among grass and bushes. Its prey consists of gazelles, small deer, hares and peafowl and other birds. The caracal is easily tamed and in some parts of India is trained to capture small antelopes, deer and large birds.

CARACALLA (MARCUS AURELIUS ANTONINUS) (A.D. 186–217), sole Roman emperor 211 to 217 and joint emperor with his father Septimius Severus 198–211, was born, with the name

Septimius Bassianus, at Lugdunum (Lyons) on April 4, 186. When his father made him Caesar in 197, he was given the name M. Aurelius Antoninus to emphasize that the new dynasty was a continuation or revival of the golden days of the Antonines. His nickname Caracalla refers to a kind of duffel coat, native to the Rhineland and Gaul, which he habitually wore.

The bitter rivalry between Caracalla and his brother Geta attracted to each the support of rival groupings in the empire, until in 212 Caracalla murdered Geta and executed his principal adherents, including the great jurist Papinian. Caracalla spent his remaining five years campaigning on the Rhine, Danube and Euphrates, leaving civilian administration to his mother, Julia Domna. He was murdered by an army officer with a personal grudge, at Carrhae in Mesopotamia, on April 8, 217.

Caracalla's reign is described by two contemporaries, Dio Cassius and Herodian, to whom he was a monster, massacring without provocation harmless Alexandrian citizens or peaceful Parthian crowds assembled for a betrothal between the emperor and their princess. Numerous portrait busts show an unusually compelling face, vigorous, alert and aggressive. Contemporary papyri, however, and occasional tales in the historians, show the emperor as a patient and good-humoured judge in the face of bombastic and obstreperous pleaders.

Caracalla's principal monuments are his colossal baths in Rome and his edict of 211, giving Roman citizenship to all free inhabitants of the empire. This was, at least in part, inspired by the financial motive of making all citizens liable to taxes payable by Romans alone; but its effect over two or three generations was to level out the historical privileges of Italy, and to open to all provincials the prizes of empire, including the throne itself.

See also references under "Caracalla (Marcus Aurelius Antoninus)" in the Index volume. (JN. R. M.)

CARACARA, the common name given to four American bird genera of the family Falconidae. Also called carrion hawks, the caracaras are recognized by their long legs and the bright-reddish naked skin of the cheeks and throat. They are gregarious and feed largely on carrion, birds, reptiles and amphibians. Audubon's caracara (*Polyborus cheriway auduboni*) is resident in Florida, Texas, Arizona and Lower California to northwestern South America, and on islands off the west coast of Mexico. Nine other species are found throughout Central and South America, including the common caracara (*P. plancus*), from the Amazon to Tierra del Fuego; the chimango or beetle eater (*Milvago chimango*), of southern South America; and the black caracara (*Daptrius ater*), of tropical South America.

CARACAS, the principal city and capital of Venezuela and of the federal district (pop. [1961] 739,255, city; 1,265,001, metropolitan area) is situated 3,000 ft. above sea level in a valley towered over by ranges of the Central highlands. Surrounded by mountains, difficult of access and not a natural focal centre for routes, nevertheless it has grown and prospered. The one principal advantage to balance the disadvantages is a pleasant and healthful climate which is generally dry and comfortably warm, though during the rainy season (June–September) the humidity is high. The dry season, extending from December to April, is delightful. The maximum and minimum temperatures range from 84° to 48° F., the annual mean being about 66°. Once it became capital of the separate Venezuelan republic in 1829, its pre-eminence was assured and subsequently maintained over its more advantageously located rival, Valencia.

Metropolitan Caracas extends throughout the valley and is expanding up the mountain slopes. The older part of the city followed the gridiron pattern of narrow streets and square blocks. Around and beyond the Casco (the old city as originally plotted) lie haciendas, then vast fields of sugar cane interrupted by compact villages. The growth of Caracas was retarded for three decades by the dictator and president Juan Vicente Gómez, who favoured Maracay, and it was not until after his death in 1935 that rapid development took place. In the 1950s, Caracas, with a growing population was in the midst of one of the world's greatest building booms and embarked on an ultramodern urbanization program. Some excepted districts were the older barrios which

BY COURTESY OF VENEZUELAN MINISTRY OF DEVELOPMENT, TOURISM DEPARTMENT
AERIAL VIEW OF THE SIMÓN BOLÍVAR CENTRE, CARACAS

have mysteriously retained some of the personality of the past. The centre of the city is the Plaza Bolívar, in which stands an impressive bronze equestrian statue of the Liberator. Around the plaza are grouped the palace of justice, city hall, ministry of foreign affairs and cathedral. Other important features of Caracas are the university, museum of fine arts, the Pantheon (where Simón Bolívar is buried), a racecourse and a bull ring.

Two great earthquakes in 1755 and 1812 destroyed most of the 16th- and 17th-century buildings. The visitor sees little today of the old Spanish colonial houses and narrow cobbled streets which once characterized the city. As the city's population soared and construction boomed, labourers migrated from the rural areas to work on construction jobs, adding to the housing difficulties, and every canyon in Caracas has become filled with shacks and shanties built with scrap materials. The government has made very great efforts to eliminate these slums and large sums of money have been spent building modern apartment houses as part of a public housing program. Caracas is today one of the world's most exciting examples of city planning.

In addition to the political factors contributing to Caracas' growth are many new industries including sugar refineries, processed foods, breweries, tanneries, paper, tobacco, glassware, textiles, rubber goods and pharmaceuticals; improved connections with the city's port, La Guaira; increased highway construction with many roads focusing upon the capital; and shifting of the headquarters of the oil industry from Maracaibo. The capital city, climatically far more agreeable, is an ideal location from which to direct both eastern and western oil-field operations. The companies also benefit from being closer to the central government, with which relations are constantly expanding. These circumstances among others have resulted in a very high cost of living.

One of the most spectacular developments in Caracas and in Venezuela is the Autopista from La Guaira to the capital via the modern and busy Maiquetia airport. It is one of the world's finest highways and probably the most costly.

Caracas was founded by Diego de Losada in 1567 and was named

Santiago de León de los Caracas for the Indians of the area who were then called the Caracas. It was sacked by Sir Francis Drake in 1595. Simón Bolívar was born there in 1783, and under his leadership it became the centre of the first colonial revolt against Spain in 1810. Caracas served successively as provincial capital, the residence of the captain general of Venezuela and capital of the republic after independence was achieved. The city today dominates all Venezuelan cultural, political and economic life; it is the manufacturing and trading centre of the country and lies in the nation's most important agricultural region. (L. WE.)

CARACCIOLO, FRANCESCO, DUCA DI BRIENZA (1752–1799), Neapolitan admiral who was executed on the orders of Admiral Nelson for supporting the republican revolution at Naples in 1799, was born in Naples on Jan. 18, 1752, of an ancient noble family. He learned his seamanship under Adm. George Rodney and fought for a time in the British service in the American Revolution. Returning to Naples in 1781, he commanded the Neapolitan fleet against the French Revolutionary army at Toulon in 1793.

Caracciolo was the best officer of the Neapolitan navy, and jealousy arose between him and the British admiral Nelson (*q.v.*) when the latter won the confidence of the Bourbon court. He followed King Ferdinand IV, however, on the royal family's flight to Palermo (in Nelson's ship) when the French were advancing on Naples (Dec. 1798). Then, with Ferdinand's permission, he returned to Naples to attend to his private affairs (March 1799). There he was persuaded to assume command of what remained of the Neapolitan navy in the service of the new republic. The Bourbons, however, raised a large army under Cardinal Fabrizio Ruffo, which recovered Naples and made republican resistance useless. Caracciolo attempted to escape but was arrested, brought in chains on board Nelson's flagship and summarily tried there. Sentenced to death for treason, he was hanged from the yardarm of his own flagship, the frigate "Minerva" on June 29, 1799.

CARACTACUS (correctly CARATACUS, the Latin form of the Celtic CARADOC) (1st century A.D.), a son of Cunobelinus, king of the British tribe of Trinovantes. His kingdom, embracing the Atrebatas of Hampshire and probably the Dobunni of Gloucestershire, lay in the west. At the time of the Claudian invasion of Britain, he led the native resistance against Aulus Plautius (A.D. 43–47), and after being defeated withdrew into south Wales (*see* BRITAIN). He was finally defeated by Ostorius Scapula in A.D. 50, somewhere on the Welsh marches, in the territory of the Ordovices. He himself fled to the Brigantes, whose queen, Cartimandua, delivered him to the Romans. He and his family featured in a victory parade of Claudius, who granted them pardon and life.

See Tacitus, *Annals*, xii, 31, 37; *Histories* iii, 45; Dio Cassius, ix, 19–22. (I. A. RD.)

CARAGIALE, ION LUCA (1852–1912), Rumanian playwright and prose writer of great satirical power, was born at Haimanale, near Ploesti, probably on Jan. 30, 1852. His comedies expose the effects on Rumanian urban society of over-hasty introduction of a modern way of life, and the comical results of social and political change. *Comul Leonida* ("Mr. Leonida"; 1879), *O noapte furtunoasă* ("A Stormy Night"; 1880) and *O scrisoare pierdută* ("A Lost Letter"; 1884) are among the most popular. With *Năpasta* ("The False Accusation"; 1890) he created the peasant drama. His short stories, *O făclie de Paște* ("An Easter Torch"; 1889), *Păcat* ("The Sin"; 1892) and *Kir Ianulea* (1909) are among the best prose works in Rumanian literature; *Momente* and *Schițe* are vivid sketches of the change from rural to urban society. Caragiale died in Berlin on June 10, 1912. (G. Nş.)

CARAJÁ, a tribe of South American Indians living along the Araguaia river, near the inland island of Bananal, in central Brazil. Their language may be distantly related to Ge, which is spoken by most of the surrounding tribes. The three subtribes of the Carajá—the Carajá proper, the Shambioi and the Javahé—have almost identical cultures and are all oriented toward the river rather than toward the forest. The principal source of food is fish, with agricultural produce of almost equal importance. Clearings are made in the jungle flanking the river and planted with manioc, maize and a variety of other crops. Like most tropical forest peoples, the Carajá wear little clothing but use a variety

of ornaments. Men wear labrets in the lower lip, as well as earplugs, while both sexes use a great deal of body paint and tattoo a small circle on each cheek as a tribal mark.

In the wet season large, permanent thatched houses are occupied by the members of several related families, but during the dry season flimsy shelters are built on the sandy beaches along the river. Within the village the social unit is the matrilineal extended family, and the heads of these families are the effective leaders of the society. The village chief, although granted considerable deference, has little authority. For most purposes the villages are independent of one another, but some adjoining villages cooperate in holding religious ceremonies.

An artistic people, the Carajá are noted for the singing and dancing which are prominent features of all ceremonies. The religion is dominated by the men, who hold masked dances during which they impersonate spirits and the ghosts of slain enemies.

See William Lipkind, "The Carajá," in *Handbook of South American Indians*, ed. by Julian H. Steward, Bureau of American Ethnology *Bulletin* 143, vol. 3, pp. 179-191 (1948). (S. E. L.)

CARAN D'ACHE (Fr. play on Russ. *karandash*, "pencil"), pseudonym of EMMANUEL POIRÉ (1858-1909), French caricaturist and illustrator, who was born and educated in Moscow but settled in Paris where he gained great popularity as a contributor to several periodicals. He was an early exponent of the episodic strip cartoon technique. He was also a well-known book illustrator. The grandson of a Napoleonic officer, he spent five years in the French army, and often favoured military subjects in his illustrations. Essentially self-taught, he was particularly influenced by the contemporary German caricaturists Wilhelm Busch and Adolf Oberlander. He died in Paris on Feb. 26, 1909.

CARAT, a unit of weight for diamonds, other gems and pearls; it also indicates the purity or fineness of precious metals. Originally grains or leguminous seeds were used for the weighing of precious stones and as these were not of uniform size or weight the carat in different gem centres varied considerably. Thus, the London market for many years used a carat equal to 0.2053 g. (3.163 troy grains); in Florence it was 0.1972 g.; in Amsterdam 0.2057 g., and so on. After various attempts to simplify and standardize the carat, the metric carat of 0.200 g., or 200 mg., was adopted in the United States in 1913, and has now become the standard in the principal countries of the world. The metric carat permits the weight of gems to be expressed conveniently in decimals, whereas formerly it was customary to use a clumsy series of fractions, such as $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$, $\frac{1}{32}$ and $\frac{1}{64}$ of a carat. When the term carat is used to indicate the purity or fineness of metals it means $\frac{1}{24}$ part. Thus, 18-carat gold consists of 18 parts of gold and 6 parts of alloy.

CARAUSIUS, MARCUS AURELIUS (d. A.D. 293), Roman general and usurper in Britain of the title of emperor (286-293), was of humble origin in the Belgic tribe of the Menapii. He served with distinction as an officer under the emperor Maximian against the Bagaudae and Franks in Gaul about 285-286, and was put in command of a fleet, based at Gessoriacum (Bononia, mod. Boulogne), with the task of protecting the Belgic and Armorican coast from Frankish and Saxon pirates. Accused of complicity with the raiders he anticipated his execution by revolting and occupying Britain (286-287). Maximian attacked him in 289 but was defeated, and Carausius was left undisturbed for four years. During these years he issued coins in the names of himself and "his brothers," meaning the joint emperors Diocletian and Maximian, but they did not return the compliment and probably did not recognize him officially. In 293 Constantius Chlorus received the title of Caesar, and captured Gessoriacum. Shortly afterward Carausius was murdered by Allectus, one of his ministers, who succeeded him as ruler in Britain.

See P. H. Webb, *The Reign and Coinage of Carausius* (1908). (A. H. M. J.)

CARAVAGGIO, MICHELANGELO DA (MICHELANGELO MERISI Or AMERIGHI) (1573-1610), Italian painter who virtually revolutionized Italian painting with his conception of light, colour and iconography, and infused the objects in his paintings with a degree of reality which was almost tangible. He was born

at Caravaggio near Brescia in Lombardy on Sept. 28, 1573, the son of Fermo Merisi, a mason and master builder for the marchese di Caravaggio. Caravaggio was a leader in the formation of the early baroque style.

Caravaggio's first master was Simone Peterzano (active 1573-92), a Mannerist painter from whom he gained a solid technical education during his apprenticeship in Milan (1584-88). None of his paintings from this period survive. Between 1588 and 1591 he went to Rome. Important influences from his Lombard years which led to the development of his early Roman style include the works of Antonio Campi, Girolamo Savoldo, Girolamo Romanino, Moretto and Lorenzo Lotto. From these artists Caravaggio acquired some of the characteristics of his early works; e.g., the (originally Giorgionesque) half-length figure, the simplified modeling, the use of clearly defined local colours and emphatic whites and the precise rendering of surfaces and textures. The subjects of this period are mostly adolescent boys. "Boy With a Fruit Basket" (Borghese gallery, Rome), "A Music Party" (Metropolitan museum, New York) and "Fortune Teller" (Louvre, Paris) are of this period. These early pictures reveal a fresh, direct and empirical approach; they are taken from life and are almost without trace of the academic Mannerism prevailing in Rome. They were bought by discerning private patrons, the chief of whom was Cardinal del Monte. Del Monte almost certainly secured Caravaggio his first public commission—the altarpiece ("St. Matthew and the Angel") and the two canvases on the side walls (the "Calling of St. Matthew" and the "Martyrdom of St. Matthew") in the Contarelli chapel of S. Luigi dei Francesi. The latter paintings, his first indubitable masterpieces, were very probably begun in 1598 and substantially finished by 1600. They not only caused a sensation in Rome but also marked a radical change in Caravaggio's artistic preoccupation. His activity now was devoted almost entirely to the painting of traditional religious themes to which he gave a whole new iconography and interpretation. He often chose subjects susceptible to dramatic, macabre or violent emphasis, divesting them of their idealized associations and taking his models from the streets. He used a lantern hung to one side in the shuttered studio; a harsh, raking light struck across the composition, illuminating parts of it and plunging the rest into deep shadow. This heightened the emotional tension, focused the detail and isolated the figures, usually placed in the front plane of the picture. His strong contrasts of light and darkness imposed a coherent surface pattern on the deliberately casual grouping of the figures. This insistence on clarity and concentration, together with a firmly plastic figure style, links his mature Roman work with the classical tradition of Italian painting. Classical qualities are evident in "Supper at Emaus" (National gallery, London). He subsequently restricted his palette, using only one strong colour—a warm red—and abandoned his earlier taste for gallants in picturesque costume. "The Entombment" (Vatican) and the "Death of the Virgin" (Louvre) are among the monumental altarpieces dating from before 1606.

At the peak of Caravaggio's artistic maturity and fame, his personal life became infused with turbulence and violence, and he is often mentioned as an offender in police records from 1600 until 1610. In May 1606, after a game of *palla a corda*—a kind of tennis—Caravaggio killed his opponent in a duel over payment of a bet, and was forced to flee to the Sabine mountains. There he painted two pictures and at the end of 1606 or the beginning of 1607 went to Naples where he executed many large and lucrative commissions. By Sept. 1607 he had probably left Naples for Malta where he gained several commissions and was received into the Order of St. John. However, shortly thereafter he was imprisoned because of a quarrel with a Cavaliere di Giustizia but he managed to escape to Sicily. There he moved from town to town, whether in an attempt to find sufficient commissions to finance his return to Rome or because he was being pursued by representatives of the Maltese Knights is not known. His works, e.g., the "Raising of Lazarus" (Messina), were preponderantly black and sombre. From Palermo Caravaggio went to Naples where he was so severely injured by enemies who attacked him that he was forced to remain eight or nine months. He later executed several commissions.

He left Naples, probably for Rome, in June 1610, but died of fever at Port'Ercole in July 1610.

Together with the Carracci of Bologna and Cigoli in Florence, he provided the most effective reform of the Mannerist style.

Caravaggio was a thoroughgoing self-conscious revolutionary in painting. He affected to despise the old masters, though he was not untouched by the contemporary revival of interest in the High Renaissance. He worked directly on the canvas; yet he composed slowly and painfully and his brushwork is without "personality." His ability to fuse the humble with the sublime made his paintings the greatest, most effective interpreters of the popular religious movements of his time. However, his influence in Rome, though striking, was short-lived and lasted longer and affected greater artists outside Italy, where the so-called Caravaggisti were concerned more with his genre subject matter, colour, composition and chiaroscuro effects than with perpetuating his way of spiritual communication. He had several close followers in the Netherlands, a major one in France—Georges de la Tour—and the early development of Velázquez is unthinkable without taking him into account. Rembrandt, moreover, made use of Caravaggesque devices in a highly original manner.

CARAVAGGIO, POLIDORO DA (POLIDORO CALDARA) (c. 1500–1543), Italian painter, influenced by Raphael and the classical antique, was born at Caravaggio in Lombardy. Hired first as a hod carrier during the decoration of the Vatican loggie (galleries), he was later employed as a fresco painter and worked with another young artist, Maturino da Firenzè. Together they decorated house façades in chiaroscuro. Their style, known from drawings and from engravings, derives from study of Hellenistic art and of Raphael, and is influenced by Baldassare Peruzzi. Their frescoes in S. Silvestro al Quirinale, Rome, mark the renewal of idealized classical landscape for its own sake. Rubens, Pietro da Cortona and others regarded Polidoro as an authority on antiquity.

After the sack of Rome he fled to Naples, then to Messina where in 1543 he was murdered. His altarpiece "Christ Bearing the Cross," painted in Messina, reflects Raphael's "Spasimo di Sicilia" and the influence of Diirer.

See G. Vasari, *Lives of the Most Eminent Painters*, English trans. by G. du C. de Vere (1912–15); A. Venturi, *Storia dell' arte italiana*, vol. 2 (1926).

CARAVAN, a word of Persian origin (karawan), signifying a group of merchants, pilgrims or travelers journeying together, usually for mutual protection. In India oxen were employed for transport; in mountainous areas mules, donkeys and horses. In the deserts of Asia and north Africa the animal most commonly used was the camel, because of its catholic appetite, its hardiness and its loading capacity (see CAMEL). In some areas the camel was harnessed to a cart. e.g., in the tea trade between Kalgan and Kyakhta, but usually the load was divided into two parts and secured on either side of the camel's back. In hot weather, on a long journey, a camel ordinarily carried about 350 lb., but on shorter journeys, in cooler weather, or to evade customs duties the load might be increased to 1,000 lb. Passengers were carried in panniers slung one on each side of the camel.

ALINARI
"THE ENTOMBMENT" BY MICHELANGELO DA CARAVAGGIO. IN THE VATICAN GALLERY, ROME, ITALY

The camels were supplied by the merchant or traveler, or hired from neighbouring nomads, Arabs, Tuaregs, Kazakhs, or Mongols, who were often also the drivers, being not only skilled camel herds-men, familiar with the routes, but also by their presence conferring some protection from other nomads. The leader of the caravan, elected by the members, was frequently a nomad chief. He decided the order of march and stopping places.

The size of the caravan was dependent upon the amount of traffic, the insecurity of the route, and the availability of camels. In Syria a chronic shortage of camels forced the Levant company to use caravans which were too small to confer adequate security. The largest recorded caravans were those for special purposes, e.g., the pilgrim caravans from Cairo and Damascus to Mecca, which might include over 10,000 camels or the Saharan salt caravans from Taoudenni to Tombouctou or Bilma to Air. Even in its decline in 1908 this latter caravan numbered 20,000 camels.

Ropes, passed through the nose ring and tied to the saddle of the camel in front, were used to fasten the camels together in strings of up to 40. Three or four strings might travel abreast, as was usual with nomad drivers, or the whole caravan might travel in one long line, as in some Chinese caravans.

The timing of caravans was governed by the availability of water and pasture, or, in the case of the pilgrim caravans, by the need to be in Mecca on the 8th day of the month of Zar'l hijja. Consequently the Orenburg caravan left Bukhara after the melting of the winter snow, and the Basra caravan left Aleppo after the rains of late autumn. These times might be modified by commercial considerations. The speed of a caravan varied with the heat, load, size and the availability of water and pasture. On long-distance routes it was customary to start slowly in order to allow the camels to build up endurance gradually. Once under way the caravan averaged 2 or 3 m.p.h. for 8 to 14 hours a day, or in hot weather, a night. If possible it was arranged to stop at a caravansary, which usually consisted of a courtyard, surrounded on all sides by a number of small rooms, on an elevation, with stables underneath. The endowment of caravansaries, particularly for pilgrims, was regarded as a pious duty. The great Arab traveler Ibn Batutah records the presence of caravansaries founded by the wife of Harun al-Rashid all along the Baghdad-Mecca route.

Although the opening of the sea routes to the east was partly responsible for the decline of certain routes, e.g., the Great Silk road from China to the Mediterranean, yet several important caravan routes flourished until the 19th century, when road and rail transport and the abolition of the slave trade led to their ruin. Some local caravans survive in the absence of alternative transport, and certain others because of some particular appeal or advantage. The Pomindah caravan from the Derajat in West Pakistan into Afghanistan coincides with the annual migration of the tribe; some of the pilgrim caravans continue because it is regarded as more meritorious to travel the hard traditional route, and the Saharan salt caravans because of superior qualities attributed to Saharan salt by the western Sudanese. (M. E. Y.)

CARAVANSARY (CARAVANSERAI), in the middle east, a public building for the shelter of a caravan (q.v.) and of wayfarers generally. It is commonly constructed in the neighbourhood, but not within the walls, of a town or village. It is quadrangular in form, with a dead wall outside; this wall has small windows high up, but in the lower parts merely a few narrow air holes. Inside a cloisterlike arcade, surrounded by cellular storerooms, forms the ground floor, and a somewhat lighter arcade, giving access to little dwelling rooms, runs round it above. Broad open flights of stone steps connect the stories. The central court is open to the sky, and generally has in its centre a well with a fountain basin beside it. A spacious gateway, high and wide enough to admit the passage of a loaded camel, forms the sole entrance, which is furnished with heavy doors and is further guarded within by massive iron chains, drawn across at night. The entry is paved with flagstones, and there are stone seats on each side. The court itself is generally paved, and large enough to contain 300 or 400 crouching camels or tethered mules; the bales of merchandise are piled away under the lower arcade, or stored in the cellars behind it. The upstairs apartments are for human lodging; cooking is usually carried on in

one or more comers of the quadrangle below. Should the caravanary be a small one, the merchants and their goods alone find place within, the beasts of burden being left outside. A porter, appointed by the municipal authority, is always present, lodged just within the gate. He sometimes has one or more assistants. These form a guard of the building and of the goods and persons in it, and have the right to maintain order and, within certain limits, decorum; but they have no further control over the temporary occupants of the place. It is always kept open for all arrivals from prayer time at early dawn till late in the evening. Neither food nor provender is supplied.

Many caravanaries have considerable architectural merit; their style of construction is in general that known as Saracenic; their massive walls are of hewn stone; their proportions apt and grand. The portals especially are often decorated with intricate carving; so also is the prayer niche within. (See ISLAMIC ARCHITECTURE.)

By extension, the word has sometimes been applied to well-designed motels in semitropical desert regions, even though their plans only roughly resemble the originals.

Khans—*i.e.*, places analogous to inns and hotels, where not only lodging but often food and other necessities or comforts may be had for payment—are sometimes confounded with caravanaries. They are generally to be found within the town or village precincts, and are much smaller than caravanaries. The khan of Asad Pasha at Damascus is a model of constructive skill and architectural beauty. (A. B.-B.)

CARAVEL, a light ship of the 15th, 16th and 17th centuries, much used by the Spanish and Portuguese for long voyages. Apparently developed by the Portuguese for exploring the coast of Africa, the caravel's chief excellence lay in its capacity for sailing to windward. It was also capable of remarkable speed. Two of the three ships in which Columbus made his historic voyage in 1492 were caravels, the "Niña" and "Pinta."

The design of caravels underwent changes over the years but a typical caravel of the late 15th century may be described as a broad-beamed vessel of 50 or 60 tons burden; some were as large as 160 tons. About 75 ft. long, the typical caravel had two or three pole masts, lateen rigged, *i.e.*, with triangular sails. Later versions added a fourth mast with square sail for running before the wind. Caravels were usually built with a double toer at the stern (the sterncastle) and a single tower in the bow (the forecastle). As a type, caravels were smaller and lighter than the Spanish galleons of the 16th century. In later years the term was applied to small fishing boats along the coast of France, and to a Turkish man-of-war.

CARAWAY, the fruit, or so-called seed, of *Carum carvi*, a plant of the carrot family (Umbelliferae; *q.v.*) growing throughout the northern and central parts of Europe and Asia, and naturalized in waste places in England and in North America from Newfoundland to Colorado. The plant has finely cut leaves and compound umbels of small white flowers. The fruits, commonly called caraway seeds, are flattened and oval. Caraway has a pleasant aromatic odour when bruised, and an agreeable spicy taste. It yields a volatile oil, the chief constituent of which is carvone. The plant is cultivated in north and central Europe and Morocco, as well as in the south of England, the produce of more northerly latitudes being richer in essential oil than that grown in southern regions. The oil is obtained by distillation for use in medicine as an aromatic stimulant and carminative, and as a flavouring material in cookery and in liqueurs for drinking. Caraway seeds are more extensively consumed entire, however, in certain kinds of cheese, cakes and bread.

CARAZO, a small department (area 367 sq.mi.) established in 1891 on the Pacific coast of Nicaragua. The population ([1959 est.] 73,783) is mostly concentrated in valleys and on the lower slopes of volcanic mountains in the eastern half of the department. This area, with deep fertile soils and 60 in. of rainfall annually, produces coffee, tobacco, corn, beans, other vegetables and fruits. It has many large haciendas. The departmental capital, Jinotepe (pop. [1959 est.] 5,153), at 2,511 ft. above sea level enjoys a subtropical climate and is connected by the Inter-American highway with Managua. It has a beautiful colonial church. (C. F. J.)

CARBAZOLE, or dibenzopyrrole, a constituent of coal tar, is a white crystalline solid in its pure form. Commercially it is of some importance as the raw material for a valuable dyestuff, hydron blue R, which is made in all the leading industrial nations of the world. In Europe carbazole is obtained from coal; in the United States it is made synthetically. Carbazole may be prepared synthetically by a number of processes, for the most part employing nitro and amino substituted diphenyl. For conversion to the dyestuff, it is first condensed with nitrosophenol in sulfuric acid at temperatures of from -40° to -50° C. The resulting indophenol is then reduced to its leuco compound, and this in turn is heated in alcoholic sodium polysulfide solutions until colour formation is completed. The product is a deep-blue vat dyestuff with somewhat better fastness properties than indigo. However, it is somewhat inferior in this respect to the blue vat dyestuffs derived from anthraquinone. Inasmuch as carbazole can be easily ethylated to N-ethyl carbazole, this substance is used for the production of a dyestuff, hydron blue G, which gives textile fibres a much greener shade of blue than hydron blue R.

Carbazole occurs in high boiling fractions of coal tar along with anthracene and phenanthrene. It is best separated from these materials by fusion with caustic potash, whereby the carbazole is converted into a salt, potassium carbazolate. The anthracene or phenanthrene can then be distilled off, or extracted with solvents such as coal-tar naphtha or pyridine. The crude carbazole is recovered by hydrolysis with water, and can then be purified either by crystallization from suitable solvents or by sublimation. Pure carbazole melts at 238° C.; the chemical formula is $C_{12}H_9N$. It dissolves in concentrated sulfuric acid with a yellow colour which on the addition of oxidizing agents turns to green. It forms a red picrate, $C_{12}H_9N \cdot C_6H_3O_7N_3$, melting at 182° – 186° C. The structural formula of carbazole is:

(J. H. Ss.)

CARBIDES, a class of chemical substances in which carbon is combined with a metallic or semimetallic element. The most important carbides are: (1) calcium carbide (CaC_2), used for the generation of acetylene (*q.v.*); (2) iron carbide (Fe_3C), cementite, the most important hardening constituent in steel; (3) silicon carbide (*q.v.*) (SiC), carborundum, used for grinding wheels, high-temperature refractories and electrical heating elements; and (4) tungsten carbide (WC), which is the main constituent in superhard tools for the high-speed machining of metals.

Properties.—In general, the carbides are very hard, brittle, crystalline materials which are readily reducible to powder form. Chromium carbide (Cr_4C) will scratch topaz; silicon carbide and boron carbide (B_4C) have almost the hardness of diamond. The carbides have extremely high melting points; tantalum carbide (TaC) has the highest melting point of any known substance ($4,150^{\circ}$ C.). Calcium carbide ranges in colour from clear colourless crystals for the pure form to dark gray masses for the commercial product. Most powders are dull gray, while some have colours quite different from the metal, such as bright yellow for aluminum carbide (Al_4C_3), brown for tantalum carbide and lavender for columbium carbide (CbC). When crystallized from a molten solvent metal such as nickel or aluminum, the carbides of the refractory metals form large crystals which are exceedingly pure and sparkle with a gemlike brilliance. The carbides are odourless except for those, like calcium carbide or thorium carbide (ThC_2), which react with moisture to yield acetylene and other hydrocarbon products.

Chemically, the carbides range from explosively active materials to those which are practically inert at high temperatures. Silver carbide (Ag_2C_2) is explosively violent in its decomposition; calcium carbide reacts vigorously with water to give acetylene; iron carbide reacts with dilute acids to give a mixture of hydrocarbon gases; tantalum carbide is resistant to all acids except a mixture of hydrofluoric and nitric acids and it must be

heated somewhat before it oxidizes; and silicon carbide is so inert that it withstands oxidation at white heat.

Preparation.—The two most important methods for the preparation of the carbides are. (1) the direct union of carbon with the metal; and (2) the reaction of carbon with an oxide of the metal. Some form of an electric furnace is required to obtain the high temperatures needed to complete the reactions. Henri Moissan pioneered in the fundamental investigations of many of the carbides, following his development of the electric arc furnace in 1892. The first method may be illustrated by tungsten carbide, which is made by intimately mixing tungsten powder and lamp-black, packing the mixture in a graphite crucible and heating to $1,400^{\circ}$ C. in an electric furnace of the high-frequency or muffle type. The reaction is $W + C = WC$. The second method is the more common and may be illustrated by the reaction of tantalum oxide and carbon which are placed in a similar furnace but heated to $2,000^{\circ}$ C. to complete the operation: $Ta_2O_5 + 7C = 2TaC + 5CO$. Silicon carbide, first prepared by Edward Goodrich Acheson in 1891, is made from a mixture containing silica (SiO_2), coke, salt and sawdust which when heated in still another type of electric furnace produces lustrous iridescent pale-green to sapphire-blue crystals. Silicon carbide is the most widely used of all the carbides. A similar method is used for the preparation of calcium carbide: the oxide or carbonate of calcium in the form of lime or limestone respectively is mixed with carbon in the form of coke or powdered coal and heated in an electric furnace from which the molten product is tapped off at $2,000^{\circ}$ C. Most carbides are formed at temperatures below their melting points; calcium carbide is one of the exceptions.

CARBINE, in modern military language, a light short-barreled shoulder weapon. The term came into use toward the end of the 16th century to denote a form of small smoothbore firearm, shorter than a standard musket and intended chiefly for use by mounted men. The word retained this meaning through many subsequent modifications of firearms design, including the introduction of rifling and automatic operation. (See SMALL ARMS, MILITARY.)

During the early years of the 20th century carbines were replaced in the U.S. army by the ordinary rifle, even for cavalry, because rifles had become shorter and lighter. But the carbine came back into prominence in World War II. As a personal weapon for U.S. service troops in rear areas it replaced the pistol, a short-range weapon of limited accuracy. Only three feet long and weighing less than six pounds, the new calibre .30 carbine was lighter and easier to carry than the standard rifle. It had an effective range of about 300 yd., sufficient for close-in defense. It was gas operated, semiautomatic (fully automatic in later models) and fired a light cartridge that differed from the standard rifle cartridge in several respects. During the early part of the 20th century the British army used the term machine carbine to denote the type of weapon known in the United States as the sub-machine gun, but the term was dropped to eliminate confusion during World War II. The Soviet army classed as carbines certain 7.62 mm. weapons that would be termed rifles by U.S. army standards. With adoption by the U.S. army in 1957 of a new light rifle that combined many of the best features of rifle and carbine, the World War II carbine was marked for obsolescence. (H. C. T.)

CARBO, the cognomen or third name of a Roman plebeian family of the *gens Papiria*. The following are the most important members:

GAIUS PAPIRIUS CARBO (d. 119 B.C.), tribune of the people 131 B.C., carried a law extending voting by ballot to the enactment and repeal of laws; another proposal, allowing repetition of tenure of the tribunate, was defeated by Scipio Aemilianus. In 130 he became a member of the Gracchan land commission (see GRACCHUS, GAIUS SEMPRONIUS). Carbo was suspected of having been concerned in the sudden death of Scipio (129). In 122 he deserted the Gracchans and went over to the senatorial aristocracy or *optimates*; rewarded with the consulship for 120, he successfully de-

fended Lucius Opimius, the murderer of Gaius Gracchus. But the *optimates* did not trust Carbo. He was impeached by Licinius Crassus, probably on a charge of treason or extortion, and committed suicide (119).

GAIUS PAPIRIUS CARBO (d. 82 B.C.), son of the above, was a supporter of the *optimates* and was put to death by the party of Gaius Marius (*q.v.*) in 82. As tribune in 89 with M. Plautius Silvanus he carried the *lex Plautia Papiria*, whereby the Roman franchise was offered to all Italian rebels who laid down arms and to certain people not covered by the *lex Julia* of 90 B.C.; such persons had to apply within 60 days to the praetor at Rome.

GNAEUS PAPIRIUS CARBO (c. 130-82 B.C.), nephew of the first-mentioned Gaius, was a strong supporter of the party of Marius, and took part in the blockade of Rome (87). In 85 he was chosen by Cinna as his colleague in the consulship, and the two began to make preparations against the return of Sulla (*q.v.*) from the east. Cinna and Carbo declared themselves consuls for the following year, but Cinna was murdered by his own soldiers, leaving Carbo sole consul. In 82 Carbo, then consul for the third time, fought a drawn battle with Sulla near Clusium (mod. Chiusi) in Etruria, but he was defeated by Sulla's general, Metellus Pius (see METELLUS), near Faventia. Carbo fled from Italy to Sicily and then to the island of Cossyra, south of Sicily, where he was captured; he was put to death by Gnaeus Pompeius.

CARBOHYDRATES. The carbohydrates constitute a large group of closely related organic compounds which are composed of carbon, hydrogen and oxygen. These substances, with proteins and fats, form the major components of living matter, maintaining the functional activity of the cells and serving as structural and reserve materials. Honey, cane or beet sugar, starch, cotton and vegetable gums may be cited as typical carbohydrate substances of natural occurrence.

If a single biochemical process may be regarded as more fundamental than any other, it is the photochemical assimilation of carbon dioxide from the air by the green plants and the subsequent production of carbohydrates through a complicated cycle of enzymic reactions. This process results in the recovery of carbon dioxide from the air and the conversion and storage of the atomic energy of the sun in a form utilizable by living matter.

Carbohydrate chemistry has wide industrial applications in the manufacture of paper, cloth and synthetic materials, as well as foodstuffs. Already the combined value of the industries employing carbohydrate source material far exceeds that of those using other sources, a situation offering promise for the absorption of farm crop surpluses. Furthermore, carbohydrates arise from renewal crops independent of mineral findings.

The development of the chemistry of the carbohydrates began with the investigations of Emil Fischer and his collaborators, who established the basic structures and configurations of the component units.

How these units link to form the larger molecules was elucidated largely by the methods devised by Sir Norman Haworth and his school. Claude S. Hudson and his associates determined significant fine points concerned with tautomeric or shifting structures.

The relatively simple carbohydrates, generally termed sugars, are nearly all sweet, crystalline and water-soluble solids. The early knowledge of sugars related to the art of making sweetmeats and sweetening agents and dates back to antiquity. After the conquest of Persia, the Arabs became familiar with the sugar industry and spread it through the Islamic domain, including Spain.

More complex carbohydrates are formed from the simple sugars by the combination of basic units in a manner providing almost infinite possibilities of variation. In the basic units, termed monosaccharides, the carbon atoms are joined together in a chain and are further combined with the elements of water. This provides the general formula $C_n(H_2O)_n$ and explains the origin of the name carbohydrate (Fr. *hydrates de carbone*; Ger. *Kohlenhydrate*).

A colossal number of carbohydrate compounds have been characterized and great progress has been made in the investigation of their properties and structures. These strides have culminated

in the solution of problems of exceptional interest and difficulty and have materially contributed to the understanding of the cognate subjects of the biosynthesis and biological function of carbohydrates.

The following are the main sections and divisions of this article:

- I. Monosaccharides
 1. Stereoisomerism
 2. Occurrence
 3. Properties

 10. Mucopolysaccharides

I. MONOSACCHARIDES

The monosaccharides are divided into two groups: the aldoses of the formula $\text{CH}_2\text{OH}-(\text{CHOH})_n-\text{CHO}$, related to the aldehydes; and the ketoses, of the formula $\text{CH}_2\text{OH}-(\text{CHOH})_n-\text{CO}-\text{CH}_2\text{OH}$, related to the ketones. These are further classified according to the length of their carbon chain. Thus, there are aldopentoses, aldohexoses, ketopentoses (pentuloses) and the like. More extensive variations in the structure of the monosaccharides result from the differences in the spatial arrangements of the elements of water (hydrogen, $-\text{H}$, and hydroxyl, $-\text{OH}$) attached to the carbon atoms within the chain.

1. Stereoisomerism. — The above differences in the spatial arrangements derive from the fact that the four valence bonds of the carbon atom are tetrahedrally disposed in space and if each of these bonds is attached to a different group, the result will be an asymmetric carbon which cannot be superimposed upon its mirror image. The smallest aldoses containing an asymmetric carbon are D-glyceraldehyde (I and IA) and L-glyceraldehyde (II and IIA). At this stage it should be noted that the presentation of the three-dimensional structure of the monosaccharides in the plane of the paper is a matter of some difficulty and is only attained through a number of conventions. A simple method is the formalized projection of the imaginary tetrahedra in the plane of depiction, as in IA and IIA:

As the number of carbon atoms in the chain increases, the addition of each new asymmetric carbon doubles the number of possible forms. Consequently, there are 16 aldohexoses and 8 hexuloses of the general formula $\text{CH}_2\text{OH}-(\text{CHOH})_4-\text{CHO}$ and $\text{CH}_2\text{OH}-(\text{CHOH})_3-\text{CO}-\text{CH}_2\text{OH}$, respectively. These forms are termed stereoisomers.

As will be described, the ketoses can be related to the aldoses and the aldoses can be synthesized from D- and L-glyceraldehyde by the stepwise addition of the repeating CHOH entity. By agreement, the monosaccharides related to D-glyceraldehyde are assigned the configurational symbol D and those related to L-glyceraldehyde carry the configurational symbol L. This divides the monosaccharides into two series. The mirror image of each compound belonging to the D series forms the corresponding member of the L series. Such

pairs of stereoisomers are termed enantiomorphs.

The presence of an asymmetric carbon atom in the molecule results in the phenomenon of optical activity, that is, the rotation of the plane of polarized light by solutions of the compound (see STEREOCHEMISTRY). The direction and degree of optical rotation, determined under defined conditions, are expressed as specific rotation, $[\alpha]$, and are characteristic of each sugar. The enantiomorphous compounds rotate the plane of polarized light to the same extent but in opposite directions. Those that rotate to the right or positive direction are said to be dextrorotatory and the others are termed levorotatory. For instance, the naturally occurring D-glucose, $[\alpha]_D^{20} +52.2^\circ$, is dextrorotatory and the synthetic L-glucose, $[\alpha]_D^{20} -52.2^\circ$ (measured in dilute aqueous solution at 20°C . with light of $589.25\text{ m}\mu$ wave length), is levorotatory. The formula I, originally assigned to the dextrorotatory form of glyceraldehyde purely by convention, has been proved to conform to reality. Since the configurations of the other sugars are related to this standard reference substance through the study of their physical and chemical properties, an absolute basis for the assignment of correct projection formulas to the various monosaccharides is so provided. It should be noted that all the D-sugars are not necessarily dextrorotatory and that the configuration of the highest numbered (see III) asymmetric carbon atom determines whether a compound belongs to the D or L series, irrespective of the direction or sign of the optical rotation.

2. Occurrence. — A wide variety of monosaccharides is found in naturally occurring materials as free sugars or as components of more complex substances. D-Glucose (III) is by far the most widely distributed sugar. In the free state it is found in fruits, honey, plant juices, blood and diabetic urine. Cellulose, starch, glycogen and dextran are formed from the combination of D-glucose units. Other naturally occurring aldohexoses are D-galactose (IV), L-galactose (V) and D-mannose (VI). In the ketose series, D-fructose (VII) is of major natural occurrence. This sugar is frequently found in association with D-glucose, either

in the free state or in combination as the disaccharide sucrose (cane sugar). Inulin (from dahlia tubers) and the fructans from grasses are polysaccharides composed of D-fructose units. The heptulose D-alto-heptulose (sedoheptose) and D-erythro-pentulose, a ketopentose (VIII), are considered to be important transition products in the process of photosynthesis. The aldopentoses found in nature are L-arabinose (IX), D-arabinose (X), D-ribose (XI)

and D-xylose (XII). L-Arabinose and D-xylose are found in plant exudates (gums), in plant structural materials (as corncobs) and in bacterial polysaccharides. D-Ribose is one of the carbohydrate constituents of cell nuclear material (nucleic acids); the other carbohydrate constituent is a modification of this sugar termed "2-deoxy-D-ribose" (XIII). D-Arabinose has been isolated from the tubercle bacillus (*Mycobacterium tuberculosis*). The trioses D-glyceraldehyde and dihydroxyacetone occur in their phosphate deriva-

tives as intermediate metabolic products.

As with the "2-deoxyribose" already mentioned, not all of the naturally occurring monosaccharides conform to the general pattern described above. The amino sugar D-glucosamine (XIV), found in animals, bacteria and fungi, contains the elements of ammonia ($-\text{NH}_2$ and $-\text{H}$). In the deoxy sugars, one or two of the $-\text{OH}$ groups are replaced by hydrogen atoms, as in "2-deoxyribose," 6-deoxy-L-mannose (L-rhamnose, XV) and 2,6-dideoxy-D-ribohexose (digitoxose, XVI). The *Strophanthus* and Convolvulaceae glycosides contain a variety of deoxy sugars. D-Glucuronic acid (XVII) and other uronic acids have a carboxylic acid function. Some sugars, as streptose (XVIII), a component of the antibiotic streptomycin, contain a branched carbon chain. The alditols are polyhydric alcohols that are reduction products of the carbonyl functions present in aldoses and ketoses. Sorbitol (D-glucitol, XIX), found especially in the fruits of Rosaceae, belongs to this category. The inositols, (CHOH),, with a cyclic carbon chain, provide another variety of naturally occurring polyhydric alcohols.

3. Properties. — The normal aldoses and ketoses differ in the position of their carbonyl group ($>\text{C}=\text{O}$). The aldoses, with the carbonyl group at position one, react as polyhydroxy aldehydes and the ketoses, having the carbonyl group at position two, react as polyhydroxy ketones. As noted above, the four valence bonds of the carbon atom form a tetrahedron. Consequently, the carbon atoms are joined together through an angle of $109^\circ 28'$. This creates an inherent tendency in the sugar molecule to curl and brings the carbonyl function in a position to react with one of the hydroxyl groups. The reaction products are the cyclic forms of the monosaccharides (designated monocyclic hemiacetals) in which an oxygen bridge joins two of the carbon atoms. This process alters the carbonyl function and forms a new asymmetric carbon atom with a hydroxyl group that can be oriented in either of two directions to form stereoisomers designated anomers. Six-membered (pyranose) and five-membered (furanose) rings are preferred, with the former being the more stable. Thus, an aqueous solution of D-glucose will be a mixture consisting mainly of two crystallizable and interconvertible forms designated α -D-glucopyranose and β -D-glucopyranose. The former compound (XX) melts at 146°C . and exhibits a specific rotation of $+112^\circ$ while the latter (XXI) melts at $148^\circ\text{--}150^\circ \text{C}$. and possesses the lower dextrorotation of $+19^\circ$. When either form is dissolved in water, the rotation undergoes a spontaneous change termed mutarotation with the eventual establishment of the equilibrium value of $+52.5^\circ$. This change is promoted (catalyzed) by both acids and bases but especially by bases with the catalytic action of water being due mainly to its slight dissociation into hydroxyl ions.

Although the above equilibrium favours the structures XX (about one-third) and XXI (about two-thirds), an aqueous solution of D-glucose can react in both cyclic and acyclic (aldehydo) forms.

The true spatial relations of XX and XXI are better represented by XXA and XXIA and even better by the statistically favoured staggered ring conformation shown for the α -D anomer in XXB.

We will examine next the general properties of D-glucose and D-fructose as typical examples of members of the aldose and ketose groups of monosaccharides.

4. D-Glucose (dextrose or grape sugar) is fermentable by yeast. It exhibits aldehydic properties inasmuch as it reduces alkaline copper solutions, is oxidized by hypohalite ions to an aldonic acid (D-gluconic acid, XXII) without loss of carbon and gives characteristic derivatives with such reagents as phenylhydrazine, hydroxylamine and ethanethiol (see XXIII). It does not, however, give a normal Schiff colour reaction, which is specific for the simple aldehydes. The aldehydic function disappears when the sugar is hydrogenated, the product being the alditol D-glucitol (sorbitol, XIX) which when further reduced with hydrogen iodide gives a derivative of normal hexane (XXIV).

This proves that the six carbon atoms of glucose are arranged in an unbranched chain. The oxidation of D-glucose, or of D-gluconic acid, with nitric acid yields a dibasic acid, D-glucaric acid (saccharic acid, XXV). Another oxidation product is D-glucuronic acid (XVII).

The action of hydrogen chloride on a solution of D-glucose in methanol at 100°C . provides a mixture of two crystalline substances which are interconvertible when dissolved in hot methanol containing acid. These substances are related to each other in the same manner as α - and β -D-glucopyranose and are termed methyl α -D-glucopyranoside (XXVI) and methyl β -D-glucopyranoside (XXVII). They can be considered as mixed acetals and are members of the group of substances known generically as

glycosides. The nonreducing (toward mild oxidizing agents) acetal linkage in the glycosides undergoes hydrolysis (chemical fixation of the elements of water) by acids or by enzymes to regenerate the original sugar and the hydroxylic compound. When the hydroxylic component is another monosaccharide, the combination is termed a disaccharide (see below).

Other ring structures for D-glucose derivatives are known to the chemist. The primary and secondary alcohol groups in the sugar rings can form derivatives characteristic of such groups. Thus, they can form esters with carboxylic and inorganic acids and they can form ethers, of which the methyl and benzyl ethers have been especially useful to the structural and synthetic chemist.

5. D-Fructose (levulose) and other ketoses share most of the properties described for D-glucose and other aldoses. A principal difference between the two groups is that the ketoses are resistant to oxidation with hypohalite and cannot be converted to aldonic acids without loss of carbon. The ketoses all exhibit abnormal mutarotatory characteristics (as does D-ribose) and it is probable that furanose and acyclic (keto) forms constitute significant components of their equilibrium mixtures. When in combination with other monosaccharides in nature, D-fructose always occurs in its furanose form.

D-Fructose and D-glucose are closely related in structure and are in fact interconvertible by chemical and biological reactions. They both yield a highly crystalline and characteristic compound known as D-glucose phenylosazone (XXIX) on reaction with phenylhydrazine, the initial product being the phenylhydrazones XXVIII and XXX. Oxidation of these products with excess reagent and condensation with a second molecule of phenylhydrazine results in the formation of the phenylosazone. Since the oxidation takes place at position two of the D-glucose and position one of the D-fructose, the phenylosazone formed from each is the same.

6. Interconversion and **Synthesis**.—By combining certain reactions, it is possible to pass from any monosaccharide to one containing an additional carbon atom. Thus, the addition of hydrogen cyanide to an aldose gives two products (nitriles) which on subsequent hydrolysis to the aldonic acid and appropriate reduction of the lactone (inner ester) of the acid yields the two higher aldoses, as shown below (R = the remainder of the sugar molecule).

Another synthesis of higher aldoses involves the sequence: $\text{R}-\text{CHO} \rightarrow \text{R}-\text{CHOH}-\text{CH}_2\text{NO}_2 \rightarrow \text{R}-\text{CHOH}-\text{CH}=\text{NO}_2\text{Na} \rightarrow \text{R}-\text{CHOH}-\text{CHO}$.

The opposite procedure, or degradation, can be accomplished by several methods. In one of these the calcium salt of, for example, D-gluconic acid is oxidized with hydrogen peroxide in the presence of ferric acetate, whereupon the following reaction takes place: $\text{R}-\text{CHOH}-\text{CO}_2\text{H} \rightarrow \text{R}-\text{CHO}$. In this case D-arabinose is formed.

The action of mild bases on the aldonic acids results in the inversion of configuration (2-epimerization) on the carbon (second) adjacent to the carboxyl function. A means is thus provided for the conversion (after subsequent reduction of carbon one to the aldehyde stage) of D-glucose into its 2-epimer D-mannose. Action of mild bases on the aldoses or ketoses leads to a mixture in which the ketose predominates. The ketoses may

also be synthesized from the next lower aldoses by the following sequence of reactions performed on suitably substituted sugar derivatives: $\text{R}-\text{CHO} \rightarrow \text{R}-\text{CO}_2\text{H} \rightarrow \text{R}-\text{CO}-\text{Cl} \rightarrow \text{R}-\text{CO}-\text{CHN}_2 \rightarrow \text{R}-\text{CO}-\text{CH}_2\text{OH}$.

II. OLIGOSACCHARIDES

As noted above, the glycosidic function of a monosaccharide can react with one of the several free hydroxyl groups (including the hydroxyl group at position one) of another monosaccharide to form a disaccharide. Variations in the component monosaccharides and their ring structures, as well as the position and anomeric form of the glycosidic linkage, can provide an immense number of disaccharides. These compounds can further react to form trisaccharide-higher oligosaccharides and polysaccharides. The oligosaccharides contain an established number, less than 10, of monosaccharide units while the polysaccharides contain an estimated large number, generally 100 or more, monosaccharide units. In analogy with the glycosides, the acidic or enzymic hydrolyses of these materials will produce their original components. The glycosidic (acetal) linkage in some aldose disaccharides involves both hydroxyl groups at position one (potential carbonyl functions). Thus, they cannot display the reducing and other properties associated with the potential carbonyl function and are termed nonreducing disaccharides. In reducing disaccharides one of the glycosidic hydroxyl groups is still available. These compounds reduce Fehling's reagent and may be crystallized in anomeric forms which mutarotate in solution. They form osazones and if the reducing monosaccharide is not a ketose, they can be oxidized with hypohalite to aldonic acids or reduced to the combination of a monosaccharide and an alditol.

When the reducing monosaccharide is a ketose, the reduction provides a mixture of the two corresponding alditol derivatives. These reactions can also be applied to the higher oligosaccharides. An important property of the oligosaccharides and of the more complex carbohydrates is their partial hydrolysis by acids or enzymes to smaller fragments including disaccharides. Thus, the isolation of disaccharides from such hydrolytic products provides a method for investigating the structure of complex carbohydrates (fragmentational analysis). The various structural features of a disaccharide can be determined by a combination of physical and chemical properties some of which have been briefly mentioned.

In general, the reducing oligosaccharides, with the notable exception of lactose, originate from the partial hydrolysis of polysaccharides, higher oligosaccharides and plant glycosides. In

contrast, the nonreducing oligosaccharides are mainly found in the plant products as the free compounds. The following is a brief description of certain reducing and nonreducing disaccharides and oligosaccharides.

1. Maltose (malt sugar) is formed by the action of the amylase enzymes (from germinating cereal grains) on starch. Maltose is a reducing sugar which crystallizes as the β anomer, and is hydrolyzed to its D-glucose components by the enzyme maltase, which specifically cleaves the α -D-glucosides. It has been shown that the glycosidic linkage in this compound (XXXI) involves position four of the reducing monosaccharide.

2. Cellobiose is obtained as its acetate derivative by the partial cleavage of cotton cellulose with a mixture of sulfuric acid and acetic anhydride. It is hydrolyzed by the enzyme emulsin. Except for the anomeric form of the glycosidic linkage, which is β -D-(1 \rightarrow 4), cellobiose (XXXII) has all the structural features of maltose.

CH₂OH

5. Melibiose, a constituent of the trisaccharide raffinose, is composed of D-galactopyranose and D-glucose joined through an α -D-(1 \rightarrow 6) linkage.

6. Sucrose (cane sugar, beet sugar) is commercially the most important sugar. It is formed as a product of photosynthesis and constitutes the main sugar in the sap of plants. For a description of its physical properties and the processes for manufacturing it see SUGAR. Structurally, sucrose has been shown to be a non-reducing disaccharide in which the α form of D-glucopyranose is combined with the β form of D-fructofuranose (XXXIII). Sucrose is readily hydrolyzed to these monosaccharides by the action of dilute acid or by the enzyme invertase. Since, despite the positive optical rotation of sucrose, the mixture of equilibrated hydrolytic products is levorotatory, this process is termed inversion.

found in a variety of plant products.

7. Trehalose, found in fungi and mushrooms, is another biologically significant nonreducing disaccharide. It is formed by the combination of two α -D-glucopyranose units.

III. POLYSACCHARIDES

The polysaccharides form a large group of natural products that are widely distributed in living matter. The established general physiological functions of these compounds are to serve as reserve foodstuffs or as structural and protective materials. In their protective capacity they are found in the exoskeletons of crustaceans and insects, the capsular material of certain bacteria and as gums and exudates which seal plant wounds. As structural materials, they help to maintain the rigidity of plants and they form the main constituents of plant mucilages, animal joint fluids and animal cartilages. The constituents responsible for the specificity of blood-group substances, the immunological properties of cer-

3. Gentiobiose is a component of the trisaccharide gentianose and certain plant glycosides. It contains two D-glucopyranose units joined through a β -D-(1 \rightarrow 6) linkage. The sugar is an isomer of isomaltose, a minor hydrolytic product of starch. The glycosidic linkage of isomaltose is α -D-(1 \rightarrow 6).

4. Lactanose (the milk sugar) is a constituent of the trisaccharide raffinose. It is composed of a D-galactopyranose unit joined through a β -glycosidic linkage to position four of a D-glucopyranose unit and thus it resembles cellobiose.

The chemical combination of sucrose with D-glucose and D-galactose provides a group of oligosaccharides, including melzitose, raffinose and gentianose,

tain materials and the anticoagulant function of animal tissue components have been shown to be polysaccharide in nature.

Chemically, the polysaccharides may contain one or several monosaccharide constituent units. The former varieties (homoglycans), represented by cellulose and starch, are more abundant while the latter substances (heteroglycans) are more numerous. These compounds may have linear structures, as cellulose, branched structures, as gum arabic, or a mixture of both, as the starches (see below). The linear polysaccharides often pack together with frequent secondary attachments (hydrogen bonding) to provide a rigid structure. The branched polysaccharides, on the other hand, are generally water soluble and make cohesive and thick pastes.

1. Cellulose.—The purest form of cellulose (*q.v.*) is cotton fibres, which are single cells ranging from 10 to 50 mm. in length. Other commercial sources are wood, flax, hemp and straw. The manifold industrial uses of cellulose (see PAPER; SYNTHETIC FIBRES) depend primarily on its fibrous nature, which results from the linear structure of the molecule, shown in skeleton form in XXXIV.

Cellulose constitutes the main component of the cell walls of land plants and as such it is the most abundant naturally occurring organic substance. The biological function of cellulose is reflected by its insolubility, its chemical inertness and its physical rigidity.

Chemically, cellulose is composed of D-glucose units joined together end to end through β -D-(1 \rightarrow 4) links. This is partially demonstrated by fragmentational analysis which gives the disaccharide cellobiose (shown in brackets in XXXIV) and a group of larger fragments. The chain length, that is, the average number of D-glucose units, often described as the degree of polymerization (D.P.), may be determined by several physical and chemical methods, including viscosity measurements. The result varies according to the source of the cellulose, the treatment to which it has been submitted and even the method of determination. The D.P. of native cellulose is considered to be in excess of 3,000 and perhaps several times this value.

Nitrate esters of cellulose, of varying degrees of nitration, are used for the production of explosives (guncotton) and plastic materials.

XXXIV

XXXV

2. Starch.—Large amounts of starch (*q.v.*) are laid down in the storage organs of plants. These include seeds, tubers, roots and stem pith. The starch appears in the form of distinct granules characteristic of their origin. These starches provide a reserve food supply for the plant, sustain the root or tuber through winter dormancy and nourish the growing embryo during the germination period. The main commercial sources of starch are corn (maize), potato and tapioca.

Amylose XXXVI

Amylopectin XXXVII

Most of the common starches are a mixture of two different molecular species. These are amylose, which has a linear structure (XXXV, XXXVI), and amylopectin, which has a branched or bushy structure (XXXVII).

The proportion of the two fractions is again characteristic of each species. Potato starch and cereal starches contain about 15% to

30% amylose. However, in the waxy cereal grains which constitute genetic varieties of corn, rice and grain sorghum, originating in China, the starch consists almost entirely of amylopectin. The starches from wrinkled-seed green peas and certain varieties of sweet corn, on the other hand, consist of a preponderant amount of amylose.

Unlike cellulose, the starches can be dispersed in hot water. When a suspension of starch granules in water is heated to a certain critical temperature, the granules suddenly swell and an opalescent dispersion is formed (gelatinization) which sets to a paste when cold. Amylose is considered to contribute jelling characteristics and amylopectin the gummy or cohesive properties to the paste.

Starch is hydrolyzed by dilute acids and the group of enzymes known as the amylases. Complete acid hydrolysis provides a quantitative yield of D-glucose, while the enzymic hydrolysis gives mainly the disaccharide maltose (XXXI). Maltose bears the same relation to starch as cellobiose does to cellulose. A large number of higher fragments, known as dextrans, have been prepared by the controlled action of acids and heat on starches.

Amylose (XXXV, XXXVI) consists of a long chain of D-glucose units (about 200 to 500) joined together through α -D-(1 \rightarrow 4) links. The linear structure thus produced has, unlike cellulose, all the $-\text{CH}_2\text{OH}$ residues at one side and has a tendency to coil in a helical form. In amylopectin (XXXVII) the units are joined together in a manner which provides a highly branched structure. At the branching points the D-glucose molecule is attached to other units through position six, α -D-(1 \rightarrow 6), as well as positions one and four, α -D-(1 \rightarrow 4). In addition to these major interconnecting links, later investigations have also proved the presence of a small number of α -D-(1 \rightarrow 3) links. The branched and unbranched components of starch are distinguished by the colour of the respective iodine complexes (amylose, blue; amylopectin, reddish-purple), and can be separated by the addition of amyl alcohol, and many other simple organic compounds, which precipitate the amylose fraction in a microcrystalline complex.

New light has been shed on the course of biogenesis of starch by the laboratory synthesis of each of its components. This has been made possible by the use of two enzymes isolated from a number of natural sources, in particular from potatoes. It would seem that polymerization of D-glucose to give starch in the plant and glycogen in the animal, as well as its combination with D-fructose to form sucrose, is effected by the intermediate formation of a phosphate ester of D-glucose, α -D-glucopyranose 1-phosphate.

3. Glycogens are quite similar to amylopectins and serve as reserve carbohydrates in animals. These substances are also produced by yeast, fungi and algae. Like amylopectins, glycogens have very high molecular weights and branched-chain structures composed of D-glucose units. The principal difference between them is that the glycogens have more frequent and shorter branches. This results in a more compact and bushlike molecule, with a higher solubility and lower viscosity.

4. Dextrans are the polysaccharides found in the slimes produced by the growing of certain bacteria, particularly *Leuconostoc mesenteroides*, on solutions of sucrose. They have a high molecular weight and are composed of D-glucose units predominantly joined through α -D-(1 \rightarrow 6) linkages. Partially hydrolyzed dextrans, dissolved in physiological saline, provide a substitute for blood plasma in the treatment of shock.

5. D-Fructose polymers (fructans) supplement or replace starch as reserve carbohydrates in certain plants, particularly the Compositae and Gramineae. Inulin, widely distributed in many roots and tubers (as the Jerusalem artichoke and dahlia) falls in this category. It is composed of 30 to 40 D-fructofuranose and 1 or 2 D-glucopyranose units. The D-fructose radicals are joined together with β -D-(1 \rightarrow 2) links in a chain which ends with a sucrose moiety. Other varieties of fructans are found in grasses or are produced by a number of microorganisms including *Bacillus subtilis*.

6. Hemicelluloses.—There is a wide range of water-insoluble polysaccharides found in plant cell walls in association with

cellulose. The nature and composition of these substances are not as yet completely defined. They contain a large amount of xylans, with α -D-(1 \rightarrow 4) linked D-xylopyranose units, and other combinations of D-xylose, L-arabinose, D-glucose, D-galactose, D-mannose, D-glucuronic acid and D-galacturonic acid. The solubility of hemicelluloses in dilute alkaline solutions provides a method for their separation from cellulose.

7. Pectic materials are found in the cell walls and intercellular layers of plant tissues. They have great jelling power and are commercially produced from citrus rind, apple pomace and beet pulp. They are composed of a poly-D-galacturonic acid, partially esterified with methanol, in association with an araban and a galactan.

8. Plant carbohydrate gums constitute a group of polysaccharides with very complex structures. Their solutions are highly viscous. Gum tragacanth is an exudate from small thorny shrubs of the genus *Astragalus* (order Leguminosae) found in the middle and near eastern countries. Gum arabic is produced by small trees of the *Acacia* genus when growing in warm, semiarid areas. The latter substance contains L-arabinofuranose, D-galactopyranose, L-rhamnose (6-deoxy-L-mannose) and D-glucuronic acid.

9. Chitin is the polysaccharide found in the exoskeletons of crustaceans and insects. Crab and lobster shells contain about 25% chitin and 75% calcium carbonate. The structure of chitin is similar to that of cellulose but differs in that chitin is composed of D-glucosamine units in which the amino groups are acetylated. In other words, in chitin the hydroxyl group at position two of the D-glucose unit is replaced by an acetamido ($-\text{NHCOCH}_3$) group. The substance is quite inert and difficult to hydrolyze.

10. Mucopolysaccharides encompass a group of physiologically significant substances which include: chondroitin-sulfuric acid from cartilage; heparin, the anticoagulant constituent found in the mast cells of animals; mucoitin-sulfuric acid found in gastric mucosa and cornea; and hyaluronic acid from animal joint synovial fluid, umbilical cord, the capsules of certain bacteria and animal tissues in general. These polysaccharides contain alternating units of an amino sugar (D-glucosamine or D-galactosamine) and a uronic acid (D-glucuronic acid). In the native form they are associated with proteins and carry sulfate and acetamido groups. Hyaluronic acid is not sulfated.

CARBOLIC ACID: see PHENOLS.

CARBOLOY: see TOOL STEEL.

CARBON, a nonmetallic element belonging to the solids, is found in both free and combined states. An estimated 800,000 carbon compounds are described in chemical literature, and chemists synthesize many new ones each year. Much of the diversity and complexity of organic forms is due to the capacity of carbon atoms for uniting with each other in various chain and ring structures and three-dimensional conformations, as well as for linking with other atoms.

Most of the energy of our bodies, as well as that which drives our machines, is supplied by the oxidation of carbon and its compounds, and every form of animal and plant life requires carbon for survival. Plants obtain it from the carbon dioxide in the air, converting carbon dioxide and water into carbohydrates in the process of photosynthesis. Animals consume the carbohydrates, returning carbon dioxide to the atmosphere by the processes of exhalation and excretion and the decomposition of their bodies under bacterial action after death. This endless chain linking animal and plant life is known as the carbon cycle.

Carbon (mainly in the combined state) is widely distributed in the earth's crust, though it comprises only about .2% of the outer ten miles. Carbon dioxide, which constitutes approximately .03% by volume of the atmosphere, is found also in all natural waters. Carbon is a constituent of coal, petroleum and natural gas, and of many minerals (see CARBONATES).

Only three of the many forms of carbon can be definitely characterized: diamond, graphite and black carbon, all stable at ordinary temperatures and insoluble in common solvents. Diamond and graphite are crystalline; black carbon is more or less amorphous, depending on the mode of preparation, and there are many varieties.

Carbon is of prehistoric discovery and belongs to Group IV in the periodic classification of the elements, being related to silicon. Its principal valency is four, but a few compounds of mono-, di- and trivalent carbon have been prepared. The four valency electrons of the carbon atom may be shared with those of other atoms to form a stable system of eight electrons (an electron octet).

The symbol of carbon is C; atomic number, 6; atomic weight, 12.011; atomic radius, 0.77 Å (single bond); and orbital arrangement of electrons, $1s^2 2s^2 2p^2$, where the superscript indicates the number of electrons in the corresponding sublevel. Carbon sublimates at $>3,100^\circ$ C. and boils at about $4,200^\circ$ C. Six isotopes of carbon are known: C^{10} , C^{11} , C^{12} , C^{13} , C^{14} and C^{15} . Isotopes 12 and 13 are stable; the others are radioactive, having half-lives as follows: C^{10} , 20 sec.; C^{11} , 20.5 min.; C^{14} , about 5,560 yr.; C^{15} , 2.4 sec. Carbon forms several oxides of which the most common are carbon monoxide (CO) and carbon dioxide (CO_2) (for other oxides see CARBON, OXIDES OF). At ordinary temperatures it combines with sulfur vapour to form carbon disulfide (CS_2), and with silicon and with certain metals to form carbides (*q.v.*). When carbon is heated with nitrogenous substances and alkaline carbonates, cyanides are formed. It combines directly with hydrogen to form acetylene (C_2H_2) when an electric arc is passed between carbon poles surrounded by hydrogen; small proportions of methane (CH_4) and ethane (C_2H_6) are also produced. At a lower temperature ($1,200^\circ$ C.) almost quantitative yields of methane are obtained. Carbon unites directly with fluorine (but not with other halogens) at room temperature to give the tetrafluoride (CF_4). At high temperatures carbon is a good reducing agent and large quantities of it, in the form of coke, are used in metallurgical processes for the reduction of metallic oxides such as those of iron and zinc.

Diamond.—The hardest substance found in nature, diamond (*q.v.*) has a value of 10 (the highest) on the Mohs scale. In 1957 a new substance, borazon (cubic boron nitride), was synthesized; it is as hard as diamond and scratches it with ease. Diamond is a poor conductor of heat and electricity. Its atomic heat is 1.25 at ordinary temperatures, as compared with 6.4, the Dulong and Petit average value for a solid element. At 985° C. its atomic heat is 5.5; at -186° C., 0.03; and at -227° C. it is almost nil. The specific gravity of diamond is 3.51, the refractive index is 2.4173 (for sodium light), and it belongs to the regular (isometric) system, though the actual crystal shape varies in different localities; *e.g.*, Brazilian diamonds are cubic; those from South Africa are usually octahedra or hexakisoctahedra.

Within the diamond lattice each carbon atom is surrounded by four others in the form of a regular tetrahedron; this arrangement confirms the tetravalency of carbon and the postulated directionality of its valence bonds. Pure diamonds are colourless and transparent, but they are frequently coloured red, blue, green or yellow because of small amounts of impurities; all except the yellow stones are highly valuable as gems. Carbonado and bort are black diamonds; they are valueless as gems, but on account of their extreme hardness they are extensively used in making tools for drilling, cutting and grinding. Artificial diamonds were prepared at General Electric Research laboratories in 1955. Previous claims by H. Moissan in 1893 and by others at different times have not been authenticated.

Graphite.—Widely distributed in nature; graphite (*q.v.*) is found as soft, gray-black, shiny leaflets. It is also manufactured

on a large scale; the Acheson process yields one of the purest grades, having an ash content of only 0.5%. Graphite feels cold and greasy to the touch, has a specific gravity of about 2.25 (for the purest) and, unlike diamond, is a good conductor of heat and electricity. Its structure consists of connected planar hexagonal rings linked vertically to similar planar rings, thus producing the characteristic layer arrangement of graphite. It appears to be the most stable form of carbon as indicated by its heat of combustion, the best measure of the relative energy content, the value being slightly less for graphite (about 7,832 cal. per gram) than for diamond (7,873 cal. per gram). The hardness of graphite varies between 0.5 and 2.0, the low value being due to the fact that the ordinary test is made parallel to the cleavage planes; at right angles to these planes its hardness approaches that of diamond. Most varieties of graphite are attacked by strong oxidizing agents such as mixtures of sulfuric acid with nitric acid, chromic acid or chlorates to give graphitic acids and finally mellitic acid, $C_6(COOH)_6$, whereas diamond is unaffected by such treatment. In 1942–45 graphite was first used as a moderator in the production of neptunium and plutonium from uranium in connection with the development of the atomic bomb. Vitreous carbon is a graphite which approaches the diamond in properties. It is formed by the decomposition of hydrocarbon gases on smooth surfaces (such as glazed porcelain) at a temperature above 650° C.—a topochemical process.

Black Carbon or Amorphous Carbon.—This heading includes coke (see COKE, COKING AND HIGH-TEMPERATURE CARBONIZATION), lampblack, carbon black or gas black, gas carbon or retort carbon, soot and the charcoals (*q.v.*), of which there are many varieties, each depending upon the process employed in the manufacture and upon the starting material. Actually, X-ray examination of various "amorphous" carbons has shown them to be more or less crystalline, resembling graphite in structure; but there are many intermediate stages between amorphous carbon and graphite. All varieties are more or less readily attacked by the strong oxidizing agents that react with graphite. Carbon black is used extensively in the manufacture of automobile tires and printer's ink. The charcoals (sugar charcoal, wood charcoal, animal charcoal or bone black, etc.) are very porous, and consequently their specific gravity is apparently only about 0.25, but when the air is pumped out of the pores this becomes 1.4–1.9. Charcoal is hard and brittle and is a poor conductor of electricity. Like soot it is dead black and without lustre.

One of the most important varieties of black carbon is activated carbon. This product is made by heating inactive carbon in steam (or other gases); it has a great capacity for adsorbing dissolved substances, as well as great power of adsorbing gases. This property makes activated carbon valuable as a decolorizing agent, as, for example, in sugar refining, and also useful for the removal of many gases and vapours from contaminated air. It is the principal component in gas masks.

(J. H. Y.)

CARBON, OXIDES OF. Two well-defined oxides have been formed by the direct union of carbon and oxygen, *viz.*, the monoxide (or carbonic oxide), CO, and the dioxide (or carbonic acid gas), CO_2 . Additional oxides have been prepared from specific carbon compounds by suitable chemical reactions. Those so far described are carbon suboxide, C_3O_2 ; pentacarbon dioxide, C_5O_2 ; and mellitic anhydride, $C_{12}O_9$.

Whenever carbon burns in oxygen, carbon monoxide and dioxide are produced simultaneously (T. F. E. Rhead and R. V. Wheeler), the relative proportions depending upon the temperature, the amount of oxygen and other conditions. Both gases enter into many reactions of the greatest industrial importance. A number of the most widely used metallurgical processes depend for their success on the proper control of the equilibrium $CO_2 + C \rightleftharpoons 2CO$. This equilibrium determines the composition of producer gas. At atmospheric pressure the carbon oxide content of producer gas is 94% carbon monoxide at 850° C. and 99% at 950° C. However, at constant temperature an increase in pressure tends to increase the carbon dioxide content. If steam reacts with carbon

both oxides are produced in accordance with the "water gas" equilibria $C+H_2O \rightleftharpoons H_2+CO$ and $CO+H_2O \rightleftharpoons CO_2+H_2$. Theoretically, pressure does not affect the second of these reactions but an increase in pressure hinders the first. At high temperatures, above $900^\circ C.$, carbon monoxide and hydrogen predominate, while at lower temperatures the principal products are carbon dioxide and hydrogen. This is important because the chemical industry has demanded more and more of one or the other of these mixtures. At high temperature the reaction between steam and natural gas produces the same set of products so that the second of the "water gas" equilibria is also involved. Thus it becomes necessary to understand these equilibria (for the fundamental principles of which, reference should be made to the articles CHEMISTRY: Physical Chemistry; THERMODYNAMICS) when dealing with the production of the two oxides now to be described.

Carbon monoxide is a colourless and odourless gas. It does not ordinarily occur in the atmosphere but is known to be present in volcanic gases. The poisonous nature of the gas is the result of its uniting with the hemoglobin of the blood to give carboxyhemoglobin. As low a concentration as 0.14% in air is dangerous, while 0.4% is nearly always fatal in less than 30 minutes. Coal gas contains (6%–12%) carbon monoxide and it is readily detected in the exhaust gases of motorcars. On a still day it has been known to accumulate from this source to such an extent in the congested areas of large cities that pedestrians have developed headaches from its poisoning action. Large tunnels that have been constructed to carry heavy motor traffic have automatic devices which start the operation of ventilating fans before the carbon monoxide reaches dangerous proportions.

This gas was first prepared and isolated by J. M. F. de Lassone (1776) by heating zinc oxide with carbon, and was for a time considered to be identical with hydrogen. However, W. Cruikshank (1800) and F. Clément and J. B. Désormes (1801) proved it to contain only carbon and oxygen, and J. Dalton (1803) showed that it had only half as much of the latter per weight of carbon as carbon dioxide. It may be prepared by passing carbon dioxide over red-hot carbon or red-hot iron; by heating many metallic oxides with carbon; by heating formic or oxalic acid or their salts with sulfuric acid (in the case of oxalic acid an equal volume of the dioxide is produced); or by heating potassium ferrocyanide with a large volume of concentrated sulfuric acid: $K_4Fe(CN)_6 + 8H_2SO_4 + 6H_2O \rightarrow 4KHSO_4 + FeSO_4 + 3(NH_4)_2SO_4 + 6CO$. Carbon monoxide has a density of 0.967 (air = 1) and is not easily liquefied; its critical temperature is $-139.5^\circ C.$ and its critical pressure 35.5 atm.; its boiling point is $-192^\circ C.$ and its melting point $-207^\circ C.$; it is only slightly soluble in water. In these as well as other physical properties it shows a close resemblance to nitrogen. Carbon monoxide burns with a well-known blue flame, giving off the dioxide, but its burning is greatly retarded in very dry air or oxygen. It combines directly with heated alkaline hydroxides (or soda lime) to give formates ($KOH+CO \rightarrow HCOOK$) and with chlorine to give carbonyl chloride. Under high pressures, suitable mixtures of carbon monoxide and hydrogen react over specific catalysts to give alcohols while other ratios of the same gases (synthesis gas) over different catalysts form liquid fuels (F. Fischer-H. Tropsch). Both are reactions of increasing industrial importance. It was reported in 1945 that carbon monoxide would combine with acetylene and water, or like substances, in the presence of nickel carbonyl, $Ni(CO)_4$, to form acrylic acid ($CO+C_2H_2+H_2O \rightarrow CH_2:CHCOOH$) or its derivatives (see PLASTICS). Carbon monoxide unites with many metals (e.g., nickel, iron, cobalt, molybdenum, ruthenium, etc.) to give a series of carbonyls (see CARBONYLS, METAL), that of nickel being used in the manufacture of the pure metal. Potassium carbonyl, $K_6(CO)_6$, at times formed in heating potassium carbonate with coke, as well as by direct union, is explosive and is of a different type, being a benzene derivative. Carbon monoxide is often a powerful reducing agent, and its reduction of iodine pentoxide to iodine is used to detect and determine minute quantities of the gas in air. In 1918 a catalyst, hopcalite, was developed which would oxidize carbon monoxide in any air which passed through it. This catalyst has become an important material in gas masks where protection

against this gas is desired. The gas is absorbed by ammoniacal or hydrochloric acid solutions of cuprous chloride (colourless crystals of the resulting compound, $CuCl \cdot CO \cdot 2H_2O$, have been obtained) and this reaction is used in gas analysis and on a large scale in the purification of such gases as the hydrogen used in the synthesis of ammonia. Carbon monoxide is finding an ever wider use in synthetic chemistry.

Carbon dioxide was first discovered by J. B. van Helmont (1577–1644) who observed that it was formed in the products of combustion and fermentation. Later J. Black named it "fixed air" because of its being a constituent of carbonated alkalis. A. L. Lavoisier (1743–94) demonstrated its nature by burning carbon in oxygen. Carbon dioxide is a regular component of the atmosphere (normally 3 vol. per 10,000), and is found in mineral waters, volcanic gases, the gases issuing from some gas wells, certain grottoes near Naples and in Poison valley, Java. It is a constituent of the carbonates found in many minerals (see CARBONATES). It is formed in the process of respiration, in the combustion of all carbonaceous material and in fermentation, some of the liquid and solid carbon dioxide of commerce being derived from breweries. In the presence of sunlight, the green chlorophyll of plants is able to convert (photosynthesis) carbon dioxide and water into carbohydrates and oxygen ($6CO_2+6H_2O \rightarrow C_6H_{12}O_6+6O_2$). This is one of the fundamental reactions of the life process. Industrially, carbon dioxide is used in the manufacture of soda by the Solvay or ammonia-soda process (see ALKALI MANUFACTURE), in the sugar industry, in the preparation of mineral waters and carbonated beverages, in the production of dry ice and in the fighting of fires. Automatic refrigeration in insulated pressure tanks has made it possible to transport and use large volumes of liquid carbon dioxide. Fire trucks carrying several tons of this liquid have proved their merit especially in rapid control of fires in planes that crash at airports.

Carbon dioxide is a colourless gas, possessing a faint pungent smell and a slightly acid taste. It may be prepared by burning carbon in an excess of air or oxygen, by heating many carbonates or bicarbonates or by the action of acids on these: $M_2CO_3+2HCl \rightarrow 2MCl+H_2O+CO_2$. It does not burn and does not ordinarily support combustion, but metals such as magnesium when ignited will continue to burn in it, giving oxides and liberating carbon. It is 1.53 times heavier than air, and requires only a pressure of 3 j atm. to liquefy at $0^\circ C.$ Critical temperature and pressure are $31.1^\circ C.$ and 73 atm. respectively; the liquid freezes at $-56.6^\circ C.$ under 5 atm., and the solid sublimates at $-78.5^\circ C.$ under atmospheric pressure. The solid "snow," often called dry ice, has become widely used where low temperatures are desired, as in the preservation of frozen foods. At $0^\circ C.$, 1 vol. of water dissolves 1.79 vol. of the gas (0.33%), and it is twice as soluble in alcohol. The solubility in water markedly increases with pressure, making possible the preparation of carbonated beverages. The aqueous solution is feebly acidic, as a result of the presence of a small proportion of carbonic acid, H_2CO_3 ; solutions of caustic alkalis absorb the gas readily to give carbonates and ultimately bicarbonates.

The physical properties of carbon dioxide are remarkably similar to those of nitrous oxide. The gas reacts with limewater or baryta water to give a white precipitate of the corresponding carbonate, making possible its detection and estimation. Carbon dioxide and ammonia gases unite to give ammonium carbamate, NH_2COONH_4 (see AMMONIA). If passed over molten sodium, carbon dioxide converts it to sodium oxalate, $Na_2C_2O_4$. At high temperatures the gas dissociates slightly: $2CO_2 \rightleftharpoons 2CO+O_2$; under atmospheric pressure the decomposition amounts to only 0.1% at $1,300^\circ C.$ but rises to about 40% at $3,000^\circ C.$

Additional Oxides.—Carbon suboxide was first produced in 1906 by O. Diels and B. Wolf. They heated the ethyl ester of malonic acid with phosphorus pentoxide to $300^\circ C.$ under diminished pressure, the reaction being essentially one of dehydration: $CH_2(COOC_2H_5)_2 \rightarrow 2C_2H_4+2H_2O+C_3O_2$. Since then it has been made in a number of ways, but the highest yield has been obtained by the pyrogenic decomposition of diacetyltartaric anhydride. When cooled the gas readily condenses to an almost colour-

less, refractive, extremely mobile liquid which boils at 6.3° C. The liquid may be frozen to a solid which melts at -107° C. The oxide is very reactive and has the properties of a ketene (*q.v.*). Spectroscopy proves the structure of the molecule to be linear, $\text{OC}:\text{C}:\text{CO}$, and its chemical behaviour shows it to be the anhydride of malonic acid. When burned with oxygen it gives an amount of carbon dioxide which confirms its composition ($\text{C}_3\text{O}_2 + 2\text{O}_2 \rightarrow 3\text{CO}_2$). It is a colourless suffocating gas which tends to polymerize to a red-brown solid on a number of surfaces. The liquid often turns to a polymerized dark-red mass on standing. This compound is the second in a series of carbon oxides having the general formula C_nO_2 where n is always an odd number, the first member of the series being CO . Theoretical considerations rule out the possibility of any linear C_nO_2 oxides of carbon having an even number of carbon atoms. In 1937 A. Klemenc and G. Wagner reported that they had prepared small quantities of the third member of this series, pentacarbon dioxide, C_5O_2 . They claimed to have obtained this oxide along with C_3O_2 while dehydrating malonic acid but they never found it when decomposing diacetyl-tartaric anhydride. Grave doubt has arisen as to the actual production of a pure pentacarbon dioxide. Mellitic anhydride, C_{12}O_9 , is a different type of oxide of carbon. It has been made by dehydrating mellitic acid. $\text{C}_6(\text{COOH})_6 \rightarrow \text{C}_{12}\text{O}_9 + 3\text{H}_2\text{O}$. Mellitic acid is a benzene derivative, as is the anhydride. (L. H. R.)

CARBONADO is a dark massive form of impure diamond, known also as carbonate and in trade simply as carbon. It is sometimes called black diamond. Once of little or no value, it came into use on the introduction of diamond drills (see DRILLING MACHINERY), and is extremely valuable for mounting in the steel crowns used for diamond boring and for other industrial uses. Generally it is found in small masses of irregular polyhedral form, black, brown or dark gray in colour, with a dull resinoid lustre; it breaks with a granular fracture, paler in colour and in some cases resembling that of fine-grained steel. Being slightly cellular, its specific gravity is rather less than that of well crystallized diamond. It is as hard as the more familiar form of diamond but less brittle. Carbonado is found chiefly in the state of Bahia in Brazil, where it occurs in the cascalho or diamond-bearing gravel. Borneo also yields it in small quantities.

CARBONARI were members of certain secret revolutionary societies of the early 19th century. Too many of the secret societies of the period have been inaccurately called Carbonarist by their friends and enemies alike and the term is often used loosely to mean any Italian conspirator of that time. The real Carbonari (Ital. "charcoal burners") have left few unambiguous records.

There are hints that a trade fraternity of the charcoal burners of the Jura and the Black forest which existed in the 18th century began to have some political significance during the early years of the Directory in France, but the Carbonari proper first appear definitely under Napoleonic rule in Italy. Guesses as to the precise date of their origin have varied between 1802 and 1810, and some have claimed even to trace them back before 1799 to the secret anti-French organizations of those years. From the beginning, however, the appearance of the Carbonari is linked with the French army, which always contained some republican officers hostile to the Bonapartist evolution of France toward monarchy. In 1806 a French-Swiss regiment was stationed at Capua, and it is there that almost at once the first firm indications of Carbonarist lodges can be detected.

The nature and function of the lodges is easier to describe than their origins. Their ritual was strongly marked by masonic and Christian symbolism. Members addressed one another as *buoni cugini* ("good cousins") and the sect revered God as the "Grand Master of the Universe." They were recruited mainly from the nobility and official classes and always included many officers of the Italian army of Joachim Murat. Later, more small landowners came to join the lodges. Although the aims of the lodges varied from time to time, the general function of the organization was to provide foci for political opposition first in Napoleonic and then in Restoration Italy. They for some time hoped to achieve constitutional guarantees and the protection of Italian interests against the French with Murat's help. When this hope faded they

turned against Murat. It has been alleged that some of the lodges were then used as subversive organizations by the British operating from Sicily, but their next major development came during Murat's campaign in 1814. The Carbonari then spread with the army's movement northward and by the end of that year were co-operating with other secret anti-French societies in Lombardy.

After 1815, the Carbonari in the kingdom of the Two Sicilies took up a decisively anti-Bourbon and constitutional attitude. Their most spectacular achievement was the Neapolitan revolution of 1820 which began, significantly, with a military mutiny. Unfortunately, the successful revolutionaries were unable to remain in agreement among themselves, and the new regime only survived a few months before it was overthrown by Austrian intervention. This action helped to bring to a head another plot in Piedmont. The Carbonari were supposed to be involved in this outbreak (which certainly included members of secret societies known as Federati), but their precise role is uncertain. There had been other examples of Carbonarist activity in Italy (notably in the Legations), but the last kick of the movement came with the revolutions in Bologna, Parma and Modena in 1831. After this, Mazzini founded his own Giovine Italia movement because he was convinced of the ineptitude of the Carbonari. At this point they leave the stage of Risorgimento history.

Outside Italy, a similar movement called the Charbonnerie had taken root in France. It had participated in outbreaks in 1821, and La Fayette himself had condescended to be its head. An international organization called the Charbonnerie Démocratique Universelle continued to operate for a few years after 1830 under the leadership of Filippo Michele Buonarroti (1761–1837), but achieved little. Both the fears of its enemies and the hopes of its friends had always exaggerated the potential of the Carbonarist movement and still make it difficult to discern its true significance. It seems likely nonetheless that, if the Neapolitan revolution of 1820 is excepted, its importance was always mythological and moral rather than practical.

Pepe, *Memoirs*, Eng. trans. (1896). (J. M. Rs.)

CARBONATED BEVERAGES: see SOFT DRINKS.

CARBONATES. Metallic carbonates are the salts of carbonic acid. The carbonates of sodium, calcium and magnesium are particularly important as industrial chemicals. These and other metallic carbonates are described under the various metals. Organic carbonates are the esters of carbonic acid and ortho-carbonic acids. Carbonic acid (H_2CO_3) is formed when carbon dioxide is dissolved in water. $\text{CO}_2 + \text{H}_2\text{O} = \text{H}_2\text{CO}_3$. Being a dibasic acid it forms two series of salts, the normal carbonates (*e.g.*, Na_2CO_3) and the acid carbonates or bicarbonates (*e.g.*, NaHCO_3). Carbonic acid is one of the feeblest of the acids, is very unstable and exists only in dilute aqueous solution. Dissociation constants: primary, 4.3×10^{-7} (25° C.); secondary 4.7×10^{-11} (25° C.). Attempts to obtain the acid in the free state have not been successful.

Metallic Carbonates.—Many of the metallic carbonates are white solids, but some, such as those of copper (blue or green) and nickel (green), possess colours which are characteristic of the metal concerned. Many are found as minerals, the more important of such naturally occurring carbonates being cerussite (lead carbonate, PbCO_3), malachite and azurite (both basic copper carbonates), smithsonite (zinc carbonate, ZnCO_3), witherite (barium carbonate, BaCO_3), strontianite (strontium carbonate, SrCO_3), calcite and aragonite (calcium carbonate, CaCO_3) and dolomite (calcium magnesium carbonate, $\text{CaCO}_3 \cdot \text{MgCO}_3$). Sodium "sesquicarbonate," $\text{Na}_2\text{CO}_3 \cdot \text{NaHCO}_3 \cdot 2\text{H}_2\text{O}$, occurs as a deposit in African lakes and is called trona. Most metals form carbonates (aluminum and chromium are exceptions), the alkali metals yielding both acid and normal carbonates of the types MHCO_3 and M_2CO_3 (M = one atom of a univalent metal), while bismuth, copper and magnesium appear to form only basic carbonates. The

acid carbonates (bicarbonates) of the alkali metals can be prepared by saturating an aqueous solution of the alkaline hydroxide with carbon dioxide, $M.OH + CO_2 = MHCO_3$, and from these acid salts the normal salts may be obtained by gentle heating, carbon dioxide and water being evolved at the same time, $2MHCO_3 = M_2CO_3 + H_2O + CO_2$ (see ALKALI MANUFACTURE). Because of the slight ionization of carbonic acid, soluble carbonates undergo a significant hydrolysis in water solution and are alkaline, $CO_3^{2-} + H_2O = HCO_3^- + OH^-$; the bicarbonates are much less hydrolyzed and only faintly alkaline. Most other carbonates are formed by precipitation of salts of the metals by means of alkaline carbonates. All carbonates, except those of the alkali metals and of thallium, have low solubilities in water, and the majority decompose when heated strongly, carbon dioxide being liberated and a residue of an oxide of the metal left. Carbonates of the heavy metals, such as silver, yield the metal on strong ignition. Alkaline carbonates undergo slight decomposition, even at a bright-red heat. The carbonates are decomposed by mineral acids, with formation of the corresponding salt of the acid and liberation of carbon dioxide. Many carbonates which are insoluble in water dissolve in water containing carbon dioxide, giving bicarbonates, which cause "temporary" hardness (see CALCIUM: *Compounds*).

Organic Carbonates.—The organic carbonates are the esters of carbonic acid, H_2CO_3 , and of the unknown orthocarbonic acid, $C(OH)_4$. The acid esters of carbonic acid of the type $HO.CO.OR$ are not known in the free state.

Potassium ethyl carbonate, $KO.CO.OC_2H_5$, is obtained in the form of pearly scales when carbon dioxide is passed into an alcoholic solution of potassium ethoxide, $CO_2 + KO.C_2H_5 = KO.CO.OC_2H_5$. It is not very stable, water decomposing it into alcohol and the alkaline carbonate. The normal esters may be prepared by the action of silver carbonate on the alkyl iodides, or by the action of alcohols on the chlorocarbonic esters. These normal esters are colourless, pleasant-smelling liquids, which are readily soluble in water. They show all the reactions of esters, being readily hydrolyzed by caustic alkalis, and reacting with ammonia to produce carbamic esters and urea. Heating with phosphorus pentachloride eliminates an alkyl group and a chlorocarbonic ester is formed. Dimethyl carbonate, $CO(OCH_3)_2$, is a colourless liquid, which boils at $90.6^\circ C.$ and is prepared by heating the methyl ester of chlorocarbonic acid with lead oxide. Diethyl carbonate, $CO(OH_2C_2H_5)_2$, is a colourless liquid which boils at $125.8^\circ C.$; its specific gravity is 0.975. When it is heated to $120^\circ C.$ with sodium ethoxide it decomposes into ethyl ether and sodium ethyl carbonate.

Orthocarbonic ester, $C(OC_2H_5)_4$, is formed by the action of sodium ethoxide on chloropicrin, $CCl_3NO_2 + 4C_2H_5ONa = C(OC_2H_5)_4 + NaNO_2 + 3NaCl$. It is an ethereal-smelling liquid, which boils at about $159^\circ C.$, and has a specific gravity of 0.919. When heated with ammonia it yields guanidine, and boiled with alcoholic potash it yields potassium carbonate.

Chlorocarbonic ester, $Cl.CO.OC_2H_5$, is formed by the addition of well-cooled absolute alcohol to phosgene (carbonyl chloride). It is a pungent-smelling liquid, which fumes strongly on exposure to air. It boils at $94^\circ C.$, and has a specific gravity of 1.138. When heated with ammonia it yields urethan. Sodium amalgam converts it into formic acid; with alcohol it yields the normal carbonic ester. It is easily broken down by many substances into ethyl chloride and carbon dioxide.

Percarbonates.—Barium percarbonate, $BaCO_4$, is a white solid obtained by passing an excess of carbon dioxide into water containing barium peroxide in suspension; it is fairly stable, and yields hydrogen peroxide when treated with acids. Two potassium percarbonates having the formula $K_2C_2O_6$ are known. One is obtained by the electrolysis of a concentrated solution of the carbonate at $-20^\circ C.$, and the other by the action of carbon dioxide on potassium peroxide; the former liberates iodine from a solution of potassium iodide without loss of oxygen: $K_2C_2O_6 + 2KI = 2K_2CO_3 + I_2$, but the latter suffers loss of a part of its oxygen in the same circumstances. Sodium carbonate is not sufficiently soluble to permit percarbonates to be made by the electrolytic method, but the other method gives rise to a number

of percarbonates; e.g., $Na_2C_2O_6$, Na_2CO_4 , Na_2CO_5 , $NaHCO_4$. The first of these resembles the second type of potassium percarbonate. An attempt has been made to classify percarbonates according to whether they are (1) merely carbonates with hydrogen peroxide in crystallization; (2) permonocarbonates; or (3) perdicarbonates (compare persulfates). Percarbonates find their chief use in bleaching, and the potassium salt is used as antihypo in photography for eliminating excess of hypo. (J. H. Y. j)

CARBON BLACK, a generic term for a group of intensely black, finely divided forms of amorphous carbon made by thermal decomposition, or partial combustion, of the vaporizable portion of any carbonaceous material. Common soot produced by a smoky oil or coal fire is a form of carbon black similar to lampblack.

Over 90% of all carbon black produced is used as a reinforcing filler in rubber goods, principally tires. Its use greatly increases the abrasion and wear resistance of rubber articles. A standard passenger automobile tire contains approximately five pounds of carbon black and ten pounds of natural or synthetic rubber. Without the help of carbon black, the synthetic rubber of World War II would have been almost useless for tire manufacture.

The second most important use of carbon black is as a pigment in inks, chiefly newsprint inks. Other uses are in protective coatings, plastics, phonograph records, paper, carbon paper and batteries; in these applications, carbon black may have a variety of functions; e.g., pigment, filler, reinforcing agent, electric conductor or chemical reducing agent.

Types.—Carbon blacks are designated as channel or impingement, furnace, thermal, lamp-, or acetylene blacks, depending upon the process of manufacture. Furnace and channel blacks are the most widely used.

All are fundamentally similar but wide variations in particle diameters occur among the various types. Carbon blacks are among the most finely divided materials known; certain impingement blacks have particles as small as .000004 in. in diameter. Carbon blacks contain 88%–99.5% carbon, 0.3%–1% oxygen, 0.1%–1% hydrogen, up to 1% inorganic material, small amounts of tarry matter and traces of sulfur. The electron microscope reveals the primary particles to be spherical; diffraction of X-rays indicates a structure similar but less regularly crystalline than graphite. Prolonged heating at the $3,000^\circ C.$ level changes carbon black to graphite.

Carbon blacks should not be confused with animal, vegetable and mineral blacks, which are in the nature of chars made by heating bones, plant matter or carbonaceous mineral matter in closed retorts. When ground to pass a screen having 325 meshes per inch, these products find limited use as pigments.

Channel (impingement) black is made by the impingement of smoky flames from tiny gas jets on iron channels; the deposited black is removed by moving the channels over stationary scrapers. A single plant consists of hundreds of sheet-iron "hothouses" enclosing several hundred thousand flames.

Furnace blacks are made by incomplete combustion of gaseous or liquid hydrocarbons in refractory chambers. This process has increased rapidly in importance, largely because of the impact of World War II. Products with a wide range of particle size can be produced by the furnace process; fuels of all types, even heavy pitches, can be used.

Thermal blacks are produced when hydrocarbons are decomposed by contact with heated refractories in the absence of air.

Lampblack manufacture involves the burning of oil, usually coal-tar creosote, in shallow pans set inside a furnace. The draft is regulated to give a heavy cloud of smoke, which is allowed to settle in large brick chambers. Lampblack is the oldest known black pigment, but has been going out of favour since the development of channel blacks. A deep-black pigment, its principal use is for tinting paints.

Acetylene black is formed when acetylene gas preheated to $800^\circ C.$ spontaneously decomposes in the absence of air in refractory chambers. Its principal use is in applications where high electrical conductivity is required; e.g., in dry cells.

Production.—The U.S. is the world's largest producer of carbon black. Total annual U.S. production of furnace, channel and

thermal blacks rose from about 50,000,000 lb in 1920 to about 2,000,000,000 lb. four decades later. Before World War II, all carbon black was made from natural gas and most of it by the channel process (100% up to 1923). By 1945 production by the furnace and channel processes was about equal, and thereafter more carbon black was produced by the furnace process, principally from liquid hydrocarbons. This trend was strengthened because of the rising cost of natural gas, the greater flexibility of the furnace process and the technical superiority of oil-furnace blacks in many applications.

The United Kingdom is the second largest carbon-black producer, followed by Germany, Canada and France. Canada produces most of the world's supply of acetylene black. Lamp- and by-product thermal blacks are produced in small amounts in many countries.

CARBON DIOXIDE: see CARBON, OXIDES OF.

CARBON DISULFIDE OF CARBON BISULFIDE, a chemical compound with the formula CS₂, is a colourless and extremely volatile liquid with a sweet, ethereal odour and an acrid taste. It is toxic and inflammable. The compound is used primarily in the manufacture of viscose rayon and cellophane. It was discovered in 1796 by W. h. Larnpadius, who obtained it by heating a mixture of charcoal and pyrites. In 1802 F. Clément and J. B. Désormes obtained the compound by heating charcoal with sulfur.

Preparation.—The traditional method of preparing carbon disulfide commercially is by the reaction of carbons, chiefly charcoal, with sulfur at temperatures of 800° to 1,000° C. in direct-fired retorts or electric furnaces. In the early 1960s major quantities were also produced from the reaction of methane and sulfur as follows: CH₄ + 2S₂ → CS₂ + 2H₂S. In this process, sulfur and methane are preheated together in a tube furnace, then reacted in catalyst chambers at temperatures of 500° to 700° C. The carbon disulfide is separated from the hydrogen sulfide by absorption in oil followed by stripping and distillation. The process is made economical by the high sulfur recoveries achieved in the associated process for the reconversion of hydrogen sulfide to sulfur by oxidation.

Uses.—Viscose rayon and cellophane have long been principal consumers of carbon disulfide, accounting for about 60% and 15%, respectively, of total carbon disulfide production in the early 1960s. The manufacturing process for both products involves the treatment of wood pulp (cellulose) with caustic soda to form alkali cellulose, which is then treated with carbon disulfide to form cellulose xanthate, according to the formula: cellulose-ONa + CS₂ → cellulose-OCSSNa. The cellulose xanthate is produced as a viscose solution which is spun into filaments or drawn into films. These are fixed by passing through a bath of sulfuric acid with regeneration of cellulose and evolution of carbon disulfide. The production of carbon tetrachloride consumes an additional 15% of disulfide production. In this process, carbon disulfide is treated with chlorine to produce carbon tetrachloride and sulfur monochloride (CS₂ + 3Cl₂ → CCl₄ + S₂Cl₂); the sulfur monochloride is then treated with carbon disulfide to give an additional yield of carbon tetrachloride (CS₂ + 2S₂Cl₂ → CCl₄ + 6S). Other chemicals produced from carbon disulfide include the dithiocarbamates, which are used as accelerators in rubber vulcanization and are also popular as organic fungicides. The former application accounts for about 5% of the carbon disulfide consumption. Other chemicals produced from carbon disulfide include ammonium thiocyanate and thiourea, both of which have a variety of minor industrial uses.

Properties.—The compound is composed of 12 parts by weight of carbon and 64.1 parts by weight of sulfur. On aging it acquires a very unpleasant odour and tends to darken in colour. It boils at

46.3° C. and freezes at -112° C. The critical temperature of carbon disulfide is 273° C; its critical pressure, 75 atm; its specific gravity (25°/4° C.), 1.2559; and its refractive index (25° C.), 1.628.

The compound is only slightly soluble in water but is miscible in all proportions with absolute alcohol, ether, benzene and various light oils. It is an excellent solvent for sulfur, phosphorus, iodine, rubber, resins, waxes, vegetable and animal fats and oils.

Considerable caution must be exercised in the use of carbon disulfide due to its inflammability and toxicity. Concentrations in air of from 1% to 50% by volume are explosive. Carbon disulfide ignites spontaneously in air at 100° C. The maximum allowable concentration in air for continuous exposure of human beings is 15-20 parts per 1,000,000. Continued exposure to toxic concentrations produces nervousness, insomnia, irritability, excessive fatigue and loss of appetite. For acute poisoning administration of artificial respiration may be necessary. A concentration of 4,000 parts per 1,000,000 may be fatal in one to two hours. (A. G. Dr.)

CARBONIFEROUS SYSTEM AND PERIOD. The Carboniferous system consists of rocks formed during the next to last or Carboniferous period of the Paleozoic era. This period lasted about 50,000,000 to 60,000,000 years and began about

285,000,000 years ago. This discussion of the geologic record of this system and period, sometimes referred to as the age of coal swamps and as the age of amphibians, is divided into three main sections covering the rocks identified with the system, the animal and vegetable life of the period and the economic products, including coal and oil, that provided so much of the power for the Industrial Revolution. For further discussion of the origins and formation of Carboniferous rocks see GEOLOGY. Additional information on life in the Carboniferous period may be found in the articles PALAEOBOTANY and PALAEOZOOLOGY. The economic products are discussed also in individual articles, as COAL AND COAL MINING.

Following are the main divisions of this article:

- I. Rocks of the Carboniferous System
 - A. Classification and Terms
 - B. Lower Carboniferous (Mississippian)
 1. Mississippian of North America
 2. Lower Carboniferous of Europe and Asia
 - C. Upper Carboniferous (Pennsylvanian)
 1. Pennsylvanian of North America
 2. Upper Carboniferous of Europe and Asia
 - D. Carboniferous of Southern Hemisphere and India
 - E. Igneous Rocks
- II. Life of the Carboniferous
 1. Marine Life
 2. Land Life
- III. Economic Products

I. ROCKS OF THE CARBONIFEROUS SYSTEM

The Carboniferous system overlies the Devonian and underlies the Permian system. It was first distinguished in England and Wales and named in 1822 for its important coal deposits. The stratified rocks of this system attain a maximum thickness of more than 40,000 ft. but are much thinner in most areas.

A. CLASSIFICATION AND TERMS

The Carboniferous rocks generally are divided into two parts representing about equal intervals of time. In North America the term Carboniferous system or period is rarely used and these two parts are considered to be separate systems known as Mississippian (older) and Pennsylvanian (younger) which are approximately equivalent to the Lower and Upper Carboniferous divisions of Europe respectively. This different terminology on opposite sides of the Atlantic results from recognition of a widespread unconformity or break in deposition separating the Mississippian and Pennsylvanian in the central United States, showing that the Mississippian rocks were gently folded and eroded before the Pennsylvanian strata were deposited. The unconformity is particularly pronounced in Illinois where, from south to north, the Pennsylvanian gradually overlaps the truncated edges of 5,000 ft. of older strata and finally comes to rest on the Middle Ordovician. Somewhat comparable breaks are recognized in Europe but no single unconformity there serves to divide the Carboniferous into two such well-marked divisions.

These unconformities and others that vary considerably in importance from place to place record episodes in a succession of late Paleozoic earth movements related to the uplifting and folding of ancient mountains long since destroyed by erosion. The disturbances began in late Devonian time, recurred at intervals throughout the Carboniferous and Permian periods and finally terminated the Paleozoic era. In Europe the remnants of these mountains extend from southern England and Spain through France and central Germany. They are known to geologists as the Hercynian or Variscan ranges (see EUROPE: Physical Geography) and are sometimes termed the Paleozoic Alps although they are no longer conspicuous topographically and are quite distinct from the modern Alps. In North America somewhat similar mountains were formed along the Atlantic and Gulf coasts but the remains of the earlier ranges are less clearly recognizable. There these movements culminated in the folding of the present Appalachian mountains and are considered preliminary phases of what is termed the Appalachian revolution which profoundly changed the geography of all eastern North America.

The geological development of Europe and that of North America differed in important respects. In North America, Upper Carboniferous strata pass upward into the Permian system without interruption or any important change in character, and no sharp boundary exists between these systems except in west Texas. For this reason the United States geological survey for many years included the Permian rocks in the Carboniferous system. In some other parts of the world where the Carboniferous and Permian are not readily separable these strata are known as Permian-Carboniferous.

Such differences in the usage of geologic terms occur because classification into geologic systems, worked out in western Europe and Great Britain during the first half of the 19th century, is not entirely satisfactory in other regions where geologic happenings were not the same. The European classification is acknowledged universally, however, as the standard and an attempt is usually made to distinguish the same systems everywhere.

B. LOWER CARBONIFEROUS (MISSISSIPPIAN)

1. Mississippian of North America.—These Lower Carboniferous rocks were named from the upper Mississippi valley, and the formations distinguished in that area, totaling about 3,000 ft. in thickness, constitute the standard succession for North America. They are nearly continuous and horizontal in most of the United States between the Appalachian and Rocky mountains, but gentle dips carry them beneath younger rocks in the Appalachian basin extending from Ohio and Pennsylvania to Alabama,

ILLINOIS STATE GEOLOGICAL SURVEY PHOTO

FIG. 1.—UPPER MISSISSIPPIAN LIMESTONE IN MISSISSIPPI RIVER BLUFF, ALTON, ILL.

the Michigan basin, the Illinois basin, including parts of Indiana and western Kentucky, and the western interior basin between the Rocky mountains and Mississippi river. Mississippian rocks also are widely distributed in the Rocky mountains from Alaska to northern Mexico and in the maritime provinces of Canada. They probably occur much altered by pressure and igneous action in New England and in some areas adjacent to the Pacific coast.

Limestone is the predominant rock of the Mississippian series, and the fossils which it encloses record the presence of an ancient shallow sea which at one time or another during this period covered the greater part of the United States. This sea was bounded on the north by low-lying land in what is now eastern and central Canada. On the east it was bordered by a long, narrow, partly mountainous land near the present Atlantic coast. On the west a similar land area probably extended northward from northern California but its nature and extent are not well known. This Mississippian sea is believed to have had no direct connection with the Atlantic ocean, and the Mississippian rocks of eastern Canada probably never were continuous with those of the United States. Land also lay close somewhere to the south but it is not known if this was continuous with the Atlantic land area.

During Mississippian time these lands, and particularly the higher ones, were eroded; rivers carried sand, silt and mud from them into the central sea where sediments settled to form beds of sandstone and shale associated with the limestone. These lands no longer exist in their original condition and their presence, extent and character must be inferred from the distribution and nature of the sediments derived from them.

The Mississippian rocks of the Mississippi valley are divided into four series, identified as the Kinderhookian (from Kinderhook, Pike county, Ill.), Osagian (from the Osage river, Missouri), Meramecian (from the Meramec river, Missouri) and Chesterian (from Chester, Randolph county, Ill.). Just as the Carboniferous is a standard division of the world, these are the standard Mississippian divisions of North America.

Kinderhookian Series.—At the base of the oldest or Kinderhookian formation of the Mississippi valley area, and therefore at the base of the Mississippian, is a black shale which overlaps at some places onto much older rocks. Similar shale is continuous from the Mississippi valley to New York, Alabama, New Mexico and Alberta. In most of these regions comparable overlap does not occur and the black shale commonly overlies rocks with Upper Devonian fossils. The shale thickens greatly in New York and Pennsylvania, however, and encloses limestone with Middle and Upper Devonian fossils. Obviously the black shale is not the same age everywhere. It began forming in some areas in Middle Devonian time and was still being deposited in others in the early part of the Mississippian period. The black shale contains few

fossils that indicate its age and consequently the exact boundary between the Devonian and Mississippian systems is in doubt in many areas.

In the Mississippi valley the Kinderhookian consists of several locally developed and variable formations. It is separated from the overlying Osagian series by a break in deposition, indicating that the sea withdrew temporarily from that region. Fossils show that Kinderhookian rocks exist both to the east and west, but these strata are different in composition and not readily distinguishable from similar overlying Osagian beds. In the north-eastern region the Mississippian is more naturally divisible into two parts, gray sandstone below (equivalent to the Kinderhookian, Osagian and Meramecian series) and red beds above (equivalent to the Chesterian). A short distance southward the middle beds change to limestone and this third division, mostly of Meramecian but partly of Chesterian age, separates the other two. The lower sandy division includes workable coal seams in western Virginia. The western Mississippian also generally consists of two lithologically distinctive parts, the lower being limestone up to 1,000 ft. thick approximately corresponding to the Kinderhookian and Osagian and an upper heterogeneous shaly part of Meramecian and Chesterian age.

Osagian Series.—The Osagian series of the Mississippi valley is mostly coarse crystalline limestone with many flint nodules, and these characteristics persist with little change to New Mexico. Eastward, limestone gives place to shale and sandstone. Limey lenses occur in Indiana, but no limestone is present in Ohio and eastern Kentucky where beds with rounded pebbles make their appearance. In Pennsylvania these beds are mainly sandstone. This distribution of sediments is evidence of the land area that was most elevated or most extensive east of central Pennsylvania. The sands, silts and muds were probably contributed by one or more westward-draining rivers and formed an extensive delta in the shallow sea that was a continuation of and overlay a similar delta built up in the same region during late Devonian time.

Meramecian Series.—In Illinois and Missouri the Meramecian series consists mostly of fine-grained darker-coloured limestone, some of which is quite bituminous. These beds are more uniformly developed east of the Mississippi river than underlying Osagian limestone and their extension into Ohio and West Virginia demonstrates that the nearby land was contributing much less sediment. This land probably stood less high than formerly, either because it was much worn down by erosion or had subsided. Clay and silt associated with marine limestone in Iowa suggest low-lying land to the northwest where a broad peninsula is believed to have extended from the Canadian land area southwestward from

BY COURTESY OF CHICAGO NATURAL HISTORY MUSEUM

FIG. 3.—RESTORATION OF A SMALL PENNSYLVANIAN AMPHIBIAN (DIPLOVERTEBRON)

Minnesota to Colorado and separated the interior North American sea from a wide strait occupying the Rocky mountain region northward to the Arctic ocean. Also toward the end of Meramecian time the Ozark area of Missouri became an island and erosion produced sand that was mixed with the limestone deposited on its shores. In several areas Meramecian rocks include light-coloured oolitic limestone indicative of very shallow warm water. Beds of gypsum are much less common, but their occurrence in Iowa, Michigan, Indiana and eastern Canada is evidence of the existence of local basins, cut off at times from the sea, where evaporation greatly exceeded rainfall and the inflow of fresh water.

Chesterian Series.—The Upper Mississippian or Chesterian is separated from the Meramecian by another unconformity recording temporary but widespread emergence. The Chesterian series consists of a variety of rocks generally including much shale and some sandstone alternating with marine limestone. The sea in which they were deposited was less extensive, particularly to the north, than in earlier Mississippian time. Eight or more fluctuations in its level are shown by the rhythmic recurrence of alternately deeper and shallower water sediments somewhat similar to the more perfect sedimentary cycles of the following Pennsylvanian period. At times the sea completely withdrew from the north and left considerable portions of its former bed as temporary land and some of these areas supported dense growths of vegetation whose remains are preserved as thin local noncommercial coals.

Other Formations.—In southern Arkansas, nearby Oklahoma and west Texas the main part of the Mississippian period is unrepresented in the rocks. A thick flinty formation occurs there in the position of the black shale and is believed to bridge the Devonian-Mississippian boundary. Above it are thousands of feet of shale and sandstone without fossils that may be youngest Mississippian and oldest Pennsylvanian. They are evidence of a southern land area (elevated at this time and rapidly eroded) which is now so completely buried beneath much younger rocks that its exact location is unknown.

The precise upper boundary of the Mississippian system also is uncertain in the eastern United States between West Virginia and Alabama. In much of this region the uppermost Mississippian includes red beds and the Pennsylvanian is generally considered to start with the first massive conglomeratic sandstone. Strata of this type, however, probably are not exactly the same age everywhere and consequently the recognized boundary is not entirely consistent. In Wyoming and Montana unfossiliferous red beds separate known Mississippian and Pennsylvanian rocks. Different geologists refer them to one or the other or divide them between the two systems. In other parts of the west the boundary occurs in the midst of thick shaly deposits that are Mississippian below and Pennsylvanian above.

The Mississippian of New Brunswick, Nova Scotia and Newfoundland consists of sandy and shaly strata, bearing terrestrial and fresh-water fossils including erect stumps of trees, separated into two parts by red beds with layers of marine limestone and gypsum and some rock salt. Intermittent occurrence, coarse conglomerates and considerable variation from place to place suggest that these strata were deposited in restricted intermountain basins.

2. Lower Carboniferous of Europe and Asia.—The general nature of the Lower Carboniferous in parts of western Europe and the British Isles is quite similar to that in the Mississippi valley of North America. These beds are termed Dinantian and

are divided into parts named from localities in Belgium, as indicated in the accompanying chart. Older beds known as the Famennian that are transitional with the underlying Devonian in certain areas are included in the Carboniferous by some geologists and the lower boundary is disputed there as it is in parts of North America.

				Kinder- hookian	

In England, Belgium and northern France the main part of the Lower Carboniferous consists of cliff-forming limestone reaching a thickness of 4,000 ft. in south Wales. Above and below are shales and sandstones that may be coal-bearing. Where dark shaly strata of this type are particularly well developed they are known as the Culm. The Lower Carboniferous limestone accumulated in a bay with land to both north and south. The southern land was more prominent and probably was elevated into mountains like those on the eastern margin in North America. Sediments were washed into the bay from both directions, the lower and upper parts of the limestone grade laterally into shaly and sandy strata and consequently the limestone becomes thinner and represents less time in these directions. Also rise of sea level or sinking of the northern land resulted in shifting of the coast line and Viséan beds overlap the underlying Tournaisian and succeed older rocks, some of which had been folded and deeply eroded, particularly in the northern British Isles. In northern England and the central valley of Scotland the Viséan consists of shales, limestones and sandstones with coal beds arranged in the same general type of cycle that is so characteristic of the Upper Carboniferous.

Carboniferous rocks are widely distributed in Europe except in Scandinavia and the Baltic region. Because of the Hercynian and relatively recent Alpine disturbances, however, they are much more discontinuous and structurally complex than in North America. For these reasons, and also because they are buried beneath younger rocks in many areas, the relations of the several subdivisions to each other and their variations from place to place, as well as the geologic history of the Carboniferous period, are less well known in Europe, especially outside the more intensively studied areas. Both marine and terrestrial beds occur in the Lower Carboniferous, either separately or interstratified. The presence in the same area of coal, produced by compression of partly decayed land plants, and thin limestones or other layers with fossilized marine animals shows that parts of Europe lay very

close to sea level and alternately rose and sank with reference to this critical line.

The limestone deposits of western Europe decrease in importance eastward. The Lower Carboniferous of central Germany consists of shale with some limestone lenses. Similar beds, becoming sandy or even conglomeratic and containing plant fossils, extend eastward to the Czechoslovakian border region and into Silesia. Throughout much of this region the Carboniferous is transgressive onto older beds and the Viséan is more extensive than the Tournaisian. Especially noteworthy areas of Lower Carboniferous rocks occur in the U.S.S.R. Near Moscow the Tournaisian consists of shale and sandstone with lignitic coal beds. Limestone becomes important in the Viséan, which also includes coal in its lower part. Both contain abundant marine fossils in some layers.

In the Donets basin of southern U.S.S.R. the thick Lower Carboniferous consists of interbedded marine and terrestrial strata, but there is little coal. On the flanks of the Ural mountains much limestone is present but the middle part is shaly and coal-bearing.

The Lower Carboniferous of Spitsbergen far north of the Arctic circle contains coal and fossil plants very similar to those known from much more southerly regions, showing that a mild climate prevailed in that part of the world during the Carboniferous period.

Several small coal basins in France include only terrestrial strata that accumulated in depressions between mountains that were rising in that region. They are comparable to similar occurrences in eastern Canada. Lower Carboniferous beds in which limestone is conspicuous are present in small areas in the Mediterranean region from Spain to the Balkans and Asia Minor but little is known about the geologic details. Fossils prove the existence of both Tournaisian and Viséan in Morocco and Algeria. Both divisions are also present in Iran and south China but the Tournaisian seems to be unrepresented in many other parts of eastern Asia except possibly Japan. Viséan limestone, however, has been recognized in the Altai and Kunlun mountains, in the T'ien-shan and the Himalayas and in Indochina, Malaya and Japan.

C. UPPER CARBONIFEROUS (PENNSYLVANIAN)

1. Pennsylvanian of North America.—Profound geographic changes occurred in North America at the beginning of the Pennsylvanian period. Marginal lands, particularly those to the east and south, were uplifted to mountainous heights and rapid erosion began. The central continental area was slightly uplifted and gently warped. The interior sea withdrew from most of the region occupied during Mississippian time. At first deposition was restricted to troughs adjacent to the newly raised uplands, particularly in West Virginia, Alabama, Arkansas and Oklahoma, but as these filled, the sea temporarily returned and sediments were carried farther westward and northward until they blanketed most of the continental interior, including the peninsula projecting southwestward from Minnesota. Pennsylvanian rocks overlap the Mississippian (in which river valleys 300 ft. deep had been cut) and extend beyond them onto older rocks.

The crustal movements which produced these changes were related to part of the Hercynian disturbances of Europe but in the interior of North America they were less complicated and widespread and involved a smaller number of episodes of generally less intensity. In North America the Appalachian revolution, presumably at the end of the Permian period, which followed the Carboniferous, produced folding and overthrusting of the Appalachian mountains in the east and the Ouachita mountains in the interior by forces acting from the east and south. In central and eastern North America little subsequent deformation occurred, and late Paleozoic history is much clearer than in Europe. At the time of the Appalachian revolution rocks of the central United States were gently warped, accentuating older broad folds and intervening basins. Post-Paleozoic erosion removed all Pennsylvanian rocks and some older strata as well from the upward areas and the Pennsylvanian is preserved in the four previously mentioned basins east of the Rocky mountains where they are

inclined so gently that they generally appear horizontal to the eye.

Pennsylvanian rocks were deposited under a variety of conditions ranging from normal clear sea (limestone with marine fossils) through shallow near-coastal waters (shale with marine fossils), deltas (shale and silt with no fossils or only brackish water fossils) and lowland marshes (coal) to great areas of terrestrial alluviation (shale, silt and sand with poorly preserved plant fossils). In general, terrestrial rocks dominate close to the sediment-contributing uplands, and marine rocks are most important far from these sources. Consequently in passing westward from the Appalachian coal fields, the Pennsylvanian system gradually changes and is quite differently developed in such areas as Pennsylvania to the east and Nebraska to the west.

The Pennsylvanian system was named from the state of Pennsylvania where coal was first mined importantly and where the geology of these rocks was first carefully studied. Although coal seams are distributed throughout the 4,000 ft. of the coal measures in that region, they are thickest and most continuous in two parts separated by less-productive strata. On this basis the system is divided into four parts that are commonly termed groups or series. Important coal beds serve as boundaries and these divisions are recognized by tracing the coals or by correlations based on plant fossils.

Coal beds are present in the Pennsylvanian west of the Mississippi river but they are fewer, thinner and relatively unimportant. Marine limestones are abundant, however, and much more conspicuous. Subdivisions there are based on lithologic differences, and groups with prominent limestones are distinguished from others without them. Correlations are made by tracing limestones, matching sequences of different kinds of strata and by the similarity of marine fossils. These groups continue southwestward to Oklahoma where their relations to several mid-Pennsylvanian disturbances, particularly evident in the Arbuckle mountains, have been determined, and they are combined to form series of historical significance.

In this way two different classifications of Pennsylvanian rocks have been set up in the United States; they are difficult to compare. One is based primarily on terrestrial rocks and land plants while the other is dependent largely upon marine rocks and marine animals. Conspicuous changes in both land and marine organisms rarely, if ever, resulted from the same happenings and consequently conclusions regarding significant stratigraphic boundaries and correlations based on such different evidence are not likely to agree. The Pennsylvanian plants of North America are so similar to those of Europe that these regions are believed to have been directly connected, and intercontinental correlations based on plant fossils are considered most reliable. The seas which flooded portions of these continents, however, were not so closely connected that marine animals could migrate from one to the other easily, and only the marine fossils of the Pacific coastal region are very similar to those of Europe and Asia. Because marine fossils are commoner and more widely distributed in North America, however, than are the plants, these fossils generally are more serviceable for correlation on that continent.

Cycles of Deposition.—The different kinds of Pennsylvanian rocks commonly are arranged in a regular order that is repeated many times. Each of these similar units is known as a cyclothem and records a cycle of deposition. This peculiar and recurring sedimentary pattern and the common occurrence of coal are the two most noteworthy features of the Pennsylvanian.

Pennsylvanian cyclothem vary considerably, depending upon the relative importance of the marine and terrestrial beds which they include. A characteristic intermediate type with both coal and marine limestone well developed is common in Illinois. Such associations show that coal swamps recording low-lying land, were drowned by advance of the shallow sea, and most coals are immediately overlain by beds with marine or brackish water fossils. About 50 coals, most too thin to mine, are present in Illinois; and alternation between land and sea occurred nearly that many times.

In West Virginia, where about 100 coals occur, marine or brackish water fossils are much less common and obviously many

marine invasions of Illinois did not extend much farther eastward. In contrast, coals are scarce in Nebraska but marine limestones are abundant, comparatively thick and pure. Evidently, withdrawals of the sea permitting luxurious growth of swamp vegetation in Illinois did not all continue farther west.

Cyclothem are less readily recognizable where both coals and strata with marine fossils are not associated. Coals are more important than limestones in identifying cyclothem because most cyclothem include only one coal whereas two or more limestones may occur. Also the position of a coal often is identified by an old soil with abundant root markings even if no coal is present. Finally the characteristic relationships of other types of strata marked by individual peculiarities aid in recognizing incompletely developed cyclothem.

Pennsylvanian cyclothem record a rhythmic periodicity in the ebb and flow of shallow seas and alternate rapid and slow deposition of sediments eroded from the higher land. Interfingering of marine and terrestrial rocks is striking in some areas. Coals and limestones accumulated slowly, and their purity shows that erosion of the land was slight. Alternating shales and sandstones were deposited rapidly and record times of much more active erosion.

No entirely satisfactory explanation accounts for cyclothem. Shallow seas may have advanced and retreated because of alternate uplifts and depressions of the continents or the continents may have been stable and sea level fluctuated because large quantities of water were withdrawn from the oceans to form great glaciers in the southern hemisphere and then returned when the glaciers melted. Alternate rapid and slow erosion may record important rising and sinking of mountainous areas or it may have resulted from climatic changes, particularly variations in amount of rainfall. Many uncertainties exist. If, for example, the last explanation is favoured, increased rainfall might have been followed by increased erosion or it might have permitted the growth of sufficient vegetation to protect the land against rapid and severe erosion.

Other Occurrences.—In the United States the Pennsylvanian subdivisions succeed each other regularly and without interruption except in a region extending from western Arkansas to Colorado where several local but noteworthy disturbances produced the first uplifts in the Arbuckle and Wichita mountains and another range near Amarillo, Tex., now completely buried by younger strata. The resulting unconformities, showing angular discordance and much erosion, separate the series of the western dominantly marine Pennsylvanian sequence.

Pennsylvanian strata are widespread in the Rocky mountains, but their interrelations are not well known. Thick arkosic or feldspar-rich sandstone deposits in Colorado and neighbouring states, overlapping at some places onto Pre-Cambrian granite, record nearby mountains first uplifted in the latter half of the Mississippian period. They have been termed the ancestral Rockies although they are structurally unrelated to the present Rocky mountains. Southward and southwestward the Pennsylvanian includes much shale and sandstone, and neither the lower nor upper boundaries are well marked. Salt and gypsum occur in Utah. To the north the Pennsylvanian is largely sandstone enclosed between red beds of uncertain age. In some areas a peculiar rhythmic alternation of sandstone and limestone suggests cyclothem quite different from those of more eastern regions.

Upper Carboniferous rocks in eastern Canada are more than 10,000 ft. thick and consist entirely of terrestrial sandstone and shale with coal seams in New Brunswick and Nova Scotia. They probably accumulated in several disconnected basins separated by mountainous ridges.

Pennsylvanian strata have not been identified in the Pacific coastal belt and Alaska, where rocks bearing fusuline Foraminifera (*q.v.*) fossils are generally considered Permian and transgressive onto older rocks.

In west Texas the Permian overlies folded and eroded Pennsylvanian strata. Elsewhere in North America these systems are not separated by structural discordance or a break in deposition and the boundary is determined by plant fossils in the northern Appalachian region and marine fossils west of the Mississippi river.

2. Upper Carboniferous of Europe and Asia.—In England the Carboniferous is divided into three parts known as the Carboniferous Limestone series (oldest), Millstone Grit and Coal Measures (youngest). The Upper Carboniferous generally is considered to begin at the base of the Millstone Grit, but sandstones of this division appear at somewhat different stratigraphic levels in different areas and consequently the boundary is not consistent and is comparable to that separating the Mississippian and Pennsylvanian in the Appalachian district of North America. In some parts of England and Scotland, however, the two divisions of the Carboniferous are separated by an unconformity and the Upper overlaps onto various zones of the Lower or onto older rocks.

The Millstone Grit is approximately equivalent to the Namurian of the continent. Like the latter it is transitional between the Lower Carboniferous and the Coal Measures (or Westphalian) as it includes both coal seams or beds with plant fossils and thin but widespread marine limestones. The sand was produced by rapid erosion of an upland area in the vicinity of northern Scotland. The Coal Measures of England reaches a thickness of about 7,000 ft. and in some areas grades upward into Upper Carboniferous red beds.

At the end of Lower Carboniferous time in western Europe, folded and faulted mountains known to geologists as the Armorican range extended from western France into southern Germany. Large quantities of sediment washed northward from their slopes into a subsiding basin of which the present important coal fields as far east as Silesia are dismembered parts. These mountains were worn down rapidly and in later Carboniferous time another upland to the north was the principal source of sediments. In part of the great coal basin the Lower Carboniferous passes into the Upper without a break, but sediments spread out over a larger area and overlap onto older rocks much as they do in North America.

Upper Carboniferous coal seams (there are about 300 in Silesia) occur in cyclic arrangement with other kinds of rocks. Cyclothem comparable to those of North America, except that marine strata are much less common, are widely recognized. The marine bands record periodic and temporary submergences that arrived from eastern Europe. These became less and less extensive westward with the passage of Upper Carboniferous time.

The Upper Carboniferous of the U.S.S.R. is dominantly marine. These strata overlie the Lower Carboniferous in the Moscow region, the Donets basin of the Ukraine and the Ural mountains. In the Timan of northern U.S.S.R. they overlap onto the Devonian and record late Carboniferous submergence in that region. The Moscovian formation near Moscow, in the Urals and in northern U.S.S.R. consists of limestone with considerable shale. In the Donets region it is more than 15,000 ft. thick and also includes sandstone and many coal seams. The Uralian formation of the Donets is nearly as thick, but coals become rarer upward. In other parts of the Soviet Union, the Uralian is generally similar to the underlying Moscovian.

Correlations of the Upper Carboniferous are not entirely satisfactory because of the difficulty of comparing marine fossils of the Russian sequence with land plants of the western countries. Also, some of the Stephanian floras of central France which grew in intermountain basins are somewhat different from presumably contemporaneous floras of late Westphalian type to the north. The upper boundary of the Uralian in eastern Europe has been much disputed. Beds included in the upper part of this division by some geologists are classed with the Permian by others who define the Uralian on the basis of marine fossils, chiefly fusulines and ammonoids, best known in the uninterrupted North American sequence. In western Europe the end of the Carboniferous period corresponded with an important change in climate and the overlying Permian, unconformable in some areas, is noteworthy for its red beds and the great salt deposits of Germany which are evidence of arid conditions.

In southern Europe and the Mediterranean region, presumably Upper Carboniferous strata include limestone in several widely discontinuous areas. Coal occurs in the Westphalian of Spain and to a lesser extent in the western Alps. Eastward the distinction

between Upper Carboniferous and Permian is somewhat uncertain, but the former is probably present in the Balkans and Turkey.

The Upper Carboniferous is generally less extensive in Asia than the Lower. The Moscovian is not well known except in parts of Iran and China. It probably is present in Manchuria, Korea and Japan and in eastern Asia generally overlies the Ordovician. It has been reported in the Kunlun mountains and in the T'ien-shan overlies folded Lower Carboniferous strata. Limestone of possible Moscovian age occurs in Malaya, and equivalent Culmlike beds have been described in Thailand. Probably much of the supposed Uralian reported from scattered localities in Asia is actually Permian.

The Upper Carboniferous of northern Africa is poorly known. Possibly some limestones of a predominantly sandstone sequence in upper Egypt and the Sahara may be of this age, and its occurrence in Morocco is possible.

D. CARBONIFEROUS OF SOUTHERN HEMISPHERE AND INDIA

The continents of the southern hemisphere were not so extensively submerged by shallow seas during the Carboniferous period, and rocks of this age are largely terrestrial deposits. Most remarkable are tillites, reaching a thickness of 2,000 ft. in South Africa, formed by the action of glaciers. These are similar to boulder-bearing clays in North America and Europe, which record the presence of much more recent Pleistocene glaciers, but they have been indurated to form hard rock. Associated fossils are not abundant or sufficient to date these beds with certainty. For many years they were considered Permian but gradually accumulating fossil evidence, particularly from Australia, suggests late Lower and Upper Carboniferous age.

Similar glacial deposits and other terrestrial beds occur in southern and central Africa and Madagascar, in the Falkland Islands, central Argentina, Uruguay and southern and eastern Brazil, in eastern and western Australia and Tasmania and in India. They record remarkably similar conditions in these widely separated areas and suggest former close association if not direct connection. Two theories postulate the existence of a southern continent, Gondwanaland (*q.v.*), quite different from any existing today. One is that South America, Africa, India, Australia and probably Antarctica were joined by extensive areas of intermediate land which later sank beneath the South Atlantic and Indian oceans. The other supposes that a much smaller Gondwanaland broke apart in post-Paleozoic time, and its fragments separated to become the southern continents. According to both theories, the peninsula of India was a part of Gondwanaland, as its geologic nature and history are similar to the present southern lands but quite different from other parts of Asia.

The orientation and nature of grooves in the underlying rock surfaces produced by grinding of the ice show that late Paleozoic glaciers moved northward in India and southward in South Africa, indicating glacial centres in what is now the equatorial zone. This seems a most unlikely place for great glaciers to originate, and some geologists conclude that Gondwanaland originally lay at or near the south pole.

Late Paleozoic invertebrates and plants have been found in some other parts of the southern hemisphere and in Africa north of the equator but their geologic relations are poorly known and their ages uncertain. Some are Permian but others are probably Upper Carboniferous. Lower Carboniferous fossils are almost unknown except in north Africa.

E. IGNEOUS ROCKS

Igneous and volcanic rocks of possible Carboniferous age occur in several parts of the world but mostly in areas of complex geology where their relations are not well understood. Lava flows and volcanic cones associated with Carboniferous rocks are conspicuous in southern Scotland and presumably related dikes and sills are present in northern England. More limited volcanic activity occurred in Ireland and central France.

Both extrusive and intrusive igneous rocks of Carboniferous age are known in the maritime provinces of Canada. In New England an extensive series of igneous rocks intimately associated with the

metamorphic complex of that region is probably Carboniferous. Intrusive granites farther south in several Atlantic states are of uncertain but possibly similar age.

The stratigraphic sequence of the North American Pacific coast is poorly known, but intrusive and extrusive Paleozoic rocks occur from northern California to Alaska and some are almost certainly of Carboniferous age.

In Asia, volcanic tuffs and lava flows of Lower and Upper Carboniferous age have been reported in the T'ien-shan. Late Carboniferous or early Permian eruptive igneous rocks occur in Kashmir and somewhat similar rocks have been observed in southern Malaya.

Volcanic rocks are associated with some glacial beds in Australia, and igneous intrusions of approximately similar age occur in other areas.

II. LIFE OF THE CARBONIFEROUS

1. Marine Life.—Several thousand fossil plant and animal species are known from Carboniferous rocks. They are important because similarity of fossils indicates approximate time equivalence of the rocks containing them. Also they furnish much information concerning some of the conditions prevailing at the time and place where these organisms lived. (*See FOSSIL.*) Marine invertebrates are abundant and occur in greatest variety. As in older Paleozoic systems, fossils of brachiopods are common but there are fewer kinds than in the Devonian. Only one group, the Productidae, shows great advancement and expansion (*see BRACHIOPODA: Palaeontology*). Crinoids or sea lilies reached their acme of differentiation and abundance in the Lower Mississippian, particularly in the shallow North American sea. Some limestones consist almost exclusively of the dismembered skeletons of these animals which live today mostly in the deep seas. The related, long-extinct blastoids achieved their greatest abundance in the Upper Mississippian.

For the first time the tiny shells of Foraminifera are abundant as fossils in the Carboniferous. At some places they occur in enormous numbers and constitute the greater part of limestone beds. In the middle Mississippian of Indiana individuals of a single coiled species less than a millimetre in diameter are abundant and easily mistaken for oolites. In the Upper Carboniferous another and larger type represented by many species, known collectively as fusulines, is widely distributed and common in many limestones. They are about the size and shape of wheat grains with complex internal structures demonstrating rapid evolution. They appear in the uppermost Mississippian and continue into the Permian. Several distinctive genera are useful for long-distance correlation because they existed for only a few million years and are therefore excellent guide fossils to restricted time zones.

Among the mollusks, gastropods and pelecypods are abundant, varied and well preserved, especially in the Pennsylvanian shales of the United States. Cephalopods are of great interest, particularly in Europe, because the ammonoids or goniatites began to differentiate importantly in the Mississippian and they, together with the crinoids, are the most reliable fossils for long-range correlation in the Lower Carboniferous (*see AMMONITE*). The simpler nautiloids are less common and smaller than in many older rocks. Bryozoans are abundant and among several distinctive types are some with screwlike axes. Corals are more important in western Europe than in America and trilobites are much less numerous and diversified than in the older geologic systems.

Sharklike fishes were common and are known from teeth often found in limestone. The most important group evidently fed upon shellfish because their teeth are flattened for crushing and grinding. The bones of these fish are rarely found and probably were cartilaginous like those of modern sharks and therefore poorly adapted for fossilization.

Several fresh-water animals are known, including a shark with sharp needlelike teeth, several other kinds of fish, a variety of mollusks and worms that inhabited tiny coiled tubes. This type of fauna undoubtedly was much larger but it lived under conditions generally unfavourable for preservation.

2. Land Life.—Land life was dominated by amphibians which evolved from specialized fish in the Devonian and in turn gave rise to the first reptiles in the Carboniferous. Individuals mostly were small. Complete skeletons are rare, but footprints show that these creatures were abundant in some areas. There were many kinds of insects although fossils are known from only a few localities. The most common are primitive cockroaches; also included are the largest insects ever found, dragonflylike creatures, with wing spans of more than two feet.

The Carboniferous rocks furnish the first evidence of an abundant, diversified and widely distributed land flora. Plants, including trees 40 ft. or more tall, grew during the Devonian; but remarkable advancement occurred during the Carboniferous and a characteristic Flora spread all over the earth and provided material for the world's most valuable coal deposits. A variety of drifted stems is known from a few marine formations, but most of the fossils are leaf impressions in terrestrial shales. Many are strikingly similar to modern ferns: they belong to two groups, one the true ferns and another that reproduced by seeds instead of spores. They include small herbs, vines and even trees 50 ft. tall. The giants of the Carboniferous forest) however, were trees 100 ft. high related to the modern club mosses. Their trunks are marked by prominent diamond-shaped scars where narrow straplike leaves had been attached. Another common type is quite similar to the horsetail rushes of today but many times larger. Also the first conifers, the ancestors of present-day evergreens, made their appearance in the Upper Carboniferous. The structure of all these plants shows that they grew rapidly under moist temperate conditions. The general absence of growth rings indicates lack of important seasonal variations and the occurrence of fossils in the far north suggests that the earth was not so distinctly zoned climatically during the Carboniferous period as it is today.

III. ECONOMIC PRODUCTS

Coal is the outstanding mineral product of the Carboniferous, and most of the important coal fields of Europe and North America occur in strata of this age. Regions of particular importance are the eastern and central United States, Great Britain, the Ruhr and Saar areas of western Europe, Silesia and the U.S.S.R. Most of the coal is of Upper Carboniferous or Pennsylvanian age, but Lower Carboniferous coal seams also occur and are mined particularly in Europe.

Large amounts of petroleum are obtained from Carboniferous rocks only in the United States, where oil fields of this age extend from Pennsylvania to Texas.

Many metalliferous mineral deposits were formed at the time of the Hercynian disturbances in Europe, Asia and Australia and date from the mid-Carboniferous into the Permian. They resulted largely from the action of mineral-bearing solutions derived from igneous intrusions and occur in rocks mostly older than the Carboniferous. They include tin in Cornwall and Saxony, silver and gold in France and Germany, copper and sulfur in Spain and platinum in the Urals. Similar deposits occur in China, Japan, Burma and Malaya. Also tin, tungsten, gold and bismuth of this age are mined in Australia and New Zealand. Comparable deposits are almost unknown in the western hemisphere.

Carboniferous rocks also contain mineral deposits of later origin. These include the zinc and lead of Oklahoma and Kansas, the ores at Bingham, Utah, the lead of the old mining district in central England, the fluorite veins of Illinois and Kentucky and many others.

Commoner mineral products of the Carboniferous such as clay, sand, limestone, etc., are too widely utilized to be mentioned individually except perhaps the Bedford limestone of Indiana, which is shipped all over the United States and to some other countries for building purposes.

CARBONIZATION, LOW-TEMPERATURE. The term low-temperature carbonization designates processes in which coal is partially coked under conditions such that the temperature of the resulting char or coke does not exceed about 600° C. (1,112° F.). The designation is an empirical but convenient method of roughly characterizing the resulting products and of distinguishing them from those which have been processed under high-temperature conditions, 900° to 1,100° C. (1,652° to 2,012° F.) as in the manufacture of metallurgical coke, or in the intermediate temperature range.

Interest in low-temperature carbonization processes is based chiefly on the production of (1) a readily ignitable and smokeless solid fuel of suitable size and superior value for use in residential or small commercial heating units; (2) a char of suitable properties to serve as fuel for power plants, gasification processes or as an additive or substitute material for use in blends of coal charged to high-temperature coke ovens; and (3) a large volume of tar for by-product credit in the form of liquid fuels, solvents, pitch and a potentially wide variety of commercial chemical products. Substantial effort and large sums of money have been expended over a period of many years in attempts to develop a practical and economic low-temperature process. Out of literally hundreds of proposed processes, only a handful have reached a measure of success on a commercial basis, such as the Coalite and Rexco processes in England, the Krupp-Lurgi process in Germany and the Disco process in the United States. Of those that have failed, many have done so because of practical engineering difficulties and almost all because of economic considerations. Economic difficulties are primarily concerned with the inability to gain sufficient by-product credit from the tars and oils to yield an incentive profit and the inability to overcome the resistance of prospective residential or industrial customers to higher prices on a tonnage basis for the solid fuel, whatever its advantages may appear to be.

Products of Low-Temperature Carbonization. — The yields of solid, liquid and gaseous products when coal is carbonized vary with the temperature employed, the rank and type of coal and the method of carbonization. Temperature is an important factor which determines the extent to which the coal substance is decomposed and the type of product. The effect of carbonizing temperature on the average relative yields of products from a bituminous coal, Pittsburgh bed, are compared in the table.

Effect of Temperature of Carbonization on the Relative Yield of Products
(U.S. Bureau of Mines—American Gas Association Assay Test)

Product	Yield per ton of coal, Pittsburgh bed, at various carbonizing temperatures (° C.)						
	500°	500°*	600°	700°	800°	900°	1,000°
Coke, lb.	1,530	1,064	1,432	1,382	1,350	1,320	1,348
Gas, cu. ft.	2,700	3,050	4,400	6,800	8,600	10,400	11,600
Tar, gal.	24.7	12.1	25.1	24.0	22.1	18.8	10.7
Light oils, gal.	3.5	1.7	3.8	4.2	3.7	3.7	3.9
Ammonia (as sulfate), lb.	3.6	9.2	12.2	24.1	25.3	22.3	17.2
Volatile matter, coke, %	19.4	14.2	6.3	3.1	3.0	1.9	1.4
Hydrogen in gas, dry, %	18.6	21.2	20.2	42.1	50.0	52.3	54.0
Methane in gas, dry, %	53.6	34.7	51.1	37.6	32.2	30.3	29.4
Heating value of gas, B.T.U. per cu. ft.	890	612	805	679	642	600	586

*Subbituminous, Wyoming, as mined. Source: U.S. Bureau of Mines, *Monograph 5*.

111 general, carbonization at low temperatures produces a higher yield of coke or char which is more reactive and easily ignited than is high-temperature coke, but which is not suitable for metallurgical uses such as in blast furnaces and foundry cupolas. The percentage of volatile matter remaining in the coke is a measure of reactivity, low volatile-matter content being associated with low reactivity and relative difficulty of ignition. The yield

of tar and oil products is considerably higher for a low-temperature process because decomposition has been less severe. At low carbonizing temperatures, the proportions of pitch and aromatic compounds in the tar are lower, but the contents of tar acids and paraffinic neutral oils are higher. A smaller volume of fixed gases is produced, but the gas is higher in methane and ethane which have high heating values, and lower in hydrogen. As a result, the gases produced from many coals at 500° C. have heating values almost twice that of gases produced at 1,000° C., although only about one-fourth as much gas is evolved.

The rank of coal also is a factor in determining relative yields of products. At the same carbonizing temperature, high-rank bituminous coals give higher yields of products than do the subbituminous and lignitic coals, which are much higher in moisture content. This is illustrated by comparing the two 500° C. columns in the table for bituminous and subbituminous coals.

Types of Processes. — Low-temperature carbonization processes may be grouped in two general classes, depending upon whether external or internal heating is used. Methods employing external heating, in which the charge of coal is held in ceramic or metal retorts heated on the outside, suffer from the disadvantage that coal is a poor conductor of heat, and carbonization proceeds very slowly. To overcome this disadvantage, a wide variety of procedures involving stirrers, reciprocal motion, revolving retorts and a multiplicity of heated surfaces have been used. The objective has been to heat the coal in thin layers, or to impart motion and bring fresh coal in contact with the heated surfaces. Obviously, these procedures add to the mechanical complexity of the system. The second general class of processes involves passing heated gases through the charge of coal, usually upward. Thus, the coal is in direct contact with the heated medium, and the rate of carbonization is controlled by varying the quantity and temperature of the heated gases. Difficulties are encountered with coking coals unless a preliminary treatment is used to reduce their agglomerating tendencies.

Since World War II a number of processes based on fluidization (the processing of a solid in such a form that it can be handled as a fluid) have been developed to the pilot-plant stage. These methods must use small-sized coal and are limited to the production of char of the same nominal size. Improved rates of heat transfer from the heated gas to the coal particles are achieved through fluidization, and the yields of primary tar are higher because of improved temperature control. There is also the possibility of being able to process coking coals by the dilution effect of recirculating heated and partially devolatilized char. Fluidization holds promise of reduced processing costs and increased yields of products, and several large programs of research and development on a pilot-plant scale were begun during the period 1950-56, including studies of the properties and uses of the tars and oils produced. Again, the economics of the situation will determine the success of a fluidized operation, but it is possible that an integrated system involving power plants, carbonizers and chemical tar processing may be evolved at favourable locations in coal-producing areas.

See also COKE, COKING AND HIGH-TEMPERATURE CARBONIZATION; COAL AND COAL MINING. (H. W. N.)

CARBON MONOXIDE POISONING results from breathing air containing the gas. Carbon monoxide is produced by burning carbon-containing fuels in a deficiency of air or oxygen. Common producers are room heaters, gas ranges, automobile exhausts, mine explosions, blasting, iron and steel furnaces and burning electric installation. Since the gas is colourless, tasteless and odourless (in the concentration usually encountered), its detection is difficult. Mice and birds are more quickly affected by it than man. The activated iodine pentoxide indicator, however, detects the presence of dangerous amounts in less than one minute.

The gas exerts its extremely dangerous action on the body by forming a relatively stable compound with hemoglobin, carboxyhemoglobin, which prevents it from carrying oxygen and therefore produces asphyxia. The carboxyhemoglobin has a characteristic cherry red colour; hence cyanosis is usually absent in carbon monoxide poisoning, the skin being pink or pale and the lips bright red.

Frequent symptoms are headache, weakness, nausea, fainting, paralysis of the nervous system and slowing of pulse and respiration.

Treatment is by removal of the victim to fresh air; application of artificial respiration, administration of pure oxygen, or a mixture of 5% of carbon dioxide in oxygen for 20 minutes or more; stimulation of circulation; complete relaxation; symptomatic treatment for aftereffects. Carbon monoxide poisoning may cause death or permanent mental deterioration unless treatment is prompt and effective. See also **HYPOXIA**.

CARBON PAPER, a tissue of varying weight coated with a colour, generally carbon black, and some waxy medium. It is usually coated on one side but may be coated on both sides for special purposes. For typewriting duplication, which is its chief usage, it is coated on one side only. The paper upon which the coating is applied varies in weight from four to ten pounds per ream of 430 sheets, 20 by 30 in.; and is made from fibres such as rag, wood, manila and jute. Since it must be strong and durable it must not contain any ground wood pulp. The coloured waxy material that transmits the duplication is soft so that at least five copies can be made. It is also so strongly coloured and of such durability that a sheet will make at least 12 first carbons that are clear and legible. This coating is composed of waxes such as Japan, paraffin and carnauba, and such oils as olein and rosin thoroughly amalgamated with a colour, which in the case of black paper is always carbon or gas black.

In coloured papers the colour consists of an aniline dye base combined with such fatty acids as stearic and oleic or a fat-soluble dye dissolved in the olein or rosin oil present in the mixture. Copy papers have been adapted to photocopy uses. These papers must be fast to light and are made in various colours including white. The chrome yellows, iron blues and fast coal-tar red pigments are used for the colours and titanium dioxide for the white.

The manufacture of carbon paper embraces two processes, viz., the preparation of the coating material and its application to the paper. The waxes and oils are melted in a steam-jacketed kettle at a temperature of approximately 300° F. and the colour stirred in. Afterward the hot mixture is passed through a steel-plate grinding mill and is then ready for the coating machine. This machine, of web-type operation, takes the paper in roll form, passes it over the coating roller that revolves in a steam-heated ink fountain containing the hot coating mixture and then leads the paper over a spiral-wire wiper that controls the thickness of the coating. From this wiper the web of carbon paper passes over water-cooled rollers that chill and harden the coating, and subsequently it is rolled upon itself at the end of the machine. The roll is then cut into sheets in sizes according to its usage. (N. U.)

CARBON TETRACHLORIDE (TETRACHLOROMETHANE) is important as a solvent, chemical intermediate and fire-extinguishing agent. It is a colourless, mobile, noninflammable liquid; chemical formula CCl_4 , molecular weight 153.84, boiling point 76.7° C. (170° F.), specific gravity 1.595 at 20° C. One volume of carbon tetrachloride dissolves in 2,000 volumes of water, but it is miscible in all proportions with alcohol, ether, benzene and other organic solvents; it dissolves many oils, greases, waxes and tars. Carbon tetrachloride is toxic, causing liver and kidney damage. The maximum safely allowable concentration of the vapour in air is probably less than 100 parts per 1,000,000.

The solvent properties of carbon tetrachloride make it useful for commercial dry cleaning of fabrics; it has also been used for degreasing metal surfaces but is less satisfactory for this purpose than trichloroethylene. Since it readily volatilizes to form a heavy noninflammable blanket of vapour, it is important in fire-extinguishing apparatus, especially for small electrical fires. This use may be dangerous since phosgene can be formed under certain conditions.

Carbon tetrachloride was first prepared in the early 1840s by the action of chlorine on chloroform or methane. It is currently produced industrially by the reaction of chlorine or sulfur dichloride with carbon disulfide.

CARBONYLS, METAL. The metal carbonyls are compounds of carbon monoxide with heavy metals. In general they are produced by direct action of carbon monoxide on the finely divided metal. Some of these unique metal compounds are highly volatile and readily decompose into carbon monoxide and metal. They are used in the preparation of metals of exceptionally high purity and as catalysts in organic syntheses.

Only the transition elements of Groups VI, VII and VIII of the periodic system are known to form metal carbonyls. Metal carbonyls were originally regarded as unique and extraordinary compounds which did not conform to the then known rules of valence. Advances in the understanding of the metal-carbon bond and of the electronic configuration of transition metals has removed much of the mystery that first surrounded this class of compounds. The metal carbonyls and their derivatives are treated as a separate group because their properties and chemistry differ from those of the organometallic compounds and other metal complexes. The first metal carbonyl to be discovered (Ludwig Mond [*q.v.*], 1890) was that of nickel, $\text{Ni}(\text{CO})_4$.

The Known Metal Carbonyls and Their Properties

Group VI	Group VII	Group VIII	
Cr(24)	Mn(25)	Fe(26)	Ni(28)
$\text{Cr}(\text{CO})_6$ sublimes colourless rhombic	$\text{Mn}_2(\text{CO})_{10}$ m. p. 154° C. sublimes golden yellow	m. p. -20° C. b. p. +103° C. yellow $\text{Fe}(\text{CO})_5$ comp. 100° C.	$\text{Ni}(\text{CO})_4$ m. p. -25° C. b. p. +43° C. colourless

			$\text{Pt}(78)$

Composition, Properties and Structure. — In the table are listed all the metal carbonyls known in the early 1960s. Two types of carbonyls can be distinguished: mononuclear carbonyls (containing one metal atom per molecule) and polynuclear carbonyls (containing two or more metal atoms per molecule). Some metal carbonyls form only mononuclear carbonyls, e.g., nickel, $\text{Ni}(\text{CO})_4$; some form only polynuclear carbonyls, e.g., cobalt, $\text{Co}_2(\text{CO})_8$; and some form both, e.g., iron, $\text{Fe}(\text{CO})_5$ and $\text{Fe}_3(\text{CO})_{12}$. The composition of the mononuclear carbonyls is governed by a simple rule which states that the effective atomic number (E.A.N.) of the metal in a metal carbonyl is that of the inert gas of the completed period in which the metal is situated. The E.A.N. is the total number of electrons which surround the nucleus of the metal. This number is composed of the electrons belonging to the metal (the atomic number of the metal) and the number of electrons contributed by the carbonyl groups. Each carbonyl group ($:\text{C}=\text{O}$) donates two electrons (indicated by the two dots) to the metal. The following example will serve as an illustration: the E.A.N. of nickel in $\text{Ni}(\text{CO})_4$ is 36; i.e., 28 (atomic number of nickel) plus 2×4 (electrons donated by the four $:\text{C}=\text{O}$ groups). The rare gas

of the completed period in which nickel is situated is krypton, with an atomic number of 36. The composition of polynuclear carbonyls is also related to rare-gas configuration. This relationship is demonstrated by the formula

$$G - \frac{xM + 2y}{x} = x - 1$$

from which the composition of any polynuclear carbonyl may be derived. G is the E.A.N. of the next rare gas, M the atomic number of the metal, x the number of metal atoms and y the number of carbonyl groups.

The concept of E.A.N. correlates the composition of the metal carbonyls on a purely formal basis and also implies a relationship between the carbonyls and the rare gases. This relationship manifests itself in the volatility of the carbonyls as demonstrated in the table.

The volatility of the metal carbonyls is especially impressive when compared with that of other compounds of similar molecular weight. For example, the saturated hydrocarbon, $C_{12}H_{26}$, with a molecular weight of 170 boils at $215^\circ C$. while $Ni(CO)_4$ with a molecular weight of 171 boils at $43^\circ C$.

In all mononuclear carbonyls the metal-carbon-oxygen bonds extend linearly from the central metal atom. The configuration of the hexacarbonyls of chromium, molybdenum and tungsten is that of a regular octahedron. Iron pentacarbonyl possesses the configuration of a trigonal bipyramid and nickel carbonyl that of a regular tetrahedron. The dimeric carbonyls of iron (I) and cobalt (II) contain three and two bridge carbonyls, respectively. The

configuration of $Fe_2(CO)_9$ is that of two octahedra joined face to face (I), while in $Co_2(CO)_8$ two trigonal bipyramids are joined edge to edge (II). Not all binuclear carbonyls contain bridge carbonyls. In the binuclear complex $Mn_2(CO)_{10}$, for instance, the two $Mn(CO)_5$ groups are linked by an Mn-Mn bond.

The metal-carbon-oxygen bonds may be viewed as a hybrid of the two structures:

The carbon-oxygen bond is thus intermediate between a triple bond as in carbon monoxide and a double bond as in ketene or carbon dioxide.

Reactions of the Metal Carbonyls.—The reactions of the metal carbonyls are characterized by the tendency of the metal atom to retain its rare-gas configuration. They may be divided into reactions involving substitution of one or more carbonyl groups and electron-transfer reactions. Examples of these reactions follow.

Substitution Reactions.—Both terminal and bridge carbonyl groups are in some cases replaceable by atoms or molecules which can provide the same number of electrons as the displaced carbonyl group. Thus two atoms of iodine, 2I, provide two electrons and can therefore replace one carbonyl group to form $Fe(CO)_4I_2$. Other examples are triphenylphosphine, $:P(C_6H_5)_3$, with two, and nitric oxide, $:NO$, with three available electrons. One triphenylphosphine molecule replaces one carbonyl group as in $(CO)_3NiP(C_6H_5)_3$, and two nitric oxide molecules replace three carbonyl groups as in $(CO)_2Fe(NO)_2$. An interesting reaction is the sub-

stitution of the two bridge carbonyls in $Co_2(CO)_8$ by acetylene to give a dicobalt hexacarbonyl acetylene complex:

Acetylene may be viewed as containing two pairs of available electrons in the two π orbitals of the carbon-carbon triple bond.

Electron-Transfer Reactions.—When iron pentacarbonyl is treated with a solution of sodium in liquid ammonia, carbon monoxide is evolved and the salt $Na_2Fe(CO)_4$ formed:

In this reaction two electrons are transferred from the sodium to iron pentacarbonyl. These two electrons replace the two electrons donated by the carbon monoxide group with the result that the E.A.N. of iron in the anion $[Fe(CO)_4]^{--}$ is the same as that in $Fe(CO)_5$; *i.e.*, that of a rare gas.

An interesting intermolecular electron-transfer reaction takes place when iron pentacarbonyl is dissolved in certain amines such as butylamine or piperidine. In these amines iron pentacarbonyl dissociates according to:

In both the cation $[Fe(CO)_6]^{++}$ and the anion $[Fe(CO)_4]^{--}$ the E.A.N. of the iron is that of the next rare gas, krypton.

Dicobalt octacarbonyl undergoes electron-transfer reactions similar to those of iron pentacarbonyl. Sodium in liquid ammonia reacts with dicobalt octacarbonyl according to:

The anion $[Co(CO)_4]^-$ is isoelectronic with $[Fe(CO)_4]^{--}$ and the cobalt atom possesses rare-gas configuration.

Reactions of the Metal Carbonyl Hydrides.—The carbonyl hydrides, a group of compounds derived from the metal carbonyls, deserve special mention because of their interesting reactions. These carbonyl hydrides are gases at room temperature and are readily prepared by acidifying an alkaline solution containing the corresponding anions in a current of carbon monoxide and sweeping the liberated carbonyl hydrides into a cold trap.

Electron diffraction data show that in the carbonyl hydrides of iron and cobalt the central metal atom is surrounded tetrahedrally by four carbonyl groups. The hydrogen is probably bonded by the metal atom as well as by the electron cloud of the carbonyl groups.

In the presence of a base (B) the carbonyl hydrides act as acids,

while in the absence of a base they decompose into hydrogen and metal carbonyl:

Having the elements of hydrogen and carbon monoxide built into their molecules, the metal carbonyl hydrides are capable of reacting as transfer agents of both carbon monoxide and hydrogen.

Metal carbonyl hydrides or related compounds are probably catalytic intermediates in certain technically important processes involving the addition of carbon monoxide and hydrogen to a substrate at elevated temperature and pressure. An example is the *oxo* process; *i.e.*, the conversion of olefinic hydrocarbons to the next higher alcohols:

This process is utilized by the petroleum industry to make alcohols for plasticizers.

Preparation and Industrial Application.—The carbonyls of nickel, iron, cobalt and molybdenum can be prepared by direct synthesis, *i.e.*, by treatment of the finely divided metal with carbon monoxide; the required temperatures and pressures increase from nickel to molybdenum. The carbonyls of the other transition elements are prepared from the halides at elevated temperatures and carbon monoxide pressures in the presence of halogen acceptors

such as silver or copper:

Nickel and carbon monoxide react at atmospheric pressure and room temperature, but the formation of nickel carbonyl is favoured by higher pressures and catalyzed by traces of sulfur. Outside the nickel industry, where nickel carbonyl is an intermediate in the refining of nickel ore, the only commercial use of nickel carbonyl is as a carbon monoxide transfer agent in the synthesis of acrylates from acetylene and alcohols:

Nickel carbonyl is regenerated from the salt by reduction followed by treatment with carbon monoxide. Iron pentacarbonyl can be formed at temperatures ranging from 15° to 400° C. and at carbon monoxide pressures from 1 to 1,200 atm. The usual temperatures and pressures employed are 150°–200° C. and 10–200 atm.

Iron pentacarbonyl is commercially available and is used in industry for the preparation of iron powder (carbonyl iron), which is obtained by the thermal decomposition of the carbonyl. Because of its high purity and desirable magnetic properties, carbonyl iron is used by the electronic industry for the production of magnetic devices, particularly of the high-frequency type. Carbonyl iron also finds application in powder metallurgy.

Dicobalt octacarbonyl is not available commercially. Metallic cobalt and cobalt salts react very slowly with pure carbon monoxide. In the presence of hydrogen, however, the cobalt salts react rapidly at 200–300 atm. and 150°–160° C.:

Toxicity and Safe Handling.—Danger from the toxicity of the metal carbonyls and their derivatives is directly related to their volatility. Extreme care must be exercised in the handling of the carbonyls of iron and nickel and the carbonyl hydrides of iron and cobalt. Due to their low vapour pressure the carbonyls of the other transition elements do not present a health hazard. Here the only danger lies in the evolution of carbon monoxide which may be liberated by the thermal or chemical decomposition of these carbonyls. Nickel and iron carbonyl are toxic even when inhaled in small amounts, and the liquid may be absorbed through the skin. There is little information upon which to base an estimate of a maximum permissible concentration. The safe amount for eight-hour exposures is probably below one part per 1,000,000 in the working atmosphere.

With the exception of the carbonyls of chromium, molybdenum and tungsten, all metal carbonyls are more or less readily attacked by oxygen and present a fire hazard. Nickel and iron carbonyl are inflammable and may ignite spontaneously even at room temperature when brought into contact with air.

CARBORUNDUM, a proprietary name for silicon carbide (q.v.).

CARBOXYLIC ACIDS constitute an important family of organic chemical compounds which contain the acidic carboxyl group,

The carboxylic acids are widely distributed in nature; ranging from vinegar, an aqueous solution of acetic acid, $\text{CH}_3\text{CO}_2\text{H}$, to caproic acid, $\text{C}_5\text{H}_{11}\text{CO}_2\text{H}$, the source of the characteristic odour of goats, to citric acid, $\text{HO}_2\text{CCH}_2\text{COH}(\text{CO}_2\text{H})\text{CH}_2\text{CO}_2\text{H}$, the chief acid constituent of citrus fruits. The carboxylic acids participate in metabolic processes. They are useful in organic synthesis and have a wide variety of industrial applications. For information on the applications of the various members of the family, see *Specific Carboxylic Acids*, below.

Those carboxylic acids with straight carbon chains were isolated

Normal Carboxylic Acids (Fatty Acids)

To. of carbon atoms	Common name	Systematic name
1	Formic acid	Methanoic acid
2	Acetic acid	Ethanoic acid
3	Propionic acid	Propanoic acid
4	Butyric acid	Butanoic acid
5	Valeric acid	Pentanoic acid
6	Caproic acid	Hexanoic acid
7	Lauric acid	Dodecanoic acid
8	Palmitic acid	Hexadecanoic acid
9	Stearic acid	Octadecanoic acid

first from natural sources, particularly from fats, and are frequently called fatty acids. They were originally given common names indicative of their source. More recently the naming of carboxylic acids has followed the nomenclature system set up at the Geneva conference of 1892. The common and systematic names of normal (straight-chain) carboxylic acids are given in the table. It is seen that the systematic names are derived from the names of the corresponding hydrocarbons by dropping the final e and adding the suffix *oic*.

Preparation.—Sodium formate, the salt of formic acid, is made by a reaction of carbon monoxide and caustic soda at elevated temperature and pressure. This reaction was one of the earliest used commercially for the synthesis of an organic compound from inorganic components, carbon and salt being the ultimate raw materials. Formic acid can be liberated from the sodium salt by adding a mineral acid.

Acetic acid is by far the most important commercial carboxylic acid from the standpoint of the quantity used. It usually is sold as glacial acetic acid: so named because on cold days it freezes to an icelike solid. Acetic acid is the chief component of vinegar, produced by the air oxidation of the ethyl alcohol in fermented fruit juices or fermented malt in the presence of various species of the bacteria genus

Pyroligneous liquor from the destructive distillation of wood contains 4%–10% of acetic acid which may be recovered in the form of its calcium salt by neutralizing with lime and distilling to dryness. After 1952 increasing amounts of acetic acid were made by the air oxidation of butane in the liquid phase with manganese and cobalt acetates as catalyst. Acetic acid is also prepared industrially by the oxidation of acetaldehyde from calcium carbide.

Propionic acid and butyric acid may be made by the oxidation of the corresponding alcohols or aldehydes, or by special fermentation processes from starch. The higher normal acids having an even number of carbon atoms are obtained by the hydrolysis of fats.

Benzoic acid, $\text{C}_6\text{H}_5\text{CO}_2\text{H}$, consisting of a carboxyl group on a benzene ring, can be prepared by the oxidation of toluene, $\text{C}_6\text{H}_5\text{CH}_3$, with potassium permanganate or chromic acid. The procedures given above illustrate the many kinds of oxidation reactions that can be utilized to synthesize carboxylic acids. These synthetic methods reflect the fact that the carboxylic acids are organic compounds in a fairly high state of oxidation.

Another general method of preparation of carboxylic acids is the hydrolysis of organic cyanides:

On a laboratory scale, the use of a Grignard reagent for the preparation of carboxylic acids is convenient.

Physical Properties.—The odour of the lower members of the carboxylic acid family is sharp or acrid and the acids from C_4 through C_8 have a distinctly disagreeable odour. The odour of rancid butter and strong cheese is due to volatile carboxylic acids. The higher acids are practically odourless because of their low volatility. The boiling points of carboxylic acids are abnormally high because dimeric complexes involving two hydrogen bonds are formed:

Chemical Properties. — The most important chemical reaction of carboxylic acids is their ionization to produce protons and thus an acidic solution.

The carboxylic acids up to and including butyric acid are soluble in water, giving an aqueous solution which is acidic and which has a sour taste. The acidity of simple carboxylic acids is less than that of mineral acids such as sulfuric acid, but more than that of most other organic compounds. The neutralization of a carboxylic acid by a standard solution of a base is often used for identification purposes since the equivalent weight of an acid as determined with a standard base, the neutralization equivalent, is a characteristic property of each carboxylic acid.

Up to C_{10} the salts of carboxylic acids, formed by neutralization, are very soluble in water. The salts of carboxylic acids from C_{10} to C_{18} are soaps and form colloidal solutions in water. The structure of the salt of a carboxylic acid illustrates an important structural concept in organic chemistry. Although the structure A implies two different kinds of oxygen atoms in the anion of the salt, it is found that the two oxygen atoms are in fact equivalent

as depicted in structure B. Whereas the carbon-oxygen bonds in the hypothetical structure A are single and double bonds, the bonds in structure B are both one and one-half bonds.

There are a number of other important chemical reactions of carboxylic acids. The hydroxyl (OH) group of a carboxylic acid can be replaced by a halogen atom to yield an extremely reactive compound called an acyl halide

The acyl halides are useful in the preparation of a number of derivatives of carboxylic acids called esters; amides and anhydrides.

Esters can also be prepared directly from carboxylic acids by reaction with alcohols with the loss of water. Sulfuric acid or hydrochloric acid is ordinarily utilized as a catalyst for this reaction. Since this is a reversible reaction, esters may be split by

water (hydrolysis) to yield carboxylic acids. The hydrolytic reaction is catalyzed by either strong acids or strong bases. When alkaline hydrolysis is used, the process is referred to as saponification because the preparation of soap utilizes this process.

The base-catalyzed hydrolysis goes to completion and requires one equivalent of alkali for each equivalent of ester. The saponification equivalent of the ester (the equivalent weight of the ester as determined by saponification) is a characteristic property of individual esters.

Carboxylic acid derivatives are, in general, relatively reactive

compounds because various reagents can interact with them via addition to the carbon-oxygen double bond to form an unstable intermediate which can decompose to form the products of the reaction.

Carboxylic acids can be decarboxylated to yield an alkane (a hydrocarbon). This process requires elevated temperatures and/or strong alkaline conditions because it involves the scission of a carbon-carbon bond, energetically a difficult process.

The carboxyl group can be transformed to a lower oxidation state by suitable reducing agents. The most efficient agent for laboratory purposes is lithium aluminum hydride which reduces a carboxylic acid to the corresponding alcohol.

Specific Carboxylic Acids. — Acetic acid is used where a cheap organic acid is required such as in the preparation of metallic salts, of acetic anhydride and of esters; it is also used in the manufacture of cellulose acetate rayon and white lead. It is used as a precipitating agent for casein from milk, and for rubber or synthetic rubber from their aqueous emulsions. Propionic acid and butyric acid are used in the manufacture of cellulose acetate-propionates and acetate-butyrate. Calcium propionate is used in bread to prevent molding and ropiness. Tuberculostearic acid, from the fatty capsule of the tuberculosis bacillus, *Mycobacterium tuberculosis*, is a derivative of stearic acid.

Waxes, fats and oils of natural origin are mainly esters of higher straight-chain carboxylic acids. The waxes are defined as esters of high molecular weight monohydric (one hydroxyl group) alcohols with the common even-numbered carboxylic acids. Carnauba wax, beeswax and spermaceti are three important examples of the wax family. Fats and oils are esters of higher carboxylic acids and a trihydric alcohol, glycerol, $\text{HOCH}_2\text{CHOHCH}_2\text{OH}$. Esters of glycerol, called glycerides, have the general formula $\text{RCO}_2\text{CH}_2\text{CH}(\text{O}_2\text{CR}')\text{CH}_2\text{O}_2\text{CR}''$, and are differentiated by the fact that fats are solid at room temperature whereas oils are liquid. The chemical difference between fats and oils lies in differences in the carboxylic acid components of the glycerides. The carboxylic acid components of the fats are predominantly saturated (contain only single bonds in the carbon chain), but the carboxylic acid components of oils are predominantly unsaturated (contain double bonds). The lower melting point of oils is also a result of the lower molecular weight of the carboxylic acid components. The drying oils are an important class because they contain carboxylic acid constituents which are highly unsaturated, containing approximately three double bonds per carboxylic acid unit. The drying oils are easily susceptible to autoxidation and polymerization, giving rise to their principal use as film formers in paints and other coatings. (See OILS, FATS AND WAXES.)

When the glycerides are saponified, the salts of carboxylic acids are formed. The alkali metal salts of carboxylic acids containing from 10 to 18 carbon atoms are known as soaps. The characteristic of these compounds is a long oil-soluble hydrocarbon chain attached to a water-soluble carboxylate ion, and hence they act as wetting agents, emulsifying agents and detergents. Ordinary soaps usually are sodium salts; soaps made from saturated carboxylic acids are hard whereas those made from unsaturated carboxylic acids are soft. (See SOAP.)

A number of substituted carboxylic acids are known, including halogenated, hydroxy and amino acids. The α -halo acids are ordinarily made by the direct halogenation of the carboxylic acid in the presence of a small amount of phosphorus trihalide.

The α -halo acids are more acidic than the unsubstituted acids. Fluoroacetic acid is toxic to mammals, and its sodium salt, known as 1080, is used as a poison for rodents. Trichloroacetic acid and especially trifluoroacetic acid are among the most acidic organic compounds. The α -hydroxycarboxylic acids may be prepared by

the hydrolysis of the α -halo acids. The γ - and δ -hydroxy acids form cyclic esters called lactones. Lactic acid, $\text{CH}_3\text{CHOHCOOH}$, is the acid formed when milk turns sour through the action of *Lactobacillus* on lactose.

The most important class of substituted carboxylic acids are the α -aminocarboxylic acids commonly known as α -amino acids. A general method for the synthesis of α -amino acids in the laboratory is the reaction of α -halo acids with ammonia.

A second method known as the Strecker synthesis consists of the reaction of an aldehyde or ketone with a mixture of ammonium chloride and sodium cyanide, followed by hydrolysis of the amino nitrile. Sometimes α -amino acids are isolated by the hydrolysis of proteins since proteins are high molecular weight compounds consisting of mixtures of α -amino acids in combined form. Several dozen α -amino acids occur in proteins; of these valine, leucine, isoleucine, phenylalanine, threonine, tryptophan, methionine, lysine, arginine and histidine have been shown to be essential amino acids for the growth of rats. Studies so far made indicate that the requirements of other species appear to be similar to those of the rat.

Dicarboxylic acids are of considerable importance. Adipic acid, $\text{HO}_2\text{C}(\text{CH}_2)_4\text{CO}_2\text{H}$, is the most important of the dicarboxylic acids commercially. It is produced by the catalytic air oxidation of cyclohexane in the liquid phase and by the carbonylation of tetrahydrofuran. Adipic acid is an intermediate for the synthesis of nylon 66 which is a polyamide formed by heating the hexamethylenediamine salt of adipic acid. The number 66 indicates that this particular nylon has two six-carbon substituents. An-

other important technical use for adipic acid is in the manufacture of urethan rubbers.

Maleic acid, *cis*-ethylenedicarboxylic acid and fumaric acid, the corresponding *trans*-isomer, are classic examples of geometrical isomerism. Maleic acid readily yields an anhydride on heating, indicating that the carboxyl groups are on the same side of the double bond. Fumaric acid, in which the carboxyl groups are on opposite sides of the double bond, does not yield an anhydride easily. Maleic acid is obtained in the form of its anhydride by the catalytic air oxidation of benzene

The most characteristic reaction of maleic anhydride is its 1,4-addition to conjugated dienes such as butadiene or cyclopentadiene, reactions known as Diels-Alder syntheses.

Hydroxy polycarboxylic acids are found frequently in nature. Tartaric acid, $\text{HO}_2\text{CCHOHCHOHCO}_2\text{H}$, is one of the most widely distributed plant acids. Its potassium acid salt, found in grape juice, is used as the acid component of some baking powders. Sodium potassium tartrate, known as Rochelle salt, is used as a purgative. Citric acid is the chief acid constituent of citrus fruits.

Carboxylic acids which contain a carbonyl function ($\text{C}=\text{O}$) in a position beta to the carboxyl group decarboxylate on mild heating. This reaction occurs readily with malonic acid,

$\text{HO}_2\text{CCH}_2\text{CO}_2\text{H}$, and acetoacetic acid, $\text{CH}_3\text{COCH}_2\text{CO}_2\text{H}$.

Since these carboxylic acids are unstable, they are usually prepared in the form of their respective esters. Ethyl malonate is made from bromoacetic acid through cyanoacetic acid. Ethyl acetoacetate is made by the condensation of two moles of ethyl acetate with sodium ethoxide, an example of the Claisen ester condensation. Both diethyl malonate and ethyl acetoacetate are important synthetic intermediates since each contains an active methylene group, a $-\text{CH}_2-$ group which is adjacent to two carbonyl functions. The hydrogen atoms of an active methylene group are easily removed by basic reagents, giving the corresponding organic anion which can then participate in reactions with alkyl halides to form a multitude of derivatives.

Ethyl acetoacetate exhibits a classical example of tautomerism, defined as the dynamic equilibrium between two spontaneously interconvertible isomers. In 1911 L. Knorr succeeded in isolating two forms of ethyl acetoacetate, a ketonic form which reacts with hydroxylamine and hydrogen cyanide, and an enolic form which reacts instantaneously with bromine and with ferric chloride. On permitting either isomer to reach room temperature; the equilibrium mixture was obtained. This interconversion is catalyzed by

traces of acids or bases, including glass. Pure ethyl acetoacetate contains an equilibrium mixture of 8% enol and 92% ketone.

It has been shown that a number of hydroxy carboxylic acids, α -keto acids and α -amino acids are involved in the metabolism of carbohydrates, proteins and fats in animals. The oxidation of the metabolite, pyruvic acid, $\text{CH}_3\text{COCO}_2\text{H}$, studied in detail, indicated that the oxidation was greatly increased in the presence of small amounts of fumaric acid, succinic acid, malic acid, oxaloacetic acid, α -ketoglutaric acid and citric acid. H. A. Krebs suggested in 1940 that the oxidation involves a reaction cycle in which the various carboxylic acids are involved as intermediates that are continuously synthesized and destroyed. Likewise in the photosynthetic fixation of carbon dioxide in plants. M. Calvin showed that various hydroxy acids and keto acids including glyceric acid, pyruvic acid, glyoxylic acid and glycolic acid are involved in a cyclical process which converts carbon dioxide and water into carbohydrates and oxygen. Combustion of fat in the body is a rich source of energy. It has been shown by R. Schoenheimer that degradation of the carboxylic acids in fats occurs by two-carbon units, which accounts for the prevalence of even-numbered carboxylic acids in nature. In the 1920s it was shown that certain unsaturated carboxylic acids are needed in the diets of rats. These acids lower serum cholesterol and deficiency of them may be relevant to certain very important clinical conditions such as atheroma and coronary thrombosis.

Benzoic acid, the principal aromatic monocarboxylic acid, $\text{C}_6\text{H}_5\text{CO}_2\text{H}$, is manufactured by the oxidation of toluene, $\text{C}_6\text{H}_5\text{CH}_3$, by the hydrolysis of benzotrichloride, $\text{C}_6\text{H}_5\text{CCl}_3$, or by the decarboxylation of phthalic acid. Sodium benzoate, utilized as a food preservative to prevent the growth of microorganisms, is as effective as the parent benzoic acid. Benzoyl peroxide, which is used as a bleaching agent for edible oils and fats and as a catalyst for free radical polymerization reactions, is prepared by the reaction of benzoyl chloride, $\text{C}_6\text{H}_5\text{COCl}$, and sodium peroxide.

The *o*, *m* and *p*-benzenedicarboxylic acids, known as phthalic acid, isophthalic acid and terephthalic acid, respectively, are important bifunctional organic compounds which are used extensively for the synthesis of polymeric materials. Phthalic acid is easily dehydrated on heating to form the cyclic phthalic anhydride. Therefore, phthalic anhydride is the material ordinarily encountered. It is prepared usually by the air oxidation of naphthalene on a vanadium pentoxide catalyst. Phthalic anhydride is utilized

for the production of alkyl esters of phthalic acid which are used as plasticizers of synthetic polymers. It is further used for the manufacture of polyester resins such as glyptal (from glycerol and phthalic anhydride) which are members of the class of polymeric substances known as alkyd resins derived from polyfunctional alcohols and polyfunctional acids.

Isophthalic acid and terephthalic acid are made by the air oxidation of the corresponding dimethylbenzene in the presence of a soluble cobalt or manganese salt. These bifunctional carboxylic acids are also utilized in the production of polymeric esters. Fibres spun from the polymeric ester of terephthalic acid with ethylene glycol, polyethylene terephthalate, have superior properties and are called Terylene or Dacron.

A number of derivatives of benzoic acid are of importance. Saccharin is the imide of the mixed anhydride of *o*-carboxybenzenesulfonic acid. Methyl *o*-aminobenzoate (methyl anthranilate) is used as synthetic grape flavour; *p*-aminobenzoic acid is present in the vitamin B complex and makes up a portion of the folic acid molecule. Although its necessity in the human diet has not been established, it is necessary for the growth of certain bacteria. The effectiveness of the sulfa drugs in combating infections by such organisms stems from the inhibition by the sulfa drugs of essential metabolic processes of the microorganisms because of the structural similarity of the sulfa drugs to *p*-aminobenzoic acid. Certain *p*-aminobenzoic acid esters have local anesthetic action; for example, procaine, the ethyl ester; Butesin, the butyl ester; and Novocaine, the β -diethylaminoethyl ester. Aspirin, the important antipyretic and analgesic drug, is acetylsalicylic acid (*o*-acetoxybenzoic acid).

See A. W. Ralston, *Fatty Acids and Their Derivatives* (1948).
(M. L. B.)

CARBUNCLE, in medicine, a deep boil (see BOIL AND CARUNCLE); in jewelry, a stone cut with a convex but unfaceted surface (see LAPIDARY AND GEM CUTTING: The Renaissance).

CARBURETOR, a device to form an explosive mixture of air and a hydrocarbon liquid fuel of a volatile nature, such as gasoline.

The function of a carburetor may be divided into three steps: to discharge into the air stream the desired amount of fuel; to atomize the fuel; and to make a homogeneous air-fuel mixture. (See AUTOMOBILE.) Carburetors have to be multiplied in large power-engine outfits for airplanes, four being employed for a 12-cylinder engine, and they require an altitude control to compensate for the rarer atmosphere at high altitudes. Carburetion is a process also required in the manufacture of air gas and carbureted water gas (see WATER GAS). See also AIRCRAFT PROPULSION; INTERNAL-COMBUSTION ENGINES.

CARCASSONNE, a city of southwestern France, capital of the *département* of Aude (*q.v.*), located 57 mi. S.E. of Toulouse, near the eastward bend of the Aude river, which divides it into two distinct towns, the Ville Basse (lower town) and the ancient Cité. The Cité contains the finest remains of medieval fortifications in Europe. The town lies in the gap between the Montagne Noire on the north and the outliers of the Pyrenees on the south. Pop. (1954) 31,305. It is the seat of a bishop and has a court of assizes.

Carcassonne lies on railways from Bordeaux to Lyons-Geneva and from Hendaye to Marseilles-Ventimiglia (Vintimille) and also on the line Paris-Port Rou-Barcelona. It is crossed by two main roads and is served by numerous motorbus lines. There is an airport.

Ville Base.—The Ville Basse, at the centre of which is concentrated the town's business, is surrounded by a belt of boulevards embellished by trees and gardens. Its principal ancient monuments are the church of St Vincent and the cathedral of St. Michael (both late-13th century); the small chapel of Notre Dame de la Santé (15th century), at one end of the 14th-century Pont Vieux; Neptune's fountain (1770), on Place Carnot; and the

Montmorency house (16th century), at the top of the Rue Trivalle. Modern architecture is represented by the Municipal theatre, the town hall and the Monument to the Resistance, by Iché. The town has an art museum and boys' and girls' secondary schools.

The old cloth industry is completely extinct. The town is an important wine market, and the vineyards of the vicinity are one of the chief sources of its prosperity, which is enhanced by its position on the Canal du Midi. Carcassonne factories produce agricultural implements, molded rubber parts for automobiles and preserved fruits and jams, but because of the Cité and its picturesque location, it is essentially a tourist town. It is surrounded by numerous castles and abbeys, and nearby are the Mediterranean seaside resorts, the Pyrenean winter sports resorts and many spas. It also lies on the "Route Mariale," joining Rome to Lourdes and to Fátima, Port.

Cité.—The Cité occupies the summit of an abrupt and isolated hill on the right bank of the Aude. Its ancient fortifications consist of a double line of ramparts, separated by an outer ward called the lices. The walls (the inner 1,200 yd., the outer 1,640 yd.) are protected at frequent intervals by towers, some of which served as watchtowers, and can be entered only by two gates, the Narbonnese to the east and the Aude to the west, both of which are also elaborately fortified. In the interior, and to the north of the Aude gate, the castle, Chateau Comtal, adjoins the fortifications.

Excavations of 1923 and 1927 show that the site on which the Cité lies was occupied as early as the 5th century B.C. by Iberians, who were followed by Gallo-Romans. The inner rampart of the Cité was constructed during the reign of the Visigothic king Euric I, in A.D. 485. It was besieged, without success, in 508 by Clovis, occupied by the Saracens in 728 and conquered by Pepin the Short in 752.

From 819 the Cité was in the possession of a succession of counts and viscounts. Under the Trencavel dynasty (viscounts of Carcassonne and of Béziers) was constructed the cathedral of St. Nazaire (1096-1150), and about 1125 the Château Comtal was incorporated in the Visigothic rampart.

After suffering badly in the Albigensian wars (see CATHARI), the viscounty of Carcassonne, together with that of Béziers, was

W. SUSCHITZKY

TOWERS AND RAMPARTS OF 12TH-CENTURY CASTLE ABOVE RESIDENTIAL STREET WITHIN THE MEDIEVAL WALLED SECTION (CITÉ) OF CARCASSONNE

confiscated to the crown in 1247. A revolt of the city was punished in 1210 by the expulsion of its principal inhabitants, who took up residence on the other side of the river, thus founding the Ville Basse. With Carcassonne now joined to the French crown, great works were undertaken. The Romanesque transept and choir of St. Nazaire were replaced by a Gothic choir and transept (the nave has remained Romanesque). Beautiful stained-glass windows of the 13th–16th centuries now light the church. In the chapels can be seen the tomb of Bishop Pierre de Rochefort (13th century), statues of SS. Peter and Paul (14th century), Pierre de Rodier's "Stone of the Siege" chapel (13th century), the tomb of Bishop Radulph (13th century) and a *Pietà* of the 16th century. The outer rampart was constructed during Louis IX's reign, and the works were continued by his son, Philip III, who added to the inner rampart the beautiful Narbonne gate and the Tour du Trksaut (or Trésor), immediately to the north of the gate.

The town's importance as a frontier station ended in 1659, when the province of Koussillon was annexed to France. Thereafter the ramparts were no longer kept in repair and gradually were abandoned. In 1844 E. E. Viollet-le-Duc undertook the restoration of the church of St. Nazaire and, from 1852 to 1879, that of the fortifications. The work was continued and by mid-20th century was nearly complete. The Cité, whose narrow streets are still inhabited by a population of about 1,000, may be seen in all its former splendour.

CARCHEMISH, an ancient city-state near modern Jerablus, Syr., 63 mi. S. E. of Aleppo, in the Aleppo *muhafazet* of Syria, was on the west bank of the Euphrates river, near the Turkish border. It commanded a strategic crossing of the river for caravans engaged in Syrian, Mesopotamian and Anatolian trade. The site, which occupied over 230 ac., included within the inner town (80 ac.) a high citadel overlooking the river, and a larger area of outer town strongly defended by high walls. The principal excavations were conducted between 1911 and 1920, first by D. G. Hogarth, and subsequently by C. L. Woolley, who had the largest share in the work.

The place was first occupied in the Neolithic period, as was proved by the discovery of obsidian and flint blades, together with monochrome black burnished pottery, on pebble floors at the base of the mound. Kilns of the subsequent Chalcolithic stage, in the neighbouring village of Yunus, yielded the famous prehistoric Halaf ware. Later finds from Carchemish include the Uruk-Jemdet-Kasr pottery, which was a typical product of the south Euphrates valley in Sumerian cities of about 3000 B.C. The end of the Early Bronze and the Middle Bronze Ages are represented by tombs. Stone cist graves with the dead laid out at full length yielded large quantities of pottery, especially the champagne-glass type with high pedestals, widespread both in northern Iran and in Anatolia, about 2000 B.C. Cast copper weapons, including daggers, poker-butt spears, flat ax blades and elaborate pins, attest a highly competent metallurgy at this period. The so-called Amarna cist graves of the Late Bronze Age produced typical Syrian pottery and metal, toggle pins and some jewelry.

Written records concerning Carchemish first appear in the Mari letters (royal archives of Mari), contemporary with Hammurabi (18th century B.C.), when there is a mention of a king named Aplananda. At that time the city was an important entrepôt for the wood trade and appears to have been engaged in the transshipment of Anatolian timber down the Euphrates. During the eighth campaign of Thutmose III, about 1370 B.C., it was evidently an independent state. The Hittite conqueror Suppiluliumas (1375–35 B.C., according to some authorities), however, established his son as king of the city, which he used as a buffer state against three potential rivals, Assyria, Mitanni and Egypt. With the fall of the Hittite empire, Carchemish was probably overrun by the "Peoples of the Sea." Cremation burials in urns then occurred for the first time. Subsequently the district became prone to direct attack from Assyria. In the reign of Shalmaneser III (859–824 B.C.)

the city was forced to pay a heavy tribute and finally capitulated to Sargon II in 717 B.C. The last important historical event connected with it was the battle fought in 605 B.C. at which Nebuchadnezzar II put an end to the pretensions of Pharaoh Necho to dominate Syria. A house in the outer town provided a dramatic illustration of Egypt's lost prestige: it contained clay seal impressions bearing the cartouche of Kecho, a bronze ring with the cartouche of Psamtik I, and Egyptian-style alabaster vases with hieroglyphic inscriptions. Its burnt ruins littered with evidence of a desperate struggle included hundreds of arrowheads of bronze, as well as iron.

The town was defended by thick double walls with sally ports, embankment, fosse and powerful towered gates. Rubble, timber, ashlar masonry and mud brick were used in its construction. Among the buildings a *bit hilani*, or residence with columned portico, a palace and a temple were identified; a broad flight of stairs flanked by sculpture ascended into the citadel. The rich series of carved stone orthostates found on the citadel depicted warriors, hunting scenes, magical winged figures and processions of the gods in an eclectic style peculiar to northern Syria. They were associated with Neo-Hittite hieroglyphic inscriptions which referred to a dynasty of local kings. Many traits of Assyrian art may also be discerned, particularly in the later sculpture when Carchemish became increasingly subject to Assyria. Certain divinities—storm god and mother goddess—appeared to have Hurrian names, and indeed it may be the Hurrians of northern Syria who formed the largest element in the population and were responsible for this art. After the 6th century the site ceased to be important, but there was evidence of Hellenistic occupation. In Roman times Carchemish was known as Europus, and excavations have revealed a number of Roman villas.

CARCHI, the northernmost of the highland provinces of Ecuador, is bounded north by Colombia east and south by Imbabura province and west by Esmeraldas province. Area 1,383 sq mi. Pop. (1960 est.) 101,000. The capital is Tulcán, occupying the basin of Tulcán, in which most of the people are concentrated. In the basin the farms produce wheat, barley and potatoes. At lower elevations there is some production of maize, sugar cane, coffee and fruit, and cattle raising. A large part of the province, however, is high and is used for the grazing of sheep. The chief manufactures of Tulcán are woolen goods, including rugs and ponchos. The province is served by the Pan-American highway.

(P. E. J.)

CARCINOGENIC CHEMICALS, or chemical carcinogens, are a diversified group of chemical compounds capable of giving rise to tumours in animals and, in some instances, in man. The term carcinogen strictly implies a compound that can produce a malignant tumour, but it has been used commonly in a loose sense to indicate the production of either benign or malignant tumours in a variety of tissues. The more general terms tumourigen or oncogen have been adopted by some writers; in this discussion the term carcinogen will be used in its broad sense and considered synonymous with these more correct forms.

Although about 500 compounds are known to be carcinogenic under certain conditions, all of them fall clearly into a few chemical classes; the majority of these compounds are synthetic analogues of known carcinogens, prepared in an effort to determine the chemical requirements of such biological action. The manner in which these compounds were discovered is of considerable interest, particularly when assessing their possible role in human cancer. In the most studied groups of these agents, the polycyclic hydrocarbons and certain aromatic amines, observations made clinically in man have eventually led to laboratory confirmation of carcinogenic action. Thus, the observation by Percival Pott in the 18th century that soot appeared to be a factor related to a high incidence of cancer of the scrotum in chimney sweeps led to the experimental demonstration in 1915 by K. Yamagiwa and K. Ichikawa that repeated applications of coal tar could give rise to

cancer in the skin of rabbits. This experiment, in turn, provided the basis for the synthesis of the first pure chemical carcinogen, the polycyclic aromatic hydrocarbon 1,2,5,6-dibenzanthracene; subsequently a second pure carcinogenic hydrocarbon, 3,4-benzopyrene, was isolated from coal tar.

Similarly, a clinical observation in 1895 that there was a high incidence of carcinoma of the bladder among workmen in the aniline dye industry was the foundation of the later demonstration that dogs would develop cancer of the bladder when fed β -naphthylamine for several years. The potent carcinogen 2-acetylaminofluorene was discovered in the course of a routine toxicity test. This compound was synthesized as an insecticide, and before being allowed to come into contact with human beings was tested by feeding to rats for two years. The development of multiple tumours in these animals prevented this agent from becoming a potential hazard to man. Carcinogens such as some dyes of the azo group and certain carbamates have been discovered in the course of basic laboratory investigations. Other leads to the occurrence of carcinogens have come from epidemiological observations; one instance of this is the alkaloids from the *Senecio jacobaea* plant, which was investigated in relation to a high incidence of primary liver cancer in Bantu tribes.

The major implication of the pattern taken by this research is that the range of activity of these agents is likely to encompass many species and that a positive finding in an animal is likely to have a significance for human beings.

Polycyclic Hydrocarbons.—Of the various groups of carcinogenic chemicals, those most studied have been the polycyclic hydrocarbons. After the synthesis of 1,2,5,6-dibenzanthracene and the isolation of 3,4-benzopyrene, there was a great desire to establish the nature of the basic molecule necessary to such biological action. This resulted in the synthesis of a large number of compounds, the majority of them derivatives of 1,2-benzanthracene. It was found that, by substitution with methyl groups on various parts of this molecule, compounds with vastly different carcinogenic potencies could be obtained. Specifically it was found that 9,10-dimethyl-1,2-benzanthracene was the most potent compound that could be synthesized.

After a time it became apparent that a whole variety of modifications could be introduced into the molecule and that it would still retain its biological activity; thus a nitrogen-containing acridine nucleus could be substituted for the central ring, or a carbazole ring could be used. In either of these instances a new series of carcinogens could be synthesized.

No complete explanation of the nature of the molecular configuration essential to carcinogenic activity has been devised. Certain physicochemical considerations of the electronic densities at specific regions of the molecule have been equated, however, with variations in biological potency. Of all these compounds the most potent—1,2,5,6-dibenzanthracene, 3,3-benzopyrene, 9,10-dimethyl-1,2-benzanthracene and 20-methylcholanthrene—have been used extensively for biological experimentation. It would appear likely that, primarily, these agents act directly on the tissue with which they are placed in contact. Thus when they are painted on the skin, skin tumours (benign papillomas and malignant squamous cell carcinomas) are induced; when they are injected subcutaneously, local connective-tissue tumours (sarcomas) are induced; when they are injected into a variety of different tissues, tumours arise from the tissue of contact. Thus when such a compound is implanted in the brain, brain tumours (gliomas) occur; in bone, bone tumours (osteogenic sarcomas); and so on.

By using specially inbred mice, it is possible to show that, these compounds may also have a remote action. Strain A mice, for example, develop lung tumours (pulmonary adenomas) with some frequency without any treatment; when these mice are treated with carcinogens by skin application, injection or by mouth, they will develop many more lung tumours and with greater rapidity. Similarly, other mice, such as the Ak strain, have an increased incidence of leukemia under similar conditions.

There is considerable variation in the response of different species to treatment with the polycyclic hydrocarbon compounds. The difference is often one in time; thus it may take mice three

months to develop skin tumours when painted with a particular agent, whereas guinea pigs require nine months. This difference has often been equated with the life span of the animal, but this concept, although it has some support, is not universally true. In other instances, treatment of different species with the same compound in the same manner may result in the production of a different type of tumour. Thus a single application of 9,10-dimethyl-1,2-benzanthracene may give rise to few or no tumours in many species; in the Syrian golden hamster it will result in the occurrence of many pigmented (melanotic) tumours. The variety of species known to respond to these carcinogens is large, however, including mice, rats, guinea pigs, rabbits, hamsters, dogs, cats; monkeys, different birds and amphibians.

In certain occupations where a high incidence of a particular cancer has occurred, association with a single chemical may often be established. Where cancer occurs in whole segments of the population, possibly as a result of contact with a factor generally present in the environment, such an association is far more difficult to establish. A case in point is the increased incidence in lung cancer observed in many countries after about 1930 and associated epidemiologically with both cigarette smoking and atmospheric pollution. Carcinogenic hydrocarbons, notably 3,4-benzopyrene among others, have been isolated from tars of cigarette smoke and from soot of polluted atmospheres. Since the entire urban population of the world undoubtedly has contact with these agents, it becomes vitally important to know what quantities constitute a hazard. In experimental efforts to quantify the effects of these compounds, it has been found that they can act at low levels; 0.4 micrograms of 1,2,5,6-dibenzanthracene injected once are enough to produce a malignant tumour in a mouse. Other studies have shown that a single application to the skin of an amount of carcinogen inadequate to induce a tumour will produce nevertheless a latent tumour change. Skin so treated will develop tumours if subsequently treated with a secondary agent (promoting agent) that itself is not necessarily carcinogenic. The matter of establishing a tolerance level to these materials is thus complex and quite unsolved.

Aromatic Amines.—The aromatic amine β -naphthylamine, unlike the polycyclic hydrocarbon carcinogens, induces tumours in only one organ, the bladder, and that following oral administration. It would appear that this compound is not directly carcinogenic to the tissue with which it comes into contact, but that it has first to be metabolized to the active form by the organism and that in this instance the active product is excreted in the urine, thus producing tumours at the site of maximal concentration, the urinary bladder. A similar situation holds for the compound 2-acetylaminofluorene, which produced a variety of tumours when fed by mouth. This compound has been shown to be changed in the intestine to 2-aminofluorene (deacetylation), a compound that, unlike its precursor, is active by injection.

With β -naphthylamine there is marked species specificity. Only in the dog, after many years of feeding, do malignant bladder tumours occur; many other species of laboratory animals do not react to this compound. That this is due to the metabolic pathway by which the dog transforms the compound to its active form is shown by the development of bladder tumours in mice following direct bladder implantation of breakdown products of β -naphthylamine. As contrasted with β -naphthylamine, 2-acetylaminofluorene gives rise to tumours in a variety of tissues after oral administration, including the breast, liver, intestine, brain and ear duct among others; it is equally active in many different species of laboratory animal.

Azo Dyes.—The azo-dye carcinogens are best represented by o-aminoazotoluene and p-dimethylaminoazobenzene (butter yellow); as with other groups of carcinogens, many analogues of these dyes have been synthesized and tested. They have been studied largely in the rat; when incorporated in the diet (usually at a level of 0.06%) they give rise to tumours of the liver after three to four months. For the most part they are active, although less so, in the mouse; they are active in some other species (the dog, for example) but again only weakly so and would appear to be primarily potent carcinogens to the rat.

These compounds have been used extensively in studies of the biochemical mode of action of carcinogens. One series of experiments showed that the azo-dye carcinogens become bound to proteins in the liver. It was suggested that this is an essential step in the development of tumours by carcinogens, and a general concept, the protein-deletion hypothesis, was based on this work. After the demonstration that the azo-dye carcinogens became bound to protein, investigations showed that the polycyclic hydrocarbon carcinogens, too, become protein bound; in these latter compounds, however, the specificity of the situation is not so clear. Of the many other studies of the biochemical changes undergone by carcinogenic chemicals, few appear more closely related to the specific biological action than these investigations.

Urethan.—Urethan (ethyl carbamate) is a simple aliphatic compound that is well known as a hypnotic. It was found to be capable of giving rise to lung tumours in mice following administration by either mouth or injection. Experimental evidence indicated that this compound has to undergo certain reactions within the organism before it becomes active; placed in direct contact with the tissue it does not produce tumours: blood from an animal given urethan by mouth, however, does appear to contain an unknown factor that can act directly. In 1937 A. Haddow developed the theory that agents found to be carcinogenic would also possess the property of inhibiting the growth of tumours. As a result urethan was investigated as a therapeutic agent for certain forms of leukemia and was found to be useful. Conversely, nitrogen mustard, a compound originally tested as a chemotherapeutic agent in cancer, was found to be capable of inducing lung tumours in mice following intravenous injection.

Plastics.—Of the many known carcinogens, none are more puzzling than the various plastics, notably cellophane, that have been found to induce tumours (sarcomas) in rats and mice when inserted under their skin. A small fragment of any of several plastics will give rise initially to a massive fibrous tissue reaction, and after a few months, in 20% or more instances, this will develop into a malignant tumour. Since powdered plastics are relatively inactive in this situation, it would seem clear that the physical configuration of the material is of immense importance. In any event, it is difficult to conceive of a biochemical reaction resulting in any degradation of this material as part of the biological process.

Natural Carcinogens.—In addition to these many synthetic materials, certain naturally occurring substances have been found to have similar carcinogenic effects. Notable among these are the alkaloids from *Senecio* that have been found to give rise to liver tumours in rats on feeding; tannic acids, which will give rise to similar tumours following intraperitoneal injection; and ergot, which has been found to give rise to tumours of nerves (neurofibromas).

Conclusion.—This short survey has not, of course, described all the known carcinogens, but it has encompassed the main groupings. It can be seen that human beings live in a sea of carcinogenic materials, and it is obvious that they must have some tolerance to them. There are great variations in potency among these agents, and toxicological test methods at least can obviate human contact with certain of the more potent compounds. The matter of the less potent compounds and tolerated levels of these materials poses serious practical problems. In conclusion, a great variety of chemical compounds, undoubtedly with very different biochemical properties, can all bring about the same pathological reaction in animals, namely the induction of benign and malignant tumours. This property is shared with ionizing radiations and certain viruses and hormones (estrogens notably). A final evaluation of this situation must encompass all these facts, and a comprehension of the biological nature of the process may be the major missing link. See also CANCER; CANCER RESEARCH.

CARDAMOM, a spice consisting of whole or ground seeds of *Elettaria cardamomum*. The seeds usually reach marketing centres in the dried capsules, and in commerce the capsules are called cardamoms. India, Ceylon and Guatemala are the main countries of production. Some cardamoms may be collected from wild plants, but most are produced under cultivation. The cardamom plant, a member of the ginger family (Zingiberaceae) and a native of moist forests of southern India, is a herbaceous perennial of which numerous varieties exist. From its branching rootstock arise leafy shoots 5 to 18 ft. tall. The flowering shoots, two to four feet long, may be upright or sprawling. Each bears numerous 11-in. flowers, which have three greenish petals and a purple-veined white lip. Cardamom capsules, variable in size and shape, contain 13 to 20 dark, angular seeds.

An essential oil in the seeds gives cardamom its flavour and aroma. Cardamom is used to flavour curries, liqueurs, sauces, pickles and baked goods. Medicinally it is employed as an aromatic stimulant, carminative and flavouring. The name cardamom is sometimes applied to similar spices derived from several other members of the ginger family (*Amomum*, *Aframomum*, *Alpinia*). These are used locally in Africa and Asia or sometimes as adulterants of true cardamoms.

See *The Wealth of India*, vol. iii (raw materials) (1952); E. Guenther, *The Essential Oils*, vol. v (1952). (J. W. TT.)

CARDANO, GERONIMO or GIROLAMO (JEROME CARDAN) (1501-1576), Italian physician, mathematician and astrologer, was born at Pavia, Sept. 24, 1501, the illegitimate son of Fazio (Bonifacius) Cardano. Fazio, a friend of Leonardo da Vinci, was a jurist and public lecturer on geometry in Milan. Gerolamo was educated at the universities of Pavia and Padua, receiving his medical degree in 1526. In 1532 he moved to Milan, where he lived in great poverty until he succeeded in being appointed lecturer in mathematics. In 1536 he violently attacked the practices of the medical profession, particularly in Milan, in the book *De malo recentiorum medicorum medendi usu libellus*. Through the support of prominent sponsors he was admitted to the college of physicians in 1539, and shortly afterward he became rector. His fame as a physician grew rapidly, and many of Europe's crowned heads solicited his services; however, he valued his independence too much to become a court physician. In 1552 he undertook a journey to Edinburgh to treat the archbishop of Scotland, John Hamilton, for asthma; the treatment was successful, and Cardano was richly rewarded by the archbishop. In 1543 he accepted a professorship in medicine in Pavia.

Cardano's numerous medical publications show a tendency to rely more on his own experiences than the tenets of Galen and Hippocrates. He gave the first clinical description of typhus fever, was among the first to write on the treatment of syphilis and had some notion of infection. He made useful suggestions for the instruction of the deaf-mute and blind. He has been called a forerunner of Lombroso in his hook on metoposcopy—the determination of character from facial traits.

As a mathematician, Cardano was the most outstanding figure of his time. In 1539 he published two books on arithmetic embodying his popular lectures, the more important being *Practica arithmetica et mensurandi singularis*. At the time it was known that the solution of the cubic equation had been discovered and that Niccoio Tartaglia (*q.v.*), the Venetian mathematician, was in possession of the method. Cardano tried to obtain permission to print it; this Tartaglia refused, but he confided the solution to Cardano, who swore to keep it secret. In 1545 appeared Cardano's book *Artis magna sive de regulis algebraicis*, one of the cornerstones in the history of algebra. Among many new facts it contained the solution of the cubic equation and also the solution of the quartic equation found by Cardano's former servant, Lodovico Ferrari. The publication led to a bitter dispute with Tartaglia, conducted mainly by Ferrari while Cardano kept aloof. Cardano also wrote other mathematical works. His book on games of chance, *Liber de ludo aleae*, presents the first systematic computations of probabilities, a century before Pascal and Fermat.

Cardano's popular fame was based largely upon his books dealing with scientific and philosophical questions. Most successful and widely pirated by the printers was *De subtilitate rerum*, a collection of physical experiments and inventions, interspersed with anecdotes. Of a similar nature was *De rerum varietate*; more philosophical were *De utilitate ex adversis capienda* and *De comferte*.

Cardano's later life was tragic. His wife died in 1546, leaving him with three children. Giambattista, the idol of his father, studied medicine and practised in Milan. He married a disreputable girl, Brandonia Seroni, who was conspicuously unfaithful to him, and with the assistance of a servant Giambattista finally poisoned her. Cardano made every effort on behalf of his son, but to no avail. In 1560 Giambattista was executed for the murder of his wife, and Cardano never recovered from the blow. In 1562 he received an appointment to a professorship in Bologna, and for a few years he lived fairly undisturbed except for the escapades of his scoundrel son Aldo. In 1570, however, Cardano was suddenly arrested on the accusation of heresy. After several months in jail he was permitted to abjure privately, but lost his position and the right to publish books. He died in Rome on Sept. 20, 1576, after completing his autobiography, *De propria vita*.

BIBLIOGRAPHY.—Cardano's literary production was enormous; his works were published by Sponius in a ten-volume folio edition (1663). See also H. Morley, *Jerome Cardan* (1854); W. G. Waters, *Jerome Cardan* (1898); A. Bellini, *Gerolamo Cardano* (1947); Oystein Ore, *Cardano, the Gambling Scholar* (1953). For autobiography see J. Cardan, *The Book of My Life*, trans. by J. Stover (1930). (O. Oc.)

CARDBOARD: see PAPERBOARD.

CARDENAS, LAZARO (1895–), president of Mexico, was born in Jiquilpan, Michoacán, May 21, 1895. His formal education stopped when he reached the age of 11, for the town had no secondary school. But Cárdenas was an avid reader, and at 16 he began to write for newspapers. At 18 he joined the revolutionary forces of Guillermo García Aragón and after several campaigns became a brigadier general. At 25 he was appointed provisional governor of Michoacán, and he retained this post in subsequent elections until he became minister of interior in 1931. Two years later he became minister of war and marine. In 1934, while still in his thirties, he was elected president of Mexico.

Cárdenas immediately put into action the National Revolutionary party's six-year plan for social and economic reform. Pursuing democratic methods and enjoying the support of the great majority of the people, including communist-dominated labour unions, Cárdenas made radical changes. Public education received a tremendous impetus. By an expropriation law, the government took over many industries that had been closed by strikes and turned them into co-operatives for the workers. With compensation, the oil industry was nationalized on March 18, 1938. Large areas of vast estates were divided among the landless farmers. Between 1934 and 1940 Cárdenas placed about 40,000,000 ac. in peasant hands. He refused to live in Chapultepec castle, the home of Mexican chief executives since the days of Maximilian, and turned it into a museum. President Cárdenas would appear in villages and listen to the peasants' complaints and needs. He piped drinking water into hamlets, built bridges and established hospitals supported by municipally owned motion-picture theatres.

When his presidential term ended in 1940, Cárdenas retired to private life at Pátzcuaro. Recalled as minister of national defense he made sweeping reforms in the Mexican army. He returned to Pátzcuaro after the war and remained a potent force in behind-the-scenes national politics, though he rarely made public appearances; See also MEXICO: *Independent Mexico*. (Hu. ST.)

CARDENAS, a city in Matanzas province, Cuba, about 75 mi. E. of Havana. It is one of the chief ports of the island, being located on the shore of a large bay and sheltered by the long Hicacos peninsula. The port handles sugar from about 20 sugar mills in its fertile hinterland. Industries include sugar refineries, rum distilleries and plants manufacturing rope from henequen. The city has good transport communications with the rest of the island. Varadero beach, a well-known resort area; is located about 8 mi. N.N.W. of Cárdenas.

Cárdenas was founded in 1528 and grew steadily (pop., [1953] 43,750). The large zone of unhealthy marshes was converted into a well-laid-out city with beautiful plazas, including one with Cuba's first public monument honouring Columbus, given by Queen Isabella II in 1862. Cárdenas was the scene of the first bloodshed in the Spanish-American War, May 11, 1898.

(D. R. D.)

CARDIAC CATHETERIZATION, a procedure by which a flexible tube is inserted into a vein and passed along the course of that vein and into the heart. It is used for injecting drugs directly into the heart, for measuring the blood flow and the pressures in the heart and central blood vessels and for studying the physiology of the heart, lungs and other organs, in health and disease. The procedure was originated by Werner Forssmann (*q.v.*), who in 1929 opened a vein in his own arm, inserted the tip of a catheter—a flexible tube about $\frac{1}{8}$ in. in diameter and $2\frac{1}{2}$ ft. long—and passed it up his arm vein, along the intra-thoracic veins and on into the right chamber of his heart, taking an X-ray to prove its location. His purpose was to find a safe means of injecting drugs directly into the heart; subsequently the method was adopted for other uses, proving to be safe and painless.

André Cournand and Dickinson W. Richards (*qq.v.*) in New York were the first to carry out comprehensive research with this method. They studied patients in wound shock during World War II, and measured effects of plasma and whole blood in treatment. Later the method was widely used in the diagnosis of congenital heart disease, exploring narrowed passages and abnormal communications between heart chambers.

In 1956 Cournand, Forssmann and Richards were awarded the Nobel prize in medicine and physiology. (D. W. Rs.)

CARDIFF (CAERDYDD), the capital of Wales, city, county borough, seaport and county town of Glamorganshire. is situated near the mouth of the river Taff, which flows into the Bristol channel. 145 mi. W. of London by rail and 160 mi. by road.

Although the town is old, the development of Cardiff dates from the 19th century and paralleled the development of the south Wales coal and iron fields. In 1801 the population numbered 1,870. By 1861 it had increased to 32,954, by 1931 to 226,037, and by 1961 it had reached 256,270. Originally the borough comprised the ecclesiastical parishes of St. John the Baptist and St. Mary the Virgin, but in 1875 and 1805 it was extended to include Roath and a large part of Llandaff, known as Canton, on the west of the Taff. The whole area was united as one civil parish in 1903 and made a city in 1905. Further extensions included the ecclesiastical city of Llandaff (*q.v.*), with its cathedral, in 1922; Rumnep, in Monmouthshire, in 1937; and part of St. Mellons, also in Monmouthshire, in 1950. The city was recognized as the capital of Wales in 1955.

Cardiff is divided into three parliamentary divisions, one of which includes the town of Penarth. The municipal borough consists of 17 wards, each represented by three councilors and one alderman. The chief citizen is styled lord mayor. The county assizes are held alternately at Cardiff and Swansea. Cardiff has a separate commission of the peace, with a stipendary magistrate, and a separate court of quarter sessions, under a recorder.

The City.—Cardiff is well laid out, with a magnificent group of public buildings in Cathays park. These edifices mostly of Portland stone, include the law courts (1904); the city hall (1904), whose marble hall contains some fine statues of Welsh heroes; the University College of South Wales and Monmouthshire (founded 1883 and formally opened in 1909), with faculties of arts, education, music, science and theology; and the Glamorgan county hall (1912); the Welsh College of Advanced Technology (1916); the National Museum of Wales (1927), housing the valuable Llandinam collection of pictures, as well as collections of rare silver and china; the offices of the ministry of housing and local government and the Welsh board of health (1938); and the Welsh National Temple of Peace and Health (1938). Alexandra gardens, in the centre of Cathays park, contain the Welsh National War memorial.

Cardiff castle was given to the city in 1947 by the 5th marquess

E. W. TATTERSALL BY PERMISSION OF TOWN CLERK, CITY HALL, CARDIFF

CARDIFF CASTLE AS SEEN FROM THE CASTLE GREEN

of Bute. and the rooms, other than the state rooms, are used as the College of Music and Drama. The well-preserved Norman keep of the castle is one of the best of its kind in existence. St. Fagans castle, $4\frac{1}{2}$ mi. to the west, houses the Welsh Folk museum. The Welsh regional headquarters of the British Broadcasting corporation is centred in the city.

The city's parks and open spaces include part of the Heath estate; Roath park, with a lake and botanic garden; and also the Leckwith woods, on the west of the city. The Sophia Gardens field, beside the Taff, is a site for Welsh national shows, and the castle green is ideal for spectacular events, while the castle grounds (outside the castle wall) are used for recreational purposes. Sporting amenities include rugby football and county cricket at Cardiff Arms park, association football at Ninian park, athletics and cycling at Maindy stadium and swimming at the Wales Empire pool.

The castle dominates the centre of Cardiff, of which the main shopping thoroughfares are Queen street, continuing into Duke street, and High street, leading into St. Mary street. Nearby is the parish church of St. John the Baptist, built in Perpendicular style. The fine tower was constructed in the 15th century, supposedly by a mason named Hart (possibly William Hart), who also built the towers of Wrexham and St. Stephen's, Bristol. The sculptured stone reredos by Sir Goscombe John was erected in 1896. A number of stained-glass windows and mural tablets commemorate distinguished leaders of the Order of St. John. The cathedral of St. David, destroyed in World War II but subsequently restored, has since 1916 been the seat of the Roman Catholic archbishop of Cardiff. The Baptist Theological college of Pontypool was transferred to Cardiff in 1895.

The Taff is spanned by two important bridges: one a four-arch bridge, rebuilt during 1858–59, leading to Llandaff, and the other a cantilever bridge with a central swinging span of 190 ft.

Cardiff was badly damaged by air raids in 1941. Comprehensive redevelopment of the city proceeded in the early 1960s, particularly in an area of cottage properties known as Temperance town at the southern end of St. Mary street adjoining the main railway station. The area was laid out as a central bus station flanked by shops and offices, while on the north side was constructed the splendid Wales Empire pool, where the 6th British Empire and Commonwealth games were held in 1958.

Communications.—Bus services connect Cardiff with the whole of south Wales. Cardiff General station lies on the main railway line from London (Paddington) to Fishguard and Goodwick, north Pembrokeshire, express trains covering the distance from London in three hours or less, while other main lines

connect the city with the chief towns of the English Midlands.

During the summer a ferry steamer service is operated between Cardiff and Bristol, Weston-super-Mare and Ilfracombe, thus facilitating pleasure travel from south Wales to the coasts of Somerset and north Devon. The city's airport, originally at Pengam Moors, $2\frac{1}{2}$ mi. E., is now at Rhosee, 12 mi. W., and provides services to London, Dublin, Jersey, Paris and Ostend.

Industries and Commerce.—Edward II's charter of 1324 indicates that Cardiff was a trading and shipping centre of some importance, and from 1327 to 1332 it enjoyed a brief existence as a staple town. During the reigns of Elizabeth I and James I it was a notorious resort of pirates. It was for centuries a "head port," its limits extending from Chepstow to Llanely. In the 18th century it sank to the position of "a creek" of the port of Bristol, but about 1840 it was made independent, its limits for customs purposes being defined as from the Rhymney estuary to Nash point, so that technically the port of Cardiff includes Barry and Penarth.

Until the end of the 18th century there was only a primitive quay on the riverside for shipping purposes. Coal was brought down from the hills on the backs of mules, and iron was carried in two-ton wagons. In 1794 the Glamorgan canal from Merthyr Tydfil to Cardiff (most of which now belongs to the corporation) was opened, anti four years later the first dock was built at the canal terminus. With the growth of demand for south Wales steam coal (1850–1914), Cardiff developed rapidly and became one of the greatest coal-exporting ports in the world. During the same period occurred the vast development of the iron industry in the hinterland. Cardiff lay at the base of the mining and industrial valleys, such as that of the Rhondda (*q.v.*), and railways from all directions focused there, the slope from the high-lying coal-fields facilitating transport of the heavily laden trains and the returning empty wagons.

The influence of John, 2nd marquess of Bute (1793–1848), can hardly be overestimated. He risked his entire fortune in the promotion of a docks scheme. In 1830 he obtained the first act for the construction of a basin and dock (now known as the Bute West dock), which was opened in 1839. Following the opening of the Taff Vale railway in 1840 and the South Wales railway to Cardiff ten years later, the trustees of the marquess built the Bute East dock and basin, which was completed in 1859. The Rhymney railway to Cardiff was completed in 1858, and the Roath basin was opened in 1874 and the Roath dock in 1887. Other authorities had opened a dock at Penarth (*q.v.*) and obtained powers to build docks at Barry. Subsequently the Queen Alexandra dock was opened in 1907, bringing the whole enclosed deepwater area of Cardiff, Penarth and Barry to about 305 ac. Timber floats occupy about 22 ac., and there are about 7 mi. of quays and 12 dry docks.

The shipment of coal and coke, which totaled about 4,500 tons in 1839, had risen to more than 19,000,000 tons in 1913. The period following World War I saw a great disruption of Cardiff's export trade, and by 1938 coal and coke shipments had risen to only 5,229,000 tons. They fell away again after World War II and were less than 250,000 tons in the early 1960s. Efforts were made to increase trade in general cargo, and many new industries were started. Copper works had already been established in Cardiff (1866), followed long after by tin-stamping and enamel works, and, with the replacement of local by imported ores, the smelting works had migrated to the coastal regions near the city, particularly the east moors stretching toward the outlet of the Rhymney river. In 1888 about 90 ac. were acquired for ironworks, which developed into a vast iron and steel undertaking. There are cattle lairs and abattoirs near the Cardiff wharf, and the King's wharf cold-storage premises are among the most modern in the United Kingdom, while oil and gasoline are distributed over a wide area from a base at the docks. There are also ship-repairing yards, large grain mills and breweries, a biscuit factory, wire and hemp roperies, general foundries and engineering works. Many inhabitants of adjoining areas find their livelihood in Cardiff. (S. T.-J.)

History.—The origin of the name Cardiff is disputed. The early forms Cayrdyf, Kairdif, Keyrdyf seem to derive from Welsh

caer ("fort") and *tyf*—mutated to *dyf*—from *tami*, the genitive of a primitive form *tamos*, the Old Welsh for Taf or Taff. The name thus signified the fort of the Tati. The modern Welsh form Caerdydd dates only from about the 16th century. The site was first occupied by a Roman auxiliary fort, enclosed by a ditch and a vallum (rampart), and built about A.D. 75 on the left bank of the Taff, at the crossing place of the main Roman road from Gloucester to Carmarthen, in a campaign against the Silures (*q.v.*) conducted from the legionary fortress of Caerleon (Monmouthshire). By the 3rd and 4th centuries the fort had been strengthened by the construction of a massive stone circuit wall ten feet thick, this to meet the attacks of sea raiders from Ireland. Traces of these defenses are perceptible at various points along the curtain wall of the castle, and a fine stretch of the original Roman wall, 17 ft. high in one section and about 90 yd. long, was uncovered on the southern side.

With the withdrawal of Roman forces from Britain by the late 4th century, the fort was probably abandoned, but of the fate of the civil settlement which had grown up outside the south gate little is known. Not until the coming of the Normans, about 700 years later, were there renewed signs of occupation! though in the intervening centuries Norsemen made sporadic landings and established occasional trading posts along the neighbouring coasts. Though William I passed through in 1081, the first Norman occupation dates from the years 1090 to 1093, when Robert Fitz Hamon, earl of Gloucester, following the course of the Roman road into south Wales, led an expedition to conquer the Welsh kingdom of Morgannwg. The ruined fort at Cardiff offered a defensible site, and within its circuit Fitz Hamon strengthened the existing embankments and raised a moated mound, surmounted with a wooden palisade, to form a shell keep. This was henceforth the *caput* ("head") of the new Norman seigniorship (lordship) of Glamorgan and the chief residence of its lords. About 50 years later the keep was reconstructed in stone, much in its present form. Outside the castle arose the borough where the trade was concentrated; this was the nucleus of modern Cardiff. Within ten years of the conquest burgesses had settled there and before 1147 received from the Norman lord a charter of privileges, later supplemented by other charters, notably the charter of Hugh le Despenser in 1340, granting rights of trade and self-government. A charter of incorporation was granted by James I in 1608. By the end of the 13th century Cardiff had about 400 burgesses. It was enclosed first by an embankment and later by a wall entered by four gates, the main axis extending along High street and St. Mary street from the castle to the south gate of the town near the present main railway station. The guildhall stood in the centre of High street on a plot of land granted by the lord to the townsmen in 1338, and in the same and adjacent streets were held the weekly market and the two annual fairs.

Outside the northwest wall of the castle a Dominican friary was founded by the lord, Richard de Clare, in the year 1242, and later a Franciscan friary arose immediately outside the northeast wall. Both houses suffered dissolution in 1538, the latter being acquired by Sir George Herbert of Swansea, whose son William built on the site the Herbert house (c. 1570), now in ruins. Within the town, near the south gate and on the left bank of the Taff, stood the parish church of St. Mary, which during the 12th and early 13th centuries served as a priory of Tewkesbury abbey. From 1607, when the church was seriously undermined by the great flood of the Tati, its importance as the parish church declined, its place being taken by the chapel of St. John the Baptist, reconstructed in the 15th century.

On the death of Robert Fitz Hamon, the castle and seigniorship passed to his daughter, who by marriage brought them to Robert the Consul, the natural son of Henry I, and it was during his tenure that his uncle Robert Curthose, duke of Normandy, was confined in the castle from 1126 to 1134. Later the inheritance passed through the families of Clare, Despenser, Beauchamp and Neville to Richard III, on whose death at Bosworth it escheated to Henry VII to be granted to his uncle Jasper Tudor, and in 1550, in the reign of Edward VI, to Sir William Herbert, later created earl of Pembroke. In 1766 the estate passed by the mar-

riage of the heiress of Herbert, Viscount Windsor, to John, earl of Bute, who was created Baron Cardiff in 1776 and marquess of Bute in 1796.

In the time of Gilbert de Clare (1263–95) the domestic apartments in the castle keep were rebuilt, and a powerful interior wall linked the keep with the Black tower to enclose the inner and middle wards. The castle was stormed and much of the town burnt by the Welsh (1404) during the revolt of Owen Glendower (*q.v.*). In the Civil War Cardiff was held for the king, but in 1645 it fell by local agreement to parliamentary control, and royalist forces, besieging it from Raglan in 1646, failed to recover it. With the coming of Lord Bute in the latter half of the 18th century, further steps were taken to improve the castle as a place of residence by the removal of the interior walls. Later! in the time of the 3rd marquess and especially during 1865–75, considerable extensions were made to the existing residential apartments, and an elaborate scheme of interior decoration was carried out under the guidance of the architect William Burges.

(W. RE.)

CARDIGAN, JAMES THOMAS BRUDENELL, 7TH EARL OF (1797–1868), English general, famous for leading the charge of the light brigade, was born at Hambleden, Buckinghamshire, on Oct. 16, 1797, and educated at Christ Church, Oxford. He entered the army in 1824, at a later age than was then usual, and quickly purchased promotion, becoming lieutenant colonel of the 15th hussars by 1832. A martinet of uncertain temper, he quarreled with his officers, illegally placing one in arrest, and was censured by the ensuing court-martial and forced to give up his command (1834). But in 1836 family influence secured him the command of the 11th light dragoons (renamed the 11th hussars in 1840). He inherited his father's earldom and fortune in 1837. By spending an estimated £10,000 a year from his private purse, he made the regiment the smartest in the service; but again there was trouble because of his severity toward his officers, which led to a duel with one of them, Captain Tuckett, who was wounded. Cardigan faced public anger by demanding trial by his peers and won his case on a technical point of law. He retained command of his regiment until his promotion to major general in 1854.

On the outbreak of the Crimean War (1854) he was appointed commander of the light cavalry brigade, under his brother-in-law the earl of Lucan, with whom he was on bad terms. His brigade saw little action before Oct. 25, 1854, when the celebrated charge of the light brigade took place (see BALAKLAVA, BATTLE OF). Although Cardigan queried the ambiguous order from Lord Raglan which originated the charge, he did not hesitate when the order was repeated but led the maneuver steadily and gallantly. The charge so struck the imagination of the British public that Cardigan was lionized on his return to England, where he was appointed inspector general of cavalry. Later when Colonel Calthorpe published a book falsely asserting Cardigan had not led the charge, he sued the author for libel but was nonsuited on a technicality. He died at his home at Deene Park, Northamptonshire, on March 28, 1868, from injuries received in a riding accident.

CARDIGAN (ABERTEIFI), a municipal borough and county town of Cardiganshire, south Wales, lies 28 mi. N.W. of Carmarthen, on the river Teifi. 3 mi. from its mouth. Pop. (1961) 3,780. In 1135 the Cymry (Welsh) defeated the Norman-English forces at Crug Mawr-Banc y Warren, and numerous castle ruins in the Teifi valley bear witness to the battles fought there in the past.

An arched bridge which links the town with Pembrokeshire is said to have existed since 1136. Traces of the 12th-century Norman castle remain in the grounds of Castle Green, which stands on the ancient site. Tradition maintains that the first national Eisteddfod (*q.v.*) of Wales was held within the castle precincts in 1176 when Lord Rhys (Rhys ap Gruffydd) sponsored the festival, which was attended by 30,000 people. A few miles south at Pentre Evan is a pre-Roman burial chamber. Cardigan was first incorporated (1284) by Edward I. When the castle fell to the parliamentary forces in 1645 Jeremy Taylor was among the captured garrison. Mrs. Katharine Philips, the "matchless Orinda" of his *A Discourse of . . . Friendship* (1657), lived at the priory built on the site of a Benedictine house and now a memorial hospital. In 1653 the corporation established a free grammar school which moved to its present grounds in 1898. Since then the school has seen many extensions including a Further Education centre catering to the personnel of the Royal Aircraft establishment at Aberporth, five miles away. Cardigan was the scene of the Rebecca riots (1843), a movement of farmers against the existence of the tollgates, which were subsequently removed. In front of the guildhall, built in 1858-60, is a cannon taken during the charge of the light brigade, which was led by Lord Cardigan in 1854. The town has become a tourist centre, with rail and road communications. The Teifi and its tributaries provide good fishing and there is fine coastal scenery. (T: Ev.)

CARDIGANSHIRE (Welsh *SIR XBERTEIPI OF CEREDIGION*), a county of South Wales, is bounded north by Merionethshire, east by Montgomeryshire, Radnorshire and Brecknockshire, south by Carmarthenshire and Pembrokeshire and west by Cardigan bay and the Irish sea. With an area of 692.7 sq.mi. it ranks fifth in size of the Welsh counties.

Physical Features.—The county, composed mainly of Silurian rocks: with some Ordovician in the higher areas of the northeast, may be divided into two major relief regions, both characterized as erosion surfaces, or plateaus. The first is the high plateau, mainly 1,500-1,700 ft. above sea level! forming an arc parallel to the coast on the eastern edge of the county. From this plateau the Plunlumon or Plynlimon (*q.v.*) range rises to form a group of monadnocks which reach a maximum elevation of 2,468 ft. The coastal plateau rises sharply from the coast to heights of 400-600 ft. In the south the area between these regions is occupied by the upper vale of Teifi and the Mynydd Each upland (1,000-1,500 ft.); in the north it is made up of well-dissected hill country. This northern region contains metalliferous deposits, widely exploited in the 19th century, mainly of lead, but with some zinc and silver. Such exploitation has ceased. Coastal scenery, because of the coastal plateau, is mainly cliffed, but in the south there is a narrow discontinuous lower platform of boulder clay, while in the extreme north the Borth storm beach is fronted by an extensive development of sandy beach.

The river system of the high plateau is orientated to an old north-south drainage pattern, and valleys are open and shallow. The drainage of the coastal plateau is mainly east-west, and there the streams are more vigorous with well-developed youthful or early mature valleys. As a result, some of the high plateau streams have been liable to capture, and of these the Rheidol, with its spectacular elbow at Devil's bridge, is a classic example. On the northern fringe of the high plateau there are evidences of glaciation in the form of cirques, but elsewhere in the county glaciation was depositional rather than erosional in its effects. Thus much weathered material was removed from the higher areas and deposited as boulder clay on the coastal plateau and in the valleys. Glacial deposition is probably also the explanation for the sub-merged *sarnau* ("causeways"), *e.g.*, Sarn Cynfelin, which run out at right angles from the coast. Two extensive areas of lowland peat bog are worthy of note: Tregaron bog (Cors Caron) in the Teifi valley, probably a postglacial lake bed, and Borth bog (Cors Fochno), the result of silting behind a postglacial storm beach.

Apart from the immediate coastal area! therefore: the county has two distinct landscapes. The coastal plateau is well dissected: with medium quality farmland developed on heavy boulder clay soils, a landscape which is enclosed and well wooded both with

hedgerow timber and small plantations. The high plateau, by contrast, is an open, rolling and often bleak landscape, exposed to strong westerly winds and often suffering from indeterminate drainage. Grassland degenerates from mountain fescue to *Nardus* and *Molinia*, and there are frequent patches of heather moor and upland peat bog. In this area the forestry commission's plantation of conifers are making their greatest contributions to the economy and their chief alterations to the landscape.

The coastal plateau is able to support an average-density rural population, mainly dependent upon milk production and stock raising. The high plateau, whose land is suitable for only large-scale sheep farming or forestry, carries a sparse population and suffered severely from depopulation in the mid-20th century. It was the subject of special surveys both by the Welsh Agricultural Land subcommission (1956) and by the Mid-Wales Development association (1960). Their conclusions stressed the need for the establishment in the area of stable economic conditions which would lead to much needed improvement of rural services. Such economic stability might well involve the reorganization of the traditional family farm and its replacement by economically viable and well-equipped farm units, coupled with an extension of forestry. (J. G. T.)

The Nature Conservancy has declared the following areas as nature reserves: Tregaron bog. Derwen moods in the Rheidol valley, and the woods on the east and west banks of the Rheidol river north of Devil's bridge. It has scheduled as sites of special scientific interest: Cardigan Island, Maes Goleu bog, Allt Wen, Towy valley, Craig-y-Filfran, Borth bog, Twyni Mawr and Dovey marshes, Figyn Blaen Brefi, the valley of the Rheidol from Parson's bridge to Ponterwyd, and the Llyfnant valley.

Prehistory and History.—As in other regions of western Britain, the earliest remains of man are found on the high ground, which in the north and south is dotted with tumuli and cairns. The finds of the Bronze Age are not numerous but include a number of stone battle-axes. They are all on the western side, marking possible trackways from the interior as well as ways in from Ireland. One of the most conspicuous features of northern Cardiganshire is the large number of hilltop camps supposedly of the pre-Roman Iron Age "B." They seem to be associated with the metalliferous veins in the north and guard important landing places on the coast; *e.g.*, at Pendinas, Aberystwyth and Llanrhystud. There are traces in the eastern part of the county of a Roman trackway, known as Sarn Helen, which seems to have run via Pontllanio through the hills to Carmarthen. The post-Roman centuries were marked by numerous raids; especially from Ireland upon the open coast, perhaps aimed at the mineral wealth. The place-name "Gwyddel" (Irish) occurs frequently in the region behind the open coast. Raids were long continued and later included Scandinavian elements from their settlement at Dublin.

Counteracting, as it were, this movement of destruction was the civilizing and Christianizing influence of the Celtic saint movement which seems to have been a special feature of this county. Llanddewibrefi, a village in the centre of the county, is said to have been the headquarters of St. David, the patron saint of Wales; while St. Padarn founded Llanbadarnfawr (1 mi. E. of Aberystwyth), which in the 8th century became merged in the see of St. David's. A memorial of these days is the church of Ysbytty Cynfyn (14 mi. E. of Aberystwyth). In its churchyard walls are included megalithic stones which once formed part of a stone circle; this illustrates the continuity of tradition which is an important feature of the far west.

In post-Roman days the whole basin of the Teifi is said to have fallen to the power of Ceredig, son of Cunedda Wledig of north Wales, and the name of the present county was derived from Ceredig's name. Norman penetration of hilly Cardiganshire was slow. The county was granted: it is said, in 1110 to Gilbert Fitz-Richard of Clare, and its history during the 12th and 13th centuries is one of a long series of skirmishes between the Normans, who sought to keep open the valley lines of communication, and the Welsh herdsmen among the hills. The unsettled state was such that in the early 15th century Owen Glendower actually held a court in Aberystwyth castle. The Cistercian abbey of St. Mary

at Strata Florida, founded by Rhys ap Gruffydd (first extant charter 1184) continued to be influential during the periods of Welsh independence. By the Statutes of Rhuddlan (1284) Edward I constituted Ceredigion out of the former principality of R'ales as a shire on the English model, dividing the new county into six hundreds (ancient territorial divisions) and fixing the assizes at Carmarthen. By the Act of Union, in the reign of Henry VIII, the boundaries of the county were enlarged to their present size by the addition of outlying portions of the marches around Tregaron and Cardigan, and the assizes were assigned to the county town. Under Henry VIII the county was first empowered to send a representative to parliament, and under Mary I the same privilege was extended to the boroughs.

During the Civil War the castles of Cardigan and Aberystwyth were held for Charles I and reduced to ruins by the Cromwellian forces. The county became in the 18th century the centre of the Methodist movement, which seems to have had its greatest influence among the shepherds and cattle herders of the moorland. Daniel Rowlands (1713-90), the curate of Llangeitho, a village almost in the centre of the county, became one of the chief leaders in this important movement.

Population and Administration.—The area of the administrative county is 692.7 sq.mi., and its population in 1961 was 53,564. The municipal boroughs are Aberystwyth (10,418), Cardigan (3,780) and Lampeter (1,853; *qq.v.*). Aberayron (1,220) and New Quay (951) are urban districts, and there are 4 rural districts and 72 parishes.

Aberystwyth is the home of the founder college of the University of Wales, the National Library of Wales, the Welsh secretariat of the ministry of agriculture, fisheries and food, the Welsh directorate of the forestry commission, the Royal Commission on Ancient Monuments in Wales and Monmouthshire and the main offices of the county council. Nearby are the plant breeding station at Gogerddan and the Welsh agricultural advisory service at Trawscoed. Quarter sessions and the assizes for the county are held at Lampeter. There are 11 petty sessional divisions. The county council holds its meeting in Aberayron. The county lies wholly in the diocese of St. David's.

The difficulties of communication between England and Cardiganshire enabled the county to retain the Welsh language to such an extent that it is still predominantly Welsh-speaking. The use of Welsh is encouraged in the schools, and Welsh books are produced in Aberystwyth and Llandyssul. Cardigan, the birthplace of the Welsh Eisteddfod (*q.v.*), holds a seminational Eisteddfod each year in May.

The Economy.—The 17th and 18th centuries saw the coastal towns and villages, especially Cardigan, Llangranog, Tresaith, Aberporth, New Quay, Aberayron, Aberystwyth and Borth, enjoy a brisk coastal trade, chiefly with Bristol. Because of difficult landward communications almost all imported material came by sea. Fishing, always important, continues on a small scale; while many places have become summer resorts for the English Midlands and south Wales. The export trade as well as the general prosperity of the northern half of the county was increased between 1830 and 1880 by the extensive mining of lead. The mines were worked intermittently for centuries, possibly from prehistoric days, but they reached their last maximum about 1870 when, because of difficulties of railway transport, obsolete machinery and the importation of foreign ores the industry dwindled and almost passed away. Many families migrated to south Wales, and others turned to the scanty pastoral resources of the moorlands.

The unsettled state of agriculture in the mid-19th century produced in Cardiganshire great activity during the Rebecca riots (*q.v.*), as well as political agitation against the payment of tithes and general evictions (1864). The great movements of the Industrial Revolution affected Cardiganshire adversely. It ultimately destroyed local industries and seafaring activity and caused the county's greatest export henceforth to be men and not goods. Many left to become milk vendors and drapers in the cities, particularly London. The only industry that escaped complete extinction was weaving, at Talybont in the north and in the lower

Teifi valley, where the water is especially suitable for weaving processes.

The Rheidol Hydroelectric project in the north, the Royal Aircraft establishment at Aberporth, near Cardigan, the Milk Marketing Board factory at Felinfach, Ystrad Aeron in central Cardiganshire; and the Teifi Pools Water scheme, in the Tregaron area, are the most important mid-20th century industrial developments. Continuing depopulation (accelerated by the mechanization of agriculture) is the most serious social and economic problem. The Mid-Wales Industrial Development association, comprising representatives of the Cardigan, Brecknock, Radnor, Montgomery, and Merioneth county councils, and with the co-operation of the University College of Wales, Aberystwyth, has endeavoured to attract light industries into the area of the five counties. The county has long been celebrated for its breeding of Cardiganshire corgi dogs and horses (particularly Welsh cobs). The monthly horse fairs at Llanybyther, just over the border in Carmarthenshire, are well attended by English and Welsh dealers. There are several small packs of foxhounds in the county. Tregaron is a centre for pony trekking. There is considerable fresh-water fishing in the rivers and lakes; coracle fishing is still practised on the Teifi.

Aberystwyth is the terminus of the railway from Shrewsbury, and of that from Carmarthen via Lampeter and Tregaron. Secondary lines for freight traffic run from Pencader to Xberayron. Cardigan town is reached by a branch line from Whitland, Carmarthenshire. There is a miniature line from Aberystwyth to Devil's bridge. (J. E. R. C.)

CARDINAL, in the Roman Catholic Church, the title of the highest dignitaries next to the pope, the members of a spiritual body called the Sacred College of Cardinals. Their most lofty function is the election of the pope (see CONCLAVE), and they are the administrators of the church while the Holy See is vacant; but they have many duties to fulfill during a pope's reign. They are the assistants of the pope in the government of the church, being members of the Roman congregations and of the offices and tribunals of the Roman curia (see CURIA ROMANA); they may be charged with special missions abroad, such as that of legate; and also, on the rare occasions when the pope himself officiates in the liturgy, they have special functions in the ritual, according to the ancient functions of the several orders to which they may belong. (See further VATICAN, THE.) Cardinals are required to reside in Rome; but cardinals who are residential bishops in their own dioceses (other than the cardinals suburbicarian bishops) are dispensed from the obligation of continual residence in Rome.

As early as the end of the 5th century the term cardinal was applied at Rome to the priests permanently attached to the Roman *tituli* or parish churches immediately under the pope. It was also used until late in the middle ages for the leading clergy of the more important churches; but the title was gradually confined by usage to the Roman cardinals, until Pius V in 1567 reserved it to them exclusively.

The Three Orders.—The grouping of the cardinals into a single body is connected, in the case at least of cardinal priests, with the ancient presbyterium, which existed in each church from the earliest times; but the Sacred College as such was not definitively constituted until, in the 12th century, the three orders of cardinals were united in a single body for papal elections (see CONCLAVE). Up until that time the elements remained distinct, and there were separate classes: the "Roman" bishops (*i.e.*, bishops of sees near Rome); presbyters of the *tituli* of Rome; and the Roman deacons. Nowadays, the Sacred College is still composed of three orders, known as cardinal bishops, cardinal priests and cardinal deacons.

Cardinal Bishops.—Cardinal bishops are the bishops of suburbicarian churches, situated in the immediate neighbourhood of Rome.

Very early we find them assisting the pope in his ritual functions and in dealing with important business: they formed a kind of permanent synod; and they also took the place of the pope in the ceremonies of the liturgy, except the most important ones, and especially in the service of the patriarchal basilicas of Rome. The *Life of Stephen III* (IV; 768-772) in the *Liber Pontificalis* states that he ordered solemn Mass to be said every Sunday on St. Peter's altar in the Lateran church. *u septem Episcopis cardinalibus hebdomadarius, qui in ecclesia Salvatoris observant.* In 1058 they were called "cardinal bishops of the Lateran church" (St. Peter Damian, *Ep. i. lib. ii*). Their sees were seven: Ostia, Porto, Santa Rufina (Sylva Candida), Albano, Sabina, Tusculum (Frascati) and Palestrina. The union of the sees of Porto and of Santa Rufina (by Pope Calixtus II) reduced the number to six; but the addition of Velletri made it seven again. The cardinal bishop of Ostia is ex officio dean of the Sacred College and consequently dean of the suburbicarian bishops; from time immemorial he has had the right of wearing the pallium at the consecration of a pope who is not already a bishop. As he always unites Ostia to the see held by him before becoming dean, the number of cardinal bishops is six, though there are seven sees.

Cardinal Priests.—The second order of cardinals is that of the cardinal priests. It represents and is a continuation of the ancient presbyterium; but in Rome the process of evolution was different from that in the other episcopal towns. In the latter, the division into parishes was but slowly accomplished. The bishop and the higher clergy, forming what became the chapter, were in residence at the cathedral, which was strictly the one parish church in the town. At Rome, on the contrary (and doubtless at Alexandria), certain churches, to which were attached certain districts, were at an early date entrusted to one or more priests. These churches, in which the sacraments of baptism and penance were administered, were called *tituli* ("titles"). According to the *Liber Pontificalis* the *tituli* of Rome, numbering 25, were already established as early as the 1st century; this seems hardly probable, but it was certainly the case in the 5th century. The priest (or the principal priest of two or more attached to the same church) serving one of these churches was the *presbyter cardinalis* of that title. Thus the Roman presbyterium did not give rise to a cathedral chapter but to cardinal priests, each attached to his *titulus*.

As the high clergy of Rome gradually acquired a more important status, the relations between the cardinal priest and the church of which he bore the *titulus* became more and more reduced; but they have never entirely ceased. Every cardinal priest has his *titulus*, a church in Rome of which he is the spiritual head and the name of which appears in his official designation. For example, *Guglielmus, tituli sancti Clementis sanctae Romanae Ecclesiae presbyter cardinalis O'Connell* ("William O'Connell, Cardinal Priest of the Holy Roman Church of the title of St. Clement"). When the attachment of the cardinal priest to his *titulus* had become no more than a tradition, the number of cardinalial *tituli*, which in the 11th century had reached 28, was increased according to need, and it was held an honour for a church to be made titular.

Cardinal Deacons.—The third order of cardinals is that of the cardinal deacons. From an early date Christian Rome was divided into seven regions, each of which was administered (especially as regards the care of the poor) by a deacon. In the course of time this division of the city disappeared, and the deacons came to be specially associated with certain diaconal churches and gradually acquired a position analogous to that of the cardinal priests. In the 8th century Pope Adrian found 16 *diaconiae* and founded 2 others: in the 12th century the cardinal deacons, who then numbered 18, were no longer distinguished by an ecclesiastical district but by the name of the church connected with some *diaconia*; and a cardinal deacon's connection with his *diaconia* eventually became merely nominal. A cardinal deacon does not mention his *diaconia* in his official signature: *Joannes cardinalis Mercati* ("John cardinal Mercati").

Promotion.—When a suburbicarian see or a cardinalial title becomes vacant, the cardinal next in seniority can claim promotion to it. Cardinal deacons can pass in this way after ten years to the order of cardinal priests.

Creation.—The creation of cardinals is the function of the pope alone. It is accomplished by the publication of the persons chosen by the pope in secret consistory (*q.v.*). No other formality is essential: the provision of Eugenius IV, requiring the reception of insignia for promotion to be valid, was annulled by Pius V in 1571. Similarly, neither the consent nor the vote of the Sacred College is required. The injunctions of the councils of Constance and of Basel as to the written vote of the cardinals became before very long a dead letter. Still, however, in the consistory, when the pope has nominated those whom he desires to raise to the purple, he puts to the cardinals present the question: *Quid vobis videtur?* ("What is your opinion?"). The cardinals bow their heads as a sign of their consent and the pope then continues, *Itaque, auctoritate omnipotentis Dei, sanctorum Apostolorum Petri et Pauli, et Nostra, creamus et publicamus sanctae Romanae Ecclesiae cardinales* 9. et N., et c. ("Therefore, by authority of Almighty God, of the holy apostles Peter and Paul, and of Ourselves, we create and publish as cardinals of the Holy Roman Church . . .").

The new dignitary, who has been warned of his nomination several weeks in advance by *biglietto* ("note") from the office of the secretary of state, is then officially informed of it by a *cereemoniaris* of the pope; he at once waits upon the pope, to whom he is presented by one of the cardinals. The pope invests him with the mozzetta or cape and with the red biretta, but there is no formal ceremony. The conferring of the cardinal's red hat takes place a few days later in a public consistory; while placing the hat on his head the pope pronounces the following words: *Ad laudem omnipotentis Dei et Sanctae Sedis ornamentum, accipe galerum rubrum, insigne singularis dignitatis cardinalatus, per quod designatur quod usque ad mortem et sanguinis effusionem inclusive pro exaltatione sanctae fidei, puce et quiete populi christiani, augmento et statu sacrosanctae romanae Ecclesiae, te intrepidum exhibere debeas, in nomine Patris et Filii et Spiritus Sancti* ("To the praise of Almighty God and to the decoration of the Holy See, accept this red hat, the sign of the singular dignity of the cardinalate, by which is symbolized your duty of showing yourself fearless even to death and the shedding of blood, inclusively, for the exaltation of the holy faith, for the peace and quiet of Christian people, for the increase and maintenance of the Holy Roman Church, in the name of the Father and of the Son and of the Holy Spirit"). While pronouncing the last words the pope makes the sign of the cross three times over the new cardinal. The public consistory is immediately followed by a secret consistory, to accomplish the last ceremonies. The pope begins by closing the mouth of the new cardinal, as a symbol of the discretion that he should observe; after this he bestows on him the cardinal's ring, assigns him a *titulus* or *diaconia*; and finally, after going through the formality of consulting the Sacred College, finishes with the symbolic ceremony of the opening of the mouth, signifying the right and duty of the new cardinal to express his opinion and vote in the matters which it will fall to him to consider.

When the new cardinal is resident abroad, a member of the *guardia nobile* is sent on the day of the consistory to give him the cardinal's calotte (a red skullcap): after a few days the red biretta is brought by a Roman prelate and is conferred on him with great pomp.

Sometimes the pope announces the creation of cardinals whose names he does not divulge but reserves the right of publishing at a later date. These cardinals, whose names he conceals "in his breast," are for that reason called cardinals *in pectore* (in Italian, *in petto*). This practice seems to go back to Martin V, who may have used this expedient to avoid the necessity of soliciting the votes of the cardinals; but for a long time past the popes have resorted to it for quite other reasons.

If the pope dies before making known the cardinals *in pectore*, the promotion is void; if he publishes them, they take rank from the day of the first announcement. In March 1875 Pius IX announced the creation of several cardinals *in pectore*, whose names would be given in his will. It was pointed out to him that this posthumous publication would not be a pontifical act and ran the risk of being declared invalid, and he published the names in a subsequent consistory (Sept. 17).

Canonical Requirements.—Cardinal bishops must naturally have episcopal ordination; for cardinal priests it is enough to have received the priesthood, though many of them are actually bishops; for cardinal deacons it used to be enough to have received the diaconate, but in 1918 the Code of Canon Law (canon 232, i) made it obligatory for them to have been ordained priest.

Up to the middle of the 16th century there were instances of unfortunate and even scandalous appointments to the cardinalate of very young men, of relatives or favourites of the popes and of men whose qualifications were by no means ecclesiastical; but a reform was effected by the Council of Trent and carried further by the bull *Postquam terris* (Dec. 3, 1586) of Sixtus V, most regulations of which are still in force.

A cardinal must, in the year of his promotion, be of the canonical age required for his reception into the order demanded by his rank; viz., 22 years of age for the diaconate, 23 for the priesthood and 30 for the episcopate. If not already ordained, he must take orders in the year of his appointment. Men of illegitimate birth are excluded.

The personal qualities to be expected in a cardinal are learning, holiness and an honourable life. In this connection it is noteworthy that, under Sixtus V's regulations, the mendicant orders have been represented in the Sacred College by at least four theologians. The cardinals' hats granted at the request of the heads of Catholic states are subject to preliminary negotiations analogous to those concerning nominations to the episcopate, though entailing no concordatory agreement, in a strict sense, on the part of the popes.

The Composition of the Sacred College.—Prior to the accession of Pope John XXIII there were 7 suburbicarian bishoprics, 53 cardinalitial *tituli* and 16 cardinalitial *diaconiae*. The number of cardinals, however, had been limited by Sixtus V to 70; i.e., 6 cardinal bishops; 50 cardinal priests and 14 cardinal deacons. This maximum strength of 70 members was not always maintained for the Sacred College (though it was reached in the consistories of Feb. 18, 1846, and Jan. 12, 1953). In the consistory of Dec. 15, 1958, however, Pope John XXIII set aside the old maximum by creating 23 new cardinals in addition to the existing 51, which raised the actual total to 74. No new maximum was set and, in subsequent consistories, the total membership of the Sacred College rose to more than 85. Most of those appointed were cardinal priests, and it thus became necessary to increase the number of *tituli* as the older ones were assigned.

Before the Sistine legislation, the number of cardinals had varied considerably. In 1331 John XXII said that there were 20 cardinals; in 1378 they were reckoned at 23. Their number increased during the Great Schism because there were rival obediences. The councils of Constance and of Basel reduced the number of cardinals to 24; but in the 16th century that number was more than doubled. In 1517 Leo X, to secure a majority in the Sacred College, created 31 cardinals at once.

The original cardinals, as has been said, were members of the Roman clergy or of the suburbicarian episcopate; and there was an Italian majority in the Sacred College from the end of the Great Schism until 1945, when appointments made by Pius XII reduced them to a minority. As early as the 11th century, however, there are cases of the pope's raising to the cardinalate persons not belonging to the Roman clergy; particularly abbots, who were not even required to give up the direction of their monasteries. In the 12th century a few cases occurred of the pope's raising bishops to the cardinalate without requiring them to leave their sees; and also of his conferring foreign bishoprics on cardinals. In 1331, as was to be expected during the Avignonese period of the papacy, John XXII remarked that 17 of the 20 living cardinals were French.

The councils of Constance and of Basel stipulated that not more than one-third of the total number of cardinals should belong to the same country; but this ruling (together with the same councils' decisions that cardinals be at least 30 years old and that one-third of their number should consist of university graduates! was soon allowed to lapse.

Rank.—The dignity of the cardinals is a participation in that

of the sovereign pontiff and, as such, places them above all other ecclesiastical dignitaries. This rank was first attributed to the cardinal bishops and afterward claimed by the rest. Their common prerogative was definitively established when they became the sole electors of the pope, at a period when the papacy shone with its most brilliant lustre. For example, at the Council of Lyons in 1245 all the cardinals took precedence of the archbishops and bishops. It was in 1245, or perhaps the year before, that Innocent IV granted the cardinals the privilege of wearing the red hat (the scarlet robe, which still forms their costume of ceremony, was already worn by cardinals performing the functions of legate, and its use was soon extended to all). As to their relations with the laity, cardinals were assimilated to the rank of princes of the blood royal in countries where the sovereign professed the Roman Catholic religion. They were granted the official style of "eminence" by Urban VIII (1630).

The position of the cardinal bishop of Ostia within the Sacred College has been explained above. In the government of the church, the pope may assign the control of the ministries of the Roman curia to whichever cardinal he chooses. The cardinal secretary of state is his prime minister and one of the palatine cardinals (heads of his personal household); another palatine is the cardinal datary; the cardinal camerlengo or chamberlain, head of the Apostolic Camera, exercises all external authority during a vacancy of the Holy See.

CARDINAL (*Richmondena cardinalis*), a favourite American bird of the family Fringillidae (grosbeaks, finches, sparrows and buntings).

The male is a crested red bird seven and one-half to nine in. long, with black at the base of the red bill and a black throat. Its cheerful, varied, whistling song can be heard throughout the year, and in the winter its red plumage makes a startling contrast when snow is on the ground. The female also sings, though more

JOHN H. GERARD

CARDINAL (*RICHMONDENA CARDINALIS*) OF EASTERN, CENTRAL AND SOUTHWESTERN U.S.

softly. Her plumage is grayish-olive above and pale buff below, with a strong tinge of red on crest, wings, tail and bill. The nest is loosely built at varying heights in a tree: bush or vine and usually has three whitish eggs marked with shades of brown and purple.

The type species ranges over most of the United States and southeastern Canada. Six other subspecies range into Mexico. Males in the subspecies differ mainly in size and depth of colour. The females show the greatest variation. In the gray-tailed cardinal (*R. c. canicaudus*) the gray tail is peculiar to the female.

Cardinals feed mainly on seeds and fruits, but almost 30% of their food consists of noxious insects. Cardinals are not migratory. They have been introduced into Bermuda and Hawaii.

(K. P.)

CARDINAL FLOWER (*Lobelia cardinalis*), a late-flowering herbaceous perennial of the lobelia family, widely distributed in eastern North America. It grows in moist rich soil, often on muddy banks, from southern New Brunswick and Ontario westward to Colorado and south to Florida and Texas, blooming in

late August or September. The plant, which attains a height of from 4 to 6 ft., bears a large cluster of showy, intensely red flowers, each about an inch long with a three-divided lower lip and a slender upright portion. This plant is one of the most handsome of North American wild flowers. See also *LOBELIA*

CARDINALS, COLLEGE OF: see *CARDINAL*; *VATICAN*, *THE*.

CARDING, the process of using the card for combing textile fibrous materials. It consists in combing or brushing fibres until they are straight and placed in parallel lines; in doing this, imperfect fibres are separated, impurities are removed and sound fibres are in condition for further treatment. The bracted flowers of the teasel (*qv*) once used gave place to hand cards, which were essentially wire brushes, and these to stock cards. Mechanization of carding began in the 18th century; Sir Richard Arkwright introduced an automatic carding machine, and the process remains essentially the same as established by him. See *COTTON MANUFACTURE*, *JUTE*; *WOOLLEN MANUFACTURE*.

CARDOON (*Cynara cardunculus*), a thistlelike perennial herb of the composite family (Compositae: *qv*), from southern Europe and north Africa; it is a near relation of the artichoke (*qv*). The edible part, the chard (not to be confused with Swiss chard or leaf beet), is composed of the blanched and crisp stalks of the inner leaves. (The common artichoke is also used for the production of chard.) Besides the common and Spanish cardoons, there are the prickly leaved Tours cardoon, the red-stemmed cardoon and the Paris cardoon, all of superior quality, the Paris being the largest and most tender. The species was introduced into South America and spread over great areas of the pampas.

CARDOZO, BENJAMIN NATHAN (1870-1938), ITS. judge and jurist important for his emphasis upon the role of the judicial process in the creation of law, was born May 24, 1870, in New York, N.Y., where he studied arts and law at Columbia university. In 1891 he was admitted to the bar. For 23 years he practised in court and office with skill matched only by carefulness in matters of fact and decency. Hardly had he been elected justice of the supreme court of New York in 1914 when he was pressed for appointment to New York's highest court, the court of appeals. In 1926 he became chief judge on that seven-man bench. In 1932 on Oliver Wendell Holmes's retirement from the U.S. supreme court, Cardozo was appointed his successor by Pres. Herbert Hoover who acted upon the advice of Sen. William E. Borah of Idaho in disregarding possible political objections to Cardozo (there were already two New Yorkers and one Jew on the supreme court). Cardozo served through the Kew Deal turmoil, until his death on July 9, 1938, at Port Chester, N.Y.

Cardozo's influence was powerful in wisely reshaping legal doctrine to modern need. It was even more influential in reshaping the whole manner in which appellate courts in the U.S. handle their vital work. Long before he left the New York bench he had wrought it into the most forward-looking state court, with traditions of outlook and craftsmanship which continued beyond his time. In 1914 it had been standard thinking that a court's business was never to make but only to find the law, and that neither court nor written opinion had any concern with policy. In consequence the appellate courts' duty to justice was partly concealed and partly botched, and the ongoing job of slow, steady judicial revision needed to keep law abreast of changing times, had lamed. Cardozo became the most striking single figure in the general recapture by the appellate bench of that grand tradition of conscious and continuous re-creation of legal doctrine which had characterized U.S. law before 1865. Partly he did this by way

HORACE MCFARLAND CO.
CARDINAL FLOWER (LOBELIA
CARDINALIS)

of general writing. He spoke not as a heretic from outside but from orthodox experience on a respected bench and with constant instances from cases in whose decision he had shared. He examined on four successive occasions between 1921 and 1932 (see below) the problems, processes and limits of judicial creation. He not only made such creation respectable and interesting but also showed how to hold it within sharp and needed control.

Two matters his essays missed. Of the first Cardozo was never aware. That is the degree to which a reshaping of authorities takes place in any lawyer's mind without conscious effort, as they simply fall into line to produce an "obvious" result. The second has to do with one of his major labours as a judge, the duty whose performance he lived, but which was to him so obvious that he never developed it in commentary: that is, the burden resting on the sound appellate judge to build the law he works with into a phrased, guiding whole? and to clean up the older authorities behind him, each time, for a neat, fresh start.

In this aspect his teaching must be derived from his opinions. Thus in the famous *MacPherson v. Buick Motor Co.*, 217 N.Y. 382 (1916), which established the right of a consumer to sue for injury caused by negligence of a manufacturer with whom the consumer had no "direct contractual" relation, 65 years of confused case authorities were picked up, cleaned up and removed from need of further consultation. Thus again, in *Ultramares Corp. v. Touche*, 255 N.Y. 170 (1931), Cardozo limits with candour and clarity that responsibility to third parties for negligent misrepresentation which he had himself initiated in *Glanzer v. Shepard*, 233 N.Y. 236 (1922). On the supreme court he voted consistently with the liberal group but with a steady concern for forming and phrasing theory that might guide the court in its future decisions. He built with care and caution and with a passion for the general welfare which few have matched. His theory about legitimate legislative classification was peculiarly valuable. An example is his dissent in *Liggett Co. v. Lee*, 288 U.S. 517 (1933). Perhaps his most striking majority opinion was that in the early *Great Northern Railroad Co. v. Sunburst Oil & Refining Co.*, 287 U.S. 358 (1932), which followed up his general interest in appellate judging by declaring constitutional a court's following an old authority while announcing that in any future case it will treat that authority as overruled.

Cardozo had a grace, care and power in language which made him one of the few great American legal stylists. He had a personal beauty in his life which has probably never been matched on the C.S. bench. His greatest judicial contemporary, the tough-minded Learned Hand, said: "He was wise because his spirit was uncontaminated, because he knew no violence, or hatred, or envy, or jealousy! or ill-will. I believe it was this purity that chiefly made him the judge we so much revere; more than his learning, his acuteness, and his fabulous industry." Cardozo's writings on appellate judging are *The Nature of the Judicial Process* (1921); *The Growth of the Law* (1924); *The Paradoxes of Legal Science* (1928); and, in culmination, the neglected paper on *Jurisprudence* (1932)—all in Margaret Hall (ed.), *Selected Writings* (1947). He also wrote *Law and Literature and Other Essays* (1931).

See especially the joint issue of the *Columbia, Harvard and Yale Law Reviews* (Jan. 1939), and the biography by Felix Frankfurter in *Dictionary of American Biography*, supp. ii (1958). (K. N. L.)

CARDS, PLAYING. For at least 600 years in Europe and for many centuries more in oriental countries playing cards have been a principal implement of gaming, conjuring and divination. They were important in early iconography and have been much used as an aid in education. During the 20th century they have served chiefly as equipment for casual pastimes.

The Origin of Playing Cards.—The history of playing cards has engaged the attention of more or less serious students since the 17th century and there is a large literature on the subject. However, the apparent anxiety of these students to establish a definite time and place for the "invention" of playing cards persuaded most of them to credit legends unduly and construe obscure sources to suit their own conjecture. For example, the assertion has been made that playing cards were invented in China for a concubine of the emperor S'eun-ho, A.D. 1120, the source ad-

duced being a Chinese encyclopaedia of 1678. Yet T. F. Carter in *The Invention of Printing in China* (1925) cites a reference to playing cards in China A.D. 969.

Long before that (early in the T'ang dynasty) the Chinese had paper money which Chinese cards so resembled in design that their respective times of emergence could hardly have been long separated. Originally the cards and money may have been identical or, since in many societies gaming implements preceded money, either may with equal likelihood have engendered the other. In fact, controversy over the origin of playing cards has tended to divert opinion from the logical inference that playing cards were probably coeval, or nearly so, with the graphic arts in all countries where those arts emerged, and so could have originated among any or all the peoples—Egyptians, Arabs, Hindus, Chinese—to whom, variously, their invention has been credited.

The first use of playing cards was at least as much for divination (*q.v.*) as for gaming and may be identified with religious rites and symbols. The passage about playing cards in China referred to by Carter is concerned with an augury drawn from cards. Stewart Culin showed that the designs of the earliest Korean cards—which, he believed, antedated the Chinese "money cards"—were derived from the divinatory use of the arrow. Hindu cards had ten suits, representing the ten incarnations of Vishnu. Through the middle ages playing cards were used in both Europe and Asia for fortune telling, and this practice has continued. Catherine P. Hargrave (see Bibliography, below) draws attention to the fact that a Saracen card game introduced into Italy in the 14th century was called *naib* (possibly the etymological source of *naipes*, the Spanish word for playing cards) and that *naibi* in Hebrew means "sorcery."

The time and place of the introduction of playing cards into Europe are no less matters of controversy than the origin of cards. That they were carried home by returning crusaders, or were introduced into Spain or Italy by the Saracens, or were brought into eastern Europe by gypsies or by Tatars are some of the theories that have won support. If any of them is correct Europe has known playing cards since the 13th century.

However, supposed references to playing cards in a German manuscript of about 1300 and a French poem of 1328 are disputed. The earliest undisputed references are of the late 14th century, and at about the same time in different countries: Germany 1377, Italy 1377, Luxembourg 1379, France 1382, Spain 1387. While this does not disprove an earlier existence of playing cards in Europe, it is argued that, for example, Dante's failure to mention them is significant, just as a similar omission by Chaucer indicates a comparatively late start for cards in England.

The Tarot Deck.—It is conceded that the earliest cards made in Europe were the tarots (called also, collectively, the Tarot) and that they were indigenous to Italy. The tarots were picture cards, as distinguished from the cards brought in from the east, which were divided into suits and numbered as are modern cards. There are 22 tarots. Twenty-one of these are numbered, 1 to 21, and are allegorically representative of material forces, natural elements, virtues and vices; the 22nd, unnumbered, is *il matto* (in French, *le mat*), the fool—precursor of the joker. W. M. Seabury in *The Tarot* (1951) related the themes of the tarots to the symbolism of Dante's *Divine Comedy*. If he was correct, the tarots cannot have originated earlier than 1320. A modern instance of the use of the symbolism of the tarot deck is in T. S. Eliot's poem *The Waste Land*.

The tarots were apparently used first for fortune telling and remain the favoured cards of professional fortune tellers. Sometime during the 14th century they were combined with 56 number cards of the oriental kind, making a 78-card deck, with which was played the earliest form of a game (Italian *tarocchi*, German *Tarok*, French *tarot* or *tarau*) still popular in central Europe. The 22 tarots were called *abouts* ("trumps") or *naibes*. The 56-card deck had four suits, probably modeled on the four suits of Chinese cards (coins, strings, myriads, tens of myriads). In each suit there were four coat cards (court cards or face cards), the king, queen, knight and knave or page, and ten numbered cards from 1 (ace) to 10. (See also **TAROK**.)

Later Decks.—From these 56 cards evolved many shorter decks, most of them still in use. In Italy and Spain the standard deck became 40 cards, each suit having ace, 2, 3, 4, 5, 6, 7, knave, queen or knight and king. The Germans developed 32- and 36-card decks, each suit having ace, 7, 8, 9, 10 and, respectively, three or four face cards. The French adopted the 32-card deck plus a 52-card deck (ace to 10, knave, queen and king in each suit) that became standard in English-speaking countries. The suits had different names and often different symbols in the various countries. The English adopted the French symbols but gave them different names; the French ♠ (*pique*, "pike") looked like a spade to the English; the French ♦ (*carreau*, "square") became the English diamond, and the French ♣ (*trèfle*, "trefoil") became the English club. The traditional suit designations are:

English	French	German	Spanish	Italian
spade	<i>pique</i>	<i>grün</i> ("leaf")	<i>espada</i>	<i>spada</i> ("sword")
heart	<i>coeur</i>	<i>Herz</i>	<i>copa</i> ("cup")	<i>coppa</i> ("cup")
diamond	<i>carreau</i>	<i>Schelle</i> ("bell")	<i>oro</i> ("gold")	<i>denaro</i> ("money")
club	<i>trèfle</i>	<i>Eichel</i> ("acorn")	<i>basto</i>	<i>bastone</i> ("rod")

However, the spread of games such as whist and piquet (*qq.v.*) made the 52- and 32-card decks and the French names current among card players throughout the world.

Manufacture and Sale of Playing Cards.—The earliest European cards were elaborately hand painted and were too costly for general use, but early in the 15th century wood engraving found its principal expression in the printing of playing cards, and they spread rapidly among the common people. Games of cards may have been late in reaching England, but by 1463 the English card makers petitioned for and were awarded a prohibition on the importation of playing cards. The wood-engraved cards were often coloured by means of stencils and dyes, a process of manufacture that remained in common use for more than 350 years.

For centuries playing cards have been made of pasteboard, for only the paste can make them properly opaque. In modern plants they are either printed or lithographed (usually the latter) one or two packs to the sheet, each pack comprising 52 cards plus 2 jokers. Early cards were either square, extremely oblong or (rarely) round and, in some cases, as large as 6 × 4 in.; the popular modern sizes are 33 × 23 in. and 33 × 2¼ in. The cards are die cut, with rounded corners, from the large sheet; then scraped, sanded and sometimes lacquered or gilded on their edges. Every card manufacturer employs secret refinements on this process. After 1934 some cards were printed on plastic (usually acetate cellulose) material.

The annual sale of playing cards can be accurately ascertained in nearly every country from tax records, but fluctuations are due more to economic conditions than to the volume of card playing. In the U.S. in the early years of the 20th century, 30,000,000 to 40,000,000 decks were sold each year, with sales reaching 54,000,000 in 1929. During the depression of the 1930s card playing increased (because it was an inexpensive diversion) but the annual sale dropped below 40,000,000, since cards were less often replaced. In 1941 the sale reached 54,000,000 again and during World War II approached 100,000,000, of which about 30,000,000 decks were distributed free to servicemen. After World War II the sale remained fairly constant at 60,000,000 to 70,000,000 per year. In the United Kingdom during the same period the annual sale was 5,000,000 to 11,000,000 decks.

Taxes on playing cards are almost universal. In France and Spain their manufacture is a state monopoly. In England a patent to collect a duty on playing-card imports was granted in 1615 by James I to Sir Richard Coningsby; the first internal tax came in 1628, when Charles I agreed to bar all imports and the manufacturers paid 2 s. per gross of packs to the crown and 1 s. to the collector, one farthing per pack in all. This tax was gradually increased until in 1828 it had reached half a crown per pack. After 1765 the tax stamp had to be printed on the ace of spades, whence the tradition of the ornate design of that card. After 1828 the tax was reduced to a moderate figure. In the United States playing cards have been taxed since 1894.

Card Design.—The evolution of playing-card design has been

notable but slow. Until the 20th century, playing cards were much used for gambling games, and gamblers' superstitious fear of change delayed improvements. The gambler's fear of being cheated prevented the use of decorative back designs until after 1850, for it was felt that plain white backs could not be marked so easily. Cards depicting national heroes and current events have appeared but have succeeded only as novelties; Soviet Russia's effort to replace traditional royal designs with revolutionary figures was abandoned in 1928, and the figures on British and U.S. court cards are still costumed as of the time of Henry VII and Henry VIII. It was not until after 1870 that double-headed cards (which are right side up either way) with corner indexes became standard. Collections of playing cards may be found in many countries, among the most notable being the one in the British museum.

The Use of Cards.—Cards similar in form to playing cards have been much used for games requiring other than the usual designs and for various other purposes. One of the earliest manuscript references to card playing (1377) was the work of a monk who approved it as a harmless pastime, and through the 16th century several clerics issued playing cards bearing scriptural passages, but after card playing became widespread it was looked upon with disfavour by the church. The Puritans termed playing cards "the devil's picture book," and to them and among many other Protestants it was sinful even to have playing cards in the house. After 1843, especially in New England, cards in various designs dissimilar to those of standard playing cards were produced, and these were frequently deemed permissible in homes where other card playing was not allowed. One of the most popular of these games, rook, consists of four suits of consecutively numbered cards. The disappearance of faro (*q.v.*) and other card games from gambling houses and the fact that in the United States most card games are played without stakes and in Great Britain for insignificant stakes or none have greatly decreased the objections to playing cards per se; contract bridge, for example, is played in many churches. For the history and rules of the various card games see BRIDGE; WHIST; and similar articles.

After about 1508 efforts were made to render education easier and more palatable by printing instructive texts on the faces of playing cards. Cardinal Mazarin taught young Louis XIV his geography, history and other studies by this means. There is hardly a subject, from theology to war, which has not inspired a set of educational playing cards.

CARDUCCI, BARTOLOMMEO (BARTOLOMÉ CARDUCHO) (1560–c. 1610), Spanish painter, architect and sculptor. was born in Florence, Italy, where he studied architecture and sculpture under Ammanati and painting under Federigo Zuccaro. He accompanied the latter to Madrid, where he painted the ceiling of the Escorial library, assisting also with the frescoes that adorn the cloisters. Most of his works are to be found in Spain, where he enjoyed continued royal patronage. He died in Madrid.

His younger brother was Vincenzo Carducci (*q.v.*).

CARDUCCI, GIOSUE (1835–1907), Italian poet, winner of the Nobel prize for literature in 1906 and one of the most influential literary figures of his age, was born at Val di Castello, near Lucca, on July 27, 1835, the son of a republican country doctor. After a childhood spent in the wild Maremma (southern Tuscany), he studied at the University of Pisa and in 1860 became professor of Italian literature at Bologna, where he lectured for over 40 years. He was a senator of Italy, and revered by the Italians as a national poet. He died at Bologna on Feb. 16, 1907.

Carducci was in his youth the centre of a group of young men determined to overthrow the prevailing romanticism and to return to classical models. Giuseppe Parini, Vincenzo Monti and Ugo Foscolo were his masters, and their influence is evident in his first books of poems (*Rime*, 1857; later collected in *Juvenilia* and *Levia gravia*, 1868). He showed both his great power as a poet

and the strength of his republican, anticlerical feeling in his hymn to Satan, "Inno a Satana" (1863), and in his *Giambi ed epodi* (1867–69), inspired chiefly by contemporary politics. Its violent, hitter language, sometimes showing the influence of Hugo and Heine, reflects admirably the virile, rebellious character of the poet. The *Rime nuove* and the *Odi barbare*, which appeared in the 1880s, contain the best of Carducci's poetry: the sensitive evocations of the Maremma landscape and the touching memories of childhood in "Idillio maremmano," "Davanti San Guido," "San Martino"; the sad lament for the loss of his only son in "Funere mersit acerbo" and "Pianto antico"; the inspired representation of great historical events in *Ca ira*, "Sui campi di Marengo," "Comune rustico," "Canzone di Legnano"; and the ambitious attempts to recall the glory of Roman history and the pagan happiness of classical civilization in "Davanti alle Terme di Caracalla," "Nell'annuale della fondazione di Roma" and "Alle fonti del Clitumno." Carducci's enthusiasm for the classical in art led him to adapt Latin prosody to Italian verse, and his *Odi barbare* are written in metres imitative of Horace and Vergil, sometimes with excellent results, but he reverted to traditional Italian metres in his last book, *Rime e ritmi*, 1899. Carducci was a professor as well as a poet, and when writing about historical subjects he was inclined to indulge in rhetorical tirades and to overcharge his genuine inspiration with detailed erudition. On the other hand, his scholarly research in Italian literature was warmed by his poetic imagination and style, so that his best prose works (especially his essays on Parini, on Politian (Poliziano) and on the minor 18th-century Italian poets) equal his poetry.

BIBLIOGRAPHY.—Carducci's complete works, including letters, were edited by L. Federzoni (1935–57); G. L. Rickersteth translated and edited a selection from his poems (1913). See also O. Williams, *Giosue Carducci* (1914); G. Papini, *L'uomo Carducci* (1918); B. Croce, in vol. 1 of *La letteratura della nuova Italia* (1914–45). (F. D.)

CARDUCCI, VINCENZO (VICENTE CARDUCHO) (1578–1638), Spanish painter, born in Florence, Italy, was the brother of Bartolommeo Carducci (*q.v.*), whom he accompanied to Spain in 1585. Vincenzo succeeded his brother in 1609 as court painter to Philip III. Trained by his brother in the style of Italian mannerism, he was one of the leading artists in Madrid until the arrival of Velázquez, by whom he was soon overshadowed. Under his direction, Carducci painted three battle scenes for the Buen Retiro palace (now in the Prado museum), but he was chiefly a religious painter. He is also known as the author of the *Diálogo de la Pintura* (1633), an academic treatise on art. He died in Madrid. (E. Hs.)

CARDWELL, EDWARD CARDWELL, VISCOUNT (1813–1886), English statesman, famous for his reform and reorganization of the army, was born in Liverpool on July 24, 1813, and educated at Winchester and at Balliol college, Oxford. where in 1835 he followed the example of his later leaders Sir Robert Peel and W. E. Gladstone by obtaining a double first. Elected a fellow of Balliol, he was called to the bar in 1838: but his ambitions were political rather than academic or legal. Cardwell entered parliament as Conservative member for Clitheroe in 1842; he became member for Liverpool in 1847 but lost the seat in 1852 because he had supported repeal of the navigation acts: from 1853 until the end of his political career he represented the city of Oxford.

Personally as well as politically an admirer of Peel, whose friend and literary executor he subsequently became, Cardwell was appointed financial secretary to the treasury in 1845. After the Conservative schism over the repeal of the corn laws, he was prominent as a Peelite and, on the formation of Lord Aberdeen's ministry in 1852, became president of the board of trade, though without a seat in the cabinet. Cardwell's administrative talents were soon displayed in a major reorganization of his department and an important codification of merchant shipping law in 1854. Resigning with the rest of the Peelites after the breakup of the coalition in 1855, he refused Lord Palmerston's offer of the chancellorship of the exchequer but entered the cabinet in 1859 as chief secretary for Ireland. He became chancellor of the duchy of Lancaster in 1861 and secretary for the colonies in 1864, remaining at the colonial office until the fall of Lord John Russell's

ministry (1866). At the colonial office Cardwell consolidated his reputation as an able, liberal-minded minister, encouraging greater colonial responsibility for defense and in commercial policy, and preparing the way for the federation of Canada. In divided cabinets he had become the close associate and main ally of Gladstone, who appointed him secretary for war in 1865. In this office, during the next five years, Cardwell made his name.

Despite bitter opposition, the purchase of commissions was abolished, thus permitting the selection and promotion of officers by merit. Improved conditions for the ordinary soldier stimulated recruitment, and the introduction of the short-service engagement made possible the creation of an effective reserve. Regular regiments were regrouped on a county basis, in conjunction with volunteer units, and organized on the system of "linked battalions," one at home matching another in foreign service. Some progress was made in modernizing arms and equipment, while the structure of the war office was much improved, notably on the staff side. The commander in chief was subordinated to the secretary of state. These reforms not only enhanced the strength, efficiency and flexibility of the army but also saved money. Ironically, however, cabinet dissension over Cardwell's demand for larger military estimates in 1874 was one reason for the premature end of Gladstone's first government.

Undermined by overwork in the face of prolonged hostility, Cardwell's mental and physical health broke down; he took no further part in politics after 1874 when he was made a viscount. He died at Torquay on Feb. 15, 1886. Lacking the parliamentary gifts of his colleagues among the Peelites, Cardwell had proved a versatile administrator of unusual capacity. With sympathetic leadership he was always an excellent head of a department; under Gladstone he attained greatness as the most successful military reformer of the 19th century, whose work laid the foundations for the 20th-century development of the British army.

(A. F. T.)

CAREW, RICHARD (1555-1620), English poet and antiquary, known for an early history of Cornwall, was born on July 17, 1555, at East Antony, Cornwall. At the age of 11, he entered Christ Church, Oxford, and when only 14 was chosen to carry on an extempore debate with Sir Philip Sidney in the presence of the earls of Leicester and Warwick and other nobleman. On leaving Oxford he spent three years at the Middle Temple and later traveled abroad. He entered parliament in 1584, was appointed high sheriff of Cornwall in 1586 and served under Sir Walter Raleigh, then lord lieutenant of the county, as treasurer. His erudition was praised by Ben Jonson and John Dunbar, and he was a friend of William Camden and Sir Henry Spelman. His enduring work, begun about 1589, is the *Survey of Cornwall* (1602; reprinted 1769 and 1811). A modern edition was edited by F. E. Halliday (1953). It is interesting for the picture it gives of the life of a country gentleman at the end of the 16th century. Carew's other works are a translation of the first five cantos of Tasso's *Gerusalemme*, originally published without the author's knowledge and entitled *Godfrey of Bulloigne, or the Recovery of Hierusalem* (1594); *The Examination of Men's Wits* (1594), a translation of an Italian version of Juan Huarte's *Examen de Ingenios*; and *An Epistle Concerning the Excellencie of the English Tongue* (1595-96?; printed 1614). Carew died on Nov. 6, 1620.

His son, Sir RICHARD CAREW (d. 1643?), was part author of *The True and Readie Way to Learn the Latin Tongue* by writers of three nations, edited and published by Samuel Hartlib (1654).

CAREW, THOMAS (1594 or 1595-1640), English poet and the first of the Cavalier song writers, was born in 1594 or 1595, probably at West Wickham in Kent, the son of Sir Matthew Carew, master in chancery, and his wife Alice Ryvers, daughter of Sir John Ryvers, lord mayor of London. He was educated at Merton college, Oxford, graduating in 1611, and at the Middle Temple. After a period in the service of the ambassador Sir Dudley Carleton at Venice, he continued as Carleton's secretary on an embassy to The Hague in 1616 but was discharged for traducing Sir Dudley and Lady Carleton in some "idle writing." His next employment was with Sir Edward Herbert (later Lord

Herbert of Cherbury) on an embassy to Paris in 1619. Subsequently he enjoyed the important patronage of Christopher Villiers, earl of Anglesey, the duke of Buckingham's younger brother. In 1630 he received a court appointment as gentleman of the privy chamber and at about the same time was made "sewer in ordinary," or server at table, to the king. Clarendon recalls him as "a person of a pleasant and facetious wit" among a brilliant circle of friends that included Ben Jonson. In 1634 his masque *Coelum Britannicum* was performed in the banqueting house at Whitehall by the king and his gentlemen, and it was printed later in the same year. His poems circulated in manuscript, and some were set to music by Henry Lawes and other composers. There is a well-authenticated tradition that he died with expressions of remorse for a life of libertinism. He was buried on March 23, 1640, in the Church of St. Dunstan's in the West, London. His collected poems were published a few weeks after his death.

Most of Carew's work consists of amatory or occasional lyrics, notable for their ease of language and skilful control of mood and imagery. His brilliantly sensuous poem "A Rapture" is his longest. He was a meticulous workman, and his friend Sir John Suckling bantered him on the "hard bound" Muse that made him write with such "trouble and pain"; but Carew's own verses addressed to Ben Jonson show that he was proud to share Jonson's creed of painstaking perfection. Though he greatly admired Donne, whom he called king of "the universal monarchy of wit," Donne's direct influence is apparent only in an occasional phrase or image. There is a larger debt to Italian poets, particularly Giambattista Marino, on whose work Carew bases several of his lyrics. His masque derives much of its substance from philosophic dialogues by Giordano Bruno.

See the poems and masque, ed., with an introduction and notes, by Rhodcs Dunlap (1949); Edward I. Selig, *The Flourishing Wreath* (1958). (R. Dr.)

CAREY, HENRY (c. 1687-1743), English poet and musician best known for his ballads, especially "Sally in Our Alley." His date and place of birth are unknown but he was reputed to be an illegitimate son of George Savile, marquess of Halifax. He came to London, perhaps from Yorkshire, sometime before 1713, when his first book of poems was published, studied music and began to work for the theatres. His first independent work was the farce *The Contrivances; or More Ways Than One* (1715), of which he wrote both words and music. His *Hanging and Marriage; or the Dead Man's Wedding* was acted in 1722 and *Chrononhotologos*, a successful burlesque of theatrical bombast, in 1734. The best of his other pieces were *A Wonder; or the Honest Yorkshireman* (1735), a ballad opera; and *The Dragon of Wantley* (1737), a burlesque opera, with excellent music by J. F. Lampe. His musical interlude *Nancy; or the Parting Lovers* (1739) was also popular and revived later under the titles *True Blue* and *The Press Gang*. "Sally in Our Alley" was first printed in his *Musical Century* (1737), a collection of his best poems set to music, although the tune usually associated with it is not Carey's. Despite the popularity of his works, Carey suffered from great poverty, partly the result of the "pirating" of his plays and poems by unscrupulous printers, and on Oct. 4, 1743, he hanged himself in London. In 1795 his son put forward a claim that Carey was the author of "God Save the Queen," but the theory was later discredited.

See F. T. Wood (ed.), *The Poems of Henry Carey* (1930).

(Cs. Ch.)

CAREY, HENRY CHARLES (1793-1879), U.S. economist and sociologist, often called the founder of the U.S. school of economics, was born in Philadelphia, Pa., Dec. 11, 1793, the son of Mathew Carey, Irish-Catholic political refugee, writer and publisher. Henry Carey became a partner in Carey, Lea & Carey, a leading U.S. publishing house, and later its president. His education, though informal, resulted in a cursory acquaintance with many fields of learning.

After 1835 he devoted himself to writing sociological and economic books and pamphlets. Among his more important works are *Essay on the Rate of Wages* (1835), *Harmony of Nature* (1836), *Principles of Political Economy* (1837-40), *The Past,*

the Present, and the Future (1848), *Principles of Social Science* (1858-60) and *The Unity of Law* (1872). His works were translated into at least eight languages, many persons finding in them a foil to *laissez-faire*.

He became increasingly critical of English classical political economy. An optimist, he looked upon nature's laws as conducive to steady economic progress and to the harmony of diverse economic interests. A Republican and a nationalist, he believed protection initially essential to the industrial development of rising nations. His home served as a *salon* to disciples and visitors, and his reputation was perhaps greater abroad than at home. Carey died in Philadelphia, Oct. 13, 1879.

See Arnold W. Green, *Henry Charles Carey* (1951). (J. J. S.)

CAREY, MATHEW (1760-1839), publisher and publicist, who is best remembered as an early expositor and advocate of measures for U.S. national economic development, was born in Dublin, Ire. He was crippled by an accident in infancy, which perhaps induced his studious habits. He apprenticed himself to a printer, published his first article at 17 and soon was persecuted for his expressions of resentment at English oppression of Catholic Ireland. Fleeing to Paris, he worked for Benjamin Franklin, knew the marquis de La Fayette and learned of American ambitions. He sailed for Philadelphia, Pa., in 1784. With letters from Franklin and a timely loan from La Fayette, he published a succession of journals, of which the *American Museum* was of enduring value. Financial success came when he abandoned journalism for the book trade. He reprinted European works and promoted the sale of books by American authors. His own *Olive Branch* (1814) sought to reconcile Republicans with Federalists. A charter member of the Philadelphia Society for the Promotion of National Industry, he wrote most of its *Addresses*, which revived Alexander Hamilton's arguments for tariff protection. Canals, turnpikes and railroads owed much to his industrious propaganda. Carey founded the Hibernian society and contributed to many other charities.

(B. M.)

CARFIN, a large village in Lanarkshire, Scot., lies on the northeastern border of Motherwell, about 13 mi. S.E. of Glasgow. It is noted for the grotto, dedicated in 1922 to Our Lady of Lourdes, in which are the Little Flower shrine to St. Thérèse of Lisieux and other shrines. The place has become a pilgrimage centre for Roman Catholics from all over Great Britain. Although it was formerly a coal-mining community, the inhabitants, many of Irish extraction, are now chiefly engaged in the iron- and steel-works of the area around Motherwell and Wishaw.

CARGILL, DONALD (1619?-1681), a leader of the extreme Scottish Covenanters, was born at Rattray, Perthshire. In 1655 he was appointed to the Barony parish in Glasgow but was ejected in 1662. He continued his ministry in house conventicles and at great field meetings. He escaped to Holland after being wounded at Bothwell bridge (1679). On his return he drew up a covenanting manifesto, the Queensferry paper, and joined Richard Cameron (*q.v.*) in publishing the Sanquhar declaration. In Sept. 1680 he solemnly and publicly excommunicated Charles II but was taken prisoner and executed as a traitor in Edinburgh on July 27, 1681.

(H. W.A.)

CARGO CULTS are religious movements which have as their most characteristic feature the belief that spiritual agents will at some future date divert tremendous cargoes of the most sought-after manufactured wealth into the hands of the cult members. For this reason the cults have been labeled messianic; *i.e.*, concerned with a utopian future brought about by the intervention of a messiah. Their typical manifestations have occurred in New Guinea and the islands of Melanesia, among peoples of recent or marginal contact with western civilization. The distribution of the cults, which have been recorded since the 19th century and which have been noticed in considerable number since World War II, suggests that they are a response to the confusions and insecurities brought about by limited understanding and participation in western society, religion and economy. The participants do not understand the nature of manufacturing or commerce and have limited purchasing power: they seek to rationalize their situation by reference to religious and magical symbols derived from

Christianity and from indigenous Melanesian belief.

Within this framework there are numerous variations. Some movements have been labeled nativistic or revivalistic, since the dominant theme is a turning away from western society and an affirmation of Melanesian independence. In some cases this involves a belief in a reversal or drastic revolution in the social order, including a rearrangement of sexual mores: the dominance of Melanesian over European, and the destruction of money and existing forms of wealth. In numerous recent examples, the participants have built airstrips and immense warehouses to receive the expected cargo. A typical version of the central myth is that God (or Jesus or angels) has been labeling crates of produce with the addresses of the Melanesians but the avaricious Europeans have been intercepting the ships and altering the addresses.

Such movements can readily develop political overtones. Despite their widely different and largely independent geographic origin, there have been instances of the movements organizing across cultural boundaries. The anti-European flavour and the evident capacity for organization have suggested that the movements can be interpreted as quasi-nationalistic. Governments, concerned with this aspect and with the disruption of life occasioned by the large emotional meetings, the destruction of resources, and the utopian fantasies, have endeavoured to ban the movements. Such policies have not been successful and have now given way to attempts at political and economic education.

The modern elements in the movements should not blind us to their traditional basis of operation. Dreams, prophecies, ritual experiment and many other features seem typical of Melanesian traditional cults, as is the concern with material well-being. Even so, much of the symbolism is derived from a misunderstanding of elements in western behaviour, attaching, for instance, a ritual importance to flags, military drill and rules of club organization.

(C. S. RE.)

CARIA, an ancient district of southwestern Asia Minor, roughly corresponding to the modern Turkish districts of southern Aydin and western Mugla. Extending to the Maeander (Buyukmenderes) river in the north, it bordered on Ionia and Lydia, in the east on Phrygia and Lycia and in the southwest on the Aegean sea. Much of the coast was Greek, the most powerful cities being Cnidus and Halicarnassus (*qq.v.*); from the 4th century B.C. the southwestern corner of Caria belonged to Rhodes. The region that was Caria is mountainous (rising to 7,570 ft. near the Lycian border), with extensive scrub and pine forests and abundant pasturage for goats; but it also provides arable land in the valleys and small plains in the tableland. The coast is formed of promontories separated by the Gulfs of Mandalya, Kerme (Cos) and Sombeki (Syme).

The ancient Greeks believed that the Carians originally inhabited the Aegean archipelago and retired thence into Caria, and it is true that the interior of what was Caria appears almost devoid of prehistoric remains. The Carians, however, considered themselves indigenous and claimed brotherhood with the Lydians and Mysians, whom they admitted to the worship of Carian Zeus at Mylasa (now Milas). A number of Carian inscriptions are preserved, and the language seems to have been in use until the 3rd century B.C., when it was effectually superseded by Greek. It was probably not Indo-European, and the script, though mainly alphabetic, is still imperfectly understood. In early historical times the Carians lived in hilltop villages grouped by the rule of local dynasties and by common worship at the principal sanctuaries. In early times they were noted as seafarers and mercenaries. The most important city of Caria was Mylasa (with the neighbouring sanctuary of Labraunda), though Stratonicea (about 16 mi. E. of Mylasa), with the sanctuary of Panamara, came to rival it in the 3rd century B.C.

Caria was subject to the Lydians under Croesus (*q.v.*) and so was annexed to the Persian empire after the fall of Sardis in Lydia about 546 B.C. West Carian dynasts joined the people of Miletus in the unsuccessful Ionian revolt (c. 499–493 B.C.) and destroyed a Persian army under Daurises (c. 496). About 30 years later the independent communities on the coast were drawn into the Delian league (Confederacy of Delos) by Cimon (*q.v.*), while inner Caria was left under the rule of the Persian satrap in Sardis. After the execution in 395 B.C. of the loyalist satrap Tissaphernes (*q.v.*), the whole of Caria became a separate Persian satrapy governed by a dynasty of Mylasa. The successive dynasts were Hyssaldomus, his son Hecatomnos (390–377 B.C.) and the five children of the latter: Mausolus (377–353), his sister and widow Artemisia (353–351), Idrieus (351–344), his sister and widow Ada (344–340) and Pixodarus (340–c. 335). The last-named was followed by his daughter Ada and her Persian husband Orontopates, whose power was broken by Alexander the Great and his generals in 334–333 B.C. after a fierce struggle, the elder Ada being restored to power. This native dynasty extended its rule beyond the boundaries of Caria and in the Greek islands, and Mausolus (*q.v.*) transferred the capital to the coastal city of Halicarnassus, where his tomb came to rank as one of the seven wonders of the ancient world.

The revival of the Persian central power under Artaxerxes III (Ochus) after 358 prevented the Hecatomnid dynasty from equaling the growing power of Macedonia under Philip II.

The great achievement of this dynasty was the hellenization of Caria. Greek institutions were deliberately implanted, and the Greek way of life was fostered. Archaeological survey has recently shown that the ancient village pattern was transformed into a network of cities designed and built in Greek fashion. These cities afford some notable examples of ancient fortification and city planning, and the Carian cities thereafter prided themselves on their Hellenism. After the wars of Alexander's successors (320–301) the history of Caria is that of the autonomous cities and communes under Ptolemaic and Seleucid supremacy and under Rhodian and Pergamene rule and, from 129 B.C., in the Roman province of Asia. The region formed the Cibyræot theme of the Byzantine empire (*q.v.*) until it was overrun by the Turks in the 13th century.

See Strabo, *Geography*, xiv.

(Jo. M. Co.)

CARIB, the warlike and cannibalistic Indians who at the time of the Spanish conquest occupied the Lesser Antilles and parts of the adjoining mainland of South America. Their practice of eating their enemies so captured the imagination of the Europeans that the Caribbean sea was named for them. The English word "cannibal" is derived from one of the terms used by the Arawak to refer to the Carib. Today the term "Carib" or "Cariban" is used to designate a linguistic family which includes not only the language of the Antillean Carib but also many related Indian languages spoken in South America.

The Antillean Carib, who originated in northern South America, had seized the Lesser Antilles from Arawakan tribes only a short time before the arrival of the Spanish. Their raids, made over long distances in large dug-out canoes, had as their main objective the taking of captives. Women became the wives of their captors, while the men were tortured, killed and eaten during an elaborate victory celebration.

Most of the Cariban-speaking tribes lived in the Guianas and in the area south to the Amazon river. Although some of these tribes were warlike and practised

cannibalism, most of them seem to have been less aggressive than the island Carib. They lived in small settlements, grew manioc and a variety of other crops and hunted with blowgun or bow and arrow. Like most peoples of the tropical forest, they used little if any clothing but decorated their bodies with painted designs and a variety of ornaments. Each village, which was composed of several extended families, had a headman or chief with little real authority and was ordinarily politically independent of all other villages. Religious practices included few large or intricate ceremonies, and in their beliefs they stressed a great number of spirits which were thought to be malevolent and responsible for illness. The religious leader, who claimed control over certain of these spirits, used his power primarily in curing.

Other Cariban tribes lived far to the west on the wooded slopes of the Andes along the boundary between Venezuela and Colombia. Little is known of these tribes, but they seem not to have been very different from the Guiana Carib. To the southeast, in the headwaters of the Xingó river in central Brazil, the Kuikuru, Bacairi and other Cariban-speaking tribes lived in close association with tribes of other linguistic stocks. They seem to have been influenced by their neighbours to the extent of borrowing such traits as ceremonies featuring masked dances and a fairly elaborate art style.

(SE L.)

CARIBBEAN SEA, an overdeepened, suboceanic basin, including all water north of Venezuela, Colombia, Panamá and Costa Rica, east of Nicaragua, Honduras, Guatemala, British Honduras and the Yucatán peninsula of Mexico, south of the Greater Antilles and west of the Lesser Antilles of the West Indies. Its north-south width ranges from 380 mi. to about 700 mi., and its maximum length is more than 1,500 mi.; its total area is approximately 1,049,500 sq mi. The Caribbean sea and the Gulf of Mexico (see MEXICO, GULF OF) have been considered together, especially by German oceanographers, under the name of the American Mediterranean sea because of the largely enclosed nature of these water channels between North and South America.

Oceanography.—The Caribbean sea has the shape of a wide and somewhat irregular channel, with a protuberance toward the northwest where it connects to the Gulf of Mexico through the Yucatán channel. The eastern end opens toward the tropical part

CARIBBEAN SEA AND ADJACENT COUNTRIES

of the North Atlantic ocean through the Lesser Antilles (latitude 10° to 18° N.). The opening to the Atlantic is partly closed by the submarine ridge on which the Lesser Antilles lie. The numerous small islands of the Lesser Antilles, or Caribbees, are somewhat regularly spaced along the ridge, whose saddles between islands rise to less than 2,000 ft. below sea level. The greatest depth of passage connecting the eastern Caribbean with the Atlantic is Anegada passage, whose submarine channel across the Caribbean submarine ridge south of the Virgin Islands is more than 6,000 ft. deep. Windward passage between the eastern end of Cuba and northwestern Haiti has a threshold depth of 5,500 ft. below sea level. The highest elevation of Yucatan channel is 6,800 ft. below sea level directly west of the western end of Cuba.

The Caribbean consists of a series of elongate depressions separated by submarine ridges. In this respect, the Caribbean is like the Mediterranean sea; however, the Caribbean is deeper, though smaller than the Mediterranean, and has deeper connections with the Atlantic ocean. The Caribbean is not a continental sea by origin, nor is it entirely oceanic, though it is more like an ocean basin in structure (*see* OCEAN AND OCEANOGRAPHY: *The Ocean Basins*). On the basis of geological structure, the Caribbean consists of two major parts—the large eastern region and the small western region, also called the Cayman sea. These two regions are separated by a broad submarine platform, extending from Honduras and Nicaragua northeastward to Jamaica and thence to the southwestern tip of Haiti. Upon this broad platform lie the shallow banks Mosquito, Rosalind and Pedro. Within these complex and deformed basins the bottom in the western region shows southwest-northeast trending troughs and ridges, whereas the eastern region's ridges and troughs trend nearly north-south in alignment with the Caribbees arc.

The major basin southeast of the Jamaica rise is divided into a western half (Colombian basin) and an eastern half (Venezuelan basin), by Beata ridge which extends southwestward from Hispaniola. Beata ridge decreases in elevation toward the south until a connection between western and eastern halves is made at a depth of more than 13,000 ft. In the southern part of the Venezuelan basin, within 200 mi. of the coast, is Tanner deep—about 17,000 ft. below sea level. An east-west fault trough less than 100 mi. S. of Hispaniola and Puerto Rico also drops to 17,000-ft. depths. To the east of the Venezuelan basin lies Grenada trough, bounded on the east by the Lesser Antilles and their supporting ridge and dropping to more than 13,000-ft. depth in the south. Aves swell, trending north-south like Grenada trough, separates the latter from the Venezuelan basin and rises to Aves Island in the north and to a threshold of 5,200 ft. The main channels from Grenada trough to the Atlantic are Martinique channel (3,450 ft.) and St. Lucia channel (3,550 ft.).

The western or Cayman sea part of the Caribbean contains the Caribbean's greatest known depth—Bartlett deep at approximately 22,788 ft. below sea level between Cuba and Jamaica. The western region is divided into two parts by Cayman ridge, which lies more than 9,000 ft. below the surface water in places. The long ridge separates the Yucatan basin to the north from Cayman or Bartlett trough to the south; all three features trend nearly east-west. Between Cuba and Jamaica, Bartlett trough is everywhere more than 15,000 ft. deep and its margins are steep, straight escarpments. This great fault trench consists of a number of tilted fault blocks, though the floor is relatively broad.

The topography of the Caribbean basins is in general very rugged, with deep trenches adjacent to steep-sided ridges. Many of the ridges rise above sea level, though only a relatively short height when compared with the depths. The mountainous backbone of Puerto Rico, for example, rises to 4,400 ft. above sea level, but the ridge slopes steeply down into the Caribbean to a depth of 17,000 ft. within 55 mi. of the coast line and slopes steeply down into the deepest deep in the Atlantic (30,180 ft. below sea level) within 75 mi. of the north coast. The escarpment north of St. Croix Island descends to more than 14,000 ft. in a distance of less than five miles.

The continental shelf, except for the broad swell northeastward from the boundary of Honduras and Nicaragua, is narrow. It en-

compasses Trinidad and other islands off the northeastern coast of Venezuela but hugs the coast line from Venezuela to the Costa Rica-Nicaragua boundary, being less than 30 mi. in width throughout that long stretch of coast. Again, the continental shelf narrows to less than 30 mi. along the north coast of Honduras and continues around the Gulf of Honduras to the northeastern tip of Yucatan.

The entire Caribbean area appears to have been extensively intruded by large bodies of basaltic magma which developed deep within the mantle of the earth and moved upward. Active volcanism around the margins of the sea and constant seismic disturbance represent continuous readjustment of the crust. Coral growth and limestone formation are also found in the warm waters.

Tidal movements in the Caribbean sea are small, partly because of the enclosed nature of the region. The tide ranges up to two feet but averages only about one foot.

Surface ocean currents pass strongly through the Caribbean sea from the Atlantic and continue with increasing speed through the Yucatan channel. There a significant portion turns sharply to the right and flows with great velocity out through the Straits of Florida into the North Atlantic. Water tends to build up in front of the narrow Yucatan channel because of the prevailing easterly winds. The upper waters are mainly of North Atlantic origin but contain a considerable admixture of South Atlantic origin. Below the upper water a considerable amount of South Atlantic water enters the Caribbean. Numerous eddies are present on the flanks of the main current, which flows essentially through the middle of the Caribbean at an average speed of about one mile per hour. The most conspicuous countercurrents are the one flowing counterclockwise in the southern part of the Colombian basin and the one flowing back eastward along the southern coast of Cuba.

Waters from the Atlantic ocean can pass somewhat freely through the Caribbean at depths less than about 2,500 ft., this being the sill control depth of the Straits of Florida, but communication with large water bodies of the Atlantic at greater depths is largely restricted. Water masses entering the Caribbean sea from the tropical North Atlantic have a thin homogeneous top layer of warm water, below which is a nearly discontinuous decrease in temperature. The water shows a streaky distribution of salinity when it enters between the Lesser Antilles, but bands of alternating salinity are smoothed out rapidly in the Caribbean because of intense mixing. Salinity of the deep water is uniform. Deep water in the eastern part of the Caribbean sea is renewed by inflow across the Lesser Antilles sill and is therefore of lower density than that of the adjacent Atlantic ocean.

The prevailing winds over the Caribbean sea are the very persistent northeast trade winds. Except for diminishing slightly in constancy and force from September to November, the winds blow consistently from the east or northeast more than 70% of the time at mean velocities of about ten miles per hour—gentle to moderate breezes. Fog is rare over the ocean in this area. Average air temperature varies from about 78° F. in February to 83° F. in September over most of the region, and the surface-water temperature averages practically the same. The Caribbean region is visited each year, generally from August to October, by terrific hurricane storms which usually move from east to northwest.

History.—The location of the Caribbean sea—a large, deep, tropical sea between North and South America—has had varied effects upon the inhabitants living close to its shores and upon peoples in more distant places. The Isthmus of Panamá, less than 35 mi. wide at its narrowest point, and in fact the entire isthmus of Central America, narrowly separates the Caribbean, as a part of the Atlantic system, from the Pacific ocean. Part of the historical significance of the Caribbean stems from its position between North and South America and part is related to its location between the Atlantic and Pacific oceans.

The Caribbean was discovered by Columbus in his search for a passage to the lands of the far east. Its name—Mar Caribe—stemmed from its characterization as the sea of the fierce Caribbean Indian natives who inhabited the Lesser Antilles. Spanish control of the Caribbean after discovery was practically undisputed during the first century of development. Spanish adventurers searched

for quick fortunes, and the discovery of gold and silver around the Caribbean resulted in a steady flow of treasure from the new lands back to Spain. Permanent settlement was insignificant during the 16th century. Spanish conquest, centred first at Santo Domingo on Hispaniola, reached out to the other large islands, then to the highlands of Mexico and Central America and to South America. Balboa's discovery of the Pacific in 1513 led to the eventual conquest of Andean South America and to the use of the Isthmus of Panamá as a route for transshipment of goods from Peru and Argentina. Such advanced civilizations as the Incas in Peru and the Aztecs in Mexico were brought under Spanish control.

The importance of the Caribbean as a trafficway for convoys of Spanish treasure ships soon led to raids by pirates, freebooters and buccaners. Fortified cities on the "Spanish Main," the mainland bordering the Caribbean, and on the islands were raided by English, French and Dutch pirates, privateers and warships. The Lesser Antilles, having been passed over by the Spanish because of lack of treasure, became objects of conflict, especially between Britain and France. The 17th century witnessed settlement of the Lesser Antilles by British, French, Dutch and Danish colonists and the wresting of Jamaica from Spain by Britain in 1655. Thereafter, inroads were made against the strong mercantilist policy that Spain had been enforcing for its colonies. Spain suffered from contraband trade and from the capture or sinking of many treasure-laden ships.

The tropical possessions of western European powers in the Caribbean began to yield great wealth in the form of sugar and other plantation products as the era of slavery developed and many thousands of Negroes were brought over from Africa. During the 18th century tropical American colonies were considered much more valuable than the recently established colonies in temperate North America. France, having taken over the western part of Hispaniola from Spain in 1697, lost the colony when the Negroes revolted successfully during the French Revolution and Haiti became independent in 1804. Shortly thereafter, the Spanish possessions began to break away from Spain's control, and new nations appeared on the borders of the Caribbean. By 1850 the independent nations of Mexico, Guatemala, Honduras, Nicaragua, Costa Rica, Colombia, Venezuela, the Dominican Republic and Haiti faced the Caribbean. It remained for Spain to lose Puerto Rico to the United States and Cuba to independence and for Colombia to lose Panama to independence around the turn of the 20th century.

The value of the narrow isthmian section between the Caribbean and the Pacific was considerably heightened after the discovery of gold in California in 1849. The trip from the Atlantic seaboard of the United States to Panamb, thence across the isthmus to the Pacific and on by ship to California was less arduous than the long trek across the plains and mountains and deserts. A railroad was constructed across the isthmus and talk of an isthmian canal increased. Several possible routes to connect the Caribbean and Pacific were discussed, including one through Lake Nicaragua. A French company began construction of a canal across Panamb (Colombia) in the 1880s, but the venture failed because of financial difficulties and disease. A treaty signed between the United States and Great Britain in 1901, guaranteeing British use of the canal, provided that the United States should build and fortify it. After the failure of negotiations with Colombia and the Panamá revolution in 1903, canal construction was assumed by the U.S.

The opening of the Panama canal (*q.v.*) in 1914 proved to be a boon to the western coast of South America as well as to the two coasts of the United States. It made the long, dangerous voyage around the southern tip of South America unnecessary. In effect, construction of the canal extended the southern boundary of the United States. Certainly foreign policy was conditioned by the canal situation. United States naval bases in Cuba and Puerto Rico were augmented by the purchase of the Danish West Indies in 1917, making possible the use of the valuable harbour at St. Thomas in the Virgin Islands to safeguard Anegada passage, the shortest route from Europe to the canal. Evidence of continued concern for the strategic importance of the Caribbean was shown during World War II, when the United States negotiated for additional naval bases and for air bases in a number of places. There

remain in the Caribbean region, in addition to the independent nations, possessions of the United States, Great Britain, France and the Netherlands, and the West Indies islands of the Commonwealth of Nations.

The strategic significance of the Caribbean has resulted in a policy of paramount interest of the United States in the region. Such interest was manifested from time to time by direct intervention in certain countries on the grounds that, if the United States did not step in and temporarily administer the affairs of countries which could not govern themselves, European nations would seek to do so. Financial intervention, aggravated by default on foreign loans and threatenings by European creditor governments, occurred in the Dominican Republic in 1907, when the United States assumed control of customs collections, in Nicaragua in 1912 and in Haiti in 1915. The United States sought to strengthen its position in the Caribbean by trying to establish political and economic stability in the chaotic countries, and financial control continued for many years, accompanied by military intervention.

The development of an aggressive interpretation of the Monroe Doctrine in the Caribbean resulted in increasing objections by the larger Latin-American nations. After about 1930, therefore, United States policy began to shift toward an attitude of "good neighbourliness." The Platt amendment, which had ensured the right of the United States to interfere in Cuban affairs, was abrogated in 1934. Control of the affairs of Haiti, Nicaragua and the Dominican Republic was relinquished in the 1930s. After 1945 the United States and the Caribbean nations began to co-operate in mutual-aid programs, especially in public health, agriculture and education.

The Caribbean washes the warm shores of 11 republics and of many small islands. In general, the West Indies are very densely populated as a result of the development of plantation agriculture. In contrast, Caribbean coastal regions of the mainland countries are sparsely populated, largely due to difficulties of settlement in the dense tropical forest areas. The tropical highlands of those countries are more densely settled. Generally regarded as underdeveloped, these countries nevertheless provide a significant part of the world's supplies of sugar, bananas, coffee, cacao and hard fibres. Moreover, oil, produced in great quantities in Venezuela and in lesser amounts in Colombia and Trinidad, and iron ore from Venezuela and bauxite from Jamaica move across the waters of the Caribbean. The strategic significance of the Caribbean waterway was apparent during World War II when German submarines sank hundreds of freighters and tankers and even shelled the large oil refinery on Aruba. The United States, as the great consumer of most of the commodities moving across the Caribbean, is concerned about the sea—not as an American lake or a closed sea, but as an open highway with the United States in charge of traffic.

CARIBBEE ISLANDS, generally known as the Lesser Antilles, though sometimes applied to the whole of the West Indies. The name was derived from the Caribs, the native peoples occupying most of the small islands at the time of discovery. The group includes islands belonging to the United States, Great Britain, France, the Netherlands and Venezuela. They compose a long arc of small islands extending from Puerto Rico to the northern coast of Venezuela. See ANTILLES; BARBADOS; CARIBBEAN SEA; CURAÇAO; LEEWARD ISLANDS; MARGARITA ISLAND; TOBAGO; TRINIDAD; VIRGIN ISLANDS; WEST INDIES; WEST INDIES (FEDERATION), THE. (D. R. D.)

CARIBOO MOUNTAINS in southeastern British Columbia, Can., form the most northerly subdivision of the Columbia mountains. Lying within the area enclosed by the great bend of the Fraser river and its tributary the North Thompson, they extend for about 190 mi. and constitute a rugged and scenic area. Highest in the southeast where they form serrated ridges reaching 11,750 ft. (Mt. Sir Wilfrid Laurier), they rise sharply above the Rocky Mountain trench but decline gently northward and westward, merging with the eastern edge of the Interior plateau.

The Cariboo mountains are well mineralized and lode gold is mined near Barkerville, once a hustling city of 10,000 during the Cariboo gold rush in the 1860s. Aside from mining, the only significant economic activities are forestry, a little cattle ranching and some tourist catering (mostly to sportsmen). All of them (including mining) are confined to the more subdued western part of the mountains. Wells Gray Provincial park, a recreational area, lies in the southern part of the range. (A. L. Fy.)

CARIBOU, the name of the North American reindeer. There are two species, the larger woodland caribou and the barren-ground caribou. See REINDEER.

CARICATURE AND CARTOON. Caricature, cartoon (in the satirical sense), comic strip and animated film cartoon are a linked series of para-artistic creations. Historically they arose in the order given, but they all have flourished together. All use artistic means or mediums; caricature, which has been described as a counterart, underlies the others and is present in each.

I. DEFINITIONS

1. Caricature. — Caricature is the distorted presentation of a person, type or action. Commonly a salient feature is seized upon and exaggerated, or features or members of animals, birds or vegetables are substituted for parts of the human being, or analogy is made to animal actions. Generally we think of caricature as being drawn in line and meant for publication to people to whom the original is known; the personal trait is usually present.

Satirical deformations and comic analogies in sculpture, the drama and vase painting are older than purely graphic caricature. The ancient Egyptians represented men as animals; Greek comedy had by-products in burlesqued figures on vases and in terra-cotta statuettes; Romanesque and Gothic sculptors made fun of human failings in stone capitals and wood miserere-seat carvings all through the middle ages. The marginal flourishes of illuminated manuscripts contain grotesque faces and occasional exaggerated scenes from daily life, or references to the morality plays which have the same relationship to those plays as Greek clay representations have to the stage. All such works verged upon caricature in the narrow personal sense; some were caricature in a broad sense.

In the generations since caricature became a clearly defined idea, there have been occasional examples in painting and sculpture alongside the more usual drawing for reproduction.

The word caricature derives from the Italian verb *caricare* ("to load," "to surcharge" as with exaggerated detail) and seems to have been used first by Mosini in *Diverse Figure* (1646), which appeared in the same year as a series of engravings after the Carracci drawings of Bolognese street types. The sculptor-architect Bernini, who was as skilled a pioneer caricaturist as Annibale Carracci, seems to have introduced the word *caricatura* into France when he went there in 1661. There is perhaps, in the choice of the verb *caricare* as a source for the noun, some influence from the idea of *carattere* ("character" in Italian) or even from *rnra* ("face" in Spanish). At any rate the face is the point of departure for most caricatures. It is conceivable that underlying the series of overlapping profiles with varieties of extraordinary noses and chins and brows which Leonardo da Vinci and Albrecht Dürer drew independently about 1500 was an observation not only of contemporary human types but of the fact that the heads of rulers on coins and medals, when worn with age, often became ridiculous. A latter-day case is the penny showing Queen Victoria, whose coiffure began to look like an elephant's head when the coin was well worn down.

Caricature, after its spread as idea and practice from Italy and France to Britain in the 18th century, became rather a broad term. In the late 19th century Gilbert and Sullivan spoke of an operetta subheroine as having "a caricature of a face." Perhaps, therefore, it is not surprising that, although cartoons as we now know them developed gradually out of caricature from the 15th century, the word cartoon is a 19th-century word. A London 18th-century alehouse sign, which was still in existence in 1857 and attributed to Hogarth, was the "Man Loaded With Mischief, or Xatrimony," which showed a man carrying his wife on his shoulders. The use of "loaded" may indicate a knowledge of the source of caricature.

2. Cartoon. — A cartoon originally was and still is a drawing, a full-size pattern for execution in painting: tapestry, mosaic, etc. The cartoon was the final stage in the series of drawn preparations for painting in classic Renaissance studio practice. In the early 1840s, when that studio practice was rapidly decaying, cartoon rather suddenly acquired a new meaning: that of pictorial parody, almost invariably a multiple-reproduced drawing, which by the devices of caricature, analogy and ludicrous juxtaposition sharpens the public view of a contemporary event, folkway or political or social trend. It is normally humorous but may be positively savage. The British comic weekly *Punch* was born (1841) in the years when the new Palace of Westminster (Houses of Parliament) was under construction. Prince Albert and his team of artistic advisers; wishing to revive fresco painting as a means of decorating the vast wall spaces of the new buildings, opened a competition. When the cartoons of the proposed compositions were exhibited, it was evident that many of the painters were unfamiliar with work on so heroic a scale, and some of their designs were ludicrous. *Punch* was quick to satirize them in a series of "Punch's Cartoons!" and thus the name was reborn. *Punch* became as powerful a vehicle of political and social comment as the *Charivari* (a French daily founded by Charles Philipon in 1832), whose name it had borrowed as a subtitle. Since that time, the cartoon has depended upon the weekly and daily press for the wide circulation called for by the cartoon's recognition value. Just as the personal caricature was for an audience which knew the original, so the cartoon was and is based on wide acquaintance with the subject. It serves as a capsule version of editorial opinion when it makes political satire, and it is a running commentary on social change, sometimes a corrective to social inertia.

3. Comic Strip. — The comic strip, which developed out of the editorial cartoon in the last years of the 19th century, is a pictorial anecdote or a serial story from contemporary anonymous history. It uses the methods of the caricaturist, the cartoonist, the dramatist and the raconteur. It depends not only upon the daily press but upon syndication (*i.e.*, simultaneous presentation in a large number of newspapers, under franchise or contract with

a syndicate which acts for the artists, receiving their drawings far in advance of publication dates, making the photomechanical reproductions and selling the matrices to subscribing newspapers). The indispensable features of the comic strip are: a sequence of pictures (usually 4 on weekdays and 8 or 12 on Sundays or in comic-book assemblies); the use of "balloons" of speech (though there are a few silent strips); and a cast of characters whose appearance and behaviour are stylized and predictable and therefore comfortable to the reader, and who provide daily surprise, suspense or laughter. Though occasionally a real person may appear among these characters (as the president of the United States appeared in "Joe Palooka"), they have not as a rule the personal nature of political caricature. Rather they typify currently admired categories of people, or comic-contemptible people whom one is glad not to be, or run-of-the-mill neighbours whose activities form a sort of continuous genre painting, or people from such special fields as sports, the business office, the armed forces or certain age groups. The attachment of readers to these characters is of enormous value to the artists and the syndicates. The death of an artist who has developed a successful family of comic-strip personages seldom means the death of the strip; rather it is carried on by an assistant or imitator, and it may gradually assume a new "handwriting." Division of labour is also practised. The continuity writer is almost as important in the comic-strip field as in motion pictures or television, and he often collaborates with more than one draftsman.

4. Animated Cartoon.— There have been numerous cases of interaction between the comic strip of the newspapers and the film cartoon. The drudgery of animating (filling in the stages of motion between key frames drawn by a head designer) has been the training ground of many comic-strip artists. (See MOTION PICTURES: *Animated Cartoons*.)

5. Relationship of Caricature and Cartoon.— It will be seen that caricature, cartoon and comic strip are often inextricably mingled. The caricaturist develops a sort of shorthand for a public man, and almost every good cartoonist develops at least one type which, despite copyrights, etc., comes like the public man into the public domain, thus enriching the political or editorial cartoon and the nonpolitical single-picture cartoon and eventually the comic strip. Conversely, such types as John Q. Public, Britannia or Peace or Labour or the Trusts may be affected by a Milquetoast, a Gibson girl, a Hokinson dowager, a John L. Lewis or a Jack Dempsey. Superman and Penny's father both have a family resemblance to the caricaturists' convention for Franklin D. Roosevelt.

The caricature and the cartoon give the reader a sense of wider reach or firmer grasp of the essences of persons, types and actions. There lies the power and popularity of the whole field of pictorial satire. Just as a member of a primitive tribe might fear to be photographed lest the possessor of his image have control over his life, so the public person must be swayed by the knowledge that a caricaturist may reveal something about him which the less observant would not have noticed. The portrait drawn by a caricaturist is an "antiportrait" belonging to a "counterart," but it is a portrait nonetheless. The caricature may be more like the man than a photographic resemblance. A public figure for whom the caricaturists have made a good symbol may wisely try to look more and more like his comic image. The public image of such a personality is to a very real extent created by political cartooning, even as the majesty of Louis XIV was largely created by Le Brun and his apparatus.

The cartoonist's skill in penetrating to the essence, in nailing down the important differentiating characteristics of people, is an eye opener to our own likes and dislikes. The uncanny eye of W. E. Hill for the cliché face and costume of the middle class, as well as his ear for the verbal cliché, would have been terrifying if it had not been of such an amiable intent. As an old verbal cliché reminds us, the gruesome and the funny are very close together. Explorations of the grounds for the power of caricature suggest that the art is akin to black magic, to hanging one's victim in effigy or sticking pins in the effigy. Perhaps it is encouraging that, in our century, most caricature is more genial than diabolic.

It is remarked both by W. Hofmann and by E. H. Gombrich and E. Kris (see *Bibliography*) that the middle ages were strong on irreverent mimicry, comic profanations of great mysteries and licentious acknowledgments of authority; and yet when personal caricature came in the high Renaissance, there was a reluctance to use so dangerous a weapon. Hofmann quotes "Jean Paul" (Johann Richter) as saying, "One's friends and relations may lead one in front of a distorting mirror, but not one's enemies." Dictators have been so aware of the power of caricature that political cartoons have often been among the early victims of censorship.

As caricature and cartoon are para-artistic, not expected to be beautiful in the conventional sense and not concerned with elegant subjects except to parody them, they have shown a certain affinity at times for forbidden subjects, erotica and pornography. From Pompeian sgraffiti and Bosch and Brueghel to Daumier, Toulouse-Lautrec and modern comic strips there have been privately circulated or at least somewhat covert variants of published material.

II. HISTORY

A. ORIGINS OF CARICATURE AND CARTOON

1. Individual Satire.— Caricature was a product of the Renaissance and Reformation emphasis on the importance of the individual. If a man was seen officially as an emperor, he was seen unofficially to have feet of clay or to be wearing no clothes. From about the first third of the 16th century the emphasis on decorum was so strong in Italy, and spread so fast northward and westward, reinforced by a still more solemn decorum from Spain, that it produced a reaction. Erasmus' *Praise of Folly* was both a Renaissance effort and a carry-over of medieval mockeries; the marginal drawings made in one copy of it by Hans Holbein the Younger (1497–1543) are neither caricature nor cartoon in the modern sense, but they are in the same stream of subjective comment on objective observation as Leonardo's and Diirer's exaggerated profiles. Brueghel's work is full of near caricature! as in the familiar drawing of an artist who is troubled at his easel by a nosy peering connoisseur behind his shoulder. Brueghel's and Bosch's witty and sometimes horrendous dislocations of parts of the body, their combinations of human anatomy with fishes, birds, animals and windmills, and their exaggeration of obese or emaciated physical types are likewise near cartoons.

Yet true caricature in the sense of the satirical portrait of an individual is almost impossible to identify before Agostino Carracci (1557–1602). The first caricatures of persons whose names we know are by Giovanni Lorenzo Bernini (1598–1680). The Carracci workshop in Bologna and its wider circle were full of artists who possessed all the materials for a synthesis of Renaissance, Reformation and Counter-Reformation, classic, mannerist and baroque currents. They created not only a proto-Bohemian sort of artists' caste but also an academic standard for the baroque period. They could at last afford to be easy about their position and occupation, about what was objective and what was subjective. They impartially caricatured one another in the studio and the types in the street. The rise of connoisseurship and collecting in the 17th century soon produced appreciation of these caricatures outside; hence Mosini's book of 1646, the early gathering of caricature drawings into albums and the transformation of such unique sheets into multiple etched or engraved publications.

2. Social Satire.— The less personal and caricaturelike features of the modern cartoon were being slowly prepared all through the 16th century and up to the last third of the 17th. In part consciously based on Bosch and Brueghel, in part an autonomous protest against the Renaissance belief in order, symmetry and fixed canons of beauty, there rose a European family of grotesqueries with sources as mixed as its appearance. Its only visible over-all characteristic might be said to be that it reacted, from the depth of old folkways, against the novelty of the Renaissance, the new world and the various hierarchies. Echoes of the dark Gothic forests mixed with fantastic reports of travel (some of them not really new but rehashed from Marco Polo) and with travesties of the Renaissance ornament of such works as Raphael's loggias of the Vatican. One of the results was the mannerist strapwork which

became international by the third quarter of the 16th century. Another was the double images of faces and landscape or of human figure; built of books, fish or pots and pans by Giuseppe Arcimboldo (1530-1593). In a slightly different area lay two sorts of pictorial comedy. The first sort was the conscious satire by professional print makers, illustrating such works as Sebastian Brant's *Ship of Fools* or issued as independent prints. Some of them were tendentious to the point of libel (such were Cranach's attacks on the papacy, inspired by Luther); others were merely mockery, such as Hans Sebald Beham's satirical view of mercenary soldiers and their camp followers. The second sort was the unconscious pictorial comedy by comparatively untutored practitioners of woodcut or etching, hastily made and issued as newspaper extras might be issued now. These were the ancestors of the 18th- and 19th-century broadsides and *images d'Épinal*.

If caricature deals with the individual and with what makes him individual, cartoons may be said to deal with groups and with their corporate characteristics; both are connected with the Renaissance love of classification and categorizing. Up to the time in the mid-17th century when both caricature and cartoon jelled in forms which answer to the modern definition, caricature had been prepared on the whole by knowledgeable artists; and cartoons had been prepared (though often with the assistance of professional artists) at a somewhat lower level. Cartoons were created in response not merely to artistic impulses but to the same sorting-out impulses which were creating the modern state and its society, its science and its religion. Besides the sublime/ridiculous and the artist/laymen dualisms in this field, there is a sort of class dualism which is a result of historical factors rather than of general human disposition. The history of caricature and cartoon is intimately connected with the history of the day in which one class has looked at another. Although a Marxist would say that class warfare grows more bitter all the time, in cartooning it has grown less bitter. In the mid-20th century the political caricature or cartoon was much less libelous than it was in the mid-19th, and the most successful comic strips are often those which make us laugh at ourselves or our very near neighbours rather than scowl at a distant scapegoat. The shrinking world and the increasingly tight law of libel may have something to do with this.

Diirer looked down on the heavy-bodied man whom he called "farmerish": yet within two generations Brueghel was drawing peasants in a sympathetic manner. Jost Amman (1539-91) made dispassionate woodcuts and engravings of trades and professions, as did Abraham Bosse (1602-76), although Bosse did utter some lampoons on unpopular types and callings. Wenceslaus Hollar (1607-77) made endless prints of types all over Europe, with considerable attention to class but without much visible prejudice. Jacques Callot (1592-1635) satirized dandies, beggars and all classes between, and he even made the generally detested gypsies (who were not yet romantic) almost sympathetic. Rembrandt was not a caricaturist or cartoonist, but there was certainly never an artist with more sympathy for the submerged part of the population. The 17th-century Dutch in general had, as a prosperous middle-class society, little pictorially expressed opinion about class but only about behaviour (excessive drinking was merry but unsuitable). These and many other possible examples suggest a rather comfortable social climate in the 17th century: the wars of religion had quieted in France and the Low Countries, though civil war occupied Britain in the middle of the century. But by the time the Restoration had quieted Britain, a general European threat appeared in the form of Louis XIV. Against his absolutism and against his influence through agents in Britain and the Setherlands, the first modern cartoon campaign was made. It was modern in that it was on a large scale—cartoons were published on a fairly regular serial basis much like that of the modern daily newspaper's editorial cartoon (though the newspaper was still in the letter-and-gazette stage); and it was based on a fairly large and general acquaintance with the persons satirized if not always with the literary analogies used. The cartoons, which as yet made no particular use of personal caricature (that was still on a friendly studio footing), were prints made in Holland by a group of artists of whom Romeyn de Hooghe was the chief, and they were sold cheap.

There had been Dutch political cartoons, but they were laborious and appeared irregularly. The Dutch-English connection in the person of William III, the continuing threat of Louis XIV and a succession of shattering events in various spheres stimulated a vast production of cartoons from the 1680s on. The South Sea Bubble, the unpopularity of the Hanoverians in England, the increasing contact of the people of capital cities with assorted foreigners and the rise of pretensions to culture all offered butts for satire. The multiplication of images, first in the coinage, then in broadsides of military or theatrical heroes and heroines, then in the reproduction of portraits of merely "beautiful people," led rapidly to the insertion of personal caricature into what would otherwise have been simply cartoons of situation. In Britain the Georges and the Jacobites were good butts, in France the profiteering ministers and such half-admired enemies as Marlborough and Prince Eugene.

The satirical print was thus in its first political maturity a way of complaining against absolutism and bad government and corruption; to put it more broadly, it was a way of rebelling against heavy-handed control and the exclusive philosophy of conduct which says, "Either . . . or." The cartoonist was already speaking up for "Both . . . and" or at least registering his "But . . ."

As the cartoon spread—along with its almost indispensable element, caricature—it began to divide; and although the periodical carrying cartoons was not to appear regularly until the third quarter of the 18th century, nor the true comic periodical until early in the 19th, the divisions were real enough to follow from that time.

B. PERSONAL AND POLITICAL SATIRE (PURE CARICATURE)

1. 18th Century. — About 1740 the English print maker Arthur Pond published together 25 *caricaturas* after original drawings by Annibale Carracci, G. F. Barbieri ("Guercino"), Pierirancesco Mola, Ghezzi and even Watteau (a drawing of a Huguenot physician made during Watteau's short English visit in 1719-20). This collection must have been effective in spreading the idea and the word, for it was an excellent performance. Pier Leone Ghezzi (1674-1755) was probably the first professional caricaturist, for he made a living with his pen portraits of Romans and visitors to Rome, many of which he engraved. He was a minor master in comparison to Giovanni Battista Tiepolo (1696-1770), yet the caricatures by the greater man, delightful though they are, appear to deal with types or at least with anonymous individuals rather than with namable ones. Tiepolo's pen-and-wash drawings were a small side issue in his enormous production, nor were they engraved or otherwise multiplied in his lifetime. Both artists had an eye to ungainly legs and posture, and to the odd behaviour of clothes to suit the wearer, as well as to the obvious features of the face.

On the heels of Pond's reproductions came the handbill-like personal caricatures circulated from time to time. Apparently begun in the 1760s by George Townshend (later Marquess Townshend), these were comic portraits with punning titles or accessories, intended by disingenuous means to avoid being outright libelous. A flood of imitations followed, and it was not long before Townshend's cards became comic illustrations in magazines such as the *London Magazine*, the *Political Register* and the *Town and Country Magazine*. William Hogarth produced an unforgettable half-caricatured portrait of Simon Fraser, Lord Lovat, on trial for his complicity in the Jacobite rising of 1745.

2. Early 19th Century. — Great Britain. — Thomas Rowlandson (1756-1827), one of the few who approached Hogarth and Daumier as a satirist, created the comic images of a great many public characters in his day: royal dukes, actresses, auctioneers, Grub street men. He was the perfect professional to carry on what the amateur Townshend had begun. Like Tiepolo he was able to make the person and the costume assume a homogeneously ludicrous or pathetic-bathetic look: with iactitious coiffures, wildly frogged uniforms, enormous bosoms and bottoms and the dejected attitudes of trailing handkerchiefs.

It is interesting that the silhouette portrait (which was seldom caricatured) had its greatest flowering in the first quarter of the 19th century when costume was so picturesquely top-heavy.

Both Rowlandson and the silhouettists had lots of competition in such sound provincial caricature-portrait men as the two Dightons, father and son. Townshend's punning titles may have been transmitted to the late-19th-century "Spy" and "Ape" by the Dightons (a portrait of a broad-beamed town councilor is labeled "A View From Bladud's Buildings, Bath").

Rowlandson's contemporary James Gillray was less of an artist and more of a professional cartoonist in the modern sense. Coming from the theatre to the political scene, he brought a highly dramatic sense of situation and analogy, but he was peculiarly violent and often scurrilous or scatological. His pleasantest gift was with patterns and ornaments of costume: which he would allow to take on a luxuriant life of their own, almost foretelling Saul Steinberg's ornament. The Swiss-born English painter and teacher Henry Fuseli (1741-1825), though hardly a professional caricaturist, stood halfway between the painted Italianate caricature groups of Sir Joshua Reynolds and the Rowlandson-Gillray drawings and etchings; he had something of Gillray's theatrical manner, but his satirical drawings were more often sensual than scatological.

France.—Philibert Louis Debucourt (1755-1832), coming to maturity in the days of the *merveilleuses* et incroyables, might have equaled Rowlandson if he had not been so occupied with the intricacies of colour prints; but he produced a few superb cartoons of the Paris of his day, full of caricatures of fashionable personages.

The whole Napoleonic period gave rise to such passion that, besides the British caricaturists of "Boney," a school of French caricature was generated, the effect of which was to come after the Restoration. Two members of an older generation, Louis Léopold Boilly (1761-1845) and Jean Baptiste Isabey (1767-1855), really began the work. Boilly, starting where Debucourt left off, satirized the modes and manners of the French, often reflecting in his caricature the wide general interest in the physiognomical publications of Lavater (*q.v.*). He was not in the direct sense a political caricaturist but frequently used portraits.

Isabey was primarily a portrait painter, but he was in contact with all the great continental political personalities of the first half of the 19th century, and he caricatured many of them privately. Most of the caricatures were not published, but they had an effect among artists, as did those of Goya's prints which made their way to France.

The tendency of the Restoration to suppress Napoleonic enthusiasms provided another rich ground for cartoon as political complaint. As soon as the first stage was over (in 1830), a change of administration was accompanied by the appearance of Charles Philipon's periodical *La Caricature*, the first great vehicle of Honoré Daumier (1808-79), Henri Monnier (1805-77), Grandville and others. The presiding genius had great politico-legal skill, and knew exactly how far he and his artists could go. The famous likening of Louis Philippe to a pear, which was both a visual and a verbal pun, was not the least of *La Caricature's* successes. Daumier's colossal gifts included personal caricature, though in his later life he dealt almost entirely in more general social satire. In the early '30s he created for Philipon "Le Ventre législatif," at once a political indictment, a rogue's gallery of caricatures and a monumental composition; not to mention a long series of more detailed single antiportraits. Daumier's composite sociopolitical villain, Robert Macaire, and Monnier's Joseph Prudhomme, the sum of bourgeois pettiness, served as butts of satire when censorship caught up with directly personal caricature in Philipon's three or more overlapping papers.

3. Middle 19th Century.—Great Britain.—The specifically cartoon-bearing journal was at this time an established fact. The *Monthly Sheet of Caricatures* had begun publication in London in 1830, lithographed like Philipon's journals. In these and other of his ventures, the publisher Thomas McLean issued hundreds of political caricatures during a great formative period of modern legislation; his artist Robert Seymour was in the Gillray line rather than the later one of John Doyle, who also worked for McLean. There were naturally transitions: George Cruikshank, though he continued to use etching as Rowlandson and his own father Isaac Cruikshank had done, was Dickensian, not Sheridanlike; Seymour

used lithography. John Doyle's son Richard became one of the masters of the mid-century British school of subtler cartooning. The younger Doyle was one of the initial staff of *Punch* when Henry Mayhew started it in 1841; others were John Leech, and—later—Charles Keene, Sir John Tenniel and George du Maurier.

Punch began as a fiercely democratic weekly which applied to the young Queen Victoria and her growing family, as a matter of course, the same savage treatment that had been given by caricaturists of the previous hundred years to the Hanoverians. One of the reasons for "Punch's Cartoons" on the Westminster hall exhibition was that the unpopular foreign Prince Albert had fomented the competition. But *Punch* was not so much merely anti-royal as it was antihumbog (Thackeray after all was another of the staff). Though its first few years were marked by some of the worst puns in a punning age, it not only kept up, with its fairly small fixed staff, a remarkable fire of lampoon but soon developed the weekly full-page political cartoon, certainly one of the chief ancestors of the modern editorial cartoon. Nineteenth-century British and general European politics might be briefly comprehended in a few dozen of these. The most famous is probably still that farewell to Bismarck, "Dropping the Pilot," by Tenniel.

The woodcut technique used for many decades in *Punch* caused the cartoons on the political page, the largest in scale of the cartoons, to be almost invariably dull in surface. The speed required of the divided-labour teams which produced the cuts from the artists' drawings did not allow for the subtleties possible in such collaborations as Tenniel's Alice in *Wonderland* illustrations, which were almost as much a creation of the Dalziel shop as of Sir John. The political page, however, even when artists and woodcut technicians were far below the brilliance of a Daumier, kept even Disraeli and Palmerston sufficiently under surveillance to have a strong effect. Yet the tone of *Punch*, once it had reconciled itself in 1851 to Victoria and Albert, was marked by aptness rather than pungency, and social satire was its best field in cartoons. A sometimes neglected source for the rather cool pictorial manner of *Punch's* artists was the etched portrait caricatures of Alfred d'Orsay, belonging in style to the Regency generation but much reprinted in book form in the mid-century. They were thin lined, very open and white and elegant, the heads always a little too large.

The United States.—The young United States began to produce caricature and cartoon in good time. At first there was not quite enough objectivity of observation to allow the right balance with subjective opinion and interpretation; to some extent this was compensated for by the unconscious humour of comparatively untutored artists. Paul Revere's engraving of the Boston Massacre is certainly not a cartoon; it has proper political passion—something important to say—but no caricature except what lies unconsciously in the rather stiff drawing. The founding fathers were almost too sacrosanct to caricature, though Burr and Hamilton caught the eye of budding American cartoonists in the Gillray vein, and the War of 1812 brought out some good sheets of the same sort. Andrew Jackson, though on the whole a well-liked president, had so roughhewn a head that he became one of the best subjects for caricature, and Abraham Lincoln's great height and gauntness would doubtless have made him a cartoonist's favourite even without the passions of civil war.

Yet there was not a cartoon periodical in the manner of *La Caricature* and *Punch* until after the American Civil War. Single-sheet cartoons, usually lithographed, were common; the publishers, among whom were N. Currier (later Currier & Ives) and H. R. Robinson, overshadowed the artists at first. Two circumstances may have combined to delay the appearance of a great caricaturist: first, the fact that above all in the United States the middle third of the 19th century was an age of oratory; second, that the combination of the telegraph with the facilities of the daily paper made news, especially during the war, even more desirable than opinion. The great fighting words of the time (*e.g.*, "copperhead") came from editorial writers rather than artists. The earliest really impressive makers of personal caricature and political cartoon were David Claypoole Johnston (1799-1863) and Thomas Nast (1840-1902). Nast first made his name with war cartoons in Harper's

Weekly, which like *Punch* used the woodcut process, with an elaborate division of labour in the back shop for the rapid reproduction of cartoons and correspondents' drawings.

Italy and Germany.—The middle and late century produced in Italy so brilliant a political caricaturist as Virginio, who was to the rise of Italian nationalism what Sast had been to the South in the American Civil War; he worked for *Il Fischietto* of Turin. In 1848 *Kladderadatsch* started in Berlin. Munich had *Fliegende Blätter* and *Punsch*. *Punsch* was more political than the others, which were long-lived comic weeklies in the social-comment style. Schleich's *Punsch* cartoons mere a running Bavarian comment on Prussianism.

4. Late 19th Century.—The *United States*.—In the boom days of the 1870s Thomas Sast became a master of personal satire; his long practice in dealing with the professional wood engravers gave him at last a style and scale that triumphed over finicky cross-hatching and gave full effect to his ruinous attacks on "Boss" Tweed and other grafters: he was one of the most fertile of symbol makers outside the personal field, and is probably the creator of the Democratic donkey as well as of the New York tiger, the label for Tammany Hall.

In 1876 *Puck* was founded. It presently developed new artists, notably Joseph Keppler (1838-94) and Bernhard Gillam (1859-96). They worked in a lithographic style of considerable artistic competence, without the force of Sast or the effortless flow of Daumier, but with plenty of clever analogies and with an understanding of the sort of likeness required in caricature. The oratorical heritage caused a certain amount of literary reference not unlike that of the *Punch* political cartoons.

England.—*Punch* meanwhile had settled into its richest period, with Sir John Tenniel and Harry Furniss as political cartoonists. *Vanity Fair* (from 1868) offered some competition, especially at first with its regular coloured lithographic antiportraits. These were signed "Ape" (Carlo Pellegrini) and "Spy" (Leslie Ward, later knighted): they kept up a steady supply of big-headed comic figures against an almost invariably blank background. They also kept up the old device of never quite naming the subject in so many words, but as they were directed at a public which was "in the know," this was part of the fun. These colour caricatures, though they lacked the elegant line of a Gavarni and the occasional stabbing trenchancy of a Sast, were much loved, and were often framed and hung on private walls. Max Beerbohm (1872-1956; knighted in 1939) devoted himself largely to social and literary satire but almost always on a basis of personal caricature. His deceptively understated outlines and pallid washes, the latter used as local colour for the sake of the over-all design, were the perfect means for parodying the good taste of the *fin de siècle*. His symbols for Chesterton, Shaw, Conrad and Maugham have become almost the standard views of those writers.

Technical Developments.—Toward the end of the century there was a rebirth of personal satire which accompanied new techniques of reproduction and perfected enrichments of such older techniques as colour lithography. Photomechanical reproduction, especially after its loosening through the development of halftone, allowed direct reproduction of the artist's drawing without personal interpretation by wood engravers or other technicians. Colour lithography, which had been either limp or turgid on the whole, found in the train of Impressionism a blond new life. The caricaturists who had been able to draw directly on the stone, as Daumier did, had always had more freedom and better control over results than those who worked with pen and paper: now the latter could depend upon themselves and a photomechanical servant. *Le Rire* in Paris (from 1894), the *Yellow Book* in London (same year), *Simplicissimus* in Munich (from 1896) and *Judge and Life* in New York (from the mid-1880s) showed the work of Jean Louis Forain (1852-1931), Henri de Toulouse-Lautrec (1864-1901), "Caran d'Ache" (Emmanuel Poiré; 1858-1909), Max Beerbohm, Aubrey Beardsley (1872-98), Olaf Gulbransson (1873-1958), Thomas Theodor Heine (1867-1948), Rudolf Wilke (1873-1908), Eduard Thony (1866-1950), Charles Dana Gibson (1867-1944) and dozens of others.

France.—Toulouse-Lautrec produced large-scale posters and

earlier, polychrome lithographs for *Le Rire* and for independent distribution. He created a new style of informal composition, somewhat influenced by Japanese prints, with bright clear colour, broad, rather casual outlines drawn largely with the brush, a trick of making tone by means of spatter and a wit which saw through ugliness to a new sort of eloquence. His view of Oscar Wilde was more economical and even more devastating than Beardsley's, and his caricatures of theatre and music-hall personalities are unmatched. Caran d'Ache worked on a smaller scale with pen and brush, and was one of the most effective continental commentators on the South African War.

Germany.—The *Simplicissimus* men were all somewhat influenced by Toulouse-Lautrec in their use of white space, spatters and often random outline; they all commented on those features of German life which were most disliked outside Germany—the didactic professor, the tourist and the military dandy. Their caricatures in the last field were very thinly veiled; Eduard Thony, one of this group, had a mixed feeling for the dash and style of uniforms and against the upper-class boorishness of Prussian officers; his very large-scale brush drawings would seem to leap from the page if they were not so carefully hung up by their heads in a manner deriving distantly from Whistler.

5. 20th Century.—The *United States*.—Charles Dana Gibson was a virtuoso of the pen, using the manner of *Punch*'s Phil May as a point of departure. He used the pen as he pleased, sometimes in a direct descriptive manner, sometimes with colouristic suggestion, sometimes almost antigraphically. Though he helped to create the caricature types of Theodore Roosevelt and Woodrow Wilson, he was more a social than a personal caricaturist. He is mentioned here chiefly because of his introducing to the world American physical types called "Gibson girls" and "Gibson men." He was not really very funny but was a good editor of *Life*.

A position much like that of *Simplicissimus* was occupied in the years 1911-17 by *The Masses* of New York, which had an editorial policy based on old-fashioned socialist idealism. It was served by a remarkable group of artists whose fine drawing made their often sharp propaganda for reform tolerable in quarters where they might not otherwise have gotten a hearing. John Sloan (1871-1951), George Bellows (1882-1925), Boardman Robinson (1876-1952) and Art Young (1866-1943) were as likely to deal in general social terms as in personal ones, for by this time personal, particularly political, caricature was tending to move into the newspaper editorial cartoon or the pages of theatrical or sporting news. Bellows and Sloan were not only excellent painters but also independently lithographers, and Robinson was a fine mural painter and teacher; Art Young lived to work for the *New Yorker*. Will Dyson and (earlier) Walter Crane were British equivalents.

Photomechanical reproduction not only allowed greater freedom for comic artists: it made possible the daily newspaper cartoon and later the syndicated editorial cartoon and the comic strip. From about the same time as the new generation of weeklies we can see a rise in the use, the autographic character and the influence of pictorial journalism. John T. McCutcheon (1870-1949) of the *Chicago Tribune*, though he used a rather dry and old-fashioned pen technique, was able to range over a world that included politics, the "good old days," the mores of the moment and sports, as well as over a great network of newspapers to which his work was syndicated. His cartoon world, like that of *The Masses*, was almost entirely urban; but he was one of the first of a generally imperturbable type of American cartoonist, whose view is amused rather than aroused. And his career ran from before Theodore Roosevelt to after Franklin D. Roosevelt's time. In his line of succession stood such men as Edwin Marcus and S. J. Woolf in the *New York Times*, Oscar Cesare of the *Sun*, Herbert Block ("Herblock") of the *Washington Post*, Daniel Fitzpatrick of the *St. Louis Post-Dispatch*, Rollin Kirby of the *New York World-Telegram*, Tom Little of the *Nashville Tennessean* and others too numerous to list.

England and the Continent.—Though *Punch* continued to have first-class draftsmen in the 20th century in the daily-life sort of cartoon, Sir Bernard Partridge was not a very exciting political caricaturist. His ponderous allegories used twice as much ink as

Charles Keene would ever have needed, and three times as much as Phil May. May, who was to the aging Gladstone what Tenniel had been to the young Disraeli, could do in a few zigzags what Leech had had to hatch in with more evident labour. Phil May had served an apprenticeship in New South Wales and was in a sense the forebear of David Low (b. 1891), a New Zealander who norked for the Sydney *Bulletin* before going to Britain. Low was perhaps the best all-round man in the field since Daumier. His brush drawing was of an oriental economy, his invention of analogy gleeful without being really outside the classic British educated tradition, and his hatred reserved for a few very needful occasions. Like many before him, he employed hackneyed devices (e.g., the heads of a pack of British politicians on dogs' bodies), but by slyness of expression always managed an original twist. In the *Manchester Guardian* and the *Evening Standard* he was the outstanding political commentator of the first half of the 20th century. Indeed there was almost no one in the political field to touch him except for the Dutchman Louis Raemaekers during World War I, and Raemaekers, for understandable reasons, was bitter where Low was dry and crisp, with footnotes of rumbling laughter. Sennep of the Paris Figaro and Fritz Meinhard of the Stuttgart *Zeitung* may be mentioned in the same breath, and that is about all.

C. COMEDIES OF MANNERS (THE CARTOON)

Modes and mores are among the outward and visible signs of anonymous history. Each one of us is in the midst of them, and therefore when the cartoonist invites us to back away and look, we look at ourselves, not at an alderman or a queen or an eminent musician. Types and groups rather than politics and the politician or any namable individuals are the concern of the comedian of manners. He may love mankind for its imperfections, or set out to seek improvement, but his method will be much the same. He does not need, as the political cartoonist does, to set up allegories and analogies or to write names on labels, but he may sometimes sharpen his comment by treating human beings as animals (monkeys and apes for obvious reasons have long been the favourites, along with dogs and birds). If the personal caricature is an anti-portrait, the cartoon on human foibles is often a sort of anti-sumptuary law or a countergrammar which says, "The exceptions are more fun than the rules."

1. 16th to 18th Century.—Brueghel and Callot were certainly comedians of manners. Brueghel's picturizing of Flemish proverbs, themselves often comments on foibles, and his prints of the seven deadly sins with satirical examples filling the backgrounds combine a bit of moralizing with a delighted participant's empathic sense of the *flagrans delictus*. Callot is a shade more detached, possibly because of his more conscious style and because he was himself the print maker (Brueghel drew for professional engravers and woodcutters); but in the catalogues of byplay in his panoramic scenes of fairs and in his trick of making the beggar wear his rags handsomely he is always balancing and measuring.

Parallel to two-dimensional comment in this vein ran the theatre, notably the puppet theatre, and the performances of the jester and clown. The jester, to all intents and purposes, disappeared into such things as Rabelais's *Pantagruel* before the cartoon had acquired its modern form, though the clown certainly did not disappear into Molière. Both appeared, however, in the rather courtly comic drawings of Claude Gillot (1673-1722), Watteau's predecessor. These are not really comedies of manners, for the clowns are used as if they were monkeys aping human ways at a remove toward greater elegance rather than toward apishness. They point the way to a good many 18th-century practices: Gillot and Watteau both made decorations which included monkeys, just as Boucher and later artists were to use pseudo-Chinese scenes occasionally as ways of commenting on contemporary European life.

The *singerie*, *turquerie* and *chinoiserie* were all in the line of succession from medieval morality plays and their underlying folk wisdom, as well as more immediately from the *commedia dell'arte*, the formalized successor to the moralities. Harlequin, Columbine and the other characters of the *commedia* gave rise to a

vast body of popular caricature.

Hogarth.—It is with Hogarth that the cartoon of manners reached great stature. His series "Marriage à la Mode," the "Rake's Progress," the "Harlot's Progress," the "Four Stages of Cruelty" and the unfinished "Industrious and Idle Apprentices" were loaded with observation not only of human beings but of objects and their ecology, as if he were using his own proliferation of comic images in protest against waste of time, talents, life and pride. Hogarth, like Reynolds after him, even painted comic subjects, but he kept to social satire and avoided personal caricature. His pictures of depravity and ferocity are hard to beat, but he could put an expression of by no means unholy delight on a wicked face. In the "Laughing Audience" he gave a full measure of laughter. Hogarth's engravings ran to very large editions, and were recut and reissued and then copied at reduced scale for books of the *Complete Works*.

2. 19th Century.—Rowlandson and Cruikshank.—Rowlandson, as we said, was a political caricaturist part of the time, but above all he was a lampooner of ludicrous and excessive behaviour. He created almost unaided a gallery of types missed by Hogarth, many of which persist in British life—the antiquarian, the old maid, the harried foreign servant, the pleasantly blowzy barmaid, the decent old parson. He was by no means as bawdy as he is supposed to have been, but he liked to push action, like appearance, to an extreme. His Dr. Syntax may be called an ancestor of the comic strips.

George Cruikshank (1792-1878) carried Rowlandson's methods almost beyond extremes in his youth. He used superfantastic costume and sometimes that device of enormous heads which some 17th-century caricaturists used and which is still used by sports-page cartoonists and comic advertising artists.

Goya.—Francisco de Goya (1746-1828) of Spain is hard to place. His "Caprichos," etchings prepared by some of the most simple and trenchant brush drawings ever made, appeared in the last years of the 18th century, and can be called comedies of manners only insofar as they are related to folk sayings and the bitter-sweet Spanish folk wisdom. Thus they stand in the line of Bosch and Brueghel, so many of whose paintings were in Habsburg collections in Madrid. The "Proverbios" of 1815-19 are even more monumental transfigurations of various states of the human condition. Like the "Caprichos," they used the caricaturist's means for irony and satire, but there was little of the comic left in them, and none at all in the "Désastres de la Guerra," which used the Peninsular phase of the Napoleonic Wars as a point of departure. They are closer to universality than even Callot's similarly inspired series and are searching comments on more stages of cruelty than Hogarth covered. In them, Goya was really a political cartoonist using no names; yet he was hardly a public cartoonist in the normal sense because censorship and other factors allowed only a very small circulation of his later work until a sizable edition was printed a generation after his death. The earlier work, which contains elements of comedy, did get abroad, and had influence in France and England probably before Goya's death. Artistically if not politically his work would have had the same powerful effect whenever "discovered" or circulated.

Gavarni, Guys and Grandville.—"Gavarni" (Sulpice Chevalier; 1804-66) was more purely a comedian of manners than Daumier. Though more tender with his lithographic crayon, he was no less perceptive, no less sympathetic with the *petit parisien*. At the same time he had a grace derived from his apprenticeship in fashion illustration (which he and Eugène Lami practically invented) that produced enchanting jokes on young people in love, dandies and the theatre and circus. He worked late in life for the Illustrated London News, as did Constantin Guys (1802-92), the foreign correspondent who reported the Crimean War. Guys, a prolific draftsman who always kept a comic touch, was peculiarly subtle in reporting the great but contrived elegance of Napoleon III's court. He helped both British and French to see themselves as others saw them. "Grandville" (J. I. I. Gérard; 1803-47) was a comic artist on La Caricature who recalled some of the complicated inventions of Arcimboldo; his big-headed people seen as if in distorting mirrors and his animal analogies have been considered

among the sources for Alice in Wonderland.

Daumier.—Daumier was of course the great master of social comedy with or without political content. His series of affectionate if disenchanted comments on married life, the theatre, the courts, concierges, musicians, painters, bluestockings, bathhouses and children constitute as full a report on Paris in his time as Rembrandt's drawings were for his Amsterdam. The words were often important, especially when Daumier was indicating in his text the unspoken thoughts of his characters (thus anticipating the 20th-century cartoon in which a thought or vision is indicated as a "balloon" with cloud-scalloped edges and a picture rather than words inside). His often untidy line and knowingly casual accents of tone produced (at will) sensations of chill weather, of ecstasies of gluttony, of juvenile pride or of legal craftiness.

Punch.—With the longest continuing habit and tradition of humorous comment on the passing world, *Punch* is the only institution that approaches Daumier's personal accomplishment. Though it began in puns and peevishness, it warmed up with John Leech (1817-64), Charles Keene (1823-91), George du Maurier (1834-96), George Belcher (1875-1947), "Fougasse" (Kenneth Bird; b. 1887), H. M. Bateman (b. 1887), Nicolas Bentley (b. 1907), E. H. Shepard (b. 1879) and Osbert Lancaster (b. 1908). Leech was in a sense the pictorial equivalent of Thackeray (Thackeray was an excellent comic draftsman, but better at getting the feel of past time with a comic flavour than at considering his contemporaries other than in words). Leech and Keene belong to the era of wood-engraved reproduction; when we see today their original drawings with their own manuscript captions or dialogue, we see that something was lost in detail and finesse of line, but nothing in sense of comedy, in the affectionate tone. The enormous afflatus of the optimistic Victorians: expressed at first through the violent or bumptious Regency manner of the young George Cruikshank, was tempered by the staff-meeting or meeting-of-minds conduct of *Punch*, perhaps by Arnoldian and other outside influences. The "manners" part of the phrase "comedy of manners" became subjective as well as objective. *Punch* became and continued for three or four generations an upper-class weekly, reflecting the large knowledge of all classes which it was possible for its staff to offer its readers, and the large delight of the upper class in seeing its own foibles and those of its servants, tradesmen, lame ducks and "climbers" exposed. C. R. Ashbee (see Bibliography) has remarked on the importance of representing and manipulating dress in the 19th-century cartoon. There may have been more nuances in dress from du Maurier's to Belcher's day than we now know, but dress is still certainly one of the quickest and most comedy-susceptible points by which an artist may identify his subject. The swing of a crinoline by Leech and the curl of a cabdriver's hat-brim by Keene were perfect selective imitation, themselves almost inimitable; the crinoline and the hat are gone with those who knew how to wear them, but the picture in *Punch* remains.

Of the five-sided conversations (with parenthetical stage directions) printed under the drawings of the du Maurier period, the less said the better, except that the dialect was better than the dialogue, whether it was that of lisping young swells or the native notes of Somerset or the refined tones of footmen. The du Maurier drawing-room drawing, which certainly had an influence on Charles Dana Gibson, was (so to speak) poor in vocabulary and rich in syntax, as is usually the case with anything made for an initiated circle.

Photomechanical reproduction came in during du Maurier's day but hardly affected his generation of artists. Phil May's pen was better served by the camera and the zinc block than Leech's had been by end-grain boxwood and gravers, but the general language was the same. With the generation of George Belcher there was a great change. His own crumbly charcoal or crayon strokes were perfectly adapted to the new process—indeed it was mutual—as were the fat blacks of Forain and the mid-20th-century cobwebs of Emmett. Fougasse's highly personal little curly stick men, drawn perhaps with a signwriter's pen, could be reproduced by almost any method, but the sharp lines and solid black areas of Bateman (deriving ultimately from Beardsley's decorative style) and the thick-thin pen strokes of Shepard (more in the Keene tradition)

were well served by modern processes (see Technique). Shepard was more truly an illustrator than a cartoonist, but Bateman's towering humours and bulging-eyed apoplectic businessmen were in the direct line from Edward Lear to such frantic American cartoonists as Virgil Partch.

Busch and *Lear.*—Edward Lear is almost as hard to place as Goya. He practised as comic draftsman an economy and geniality that are hard to improve upon, but like Daumier he supposed that his own best gifts lay in another field. Humour had been brought into satire by Hogarth; a truly funny style of drawing was brought into cartooning by Lear and by Wilhelm Busch (1832-1908), the creator of Max *und* Moritz and a grandfather of the comic strip. Hitherto, standard drawing techniques had been applied to grotesque shapes and comic situations (Grandville's lithographic method was the same as Delacroix's). But Busch's lines seemed to parody in themselves the graceful contours of the serious artist, they gasped or hiccupped or stuttered, while Lear's went wandering off into a sort of joke on calligraphy (later to be described by Paul Klee). Furthermore, both these men traveled into areas of fantasy previously barely hinted at—Busch into wildly inventive naughtiness beyond the call of the bad boy's duty; Lear into solemn non *sequitur* of proto-Surrealist character ("There was an old woman of Leeds. Whose head was infested with beads. . ."). Neither can be called a direct critic of modes and manners, yet Busch's view of German middle-class life was sharper than Moritz von Schwind's, and Edward Lear was in a sense doing what the monkey pictures and *chinoiseries* had done. His people were outlandish whether they came from Cádiz or Dorking or Kamchatka, yet they represented us, and the satire was purely social and apolitical. Both the wild improbability and the spiky ungracious drawing of Busch and Lear had an ancestor in Heinrich Hoffmann's *Struwwelpeter*, whose adventures, with the original cuts, have been reprinted in many languages for many generations. *Struwwelpeter*, however, contained a sadistic element which, while ignored by the young, has at last begun to seem deplorable to their elders.

Beardsley.—Beardsley is also hard to place. He used caricaturist's methods but little of his work, except perhaps the illustrations to *The Rape of the Lock*, was actually caricature or cartoon. If some of Cranach's prints can be called illustrated libels, some of Beardsley's can be called illustrated yearnings by unfrocked lechers. They are important because their combination of large white spaces, clear lines and solid or slightly irritated blacks could be reproduced successfully in a choice of dimensions, and thus laid down a discipline for illustration, commercial art and the comic strip.

Illustration.—In the great period of illustration from the introduction of process and halftone to the perfection of colour film, there were numerous interactions between illustration and cartoon. If du Maurier's cartoons and Gibson's were often only illustrated wordy jokes, the illustrations of Randolph Caldecott, Arthur Rackham, Howard Pyle and A. B. Frost were often full of caricature. Frost in his illustrations to *Uncle Remus* was as much a cartoonist as E. W. Kemble in his Negro subjects in *Life*. Palmer Cox's "Brownies" in the American children's magazine *St. Nicholas* were among the forerunners of the comic strip; and there were still serially published independent cartoons in the tradition of Gillray, for instance the "Dark Town Fire Brigade," coloured lithographs by Thomas Worth which were among the last truly lively publications of Currier & Ives in the mid-1880s. Seventy years later the democratic conscience had grown tender enough so that jokes about minorities had to cut across colour lines or avoid them.

3. 20th Century.—The whole tenor of pictorial comedy was shifted by World War I and by the boom times thereafter. Some previously forbidden subjects became admissible. Political caricature during and after the war was excessively partisan, while the cartoons about the war itself were lenitive. Bruce Bairnsfather's Old Bill and his colleagues in Britain and the poilus of Poulbot in France got through it by joking. After it was over, the public for comic publications was greatly enlarged; while the newly rich were standard butts for cartoonists catering to all classes: they were themselves buying comic weeklies.

In the United States the usually monthly comic magazines of

universities and colleges had a sudden flowering, to such an extent that an anthology of their cartoons called *College Humor* was published for several years in the 1920s. The syndication of comic strips, which had originally been for an urban audience, called for a broadening which was reflected in weeklies. The tendency of previously serious weeklies to use small cartoons here and there, or to insert a funny page somewhere, created not only new markets for cartoonists but also a temporary decline in the purely humorous magazines, and *Punch*, *Life* and *Judge* had difficulty surviving the depression of the 1930s. The title of *Puck* had already passed to a newspaper chain which used it for a Sunday supplement, and the title of *Life* eventually passed to a periodical of different character. *Simplicissimus* never quite rose between wars to its pre-1914 stature; the effort which went into Dadaist and Surrealist publications in Germany and France in the 'aos, when art itself became an object of social satire, meant a loss to other comic publications. Meanwhile the public in general gradually became aware of modern art, and its presumed incomprehensibility became almost as routine a subject by 1940 as mothers-in-law or freshly painted park benches.

In the United States an older generation of humorists somewhat of the upper-class *Punch* style lingered briefly after World War I. Of such were Oliver Herford, whose *Alphabet of Celebrities* and other comic verses with pictures were published as small books; Peter Newell, whose highly original *Slant Book*, *Hole Book*, etc., had a sharp eye to late prewar costume; Gelett Burgess, whose *Goops* for children were spaghetti-like little figures whose behaviour pointed a moral.

But to these was now added a new generation of sophisticated but slightly flashier performers, many of them with theatrical connections, many at first employed by the fashion magazine *Vanity Fair* and later by the *New Yorker* (beginning in 1925): Ralph Barton who did superb roudés; Rea Irvin of the thin trembly line, poached eyes and almost oriental splendour; Gluyas Williams and Ellison Hoover who satirized business, industrial labour and other subjects not well known to the *Punch* tradition; and Alfred Frueh, whose caricatures of theatre people were Toulouse-Lautrec with a difference. The depression of the 1930s brought forward a few artists with a genius for social protest, few of whom had any real sense of comedy because tragedy was not to them, as it had been to Daumier, the other side of the same coin. Kathe Kollwitz in Germany was a fine artist and could have been a great cartoonist; in the United States the communist *Daily Worker* had the services of William Gropper, a distinguished lithographer and editorial cartoonist who was sometimes able to capture something of the humorous tone of the prewar *The Masses*. And it gradually became known that in communist Russia a comic magazine called *Krokodil* was allowed to gibe at the ways of its brothers and even occasionally of its masters.

The New Yorker.—The two most interesting features of cartoon and caricature in the first half of the 20th century were the rise of the one-line joke and the pictorial joke without words, and the enormous diversity of styles of drawing. The *New Yorker* was probably the inventor or reinventor of the one-line joke, certainly its chief fomentor. Five-decker dialogues with headings were swept away even from *Punch*, and there was a greater unity of words with picture, paralleling the tendency toward tabloid newspapers with large photographic halftones and very pithy text. The joke without words, often in two or more frames, was the extreme of economy of language. One result of this change was that the comedy-of-manners cartoon must convey its comment entirely through costume, setting and (to a lesser extent) situation, and the emphasis thus tended to fall more on comic situation than on plays on words, class differences or marked action. The *New Yorker* and magazines whose cartoons had been influenced by it aimed at a sophisticated audience. The *New Yorker* itself, while enjoying in its maturity a position equivalent to that of *Punch* in the 1880s, aimed its advertising and much of its writing at upper-income classes, but its cartoons were aimed at the classes described as highbrow and upper-middlebrow. Such appanages of the old-fashioned British-style upper class as servants were always treated by *New Yorker* cartoonists (notably Mary Petty) as necessarily

comic fossils of an old order, and hence in rather than out of that old upper class. Whole new areas of social-comedy subject matter arose in this magazine: the life of the Jewish community, the fauna of bars, the managerial class and its flavour, the lighter side of the well-kept woman, commercialized sports and the imagined life of colonies or races of antisocial beings (Charles Addams' people).

Modern Art Influences.—The diversity of styles of drawing reflected the influence of Post-Impressionist art quite as much as did the use of modern art as a subject for jokes. The great draftsmen who were on the edges of Impressionism (such as Toulouse-Lautrec) had much influence on caricature and cartoon; while the same photomechanical reproduction which forwarded the latter communicated modern painting to a vast public. Nonobjective art can parody only itself; therefore there has hardly been such a thing as a nonobjective or abstract cartoon; but every other phase of modern art has affected caricaturists, except perhaps on the editorial page where a conservatism like that of the literary editorial tends to reign. The loose, almost deliberately ugly method of the Expressionists got into some of the single-cartoon commentators to such an extent that their shorthand was sometimes difficult for those who did not read them daily. The meandering willful line of Paul Klee certainly influenced Saul Steinberg; the Cubists' studies in African sculpture were echoed in Covarrubias and Virgil Partch; the "classical" period of Picasso in R. Taylor and others; the curving economical line of Matisse (oddly enough) in Richard Decker. For some other influences see *Technique*. Occasionally cartoonists parodied one another: Oliver Herford once presented Gibson girls as paper dolls without expression; Al Capp in the comic strip "Li'l Abner" parodied "Dick Tracy" from time to time.

The Cartoon of Predicament or Situation.—The comic strip having taken over the comic presentation of events almost completely, especially since the rise of the one-line joke or picture caption, the modern cartoon became one largely of situation, or of predicament which was stated without a solution's being worked out or suggested. The mother of a side-show circus family, confronted with more than she can manage, simply says that aiter all she has only three hands; a young girl is in ecstasies over a sunset, while behind her a bearded artist-stereotype says, "Too much purple." Meanwhile the longer sort of comic anecdote retreated to a purely oral-aural life or to the bound volume of jokes, where it sometimes had a vignettelike illustration.

The cartoon of situation was certainly not new, but it predominated in the first half of the 20th century. Such a Daumier lithograph as the one showing a very fat woman in crinoline climbing into an omnibus bore no dialogue, but simply the caption, "A mere nothing, and the bus is full." This was a cartoon of predicament. There has tended to be a cluster of these situation subjects: the desert island no larger than a hearthrug, the man who meets a woman walking and imagines her naked (in a scalloped 'balloon'), the flying carpet with novel chauffeur or passenger, the picture gallery with mutual reaction between work of art and viewer, the psychoanalyst's couch, the big-game hunter's trophy room. If the situation was clear, not even one line of joke was required. Such cartoons had a sort of family connection with the earliest caricatures, but they were not merely antiportraits of types, they were portraits with accessories which created the predicament. So were the tiny single woodcut figures which were inserted as pictorial puns into the text pages of *Punch* in the 1840s. But the latter-day predicament may be highly complicated; in the hands of such a cartoonist as George Price, whose split pen line built up tattered edifices of dowdiness, or Emmet, whose fantastic locomotives and wispy codgers were half infernal and half heavenly, the comedy came from an accumulation of frustrating but ludicrous detail. Frustration, that renowned companion of modern life, was dissolved by laughter. Even the presumably invincible American businessman was often represented in cartoons in frustrating situations, often briskly indicated by the graphic lines on the charts in his office (Whitney Darrow was good at these). André François, who worked for both French and British papers, was a master of the rapidly sketched situation; so was the two-passenger cartoonist (a man and a woman jointly using the name "Anton") of *Punch* who kept up the tradition of satire through clothes, being particu-

"Grotesque Head in Profile to the Right" by Leonardo da Vinci (1452-1519), Italian. In the collection of Christ Church, Oxford

"Four Heads" by Albrecht Dürer (1471-1528), German. In the Nelson Gallery of Art, Kansas City, Mo.

Wash drawing of a fat woman seen from the back by Giovanni Battista Tiepolo (1696-1770), Italian. Fondazione Cini, Venice

"Marquis of Spada" by Pier Leone Ghezzi (1674-1755), Italian

Part of a page of sketches by Agostino Caracci (1557-1602), Italian

POPULAR U.S. AND ENGLISH COMIC STRIPS

larly good at pseudo-Edwardian nattiness. In the drawings of the Rumanian-born Saul Steinberg there was almost a parody of the cartoon of situation, for his lines doubled back on themselves and hit their own tails, the hand was indicated as drawing the portrait of which it was a part, or the frustrating details positively engulfed the subject (a wicker chair taken over entirely by its curlicues; tattooing extended beyond the tattooed man; the woman with a lozenge-shaped face, on her lap a baby whose lozenge-shaped face is one-quarter of the larger lozenge).

Yet there were also extraordinarily simple performances: Jean Effel's unassuming little people with their blocky legs moved gently through the trials of Adam and Eve; Jacques Faizant's bad children produced hilarious effects by conveying their concentration in a few lines; Otto Soglow's stenographic vocabulary of forms for human bodies (perhaps slightly indebted to Burgess' *Goops*) was so graphic that it could be used in minuscule dimensions with perfect legibility. On the other hand, Peter Arno's large-scale and heavy outlines, despite simple straightforward design, made his beaky and bosomy figures almost jump off the page (for many years one of his near-bawdy cartoons almost invariably occupied a position in the *Sew Yorker* on the full page immediately after "The Talk of the Town," which suggested that the political cartoon of *Punch* was being ridiculed). Ronald Searle, after a long British career of making spiky and raffish pseudo-Edwardians and fiendish schoolgirls, had a success as an artist for American advertising. A pair of delightful opposite numbers were W. Heath Robinson and the slightly later Rube Goldberg, who on both sides of the Atlantic created wild half-anthropomorphic parodies of intricate machinery. During World War II Bill Mauldin's disenchanted soldiers were proper descendants of Bairnsfather's.

D. COMIC STRIPS

1. The United States.—The U.S. innovation in cartooning went through a rapid youth and adolescence between 1896 and 1907, promptly ramified elsewhere though nowhere so luxuriantly as at home. Within 50 years it became so varied as to include booklets of vocational training, pictorial condensations of books of the Bible and well-known novels, almost naked propaganda devices and drawing styles no longer pretending to be comic, as well as story continuities containing practically nothing funny.

In February and March 1896 the colour-printed Sunday supplement of the *New York World*, which was already stocked with comic drawings, included a sort of aged baby on whose sacklike yellow garment were printed words which he presumably spoke or thought; his language was earthy. The yellow colour was at first a technical experiment; but the colour and the remarks so fascinated the public and were so plainly headed for success that William Randolph Hearst enticed the "Yellow Kid's" creator, Richard F. Outcault (1863-1928), over to his *New York Journal*. Joseph Pulitzer's *World* bought him back, and there were further bids: counterbids and competitive sensations from which the phrase "yellow journalism" arose.

James Swinnerton had, earlier in the '90s, drawn a weekly series, "The Little Bears and Tigers," for the *San Francisco Examiner*; they did not speak but they appeared regularly, and they were funny in the tradition of monkeys aping human ways and also in their own way. In themselves they were no more an absolute novelty than the "Yellow Kid," for there had been continuing casts of characters before, as in Wilhelm Busch's *Max und Moritz*. Rudolph Dirks based his "Katzenjammer Kids" (first appearance Dec. 12, 1897, in the "American Humorist" supplement to the *New York Sunday Journal*) on Busch. The kids' uproarious slapstick humour added to the features of continuing characters and words within the picture another element of the strip. Speeches in balloons (a device older than Gillray) had been used before the end of 1897 by Outcault for minor (usually animal) characters. Dirks soon borrowed them for all his characters, and he also used regular frames in succession.

Though the comic strip was complete in all essentials by the time Outcault's "Buster Brown" began in May 1902, his drawing and Dirks's were still rather fussy and in the contemporary manner of magazine illustration — echoes, so to speak, of Frost and Kemble.

When Swinnerton, moving to New York, started "Little Jimmy" in the *Sunday Journal* early in 1905, he used a new style of simple outlines, barely indicated background and comparatively large forms, adapted to rapid scanning at arm's length.

Clare Briggs, in the *Chicago American* in 1904, had begun a daily strip in which tips on horse races were given through a comic character; the sports pages were tending to bring little repeating commentator figures into their daily caricatures of sporting personalities, but these were single-panel drawings, though there had been a few two- or three-panel vertical continuities; and most importantly, the strips were still restricted to Sunday appearance. In Nov. 1907 Bud Fisher's "Mr. Mutt" (later "Mutt and Jeff") in the *San Francisco Chronicle* put the horizontal strip on a daily basis, at first as a tip sheet but soon as a standard comic. The whole thing had thus arrived at maturity, except for syndication to several papers, which was brought about by Moses Koenigsberg, editor of the *Chicago American* and founder in 1913 of the syndicate later called King Features Syndicate.

The comic strip which emigrated from the United States eventually sent back countermissionaries: at least two British strips, "Pop" and "Colonel Potterby and the Duchess," made successes in the new "old country." (W. A.)

2. Great Britain.—Though British comic strips largely followed the pattern set in the United States, Britain claimed the first regular strip character, ne'er-do-well Ally Sloper (drawn by W. F. Thomas), whose adventures, told in captions beneath a sequence of drawings instead of balloons, appeared in a weekly paper bearing his name in 1884, and persisted fitfully until 1920. But it was a long time before newspaper publishers realized that adults might enjoy comic strips. Lord Northcliffe's weekly, *Comic Cuts*, first published in 1890 (it ran for 60 years), was a big success. It was followed by *Puck* in 1910 and by *Rainbow* in 1914. All three were theoretically children's papers, *Rainbow* appealing to younger readers than the other two.

The shrewd Northcliffe was the first to realize that a strip for children in a daily paper might capture those same children as adult readers. So, in April 1915, "Teddy Tail" first appeared in his *Daily Mail*. Though Teddy has been drawn by a number of artists, he is the longest-lived daily comic strip in Britain. Teddy was followed in 1919 by A. B. Payne's "Pip, Squeak and Wilfred" in the *Daily Mirror* (this strip was finally discontinued in March 1933) and in Nov. 1920 by "Rupert" in the *Daily Express*. But the first realization that adults, too, might enjoy comic strips seems to have come to the *Daily Sketch* in May 1921 when that paper introduced "Pop," drawn by Millar Watt (Gordon Hogg has been the artist since 1948). Eighteen months later came "Dot and Carrie" in the *Stur*. It was drawn by J. K. Horrabin, and reflected that post-World War I phenomenon, the typist. A lull followed until the *Daily Mirror* began to build up its strip "stable," which began in 1929, with "The Pater," an imitation of "Pop," drawn by Harold Earnshaw, followed in 1931 by "Tich," another daily "gag" about an urchin, created by Frank and Steve Dowling. In Dec. 1932 that perky blond "Jane" arrived, as "The Diary of a Bright Young Thing," drawn by Norman Pett (Mike Hubbard took over in 1947). Six years later, when the *Mirror* was publishing "Ruggles" (a domestic strip which later broke new ground by featuring real people and real events), "Buck Ryan," the detective, and "Belinda," the blue-eyed waif, "Jane" became a serial and acquired a habit which made her the forces' "pin-up" of World War II: she regularly managed to lose her clothes. During the war the legend grew among fighting men that the more undressed Jane was the better Allied operations went. Jane continued to find it difficult to remain fully clothed, and remained by far the most widely read strip in the country until her retirement in Oct. 1959.

For a while the *Mirror* published ten strips a day, including strips about cooking, angling, do-it-yourself, gardening and dream interpretation. Later, the paper ran eight—more than any other national daily. Though toward the end of the 1950s Britain's national dailies published a total of 28 strips (of which all but 6 were home-produced), barely half the provincial daily and evening papers published strip cartoons. But a striking development was the rise of the meekly "picture-story" magazines. Pioneered

by "Marilyn" in March 195j. and copying similar publications in France and Italy, these devoted up to three-quarters of their space to romantic stories in strip-cartoon form. Within a few years five of these weeklies had between them built up a total circulation of about 2,500,000 copies a week, a figure which continued to rise.

(E. F. HT.)

3. Types of Comic Strips. — Comic strips fell into a few categories: (1) the gag strip which depended on an anecdote which ended with a bang in the fourth panel, and whose continuity lay in the cast of characters only, as in "Moon Mullins"; (2) the strip with a single protagonist, a story line and changing scene and changing minor characters, such as "Orphan Annie"; (3) conversely, the strip with a fixed cast, a story line and guest characters who lived out a long or short episode, as in "Our Boarding House" (a one-panel comic), or who came to be vanquished and die, as the villains of "Dick Tracy"; (4) the strip which had no story line but was really a cartoon of situation, such as "Bringing Up Father" and "Blondie," each of which moved in an orbit of its own; (5) the passage-of-time strip, such as "Gasoline Alley," whose characters grew up and aged realistically; (6) the special-milieu strip, such as "Joe Palooka" (boxing), "Steve Canyon" (flying) or "Modest Maidens" (the "dumb" dressed-up city girl, a one-panel comic); (7) the adventure or heroic-adversity strip, such as "Superman" or "Buck Rogers"; (8) the fantasy, either quaint ("Krazy Kat" and "Barnaby") or frantic ("Smoky Stover") or based on mock-human animals ("Donald Duck" and family); (9) the chain-of-subjects strip, as practised by Fontaine Fox, T. A. Dorgan, Clare Briggs and H. T. Webster, each of whom moved (sometimes on set days of the week) from bridge to golf or from the joys of childhood to the exploits of a famous strong woman; (10) the series strip, which could be a continuous story of the past like "Prince Valiant," or an "uplift" chronicle like that of the benevolently interfering "Mary Worth," or a limited-term serialization.

4. Comic Books. — The serious form was a favourite of the comic books. Both the newspaper syndicates and other publishers, often publishers of paper-backed books, began in the 1930s to issue pamphlets, usually in colour and printed on paper somewhat better than newsprint, which either assembled and reprinted newspaper strips or used new material aimed at special groups of possible buyers. "Mutt and Jeff" had been reprinted in book form as early as 1911. It was World War II which gave the comic book its tremendous circulation, particularly among people away from home who needed relaxation. The power of these concentrated picture books was soon observed by such differing groups as educators, the clergy and the peddlers of pornography, who promptly went to work. By 1954 the outcry against abuse of this power had led to a code of self-censorship in the industry. An interesting later case of special use of the technique was a comic-book format for a picture story of the nonviolent campaign in Montgomery, Ala., to abolish racial segregation.

III. TECHNIQUES

Obviously a caricature can be created in any medium. Our concern here is primarily with the technique of the published and widely distributed cartoon. There is an accidental kinship between the modern cartoon and the cartoon in the old sense, from which the name was borrowed. A cartoon is literally a *cartone* (in Italian, a "big sheet of paper"). The full-sized plan for a painting required a large sheet or, in the case of a fresco to cover a wall, many sheets. The process of transfer to panel or canvas sometimes involved piercing rows of dots along the drawn lines, through which powdered charcoal could be rubbed; this weakened the paper. Even when transfer by something like carbon paper was chosen, the cartoon was likely to be cast aside once it had served its purpose; cartoons for frescoes were usually transferred by slicing right into the wet plaster through the paper, which was thus cut to pieces. Hence very few old cartoons intended for execution in paint have come down to us, and the chief preserved ones are for tapestries. Ever since the application of photomechanical reproduction to modern cartoonists' drawings, the drawings themselves have been only a sort of fossil of the process rather than precious unique underlying autographs. And although they are not

destroyed by the means of reproduction, yet the reproduction is so precise that in effect the drawing becomes the printed picture.

Further, the fact that mistakes in a drawing made for reproduction can be readily corrected with opaque white, which will deceive the camera but look rather unpleasant to the eye and feel lumpy to the finger, has often caused cartoonists' original drawings to be less immediately attractive than other sorts. So they tend not to be preserved.

1. Early Practices. — In the early days of cartooning, from Romeyn de Hooghe to Gillray and Townshend and Rowlandson, the usual technique was etching. A topical story depended upon speed for its success, and etching was quick. The artist could see what he was doing when he scratched his drawing on the grounded plate, and a technician could do the biting and printing if necessary, and even perhaps the captions and the speeches in balloons, which of course had to be lettered backward. When the comic magazine arrived, the desire to combine comic drawings with stories and verses required the use of woodcut which could be printed with letterpress, and here the artist was almost wholly in the hands of the technician who translated his drawing more or less. If the artist was particular about the right-handedness of action in his characters he had to either draw his picture with left-handed action or get the woodcut specialist to use a mirror as he worked; sometimes right and left were matters of no consequence. In the case of engravings, such as Hogarth's great series, this problem also arose, as it did in lithography. Lithography, however, was a boon to artists, and its appearance at the very beginning of the 19th century was promptly followed by independent prints (Géricault, Goya) and by lithographed papers such as the *Charivari*. Again, the lettering was normally done by an assistant specialist. (See ETCHING; LITHOGRAPH; ENGRAVING, LINE; WOODCUT AND WOOD ENGRAVING; PENCIL DRAWING; PENS DRAWING.)

2. Photographic Reproduction. — Within a generation after the invention of daguerreotypy, means were sought for transferring photographic images to some other sort of multiplying device not requiring negatives. A combination of photography with surface printing from etched metal eventually provided this means. At first it was possible only to reproduce work done in lines, dots or masses of solid dark: gradations were impossible unless they were made by means of laborious pen dotting or spatters. This lack led to a search for papers with a grain which would break up lines and masses into dots or lines, from which photographic reproduction in gradations would result. Many of the drawings made after their own paintings by masters of the Impressionist movement or period were made on such papers for early photomechanical reproduction in periodicals and catalogues. Most were ribbed in imitation of the old mold-made papers with prominent laid lines which gave characteristic texture to the drawings of Hubert Robert and his contemporaries, and which may have given the inventor of these papers his idea. From such devices for physically breaking down areas into patterns of dots or lines, it was not far to the interposition of a screen between the camera film and the drawing to be photographed, which optically reduced lines and masses to dots of greater or lesser diameter but in a uniform pattern. This "half-tone" made it possible to reproduce all sorts of tones, washes and gradations. It led of course to abuses, and there is no doubt that illustrations or cartoons in line and solid tone tend to look better with letterpress than grayed halftones; but the publishers of comic magazines, with some exceptions, are not as exacting about the look of the whole page as the designers of fine printing. There is more and more a tendency to omit framing lines from magazine cartoons and to let them break into text fairly freely. In newspapers, however, because of the needs of members of a syndicate, even one-panel daily cartoons use framing lines and are kept to uniform proportions. (See PHOTO-ENGRAVING.)

3. Comic-Strip Techniques. — The demands of the comic strip are rather different from those of the cartoon-using weekly; in particular, the whole feeling and colour of the strip is keyed to the regular pattern of balloons more or less across the top of the panels. Fairly large forms, a generous use of white space and comparatively few solid blacks are the bases of a general rule resulting from long experience. It is possible to introduce areas

of halftone or of a variety of ready-made checks, stripes or dots by the use of overlays of translucent material in the process of photographing; these are sometimes used to give texture to a costume or to darken a foreground, but many artists do not seem to want to use the great discretion they require and avoid them altogether. Those who do use them give marginal directions, and in the case of syndicated comics the editors have some choice.

A rather fine, almost traditional pen-drawing style came in with the serialization of "Tarzan" as a comic strip early in 1929; an illustrator's style rather than the broad comic style seemed suitable, and it had a strong effect. Those strips which depended less on a gag than on a continued story tended to adopt the style, and "Superman," "Flash Gordon," "Rip Kirby" and the strips of Milt. Caniff, "Terry and the Pirates" and later "Steve Canyon," as well as "Male Call" during World War II, were drawn in a brush-and-pen style of considerable brilliance.

The artist working for reproduction on newsprint must, if he is going to use graded tone, remember that the halftone screen used will be much coarser than that for the glossy papers used in most weekly magazines. Regardless of the destination of his drawing, he usually works with black ink and various pens and brushes: using diluted washes if he expects to reproduce in halftone. Daily editorial cartoonists often use the lithographic crayon, which rapidly draws broad lines and can be slanted to lighten the weight of the line or rubbed to make a mass of dark (Rollin Kirby was a virtuoso). Comic-strip artists almost never use crayon or pencil except as preliminary aids before inking in. The makers of cartoons for magazines have much wider choice, though magazines tend to have their own stylebook for pictures as well as writing.

The syndicates which own the titles; general subject or story line and copyright of comic strips receive the drawn strips in batches from their artists several weeks in advance of the publication dates, which are usually indicated somewhere inconspicuously in the strip. Just as the artists often have assistants and "idea men," so the syndicate editors form an advisory staff which may affect the conduct of a strip. Once settled upon, a strip or a week's strips will be photographed and electrotyped, and from the master metal, after proof impressions taken from it are passed, papier-mâché molds or matrices ("mats" in the trade) will be made in quantity. These are shipped to the subscribing newspapers, and in due course will be used to cast plates for the rotary press. Even at this local level there will occasionally be editing; a sharp eye once in a long time will notice strange lettering in one or two balloons.

Both relief printing and lithography were being done in colour when the comic strip appeared, and the first strips, appearing only in Sunday papers, were coloured. The drawings for Sunday comic pages, normally two or three times as many frames as the daily strips: may be tried out with various colour combinations by their artists, but the final choice lies with syndicate editors and block-makers, to whom marginal directions may be given by the artists. Certain strips have divorced their Sunday story altogether from the weekday continuity, and a few have Sunday and weekday versions by different artists; but most comic strips simply recapitulate on Sunday or provide a longer version of Saturday's climax. See PRINTING.

(1870 ff.); "Champleury" (G. H. Fleury), *Histoire de la Caricature*, 2 vol. (1865), and three expanded subdivisions of this work for the ancient world, the middle ages and the Renaissance; M. H. Spielmann, *The History of Punch* (1895); E. Fuchs, *Die Karikatur der Europäischen Völker* (1901), a rather Marxian view; C. R. Ashbee, *Caricature* (1928); E. H. Gombrich and E. Kris, *Caricature* (1940), which goes to the psychological root of the matter, and "The Principles of Caricature," in E. Kris (ed.), *Psychoanalytic Explorations in Art*, pp. 189-203 (1952); W. Hofmann, *Caricature: From Leonardo to Picasso*, trans. from the German (1957), a purely European view; William Murrell, *A History of American Graphic Humor*, 2 vol. (1934, 1938); A. Nevins and F. Weitenkampf, *A Century of Political Cartoons* (1944); F. Wertham, *Seduction of the Innocent* (1954), the case against comic books; D. Low, *Cartoon History of Our Times* (1939), and many other reprints of Low; Coulton Waugh, *The Comics* (1947); Gilbert Selde, *The Seven Lively Arts*, rev. ed. (1957). Ashbee, Hofmann, Murrell and Waugh have ample bibliographies. There have been numerous volumes of reprints of well-liked cartoons. (W. A.)

CARILLON, a musical instrument consisting basically of fixed cup-shaped bells, with a total chromatic range of at least two octaves.

Originally, four small bells in a row (hence the medieval Latin form *quadrilionem*) were struck by hand with a hammer. From the 13th century onward they were operated mechanically by means of a barrel set with pegs or studs and revolving in connection with the machinery of a clock. The introduction of a keyboard mechanism to the carillon, in Antwerp about 1480, led to a great increase in the instrument's range and expression, and both these methods of playing continued in use. In hand playing, a clavier of levers and pedals is connected mechanically to the bell clappers; this arrangement allows a great range of dynamics. Older automatic systems employ a drum similar to a Swiss music box, where pegs control hammers that strike the outside of the bell.

The oldest carillon is that of 24 bells in the Kijkmuseum, Amsterdam, Neth., cast in 1554 by Pieter van den Gheyn. The carillons of Utrecht, Delft and Amersfoort (cast c. 1660) were among the most musically expressive. In Flanders the outstanding instruments were those at Bruges (cast by Joris Dumery), Antwerp, Ghent and Mechelen (cast by Frans and Pieter Hernony). Mechelen's bells became, however, sadly inferior to those of other carillons, after centuries of mechanical playing and the practising of students. Louvain was the best endowed of the older carillon cities, possessing three large instruments.

The largest modern carillons are those at Riverside church, New York city, and at the Rockefeller chapel, The University of Chicago?each of 72 bells. In the U.S. the carillon was not confined to cast bells alone. Electronics permitted a new type of instrument to be produced, with a tone identical to that of a perfect bell, and electropneumatic or all-electric systems were used for playing the carillon. Several electronic carillons were produced, but the vacuum tube was used only as the magnifier of the bell tones through audio-amplification circuits. As in the conventional carillon, the basic bell tone in the electronic carillon is generated by metal struck by a hammer. The range varies from two to five octaves.

In England carillons have never been widely popular because of the old preference for change ringing (*see* BELL), but some instruments, notably those of the Bournville trust schools, Birmingham, and the Loughborough war memorial, have been built.

Blusic for the carillon, including a set of carillon preludes, was written by the Flemish composer Matthias van den Gheyn (1721-85). Modern carillon music consists largely of arrangements of keyboard music: including fugues and sonatas for piano and organ, and arrangements of works by Handel, Bach, Mozart, Beethoven, Mendelssohn and Wagner.

(J. BL.)

CARINA, one of the three constellations into which the large southern Ptolemaic constellation Argo (*q.v.*) was subdivided. It contains many variable stars and the supergiant star Canopus (*q.v.*).

CARINTHIA (KÄRNTEN), a *Bundesland* (federal state) of the federal republic of Austria. Pop. (1961) 485,016. Area 3,681 sq.mi. (9,534 sq.km.).

Physical Geography.—Stretching from the crest of the Central Alps southward to the crests of the Carnic Alps and Karawanken, which form the boundary with Italy and Yugoslavia, Carinthia is entirely an alpine country but contains also a low-lying area, the Klagenfurt basin. This, with the eastern ranges of the Central Alps, forms lower Carinthia. Upper Carinthia consists of the more mountainous western parts.

The Drau (Drava; *q.v.*) river, from the "Tirol Gate" to its confluence with the Gail river, divides upper Carinthia into a northern part of crystalline rocks dissected by the Drau tributaries and a southern part consisting of the low and well-rounded Gailtal Alps of Triassic limestones and dolomites, the straight, wide and swampy Gail valley and the Austrian section of the rugged Carnic Alps. In the Grossglockner group Austria reaches its highest point

(12,457 ft.) and contains its longest glacier, the Pasterze, 6 mi. in length. There are two large lakes, Weissensee and Millstätter See.

The Klagenfurt basin, structurally formed, is characterized by low altitude and a gently undulating surface. Parts of the structural troughs within it are now occupied by the other two of the main Carinthian lakes, the Ossiacher See and the Wörther See. A southern trough between the Sattnitz hills and the Karawanken is followed by the Drau river and is called Rosental. There are numerous small lakes of glacial origin. During the Ice Age blockage of drainage turned the Lavanttal, also a structural basin, into a lake whose sediments gave rise to the best soils of Carinthia. The mountain groups of lower Carinthia are the Gurktal Alps in the north and the Lavanttal Alps in the east, both part of the Central Alps. Another mountainous part is the northern flank of the Karawanken.

Carinthia is the southernmost part of Austria and in the south has a Mediterranean rainfall maximum in October. Its sheltered position within a mountain frame gives few strong winds: a warm, sunny summer and, because of air drainage, a very cold winter. January means vary between 25° to 19° F. and extremes of -4° F. occur frequently. Rainfall ranges between 32-40 in. in the basins and 98 in. on the surrounding mountains.

The vegetation of Carinthia is greatly varied. On the mountains coniferous trees prevail, but on lower ground deciduous stands are frequent.

History.—This area was the core of the Celtic kingdom of Noricum, which in 16 B.C. became a Roman province. After the breakdown of Roman rule Carinthia became prey of Teutonic tribes, followed by Avars, Slavs and Bavarians. The country was then attached to Bavaria, with the result that peaceful penetration by Bavarian settlers was intensified, and they gradually assimilated the Slav population except for some parts in the southeast. In 976 Carantania, or Carinthia, became a duchy in its own right and included Styria and the present East Tirol. When the line of the Carinthian dukes died out, Carinthia became part of the great but short-lived state of Otakar II of Bohemia. In 1276 it came into the hands of Rudolf I of Habsburg, who in 1286 gave it to the count of Tirol. In 1335, however, it returned to the Habsburgs, where it remained until 1918.

After World War I Yugoslavia claimed southern Carinthia, and in 1919, 128 sq.mi. of territory was ceded to Yugoslavia and 172 sq.mi. to Italy. During the *Anschluss* the *Reichsgau Kärnten* of greater Germany, in addition to present Carinthia, consisted also of East Tirol as well as upper Carniola. It again became a *Bundesland* with its former boundaries in 1945.

Population.—The population at the 1961 census was 485,016. The density was 51 to the square kilometre (about 132 to the square mile). Ethnically: more than 90% of the population of Carinthia is German, the dialect spoken belonging to the Bavarian group. There is, however, a sizable minority of Slovenes. According to their religious denomination, 86.6% were Roman Catholics and 9.8% were Protestants. The principal towns of Carinthia are the provincial capital, Klagenfurt (*q.v.*; 71,447), Villach (*q.v.*; 33,025) and St. Veit an der Glan, its capital until 1518 (10,856).

Government and Social Conditions.—The *Land* government, elected by and responsible to the provincial diet (*Landtag*), is elected for four-year periods by popular vote. The *Landtag* is a legislative body, but the acts it passes must be approved by the federal government. Carinthia is divided into nine administrative districts, and local government is controlled by elected burgomasters and town and commune councils.

There is a fairly high proportion of larger holdings (28% are more than 50 ac.), and there are considerable possibilities of employment in industry and trade. However, difficulties are evident in the areas of dispersed settlement: distances from schools and the pronounced conservatism of the people. The custom of undivided inheritance is prevalent.

The Economy.—Farming uses about 46% of the surface and iorstry 44%, the highest after Styria. Wheat, rye and oats are grown in the Klagenfurt basin and in Lavanttal, maize (corn) in the Gail valley and fruit along the lake shores. More important

and widespread is livestock farming. Most of the forests are privately controlled, mainly by owners of large farms and estates. Timber production is considerably in excess of natural growth.

Iron ore (about 200,000 metric tons produced annually) is mined at Hiittenberg, and lead-zinc-molybdenum ore west of Villach. Austria's chief resources of magnesite (400,000 tons annually) are near Spittal an der Drau. Brown coal is produced in the Lavant valley, and associated with it is the thermoelectric power station at St. Andrä. There are hydroelectric power plants at Schwabegg and Lavamünd, and the Reizeck-Kreizeck reservoir plant, with a head of 1,800 m. (5,905 ft.), is in the Moll valley. Industry is not so well developed. Timber is the most important raw material, with paper and cellulose plants at Villach, the leading industrial centre, and at Wolfsberg, in the Lavant valley.

Carinthia is crossed by a west-east railway line, Marburg-Forzezza (Franzenfeste), and by the north-south Vienna-Tarvisio (Tarvis) line. Villach is Carinthia's main railway junction. The main road to Salzburg is via the Katschberg pass (5,384 ft.), for the Grosslockner-Hochalpenstrasse, an important route into Italy, which climbs to more than 8,000 ft. is open only during the summer months. The Vienna road leads via Neumarkt pass into the Mur valley. There is an airport at Klagenfurt, but air traffic is relatively unimportant.

CARINUS (MARCUS AURELIUS CARINUS) (d. A.D. 285). Roman emperor, 283-285. Probably named Numerius like his brother. He was sent by his father, the emperor Carus, with the title of Caesar to the army of the Rhine in 282 and became emperor in the west on his father's death in the summer of 283, his brother Yumerian becoming emperor in the east. After a campaign on the Rhine, he returned to Rome, where he celebrated games in honour of Carus' eastern victories, in Sept. 284. A few weeks before, his brother had been replaced in the east by Diocletian (*q.v.*), who spent the winter consolidating his rule in the Balkans. In the spring of 285, near Verona, Carinus defeated Aurelius Julianus, the governor of Venetia, who had proclaimed himself emperor, but a few weeks later, while in Moesia, he was killed by his own troops in the course of a battle against Diocletian on the banks of the Margus river (Morava in Yugoslavia). (J.N. R. M.)

CARISBROOKE, a village in the Isle of Wight, Eng., lies 1 mi. S.W. of Newport, in which municipal borough it was incorporated in 1933. Pop. (1951) 3,328. Lukely brook separates the village from the steep hill on which stands the castle. This shows three main periods of building—Roman, Yorman and Elizabethan. The Roman fort, the entrance of which is still visible on the eastern side, probably dates to the end of the 3rd century A.D. After the Norman Conquest William Fitz Osbern built a motte and double bailey of earthwork and timber. This castle is mentioned in the Domesday survey, and it was there that William I arrested Bishop Odo of Bayeux in 1082. Early in the 12th century the stone keep and the present stone curtain wall round the western bailey were built by the De Redvers family, who held the castle until Isabella de Fortibus sold it to Edward I in 1293. Late in the 16th century, under the threat of Spanish invasion, the castle was enclosed by an elaborate outer fortification designed by Federigo Gianibelli. Charles I was imprisoned there from Nov. 1647 to Sept. 1648 and twice tried unsuccessfully to escape. Particularly interesting is the medieval well, 161 ft. deep, the only one in Great Britain where the bucket is still drawn up by a donkey. Formerly the residence of the governors of the island, the castle contains the Isle of Wight museum. The castle is administered as an ancient monument by the ministry of works and is open to the public.

The parish church of St. Mary has a fine Perpendicular tower (15th century) and an early Norman nave. The church registers include a note of the Spanish Armada's passing the Isle of Wight in July 1588. A Roman villa of basilican type was discovered in the vicarage garden in 1859. (J. D. Jo.)

CARISSIMI, GIACOMO (1605–1674), one of the greatest Italian composers of the 17th century, chiefly notable for his oratorios and secular cantatas? was born at Marino, near Rome, and baptized there on April 18, 1605. Following brief appointments at Tivoli and Assisi, he settled in Rome in the late 1620s as director of music at the church of S. Apollinare and retained this post until he died (in Rome, Jan. 12, 1674).

Although not an operatic composer, Carissimi helped to satisfy the Italians' inordinate enthusiasm for opera, which was performed in few centres and only at certain times of the year. He made its pastoral or dramatic content and idiom available in the home and in the church through his numerous cantatas; consisting of sequences of recitatives, ariosos and arias or duets, and his 16 oratorios, which are short "substitute operas" on Old Testament subjects, performed during Lent, when operas were forbidden. In his cantatas he consolidated the pioneer work of Luigi Rossi, but in oratorio he was himself a pioneer.

Carissimi's works are marked by emotional balance and an ideal fusion of the lyrical and the dramatic; and when working on a large scale his pronounced feeling for tonality prevents any tendency to diffuseness. His genius is well displayed in his finest oratorio, *Jephtha*, lasting about 20 minutes, where both solo narrator and chorus act as commentators and the latter also take the roles of opposing groups in the story. The final chorus is particularly fine. Balance is obtained by contrasting solo arias, such as the beautiful one of Jephtha's daughter. Handel expanded this basic scheme in his oratorios: and Carissimi also exercised great influence on later music not only through his music but also through his numerous pupils.

See also CANTATA; ORATORIO.

See E. Vogel, *Die Oratorientechnik G. Carissimis* (1928). (N. Fo.)

CARLETON, WILLIAM (1794–1869), Irish novelist, outstanding as an observer of peasant life, was born at Prillisk (near Clogher), County Tyrone, Feb. 20, 1794. He was educated at peasant "hedge schools" and was originally intended for the priesthood. In 1818, however, he made his way to Dublin, where, after enduring poverty, he was commissioned to write stories illustrating the superstitions allegedly encouraged among the peasantry by the Roman Catholic Church. He soon discovered his true powers, however: the tracts became *Traits and Stories of the Irish Peasantry* (1830), his finest work. From this until his death in Dublin on Jan. 30, 1869, Carleton wrote voluminously. His best-known novels are *Fardorougha the Miser* (serialized 1837–38; in book form, 1839), *Valentine McClutchy, the Irish Agent* (1845), a vehicle for his views on the Irish land question, and *Tize Black Prophet* (serialized; 1846; in book form, 1847), a novel about the Great Famine, though his best work is undoubtedly contained in the *Traits and Stories . . .*, of which a second series appeared in 1833. These wonderful genre pictures of Irish peasant life before the famine are full of vitality and humour, an unforced tenderness toward his subject and an occasional dark intensity of foreboding. Carleton began an autobiography, which was completed by D. J. O'Donoghue and published as *Tize Life of William Carleton* (1896). (A. CR.)

CARLILE, RICHARD (1790–1843), English radical and freethinker, was a notable and successful champion of the freedom of the press. A shoemaker's son, he was born at Ashburton in Devon on Dec. 8, 1790, was educated at the village school and by 1813 was a journeyman tinman in London. Influenced by Thomas Paine's *Rights of Man*, he was converted to radicalism and from 1817 was a vigorous salesman of *The Black Dwarf* and other extreme radical weeklies. In 1817 William Sherwin made Carlile his agent for the production and sale of *Sherwin's Weekly Political Register*, with control of his shop. Carlile immediately published several radical and deist works, wrote *The Political Litany* and was consequently imprisoned for 18 weeks for blasphemy. In 1818 he published the works of Thomas Paine and his followers, for which he was fined £1,500 and sentenced to three years imprisonment (1819); the sentence was later extended. Carlile became sole proprietor of *Sherwin's Weekly Political Register* in 1819, and, changing its name to *The Republican*, he edited it from prison. When the police were not in possession, his shop was kept open

by his wife, his sister and several supporters, who mere, in turn, imprisoned, the prosecutions being encouraged by a public subscription headed by the duke of Wellington. But Carlile was victorious in 1825, when the government decided to discontinue the prosecutions. After his release he edited various new weeklies and between 1829 and 1831 conducted discussions in the London Rotunda, which became the centre of radical and free thought activities. Carlile was a pioneer of almost every extreme radical cause, including abolition of monarchy, completely secular education and the emancipation of women. He considered that freedom of speech and the propagation of knowledge were far more important than specific political and social reforms. He served further terms of imprisonment after 1825, and when he died, in London on Feb. 10, 1843, he had spent a total of nine years and four months in prison.

CARLILE, WILSON (1847–1942), founder of the Church Army (*q.v.*), was born in Brixton, London, on Jan. 14, 1847. His ambition to make a fortune in business was changed to that of "serving Christ and the men he loves" as a result of a startling experience of conversion, and he was ordained in the Church of England. In 1882 he started training lay people as evangelists in the belief that their ministry might be successful in reaching the many nonchurchgoing members of the working classes. Profoundly disturbed at the appalling conditions under which many slum dwellers lived, he launched the social work of the Church Army (1888). He was called the "archbishop of the gutter." He became a prebendary of St. Paul's cathedral (1906) and was honorary chief secretary of the Church Army until his death on Sept. 26, 1942, at Woking, Surrey.

See A. E. Reffold, *Wilson Carlile* (1947).

(E. W. CX.)

CARLINGFORD, CHICHESTER SAMUEL FORTESCUE, BARON (1823–1898), British statesman, who helped frame Gladstone's conciliatory Irish legislation, was born at Glyde, County Louth, Ire., on Jan. 18, 1823. Elected member of parliament for Louth in 1817, he married the charming and talented former Countess Waldegrave in 1863. He was appointed chief secretary for Ireland in 1865, at a time when the Fenian agitation was very active. Fortescue had always opposed religious discrimination and helped Gladstone in carrying the disestablishment of the Anglican Church in Ireland. He also did the groundwork for the Land act of 1870, which recognized the tenant's right to compensation for improvements. But he was not considered forceful enough as Irish secretary and in 1871 was transferred to the board of trade. There he remained until 1874 when, rejected by his constituency, he was raised to the peerage as Baron Carlingford. He was appointed lord privy seal in 1881. Gladstone used his experience of Ireland in framing the second Land act (1881), which established fair rent tribunals. But Carlingford declined to follow Gladstone in adopting the policy of Home Rule for Ireland and withdrew from active politics in 1886. He died at Marseilles, France, on Jan. 30, 1898, and the title became extinct. (D. G.)

CARLINGPORD (CÁRLINN), a market town and port in County Louth, Republic of Ireland, on the north side of Carlingford peninsula and at the foot of Slieve Foy. Pop. (1956) 565. The peninsula is separated from the Mourne mountains by Carlingford lough, an inlet of the Irish sea, sometimes claimed as the spot where St. Patrick landed in 432. Carlingford is built round the ruins of a castle, dating from the reign of King John, and the abbey, a 14th-century Dominican house. There are remains of 16th-century and earlier fortified houses, some of them occupied. The oyster and seaweed beds are valuable.

CARLISLE, EARLS OF. In 1322 SIR ANDREW DE HARTCLA (Westmorland) was created earl of Carlisle after the battle of Boroughbridge (see ENGLISH HISTORY). Next year he was executed for treason, having been detected in intriguing with the Scots, and his title was forfeited.

In 1622 the title was conferred upon JAMES HAY (*c.* 1580–1636), son of Sir James Hay of Kingask. He had been a gentle-

man of the bedchamber and a "prime favourite" of James I, who had already created him Baron Hay of Sawley (1615) and Viscount Doncaster (1618). He was employed on diplomatic missions to France (1616-24), to Germany (1619-20) and to Lorraine and Savoy (1628); he was interested in the plantation of New England and received a grant from James I (confirmed in 1627 by Charles I) of all the Caribbean islands, including Barbados. According to the earl of Clarendon, "he left behind him a reputation of a very fine gentleman and a most accomplished courtier, and after having spent in a very jovial life above £400,000 which upon a strict computation he received from the crown; he left not a house nor an acre of land to be remembered by."

In 1617 Carlisle had married, as his second wife, Lucy (1599-1660), second daughter of Henry Percy, 9th earl of Northumberland. Her beauty and wit, which were celebrated by the leading poets of the day, and her influence with the queen made her a conspicuous figure at the court of Charles I. She formed a close friendship with the earl of Strafford, but after his execution became an equally close friend of John Pym. Both men highly valued her friendship, which probably sprang from a taste for political intrigue, for there seems to be no justification for the charge that she was their mistress. She appears, however, at least in 1641-42, to have betrayed the confidences of both sides. Her greatest service to the parliamentary opposition was to forewarn them of the king's intention to arrest the five members (Jan. 1642). In 1647 she was accused of intriguing with the Presbyterians against the army, and during the Civil War she showed great zeal and activity in the royalist cause. She was imprisoned in the Tower from March 1649 until Sept. 1650 and, according to a royalist newsletter, was even threatened with the rack. She died on Nov. 5, 1660.

On the death of the 2nd earl, JAMES HAY, without issue in 1660, the peerage became extinct in the Hay family.

CHARLES HOWARD (1629-85), 1st earl of Carlisle in the Howard line, was the second son of Sir William Howard of Naworth, Cumberland. He became a Protestant in 1645. He bore arms on the royalist side in the Civil War but became a supporter of the Commonwealth. He bought Carlisle castle and became governor of the town; was appointed high sheriff of Cumberland (1649-50); and fought with distinction under Oliver Cromwell at the battle of Worcester, later becoming captain of the protector's bodyguard. He sat in the parliaments of 1653, 1654 and 1656; became a member of the council of state (1653); and was appointed deputy major general of Cumberland, Westmorland and Northumberland (1635). In 1651 he was included in Oliver Cromwell's house of lords. In 1659 he urged Richard Cromwell to defend himself by force against the army leaders, and after Richard's fall he was imprisoned twice. Again elected to parliament in April 1660, he was after the Restoration created Baron Dacre of Gillesland, Viscount Howard of Morpeth and earl of Carlisle (April 30, 1661). He became lord lieutenant of Cumberland and Westmorland and in 1672 of Durham, and held various other military appointments in the north. He went on embassies to Russia, Sweden and Denmark in 1663-64 and took the garter to Charles XI of Sweden in 1668. In 1673 he became deputy earl marshal, and in 1677 he was appointed governor of Jamaica and reappointed governor of Carlisle. He died on Feb. 24, 1685.

FREDERICK HOWARD (1748-1825), 3rd earl, was one of the commissioners sent out by Lord North to attempt a reconciliation with the American colonies in 1778. He was lord lieutenant of Ireland, 1780-82. He opposed William Pitt's policy on the regency question in 1788-89 and on the eastern question in 1791, but abandoned the opposition on the outbreak of war with revolutionary France. He opposed the enactment of the 1815 Corn law. He was the author of some political tracts, a number of poems and two tragedies, *The Father's Revenge* and *The Stepmother*, highly praised by his contemporaries. In 1798 he became guardian of Lord Byron, the poet, who lampooned him in *English Bards and Scotch Reviewers*. He died at Castle Howard, Sept. 4, 1825.

GEORGE HOWARD (1773-1848), 6th earl, who served under the "ministry of all the talents" (1806-07) and was lord privy seal

in 1827-28 and 1834, also made some minor contributions to literature.

His eldest son, GEORGE WILLIAM FREDERICK HOWARD (1802-64), 7th earl, after a distinguished academic career at Eton and Christ Church, Oxford, supported the parliamentary reform movement and became chief secretary for Ireland, 1835-41, lord lieutenant of Ireland, 1855-58 and again 1859-64. He, too, was the author of poems, a tragedy, a travel diary and other works. He took a warm interest in the reformation of juvenile criminals and established a model reformatory on his own estates. He died unmarried at Castle Howard, Dec. 5, 1864, and the title passed to his brother and then to a nephew. GEORGE JAMES HOWARD (1843-1911), 9th earl. He took a minor part in politics and was a strong supporter of the temperance movement but achieved greater distinction as a connoisseur of art and a painter. He died at Hindhead, April 16, 1911. His wife, Rosalind Frances (1845-1921), youngest daughter of the 2nd Lord Stanley of Alderley, was an even more enthusiastic temperance advocate, was a staunch friend of W. E. Gladstone, was keenly interested in women's education and became an advocate of woman suffrage. (R. B. Wm.)

CARLISLE, a city, municipal and parliamentary borough and the county town of Cumberland, Eng., 298 mi. N.N.W. of London and 9 mi. S. of the Scottish border by road. Pop. (1961) 71,112. Area 9.5 sq.mi. It lies on the river Eden about 8 mi. above its mouth in the Solway firth and at the junction of two tributaries from the south, the Caldew and the Petteril. Silloth, on the Irish sea, is the nearest port (23 mi. W.). Carlisle is one of the principal railway centres in Great Britain.

The area was first reached by the Romans in the late 70s of the 1st century A.D., and their leaders, Petillius Cerealis and Gnaeus Julius Xgricola, must have consolidated themselves quickly, for very early Roman pottery has been found in Carlisle. Within the next 100 years it was transformed from a settlement of crude British huts into the Romano-British Luguwallium, a town of considerable civic comfort. The large Roman fortified camp of Petriana (now in the suburb of Stanwix) housed a squadron of cavalry 1,000 strong and lay just north of the Eden on the line of Hadrian's wall (*q.v.*), which was commenced in A.D. 122 across the Tyne-Solway isthmus. The Romans held the wall and city until the reign of Magnus Maximus (*c.* 384-388), and almost every excavation in the city centre yields some relic of Roman occupation. Much of the original structure of Carlisle castle is of stones from Petriana.

Carlisle (Caer Luel of the Britons, also Karliol, hence its name) is mentioned in 685 when it was bestowed by Egfrith on St. Cuthbert to form part of his see of Lindisfarne, and when St. Cuthbert visited it in 686 he was shown the ancient walls and a Roman fountain. In the 9th century it was completely destroyed by the Danes, and in the 10th century Edmund I, the grandson of Alfred the Great, gave it (together with the whole of Cumberland) to Malcolm I, king of the Scots. Because of this the city does not appear in Domesday Book, and in *Macbeth* Shakespeare refers to the "prince of Cumberland" as successor to the Scottish throne. William II, called Rufus, claimed the city as English in 1092 and set up the walls and castle. For the next 650 years Carlisle knew little peace. In 1135 David I of Scotland again captured it; he strengthened the castle and died there in 1153. In 1157 Henry II reclaimed Carlisle from the Scottish king, and, with the granting of its first charter in 1158, the city became permanently English. This charter and a later one of Henry III in 1251 were both destroyed by fire but were confirmed by the charter of Edward I in 1293. Edward I held three parliaments in the castle, and in 1307 the hull of excommunication was read against Robert I the Bruce in the cathedral before Edward set out on his last Scottish campaign. He died just outside the city. In 1541 Henry VIII strengthened and modified the castle in view of the growing use of artillery, and had the citadel constructed as a subsidiary fortification. Elizabeth I carried out further extensive repairs, although her general policy toward the Scots was more conciliatory. In 1568 Mary (Mary Stuart) fled from Scotland and came to the castle as a guest. She remained as a captive and from Carlisle began her slow journey southward toward the execution block.

The charter of Edward III in 1352 established the city's right to "a free guild and a free election of their mayor and bailiffs," but it was with the accession of Elizabeth I that the first serious attempt was made to establish law and order. In 1561 the Dormont Book, still extant, was drawn up, setting out the oaths of the mayor (still sworn to by each succeeding mayor) and various council officials and enumerating certain bylaws. The principal, or governing, charter is the one of 1638 granted by Charles I which renews former charters and grants in addition that the royal sword, accompanied by mace-bearers, be borne before the governing body.

The longest siege endured was that of Gen. Alexander Leslie, earl of Leven, in 1644–45. It was then that almost two-thirds of the cathedral nave and much of the cloisters were pulled down to repair damage to the castle and walls. The city again fell 100 years later, this time to Charles Edward: the Young Pretender, but was retaken a few weeks later by the duke of Cumberland.

The Cathedral. — Like the castle, Carlisle cathedral, originally the church of an Augustinian priory (founded 1093), was started by William II, and the bishopric was created in 1133 by Henry I. Much of the building was gutted by the fire of 1292 and again in 1392. Only two bays of the Norman nave remain, and its arches exhibit a remarkable distortion caused by the sinking of the foundations; it is now a memorial chapel to the fallen of the Border regiment. The central tower on the cruciform building was added in the early 15th century. The choir is ornate and beautiful and retains the original 15th-century woodwork; it has some particularly fine misericords and a little-known head of Henry IV at about the time of his death. The huge Decorated east window, with its elaborate tracery, is one of the finest of its kind in Europe and contains some of the original glass dating from the mid-14th century. The fraternity, with its splendid dining hall, has a beautiful reader's pulpit. Sir Walter Scott was married in the cathedral in 1797.

The diocese covers the counties of Cumberland (except Alston parish), Westmorland (except Firbank parish) and part of north Lancashire. Convents of the Black and Gray Friars were founded in 1233, and there was a hospital for lepers.

The City. — Other notable buildings are the town hall (1717), the courthouses (which replaced the old citadel), the 14th-century guildhall (the home of the eight guilds which formerly governed the city) and Tullie House museum (built in 1689 and now the city museum and art gallery). Fragments of the city wall remain, and there is a market cross dated 1682. The corporation plate includes two 16th-century racing bells, the oldest prizes for horse racing in the country. The Border regiment is quartered in the castle, and the regimental museum is open to visitors. Only the castle keep is now of special interest. Thomas Woodrow, grandfather of Pres. Woodrow Wilson, was pastor of the Lowther Street Congregational church, 1820–35.

The constant wars and border raids impeded commerce until the second half of the 18th century, and the city's true commercial prosperity began with the railway development. The Newcastle-Carlisle railway (1835) was the first east-to-west line in England. Carlisle became a county borough in 1914 and is the shopping and marketing centre for a wide area. A belt of public park land is preserved on either side of the river. The area of the borough was extended in 1951 to provide additional land for housing. There are colleges of art and technology and a municipal airport. The principal industries are the manufacture of biscuits (cookies), textiles, metal boxes, sweets (candies), cranes and hats. The sale of intoxicating liquor became a state undertaking in 1916 ("Carlisle Experiment"), conducted first by the Liquor Control board and later, under the Licensing act of 1921, by the Carlisle and District State Management scheme.

CARLISLE, a borough of Pennsylvania, U.S., and the seat of Cumberland county, lies in the Cumberland valley, 18 mi. S.W.

of Harrisburg, the state capital. The county and town derive their names from their English counterparts. The site was first settled in 1720 by James le Tort, a French-Swiss Indian trader. Cumberland county was created in 1750, and Carlisle was designated the county town in 1751. It was incorporated as a borough in 1782.

A provincial fort was built at Carlisle in 1756 during the French and Indian War, and the town became a munitions centre during the American Revolution. It was also the home of James Wilson, signer of the Declaration of Independence, and of Molly Pitcher, Revolutionary War heroine. In the American Civil War Carlisle was occupied by Confederate troops, June 27–30, 1863, and was shelled on July 1 by Confederate cavalry under Fitzhugh Lee.

Carlisle has a distinctive atmosphere resulting from its surviving colonial structures and from the presence of Dickinson college (chartered 1783) and the unaffiliated Dickinson school of law (founded 1834). It is the site of Carlisle barracks, after 1951 the seat of the Army War college. The barracks from 1879 to 1918 housed the Carlisle Indian school, where Jim Thorpe began his athletic career.

Carlisle manufactures rugs and carpets, tires, steel castings, radio parts, paper, textiles and clothing. It adopted the commission-manager form of government in 1921.

For comparative population figures see table in PENNSYLVANIA: Population. (S. W. H.M.)

CARLISM (Spanish **CARLISMO**), the name of a Spanish political movement, now more frequently called Traditionalism, which has been the most persistent counterrevolutionary force in Spanish politics since the 1820s and originated in support of the claims of Don Carlos (*q.v.*; 1788–1855) to the throne on the death of his brother Ferdinand VII in 1833. Don Carlos and his supporters denied the validity of Charles IV's pragmatic sanction of 1789 (revoking the form of Salic law introduced into Spain by Philip V in 1713), which was first made public by Ferdinand VII on March 29, 1830, and was subsequently used to ensure the succession of his daughter Isabella (born on Oct. 10, 1830). Two full-scale Carlist wars during 1833–39 and 1872–76 (see SPAIN: History), together with many lesser struggles in the 1830s and 1850s, provided evidence of the movement's resilience and, although considerably weakened as a political force, the spirit of 19th-century Carlism was reflected in the fervour of the Navarrese *requetés* during the civil war of 1936–39 and is still represented by the Traditionalists.

In spite of being based on a strict legalistic claim, the popularity of Carlism has been mostly due to the dynamic appeal of religious fanaticism and to championship of the *fueros* of the Basque provinces, Navarre, and Catalonia, which were threatened by the liberals' centralizing policies after 1833. Carlism claims to be a national movement, but it has been primarily a rural phenomenon, rooted in the prosperous independent peasantry of these same regions. Xenophobic, antiliberal, antiparliamentary, with a strong moralistic and romantic streak, fiercely intolerant of non-Catholics, the Carlists believe in a traditional monarchy, with a king subject to natural law, and aided by a council of clerics and grandees. A revived Inquisition would, they argue, enforce uniformity of religious belief, and the resulting national cohesion would enable wide grants of provincial autonomy to be made. Later developments of Traditionalist theory under Juan Vázquez de Mella foreshadow the corporative state, with an assembly debating in secret, in which deputies would represent corporations. The principal failure of Carlism—that of not being able to develop from a regional into a national movement—has been due to its inability to resolve a number of dilemmas. By tying their cause to a dynastic claim, the Carlists often inhibited their freedom of action when their claimant was either incompetent or out of sympathy with traditional aims. By claiming to represent the purity of Catholicism, they have frequently embarrassed the church, particularly after the restoration of the monarchy in 1874 and during the pontificate of Leo XIII, when the church was trying to reach a *modus vivendi* with the liberal state. The longevity of Carlism may be explained by the innate traditionalism of a society where systems of tenure and social organization have encouraged political

and ideological solidarity against external forces of change. The Carlists have been a party of action, and their traditionalism is a mystique impervious to the arguments of political realism.

The first Carlist pretender abdicated in 1845 in favour of his eldest son Don Carlos (q.v.; 1818–61), who continued his father's tradition of revolt against the liberal branch of the family. He was succeeded in 1861 by his younger brother Don Juan (1822–87), who renounced his rights in favour of his eldest son Don Carlos (q.v.; 1848–1909), on Oct. 3, 1868. The new pretender, however, was unable to turn to his advantage the revival which Carlism experienced after the deposition of Isabella II. Attempts to promote a parliamentary party with a national appeal were rejected by Don Carlos in 1872 when he returned to the "old" Carlist tradition of mass peasant risings and mobilized his levies to resist the new king Amadeo. This was a turning point in the movement's history: it was now committed to four years of civil war in which popular sympathy gained since 1868 was lost and which, by forcing the party back to its regional base, drove it into competition with more forceful regionalist movements emerging with the development of Basque and Catalan industrialism. Only Navarre remained a reservoir of Carlist strength.

Since the 1880s the party's history has been characterized by a series of conflicts between those who argued for understandings with other Catholic parties accepting the framework of parliamentary liberalism (or with those parties resisting the encroachments of centralized state power) and those for whom tactical alliances implied a watering down of principle. The latter point of view found expression in the creation (1918) by Vázquez de Mella of the Traditionalist party, which subsequently became the principal organ of Carlism. It was merged in 1937 by Gen. Francisco Franco with the Falange, with which it had little in common.

Don Carlos was succeeded as pretender in 1909 by his only son Don Jaime (1870–1931), duque de Madrid, on whose death without issue the succession passed to his uncle Don Alfonso Carlos (1849–1936), duque de San Jaime. With Alfonso's death in Vienna on Sept. 29, 1936, the Carlist line became extinct, but he had nominated as his successor Francis Xavier of Bourbon-Parma (styled Charles IX by his adherents in Spain). By 1960, however, most Carlists had accepted the recognition given in 1958 by prominent members of their party to the son of King Alfonso XIII, Don Juan, conde de Barcelona, as rightful pretender to the throne. For a genealogical table, see BOURBON.

CARLOFORTE, capital of the small island (6 mi. by 5 mi.) of San Pietro off the southwest coast of Sardinia. Pop. (1957 est.) 7,324 (commune). It lies on the east coast of the island, 6 mi. W. by sea from Porto Vesme, on the Sardinian coast. It was named after Charles Emmanuel (Carlo Emanuele) III of Savoy, who resettled the island, after centuries of desertion, in 1738 with Genoese fugitives from the north African island of Tabarka. Today tunny fishing is its main industry. It has an observatory set up in 1899 by the International Geodetic survey as one of several special latitude observatories all on the parallel of 39° 8' N. Steamers ply from Carloforte to Porto Vesme and the island of Sant' Antioco, which is connected to the mainland by rail and road.

CARLOMAN, the name of several Frankish princes of the Carolingian family (see CAROLINGIANS). Four of them are particularly noteworthy.

CARLOMAN (d. 754), the elder son of Charles Martel (q.v.). On his father's death (741) he divided with his brother Pepin the mayoralties and authority over all the Merovingian territories, taking for himself all the northeast of the kingdom round Austrasia. He was often at war against the rebellious Alamanni and the independent tribes of Saxons and Bavarians. He helped St. Boniface to establish his archbishopric and supported his missionary work. The council convened by Carloman at Estinnes in Hainaut in 743 laid the foundations of later Carolingian administration. He retired to a monastery in 747 and died at Vienne on Aug. 17, 754, having spent his last few years at Monte Cassino in Italy.

CARLOMAN (751–771), the younger brother of Charlemagne, with whom, at the instance of their father, Pepin the Short, he was anointed king of the Franks in 754 by Pope Stephen III (II) in the abbey of St. Denis. Carloman inherited the eastern part of Pepin's lands (768). He favoured alliance with the Lombards and married Gerberga, a daughter of their king, Desiderius. Carloman died at Samoussy (Aisne), on Dec. 4, 771, and Charlemagne then annexed his territory.

CARLOMAN (828–880), the eldest son of Louis the German. Carloman rebelled against his father in 861 (together with his father-in-law Ernest, count of the Bohemian march) and in 863, but in 865 was entrusted by Louis with a share in his authority, being granted jurisdiction over Bavaria and Carinthia. After this he remained loyal to his father, even helping to suppress the rebellion of his two younger brothers (866) and taking part in a campaign against the Moravians (869). The latter by 874 were forced to admit Frankish supremacy. After the death of the emperor Louis II (875), a faction in northern Italy, led by the emperor's widow, Engelberga, favoured Carloman as candidate for the imperial crown; but Pope John VIII preferred Charles the Bald. When Louis the German died (876), Carloman succeeded him as king of some of the German territories. In undisputed control of Bavaria, he promptly crossed the Alps on the death of Charles the Bald (877) and was recognized as king in northern Italy. The pope, however, still refused him the imperial crown. Falling ill, Carloman had to renounce his lands and titles to his brother Louis the Younger. He died at Öttingen in March or Sept. 880. His illegitimate son Arnulf became emperor in 896.

CARLOMAN (d. 884), the second son of Louis II le Bègue or the Stammerer. On Louis II's death (879) Carloman was associated with his brother Louis III as king of the West Franks, but both, as the children of a first marriage which had been unacceptable to their grandfather Charles the Bald, had difficulty in obtaining recognition. On Louis' death (882) Carloman became sole ruler. He died while hunting on Dec. 12, 884.

CARLOS I (1863–1908), king of Portugal from 1889 to 1908, was born in Lisbon on Sept. 28, 1863, the son of Luis I and of Maria Pia of Savoy, daughter of Victor Emmanuel II of Italy. He married Marie Amélie of Orléans, a granddaughter of the French king Louis Philippe, in 1886 and succeeded his father on Oct. 19, 1889. Forces generated by mistakes made before his time proved to be the undoing of this talented and intelligent man, who was also known for his competent paintings and oceanographical studies. At home, republicans, disaffected monarchists and freemasons kept up a running opposition. Popular indignation over the British ultimatum of 1890 (see PORTUGAL: History) was directed against the throne and resulted in the republican revolt at Oporto (Jan. 1891). There were also rebellions in Portugal's overseas territories. Although visits of foreign rulers temporarily bolstered the prestige of the monarchy, discreditable public discussions about the king's civil list and private life ultimately jeopardized the throne. After the revolt of 1906, Carlos allowed João Franco to establish a dictatorship; Franco's repressive measures increased the activities of the antimonarchical secret societies, and they soon bore fruit. Another revolt broke out on Jan. 28, 1908. The king, then at Vila Viçosa, hurried to Lisbon. On Feb. 1, the day of his arrival there, Carlos and the crown prince, Luis Filipe, were assassinated.

CARLOS, DON (1545–1568), principe de Asturias, was the son of Philip II of Spain. His tragic death and his supposed love for his stepmother Elizabeth of Valois have often been used as a romantic plot, notably by Schiller and by Verdi. Carlos was

born at Valladolid on July 8, 1545, the only child of Philip's consanguineous marriage with Maria, daughter of John III of Portugal. All the most sinister hereditary characteristics of the houses of Trastámara, Avis and Habsburg seem to have combined in Don Carlos to produce a sickly, gluttonous, sadistic megalomaniac. Carlos repaid his father's indulgence with mortal hatred. All attempts to introduce him to political responsibility through membership of the king's councils served only to show that he was completely unfit for any authority, while inflaming his ambition. Eventually, Philip had to admit that his heir was a danger to the state, and on Jan. 18, 1568, he arrested him, writing to his sister that he must do so to fulfill his duties as a Christian prince. Carlos died in prison in Madrid on July 24, 1568. His habit of sleeping on ice in his stifling prison and his gluttony probably caused his death. There is no evidence that he was murdered, by Philip's orders or otherwise, though, within a few days, rumours of murder were whispered even in the court itself.

CARLOS, DON (1788–1855), conde de Molina, the first Carlist pretender to the Spanish throne and the second surviving son of King Charles IV, was born in Madrid on March 29, 1788. He was imprisoned in France from 1808 to 1814 and led an uneventful life until he incurred the hostility of the Spanish radicals during the constitutional period (1820–23). Although pious and rigidly orthodox, he was unwilling to pay attention to the overtures of the *apostólicos* (extreme clericals) until his brother Ferdinand VII tried to make him recognize his daughter Isabella as heir to the throne. Don Carlos refused, maintaining that by the form of Salic law established by Philip V in 1713 (subsequent revocations of which he considered invalid) he was Ferdinand's rightful successor. Since the Spanish liberals supported Isabella's claim, Don Carlos became the candidate of the clericals, asserting that he represented the true traditions of the monarchy, the church and regional liberties against the foreign innovations of liberal constitutionalism and centralization. He went to Portugal in March 1833 to meet his brother-in-law Dom Miguel, the Portuguese pretender, and, in consequence of the civil war there, was cut off from Spain when Ferdinand VII died in Sept. 1833. Don Carlos could return to Spain, where his supporters proclaimed him king as Charles V, only via England, and it was not until July 1834 that he put himself at the head of his partisans in the Basque provinces. Tomás de Zumalacárregui, his commander in chief, was a general of genius, but Don Carlos' lack of judgment prevented any early solution to the first Carlist War. After Zumalacárregui's death (1835) and the Carlists' failure to take Bilbao, the initiative passed increasingly to the liberals. When, in Aug. 1839, the Carlist general Rafael Maroto signed the convention of Vergara, by which the liberals recognized the Basque *fueros*, most of the fighting ceased and Don Carlos went into exile. He abdicated his pretensions in 1845, taking the title conde de Molina, in the vain hope that his son Don Carlos (*q.v.*; 1818–61) might heal the breach within the Bourbon family by marrying Isabella II. He died at Trieste on March 10, 1855. See also **CARLISM**. (C. A. H.)

CARLOS, DON (1818–1861), conde de Montemolin and the eldest son of Don Carlos (*q.v.*; 1788–1855), the first Carlist pretender, whom he succeeded as head of the Carlist line, with the title Charles VI, in 1845, was born in Madrid on Jan. 31, 1818. On his behalf Gen. Ramon Cabrera raised the Carlist bands in 1845 and for two years waged war (guerra de *los matiners*) in the Catalan interior. Efforts to heal the breach within the Bourbon family during the 1840s and again after 1854 broke down because of Montemolin's intransigence. An attempted *pronunciamiento* by Montemolin, his brother Fernando and the liberal general Jaime Ortega at San Carlos de la Rápita, near Tortosa, in April 1860 was a complete fiasco. The brothers were captured but were allowed to leave Spain after an abject renunciation (repudiated once safely in exile) of their claims. Montemolin died at Trieste on Jan. 13, 1861. Since his brother Fernando had died on Jan. 1, and the Condesa de Montemolin died at midnight on Jan. 13 also,

foul play was suspected but never proved. See also **CARLISM**.

(C. A. H.)

CARLOS, DON (1848–1909), duque de Madrid, styled Charles VII by the Carlists, was the eldest son of Don Juan de Borbón (1822–87) and a grandson of the first Carlist pretender, Don Carlos (1788–1855). Born at Ljubljana, in Carniola (now part of Yugoslavia), on March 30, 1848, he became the Carlist claimant when his father abdicated on Oct. 3, 1868. Don Carlos was unable to dominate the counsels of his party in the critical years after the deposition of Isabella II (1868), when Carlism experienced a revival, and his misjudgments and vacillation were responsible for many of the failures of his cause. After the election of Amadeo of Savoy as king in Nov. 1870, the Carlists became more militant, whipping up national feeling against the foreign king. Many favoured armed revolt, arguing that parliamentary corruption would prevent them from ever coming to power by constitutional means, and a rising took place in the spring of 1872, which began the second Carlist War. The Carlist defeat at Oroquieta in May 1872 showed the rising to be premature. It was the establishment (Feb. 1873) of the fiercely anticlerical first republic which enabled Don Carlos to rally support in the traditionally Carlist areas and to put large forces into the field. He returned from exile on July 16, 1873, and established his court at Estella, in Navarre, but his physical presence was a mixed blessing because he was neither a competent soldier nor an inspiring leader. Although his cause prospered during 1873–74, when the republic was distracted by the cantonalist revolts in the south, the successful coup in Dec. 1874 in favour of Isabella II's son Alfonso XII doomed the Carlists. The army and large sections of the church rallied to the restored dynasty, and by March 1876 Don Carlos was driven into exile. A uuderer and an embarrassment to foreign governments for the rest of his life, he refused to surrender his claims or to provide any real leadership for his followers, who were divided by the development of rival regionalist parties and liberal Catholicism. He died at Varese, Italy, on July 18, 1909. See also **CARLISM**.

See Conde de Rodezno, *Carlos VII, duque de Madrid*, 3rd ed. (1944).

(C. A. H.)

CARLOTA (MARIE CHARLOTTE AMÉLIE AUGUSTINE VICTOIRE CLÉMENTINE LÉOPOLDINE) (1840–1927), empress of Mexico, only daughter of King Leopold I of Belgium and Princess Louise of Orléans, was born at Laeken, near Brussels, June 7, 1840. At the age of 17 she married the archduke Maximilian (*q.v.*), brother of the emperor Francis Joseph I of Austria, and accompanied him to Mexico (1864) on his mission to accept the Mexican crown under the auspices of Napoleon III. When the French ruler decided to withdraw his troops, Maximilian's position became untenable in the face of Mexican resistance (led by Benito Juárez) and United States opposition. Carlota returned to Europe and sought aid successively and fruitlessly in Paris, Vienna and finally from the pope in Rome. Her inability to aid her husband, who was executed in 1867, precipitated a mental collapse. Carlota was cared for in a Belgian château until her death, Jan. 19, 1927. (S. R. R.)

CARLOW (CEATHARLACH), a county in the province of Leinster, Republic of Ireland, is bounded on the north by County Kildare, east by counties Wicklow and Wexford and west by counties Kilkenny and Laoighis (Leix). With an area of 346 sq.mi., it is the smallest Irish county except Louth.

Physical Features.—In the southeast is a range of barren granitic mountains (Mt. Leinster, 2,610 ft.; Knockroe, 1,777 ft.). This range is flanked on the west by Carboniferous limestone, the level expanse of which covers most of the county. In the west is the ridge of Old Leighlin bog (Gallows hill, 978 ft.), forming the beginning of the Leinster coal measures, which are worked mostly in County Kilkenny. Glacial deposits cover much of the lower land. Stretches of the river Barrow, flowing north-south through the county, are incorporated in the Dublin-Waterford canal system.

The soil of County Carlow is mainly friable loam, particularly suitable for the growing of barley of malting standard. The climate is temperate; the average annual rainfall is 35.8 in. In the past Carlow was extensively planted with hardwood trees; and after World War II, plantations of quick-growing softwoods were developed by the forestry commission. Pheasant, partridge, wood-

cock and snipe are abundant, and the Barrow and its tributaries are fished for salmon and trout.

History.—Ceatharlach (the four lakes) lay within the extensive lordship of Leinster, which fell to Richard de Clare, 2nd earl of Pembroke, in the second half of the 12th century. It later figures as the liberty of Carlow and is believed to have been confirmed as such by King John to William Marshal, 1st earl of Pembroke, and to have had the privileges of a palatinate on descending to one of the earl's heiresses. In later centuries it was a buffer area in the conflicts between the Butlers, earls of Ormonde, and the Fitzgeralds, earls of Kildare. Antiquarian relics include large dolmens and the ruins of several Norman castles, such as those at Carlow and Leighlinbridge. The remains of monastic settlements are to be found, and the 12th-century cathedral of St. Laserian, Old Leighlin, is still in use. In the south the ancient settlement of St. Mullin's (or St. Moling), with its churches and round tower, dates from the 7th century.

Population, Administration and Economy.—The population of the county was 33,345 in 1961. The chief centres of population are Carlow (*q.v.*), the county town, Bagenalstown and Tullow. The county is administered with County Kildare by a county manager, who is advised by the elected county council. The counties Carlow and Kilkenny together return five members to dail eireann (house of representatives).

Carlow is sometimes referred to as "the English county of Ireland," probably because it is more intensively cultivated than most Irish counties. Wheat and barley are the chief grain crops, and sugar beets are grown and processed. Agricultural limestone is processed and transported throughout the southeast of the county. Flour milling and malting are carried on extensively, and there are small engineering industries ancillary to agriculture. Sheep and dairy and beef cattle are raised; but since intensive wheat growing began during World War II, livestock has become secondary to tillage.

The railway from Dublin to Kilkenny and Waterford runs through the county, serving Carlow and Bagenalstown. Branch lines have been closed since World War II except for the transport of agricultural produce at certain seasons. The Barrow navigation connecting Waterford with the Grand canal system was closed for commercial traffic in 1959 but is maintained for pleasure cruising.

See John Ryan, *The History and Antiquities of the County of Carlow* (1833). (F. A. G. W.)

CARLOW (CEATHARLACH), the county town of County Carlow, Republic of Ireland, on the river Barrow, 52 mi. S.S.W. of Dublin by road. Pop. of urban district (1961) 7,707. The town, originally an Anglo-Norman stronghold, was granted a charter of incorporation in the 13th century and was reincorporated by James I, returning two members to the Irish parliament. The castle, a turreted keep of which two towers and a wall remain, was probably raised by William Marshal, 1st earl of Pembroke, between 1207 and 1213 and is the earliest of its kind in Ireland. An important dolmen is at Haroldstown, Browne's Hill, 2 mi. N.E. of the town, and at Killeslin, 3 mi. W., is a church of Norman and pre-Norman date. Here may be seen a rare example of a Hiberno-Romanesque doorway. The town is the seat of the Roman Catholic bishop of Kildare and Leighlin, whose cathedral, built in 1883, is in the revived Gothic style. St. Patrick's college (1793) is the oldest in the English-speaking world for the training of Roman Catholic priests.

The town benefited considerably by the establishment of a large beet-sugar factory and refinery. Flour, leather footwear and machinery are also manufactured. (F. A. G. W.)

CARLSBAD: see KARLOVY VARY.

CARLSBAD, a city of southeastern New Mexico, U.S., and seat of Eddy county, is best known as the gateway to Carlsbad caverns with their beautiful limestone formations (see CARLSBAD CAVERNS NATIONAL PARK). It is also a recreational centre. The city is bisected by the Pecos river; a dam in the city provides the best body of water within a 200-mi. radius, and beach facilities along the river are comparable with oceanside resorts. Mean temperature is 63° F., with an average of 336 days of sunshine

annually; swimming, boating, water skiing and golfing are enjoyed throughout the year.

Potash, discovered in 1925, is mined in significant quantities in the area. In addition, Carlsbad is a shipping point for cotton, alfalfa, wool, oil and livestock and is the centre of a rich irrigation district.

Founded in 1887, it was originally known as Eddy for its founder, Charles B. Eddy. Because of its mineral springs it acquired its present name in 1899, from the famed European spa, Carlsbad (Karlovy Vary). It was chartered as a city in 1918.

For comparative population figures see table in NEW MEXICO: *Population*. (J. E. W. B.)

CARLSBAD CAVERNS NATIONAL PARK, a tract of approximately 50,000 ac. in southeastern New Mexico, U.S., was established as a national monument in 1923 and designated a national park in 1930. Beneath the park winds a labyrinth of the largest subterranean chambers yet discovered. The total length of the rooms and passages is still unknown, but the explored part of the main cavern is 23 mi. long, of which 3 mi. are open to visitors. Of the three major levels, the deepest is 1,100 ft. below the ground. Elevators take visitors to the 750-ft. level. The second level is at 900 ft.

The caverns have been formed by the dissolvent action of water on limestone. In many of the rooms thus created, notably the Queen's chamber, the Green Lake room, the King's palace and the Papoose room, there are stalactites and stalagmites of calcite. The roof of the Papoose room supports gleaming draperylike formations. The Big room is about 1,300 ft. long and 650 ft. wide. Its ceiling arches 285 ft. above the floor. Here are the Giant dome, a stalagmite 62 ft. tall, and the Twin domes, only slightly smaller, superbly proportioned and delicately fluted.

A colony of several million bats inhabits a part of the caverns known as Bat cave during the summer months. These bats led to the exploration of the caverns in 1901, when a local cowboy, Jim White, saw them pouring from the cave's mouth at sundown to forage for insects.

As with all national parks, Carlsbad Caverns' surface area is a sanctuary for its native plants and wildlife. (Dx. B.)

CARLSBAD DECREES, a series of resolutions (*Beschlüsse*) passed by the conference of ministers of the more important German states held at the Bohemian spa of Carlsbad (now Karlovy Vary) from Aug. 6 to Aug. 31, 1819. The states represented were Austria, Prussia, Bavaria, Mecklenburg, Saxony, Hanover, Wurttemberg, Nassau, Baden, Saxe-Weimar-Eisenach and electoral Hesse. The occasion of the meeting was the desire of the Austrian foreign minister, Prince von Metternich (*q.v.*), to take advantage of the consternation caused by recent revolutionary outrages—especially the murder of the dramatist August Kotzebue (*q.v.*)—to persuade the German governments to combine for the suppression of the liberal and nationalistic agitation. (See GERMANY: History.)

The business to be discussed, as announced in Metternich's opening address, was twofold: first, matters of urgent importance necessitating immediate action; secondly, questions affecting the fundamental constitution of the German confederation. These questions were debated in 23 formal conferences. On the urgent matters there was practical unanimity. All were agreed that disciplinary measures were necessary. It was decided to lay before the federal diet definite proposals for: (1) a uniform press censorship of all periodical publications; (2) a system of "curators" to supervise universities and schools, coupled with the suppression of the recently created *Burschenschaften* (*q.v.*); and (3) the establishment of a central commission of investigation at Mainz, armed with inquisitorial powers, for the purpose of unmasking the widespread conspiracy assumed to exist. In fact, the statesmen probably overestimated the unity and strength of the opposition. Metternich's secretary, the ultraconservative Friedrich Gentz, hailed the repressive Carlsbad decrees as the "greatest retrograde step in Europe for the last 30 years."

As to the fundamental constitution of the German confederation, there was, among the statesmen at Carlsbad, a marked divergence of opinion, especially on the question of the correct interpreta-

tion of article xiii of the federal act. The controversy raged round the distinction between "assemblies of estates," as laid down in the article, and "representative assemblies," as had already been established in several German states. Gentz, in an elaborate memorandum, laid down that representation by estates was the only system compatible with the conservative principle, as representative assemblies were based on the preposterous egalitarian idea of the sovereignty of the people, which in his view was bound to lead to the decomposition of society. In answer, Graf Heinrich Wintzingerode, on behalf of the king of Württemberg, placed on record a protest in which he urged that insistence on the system of estates would stereotype caste distinctions foreign to the whole spirit of the age, would alienate public opinion from the governments and, if enforced by the central power, would violate the sovereign independence of those states which, like Württemberg, already had representative institutions. Since agreement could not be reached, the debate on the constitutional issue was adjourned until the general conference of German ministers to be summoned to Vienna later in the year.

The acts, protocols and resolutions of the conference of Carlsbad are ed. by M. de Martens, *Nouveau recueil général de traités*, vol. 4 (1846).

See V. Karell, *Der Karlsbader Congress* (1937). (H. G. Sc.)

CARLSON, EVANS FORDYCE (1896–1947), U.S. marine officer, commander of Carlson's raiders of World War II, was born at Sidney, N.Y., on Feb. 26, 1896. He ran away from home to enlist in the U.S. Army at 16 and served in the Philippines, in Hawaii and on the Mexican border before World War I. He was made a captain and served as assistant adjutant general on the staff of Gen. John Pershing in France and Germany and in the army of occupation (1917–19).

Carlson returned to civilian life in 1920 but enlisted as a private in the marine corps in 1922, being commissioned a second lieutenant the following year. He served in the West Indies with the battle fleet and in Nicaragua.

Carlson first served in China from 1927 to 1929 and returned in 1937 to spend two years as an observer of the Chinese armies, including nearly a year with guerrillas behind Japanese lines. He resigned from the marine corps in 1939 and wrote *The Chinese Army* (1940) and *Twin Stars of China* (1940).

In April 1941 he re-entered the marine corps as commander of the 2nd marine raider battalion (Carlson's raiders), used his experience in China to train the group and led it in a surprise attack on Makin Island (Aug. 1942) and in a month-long raid behind Japanese lines on Guadalcanal (Nov. 1942). He advanced through grades to the rank of brigadier general and retired in 1946 because of wounds. He died May 27, 1947.

CARLTON, an urban district in the Carlton parliamentary division of Nottinghamshire, Eng., lying immediately east of Nottingham. Pop. (1961) 38,790. The district included after 1934 the parish of Gedling and part of that of Colwick. Industries comprise mining, furniture making, hosiery and printing. Colwick has one of the largest railway marshalling yards in the country.

CARLYLE, THOMAS (1795–1881), Scots essayist and historian, who became one of a select group of sages whom the serious-minded Victorian public read avidly, discussed endlessly and revered deeply. Whether his subject was historical, political or economic, religious or biographical, his aim was always to be a prophet. He was born at Ecclefechan, Annandale, on Dec. 4, 1795, the second son of James Carlyle and the eldest child of his second marriage. James Carlyle was by trade a mason and, later, a small farmer, a man of profound Calvinist convictions, whose character and way of life had a profound and lasting influence on his son. Carlyle was devoted, too, to his mother and to his eight brothers and sisters, and his strong affection for his family never diminished.

After attending the village school at Ecclefechan, Thomas was sent to Annan academy in 1805, where he apparently suffered from bullying, and later to Edinburgh university (1809). There he read widely but followed no precise line of study. His father had intended him to enter the ministry, but Thomas became increasingly

doubtful of his vocation. He had an aptitude for mathematics, and in 1814 he obtained a mathematical teaching post at Annan. In 1816 he went to another school, at Kirkcaldy, where Edward Irving (*q.v.*) was teaching and became one of the few men to whom Carlyle gave complete admiration and affection. "But for Irving," Carlyle said later, "I had never known what communion of man with man means." Their friendship continued after Irving moved to London in 1822 and became famous as a preacher.

The next years were hard for Carlyle. Teaching did not suit him and he abandoned it. In Dec. 1819 he returned to Edinburgh university to study law, and there he spent three miserable years, lonely, unable to feel certain of any meaning in life and eventually abandoning the idea of entering the ministry. He did a little coaching and journalism; he was poor and isolated, and he was conscious of intense spiritual struggles. About 1821 he experienced a kind of conversion, which he described some years later in fictionalized account in *Sartor Resartus*, whose salient feature was that it was negative—hatred of the Devil, not love of God, being the dominating idea. Though it may be doubted whether everything was really experienced as he described it, this violence is certainly characteristic of Carlyle's tortured and defiant spirit. In those lean years he began his serious study of German, which always remained the literature he most admired and enjoyed. For Goethe, especially, he had the greatest reverence, and he published a translation of *Wilhelm Meister's Apprenticeship* in 1824. Meanwhile, he led a nomadic life, holding several brief tutorships at Edinburgh, Dunkeld and elsewhere.

On Oct. 17, 1826, he married Jane Welsh, the intelligent, attractive and somewhat temperamental daughter of a well-to-do doctor in Haddington. Miss Welsh had been one of Irving's pupils, and she and Carlyle had known one another for five years. The hesitations and financial worries which beset them are recorded in their letters. It is interesting that Carlyle, usually so imperious, often adopted a weak, pleading tone to his future wife during the time of courtship, though this did not prevent him from being a masterful, difficult and irritable husband, and, in spite of their strong mutual affection, their marriage was full of quarrels and misunderstandings.

In the early years of their marriage the Carlyles lived mostly at Craigenputtock, Dumfriesshire, and Carlyle contributed to the *Edinburgh Review* and worked on *Sartor Resartus*. Though this book eventually achieved great popular success, he had at first much difficulty in finding a publisher. It is a fantastic hotchpotch of autobiography and German philosophy, written with mingled bitterness and humour. Its main theme is that the intellectual forms in which men's deepest convictions have been cast are dead and that new ones must be found to fit the time, yet the intellectual content of this new religious system is elusive. Its author speaks of "embodying the Divine Spirit of religion in a new Mythos, in a new vehicle and vesture," but he never says very clearly what the new vesture is to be.

In 1834, after failing to obtain several posts he had desired, Carlyle moved to London with his wife and settled in Cheyne row. Though he had not earned anything by his writings for more than a year and was fearful of the day when his savings would be exhausted, he refused to compromise but began an ambitious historical work, *The French Revolution*. The story of how the partially completed manuscript was lent to J. S. Mill and accidentally burned is well known. After the accident Carlyle wrote to Mill in a generous, almost gay, tone, which is truly remarkable when Carlyle's ambition, his complete dependence upon a successful literary career, his poverty, the months of wasted work and his habitual melancholy and irritability are considered. The truth seems to be that he could bear grand and terrible trials more easily than petty annoyances. His habitual, frustrated melancholy arose, in part, from the fact that his misfortunes were not serious enough to match his tragic view of life, and he sought relief in intensive historical research, choosing subjects where divine drama, which his own life lacked, seemed most evident. His book on the French Revolution is perhaps his greatest achievement. After the loss of the manuscript he worked furiously at rewriting it. It was finished early in 1837 and soon won both serious acclaim and popular suc-

cess, besides bringing him many invitations to lecture and solving his financial difficulties.

True to his idea of history as a "Divine Scripture," Carlyle saw the French Revolution as an inevitable judgment upon the folly and selfishness of the monarchy and nobility. This simple idea was backed with an immense mass of well-documented detail and, at times, a memorable skill in sketching character. The following extract is characteristic of the contorted, fiery and doom-laden prose, alternately colloquial, humorous and grim: "An august Assembly spreads its pavilion; curtained by the dark infinite of discords; founded on the wavering bottomless of the Abyss; and keeps continual hubbub. Time is around it, and Eternity, and the Inane; and it does what it can, what is given it to do." (Part 2, book 3, ch. 3.) Though many readers were thrilled by the drama of the narrative, it is not surprising that they were puzzled by Carlyle's prophetic harangues and their relevance to the contemporary situation.

In *Chartism* (1840) he appeared as a bitter opponent of *laissez faire*, but the radical-progressive and the reactionary elements were curiously blurred and mingled. With the publication of *On Heroes, Hero-Worship, and the Heroic in History* in 1841 his reverence for strength, particularly when combined with the conviction of a God-given mission, began to emerge. He discussed the hero as divinity (pagan myths), as prophet (Mohammed), as poet (Dante and Shakespeare), as priest (Luther and Knox), as man of letters (Johnson and Burns) and as king (Cromwell and Napoleon). It is perhaps in his treatment of poets that Carlyle shows to the best advantage. Perverse though he could be, he was never at the mercy of fashion, and he saw much more, particularly in Dante, than others did. Two years later this idea of the hero was elaborated in *Past and Present*, which strove "to penetrate . . . into a somewhat remote century . . . in hope of perhaps illustrating our own poor century thereby." He contrasts the wise and strong rule of a medieval abbot with the muddled softness and chaos of the 19th century, pronouncing in favour of the former, in spite of the fact that he had rejected dogmatic Christianity and had a special aversion to the Roman Catholic Church.

It was natural that Carlyle should turn to Cromwell as the greatest English example of his ideal man, and he produced the bulky *Oliver Cromwell's Letters and Speeches: With Elucidations* in 1845. His next important work was *Latter-Day Pamphlets* (1850), in which the savage side of his nature was particularly prominent. In the essay on model prisons, for instance, he tried to persuade the public that the most brutal and useless sections of the population were being coddled in the new prisons of the 19th century. Though incapable of lying, Carlyle was completely unreliable as an observer, since he invariably saw what he had decided in advance that he ought to see.

In 1857 he embarked on a massive study of another of his heroes, Frederick the Great, and *The History of Friedrich II of Prussia, Called Frederick the Great* appeared between 1858-65. Something of his political attitude at this time can be gathered from a letter written in April 1855 to the exiled Russian revolutionary A. I. Herzen, in which he says "I never had, and have now (if it were possible) less than ever the least hope in 'Universal Suffrage' under any of its modifications" and refers to "the sheer Anarchy (as I reckon it sadly to be) which is got by Parliamentary eloquence, Free Press, and counting of heads" (quoted from E. H. Carr, *The Romantic Exiles*).

Unfortunately, he was never able to respect ordinary men. Here, perhaps, rather than in any historical doubts about the veracity of the Gospels, was the core of his quarrel with Christianity—it set too much value on the weak and sinful. His fierceness of spirit was composed of two elements, a serious Calvinistic desire to denounce evil and a habitual nervous ill temper, for which he often reproached himself but never managed to defeat.

In 1865 he was offered the rectorship of Edinburgh university. The speech which he delivered at his installation in April 1866 was not very remarkable in itself but its tone of high moral exhortation made it an immediate success. It was published in 1866 under the title *On the Choice of Books*. Soon after his triumph in Edinburgh, Mrs. Carlyle died suddenly in London. She was buried

in Haddington and an epitaph by her husband was placed in the church. Carlyle never recovered completely from her death. He lived another 15 years, weary, bored and a partial recluse. A few public causes gained his support: he was active in the defense of Governor Eyre, dismissed and deprived of £6,000 a year for what Carlyle called "saving the West Indies and hanging one incendiary mulatto, well worth gallows, if I can judge." He was excited by the Franco-German War, saying "Germany ought to be President of Europe," but such enthusiastic moments soon faded. In these last years he wrote little. His history *The Early Kings of Norway: Also an Essay on the Portraits of John Knox* came out in 1875, and *Reminiscences* was published in 1881. Later he edited his wife's letters, which appeared in 1883 under the title *Letters and Memorials of Jane Welsh Carlyle, Prepared for Publication by Thomas Carlyle*. Carlyle died in London on Feb. 5, 1881, and although Westminster abbey was offered for burial, he was buried, according to his wish, beside his parents at Ecclefechan.

It is perhaps difficult to be fair to Carlyle. Those who do not accept him as an inspired prophet find he makes intolerable claims on his readers' patience and on their emotional energy. A sentence, a paragraph can be pithy, but a whole book is always repetitive and diffuse, and he could never be fair.

Though he was a man of many words and wide learning, his religious sense, intense in its way, played always round two grand and simple ideas which many religions have in common—the terror of God's glory and the immortality of the soul. The whole of his life and writings can be seen as an attempt to secularize, to reclothe, the Calvinist insights, without mitigating them. In the effort to preserve religion while discarding its doctrines, he has affinities with several famous Victorians, particularly Matthew Arnold. But whereas Arnold, working from a moderate Anglican basis, attempted to turn Christianity into sweetness and light, Carlyle preserved to the full, and even increased the fierceness, the momentous drama, the seriousness of Calvinism. The idea of the elect and the reprobate, even though transferred into moral and secular terms, was an ever-present reality to him. For an infallible Bible he substituted an infallible History, what he called "the true epic poem and universal Divine Scripture, whose plenary inspiration no man out of Bedlam or in it shall bring in question." Though it is possible to challenge his merits as a writer, there is no doubt of his historical importance. He stirred the conscience of his century; he helped thousands to see their experiences in a historical and spiritual context and thus to find new meaning in a monotonous and drab existence; and in an age of prolonged and burdensome physical toil, he inspired thousands with belief in the dignity of their work.

CARMAGNOLA (properly FRANCESCO BUSSONE, sometimes called CONTE DI CARMAGNOLA) (d. 1432), Italian *condottiere*, whose fame rests largely on the tragic circumstances of his downfall, commemorated in verse by Alessandro Manzoni, was born at Carmagnola, near Turin, probably between 1380 and 1385. Of humble origin, he won titles and fiefs (though not that of Carmagnola) by helping Filippo Maria Visconti to restore the duchy of Milan to its full territorial dominion (*see* VISCONTI). The duke's favour evidently cooled more quickly than his captain's ambition, and in 1425 Carmagnola took service against Milan with the Venetians. His generalship proved so ambiguous and inept as to create suspicion of treason, for which he was tried, tortured and put to death by Venice on May 5, 1432.

(P. J. J.)

CARMAGNOLE, a word first applied to a Piedmontese

peasant costume (from Carmagnola, the town in Italy) well known in the south of France and brought to Paris by the revolutionaries of Marseilles in 1792. It consisted of a short-skirted coat with rows of metal buttons, a tricoloured waistcoat and red cap and became the popular dress of the Jacobins. The name was then given to the famous revolutionary song, composed in 1792. Each verse of this ends with the refrain:

Vive le son, vive le son,
Dansons la carmagnole,
Vive le son du canon!

CARMAN, (WILLIAM) BLISS (1861-1929), Canadian poet remembered chiefly for certain poignant love poems and one or two transcendental rhapsodies in celebration of nature, was born at Fredericton, N.B., on April 15, 1861, of early New England stock turned United Empire Loyalist; on his mother's side he was a distant relative of Ralph Waldo Emerson. He was educated under the famous schoolmaster George R. Parkin at Fredericton collegiate and at the University of New Brunswick. He attended lectures at the universities of Oxford and Edinburgh and at Harvard, where he was deeply impressed by the philosophy classes of Josiah Royce.

In 1890 he went to New York city and for two decades earned a living in editorial capacities on various journals, including the *Independent*, *Current Literature*, the *Chap-book* and, for a short time, the *Atlantic Monthly*. Between 1893 and 1905 he published nearly 20 volumes of verse, including almost everything of his that deserves to endure. Among these are *Low Tide on Grand Pré* (1893); three series of *Songs from Vagabondia* (1894, 1896, 1901), written in collaboration with Richard Hovey, the U.S. poet, whom he had met at Harvard; *Behind the Arras* (1895); *Ballads of Lost Haven* (1897); *Pipes of Pan* (published in five volumes under various titles, 1902-05); and *Sappho* (1904), improvisations based on the Greek fragments of Sappho. From 1904 to 1908 he was engaged in writing a series of semi-inspirational works in prose. *Thz Kinship of Nature*, *The Friendship of Art*, *The Poetry of Life* and (in collaboration with Mary Perry King) *The Making of Personality*. These added little to his reputation. His later poetry is an echo of his earlier, fainter and less compelling. Two volumes, *Sanctuary* and *Wild Garden*, were published in the year of his death, which occurred on June 8, 1929, in New Canaan, Conn.

CARMARTHEN (CAERFYRDDIN), a municipal borough and the county town of Carmarthenshire, lies on the right bank of the river Towy, 8 mi. above its mouth on Carmarthen bay, 22 mi. N.W. of Swansea. Pop. (1961) 13,249. Of great antiquity, its site on the historic south Wales coast commands the Towy route into central Wales. The main part of the town is on a hillock surmounted by the remains of a Norman castle and the modern county hall. Eastward are the parish church of St. Peter, largely of 14th-century construction, and the site of the Roman station of Maridunum.

The history of Carmarthen during the post-Roman centuries is largely uncertain, but it was of ecclesiastical rather than military importance; Merlin appears in the legends of this era. When the Normans established themselves early in the 12th century, Carmarthen began to assume its historic role as the administrative and economic centre of western Wales. Though there were earlier charters, what may be regarded as the first town charter was granted by Henry III in 1227. Llewelyn the Great, King John, Edward I, Richard II, Owen Glendower, Jasper Tudor, Sir Rhys ap Thomas and Walter Devereux, 1st earl of Essex, figure in the town's history, largely one of attacks, sieges and burnings.

On the eastern side of the town was the Augustinian priory, established by the Normans, which housed the Black Book of Carmarthen, the oldest Welsh manuscript extant, now in the National Library of Wales, Aberystwyth; while on the western side was the

Franciscan friary. In the middle ages Carmarthen was important for its wool trade, being declared by Edward III in 1353 the sole staple (mart) for Wales. As a result of the social changes in Tudor times, a guildhall was built in 1583 (replaced by the present guildhall c. 1770). Carmarthen has a place in the story of the early Protestant martyrs, among whom was Bishop Robert Ferrar of St. David's (burned in the market place in 1555). During the Civil War the castle was at first held for the king but changed hands on the appearance of Cromwell; earth defenses of the period (the "Bulwarks") have been preserved. For centuries Carmarthen was a busy river port, and on the Towy coracles may still be seen. The mayor also retains his title as "Admiral of the River Towy," bestowed by Henry VIII, who granted the borough the right (still exercised) to possess a ceremonial sword. In the 18th and 15th centuries Carmarthen was a social centre and was associated with Sir Richard Steele (buried in St. Peter's church), Bishop Connop Thirlwall, John Nash (traces of whose work still survive in the town). Sir Thomas Picton, Brinley Richards and Sir Lewis Morris. It also became a printing, literary and academic centre, and an important meeting of the renaissance Eisteddfod was held there in 1451. In 1747 an iron-smelting works was built in the town, which later manufactured tin plate until 1900. Carmarthen became a railway junction after 1856 and is now the hub of road communications in southwest Wales. The town expanded, particularly after World War II, and its population increased by almost 20%. It is the flourishing agricultural, commercial and administrative centre for a wide area. Important cattle marts are held each week, and there is a large modern milk-processing plant. Trinity college trains many teachers, and there is the extensive new West Wales General hospital.

Carmarthen, together with Lichfield, Poole and Haverfordwest, is one of the old boroughs that remain counties in themselves, a privilege granted to Carmarthen by James I in 1604. It was created a parliamentary borough in 1536 and after 1832 returned a member jointly with Llanelly, but in 1918 it was merged in the Carmarthen parliamentary division. Its commission of the peace and quarter sessions were abolished in 1551, but there is still a borough sheriff for assize purposes. (E. V. J.)

CARMARTHESHIRE (SIR GAERFYRDDIN), a county of south Wales, bounded north by Cardiganshire, east by Brecknockshire and Glamorgan, west by Pembrokeshire and south by Carmarthen bay and the Bristol channel. With an area of 519.8 sq. mi., it is the largest Welsh county.

Physical Features.—The physical core of Carmarthenshire consists of the plain of the Towy, with its continuation into the Tâf valley. This lowland, curving from a southwesterly to a westerly direction, is aligned along a denuded anticline or arch mainly floored by black shales of Tremadoc (Cambrian) Age and covered at the sides by conglomerates, sandstones and shales, with beds of volcanic ash and lava of Arenig (Ordovician) Age. Above these are shales, flags and limestones named from Llandilo, where they are remarkably developed. North of the Towy lowland, the hills are formed of Ordovician and Silurian shales and mudstones, deeply dissected and divided into two zones, one south of Brechfa, with a maximum height of 900 ft., and one north of Brechfa and the Cothi river, reaching above 1,300 ft. South and southeast of the Towy the Silurian sandstones and mudstones form the first hills; then, in order of geological succession, comes Old Red Sandstone followed by Carboniferous limestone and coal measures. The Old Red Sandstone forms to the southeast the Black mountains of Carmarthenshire, rising to 2,632 ft., and to the south of this the scarps and moorlands of the Carboniferous limestone and Millstone Grit ("Farewell rock") form the northwestern rim of the south Wales coal field, the rich coal measures of the Gwendraeth, Amman and Llanelly district being within the county. The Old Red Sandstone rocks on the southern side of the main Towy lowland form only very subordinate hill lines westward from the Black mountains, and the Towy makes its way through the Old Red Sandstone zone to an estuary formed by coastal sinking. The main drainage follows the line of the denuded anticline occupied by the Towy, whose tributaries include the Sawdde, from the southeast, and the Cothi and Gwili, which drain the northern dis-

sected uplands. The streams Gwendraeth Fach and Gwendraeth Fawr and the Loughor follow northeast-southwest lines which are characteristic of the region, and the Loughor divides the county from Glamorganshire on the east. The east-west alignment of the middle Towy is duplicated by the Tâf lowland toward the southwestern margin of the county; south of St. Clears, however, the Tâf turns southeastward to the sea near Laugharne. The land forms have been substantially modified by glacial action during the various phases of the advance and retreat of the icecaps which occurred in the Welsh highlands during the Pleistocene. Many of the hills were smoothed by the passage of ice, although erosion by ice and glacial melt water has also etched a more complicated pattern of land forms and drainage network. Deposits of boulder clay are frequent on the lower valley sides, especially west of Carmarthen town on the lowland area which shows evidences of having been a lake, probably in late glacial times. With the exception of Llyn-y-Fan, in the Black mountains, and those at Talley, which appear to have no outlet, the natural lakes are inconsiderable. The largest sheet of water is the Usk reservoir on the county's eastern boundary.

History.—The region above the 600-ft. contour is dotted with tumuli and cairns and, especially in the northwest, with menhirs and other stone monuments. Bronze objects are found especially along the southern coast and at Conwil in the Gwili valley. The hilltop camps of Romano-British age cap spurs of the high ground and seem to be situated at defensible points that guarded ways up from the sea and communications along the valleys. Carn Goch (5 mi. N.E. of Llandilo) covers about 15 ac. and is enclosed by a stone rampart. The Roman focus of ways across the country lay at Maridunum, later Carmarthen, the present capital of the county. The post-Roman centuries saw the civilizing and Christianizing influence of the Celtic saints on the one hand, leaving its mark in the dedications of rural churches, and on the other hand the numerous raids from the sea and by land of the Irish and the Scandinavians. The strong reign of Rhodri Mawr (c. 870) is said to have brought a measure of peace, and his grandson Howel the Good (Hywel Dda) was the first to codify the ancient laws of Wales at his palace of Ty-Gwyn-ar-DBf (white house on the Tâf), near modern Whitland. The period subsequent to 1080 saw the beginning of the Norman intrusion. The Normans first built castles along the coast at Kidwelly, Llanstephan and Laugharne and then penetrated up the valley ways to Carmarthen and Llandilo. Many of these castles occupy sites previously chosen for defense by earlier rulers of the country; e.g., the castle at Dinefwr, or Dynevor. This was the seat of the princes of south Wales, the central point of Ystrad Tywi (vale of Towy), the nucleus of the future county. The campaigns of Edward I gave the Normans a more unified control of the principality, and by the Statutes of Rhuddlan (1284) the counties of Cardigan and Carmarthen were formed out of the districts of Ceredigion and Ystrad Tywi. Nearly one-third of the present county, however, still remained under the jurisdiction of the lords marcher, and it was not until the act passed in 1536 under Henry VIII that these districts were added to Edward I's original shire. The surrounding hill country, ideal for sheep raising, made Carmarthenshire famous for its wool in the later middle ages.

There are few remains of the medieval monastic houses: Talley abbey (late 12th century), the only Premonstratensian house in Wales, founded by Rhys ap Gruffydd, prince of south Wales; Whitland abbey, or Albalanda, a Cistercian house, probably founded by Bishop Bernard of St. David's (mid-12th century), on a site long associated with Welsh monastic life; and the celebrated Augustinian priory of St. John at Carmarthen (12th century). Connections with the house of Tudor through Sir Rhys ap Thomas, who fought for Henry Tudor at the battle of Bosworth Field, were important in the 16th century. At Abergwili, site of the modern palace of the bishops of St. David's, Bishop Richard Davies (c. 1501–81) and William Salesbury of Llanrwst translated the New Testament and the Prayer Book into Welsh, and in the early part of the 17th century Rhys Prichard (d. 1644), the Puritan vicar of Llandovery, published his famous *Canwyll y Cymry* (The Welshmen's Candle). William Laud, as bishop, and Jeremy Taylor were

also associated with the county. The castles, especially the southern ones, made half-hearted resistance to the parliamentary forces. Griffith Jones (1683–1761), vicar of Llanddowror, founded Welsh circulating schools, the effective beginning of the modern educational movement in Wales. William Williams Pantycelyn (1717–91) was the chief hymnologist of the Welsh Methodist movement. The county was deeply implicated in the Rebecca riots (q.v.; 1843). The poet Dylan Thomas (q.v.) lived at Laugharne and is buried there.

Population and Administration.—The population, which was 167,736 in 1961, remains fairly static. The municipal boroughs are Carmarthen, Kidwelly, Llandovery and Llanely (qq.v.). There are 5 urban districts, 4 rural districts and 63 civil parishes. The county is in the south Wales circuit, and assizes are held at Carmarthen. There is one court of quarter sessions, and there are ten petty sessional divisions. The county has two parliamentary divisions, Llanely (industrial) and Carmarthen (rural), each returning one member to parliament. It is wholly in the diocese of St. David's. The northeastern part of Carmarthenshire is included in the Beacons National park, which was designated in 1955. The National trust owns about 2,400 ac. in the county.

The Economy.—Apart from the relatively small industrial southeast, the county is rural and supports extensive dairy farming, besides mixed farming and sheep rearing in the northern hills. There are several creameries based on the large milk production, though much of the prime product is exported, notably to London. In the north there are state forests and small woolen mills, which make tweeds, flannels and hosiery. Carmarthen has important weekly marts, while those at Llandovery, Llandilo, St. Clears and Whitland still flourish. Anthracite coal is mined in the southeast, where there are many mining villages, the chief towns being Llanely and Ammanford. Reorganization has closed some old collieries and modernized others; a new £13,000,000 colliery at Cynheidre started production after 1960. Other minerals worked are limestone, silica, sandstone, fire clay and a little barytes. Lead and gold, the latter extracted by the Romans, are not now worked. Llanely, the largest town, produces steel and has a modern tin-plate plant. Nearby, at Burry Port, is the Carmarthen bay power station. There are several brickworks, and other manufactures are optical lenses at Kidwelly, chemicals at Burry Port, hosiery and upholstery springs at Ammanford and automobile components and piano actions at Llanely.

After World War II the industrial region in the southeast of the county was included in the south Wales and Monmouthshire development area, and the growth of new industries was encouraged to absorb the labour made redundant by changes in the coal, steel and tin-plate industries.

The London-Fishguard railway runs via Llanely, Carmarthen and Whitland, and the line from Shrewsbury travels through Llandovery and Llandilo, with branches thence to Carmarthen, Llanely and Swansea. Road transport has made Carmarthen a considerable centre.

See J. E. Lloyd (ed), *History of Carmarthenshire*, 2 vol. (1935); B. L. Davies and H. Miller, *Carmarthenshire, the Land of Britain Survey*, part xxix (1944). (E. V. J.; Ed. BR.)

CARMEL, MOUNT, a well-defined mountain spur projecting into the sea south of Haifa, Israel. is about 14 mi. long and 8½ mi. broad. Although it does not exceed 1,800 ft., its bold outline can be seen for many miles. Its name means "garden" or "orchard"; the Arabic name Jabal Mar Elyas means "the mount of the prophet Elias (Elijah)."

The mountain is limestone in which numerous caves served as homes for early man. Excavations by the British School of Archaeology in 1929–31 revealed a series of caverns with deposits extending from the Lower Paleolithic (Old Stone Age) to the Mesolithic (locally called the Natufian) and linked the latter deposits with the lowest levels excavated at Jericho (Tell es Sultan). The most interesting discovery in the caves was of the so-called Mount Carmel man; consisting of a group of skeletons in a Mousterian level, with some Neanderthal and some Homo sapiens characteristics, it forms an important link in the study of human skeletal development.

Known to Egyptians of the Old Kingdom as the "gazelle nose" from its distinctive shape, the mountain was bypassed by the Egyptians in their campaigns against the Syrian and Palestinian city states in the time of the Middle and New Kingdoms. Thutmose III (18th dynasty) in his eighth campaign led his troops through the defiles of the mountain to defeat the Syro-Palestinian confederacy at the battle of Megiddo and to capture the city after encircling it with a wall. Mt. Carmel is mentioned in the Amarna tablets of 18th-dynasty date and in the records of the 19th dynasty; but it had no strategic importance and invading armies usually detoured it. In the first millennium Mt. Carmel marked the joint boundaries of Asher, Zebulon, Issachar and Manasseh, but the frontiers were ill-defined.

Always a sacred place and a refuge, Mt. Carmel had several deities called Baal (lord). It was the scene of the struggle and overthrow of the priests of Baal, publicly challenged by Elijah, as recounted in the Bible (I Kings xviii, 19 ff.). The exact site of this incident is uncertain but is thought to have been on the southern half of the ridge. Mt. Carmel was noted for its oracle, which was consulted by the emperor Vespasian before he attained power.

Mt. Carmel naturally became a refuge for early Christian anchorites. In A.D. 570 a monastery dedicated to the prophet Elijah was in existence, but the date of its foundation is uncertain. About 1156 the order of Carmelites (*q.v.*) was founded and a monastery built; it was rebuilt in 1767 and used by Napoleon as a hospital after his Egyptian campaign. It was burned in 1788 on his retreat and not rebuilt again until 1827. The memorial to Napoleon's soldiers was re-erected by the French in 1919. Gen. Sir Edmund (later Viscount) Allenby, following the route of Thutmose III, attacked and defeated the Turks at Megiddo in Sept. 1918. Between World Wars I and II Mount Carmel was partly reforested. (M. V. S.-W.)

CARMELITES, in England called WHITE FRIARS, one of the mendicant Roman Catholic religious orders. The origin of the order can be traced to Mt. Carmel in Palestine, where a number of devout men, apparently former pilgrims and crusaders, established themselves near the traditional fountain of Elijah. Their rule, written between 1206 and 1214 by St. Albert, Latin patriarch of Jerusalem, and approved in 1226 by Pope Honorius III, shows them already organized under a leader called Brocard. The monks had the ideal of continuing on Mt. Carmel the way of life of the prophet Elijah, whom early Christian writers picture as a monk—in fact, as the founder of monasticism. In the course of time, the Carmelites attempted to show a historical continuity of the order going back to the times of the prophet. In 1675 the Bollandist Daniel van Papenbroeck in the April volumes of the *Acta Sanctorum* rejected these claims as fables. The controversy became so hot that in 1698 a papal decree imposed silence on both parties.

The life of the early Carmelites was strictly eremitical: the monks lived in separate cells or huts, devoted to prayer and work; they met only in the oratory for liturgical services and lived a life of silence, seclusion, abstinence and austerity. Soon, however, the losses of the crusading armies in Palestine made Mt. Carmel unsafe for the western hermits, who set out, about 1240, for Cyprus, Sicily, France and England. In England early establishments were made at Alnwick (Northumberland) and Aylesford (Kent), where the first general chapter of the order was held in 1247. The institute was adapted to the conditions of the western lands to which it had been transplanted: the life was turned from eremitical into cenobitical but on the mendicant, rather than the monastic, model. The polity and government were organized on the same lines, and the Carmelites were turned into a mendicant order. Under this form (approved in 1247) the Carmelites spread all over western Europe, becoming exceedingly popular as an order closely analogous to the Dominicans and Franciscans. In the late scholastic period, the order produced such theologians as Gerard of Bologna, John Baconthorpe, Guido Terrena and Michael Aiguani, as well as the noted opponent of Lollardy, Thomas Netter of Walden, provincial of the English order. In 1432 a second mitigation of the rule by Pope Eugenius IV permitted the friars to eat meat on certain days of the week and to walk in the cloisters at suitable times. In 1452 the prior general, John Soreth, obtained

permission to affiliate devout women with the order, thus giving rise to the Carmelite nuns.

In the course of time, the religious fervour of the order declined, and this resulted in the introduction of reforms, including those of John Soreth, the Congregation of Mantua (established 1442) and Nicolas Audet. Of all the movements in the Carmelite order, by far the most important and far-reaching in its results was the reform initiated by St. Teresa of Avila. After nearly 30 years in a Carmelite convent, she founded (1562) in Ávila a small convent wherein a stricter way of life was to be observed. In spite of opposition and difficulties of all kinds, she succeeded in establishing not only nunneries but also, with the co-operation of St. John of the Cross, a number of friaries of this stricter observance. The aim of the reform was to restore and emphasize the austerity and contemplative character of primitive Carmelite life. From the fact that those of the reform wore sandals in place of shoes and stockings, they have come to be called the Discalced, or Barefooted, Carmelites, to distinguish them from the older branch of the order. In 1580 the reformed monasteries were made a separate province under the general of the order, and in 1593 this province became by papal act an independent order with its own general and government (Ord. Fratrum discalceatorum B. Mariae V. de Monte Carmelo; O.C.D.), so that there are now two distinct orders of Carmelites. After the division, the reform of the original order (Ordo Fratrum B. Mariae V. de Monde Carmelo; O. Carm.) was effected by the movement known as the Strict Observance, established in 1645, which re-emphasized the primitive contemplative ideals of the order, without, however, relinquishing the mitigation of 1432.

Both orders suffered severely from the French Revolution and suppression by Napoleon and the liberal governments of the 19th century but have since been restored in most countries of western Europe, in the middle east, Latin America and the United States. The Carmelites combine the contemplative and active way of life. While they maintain strictly contemplative monasteries, devoted exclusively to silence and prayer, they also engage in preaching, teaching, parochial work, publication of religious literature and other forms of apostolate. The order has produced a number of noted mystics in addition to St. Teresa of Ávila and St. John of the Cross; among them are St. Mary Magdalen of Pazzi and St. Thérèse de Lisieux. They conduct foreign missions in Iraq, India, Indonesia, the Philippines, Africa and the remote parts of South America.

The Carmelite cloistered nuns constitute the largest group of contemplative religious women in the Roman Catholic Church. Besides, in recent times, numerous congregations of Carmelite Sisters have been formed, devoted to teaching, care of the sick and other charitable works.

Carmelites of the Old Observance number about 3,000, the Discalced about 4,500 (both men and women). The Discalced occupy the mother house on Mt. Carmel. Friars of both branches wear substantially the same habit: brown tunic, scapular and hood, with a white mantle. The nuns' habit is the same as that of the friars, with a linen wimple and black veil.

CARMEN SYLVA: see ELIZABETH, QUEEN OF RUMANIA.
CARMINE, a red or purplish-red pigment obtained from cochineal, a red dye extracted from dried bodies of female scale insects (*Coccus cacti*) that live in tropical and subtropical America (mainly Mexico and Central America) and feed on a species of cactus (*Nopalea coccinellifera*).

Carmine is used only occasionally—for pastries, confections, cosmetics, water-soluble drug preparations and microscope stains—when a natural pigment colourant is desired. Before the advent of synthetic colouring materials, it was used more extensively, particularly for water colours and fine coach body colours.

It takes 70,000 insects to make 1 lb. of cochineal and a 100-sq.mi. plantation to yield 600 lb. Of this, only 10% forms carminic acid ($C_{22}H_{26}O_{13}$), the principal constituent of carmine.

To prepare carmine, the powdered insect mass is boiled in ammonia or sodium carbonate solution; the insoluble matter is removed by filtration, and alum is added to the clear salt solution of carminic acid to precipitate the red aluminum salt of carminic acid. Absence of iron insures color purity. Stannous chloride, citric acid, borax or gelatin may be added to regulate the formation of the precipitate. For purple shades, lime is used with the alum. Chemically, carminic acid is a complex anthraquinone derivative.

See PIGMENT, ANIMAL: *Anthraquinones*. (P. HE.)

CARMONA, ANTÓNIO ÓSCAR DE FRAGOSO (1869–1951), Portuguese general and statesman, whose long tenure of office as president of the republic brought much-needed internal stability to Portugal, was born in Lisbon on Nov. 24, 1869. Embarking on a military career, he graduated from the Real Colégio Militar in 1888 and from the Escola do Exército in 1892 and had risen by 1922 to the rank of general. Carmona was among the officers who took part in the army *coup d'état*, headed by Gen. Gomes da Costa, on May 28, 1926, and was subsequently appointed foreign minister. With Costa's removal from power, Carmona assumed the post of premier in July 1926 and the functions of chief executive in November. A bloody insurrection against the dictatorial regime was put down in Feb. 1927. Carmona then made an appeal for public support, in the form of a national plebiscite, and he was elected to the presidency. Inaugurated in April 1928 for a seven-year term, Carmona, always standing as the candidate of the government party, was re-elected in 1935, 1942 and 1949.

During these administrations he was overshadowed by António de Oliveira Salazar (*q.v.*), whom he had first brought into the government as minister of finance in 1928. Carmona died in Lisbon on April 18, 1951. A handsome man of dignified bearing, he consolidated, through the work of Salazar, the revolution that brought him to power. (M. CA.)

CARMONA, a town of southern Spain, Seville province, lies 33 km. (21 mi.) E.N.E. of Seville by road, on a ridge of the Sierra de los Alcores overlooking the plain of Andalusia. Pop. (1950) 26,887 (mun.). The town is divided into old and modern districts; the old city has Roman walls and ancient towers, gateways and forts. A large Roman necropolis nearby, discovered in the 19th century, has been excavated; Gothic, Moorish, and late Baroque styles are predominant in churches, convents and palaces. Cereals and olives are grown, and olive oil is produced. Carmona (Roman *Carmo*) was the strongest city of Hispania Ulterior under Julius Caesar. It was later strengthened by the Moors, who built the Seville gate. The lofty citadel of Peter the Cruel (1350–69) is now in ruins. (M. B. F.)

CARNA, an obscure Roman deity with an ancient shrine on the Caelian hill. At her festival on June 1 (popularly called *Kalendae fabariae*, "the bean Calends") offerings of beans and bacon were made. Originally, perhaps, an Etruscan goddess of the dead, she brought health to the vital bodily organs, repelled vampire birds from children and was associated with Janus (*q.v.*) as divine doorkeeper. (D. E. W. W.)

CARNAC, a village of northwest France, in the *département* of Morbihan (*q.v.*) and *arrondissement* of Lorient, 14 km. (9 mi.) S.W. of Auray. Pop. (1954) 1,451. It has a church, St. Cornély, in the Renaissance style of Brittany, but owes its celebrity to the stone monuments in its vicinity. The most remarkable consists of long avenues of menhirs or standing stones which date from the late Neolithic Age. The difficulty of dating them more exactly is increased by the possibility that they were not all erected at the same time. Throughout the whole district there are also passage graves of Middle Neolithic times (from 3000 B.C. onward) which were often used again at various later periods, and different types

of barrows, also Middle and Late Neolithic. About one-half mile to the northwest of the village is the *Ménec* system, which consists of 11 lines and extends a distance of 3,376 ft. The terminal circle is broken by the houses and gardens of a little hamlet. To the east-northeast there is another system at Kermario, which consists of 10 lines about 4,000 ft. in length. Still further in the same direction is a third system at Kerlescan, composed of 13 lines, about $\frac{1}{2}$ mi. in length, terminated by an irregular circle. These three systems seem once to have formed a continuous series; the menhirs, many of which have been broken up for road mending and other purposes, have diminished in number by several thousands in modern times. The alignment of Kermario points to the passage grave of Kercado, covered by a barrow, explored in 1863; and to the southeast of *Ménec* stands the great tumulus of Mont St. Michel, which measures 377 ft. in length, and has a height of 65 ft. The tumulus, which is crowned with a chapel, was excavated by René Galles in 1862; and the contents of the sepulchral chambers, which include several jadeite and fibrolite axes and callais beads, are preserved in the museum at Vannes. About 1 mi. E. of the village is a small piece of moorland called the *Bossenno*, from the *bocenieu* or mounds with which it is covered; and there, in 1874, the explorations of James Miln, a Scottish antiquary, brought to light the remains of a Gallo-Roman villa. The tradition of Carnac is that there was once a convent of the Templars or Red Cross Knights on the spot, but this, it seems, is not supported by history. Similar traces were also discovered at Mané Bras, a height about three miles to the east. The stones of which these various monuments are composed is the ordinary granite of the district, and most of them present a strange appearance from their coating of white lichens. Carnac has an important museum of antiquities (*Musée Miln-Le Rouzic*).

Carnac-Plage about 1 mi S.W. is a well-known beach resort.

CARNAP, RUDOLF (1891–), one of the chief representatives of logical positivism (*q.v.*; see also LOGIC, HISTORY OF), was born at Wuppertal, Ger., on May 15, 1891. From 1926 to 1931 he taught philosophy at the University of Vienna, where he belonged to the famous Vienna circle which first proclaimed the logical positivist doctrine. He was an editor of the movement's journal *Erkenntnis*, which appeared until 1940. In 1931 he joined the German University in Prague. The threat of German expansion under Hitler scattered the members of the group farther afield. Carnap, in 1935, emigrated to the United States, where he was professor of philosophy at The University of Chicago from 1936 to 1952, and at the University of California in Los Angeles from 1954. He also became associate editor of the *International Encyclopedia of Unified Science* which began in 1938 under the general editorship of Otto Neurath. This enterprise remained fragmentary; in a series of special studies it sought to show the universal scope of scientific method.

Like other logical positivists, Carnap rejected metaphysical statements as not just false but strictly meaningless. The extreme form of this theory uses the "strong" verification principle as a criterion: the meaning of a statement is the method of its verification—is grounded directly in observed data. This eliminates not only metaphysics but much else besides: theoretical science, too, becomes suspect. Carnap therefore came to adopt a milder form of the principle, in which the link with observation need only be indirect. Likewise he abandoned the attempt at translating all ordinary (or "material mode") statements into sense data (or "formal mode") statements.

The task of philosophy, as Carnap saw it at first, was to study the logical syntax of language; that is, the way in which language, taken as a system of formulae for calculation, hangs together. Later he came to admit as legitimate the study of how signs are

CARNARVON, GEORGE EDWARD STANHOPE MOLYNEUX HERBERT, 5TH EARL OF (1866–1923), English Egyptologist chiefly remembered for his part in the discovery of the tomb of Tutankhamen (*q.v.*), was born at Highclere, Berkshire, on June 26, 1866, and educated at Eton and at Trinity college, Cambridge. He began excavations near Thebes with Howard Carter (*q.v.*) in 1907 and discovered tombs of the 12th and 18th Egyptian dynasties near the Valley of the Kings. A further concession having been obtained in 1914, operations in the valley itself were conducted after World War I, resulting in the discovery by Carter in Nov. 1922 of the antechamber of the tomb of Tutankhamen of the 18th dynasty. On Feb. 16–17, 1923, the sepulchral chamber was opened, the actual sarcophagus being discovered on Jan. 3, 1924. Meanwhile Lord Carnarvon had died in Egypt on April 6, 1923, from the results of a mosquito bite and pneumonia.

See the memoir by Lady Burghclere in *The Tomb of Tut-ankh-Amen* by Howard Carter and A. C. Mace, vol. 1 (1923). An account of Lord Carnarvon's earlier excavations with Carter is given in their book *Five Years' Explorations at Thebes* (1912). (W. R. D.)

CARNARVON, HENRY HOWARD MOLYNEUX HERBERT, 4TH EARL OF (1831–1890), British Conservative statesman, whose liberal attitude brought him into conflict with the cabinets in which he served, was born in London on June 24, 1831. He was educated at Eton and Christ Church, Oxford, inheriting his father's earldom in 1849. He read and traveled widely, and combined charm, accuracy and literary power with a chivalrous sense of duty. He was undersecretary for the colonies in 1858–59 and was twice appointed colonial secretary (1866–67 and 1874–78). He introduced the British North America bill, from which Canadian independence derived, in 1867, but resigned in March of that year because he disapproved of Disraeli's proposals for parliamentary reform. He voted for Gladstone's conciliatory Irish measures of 1869–70. In his second term of office he authorized the annexation of the Transvaal (1877), but his schemes to make a South African federation on the Canadian pattern failed. He resigned in 1878, disapproving of the government's war policy in eastern Europe. He presided over an important commission on imperial defense from 1879 to 1882. In 1885 he joined Lord Salisbury's cabinet as viceroy of Ireland. The appointment was unfortunate, because Carnarvon had far more sympathy with Irish national aspirations than had the rest of the Conservative party; and because he and C. S. Parnell carried away opposite impressions from a secret discussion they had on Home Rule on Aug. 1, 1885. Carnarvon finally resigned, a few days before his colleagues, in Jan. 1886. He died in London on June 28, 1890.

See Sir A. Hardinge, *Life of . . . Carnarvon, 1831–1890*, 3 vol. (1925). (M. R. D. F.)

CARNATIC, a name commonly given to a region of southern India between the Eastern Ghats and the Coromandel coast, extending about 600 mi. from the Guntur district of Andhra Pradesh in the north to Cape Comorin in Madras state in the south and varying in breadth from 50 to 100 mi. Sometimes the name is used to include the Malabar coast (*q.v.*). Properly, however, it applies to the country of the Kanarese-speaking people, Kanara (*q.v.*), extending between the Eastern and Western Ghats, over an irregular area narrowing northward, from Palghat in the south to Bidar in the north, generally coincident with the modern state of Mysore (*q.v.*). The extension of the term in political usage to the eastern coastal plain began with the conquest of the whole peninsula south of the Tungabhadra river by the Vijayanagar kings (1336–1565). The Muslim states which overthrew them in the 16th century and the Mogul emperors who followed them in the 17th century continued and confirmed the practice. At the same time the true Carnatic country has been identified since the early 18th century with the area surrounding the city of Mysore.

History. — The Carnatic defined as the eastern coastal strip was

a region of great historic importance. Its fertile soil, its textile industries, its commercial trade with the East Indies and the middle east made it a seat of wealth and power from pre-Christian times.

Earlier forming part of the Pandya, Chola and Pallava kingdoms, the whole of the coastal strip was incorporated during the Vijayanagar period into that empire. After the fall of the Vijayanagar empire in 1565 the governors of Madura, Tanjore and Kancheepuram (ancient Kanchi) became independent Hindu rulers while the Muslim kingdom of Golconda encroached from the north. In 1687 the Mogul emperor Aurangzeb overthrew Golconda and in 1692 appointed Zulfiqar Khan nawab or deputy for the Carnatic with his seat at Arcot. In the early 18th century the Carnatic became dependent on the nizams of Hyderabad, the first of whom, Asaf Jah, established himself in 1724 with only a nominal dependence on the Delhi emperors. Madura became tributary to the Carnatic in 1736.

After 1748 the rivalries of the English and French East India companies led to European intervention in Indian politics. Both sides supported rival claimants to the Carnatic, the French under Joseph Dupleix supported Chanda Sahib and the British upheld Mohammed Ali. In 1752, largely because of the leadership of Robert Clive, Mohammed Ali was successful; the Carnatic then became virtually a client state of the company. The nawab depended on the company for military support; his loans from the company and its servants demoralized both the state and the company and created the scandal of the nawab of Arcot's debts. Mohammed Ali died in 1795. The Carnatic was overrun and devastated by Haidar Ali of Mysore in 1769 and 1780. Lord Cornwallis (governor general of India during 1786–93) gave orders that the company should administer the state in time of war and enforced this arrangement in the third Mysore war. Lord Wellesley (governor general during 1797–1805) repeated this in the renewed hostilities against Tipu Sahib (1799). After Tipu's overthrow Wellesley decided to take over the Carnatic on the plea of the discovery of correspondence between the nawab and Tipu. This was effected in 1801, on the death of Mohammed Ali's son, in return for a pension and the retention of the title. In 1853 the nominal sovereignty was ended by the governor general, Lord Dalhousie, the title of "prince of Arcot" being later conferred on the head of the family. Under the British crown the coastal Carnatic became the core of the Madras presidency. See INDIA: *History*.

For the various applications of the name see "Carnatic" in *Imperial Gazetteer of India* (1908). See also *Cambridge History of India*, vol. iv (1937) and vol. v (1929). (T. G. P. S.)

CARNATION (*Dianthus caryophyllus*), a spice-scented garden and greenhouse flower of the pink family (Caryophyllaceae; *q.v.*), native in southern Europe, but occasionally found in an apparently wild state in England. One variety of it is the clove pink, an especially fragrant form, while some of the widely cultivated greenhouse carnations have lost much of their odour. The original type was pure white, but since its introduction into common cultivation many varieties have arisen, which are arranged by colour patterns as follows: (1) Bizarres have a clear ground flaked with two or three colours. (2) Flakes have a clear ground flaked with a single colour. (3) Sells, of only one colour (as the common white carnation) and no other. (4) Picotee, having only the petal margined with a different colour from the basic one. (5) Fancies, those like none of the others, often mottled, flaked or spotted.

Besides these colour designations carnations are defined culturally into several well-marked groups. From the gardener's

J. HORACE MCFARLANO CO.
CARNATION (DIANTHUS CARYOPHYLLUS)

standpoint the most important, and most fragrant, are the hardy border carnations. Over much of the United States the climate is unsuited to these, but in England they are widely grown in many varieties, as they are also in southern France, northern Italy, Japan and elsewhere. They are readily grown in the open border in full sun and in a light, rich loam, but tend to die out periodically and should be renewed from fresh cuttings. In any windy site they need wires or stakes as the stems are weak. As in the greenhouse varieties they should be disbudded if the finest blooms are desired. A few of these English varieties are offered in the United States.

The ordinary carnation of the florist is grown by the millions in England and the United States, and except in very restricted areas must be grown in the cool greenhouse (not over 77° F). Rooted cuttings are planted outdoors when warm weather is assured and grown along until frost threatens. They are then moved into the greenhouse, and depending on the variety and management of light and temperature as well as feeding, will produce flowers from October to April. See PINK.

See M. C. Allwood, *Carnations, Pinks and All Dianthus*, 4th ed. (1955). (N. Tr.)

CARNEADES (214/3–129/8 B.C.), Greek philosopher, a native of Cyrene, was one of the heads of the Platonic Academy in its antidogmatic period. When on a diplomatic mission in Rome in 156/5 B.C. he delivered two orations, one praising justice (and asserting the existence of "natural" law and justice), the other praising injustice (and reducing the concept of justice to that of prudence and utility) as the only expedient way of handling private and public, particularly international, affairs, discussing in this context the problems of just and unjust war, dominion, etc. This arguing on both sides of a question expressed Carneades' attitude of suspending judgment (not one of dogmatic rejection), characteristic of what is called Academic scepticism. In the same spirit he criticized Epicurean theology (proofs of the existence of gods, doctrines concerning their nature) and, particularly, that of the Stoics (together with their theodicy, belief in providence, fate, divination, astrology, design) as inconclusive. Many of his arguments remained classic. Ultimately this noncommittal attitude was rooted in his denial that there existed any certain knowledge, either of the senses (all sensations being relative to the subject and there being no mark distinguishing true from false sense perceptions) or of the intellect.

Ever since Arcesilaus (q v) had, either as a means or as an end, urged the *epoche* or withholding of assent from any experience claiming to be knowledge, the Academy faced the objection that this attitude, even if it could be maintained, would make life impossible. Carneades met the objection by distinguishing objective (and unattainable) certainty (evidence) from subjective conviction resulting from the persuasiveness of sensations, this persuasiveness or "approvability" (*probabilitas*, usually translated "probability") being a sufficient guide for theory and practice and admitting of degrees (the highest of which was that of a sensation not contradicted by other sensations and comprehensively tested). In ethics he defended, rather than professed, the doctrine that the primary goods which man is prompted by nature to appropriate are neither pleasure nor absence of pain but rather integrity and full use of mind and body. He left no writings. His successor Clitomachus expounded his opinions. See also ACADEMY, GREEK.

CARNEGIE, ANDREW (1835–1919), U.S. industrialist who established a number of foundations and endowments for education and research. In his famous essay "The Gospel of Wealth," published in 1889, he set forth his view that the life story of a rich man should fall into two periods—the first, that of acquiring wealth, the second, that of distributing it in such a way that the surplus would be used for the general welfare; this practice he

followed in his own life. Carnegie was born in Dunfermline, Scot., on Nov. 25, 1835, and in 1848 emigrated to the U.S. with his family, settling in Allegheny, Pa. (later annexed by Pittsburgh). He began working as a bobbin boy in a cotton factory; later he was an engine tender, telegraphic messenger and operator, and for 12 years (1853–65) worked for the Pennsylvania railroad, where one of his achievements was the introduction of sleeping cars. In 1864 he bought the Storey farm on Oil creek, Pa., where much oil was brought in. Foreseeing the extent to which the demand for iron and steel would grow, he left the railroad and started the Keystone Bridge works, and from 1873 onward concentrated on steel. By 1888 he had under his control an extensive plant served by tributary coal and iron fields, a railway 425 mi. long and a line of lake steamships. In spite of the depression of 1892, marked by the bloody Homestead strike, the various Carnegie companies, aided by favourable tariff legislation, prospered. In 1901 they were incorporated in the United States Steel corporation; Carnegie then retired from business and devoted himself to the work of providing capital for social and educational advancement.

Among these activities the provision of public libraries in the United States and Great Britain (and similarly in other English-speaking countries) was especially prominent; his method was to build and equip, but on condition that the local authority provided site and maintenance. In 1900 he founded the Carnegie Institute of Technology at Pittsburgh and in 1902 the Carnegie institution at Washington, D.C. In Scotland he established a trust for assisting education at the Scottish universities, a benefaction which resulted in his being elected lord rector of St. Andrews university. He was a large benefactor of the Tuskegee institute, Macon county, Ala., under Booker T. Washington. He also established large pension funds—in 1901 for his former employees at Homestead and in 1905 for U.S. college professors (Carnegie Foundation for the Advancement of Teaching). Other notable contributions were his founding of Carnegie Hero funds, in America (1904) and in the United Kingdom (1908), for the recognition of deeds of heroism; in 1903 he donated funds for the erection of a Temple of Peace at The Hague and for a Pan-American palace in Washington, D.C., as the home for the International Bureau of American Republics. In 1911 he established the Carnegie corporation and endowed it liberally for the furtherance of civilization. (See FOUNDATIONS, PHILANTHROPIC.) Carnegie died at Lenox, Mass., Aug. 11, 1919. His autobiography was edited by J. C. Van Dyke (1920).

See Burton Hendrick, *The Life of Andrew Carnegie*, 2 vol. (1932); in J. H. H. Williams, *Men of Stress* (1948).

CARNEIA, an important Dorian festival (Sparta, Cos, etc.). While many details of it are obscure the main features are tolerably certain. It was held in the month Carneios (roughly August). The name is connected with Karnos or Karneios (probably meaning "ram"), said to have been a favourite of Apollo, unjustly killed by the Heraclidae, and therefore commemorated to appease the god's anger; perhaps he was an old god of fertility displaced by Apollo. The festival contained an agrarian element. Five young men called Karneatia were chosen out of each tribe; one man, decked with garlands, ran away and the rest followed him. The latter were called staphylodromoi (*i.e.*, "grape-cluster runners"), hence they very likely carried bunches of grapes. It was a good omen if they caught the fugitive, bad if they did not. They were under the direction of a priest called hagetes, or leader. It seems reasonable to suppose that the person they chased was the temporary incarnation of some spirit of vegetation; perhaps to catch him signified that fertility was not allowed to go away, but was secured, to be used for the next year's crops. The Carneia contained an element apparently military, since a feast was held by nine groups, each consisting of nine citizens, representing the obai or divisions.

See L. R. Farnell, *Cults of the Greek States*, vol. iv (1907).

CARNELIAN (CORNELIAN), a variety of chalcedony, a native silica, is generally of a blood-red colour, though included under this name are specimens of a reddish tint varying in colour from yellow to brown. The colouring matter is probably iron oxide in various stages of hydration, though the particles are so small that

only in thin sections under the microscope can they be distinguished from the colourless silica in which they are embedded. Though carnelians are recognized in all shades of red, it is convenient to distinguish three varieties; (1) flesh red or burned brick coloured—the typical carnelian. (2) honey coloured and (3) brown by reflected and deep red by transmitted light, usually called the sard, and formerly the most valued, because of its greater transparency and depth of colour.

Among the Greeks and Romans the carnelian was one of the most treasured stones, used especially for intaglios. Examples have retained their high polish better than many harder stones. The carnelian was also widely used for signets. Carnelians are embellished by burning and dyeing with salts of iron, and for trade purposes the natural colour is of little importance.

The chief localities are Ratanpur, India; Campo de Maia, Braz.; Surinam (Dutch Guiana); Siberia; Warwick, Queensland, Austr.; Tampa Bay, Fla.; and Chesil Bank, Dorset, Eng. See also GEM; QUARTZ. (W. A. W.)

CARNESecCHI, PIETRO (1508–1567), Italian humanist and reformer who wished nevertheless to remain within the Roman Catholic Church, was born at Florence on Dec. 24, 1508. He early enjoyed the patronage of the Medici, particularly of Pope Clement VII, to whom he became principal secretary. However, in 1540 he joined the circle of Juan de Valdés (*q.v.*) at Naples, and accepted Luther's doctrine of justification by faith, though repudiating a policy of schism. When a movement of suppression began (1546), Carnesecchi fled to Catherine de Medicis in Paris. In 1559 he returned to Rome but under Pius V the Inquisition renewed its activities in 1566 and Carnesecchi went to Florence. only to be betrayed by his patron, Cosimo de' Medici. He was executed as a heretic in Rome on Oct. 1, 1567. (G. Hu.)

CARNIOLA (Ger. KRAIN), the western region of the Yugoslav republic of Slovenia, last had significance as an administrative unit as part of the Austrian empire, when it was bounded north by Carinthia and Styria, east and southeast by Croatia-Slavonia, and southwest and west by the Küstenland (Istria and Gorizia). Its centre was Laibach (modern Ljubljana). Part of the Roman province of Pannonia in ancient times, it was occupied by the Slovenes in the 6th century A.D. Later it belonged successively to the patriarchs of Aquileia (1077–1228), to the dukes of Carinthia (1228–69), to Otakar II of Bohemia (1269–76) and to the counts of Gorizia and Tirol (1276–1335). In 1335 it passed to the Austrian house of Habsburg, under which (apart from the period of French rule, 1809–14), it was a duchy until 1849, then a crownland until 1918. It was then incorporated in the kingdom of Serbs, Croats and Slovenes. After 1947 it was located entirely within Slovenia.

See YUGOSLAVIA.

(K. LA.)

CARNIVAL, the celebration of merrymaking and festivity that takes place in many Roman Catholic countries in the last days and hours of the pre-Lenten season. The derivation of the word is uncertain, though in all probability it is directly traceable to the medieval Latin *carne[m] levare* or carnelevarium in the sense of "to take away meat" or "to remove meat," a conception which coincides with the fact that carnival is the final festivity before the commencement of the austere 40 days of Lent during which abstinence from flesh meat is observed. The historical origin of carnival is also obscure. Probably it is rooted in a primitive festivity in honour of the commencement of the new year and the rebirth of nature, though a more concrete and proximate connection may link the beginnings of the carnival in Italy to the pagan Saturnalian feast of ancient Rome.

The exact determination of the first day of carnival varies with both national and local traditions. Thus in Munich (Bavaria) carnival or *Fasching* begins on the feast of the Epiphany (Jan. 6), while in Cologne (Rhineland) it begins on Nov. 11 at 11:11 A.M. (11th month, day, hour and minute). In France the celebration is restricted to Tuesday before Ash Wednesday (Shrove Tuesday; *q.v.*) and to *mi-carême* or the Thursday of the third week of Lent. More generally the commencement date is Quinquagesima Sunday and the termination is Shrove Tuesday, though in some parts of Spain Ash Wednesday also is included in the carnival celebrations,

an observance that stems from a time when Ash Wednesday was not an integral part of Lent.

The origin and development of this festivity is so intimately tied up with Rome, Venice, Florence and Turin that carnival itself can be regarded as distinctly Italian in character. Rome was most conspicuous as the centre of carnival activity, and the splendour and richness of the festivity that marked its observance there were scarcely surpassed elsewhere.

Though Sixtus V (1585–90) set himself to restrain its excesses and lawlessness, the papal policy toward carnival was generally tolerant and moderate. The carnival sports of Rome anciently consisted of the races in the Corso, the spectacular pageant of the Agona and that of the Testaccio.

In the course of its long history the carnival played a significant role in the development of the popular theatre, vernacular song and folk dances. It also exercised a certain amount of influence on the Jewish feast of Purim.

In the United States the most notable manifestation of carnival is found in New Orleans, La. (*q.v.*), where the carnival season opens on Twelfth-night (Jan. 6), with the Mardi gras season, commencing ten days before Shrove Tuesday, marking the climax.

In North America, the term carnival also applies to a traveling amusement enterprise, including rides such as merry-go-rounds and Ferris wheels, sideshows and games of chance, which operate separately or in conjunction with fairs and expositions. When combined with one of the latter, the carnival is distinguishable by the midway, a term used both for the brightly illuminated area where the rides, shows, games and refreshments are grouped and for a broad passageway through which the patrons walk. The size of a carnival (usually called a fun fair in Great Britain) varies from two or three rides to as many as 40 or 50 amusement devices of various kinds at state and national fairs.

When space permits, the various units are located in two long lines. The concessions—games and refreshments—are located just inside the midway entrance. The shows that display freaks, unusual animals and fun houses are located at the end of the area, and the rides—Ferris wheels, merry-go-rounds and others—are set up in the centre or along the border. (R. E. McN.; C. R. Bs.)

CARNIVORE, in the broadest sense, any animal that feeds on flesh; but more precisely, any mammal of the order Carnivora, which includes the most powerful beasts of prey, as the lion, tiger, leopard and jaguar, numerous fur bearers, as the seal, fox and sable, the domesticated cat and dog and other well-known animals. In general their teeth, especially the four long, piercing canine teeth, are adapted for tearing flesh, and the toes of many species are provided with strong sharp claws for seizing prey.

The body systems of carnivores are those of other placental mammals; see the article MAMMALIA for information on respiration, digestion, reproduction, etc. The present article, concerned with those special features that figure prominently in the identification of various carnivores, is divided as follows:

- I. General
- II. Characteristic Structures
 1. Soft Parts
 3. Skull
- III. Survey of the Order
 - A. Dog and Dog Allies (Canoidea)
 1. Dog Family (Canidae)
 2. Bear Family (Ursidae)
 3. Raccoon Family (Procyonidae)
 4. Weasel Family (Mustelidae)
 - B. Cats and Cat Allies (Feloidea)
 1. Civet Family (Viverridae)
 2. Hyena Family (Hyaenidae)
 3. Cat Family (Felidae)
 - C. Seals and Seal Allies (Pinnipedia)
 1. Eared Seal Family (Otariidae)
 2. Walrus Family (Odobenidae)
 3. True Seal Family (Phocidae)
- IV. Temperaments of the Carnivores
 - v. Extinct Carnivores
- VI. Classification

I. GENERAL

For the most part the carnivores are very active, intelligent and

courageous animals, with keen senses of sight and smell. In size they vary greatly, ranging from small weasels to huge bears, which may weigh $\frac{3}{4}$ of a ton. There are about 300 species, which in their relationships form 3 groups: the catlike, doglike and seallike carnivores. Besides the cats—lion, tiger, leopard, puma, wildcat and domestic cat—the civets, mongooses and hyenas are comprised in the catlike group. In the doglike group are found in addition to the dogs, wolves and foxes, such unlike types as the bears, the raccoons, cacomistls, kinkajous, pandas, the weasels, badgers, skunks and otters. Far removed from these typical carnivores is the fin-footed seal group, which in addition to true seals includes the sea lions and the walrus.

The carnivores are well represented in all parts of the world except the Australian region, which contains only the dingo, a dog brought there by man. The polar bear and the polar fox range farther north than all other land mammals, and sea lions are found in both arctic and antarctic waters. Some important groups, however, are restricted in their distribution. The numerous civets, for example, are confined to the old world; the raccoons, except the panda, occur only in America, while in most of Africa none of the true bears is found.

Though some carnivores are destructive to domestic animals, and even to human life, many are valuable fur bearers, as the sable, otter, marten, mink, fox and fur seal, and they also hold in check various animals, as rodents, which, if unrestricted in numbers, would become exceedingly injurious to agriculture. Besides the dog and the cat, which have been household animals since ancient times, the cheetah or hunting leopard, the ferret and the mongoose are domesticated. The black fox and the mink, successfully raised for their fur, may also be mentioned.

The term Carnivora, suggesting that all the animals so designated are flesh eaters, is not entirely appropriate. Certain highly organized species of the cat, wolf and weasel kind live almost wholly upon the flesh of warm-blooded animals, for the capture of which their habits and structure are admirably adapted; but others, like most bears, are almost wholly vegetable feeders and quite unfitted for the chase. The great variation in diet and mode of life exhibited by the order is accompanied by a corresponding variation in the limbs and other external organs and by the teeth and skeleton.

II. CHARACTERISTIC STRUCTURES

No single character absolutely distinctive of the Carnivora can be named; but by the combination of a number of structural features, it may be distinguished from other orders of mammals. There are never fewer than four toes on each foot, and the first is never opposable to the rest; the digits are usually armed with compressed claws, never with nails or hoofs; there are typically two tufts of tactile "whiskers" (vibrissae) on each cheek; the tail is always present; the anus and genital organs open by separate apertures; and the mammae are abdominal. The cranial portion of the skull is always capacious as compared with the facial portion, and the brain is well or moderately well convoluted. There are two sets of teeth, milk and permanent, differentiated into incisors, canines and cheek teeth. The incisors usually number 12—3 on each side of the upper and lower jaws—the centrals being smaller than the laterals. The canines are almost always long and piercing in both jaws. The cheek teeth are rooted, never of persistent growth, and the enameled crown is raised into simple or bladeliike cusps.

1. Soft Parts.—*Vibrissae.*—The facial vibrissae consist of a tuft above each eye (superciliary), two tufts on each cheek (genal), half a dozen or more rows on the upper lip (mystacial), a few isolated on the chin and a median tuft (interramal) on the throat. As a rule they are well developed both in number and length in predatory species, especially those that hunt in foliage or undergrowth. In vegetable feeders like the bears they are, on the contrary, greatly reduced and apparently functionless.

Muzzle.—The nostrils are usually surrounded by a conspicuous area of naked, glandular skin, the rhinarium, continued in front to the edge of the upper lip as a strip of grooved skin, the philtrum. It is subject, however, to considerable variation.

Ear.—There is a well-developed erect external ear, or pinna, attached by a broad hollowed base the walls of which are strengthened by cartilaginous ridges. One of these ridges, the supratragus, is sometimes valvular, helping to close the ear opening. Another character of importance is the bursa, a pocket formed by a supplementary flap low on the posterior margin of the ear.

Feet.—In the generalized, and probably primitive, carnivore there are five digits more or less evenly spaced and forming with their tips a strongly and fairly evenly curved series. The third and fourth digits are the longest, the second and fifth shorter and subequal and the first the shortest. Each of them is supplied with a pad behind the claw; and they are all united by a flap of integument, or web, which extends nearly to the pads.

The sole is provided with a plantar pad composed of four united lobes. Behind the plantar pad there is on the forefoot a pair of large, lobate carpal pads; and on the hind foot there is a pair of elongated metatarsal pads, which extend nearly to the heel. This type of foot, called subplantigrade, passes by imperceptible gradations into feet contrasted as digitigrade (in which the digits are used for walking, as in dogs) and plantigrade (in which the whole sole is used).

There are two types of claw in the digitigrade foot: the short blunt claw of the dogs and hyenas and the sharp, retractile claw, found in some civets and most cats, which is modified for laceration of prep. The terminal bone of the digit is retracted by an elastic ligament and the sharp point of the curved claw is protected from wear by lobes of skin which ensheath it. In the seals the feet are converted into paddles, but their structure suggests that they also are modifications of the subplantigrade foot.

Anal Glands.—The rectum is typically provided with a pair of glands opening, usually by a single aperture, just within the anal orifice. The secretion probably acts in normal cases as a lubricant or disinfectant; but in some genera, especially of Mustelidae, like the skunks, the secretion is abundant and nauseous and its forcible discharge is an important means of defense. In the bears (Ursidae) the glands are developed to a negligible extent; and they are absent in the seals.

2. Skull.—The skull is extremely variable in the length, breadth and height. The length of the muzzle is correlated with the number and size of the teeth. Its nasal chambers are filled with delicate scroll-like bones, the turbinals. Of these there are two main groups: the maxilloturbinals, rising from the sides of the inner surface of the maxillae, in front; and the ethmoturbinals, behind.

On the roof of the mouth (the palate) there is a pair of openings, the posterior palatine foramina, which are usually situated on the maxillopalatine suture but may be in advance of it.

The bone containing the ear capsule is covered by the auditory bulla, composed either wholly or partly of the tympanic bone, which always forms its anterior part. The posterior part is occasionally cartilaginous, but it may be ossified. In this type of bulla the cavity is always divided into two chambers by a bony partition, which passes from the line of junction of the two bones.

Behind the bulla there is an expansion of the occipital bone, the paroccipital process, and behind the auditory opening another process, called the mastoid. Low on the inner wall of the temporal fossa is frequently a bony channel, the alisphenoid canal, through which passes a branch of the carotid artery. The incidence of this canal is remarkable, and it has been much used in classification.

3. Teeth.—These vary in number and structure in accordance with diet. The primitive number was 44, as shown in the formula $I_{\frac{3}{3}} C_{\frac{1}{1}} P_{\frac{4}{4}} M_{\frac{3}{3}}$ (for one side of the jaw). This is an abbreviation of:

incisors: upper, 3	canines: upper, 1	premolars: upper, 4
lower, 3	lower, 1	lower, 4
molars: upper, 3		
lower, 3.		

Very seldom however, is the full complement retained; the numerical reduction takes place mostly from the suppression of one or more of the front and back cheek teeth. It reaches its extreme in predatory forms like the cats and weasels where the formula may be $P_{\frac{2}{2}}, M_{\frac{1}{1}}$.

The number, arrangement and shape of the cusps are also subject to great variation, but the extreme types of dentition are derivable

from a more generalized intermediate type in which there is a gradual transition in size, shape and cusp armature throughout the series.

In the upper jaw the cheek teeth increase in size and complexity from the first to the fourth premolar and decrease from the latter to the last molar. The fourth premolar is triangular in shape and the inner portion or lobe is as broad at the base as the three-cusped bladelike outer portion of the crown. The third premolar and the first molar are also triangular and similar to the fourth premolar. In the lower jaw the teeth gradually increase in size and complexity from the first premolar to the first molar. The first three premolars have compressed three-cusped blades, with the median cusp the biggest. The fourth premolar is broader than those in front and has supplementary cusps on the inner side of the three-cusped blade, the shape of the tooth and the arrangement of the cusps clearly foreshadowing those of the first molar, in which the crown is differentiated into two subequal portions—an anterior armed with three cusps arranged in a triangle, and a posterior lower portion with an outer and an inner cusp. A first lower molar of this type is found in many genera of Carnivora.

The fourth upper premolar and the first lower molar, which are opposed in mastication? are similar to the teeth immediately before and behind them in the series, but they are larger, thus attesting to the concentration of biting power in the posterior half of the jaw. This difference in size, often accentuated, is found in many terrestrial species and, as a very general rule, these two teeth also differ considerably in shape from the others. Since this modification is an adaptation for shearing raw flesh and is particularly manifest in predatory forms, the teeth in question have been distinguished as the carnassials.

In the upper carnassial, or the fourth premolar, the modification is brought about by the reduction in size of the inner portion of the crown to a comparatively small lobe and the increase in size and compression of the median and posterior cusps of the outer portion to form a sharp-edged cutting blade. The lower carnassial, or first molar, is still more altered and may, as in the cats, be wholly converted into a cutting blade, which is formed by the enlargement and compression of the anterior median and the adjoining external cusp of the front portion of the primitive type of lower carnassial. High specialization of both carnassials as shearers, seen in the cats, hyenas, some weasels and others, is accompanied by shortening of the jaws, suppression of the second upper molar and reduction in size of the first, and loss of the second lower molar.

III. SURVEY OF THE ORDER

The existing Carnivora may be divided into two suborders: the Fissipeda or typical carnivores, with pawlike feet and cheek teeth of several kinds; and the Pinnipedia or seal group, with paddlelike feet and cheek teeth all alike. A third suborder, Creodont (see CREODONT), from which the two existing suborders have been derived, is a primitive stock, extinct since early in the Tertiary period (about 70,000,000 years ago).

The fissiped carnivores are divided into three superfamilies: the Canoidea, comprising the dog, bear, raccoon and weasel families with their various branches; the Feloidea, including the cat, hyena and civet families; and the fossil Miacoidea.

Pinnipeds, the fin-footed carnivores, are grouped into three existing families and one fossil family.

A. DOG AND DOG ALLIES (CANOIDEA)

In this superfamily, containing the dogs, bears and raccoons, the ethmoturbinals are excluded from the anterior orifice of the nasal chambers by the enlarged maxilloturbinals. The wall of the auditory bulla is composed entirely of the tympanic bone and its cavity is typically undivided. Cowper's glands are present in the male.

The families fall into three series: the dogs (Canidae) with their close relatives, the bears (Ursidae); the raccoons and their allies (Procyonidae); and the weasel-like carnivores (Mustelidae).

1. Dog Family (Canidae).—*True Canines.*—The dogs, wolves and foxes (subfamily Caninae) differ from the rest of the canoids

in possessing a caecum and a duodenojejunal flexure in the intestine, as in the feloids. Also, they are completely digitigrade and typically the formula of the cheek teeth is $P\frac{4}{4}$, $M\frac{2}{3}$, with the carnassials large and secant. The teeth, however, vary. The genus *Canis*, containing the dogs, wolves and jackals, many related genera from South America, and the foxes (*Vulpes*) have the teeth as recorded above.

False Canines.—These are members of other subfamilies. The Asiatic dholes (*Cuon*) and the South American bush dog (*Speothos*) have lost the third lower molar. The most aberrant dentition, however, is found in the foxlike African genus *Otocyon*, in which there are not only four lower and three, occasionally four, upper molars, but the carnassial teeth are not differentiated from the rest either in size or function. Another somewhat aberrant type is the African hunting dog (*Lycan*) in which the ears are large and rounded and the pollex is absent. (See Doc.)

2. Bear Family (Ursidae).—Although the bears and the dogs are shown by fossil forms to be modified descendants of the same stock, the living representatives of these families are widely divergent. The bears are heavily built, with broad, plantigrade feet, short tails, protrusible lips, reduced vibrissae and no bursa on the ear. The cheek teeth, although numerically as in the typical Canidae, are widely different in function and form, being adapted primarily for crushing hard vegetable fibre. The first three premolars above and below are practically functionless, closely crowded or widely spaced, and one or more often deciduous. The upper carnassial is small and not trenchant, and the molars have large flat tuberculated crowns.

There are several well-defined genera: *Ursus* containing the brown bear (*U. arctos*), the grizzly (*U. horribilis*) and the black bear (*U. americanus*); *Thalarcos*, the polar bear (*Th. maritimus*); *Selenarctos*, the Himalayan or Asiatic black bear (*S. thibetanus*); *Helarctos*, the Malay, or sun, bear (*H. maylayensis*); *Melursus*, the sloth bear (*M. ursinus*); and *Tremarctos*, the spectacled bear (*T. ornatus*). (See BEAR.)

3. Raccoon Family (Procyonidae).—This family is here considered to include the pandas (subfamily Ailurinae), the kinkajous, cacomistles and raccoons (Procyoninae).

Pandas.—Subfamily Ailurinae contains two forms, widely divergent in appearance and in certain anatomical features: the giant panda (*Ailuropoda melanoleuca*) and the common panda (*Ailurus fulgens*). The former inhabits Tibet and western China. It re-

(TOP LEFT) ALLAN D. CRUICKSHANK AND (BOTTOM LEFT) LEONARD LEE RUE III FROM NATIONAL AUDUBON SOCIETY, (RIGHT) H. ARMSTRONG ROBERTS
 FIG. 1.—DOG ALLIES. CANOIDEA: (TOP LEFT) RACCOON (PROCYON LOTOR); (BOTTOM LEFT) LONG-TAILED WEASEL (MUSTELA FRENATA), (RIGHT) HIMALAYAN BEAR (SELENARCTOS THIBETANUS)

sembles a white bear with black legs, shoulders, ears and eyespots, but it lacks the alisphenoid canal in the skull and the molars are broad with numerous supplementary cusps. The common panda, which occurs in southern China and northeastern India, is a small, long-tailed, arboreal species, with subplantigrade, sharp-clawed, hairy feet with greatly reduced pads, the supplementary bone on the forefoot being quite small. It also differs from the giant panda in the loss of the third lower molar, in the cheek teeth forming graduated series and being simpler in pattern and in the presence of the alisphenoid canal. The anus is encircled by a glandular pouch and the penis is small and close to the scrotum, as in some feloids.

Raccoons, *Kinkajous*, *etc.*—The subfamily Procyoninae, confined to America, differs from the Ailuridae in having the penis long, the prepuce remote from the scrotum and the anal sac and alisphenoid canal absent, in the normally developed pads on the feet and the differentiation of the upper carnassial from the third premolar. There are several tribes.

The kinkajous (Potos) are arboreal vegetable feeders, with a prehensile tail and ventral scent glands; the jaws are massive and the molars flat crowned. Raccoons (*Procyon*) have long unwebbed digits, a shortish tail and a mobile snout; the crowns of the molars are broad and tubercular, recalling those of *Ailurus*. *Coatis* (*Nasua*) have webbed feet, with fossorial claws, a very long tail, an exceedingly mobile probing snout, slender jaws and smaller cheek teeth than the raccoons but larger tusklike canines. *Cacomistles* (*Bassariscus*) are active, predaceous, genetlike animals with small paws, a long tail and trenchant dentition. The *cuataquil* (*Bassaricyon*) closely resembles the kinkajous superficially but the tail is not prehensile and the cranial and dental characters are more like those of the raccoons.

4. Weasel Family (**Mustelidae**).—This family differs from the Procyonidae in the invariable absence of the second upper molar and in the presence, except in the sea otter, of a wide angular emargination, instead of a notch or slit, between the median and posterior cusps of the upper carnassial. The genera of this family exhibit greater range in structural variation and habits than any family of Carnivora. They may be referred to five subfamilies: the Melinae, the Mephitinae, the Mellivorinae, the Mustelinae and the Lutrinae.

Badgers.—The subfamily Melinae is characterized by the upper carnassial not larger than the molar, with a large inner lobe and bluntly cusped blade; the feet are fossorial. *Meles*, the true badger, is heavily built, with narrow head, short legs and tail and a glandular subcaudal pouch. The upper molar is larger than the carnassial, the bulla is undivided and does not open into the mastoid. The badgers are found in temperate Europe and Asia. *Arctonyx*, the sand or hog badger, occurs from northern India and southern China to Sumatra. It resembles *Meles*, but the muzzle is long, mobile and piglike, while cranially the long palate, continued posteriorly by the pterygoid bones, is unique. *Mydaus*, the teledu or stink badger of Sumatra, Java and Borneo, differs from the preceding forms in the absence of the subcaudal pouch, and in the skunklike development of the anal glands, the dislike rhinarium, divided upper lip, united toe pads, reduced ear and the bulla opening into the mastoid. It has a short tail and a white stripe runs from the crown to the tail. *Helicifis*, the ferret badger, found in Southeastern Asia, is long tailed like the skunks. The upper carnassial is larger than the molar, which has only a slightly broadened talon. There are no special glands. The bulla is divided by a septum. The nose is long, ending in a naked truncated snout; the ear retains a bursa. *Taxidea*, the American badger, is only distantly related to the typical old world species, the resemblances between the two being chiefly convergent. Its broad skull, the carnassial larger than the triangular upper molar, the bulla opening to the mastoid, the metatarsus without pads, the single carpal pad and peculiar glands associated with both male and female genitalia, are distinctive characters.

Skunks.—The Mephitinae, or skunks, restricted to America and represented by three genera (*Mephitis*, *Conepatus*, *Spilogale*), have the bony palate short while the mesopterygoid fossa is long. The penis is without a bone. The anal glands are excessively de-

veloped and secrete a nauseating fluid, which may be sprayed for a distance of several yards. The conspicuous pattern and fearless behaviour of skunks make them the stock instance of warningly coloured species.

Ratels.—The Mellivorinae includes only one species, *Mellivora capensis*, the ratel or honey badger, which occurs in tropical Asia and Africa. This animal is badgerlike in appearance but the teeth are sectorial, the upper carnassial larger than the molar, with a sharp blade. The anal glands are developed as in the skunks; the anus is sunk in a pouch and the ear is reduced.

Weasels, Minks, *etc.*—The Mustelinae have the upper carnassial long with a small talon. The feet are digitigrade and not fossorial, with short, partly united digits and short, sharp claws. The weasel, stoat, mink and polecat (*Mustela*) of Europe, Asia and America, have thick-walled auditory bullae, which open to the mastoid. The muzzle is short and the dentition especially sectorial. *Vormela*, the tiger polecat of southern Europe and Asia, is characterized by its variegated dorsal coloration and unconstricted upper molar. *Martes*, the martens and sables, have four premolars and thin-walled bullae. The feet have hairy metatarsus, the carpal pads separate from the plantar pad, like *Mustela* and the ear has a well-developed marginal bursa. *Gulo*, the holarctic wolverine, is a large plantigrade relative of the martens, with heavy dentition.

The tayra (*Galera* or *Eira barbara*), of South and Central America, is probably closely allied to the martens, but the ear lacks the bursa and the feet are naked, with confluent pads. The grisons (*Grisson* and *Lyncodon*) occur in Central and South America; they are more distinct from the tayra than was formerly thought. The bullae are low, the tympanic ring in contact with their roofs and their cavities are small and undivided. The dorsal coloration is gray or whitish, while the underparts are dark brown or black, and the anal glands are well developed. The African muishonds (*Ictonyx*, *Poecilictis*) are also skunklike in coloration, being black with white stripes, but they are lighter in build and less fossorial. The cheek teeth are $\frac{3}{3}$ or $\frac{4}{4}$. The anal glands are highly effective. *Poecilogale albinucha*, the striped African weasel, is short legged and long bodied, but otherwise similar to the larger forms.

Otters.—The Lutrinae, or otters, represented by many genera (*Lutra*, *Aonyx*, *Pteronura*, *etc.*), differ from the preceding subfamilies mainly in their structural adaptations to aquatic life, and particularly in having the hind feet larger than the forefeet, with long distensible digits. The kidneys also are lobulate. The skull in shape resembles that of the Mustelinae, but the upper molar is as large as the carnassial. The family ranges all over the world apart from Madagascar and Australia.

The sea otter (*Enhydra*), which is restricted to the North Pacific, differs from the other lutrinids in the structure of the feet. The forefeet have the digits very short and tightly fused, and the hind feet very large and paddlelike with the digits progressively increasing in length from the first to the fifth. Also the cusps of the teeth are all bluntly rounded.

B. CATS AND CAT ALLIES (Feloidea)

Although the cats are highly specialized, their relatives the civets include some of the most primitive living carnivores. In the Feloidea the ethmoturbinal bones are extremely large and occupy the greater part of the nasal chambers, extending forward between and over the smaller maxilloturbinals almost to the anterior orifice of the chambers. The auditory bulla is composed of two elements: the tympanic and entotympanic, and when completely ossified, its cavity is divided by a partition springing from the line of junction of the two bones that compose its wall. Cowper's glands connected with the generative organs of the male are absent. The Feloidea are divisible into three families: Viverridae, Hyainidae and Felidae.

1. Civet Family (**Viverridae**).—The Viverridae, civets, genets and mongooses, are a confusing group of small- to medium-sized mammals largely confined to Africa and Asia (except for a species of genet found in Spain and on a few Mediterranean islands).

Civets (*Viverrinae*).—The Viverrinae, represented in tropical Asia by the civets (*Viverra*, *Viverricula*) and in Africa by the

BY COURTESY OF (TOP LEFT, RIGHT) NEW YORK ZOOLOGICAL SOCIETY; PHOTOGRAPH, (BOTTOM LEFT) R. VAN NOSTRAND FROM NATIONAL AUDUBON SOCIETY

FIG 2.—CAT ALLIES, Feloidea: (TOP LEFT) INDIAN CIVET (*VIVERRA ZIBETHA*); (BOTTOM LEFT) CANADA LYNX (*LYNX CANADENSIS*) (RIGHT) SPOTTED HYENA (*CROCUTA CROCUTA*)

typical civet cat (*Civettictis*) and the genets (*Genetta*, *Poiana*), differ from the palm civets (*Paradoxurinae*) in being digitigrade, generally with retractile claws, in having more elaborate scent glands and more trenchant teeth. The linsangs (*Prionodon* and *Pardictis*) are elegant genetlike animals found in southeastern Asia, with digitigrade feet and retractile claws: they are the only members of the S'iverridae in which the penis is small and close to the scrotum. Also the scent glands, when present, are either wholly or partly perineal, never entirely abdominal in position. The subfamily exhibits great range in structural variation.

Palm Civets (Paradoxurinae).—The oriental palm civets, ranging from India to the Philippines and Celebes, are represented by the genera *Paradoxurus*, *Paguma* and *Macrogalidia*. In a related form, *Arctogalidia*, the scent gland is absent in the male, and in the binturong (*Arctictis*) the tail is prehensile and the teeth, as in *Arctogalidia*, are not so trenchant as in the typical palm civets.

The African tree or palm civet, *Nandinia*, differs from other Viverridae in having the cavity of the auditory bulla undivided and the wall of its posterior portion permanently cartilaginous; in the large size and shelflike form of the mastoid portion of the skull and the backward direction of the paroccipital away from the bulla it resembles many of the Canoidea (see below). In other characters it shows kinship with the oriental palm civets, with which it has been affiliated. The body and tail are long, the muzzle elongate and narrow; the full complement of facial vibrissae is retained; the ear has the bursa and a ridgelike supra-tragus; the legs are short, with the feet subplantigrade, and with short, curved, partially retractile claws, evenly spaced digits, a four-lobed plantar pad, continuous on the forefoot with the bilobed carpal pad and on the hind foot with the metatarsal area which is naked and has two ridgelike pads. Also, in the skull the palatine foramina are in front of the suture, and the cheek teeth are $P\frac{3}{4}$, $M\frac{1}{2}$ and moderately trenchant.

The single species of this genus, *N. binotata*, sometimes called the two-spotted palm civet, is a spotted, omnivorous, arboreal animal the size of a small cat, restricted to the forest region of west Africa. It is an extremely interesting primitive type, resembling in many cranial and dental characters, especially in the structure of the bulla, the extinct Miacidae of the Eocene.

Hemigales.—In the three oriental genera of the subfamily Hemigalinae (*Hemigalus*, *Diplogale*, *Chrotogale*) the teeth are sharper cusped than in the civets, the feet are more digitigrade and the scent pouch is reduced in size in both sexes.

The otter civet (*Cynogale*) is a fish-eater adapted for aquatic life. The vibrissae are numerous and rigid, the rhinarium is on the summit of the muzzle, which is very wide, and the tail is

short. The scent gland is reduced and the teeth are modified for holding fish and crushing the shells of crabs and mussels. The genus ranges from Malaya to Borneo.

In the preceding groups the scent gland is present in one or both sexes. In the following three it is absent: the genus *Fossa* is a civetlike animal inhabiting Madagascar, digitigrade but with nonretractile claws; *Eupleres* also comes from Madagascar, is remarkable for the degenerate character of the teeth and feeble jaws, and the feet are subplantigrade and fossorial.

Galidines.—In the Galidiinae or Malagasy mongooses (*Galidia*, *Galidictis*, *Hemigalidia*), the scent gland is restricted to the female, the feet are narrow with nonretractile claws, the jaws are short, the teeth sectorial and the bulla has a bony tubular

meatus not found in the other groups.

Mongoose.—The subfamily Herpestinae, the true mongooses, differs from the Viverrinae in having a glandular circumanal sac into which the anus and anal glands open by separate orifices, and in the absence of the bursa on the ear. They have no perineal glands, the penis is short and close to the scrotum and there is a tubular auditory meatus in the skull. The feet are digitigrade or subplantigrade with fossorial nonretractile claws and the toes may be reduced to four on each foot. The teeth also vary, sometimes being bluntly, sometimes sharply, cusped and trenchant. This group contains a large number of genera and species found mostly in India and Africa. The best known are *Herpestes*, the typical mongoose; *Mungos*, the banded mongoose; *Ichneumia*, the white-tailed mongoose; *Suricata*, the meerkat; and others.

Foussas.—Subfamily Cryptoproctinae contains only the foussa (*Cryptoprocta*) of Madagascar. It resembles externally a large oriental palm civet, but differs in the absence of perineal scent glands, the possession of a capacious circumanal sac and of a large bone in the penis, this organ being highly complex in structure. The jaws of the skull are short and the teeth are sectorial, closely resembling those of the Felidae.

2. Hyena Family (*Hyaenidae*).—*Hyenas.*—The subfamily Hyaeninae includes the hyenas (*Hyaena*, *Crocuta*). They differ from other Feloidea in the large size of the tympanic bone, which composes nearly the whole of the bulla, the partition of the cavity lying far back. The feet are digitigrade, like those of a dog, but there is no pollex. The anal glands open into a capacious subcaudal pouch. There are no perineal glands and the prepuce is far in advance of the scrotum. The skull is massive and the teeth which are sectorial in type are very powerful. The genus *Hyaena* is represented by the striped hyena of southwestern Asia and northern Africa and by the brown hyena of southwestern Africa. *Crocuta*, the spotted hyena, which differs in the structure of the teeth and genital organs, is restricted to Africa. Hyenas are mostly scavengers, feeding upon the carcasses of big game.

Aardwolf.—The subfamily Protelinae contains only the aardwolf (*Proteles*), found on the savannas and veld of tropical and southern Africa. It resembles a small striped hyena externally except for the presence of a pollex on the forefoot. It differs, however, from the hyenas in the normal structure of the bulla and from all the land carnivores in its remarkable dentition, the cheek teeth being widely spaced, all alike and peglike, with the jaws correspondingly weak. It eats carrion and white ants.

3. Cat Family (*Felidae*).—The family Felidae contains all the cats, distinguished by the position of the posterior palatine foramina on the maxillopalatal suture and the absence of the inter-

ramal tuft of vibrissae. Four subfamilies are fossil. All existing cats belong to the subfamily Felinae. As in the linsangs (*Viverridae*), the penis is small and close to the scrotum, the vulva close to the anus, and there are no perineal glands or glandular pouch above or around the anus; but although the feet have retractile claws, they are more digitigrade than in the linsangs, the pollex being more elevated, the hallux absent and the plantar pad three lobed. In the skull the jaws are short and the teeth highly sectorial, the important cheek teeth being the two-bladed carnassials. Recent cats are all closely allied and represent surviving members of a single group. Until recently all except the cheetah were generally considered to belong to a single genus, but at least five genera can be recognized. *Felis*, the typical cats, including the domestic cat and a number of near relatives, is characterized by fully ossified hyoid, well-developed claw sheaths and long tail. Lynx differs from other cats in the absence of an upper premolar, and has short tail and tufted ears. *Neofelis nebulosa*, the clouded tiger (or clouded leopard) of southern Asia and the Greater Sunda Islands, is characterized by very long upper canines. *Panthera* contains the lion (*P. leo*), the tiger (*P. tigris*), the leopard (*P. pardus*), the jaguar (*P. onca*) and the snow leopard (*P. uncia*), which have the larynx (voice box) loosely attached to the skull by the long ligamentous suspensorium of the hyoid. The cheetah (*Acinonyx*) is distinguished from other cats by the absence of the integumentary sheaths to the claws; the hyoid is as it is in the typical cats. (See CAT.)

C. SEALS AND SEAL ALLIES (PINNIPEDIA)

The seallike mammals are often considered a separate order, but they are related to land carnivores, and are here treated as a suborder, Pinnipedia. The upper limbs are short, the feet, swimming paddles. The first and fifth toes of the hind feet are larger than the rest. The cheek teeth are all similar.

1. Eared Seal Family (*Otariidae*).—This family comprises the sea lions and fur seals; these have small external ears and progress on land in quadrupedal fashion by applying the naked soles of all four feet to the ground. The incisor teeth are present, the canines are of normal size and the cheek teeth have compressed crowns with one main cusp. They feed mostly on fish.

There are seven well-marked species, each of which has received a generic name based on cranial characters. Steller's sea lion (*Eumetopias jubata*) and the northern fur seal (*Callorhinus ursinus*) are found in the North Pacific; the California sea lion (*Zalophus californianus*) ranges from California to Japan; the Australian sea lion (*Neophoca cinerea*) inhabits Australia; the Patagonian sea lion (*Otaria flauescens*) frequents the coasts of South America; the southern fur seal (*Arctocephalus*) occurs in the South American, south African and Australian seas; and Hooker's sea lion (*Phocarcos hookeri*), also in the Australian seas. The family is thus restricted to the Pacific and southern oceans.

2. Walrus Family (*Odobenidae*).—This family contains the walrus (*Odobenus*), restricted to the northern oceans. Its limbs are like those of the *Otariidae*, but the external ear is absent and the skull is remarkably modified to carry the huge tusklike upper canines, while the cheek teeth are flat crowned for crushing the shells of mussels and oysters upon which the walrus mainly feeds.

3. True Seal Family (*Phocidae*).—This family comprises true seals. They are also without external ears, but the hind limbs are stretched backward to act as a tail fin and their soles, which like those of the forelimb are hairy, are incapable of being applied to the ground. The variation in cranial and dental characters is greater than in the *Otariidae*, the common seals (*Phoca*) and the elephant seals (*Mirounga*) exhibiting the extremes. In *Phoca* the claws are all well developed, the digits of the foreflippers are subequal and the first and fifth of the hind flippers only slightly exceed the rest and the integument is not produced beyond their tips; the incisors are $\frac{3}{2}$, the cheek teeth are cusped and mostly two rooted, the muzzle is normal, its orifice is small and encircled by the long nasals and premaxillae which are in contact. In *Mirounga* the digits of the foreflippers decrease in length from the first to the fifth, those of the hind flippers have no claws and the fourth and fifth digits greatly exceed the rest and

are lengthened by skin lobes; the muzzle of the male is developed into a distensible proboscis; the incisors are $\frac{1}{2}$, the small cheek teeth have simple crowns and one root, and the premaxillae and nasals are short and widely separated and do not surround the dilated nasal aperture. *Phoca* and its allies, e.g., *Halichoerus*, the gray seal, are found in the northern oceans. *Mirounga*, the largest of the pinnipeds, reaching a length of 20 ft., ranges from the antarctic to California; but there are many structurally intermediate genera in the northern and southern oceans.

(R. I. P.; J. E. HL.; X.)

IV. TEMPERAMENTS OF THE CARNIVORES

It is a commonplace observation that cat and dog have characteristic and incompatible temperaments. Groups of cats do not join in chasing a smaller dog, and dogs do not patiently watch a mousehole. Little reflection is required to extend such observation to other types of carnivores. Indeed, each of the principal members of the carnivore group, wild as well as domesticated, insofar as it has been familiar to European peoples, has left its stamp on folklore and even in the structure of language. We speak of the gregariousness and loyalty of dogs, of the solitary nature and stealth of cats, of the cunning of foxes and of the ferocity of weasels. The bear has two familiar characters—he is a byword for surliness, as well as for good-natured inoffensiveness—but these correspond accurately on one hand to his behaviour when annoyed (well known from the medieval bearbaiting), and on the other to his character when unmolested in the wild. The comparative study of such psychic characters applying to families and genera deserves attention.

While such widespread impressions cannot be very exactly or scientifically formulated, the fact that the mental characteristics of the familiar domestic cat may be seen in its relatives in quite the same way as anatomical peculiarities, such as the sheathed claws or vertical pupil of the eye, has profound philosophic implications. Differences of temperament in other mammalian groups, and characteristic of whole orders, elephants or monkeys for example, may be detected in a still more general way. The topic was referred to by Clarence Day in a clever evolutionary essay. This Simian World.

The importation of the giant panda, which represents a distinct subfamily of carnivores, into U.S. and European zoological gardens made observation of this previously unfamiliar creature possible. Its instant popularity, equally with its keepers and with the visiting public, obviously had as its basis a novel and distinctive set of behaviour patterns.

For a person familiar with cats and dogs to undertake the breeding of ferrets means another insight into the family characters of

carnivores. The ferret is a typical representative of the weasel family, and though as long domestic as the cat, retains much of the curiously intent ferocity of its wild relatives. The weasel temperament appears to have impressed itself on the behaviour of the smaller rodents and the rabbits that form the principal prey of the smaller members of the weasel tribe. These rodents display an unreasoning and helpless fear of the ferret, as of the weasel. The play of a tame adult ferret with a human being is startlingly different from that of a cat or a dog, and the play of young ferrets with each other is equally characteristic.

The skunks are very distinctive members of the weasel family confined to the Americas. They are still somewhat confused linguistically with the European polecat (the wild relative of the ferret). The skunk characteristic of complete fearlessness is obviously correlated with its conspicuous type of coloration and with its astonishingly effective means of defense by the spray of an overpowering scent from its anal glands. Even the fearlessness of the skunk, however, relates it psychologically to the weasel tribe, in which lack of fear of very much larger animals, even carnivores, is characteristic.

The raccoon represents still another type of carnivore whose peculiar habits and temperament have become familiar. Raccoons are said to exhibit exceptional intelligence in releasing themselves from cages, and intelligence may well be associated with their most highly developed characteristic, insatiable curiosity. It is curiosity, in turn, that makes the raccoon an easy prey to the trapper who baits his trap or snare with some unusual or glittering object.

The coat of tropical America differs radically from the raccoon in gregarious habits but betrays its relationship by an equally evident extreme of curiosity. The arboreal and nocturnal kinkajou, also thought to be a relative of the raccoons, is so distinctive in its habits that it may be expected to have quite as distinctive mental characters.

The observations and impressions of naturalists as to the minds of wild animals, and the frequently prejudiced observations of the keeper of pet animals obviously need critical sifting and experiment before the mental characteristics of animals can be associated properly with the taxonomic categories of orders, families, genera, species, races and individuals. The interrelations of habits, structure and mental characteristics likewise require more, and more critical, observation. There are, however, strong indications of such associations. (K. P. S.)

V. EXTINCT CARNIVORES

Fossil remains of the majority of the common modern genera of Carnivora are found in the Pleistocene formations along with a number of extinct types which were known to prehistoric man. Among these the most remarkable are the sabre-toothed tigers or machairodonts (see SABRE-TOOTHED TIGER), the *Arctotherium* or short-faced bear of North and South America. The cave bear of

Europe (*Ursus spelaeus*) and the California lion (*Panthera atrox*) equaled in size the largest living species. The geographic range of hyenas, lions and dholes was then extended to northern Europe, while conversely the wolverine and other northern Carnivora have been found as far south as Arkansas.

All of the families of modern Carnivora are represented in the formations of the later Tertiary period, most of them by a wider variety of types than those that survive today, and the ancestry of many of the modern genera can be traced back through the Pliocene, Miocene and Oligocene into or toward a common ancestral stock which appears to be fairly represented by the Eocene superfamily Miacoidae (comprising the family Miacidae). The Miacidae, alone among the early carnivores, acquired the true carnassial or shearing teeth of the fissiped Carnivora, and on this account they are often included in the Fissipedia. However, for various reasons they have also been regarded as pro-fissiped creodonts.

In the Oligocene numerous genera of primitive fissiped Carnivora are known from Europe, North America and central Asia. They all appear to be rather nearly related, but the beginnings of the distinctions between viverroid, musteloid and cynoid groups can be perceived and the felids are already distinct. The faunas of the three regions have much in common and these Oligocene fissipeds are evidently descended from holarctic Miacidae of the Eocene. They had apparently not yet reached Africa, although the Creodonta had preceded them into that region, at least as far as Egypt. Neither creodonts nor fissiped Carnivora are found in South America at this time; the Carnivora did not reach the neotropical region until the Pliocene, their place being taken by carnivorous marsupials in the older Tertiary of South America.

All of these Oligocene Carnivora have the scaphoid and lunar bones united. Most of them have the tympanic ring expanded into a complete bulla, but the bulla is not infrequently loosely articulated to the skull and is then usually lost in the fossil specimens.

The canoid group has the dentition $I\frac{3}{3}C\frac{1}{1}P\frac{4}{4}M\frac{3}{3}$ (or $\frac{2}{2}$); the teeth behind the carnassial are moderately reduced and of crushing type. *Cynodictis* with only two upper molars leads through a number of intermediate stages (*Nothocyon*, Upper Oligocene; *Cynodesmus*, Lower Miocene; *Galecynus* and *Tephrocyon*, Upper Miocene) into the modern Canidae; while *Daphaenus* with three upper molars leads (through *Daphoenodon* of the Lower Miocene) into the Miocene *Amphicyon* ("bear dog") with enlarged crushing and reduced shearing teeth. These equaled the modern bears in size, but were still largely digitigrade with legs of moderate length and long heavy tail. They are connected with the true bears through *Hemicyon* (Miocene), *Hyaenarctos* and *Indarctos* (Pliocene) in which the teeth progressively assume the fully specialized crushing type of the true bears, the limbs become long and straight, the feet plantigrade and the outer digit of manus and pes the largest. How near this series comes to being a direct line of ancestry is not yet settled, but it unquestionably indicates that the bears are derived from primitive Oligocene cynoids. The raccoons also appear to be derived from this primitive cynoid stock, through *Cynodon* of the Oligocene and *Phlaocyon* of the Lower Miocene, but it is probable that the modern Procyonidae are several independent parallel branches from this stock rather than a single group.

The Oligocene musteloids have the postcarnassial teeth more reduced than in the cynoids and of more or less cutting type. Their dental formula is $I\frac{3}{3}C\frac{1}{1}P\frac{4}{4}$ (or $\frac{3}{3}$) $M\frac{2}{2}$ (or $\frac{1}{1}$). None of them has acquired the expansion of the inner half of m^1 nor the flattened tympanic bulla that characterize modern Mustelidae; these characters appear in a very rudimentary stage in most of the Lower Miocene and more fully developed in the Middle and Upper Miocene mustelines, but are assumed independently in a number of separate series that lead up more or less directly into the martens, weasels, wolverines, otters, skunks and badgers.

The viverroid group is hardly distinguishable in the Oligocene by tooth characters, but it shows in contradistinction to the cynoids and musteloids a certain tendency to extend the bulla backward and expand the paroccipital process over its posterior end. The well-developed parastyle on the upper carnassial, characteristic of most modern Viverridae and Felidae, is small and inconstant in

FROM J. Z. YOUNG, "THE LIFE OF VERTEBRATES," CLARENDON PRESS, OXFORD, 1958
 FIG. 4.—EVOLUTION OF CARNIVORA

their Oligocene ancestors, and is moreover not uncommonly found in Tertiary cynoids and musteloids (*Aelurodon*, etc.). In the Miocene Viverridae the limitation of the postcarnassial teeth to two above and one (the second true molar) below, both well developed, becomes more definite, the bulla more characteristic and the division between viverrine and herpestine genera begins to be distinguishable.

A number of intermediate genera in the Miocene and Lower Pliocene (*Ictitherium*, *Lepthyaena*, *Palhyaena*) are transitional to the hyenas, which are fully developed in the Lower Pliocene and are clearly derivable from primitive civets, although the known species of these intermediate genera are not directly ancestral. Hyenas and civets are found only in the old world Tertiaries, although fragmentary remains of hyenoid Canidae from the Tertiary of North America have several times (*Aelurodon*, *Borophagus*, "Prohyaena," *Chasmoporthetes*) been mistakenly referred to these old world families. The Tertiary canids, on the other hand, are chiefly North American, while the mustelids and ursids are holarctic.

The Felidae are quite distinct in the Oligocene, and all of them show, but in different degree, an enlarged and compressed upper canine, reduced lower canine and flanged or angulate chin. They appear to fall into two series; in one these characters and associated special adaptations in skull and skeleton are decidedly more marked and are progressively increased in the Lower and Upper Miocene to culminate in the sabre-toothed tigers of the Pliocene and Pleistocene. In the other series the above noted peculiarities, already much less developed, are progressively reduced to the nearly normal condition of the modern Felidae in which upper and lower canines are nearly equal, and the chin has lost its flange. The clouded tiger (*q.v.*) of Malaysia is the most primitive living species in these as in some other particulars. Dinictis of the Oligocene, *Nimravus* and *Archaelurus* of the Lower Miocene, *Pseudaelurus* of the later Miocene, are the successive stages in the ancestry of the Felidae, while *Hoplophoneus* and *Eusmilus* of the Oligocene and *Machairodus* of the Miocene lead into the more highly specialized sabre-tooths *Smilodon* and *Megantereon* of the Pliocene and Pleistocene. In both the feline and machairodontine series there is also a progressive specialization of the shearing teeth and reduction of the premolars, these teeth in *Dinictis* being not far beyond the stage reached in the modern viverrid genus *Cryptoprocta*. (W. D. M.; X.)

VI. CLASSIFICATION

The following taxonomic scheme of the order Carnivora is one of several subscribed to by mammalogists:

- Suborder Creodonta, primitive carnivores (fossil and extinct)
 - " Fissipeda, footed land carnivores
 - Superfamily Miacoidea (fossil and extinct)
 - Canoida, dogs and dog allies
 - Family Canidae, dogs, etc.
 - Subfamily Caninae, true dog, wolf, fox, etc.
 - Simocyoninae, dhole, cape hunting dog
 - Amphicyonodontinae (fossil and extinct)
 - Amphicyoninae (fossil and extinct)
 - Borophaginae (fossil and extinct)
 - Otocyoninae, big-eared fox, motlosi (fossil and extinct)
 - Family Ursidae, all the bears
 - " Procyonidae, raccoons, pandas, etc.
 - Subfamily Procyoninae, raccoon, coati, kinkajou, etc.
 - " Ailurinae, all the pandas
 - " Cynarctinae (fossil and extinct)
 - Family Mustelidae, weasels, badgers, etc.
 - Subfamily Mustelinae, weasel, mink, marten, grison, wolverine, etc.
 - " Mellivorinae, ratel, honey badger
 - " Melinae, all the true badgers
 - " Mephitinae, skunk
 - " Lutrinae, otter
 - " Leptarctinae (fossil and extinct)
 - Superfamily Feloidea, cats and cat allies
 - Family Viverridae, civets, etc.
 - Subfamily Viverrinae, true civet, genet, linsang
 - " Paradoxurinae, palm civet, musang, binturong
 - " Hemigalinae, fanaloka, otter civet, etc.
 - " Galidiinae, Malagasy mongoose
 - " Herpestinae, meerkat, true mongoose

- Subfamily Cryptoproctinae, fousa or fossa
- " Stenoplesictinae (fossil and extinct)
- Family Hyaenidae, hyenas and aardwolves
 - Subfamily Hyaeninae, hyena
 - " Protelinae, aardwolf
 - " Ictitheriinae (fossil and extinct)
- Family Felidae, all the cats
 - Subfamily Felinae, lion, tiger, domestic cat, etc.
 - " Proailurinae (fossil and extinct)
 - " Nimravinae, false sabre-toothed tiger (fossil and extinct)
 - " Machairodontinae, sabre-toothed tiger (fossil and extinct)
- Suborder Pinnipedia, fin-footed carnivores
 - Family Otariidae, all the eared seals including fur seals and sea lions
 - " Odobenidae, walruses
 - Phocidae, all the true seals
 - Subfamily Phocinae, harbor seal, hair seal, harp seal, etc.
 - Lobodontinae, Ross's seal, leopard seal, Weddell seal, etc.
 - " Monachinae, monk seal
 - Cystophorinae, hooded seal, elephant seal
 - Family Semantoridae (fossil and extinct)
- See also Mammalia and articles on various carnivores: CAT; DOG; BEAR; RACCOON; SEAL; etc.

BIBLIOGRAPHY.—F. Bourlière, *The Natural History of Mammals* (1954); A. S. Romer, *The Vertebrate Story*, ch. 12 (1959); Ivan T. Sanderson, *Living Mammals of the World* (1955); G. G. Simpson, "The Principles of Classification and a Classification of Mammals," *Bull. Amer. Mus. Nat. Hist.*, vol. 85 (1945).

CARNIVOROUS PLANTS (INSECTIVOROUS PLANTS) are plants having the ability to capture and consume by digestion, or by the aid of bacteria, insects and other small animals (crustacea, nematodes, etc.). Thus they supplement the supplies of nitrogenous material and salts afforded them, in common with other plants, by the soil and atmosphere. The various mechanical arrangements by which these supplies of animal food are obtained and utilized are described under the headings of the various genera.

Perhaps the most generally known of the carnivorous plants occur in the family Droseraceae, and this is because of the worldwide and common occurrence of the sundews (*Drosera* species). The carnivorous genera include *Drosera*, *Drosophyllum*, *Aldrovanda* and *Dionaea*. *Byblis*, formerly regarded as another genus of this family, was later placed in a separate family, the *Byblidaceae*. *Roridula*, once regarded as carnivorous, later was shown not to be so. It is an insect catcher, but does not make use of the insects, its secretions being resinous.

The Sarraceniaceae contain the genera *Sarracenia* (nine or ten species); *Darlingtonia* (*Chrysamphora*) (one species); *Heliamphora* (four species). The *Nepenthaceae* consist of 1 large genus, *Nepenthes*, with more than 60 species.

These three families (the *Byblidaceae* aside) are closely allied and form the series *Sarraceniales* of the free-petaled section (*Choripetalae*) of the *Dicotyledons*. The curious pitcher plant, *Cephalotus follicularis*, comprises a separate family, the *Cephalotaceae*, closely allied to the *Saxifragaceae*. Finally the genera *Pinguicula*, *Genlisea*, *Utricularia*, *Biovularia* and *Polypompholix* are a distinct group belonging to the gamopetalous family *Lentibulariaceae*.

The large genus *Drosera*, of more than 90 species, is of worldwide distribution, the largest species being found in Australia, viz., *D. gigantea*, growing to a stature of three feet, with adhesive clinging leaves. Its congeners, on the other hand, are usually confined to restricted and well-defined, comparatively small areas. Thus *Drosophyllum* grows on the dry hills of Portugal and nearby Morocco. Its habitat is in contrast to that of all the other carnivorous plants, which is swampy or wet, acid and infertile soils. The two species of *Byblis* have a wide range from southwestern Australia to its northern tropics. Of the two physiologically closely related monotypic genera, *Aldrovanda* and *Dionaea*, *Aldrovanda* has a very wide range in the old world from the Iberian peninsula to Japan and in Africa certainly as far south as Mozambique. Its wide distribution may be partly explained by the fact that it is a floating swamp plant, though it appears rather particular about its immediate surroundings.

Dionaea muscipula, on the other hand, is found only in the United States, in North Carolina and to some extent in South

Carolina. The four species of *Heliamphora* are to be found on the table mountains of the Guianas and Venezuela, Mt. Roraima, Mt. Duida and Mt. Auyán-Tepuí being the three known localities. *Darlingtonia* grows in swampy places from sea level to 6,000 ft., approximately, in the coastal belt and the nearby Sierra Nevada of southern Oregon and northern California. Of *Sarracenia* there are nine or ten species, ranging from Labrador to Louisiana along the whole of the Atlantic seaboard and as far west as Winnipeg, and perhaps still farther. The richest congeries of species is in the southeastern U.S.

The approximately 60 species of *Nepenthes* are natives of the wet tropics of the old world, in the Malay archipelago, and northern Australia, Vietnam, Bengal and the Seychelles and Madagascar. Of the gamopetalous Lentulariaceae, *Pinguicula* is fairly abundant in the north temperate zone, and ranges down the Andes to Patagonia, always in moist habitats. The 250-odd species of *Utricularia* are floating aquatics that grow in quiet waters or sandy or muddy soils, moss of rocks or trees and are circumterrestrial, from Greenland to South Africa in longitude. Two closely related species of *Biovularia* are tropical American. *Polypompholix* is south and southwestern Australian, and is fairly restricted geographically. *Genlisea* is a small genus of tropical west Africa and the tropical regions of Brazil. It is worthy of remark that, with the above-named exception of *Drosophyllum*, all the carnivorous plants agree in inhabiting damp heaths, bogs, swamps, very wet soils usually of quartz sand or mud, where water is abundant and where there is a paucity of nitrogenous material and possibly of suitable salts.

There are also carnivorous plants among the fungi, speaking in the strict sense that they live on animal food. Here is meant the sort of fungi that have special arrangements or traps by which they catch their prey. The first was discovered by W. Zopf (1888). It was a fungus (*Arthrobotrys oligospora*) already described by Fresenius, but was shown by Zopf to have minute loops by which it caught live nematodes, into the bodies of which it then sent penetrating digesting and absorbing branches (haustoria). Other similar species are now known, in some of which the trapping loops are composed of three cells which immediately swell when an eelworm ventures to insert head or tail, such as *Dactylella bembicoides*. A fungus that catches armoured rotifers by means of short branches with end cells that on being attacked exude a strong adhesive was discovered and named *Zoophagus insidians* in 1911. Another similarly acting species is *Sommerstorffia spinosa*.

A number of other species with devices of other kinds (chiefly sticky discs or patches) have been described in detail. All these are of course microscopic in dimensions; accordingly there are probably many others awaiting discovery.

See F. E. Lloyd, *The Carnivorous Plants* (1942). (F. E. L.)

CARNOCK, ARTHUR NICOLSON, 1ST BARON (1849–1928), British diplomat, who did much for the successful foundation and consolidation of the ententes with France and Russia, was born in London on Sept. 19, 1849, the younger son of Adm. Sir Frederick Nicolson. He was intended to follow his father's profession, and passed through H.M.S. "Britannia," but went afterward to Rugby and Brasenose college, Oxford, and in 1870 entered the foreign office. Two years later he became assistant private secretary to Lord Granville, the foreign secretary. On the change of government in 1874 Nicolson was sent to Berlin. There and in successive posts he was fortunate in serving under distinguished ambassadors like Lord Odo Russell (afterward Lord Amthill), Sir Austen Henry Layard and Lord Dufferin. He went to Athens in 1884, and thence to Teheran (1885–88) where he was chargé d'affaires for more than two years. He learned Persian, became very popular and helped to revive British influence in Persia. Knighted in 1888, he was consul general in Budapest (1888–93), and then posted in succession to Turkey, Bulgaria and Morocco.

It was as minister in Tangier (1895–1904) that Nicolson's services first gained public notice. Britain and France were at that time rivals in north Africa, but Nicolson was quick to sense the growing challenge of Germany, and he worked for a better understanding with France. His attitude fitted the policy of Lord Lans-

downe (foreign secretary, 1900–05), who negotiated the terms of the *entente cordiale* in 1904. On Jan. 1, 1905, Nicolson was appointed ambassador in Madrid, and he attended the Algeciras conference (1906) where he enhanced his reputation by his skilful reinforcement of French demands.

He was now a leading member of the diplomatic corps and his personal influence grew as ambassador to Russia (1906–10), where his patient negotiations resulted in the Anglo-Russian entente of 1907. It was consequently no surprise when in 1910 he was called to succeed Lord Hardinge as permanent undersecretary of state at the foreign office. He had succeeded in allaying Russian distrust of Great Britain, and he now collaborated closely with the foreign secretary, Sir Edward Grey, in cementing the triple entente of Great Britain, France and Russia. He supported Grey assiduously during the critical weeks which preceded the outbreak of war in 1914, and remained at his post until 1916 when he was created Baron Carnock, of Carnock in Stirlingshire, on his retirement. He died in London on Nov. 5, 1928.

His third son, Sir Harold Nicolson (1886–), diplomat and author, published *Lord Carnock*, a biography of his father, in 1930. (A. L. KE)

CARNOT, (LAZARE) HIPPOLYTE (1801–1888), French republican statesman chiefly distinguished for his attempt at compromise on the question of religious teaching in state schools, was born at St. Omer on Oct. 6, 1801, the second son of the great Lazare Carnot. Going into exile with his father in 1815, he returned to France in 1823. He wrote, in 1830, an *Exposé de la doctrine Saint-Simonienne* and collaborated in the Saint-Simonian journal *Le Producteur*. In March 1839, after the dissolution of the chamber by Louis Philippe, he was elected deputy for Paris (re-elected in 1842 and in 1846) and sat in the group of the radical left. At the revolution of 1848 he became minister of education in the provisional government.

In proposing a law to make primary education public and compulsory, Carnot declared himself against purely secular schools, holding that "the minister and the schoolmaster are the two columns on which rests the edifice of the republic." By this attitude he alienated both the right and the republicans of the extreme left and was forced to resign on July 5.

Under Napoleon III he refused to sit in the *corps législatif* until 1864, in order not to have to take the oath. From 1864 to 1869 he was active in the republican opposition. After the fall of Napoleon he was a member of the constituent assembly of 1871, and in 1875 he was nominated a senator for life. He died on March 16, 1888, three months after the election of his elder son, Sadi Carnot, to the presidency of the republic. His publications include *Le Ministère de l'instruction publique et des cultes du 24^e février au 5^e juillet 1848* (1849) and *Mémoires sur Lazare Carnot*, 2 vol. (1861–64; new ed., 1907).

CARNOT, LAZARE NICOLAS MARGUERITE (1753–1823), French military engineer and statesman whose services to the Revolutionary armies won him the name of "the Organizer of Victory," was born on May 13, 1753, at Nolay in Burgundy, the son of a lawyer. He passed second into the Mézières school and became captain in the engineers in 1783. In 1784 his *Éloge de Vauban* won the award of the Dijon academy; and in 1786 he combated the views of the marquis de Montalembert (Marc René) on Vauban's system of fortification. He had been living at Arras from 1780 and was a colleague of Maximilien de Robespierre in the Arras academy. He married Sophie Dupont at St. Omer in 1791 and was elected to the Legislative assembly as deputy for the Pas-de-Calais. He sat on the left and was prominent in the military committee. He was one of the first deputies to be sent to the armies. On Aug. 11, 1792, the day after the attack on the Tuileries, Carnot and his friend C. A. Prieur-Duvernois (Prieur de la Côte-d'Or) were sent to secure and in fact to "purge" the army of the Rhine. Election to the Convention followed, and then a mission to Bayonne to study defense against Spain (he was to retain his interest in the eventual army of the West Pyrenees). Returning in Jan. 1793 for Louis XVI's trial, he voted death without appeal or postponement. In March he went to the army of the North, escaped by accident from C. F. Dumouriez (*q.v.*) and

organized Lille and Douai against him before turning to his special point of interest, Dunkerque. On Aug. 14 he became member of the committee of public safety, and the relief of Dunkerque was the immediate objective.

In the committee, Carnot was in charge of military affairs, aided by Prieur with the war material, but was far from being in control. At the ministry of war were Noel Bouchotte and his secretary-general Nicolas Vincent, members of the extreme left—Hébertists whom Carnot detested as "anarchists." When Dunkerque had been relieved by J. N. Houchard and J. B. Jourdan, Carnot had to sacrifice Houchard to Vincent's enmity as Gen. A. P. de Custine had been sacrificed to Bouchotte's. The new general, Jourdan, was Bouchotte's nominee, and on Sept. 28 Carnot went himself to join him in the army of the North. Carnot and Jourdan had so little experience of operations that it is impossible to say which of the two won the battle of Wattignies. Carnot's increased prestige was reflected by the appearance of new generals: Lazare Hoche. Joseph Souham and J. V. Moreau, all of whom had been at Dunkerque; Charles Pichegru and Barthélemy Schérer, who were regulars on the Rhine; and J. B. Kléber and François Marceau, replacing the "anarchist" generals in the west. By the end of 1793 Carnot could plan the victorious campaign in Flanders of 1794 and, with Robespierre, the liquidation of the ministry of war.

Carnot dismissed both Bouchotte and Jourdan, but his own position was challenged by his colleague Antoine de Saint-Just in the feud between generals Hoche and Pichegru, and in spring 1794 the success of the plan of campaign in Flanders was precarious. Carnot had not the power to combine operations and disliked a single unified command, no doubt on political grounds. But the long line of divisions along the northern frontier gradually coalesced into two masses, and their numbers prevailed. Jourdan's victory at Fleurus (June 26, 1794) gave Carnot the unwelcome prospect of a conquest of the Netherlands and the consolidation of the army of Sambre-et-Meuse under Jourdan.

A month later Carnot's own colleagues were destroyed by the revolution of Thermidor, and he was in danger, for he disliked the Thermidorians almost as much as the "anarchists." He disavowed Robespierre, quoting the retort to his own plea for humanity: "What is the importance of 6,000 men when the case is one of principle?" He urged that public opinion should not give weight to "some signatures to acts which are regarded as reprehensible." He released imprisoned generals, many of them his own friends, and restored the credit of the regular officers and regiments of the line. Three months after Thermidor he gave the Convention the list of glory: "In 17 months' campaign 27 victories, 80,000 enemy killed, 116 places taken, 90 flags . . .," adroitly including successes in eastern Spain and in Italy in which he had little personal part. In his last speech from the committee he again recalled the victories; then, on leaving the committee, he was at last promoted major in the engineers (March 21, 1795). In the Convention, however, he was constantly attacked as a terrorist and a vote for proscribing him came nearer until the debate of May 28, when the famous phrase was uttered, as reported in the *Moniteur*: "A member: 'Carnot has organized victory.' (Great applause)."

Carnot had escaped and he was not exiled from power for long. In Sept. 1795 he was chosen by 14 *départements* in the elections under the new constitution, and on Kov. 2 he was elected a member of the Directory. The next two years were the least satisfactory of his career: he could not dissociate himself from the other directors, and the generals were now strong enough to reject his plans. His two principal military operations, the campaign of Jourdan and Moreau in Germany and the Irish expedition of Hoche ended in failure—redeemed by the Italian victories of Napoleon Bonaparte which he did not plan. Politically, his past pushed him to the right farther than he wished to go, but he could not make the royalists his allies, and at the *coup d'état* of Fructidor (Sept. 1797) he had no support. All parties were glad that he escaped to Switzerland. His rejoinder from exile was effective: "Could anyone who had known me in the old days, solitary, preoccupied, a kind of philosopher, indeed an 'original', ever believe that after taking part in founding the most majestic of republics I would amuse myself by pulling it down?"

Carnot was still a lone figure when he returned to the better atmosphere of the consulate. Napoleon preferred him to the liberals. He worked with L. A. Berthier in the ministry of war and was minister for six months in 1800, dealing directly with his former protégé Moreau. He sat in the *tribunat* until 1807 but he voted against the consulate for life, and the Legion of Honour. He remained a member of the Institut and returned to his early studies in fortification. After two technical works in geometry he published *De la défense des places fortes* (1810), which influenced fortification for three generations. It was by appeal to this side of his varied talents that Napoleon after several attempts brought him back to service in Jan. 1814 as general of division and governor of Antwerp. Carnot secured the fortress when it was about to fall and held it to the peace. His conduct did him honour and his name had been useful in the last effort of the empire.

At the Restoration, Louis XVIII saw Carnot as a regicide wearing the king's own decoration of St. Louis, and would not speak to him. During the Hundred Days his republican patriotism suited the last phase of Napoleon's rule and he was minister of the interior. Once again Napoleon was using the effect of Carnot's name, but after Waterloo he gave him the compliment which was his last honour: "Monsieur Carnot, I have known you too late."

On Napoleon's abdication Carnot headed the provisional government of France until he was ousted by Joseph Fouché. Louis XVIII proscribed him and exiled him as a regicide. He died at Magdeburg in Prussian Saxony on Aug. 2, 1823.

There is an edition of his *Correspondance*, from Aug. 1793 to March 1795, by E. Charavay, 4 vol. (1892-1907). (I. D. E.)

CARNOT, (MARIE FRANÇOIS) SADI (1837-1894), French statesman, the fourth president of the third republic, was born at Limoges on Aug. 11, 1837, the son of Hippolyte and thus the grandson of the great Lazare Carnot. He went through the *École Polytechnique* and the *École des Ponts et Chaussées* and then obtained an appointment in the civil service. During the Franco-German War of 1870 he was entrusted with the task of organizing resistance in the *departements* of Eure, Calvados and Seine-Inférieure and was made prefect of the last-named in Jan. 1871. In the following month he was elected to the national assembly by the *département* of Côte-d'Or. He became minister of public works in Sept. 1880 and again in April 1885, but then passed almost immediately to the ministry of finance, which he held until Dec. 1886. On the fall of Jules Grévy in Dec. 1887 as a result of the scandal of Daniel Wilson's traffic in honours, Carnot stood for the presidency of the republic, with the support of Georges Clemenceau and others who wanted the president to be outside political controversy. He was elected by 616 votes out of 827. The major crisis during his presidency was that of the Boulangist agitation, which was surmounted when General Boulanger was compelled to leave France in 1889. The Panama scandals of 1892, if they damaged the prestige of the state, enhanced the respect felt for its head, whose integrity was beyond reproach. On June 24, 1894, after speaking at a public banquet at Lyons, Sadi Carnot was fatally stabbed by an Italian anarchist, S. Caserio.

CARNOT, (NICOLAS LÉONARD) SADI (1796-1832), French physicist, made important contributions to the study of heat. He was born at Paris. Admitted to the *École Polytechnique* in 1812, late in 1814 he left with a commission in the engineers. He became captain in the engineers in 1827, but left the service altogether in the following year. He died of cholera in Paris on Aug. 24, 1832. He was an original and profound thinker. The only work he published was his *Réflexions sur la puissance motrice du feu et sur les machines propres à développer cette puissance* (1824). This contains but a fragment of his scientific discoveries, but it is sufficient to put him in the very foremost rank, though its full value was not recognized until pointed out by Lord Kelvin in 1848 and 1849. Fortunately his manuscripts had been preserved, and extracts were appended to a reprint of his *Puissance motrice* by his brother, L. H. Carnot, in 1878. These show that he had not only recognized the true nature of heat, but had noted down for trial many of the best modern methods of finding its mechanical equivalent, such as those of

J. P. Joule with the perforated piston and with the friction of water and mercury. Lord Kelvin's experiment with a current of gas forced through a porous plug is also given. "Carnot's principle," that the efficiency of a reversible engine depends on the temperatures between which it works, is fundamental in the theory of thermodynamics. See also HEAT: *Carnot: On the Motive Power of Heat*.

CARNOTITE, a radioactive mineral that is an important source of uranium, was first described in 1899 and named after Marie-Adolphe Carnot (1839-1920), French mining engineer and chemist. It is a hydrated vanadium salt of potassium and uranium. Pure carnotite contains about 53% uranium and 12% vanadium and trace amounts of radium. It is canary to lemon-yellow and occurs as a powder of loosely coherent microcrystalline aggregates, rarely as crusts of imperfect platy crystals; it is chiefly disseminated in sandstone or locally as small pure masses, especially around petrified or carbonized tree trunks or other vegetal matter. Carnotite is of secondary origin and has formed by alteration of primary uranium-vanadium minerals. Commonly associated with carnotite is the calcium analogue, tyuyamunite, also known as calcicarnotite.

Carnotite is the most important of the secondary uranium ore minerals, having provided most of the uranium production from secondary deposits; it is also mined for both vanadium and radium. From 1911 to 1923 ores containing carnotite were intensively mined in Colorado for radium. From 1937 to 1943 carnotite was again mined, but primarily for vanadium. After World War II it became one of the most important ore minerals of uranium (*q.v.*) mined extensively in the United States. The greatest known concentration of carnotite deposits is in the western United States, particularly in the Colorado plateau area. Within the plateau, the Uravan belt in western Colorado, the San Rafael swell area in Utah and the Grants district in New Mexico are the principal mining areas. Other deposits are found in Wyoming, South Dakota and Pennsylvania. Although carnotite has been found in small quantities at a large number of localities throughout the world the only known commercial deposits, other than those in the United States, are in the U.S.S.R. Scattered deposits occur around the towns of Kokand and Ferghana in the southwestern part of Siberia near the borders of Afghanistan, India and Sinkiang.

Carnotite crystallizes in the monoclinic system as platy or lathlike crystals which are usually microscopic in size. The mineral is soft with a dull or earthy lustre and has a specific gravity between 4 and 5.

See C. Palache et al., *Dana's System of Mineralogy*, vol. ii, 7th ed. (1951); R. D. Ninger, *Minerals for Atomic Energy* (1954). (R. G. C.)

CARNOUSTIE, a small burgh and seaside town of Angus (Forfarshire), Scot. Pop. (1961) 5,511. It lies on the North sea, 11 mi. E.N.E. of Dundee by road. Carnoustie, with five miles of sands, is a tourist, golfing and conference centre. Its industries include engineering, jute works, fertilizers and canning and preserving. Panmure house, about 1½ mi. N.W., was a 17th-century mansion demolished in 1955, except for the gates, which have been kept closed since the 4th earl of Panmure escaped to France in 1715. South, along the coast of Barry Links, is Buddon Ness military training area.

CARNUNTUM, at Petronell, 20 mi. E. of Vienna, the most important legionary camp on the upper Danube frontier of the Roman empire. The position was also a starting point for the amber route to the Baltic at least as late as A.D. 65. Originally a Celtic town in the kingdom of Noricum, it was the emperor Tiberius' base for attacking the Marcomanni in A.D. 6 and soon received an earth fort for one legion, being added to the province of Pannonia. A stone camp was constructed about A.D. 73. The *legio XV Apollinaris* garrisoned it until about A.D. 114, and after that the *legio XIV Gemina*. The emperor Marcus Aurelius resided there during his campaign against the Marcomanni (171-173), when he wrote part of his *Meditations*. Lucius Septimius Severus, governor of upper Pannonia, was acclaimed emperor in the camp in 193. In 308 an important conference was held there between

the emperor Diocletian and his colleagues. After destruction by barbarians the camp was rebuilt in 375, but was finally burned about 400. The adjoining settlement (*canabae*) was made a municipium (*q.v.*) by the emperor Hadrian and given colonial status by Lucius Septimius Severus.

See E. Swoboda, *Carnuntum, die Geschichte und die Denkmäler*, 3rd ed. (1958). (G. E. F. C.)

CARNUTES, a Celtic tribe of central Gaul between the Sequana (Seine) and Liger (Loire) rivers, whose chief towns were Cenabum (Orléans) and Autricum (Chartres). In the 1st century B.C. they were dependents of the Remi who were friendly to Rome, but they broke with Julius Caesar in 53 B.C. and were the first state to move in the great rebellion next year, murdering the many Roman traders at Cenabum. Caesar retaliated by burning the town and massacring its inhabitants, but the tribe still had 12,000 men under arms in the later fighting of 52, and again gave trouble to Caesar in 51 by attacking their neighbours the Bituriges. Under the empire the Carnutes had the privileged status of *civitas foederata* (see *MUNICIPIUM*). Cenabum was made an independent *civitas* by the Roman emperor Aurelian in A.D. 275, and named *urbs Aurelianensis* (whence Orléans).

See T. Rice Holmes, *Caesar's Conquest of Gaul*, 2nd ed. (1911). (G. E. F. C.)

CARO, ANNIBALE (1507-1566), Italian poet admired for his elegant style, was born in Civitanova, in the Marche, on June 19, 1507. He was secretary to Msgr. Giovanni Gaddi in Florence and then in Rome, where in 1542 he passed into the service of Cardinal Pier Luigi Farnese. Only late in life did he acquire an independent livelihood. He died in Rome on Nov. 21, 1566.

As a lyric poet, Caro does not differ from the many contemporary imitators of Petrarch: his *Canzoniere*, containing about 100 sonnets, 5 *canzoni* and 1 *canzone* for music, is coldly academic. His satires, of which the *Nasea* is the best, belong to a literary genre already well established by Francesco Berni, and his ten polemical sonnets, *Mattaccini*, although vigorous, also conform to tradition. His *Lettere familiari* have been considered his masterpiece because of their liveliness of style. His free translation of Virgil's *Aeneid* was written to show the high standard reached by the vernacular language. Linguistically, stylistically and metrically, it is outstanding; it is written in *endecasillabi sciolti*, which became one of the classical metrical forms of Italian poetry. His *Straccioni* (1544), is one of the most original comedies of his time, being based on direct observation of popular life in Rome.

BIBLIOGRAPHY.—A well-documented study of Caro's life and works is V. Cisin's introduction to Caro's *Scritti* (1912). See also Cian's introduction to *L'Eneide tradotta da A. Caro* (1921); G. Mondaini, *I criteri estetici e l'opera poetica di A. Caro* (1897); *Comedia degli Straccioni con una nota di B. Croce* (1949). (G. A.)

CARO, JOSEPH BEN EFHRAIM: see QARO, JOSEPH BEN EFHRAIM.

CAROB, also called LOCUST or ST. JOHN'S BREAD in reference to the belief that the "locusts" upon which John the Baptist fed were actually carob pods. It is a leguminous tree, *Ceratonia siliqua*, native to the eastern Mediterranean region and introduced elsewhere, grown as an ornamental and for the edible pods. The carob, reaching 50 ft. in height, has pinnate, glossy, evergreen leaves with thick leaflets. The yellow or red flowers, borne in racemes along the branches, are without petals and are unisexual or perfect. The flat leathery pods, 3-12 in. long, contain from 5 to 15 hard, brown seeds in a sweet pulp. The primary use of carob pods, which contain about 50% sugar, is for stock food, but they are also used as food by man, especially in times of scarcity.

Gum extracted from carob seeds is used much like gum tragacanth in various industries (textile, food, pharmaceutical, leather, rubber, cosmetic, etc.). One thousand pounds of carob pods yield about 100 lb. of seeds! from which 3½ lb. of gum can be obtained. The gum-bearing tissue of the seed, removed by special machinery, is then roasted and extracted in boiling water. The liquor is evaporated, and the dried residue: carob gum, is powdered. Carob gum is imported into the U.S. from several European countries. (J. W. TT.)

CAROL I (1839-1914), first king of Rumania, was born on April 20, 1839, the second son of Prince Charles Antony of

Hohenzollern-Sigmaringen, head of the south German and Catholic branch of the Hohenzollerns. His mother was the daughter of the grand duke Charles of Baden and of Stéphanie de Beauharnais. Educated at Dresden and at Bonn. Prince Charles (Karl Eitel), as he was called before he went to Rumania, became an officer in the Prussian army and served against Denmark in 1864. The leaders of the newly united principalities of Moldavia and Walachia (*see* RUMANIA: History), balked of their original desire for a foreign prince, looked abroad again after the overthrow of Alexandru Cuza and, failing the Belgian prince Philippe comte de Flandre, offered the throne to Charles, with the tacit approval of Napoleon III. By a plebiscite held in Rumania on April 20, 1866, Charles was almost unanimously elected prince; he had to be smuggled into the country because of the hostility of Russia, Austria and Turkey, but rapidly gained general recognition. Given wide powers under the constitution of July 11, 1866, he showed great tact in dealing with the struggles between the Liberal and Conservative parties, and his administrative, economic and military reforms earned him deep respect at home and abroad.

In 1869 he married Elizabeth (*q.v.*), daughter of Prince Hermann of Wied and a Lutheran; he had already undertaken to educate his children in the Orthodox faith, despite papal disapproval. The sympathy of Rumanians with France in the Franco-German War led to a wave of hostility against the German prince, which coinciding with a railway scandal, led him to offer abdication. With difficulty persuaded to remain, Carol was later to win great popularity when he led a Rumanian and Russian contingent to victory at Plevna (Plevna) in the Russo-Turkish War of 1877-78. As a consequence of his vigorous action, Rumania secured recognition from the powers of its complete independence of Turkey in 1880 and was proclaimed a kingdom on March 26, 1881, Carol and his consort being crowned on May 22. As king, Carol proved most successful in home policy, greatly improving the financial and military position of his country. He and the queen, who became known as a poetess under the name of Carmen Sylva, gave special encouragement to the fine arts. In foreign policy Carol remained true to Germany, concluding a secret treaty with the Central Powers in 1883; the failure of Rumania, still Francophile, to implement that treaty in Aug. 1914 broke him down. On Oct. 10, 1914, he died in his palace at Sinaia. As the only child of his marriage, a daughter, had died in 1874, the succession was settled on his brother Leopold's son, who became Ferdinand I of Rumania.

See the official biography, *Aus dem Leben König Karls von Rumänien*, 4 vol. (1894-1900; abridged Eng. trans., 1899); also D. A. Sturdza, *Charles Ier roi de Roumanie: chronique, actes, documents*, 2 vol. (1899-1904). (B. BR.)

CAROL II (1893-1953), king of Rumania, was born at Sinaia on Oct. 15 (new style; Oct. 3, old style), 1893, the eldest son of King Ferdinand I (*q.v.*) and Queen Marie. He received a German military education at Potsdam but returned to Rumania when World War I broke out. He became crown prince on the death of his great-uncle Carol I in Oct. 1914. In 1918 he contracted a morganatic marriage to Zizi Lambrino, an officer's daughter, by whom he had a son, but this marriage was dissolved, and in March 1921 he married Helen, daughter of Constantine, king of the Hellenes. Carol and Helen had one son, Michael (Mihai), born in 1921, but their marriage was not a happy one. In 1925 Carol was obliged to abdicate his rights to the throne and went into exile—largely at the instigation of the Liberal party led by Ion Brătianu—on account of the scandal caused by his liaison with Magda Lupescu. He was also excluded from the Rumanian succession by an act of Jan. 4, 1926, which was confirmed in the will of King Ferdinand, who died on July 20, 1927. The young Michael was then proclaimed king under the regency council that had been set up in 1926 in view of King Ferdinand's ill-health.

Princess Helen, who had stayed in Rumania as her son's guardian, was persuaded by the Liberals to obtain a divorce (June 1928) in order to bar the way to Carol's return. The regency, however, proved unpopular, and the political opponents of the Liberals were regularly in touch with Carol during his exile in England and France. Finally in 1930 the National Peasant government under

Iuliu Maniu invited him to return. Carol was offered a place in the regency provided that he would break with Magda Lupescu, but he was determined to become king and took the oath as such on June 8, 1930. Attempts at a reconciliation with Princess Helen failed, and Magda Lupescu returned in 1931.

From the first King Carol sought to establish his own power by undermining the political parties. To that end he at one time encouraged the Iron Guard (*see* RUMANIA: History). In Feb. 1938, however, alarmed at the Iron Guard's predominance, he proclaimed a new constitution and set up a personal dictatorship. After the outbreak of World War II he was unable to resist territorial and political demands on Rumania by Germany and the U.S.S.R. and incurred such unpopularity that he abdicated for the second time in favour of his son on Sept. 6, 1940, going again into exile. In July 1947, in Brazil, he married Magda Lupescu, who was thought to be dying. Carol died at Estoril, Port., on April 4, 1953. (B. BR.)

CAROL, a kind of song affiliated with dancing and associated with the seasons of the year, especially Christmas. The German and French equivalents are Weihnachtslied and noel. Even though the general meaning of the word can be easily designated, a precise definition is impossible because the meaning of the word has not remained constant since the 14th century, when both the thing and the name came into English social life, and because it has affinities with the ballad, the hymn and the folk song, as well as with dancing. The church and the drama have also played a part in its evolution. Thus the setting up of the crib of the infant Saviour and the Holy Family, said to have been initiated by St. Francis of Assisi to inculcate the doctrine of the incarnation, was an early occasion for the singing of carols both in church and in the home.

The great age of the English carol was the 15th century, but there is a nativity carol of about 1350 that has a burden, or refrain, that runs:

Honnd by honnd we schulle ous take
And joye and blisse shulle we make.

Here is evidence of the round dance that gave the carol its original character as a dance song; and here is the recurrent burden that is the formal feature fundamental to a carol. The recurrent refrain fixed the form of the carol until the end of the middle ages.

With the coming of the Reformation and the steady growth of Puritanism, the carols, which had ranged widely in subject—Richard Kele's *Carolles Newly Imprinted* (c. 1550) contains more crucifixion than nativity carols and a few that are frivolous and even licentious—became more gloomy and began to decline. After the Commonwealth, however, Christmas festivities were revived and with them the singing of carols.

In the later part of the 18th century carols were published on broadsheets (broad-sides). The first modern collections were those of D. Gilbert, *Some Ancient Christmas Carols* (1822), and W. Sandys, *Christmas Carols, Ancient and Modern* (1833). With the concentration of the carol upon the nativity, the form became looser, although the refrain often survived, as a relic of the dance, as in "The Holly and the Ivy," a carol in which many strains, pagan and Christian, are embedded. A definition for modern times was therefore framed by Percy Dearmer (in *The Oxford Book of Carols*) as follows: "Carols are songs with a religious impulse that are simple, hilarious, popular and modern." "Modern" is added by way of paradox only to mean that the carol expressed for the ordinary man the age in which he lived. This definition does not, however, sufficiently differentiate the carol from the Christmas hymn, such as "O Come, All ye Faithful," which was a product of the 18th century.

Yet carol singing is modern in a more literal sense. At the time when Gilbert and Sandys produced their little collections William Hone in his *Ancient Mysteries Described* (1822) predicted that carols were dying and in a few years would be heard no more. He spoke too soon, for out of the Oxford movement grew a new sympathy with medieval piety, and one of the curiosities of the 20th century has been an emotion that finds in the Holy Babe, the *rosa nzyistica*, the Latin interjections of joy, something congenial, such as was absent from the Victorian ideal of Christmas, as presented for instance in Dickens' *A Christmas Carol*. The modern

revival dates from 1852 when J. M. Neale received the gift of a copy of *Piae cantiones*, a Swedish collection of 1582. In the following year he published *Carols for Christmastide*, "set to Ancient Melodies by the Rev. T. Helmore, M. A.; the words, principally in imitation of the original, by the Rev. J. M. Neale, D.D." The imitation was not always as close as it might have been: "Good King Wenceslas," which he took from *Piae cantiones*, was a spring carol, "Tempus adest floridum"; and "Christ Was Born on Christmas Day" was fitted somewhat incongruously to the tune of "In dulci jubilo." Nevertheless he started a movement for bringing back carols into church and home and open air that has steadily increased in momentum and range in England and the United States.

One of the movement's important aspects was the development of the Christmas service of lessons and carols, introduced by the first bishop of Truro in 1880. In 1918 it was first used at King's college, Cambridge, and in the following year modified to the form that, through broadcasting, became familiar in England. Even Scotland, in spite of Puritan traditions, accepted Christmas carols.

In 1871 the important collection of J. Stainer and H. R. Bramley, *Christmas Carols New and Old*, had appeared and in 1900 came the *Cowley Carol Book*, freshly inspired by a reversion to medieval mysticism.

Innumerable anthologies appeared in the subsequent six decades, enriched from still another source, the true folk carol, which was discovered in the folk-song revival that took place around 1900. *The Oxford Book of Carols* (1928), compiled by Percy Dearmer, R. Vaughan Williams and Martin Shaw, is comprehensive, in that it draws on all these sources and on foreign carols and also contains valuable historical notes.

Wassail songs, mumming songs, cumulative songs like "The Twelve Days of Christmas" belong not to Christmas but to the turn of the year. They are pagan and magical in origin, but they have made their way into the corpus of Christmas carols. Some attempt has been made to reintroduce spring and Easter carols, but the popular imagination has firmly associated carols with Christmastide. Composers have complied with the demand for new carols, so that in the 20th century as in the 15th the carol is a living and flourishing art.

CAROLE. This chain dance, indigenous to many European countries, is often assumed to be medieval and performed to the singing of the dancers, although immemorial forms persist (*hora*, farandole, carmagnole, etc.) that may be instrumentally accompanied. An indefinite number of persons without distinction of sex participate, arms linked, beating a rhythm with their feet and alternating with a leader, who determines the direction of progress and variation of the rhythm. Hence is derived the burden-and-stanza structure of the poetic medieval carol. From the chain dance the country dance is believed to have developed.

(M. J. D.-S.)

CAROLINE OF ANSBACH (1683–1737), queen consort of George II of Great Britain and Ireland, was born at Ansbach on March 1, 1683, daughter of John Frederick (d. 1686), margrave of Brandenburg-Ansbach. She married George Augustus, electoral prince of Hanover, in Sept. 1705. In Oct. 1714, when her father-in-law became king of Great Britain as George I, Caroline came with her husband to London, where her liveliness and tact helped to ease the difficult situation caused by the quarrel between George Augustus, now prince of Wales, and his father. During the period of complete estrangement from the royal court (1717–20), the prince and princess attracted many distinguished men and women of the day to their residences at Leicester house in London and at Richmond. A formal reconciliation with George I took place in 1720. In 1727 when George II succeeded to the throne, Queen Caroline's influence was effective in keeping Sir Robert Walpole in power. She caused some difficulties by sponsoring unorthodox prelates for high office in the church. She was regent of the king-

dom during the king's absences from England in 1729, 1732, 1735 and 1736–37. In her relations with her husband, to whom she bore eight children, Caroline proved herself a clever and patient woman, and retained her influence over him until her death at St. James's palace, London, on Nov. 20, 1737.

CAROLINE OF BRUNSWICK (CAROLINE AMELIA ELIZABETH) (1768–1821), queen of George IV, king of Great Britain and Ireland, second daughter of Charles William Ferdinand, duke of Brunswick-Wolfenbützel, and of George III's sister Augusta, was born on May 17, 1768. On April 8, 1795, she was married to the prince of Wales (*see* GEORGE IV), but soon after the birth of their only child, Princess Charlotte (Jan. 7, 1796), they separated, and she went to live near Blackheath. In Dec. 1805 she was accused of having given birth to a child (William Austin) but a committee of the privy council which investigated the matter acquitted her of the serious charge though it censured her levity of manners. Excluded from court after her husband became regent (1811), she went abroad in Aug. 1814 and was presently accused of "adulterous intercourse" with her Italian courier Bartolomeo Pergami (in England often called Bergami), with whom she had become infatuated. On her husband's accession in 1820 she returned to England to claim her rights as queen, whereupon the government introduced into the house of lords a bill to dissolve the marriage and deprive her of the title of queen. After a lengthy hearing of the evidence the bill was abandoned on Nov. 10, the third reading having been carried in the house of lords by a majority of only nine. Her name remained excluded from the liturgy and she was denied a royal residence, though parliament voted her an annuity of £50,000 for her maintenance. She was refused admittance to Westminster abbey at the coronation (July 19, 1821), became ill a few days later and died on Aug. 7, 1821. Although she said she had committed adultery but once—with the husband of Mrs. Fitzherbert (meaning George himself, who had been secretly married to Mary Anne Fitzherbert as early as 1785)—there can be little doubt about the guilty character of her relationship with Pergami; and had the truth about her been known, her popularity as an injured woman, which was great, would quickly have vanished. It was not until she was living abroad that her husband was told that she had tried to promote the seduction of her own daughter when she was about 16 by locking her in a bedroom with a young officer, Captain Hesse. If she was not mad, said the 3rd baron Holland, she was a worthless woman, and with that verdict posterity may agree.

CAROLINE ISLANDS, part of the trust territory of the Pacific Islands administered by the United States, extend from longitude 130° to 166° E. and from the equator to latitude 21° N. Pop. (1958) 48,271. They are divided into four administrative districts: Palau (pop. 8,987), Ponape (13,620), Truk (20,121) and Yap (5,540). The land area totals 457 sq.mi. with 3,283 sq.mi. of lagoon.

4 major geological division in the surface of the earth occurs between Truk and Yap. Designated as the sial or andesite line, it divides the Caroline Islands into oceanic islands and continental islands. The oceanic islands to the east of the sial line are great mountains of volcanic origin rising from the floor of the ocean while the continental or arcuate islands to the west of the sial line are folds in the earth's crust. On both sides of the sial line high islands rise to elevations of 500 ft. or more and low islands caused by sinking are only coral caps appearing above the surface. The continental islands contain more minerals than the oceanic islands.

While the Carolines were in Japanese possession between World War I and World War II, the high continental islands were mined for copper, iron ore, bauxite, manganese and other minerals.

The mean monthly temperatures commonly range from 79° to 83° F. Rainfall varies greatly and exceeds 180 in. on a few of the high islands. In an average year about 25 typhoons originate in the central Caroline Islands; the centres of 5 typhoons once passed over Yap within three months.

Copra is the chief export of the Caroline Islands with handicrafts a poor second. Experiments have been made in raising cacao, for which conditions have been found to be ideal in the islands.

History. — According to carbon-14 tests, the earliest dated settlement on Yap was in the 2nd century A.D., but the eastern Carolines were probably settled before that date. Great diversity of physical types, cultures and languages prevail within the Caroline Islands. Twelve languages and several dialects are found among less than 50,000 persons. Considerable Polynesian influence is found in the eastern Carolines and pure Polynesian intrusions on the islands of Kapingamarangi and Nukuoro. The western Carolines show an intermingling of Melanesian and Philippine influences. There is evidence of Chinese trade goods reaching the western islands by the 7th century A.D. Although Spanish ships visited many of the islands after their discovery in the 16th century, the Spanish did not permanently occupy them until late in the 19th century. After the Spanish American War (1898) the islands were sold by Spain to Germany. In 1914 they passed to Japan, which held them after World War I as a mandate from the League of Nations. During World War II the islands, which then had large Japanese naval and air bases, were invaded by the United States. They became a United States trust territory under the United Nations on July 19, 1947. Along with the Marshalls and the Marianas they were designated as a strategic area with ultimate responsibility resting in the security council rather than in the general assembly, as is the case with other trust territories (see TRUSTEE SYSTEM: Strategic Areas). (C. A. Mr.)

CAROLINGIANS, the name of a family that became a sovereign dynasty in western Europe. It is derived from the fact that a number of its members were called Charles (Lat. *Carolus*; Ger. Karl), eight being so named between the beginning of the 8th and the end of the 9th centuries. The most famous among them was Charlemagne.

Although it did not attain regal dignity until Pepin the Short supplanted the last Merovingian king in 751, the family had long wielded great political power. It stemmed from the marriage of a certain Ansegisel with Begga, a daughter of Pepin the Old. Ansegisel was one of the two sons of Arnulf (d. 641) and his wife Doda. This Arnulf, a counselor of Clotaire II, the Merovingian king of Austrasia, eventually became bishop of Metz (c. 614), whereupon his wife entered a convent. The Carolingians of the 9th century, seeking to improve their remotest ancestry, represented Arnulf, already popularly regarded as a saint, as having been of Gallo-Roman and Aquitanian origin. Probably he was a Riparian Frank.

Pepin the Old, also called Pepin of Landen (the name of one of his estates near Trier), served Clotaire as mayor of the palace for Austrasia. He survived a short period of disgrace and at his death (639) was greatly honoured and immensely powerful. This power was derived not from his office but from the vast extent of his lands, which were continually enlarged by his descendants up to the 9th century. These estates, situated mainly in Brabant, around the lower Meuse and between the Rhine and the Moselle, brought to the family a steady and invaluable revenue. They used it for the defense of Austrasia, to buy the allegiance of clients and in religious and monastic endowments.

Pepin had another child beside Ansegisel's wife Begga: his son, Grimoald, who succeeded him as Austrasian mayor of the palace. Rich and able, Grimoald attracted sufficient partisans to consider, when King Sigebert II died in 656, that the time was ripe to supplant the Merovingians. The Austrasian aristocracy, however, reacted violently against him, and he, his son and his brother-in-law Ansegisel were assassinated. Begga and Peppin, her son by Ansegisel, were the sole survivors among the family, which disappeared

from politics for about 20 years, though its material prosperity seems to have been undiminished.

The second Pepin, usually called Pepin of Heristal or Herstal, gradually regained the influence previously wielded by his family and became mayor of the palace in Austrasia. Profiting by his uncle's experience, he made no attempt to depose the Merovingians and instead devoted all his energies to the reunification of the kingdom, which from the end of the 6th century had been divided almost continuously between rival and warring states. The main opponent of this plan was Ebroïn, mayor of the palace for Neustria, supported by all who disliked the prospect of Austrasian hegemony. After some inconclusive encounters, Pepin, by his decisive defeat of the Neustrians at Tertry, near Péronne, in 687, became master of the entire Frankish territory which he had administered by putting the mayoralties of Neustria and of Burgundy into the hands of his own dependents.

At Pepin's death (714) the succession was uncertain. His only legitimate son had been assassinated and the claim lay between two young grandsons and a bastard, Charles, later known as Martel "the Hammer"). Pepin's widow Plectrude, anxious to retain power, turned for support to the opponents of Austrasian hegemony, and it took Charles ten years of ceaseless fighting to establish his authority. His power, not fully assured until after 725, was unassailable after his famous victory over a Muslim army near Poitiers (732). No less prudent than his father, he maintained the fiction of Merovingian rule.

At Charles Martel's death (741) his authority was divided between his two sons; but the younger, Pepin the Short, soon held the palace mayoralties of all three kingdoms, and it was he at last who dared, by deposing Childeric III, to substitute his own family for the Merovingians (751; or at the latest Jan. 752). One element of the change was politically of the utmost significance: Pepin was the first king in France anointed and hallowed to his office by the church.

Under four succeeding generations of Carolingians, from Pepin of Herstal to Pepin the Short's son Charlemagne (*q.v.*), the Frankish kingdom was gradually enlarged, until its territory reached from the Elbe to the Pyrenees and from the borders of Denmark to Rome. The Carolingians' domination over western Europe already recalled that of the Roman emperors when, in 800, circumstances led Pope Leo III to revive the imperial title for Charlemagne (Charles I both as emperor and as king of France).

The Carolingian power, however, was menaced by the traditional Frankish practice of dividing an inheritance among all the male children. At first the problem was not particularly severe: when Pepin died (768) only one of his two sons was capable of effective rule over the kingdom; and Charlemagne (d. 814) was survived by only one legitimate son, the emperor Louis I the Pious. Trouble began in Louis's reign, as his sons started disputing the allocation of territory in 830, and after Louis's death (840) a civil war broke out, to be terminated only by the division of the empire into three sections at the treaty of Verdun (843).

The eldest son of Louis the Pious was Lothair I (d. 855), who in 843 received the imperial title and Francia Media, the middle kingdom, a long central strip comprising territory which lies today in the Netherlands, Belgium, western Germany, eastern France, Switzerland and Italy. The northern part of this kingdom was in 855 made into a separate kingdom for Lothair's second son, Lothair the younger from whom it got the name of Lotharingia or Lorraine (*q.v.*), but on Lothair II's death without heirs (869) it was divided between his uncles, Lothair I's brothers. Lothair I's other two sons, Charles, king of Provence, and the emperor Louis II (the eldest of the three), who had been king of Italy, likewise died without male issue, in 863 and in 875 respectively, whereupon more complicated partitions ensued.

Francia Orientalis, the country east of the Rhine, went in 843 to Louis the Pious' third son, Louis the German, whose descendants managed, despite difficulties, to reign there until 911. Louis the German's sons, Carloman (d. 880), Louis the Younger (d. 882) and Charles the Fat, at first divided the East Frankish territory but Charles the Fat reunited it. He moreover held the imperial title, as Charles III, from 881 to his deposition in 887. Subse-

quently Arnulf, a bastard of Carloman, was emperor from 896 to 899. By this time, however, the Carolingians in the east had lost real authority, and at the death of Arnulf's son, Louis the Child, in 911, the vacant German crown was not offered to the surviving head of the Carolingian dynasty. Charles the Simple (Charles III of France). Germany needed a strong ruler, capable of organizing the defense against Hungarians. Such a one was found, in 918, in Henry I the Fowler, progenitor of the new Saxon dynasty. (See GERMANY: History.)

The civil war during and after the reign of Louis the Pious was caused by the reluctance of the elder sons to give a share of territory to Charles II the Bald, child of their father's second marriage. However, after 842, with the help of Louis the German, Charles made good his claim to Francia Occidentalis (the West Frankish kingdom; *i.e.*, France) and was recognized as its ruler in the treaty of Verdun. He was also emperor in succession to his nephew Louis II from 875 to his death in 877. Then his son and successor in France, Louis II le Bègue, died in 879, leaving the kingdom to his sons Louis III and Carloman, who lost the southeast of it to Boso of Vienne (see BURGUNDY). Their ineffectual rule and their early deaths (882 and 884) led to the kingdom being put under the protection of Charles the Fat. After his deposition the last Carolingians in France (Charles III the Simple, Louis IV d'Outremer, Lothair and Louis V le Fainéant) were challenged continually by rival kings of other families. From the end of the 9th century they retained only the appearance of authority and had lost the personal domains which had assured the power of their ancestors, and in 987 the kingdom was finally usurped by Hugh Capet. (See FRANCE: History.)

A fourth branch of the Carolingian dynasty originated when Louis the Pious assigned Aquitaine as a kingdom to his second son, Pepin. This Pepin, however, died in 838, before his father, and his son Pepin II was dispossessed by Charles the Bald.

See L. Halphen, *Charlemagne et l'empire carolingien* (1947); H. Fichtenau, *Das karolingische Imperium* (1949). See also the bibliographies to articles throughout *Encyclopædia Britannica* on individual Carolingians mentioned above. (J. DE.)

CAROLUS-DURAN: see DURAN, CAROLUS.

CARORA, a town in Lara state, Venez., on the Morere, an affluent of the Tocuyo river, about 50 mi. W. of the city of Barquisimeto and 1,128 ft. above sea level. Pop. (1959 est.) 18,115. The town is comparatively well built and possesses a fine parish church, a Franciscan convent and hermitage. It was founded in 1754, and its colonial history shows considerable prosperity, its population at that time numbering 9,000 to 10,000. Horses, mules and cattle are raised locally; and in addition to hides and leather, the town exports coffee and rubber.

CAROSSA, HANS (1878-1956), German novelist and poet, a masterly writer of autobiography and autobiographical fiction which propounds an affirmative and ethical attitude to life. Born in Tolz in Upper Bavaria on Dec. 15, 1878, Carossa studied medicine in Munich, Würzburg and Leipzig and was later a practising physician in Passau, Nürnberg and Munich. His autobiographical writings—*Eine Kindheit* (1922; Eng. trans., *A Childhood*, 1930), *Verwandlungen einer Jugend* (1928; Eng. trans., *Boyhood and Youth*, 1931), *Das Jahr der schönen Täuschungen* (1941; Eng. trans.: *The Year of Sweet Illusions*, 1951), *Rumänisches Tagebuch* (1924; Eng. trans.: *A Rumanian Diary*, 1929), *Führung und Geleit* (1933); and *Ungleiche Welten* (1951)—give a reticent, yet revealing, account of his life. His autobiographical fiction—*Dr. Bürgers Ende* (1913), *Der Arzt Gion* (1931; Eng. trans., *Dr. Gion*, 1933) and *Geheimnisse des reifen Lebens* (1936)—are lacking in plot and vivid characterization but skilfully present a contemplative view of nature and humanity. His lyrical poetry (*Gesammelte Gedichte*, 1943) is also mainly philosophical, but is at its best when, more rarely, he conveys a purely emotional experience. He died on Sept. 12, 1956, at Rittsteig near Passau.

See G. Schaefer, *Hans Carossa* (1947); A. Langen, *Hans Carossa* (1955). (H. S. R.)

CAROTHERS, WALLACE HUME (1896-1937), U.S. chemist, who developed nylon, was born at Burlington, Ia., on April 27, 1896. After taking degrees at Tarkio college, Mo., and

at the University of Illinois, he specialized in research and teaching in organic chemistry, first at the latter university and later at Harvard. In 1928 he was appointed director of research in organic chemistry by the du Pont company at their laboratories in Wilmington, Del. There he directed a series of fundamental investigations into the structure of substances of high molecular weight and into the mechanism of their formation by polymerization. These investigations led to the development of several materials of commercial importance. One of these was a polymer which could be drawn out into an artificial fibre with properties in many respects superior to those of natural fibres; it was subsequently called nylon. Another was a synthetic rubber known as Neoprene. Carothers died in Philadelphia, Pa., on April 29, 1937. (S. E. J. j)

CAROTO (CAROTTO), (GIOVANNI) FRANCESCO (c. 1480-1522), Italian painter, born at Verona c. 1480. was a pupil of Liberale da Verona; but a stay in Mantua, where he came under the influence of Mantegna, was decisive in forming his early style. On returning to Verona he became the leading artist there until his death. His later style owes something to Raphael.

Verona was a provincial centre during this period and Caroto was on the whole a derivative artist. Nevertheless, his works remain distinguished by the sound craftsmanship of the Quattrocento and by the traditional sense of colour of the north Italian schools. He painted not only religious works in oil, tempera and fresco but also individual portraits. Many of his paintings are in the gallery at Verona; some are still in the churches there for which they were painted; for example, the "Madonna in Glory With Saints" (1528) in S. Fermo Maggiore, and the "St. Ursula" (1545) in S. Giorgio. Among his earlier works is a very attractive "Entombment" in the National Gallery of Art, Washington, D.C. The landscape backgrounds of his enchanting half-length "Maddonnas" sometimes convey a feeling of mystery suggestive of Leonardo da Vinci.

His younger brother, Giovanni Caroto (c. 1490-1562?), was also a painter and an architect. He was responsible for a new edition (1540) of a book on the antiquities of Verona.

See Bernard Berenson, *North Italian Painters of the Renaissance* (1907). (M. W. L. K.)

CARP (*Cyprinus carpio*), a member of the minnow family (Cyprinidae) characterized by large scales, a long dorsal fin and two barbels on each side of the upper jaw. Wholly or partly scaleless varieties are known. It is a native of eastern Asia and has been introduced into Europe and from there into North America.

Carp inhabit warm-water lakes or ponds and slow-moving rivers; they prefer weedy places with a muddy bottom. They are omnivorous, but their favourite food apparently is midge (Chironomidae) larvae. During their efforts to obtain these larvae from the bottom of their habitat, carp roil the water. The increased turbidity has an adverse effect on many plants and animals. As a result carp are often considered undesirable and much effort has been devoted to killing them.

JOHN MARKHAM

CARP (CYPRINUS CARPIO)

The eggs usually are laid in the spring when the water temperature is between 58° and 68° F.; the eggs are deposited on vegetation or detritus, usually in regions recently inundated with shallow water. One female may lay up to 2,000,000 eggs. The eggs hatch in four to eight days. In nature, young carp reach a length of about 6 in. in one year, but in fish ponds they may grow to over 14 in. in one year. Carp reach sexual maturity in their second year and may live 47 years. They sometimes grow to more than 50 lb., and individuals of 25-30 lb. are not rare. Growth is greatest in warm seasons and apparently ceases at temperatures below 50° F. Because it is possible to produce more than 1,000 lb. per acre, carp are often raised for food, especially in Europe and Asia. The fast-growing pond-cultured individuals are reputed to have a superior taste.

See FISHES: Pikes and Carps.

(C. HU.)

CARPACCIO, VITTORE (c. 1460-1525/6), the great nar-

rative painter of the early Venetian school, was born in Venice probably about 1460. Carpaccio is mentioned for the first time in a document of 1472, and the date of his birth has been conjecturally fixed as early as 1455 and as late as 1465.

The dominant influences on Carpaccio's early works were those of Gentile Bellini and Antonello da Messina. One of Carpaccio's few indisputable early paintings is "Christ With Four Disciples" in the Contini-Bonacossi collection, Florence. Between 1488 and 1490 Carpaccio received the commission for a cycle of scenes from the legend of St. Ursula for the Scuola di Sta. Orsola, now in the Accademia in Venice. These paintings comprise an altarpiece of "St. Ursula in Glory" dated 1491, followed by nine scenes illustrating the legend of St. Ursula. In these admirably organized designs Carpaccio emerges as a mature artist of great originality, with an unrivaled gift for narrative and a masterly command of light. The genre scene of the "Dream of St. Ursula" in particular, with its wealth of naturalistic detail, is one of the most popular Venetian paintings.

Carpaccio's later career can be charted in terms of three further narrative cycles. The first of these survives intact in the Scuola di S. Giorgio degli Schiavoni in Venice. In the three scenes from the life of St. Jerome in this cycle (1502) the factor of direct observation plays an even larger part than in the St. Ursula cycle, and these paintings, from an artistic standpoint, represent the climax of Carpaccio's art. A cycle of scenes from the life of the Virgin, executed after 1504 for the Scuola degli Albanesi, is distributed between the Brera gallery in Milan, the Ca' d'Oro and the Museo Correr in Venice, and the Accademia Carrara at Bergamo; a still later cycle of scenes from the life of St. Stephen,

executed between 1511 and 1520 for the Scuola di S. Stefano, is now divided between the Kaiser Friedrich museum, Berlin, the Brera gallery, the Louvre, Paris, and Stuttgart. Concurrently with the beginning of this cycle Carpaccio executed (1510) for S. Giobbe the great altarpiece of the "Presentation in the Temple," now in the Accademia, Venice. Carpaccio's last dated works are two organ shutters for the Duomo at Capodistria (1523).

Carpaccio died in Venice between Oct. 28, 1525, and June 26, 1526.

In the 19th century Carpaccio's rendering of architecture and the luminous atmosphere of his paintings were praised by John Ruskin, but only in recent criticism have his childlike love of pageantry and his interest in storytelling come to be accepted as incidental features in a style of great seriousness and originality. Capable of psychological subtlety and (in the "Meditation on the Passion" in the Metropolitan museum, New York, and the "Dead Christ" in Berlin) of deep compassion, Carpaccio was also the first and greatest Venetian painter of vedute ("townscapes"), while his altarpieces in the Accademia at Venice and at Capodistria (1516) are some of the most majestic achievements of their time.

(J. W. P.-H.)

CARPATHIAN MOUNTAINS. These arcuate ranges form the east-central European counterpart of the Alpine fold mountain system, though not so spectacular nor so intensively surveyed. They strike off from the Danube at Bratislava in southwestern Slovakia, swinging northeastward and then east, forming the frontier with Poland and then curving southward into Rumania and finally westward to return to the Danube at Orsova, at the

defile known as the Iron Gate (*q.v.*). The Carpathians are similar in east-west extent and area to the Alps but are much lower in average elevation (highest peak, Mt. Gerlachovka, in the High Tatra, 8,737 ft.), in spite of their comparable structure and age. Except in the High Tatra (Vysoky Tatry), there is a lack of rugged peaks, permanent snow and glacial lakes, though features resulting from mountain glaciation are found in the Transylvanian Alps. In the centre of the arc, the mountains decrease from a maximum width of 180 mi. to only 60 mi. and in this region there are a number of routes connecting the headwaters of the Tisza (Tisa. Theiss, Viseu) and the Prut.

Relief and Structure.—The Western Carpathians consist of a series of Tertiary fold ranges flanking the crystalline rocks of the High Tatra and including a series of Tertiary intermontane basins. The outer ranges, known as the Western and Eastern Beskids, extend east of the upper Morava valley to the headwaters of the Tisza (Tisa; *q.v.*). They consist of a series of erosion platforms uplifted since Miocene times and they are developed on Cretaceous limestones and Flysch, a Tertiary conglomerate. The valley trenches are the sites of villages around which the land is cultivated under strips. These valleys are isolated by parallel fold ranges whose steep slopes are thickly forested, often to the summits, with beech mantling the lower slopes and conifers above. The highest ranges reach several hundred feet above the tree line, and, above the zone of *Pinus pumilio* or dwarf pine, found in the High Tatra, are the summer pastures or *halas*. Among the outer, lower ranges are the White Carpathians (Bile Karpaty), culminating in Velky Javorina (3,182 ft.). The Western Beskids are crossed by the Jablunkov pass. The Eastern Beskids attain their greatest elevation of more than 5,600 ft. in the Magura range, around the eastern end of which the Poprad valley offers a route-way, while, farther east, lies the Dukla pass on the frontier between Slovakia and Poland. There the ranges seldom exceed 3,000 ft. and are quickly wooded with fir and beech. The inner zone of the High Tatra is highly complex, consisting of a core of granite and gneiss against which Mesozoic sedimentary rocks have been folded and overthrust. This crystalline "window" is limited to the High Tatra, though "basement" rocks also occur in the High Tatra to the west and in the Low Tatra (Nizke Tatry) to the south, and again in the western part of the Slovak Ore mountains (Slovenske Rudohorie). In the south and east of the Slovak Carpathians, extensive faulting and fracturing was accompanied by volcanic extrusions in Miocene times, notably in the Matra massif in Hungary and in the north-south ranges east of Presov and Kosice, known as the Slanske Pohorie, Hegyallya or Hegyalya range. This southern region also experienced subsidence, preceding the advance of the Pliocene sea over the Pannonic basin or plain of Hungary. The region of greatest uplift and also of Pleistocene glaciation is that of the High Tatra (see TATRA MOUNTAINS), where rugged mountain scenery, pyramidal peaks and arête ridges characterize the range. There glacial lakes occur, such as Strba (Strbske Pleso) and Popradske Pleso in Slovakia and Morskie Oko in Poland. To the south, the Low Tatra culminate in Dumbier (6,703 ft.) The Slovak Ore mountains are generally lower and more broken and in the east are noted for their mineral reserves, especially iron ore. In this limestone region are found the famous ice caves at Dobsina (*q.v.*), while there are caves and grottoes with stalactites and stalagmites at Demanova. Other attractions include the cold geyser at Herlany, in the volcanic hills east of Kosice.

The structure of the Eastern Carpathians is less complex. A series of arcuate ranges form a semicircle east and south of the Transylvanian basin, culminating in the Transylvanian Alps. The Rumanian Carpathians differ widely in structure from their Slovak counterpart, though the outer zone of Flysch is a continuous feature. The system, which forms the mountain backbone of Rumania, consists of three elements: the Moldavian Carpathians, the Transylvanian Alps and the Bihar (Bihar) massif within the Transylvanian basin. The Moldavian Carpathians are a continuation of the Flysch ranges of the Eastern Beskids. Their steep, forested slopes rise to flat-topped summit ridges under 6,000 ft. In places the forest has been cleared for pastoral settlement. In contrast, the Transylvanian Alps consist of a core of metamorphic and igne-

"A SAINT READING" BY VITTORE CARPACCIO, IN THE NATIONAL GALLERY OF ART, WASHINGTON, D. C.

ous rocks, flanked by sedimentaries which have been highly folded, fractured and overthrust. The range is deeply dissected by mountain torrents which flow through deep-cut valleys incised into flat-topped ridges. As in the High Tatra, there is much evidence of local mountain glaciation, especially in the Făgăraș mountains, which rise to 8,343 ft. (Moldoveanu mountain). There cirques and arête ridges occur, and also hanging valleys (Vales Arpașului). The ridges are known as *plaiuri*, that is "routeway," since they often lead to summer pastures above the tree line. To the north lie a complex series of massifs of similar structure but at a generally lower level. They include the largely crystalline Bihor massif which rises asymmetrically from the Transylvanian basin to a culminating height of 6,063 ft. in Cucurbeta to the west. These massifs are faulted and fractured highlands, differentially uplifted in the Miocene, when volcanic outpourings also occurred.

Climate and Vegetation Zones.—The Carpathians lie in a transitional zone between central and eastern Europe, where the local climate is modified by varying elevation. The highest ranges experience considerable winter snowfall, especially on the slopes exposed to polar continental air. Whereas the heaviest precipitation exceeds 55 in. on the windward slopes of the Western Carpathians, the mean annual precipitation is under 25 in. in the Transylvanian basin and in some of the enclosed mountain valleys. These lowland regions also experience continental extremes of temperature between winter and summer; Sibiu, at 1,360 ft., recording a mean January minimum of 24° F. and a mean July temperature of 67°; so that long, cold winters with light snowfall contrast with warm summers, when the maximum rainfall occurs. Some stations record a secondary maximum in October. Climate and soil, combined with marked differences in elevation, favour a zoning of vegetation belts according to altitude. The ranges over 7,000 ft. rise into the zone of subarctic vegetation, with an alpine flora and mountain pasture, succeeded by stunted coniferous forest below 6,000 ft., especially in the High Tatra, where there are fine stands of spruce and mountain pine. The lower slopes are mantled by mixed stands of timber in which beech and oak predominate among the deciduous trees. The intermontane basins and valleys are generally cleared for pasture, as the basis of cattle and sheep rearing, while the arable land around the villages is parceled out under rye, oats and potatoes. The Transylvanian basin has a sufficiently long growing season for maize (corn) to ripen and viticulture is carried on the terraced slopes of the southern Slovak Carpathians and in the Matra.

Settlement.—Whereas the whole of the Carpathians have been settled by peasants basing their livelihood on stock farming and subsistence agriculture, there are marked regional differences, depending on local factors as well as on ethnographic history. The Western Carpathians were occupied by Slavs (*q.v.*), both Slovak and Ruthenian, though there has been much infiltration of Magyars (*q.v.*), along the valleys opening southward, where, prior to 1919, there were the large estates of Hungarian landowners. Wine, grain crops and livestock are commercially produced. Elsewhere, remoteness from major lines of communication, combined with severe physical circumstances, have meant that life in the primitive Slovak villages follows traditional peasant lines. There has been constant depopulation, in view of the overpopulation of these largely Roman Catholic villages, and much former emigration to the United States. In contrast, the mountain and lake scenery and the abundant winter snow have made possible the development of the High Tatra for winter sports and also as a summer health resort. Exploitation of timber resources and mineral ores was neglected during Hungarian rule but, under the Czechoslovak republic, a beginning was made. After 1960 the Communist regime envisaged the development of water power and industry in this hitherto neglected part of the state. The total population of Slovakia in 1957 was 3,816,037, the Carpathian towns of Kosice accounting for 79,198; Presov, 31,244, Zilina, (1959 est.) 34,234; and the ancient castle town of Nitra, (1959 est.) 32,506. The language spoken is almost entirely Slovak and the religion Roman Catholic or Greek Orthodox.

The Rumanian Carpathians formed part of the Roman province of Dacia and the Rumanian language is derived from Latin. The

mountains to the east of the Transylvanian basin served to deflect the main streams of migrants passing along the plains of Wallachia into Hungary or along the sub-Carpathian zone into the loess-covered plains of Galicia and Upper Silesia. The first agricultural settlement was in fact made by Saxons in the 12th century in the Olt (Oltu) valley, afterward known as the *Allland*, to distinguish it from the later crusading settlements made in course of the struggle between western Christendom and the Huns and Turks. Sibiu (Hermannstadt) and Brașov (Kronstadt) date from this period. Transylvania experienced centuries of incorporation in the Ottoman empire and, on the retreat of the Turks, there was a considerable influx of Germans and Magyars who came under the auspices of the Habsburgs in the 18th century as stock breeders and agriculturalists. In the later part of the 19th century the Carpathians were opened up by the construction of railways through the Iron Gate, the Surduc or Vulcan pass, the Turnu Roșu or Red Tower pass (in the transverse valley of the Oltu) and the Predeal pass. Deposits of gold have been located in the Bihor massif and petroleum has long been exploited on the flanks of the Carpathians. In contrast with the compact German townships and the agglomerations of the Magyar farmsteads are the dispersed farms of the Rumanian pastoralists. The typical peasant house, like that of the Slovaks, is built of timber, with a roof of crude thatch or wooden shingles. Most of the Rumanians are herders of sheep and cattle, and the practice of transhumance from the plains to the mountain pastures is much more widespread than in Slovakia. The more southerly location of the Transylvanian Alps also enables permanent settlement to ascend 1,000 ft. higher than in Slovakia, that is to more than 3,000 ft. In the remoter parts of the Carpathians, bears, wolves, lynxes and birds of prey still exist. On the whole, on account of general inaccessibility, the Carpathians, especially the intermontane basins, have served as havens of refuge during times of war and as nuclei for the development of separate community groups, with traditional ways of life, folklore and costume.

The Carpathians were first mapped and surveyed during the later years of the 19th century, when maps on a scale of 1:200,000 were produced by the Austrian general staff. These maps were reprinted by the Czechoslovak government, with Czech place names, between World Wars I and II.

CARPATHUS: see **KARPATOS**.

CARPEAUX, JEAN BAPTISTE (often called **JULES CARPEAUX**) (1827-1875), French sculptor, whose works expressed a rhythm and variety that were in complete opposition to contemporary academic classicism, was the son and grandson of stonemasons, was born at Valenciennes (Nord), May 11, 1827. He went to Paris in 1842 and, at first working as a messenger and as a porter in the Halles, studied at the free Petite École.

In 1844 he entered François Rude's studio at the ficole des Beaux-Arts. He won the Grand Prix de Rome in 1854, after a prolonged struggle.

In Rome (1854-61) he was greatly impressed by Michelangelo and the later technique of Donatello. To these influences, especially in his single figures and portrait busts, were added the elegance of smaller works by Verrocchio and the tranquility of the Rossellinos. Among Carpeaux's best-known works are "Ugolino and His Sons" (1861, in bronze for the Tuileries gardens), "The Dance" (1869) for the façade of Charles Garnier's Paris opera house, and the fountain at the Luxembourg gardens, Paris (1874). Carpeaux's work, prelude to that of Rodin, was under constant attack. Despite this, and the feelings of persecution that oppressed him, he gained the friendship of Napoleon III. He died at Courbevoie (Seine), Oct. 12, 1875.

CARPENTARIA, GULF OF, a southward extension of the

shallow Arafura sea and with it covering the Sahul shelf that links New Guinea with the continental block of Australia. It is connected with the Coral sea to the east by Torres strait. The gulf is about 480 mi. from north to south and about 420 mi. (maximum) from east to west. It is shut off from all oceanic circulation, except for the summer monsoon drift that enters from the northwest and passes southward along the east coast. Except in the northwest, where the edges of the Arnhem Land plateau have sunk to form a drowned coast with numerous inlets and islands (Groote Eylandt, about 36 mi. long, maximum elevation, 520 ft.), the gulf floor rises from shallow depths (average 30–40 fathoms) to form an unindented lowland fringe, perhaps a raised sea floor—50 to 100 mi. wide in the south-southwest and 100–150 mi. in the south and east, with a few off-lying islands (Sir Edward Pellew group; Wellesley Islands). Behind the often dead-flat plains the land rises gradually to the Barkly tableland (about 1,000 ft.) in the south and to the highlands of Cape York peninsula in the east. The plains—the gulf country proper—are largely floored with silts and muds washed down by the numerous rivers, some of which (Roper, McArthur, Flinders, Batavia) are navigable for varying distances inland. They have, however, markedly seasonal regimes; in summer wide areas are flooded and in winter the rivers are brackish far up their courses as the tidal range is high, although only one full tide is experienced each day in most areas. The soils, except in the alluvial flats and pockets, are perhaps poorer than would be expected and climatic conditions lead to grasslands. Mitchell grass covers extensive areas with occasional forest clumps, dense palm groves and mangrove belts near and along the coasts. The rivers abound in crocodiles and the gulf waters afford good fishing. The climate is tropical (mean annual temperature, 85°–65°; average annual rainfall 20–40 in.) and there are only two seasons, the wet (November to April) and the dry. The gulf country is, apart from mining in the Croydon area, devoted entirely to pastoral farming. There are many natives, but the scanty European population lives mainly in the inland cattle stations, in mission stations (*e.g.*, at some river mouths) and at such settlements as Normanton, Burketown and Borrooloola. Normanton, 23 mi. up the Norman river, is the port for a large, rich pastoral area, as well as for the mining (gold and silver) field of Croydon, with which it is linked by a railway (94 mi.). There are air services from Cloncurry to Mornington Island by way of Burketown and to Normanton, and a cross service between the latter two places.

CARPENTER, EDWARD (1844–1929), English writer, social reformer and pioneer of a return to rural simplicity. was born at Brighton, Sussex, Aug. 29, 1844. He entered Trinity hall, Cambridge, in 1864 and was elected fellow and ordained in 1869, but in 1874, revolting against the social and religious assumptions of his time, he became a lecturer for the newly founded university extension movement.

In 1877 he visited the United States, and met Walt Whitman, whose poetry had been influential in altering the course of his life and whose verse forms he followed in his long, unrhymed poem *Towards Democracy* (1883; expanded 1905). In 1883 he bought a small holding in Derbyshire, where he lived until 1922 with a succession of working-class friends.

As a Socialist, he was a follower of William Morris, and more interested in the reform of society and return to rural crafts than in political revolution. His papers on social subjects (*England's Ideal*, 1887; *Civilization: Its Cause and Cure*, 1889, enlarged, 1921) brought many admirers to visit him. These, and his later works on the relation of art to life (*Angels' Wings*, 1898; *The Art of Creation*, 1904), and, influenced by Havelock Ellis, on relationships between the sexes (*Love's-Coming-of-Age*, 1896; *The Intermediate Sex*, 1908) were widely translated. He died at Guildford, Surrey, on June 28, 1929.

See A Bibliography of E. Carpenter (1949); T. Swan, E. Carpenter: *The Man and His Message*, rev. ed (1922).

CARPENTER, JOHN ALDEN (1876–1951), U.S. composer of the 1920s, was born at Park Ridge, Ill., Feb. 28, 1876, and studied music in Chicago and at Harvard university. He became vice-president of his father's railway and shipping business, but maintained his interest in music and in 1906 studied for a short

time with Sir Edward Elgar in Rome, continuing his studies from 1908 to 1912 with Bernhard Ziehn in Chicago. His orchestral suite *Adventures in a Perambulator* (1915), inspired by a child's view of city life, shows his gift for musical humour and effective orchestration. The piano *Concertino* (1917) was similarly successful. His ballets include *Krazy Kat* (1922), using jazz idioms, and his powerful *Skyscrapers* (1926), written at the suggestion of Diaghilev. Carpenter's output was small but of a generally high quality. It includes settings of poems of Rabindranath Tagore and chamber works. He died in Chicago on April 26, 1931.

CARPENTER, MARY (1807–1877), English philanthropist, social reformer and founder of free schools for poor children, the so-called "ragged schools," was born at Exeter, Devon, on April 3, 1807 the eldest child of the Unitarian minister Lant Carpenter. Having studied in her father's school in Exeter, and after a short experience as a governess, she opened, with her mother, a girls' school in Bristol in 1829.

In 1833, through the Boston philanthropist Joseph Tuckerman, she became interested in India, which she visited four times during her life. In 1846 she founded a ragged school in a slum area of Bristol, and a reformatory for boys in 1852, followed by another for girls in 1854.

After her third visit to India (1869–70), she decided that she could supervise the work there more effectively from England and inaugurated in 1870 a National Indian association to inform English opinion on the needs of India. In 1873 she visited the United States and Canada and pointed out the defects in the American prison system. She also studied the prison system of Louis Guillaume at Neuchâtel. She supported the movement for higher education for women and wrote pamphlets and books on ragged schools, reformatories, juvenile delinquency and Indian social reform. These aroused much interest and were responsible for government legislation in regard to reformatories and industrial schools. Mary Carpenter died at Bristol on June 14, 1877.

See J. Estlin Carpenter, *Life and Work of Mary Carpenter* (1879). (S. J. C.)

CARPENTRY, the art and trade of cutting, working and joining timber into structures. The carpenter may be distinguished from his fellow craftsman, the joiner, by the fact that he is responsible for work on the skeleton of a building. He is thus concerned with the stability of the structure rather than its appearance, and a great deal of his work is carried out with unplanned timber and is normally hidden by subsequent finishes. Joinery (*q.v.*) is concerned with the wrought work and finishes in a building, such as windows, doors, paneling, cupboards, etc.

In the past, when buildings were frequently wholly constructed of timber framework, the carpenter played a considerable part in the construction of buildings and, apart from the mason, was the principal building worker. The scope of the carpenter's work has however, altered. The increasing use of concrete and steel, especially for floor and roof construction, means that the carpenter plays a smaller part in the construction of buildings except for those of domestic scale; on the other hand, the part played by the carpenter in the construction of temporary forms for concrete casting has increased enormously.

The relative rise in the cost of timber since World War II has also called for revision in traditional practices and the application of engineering calculation, rather than empirical and rule-of-thumb methods, to the design of timber structures. Much traditional timber construction is wasteful from the point of view of the amount of timber used to the amount of work done, and developments such as stress grading of timber, improved mechanical joints and the exploitation of the inherent strength of laminated timbers have all brought new developments to carpentry. These changes have placed a new emphasis on factory work (indeed, laminated and specially glued framework units can only be made under precision factory conditions), but traditional carpentry methods are still widely used, and the ease with which timber can be cut and worked on the job will always mean that for many uses the traditional methods are both speedy and economical.

The work of the carpenter at building sites may be divided broadly into two main categories: the structural work, such as

floor and roof framing, which is permanently incorporated into the building; and the temporary work, which enables excavators, masons, bricklayers and concreters to complete theirs. The considerable employment of cast concrete work in modern buildings calls for the extensive use of timber formwork. Although this work is only in use for a short while, it is frequently as complicated in design and construction as a permanent structure and occupies a good part of the carpenter's time on building sites.

Timber Preparation.— Timber used by carpenters reaches the site as sawed in the mill, either in scantlings (beams and small sections) or in planks ready for incorporation into the work. Much of the timber imported into countries is already cut to section and seasoned. The principal timbers used in carpentry are in the softwood group and include redwoods (pine, fir, etc., from Baltic sources), Canadian spruces and Douglas fir. British Columbian pine (from Canada), Oregon and pitch pine (from the United States) and western red cedar. The latter can be used not only for framing and structural purposes but also because it needs no special preservation treatment, for external covering such as weatherboarding and roof shingles. The timbers traditionally used in framework: such as oak and elm, are now used only in the repair of historic buildings.

Joints.— The principal task of the carpenter on the site is to cut and fix the timbers with such jointing as is necessary. In this work the traditional hand tools are still largely used, although powered hand tools are coming increasingly into use. The latter are most useful for saving time, especially when there is much repetitive work: for example, in the cutting, squaring and birds-mouthing (see fig. 3) of roofing rafters. Some work, such as framed partitions or built-up roof trusses, may be cut and fitted in the workshop and then delivered to the site ready or partially ready for fixing.

The principal hand tools in use are rules, axes, saws, mallets, hammers, chisels, gouges, augers, pincers, compasses: bevels, marking gauges and planes (see WOODWORKING MACHINERY).

Joints are made in different ways according to the use to which they are to be put and the stresses or thrusts which they must resist. In addition to specially designed steel connectors, now widely used in roof framing, much use is made of wire nailing, which is mechanically very strong. Where timber joints are used for special purposes, they are usually of well-recognized traditional design and may be broadly grouped as follows:

Lap joints, fish joints and scarf joints are used generally for lengthening heavy timbers, using iron bolts and straps, and for jointing long runs of timbers such as wall plates which, for convenience, are inserted in short lengths. Scarf joints are used for lengthening beams, particularly in the case of repairs to defective timber structures when the ends of beams or rafter feet have rotted.

Flitched joints have considerable mechanical advantage; they consist of a built-up beam using two or more timbers of small cross

BRIAN SAGEGAR

FIG 2 — SINGLE UPPER FLOOR SHOWING TRIMMED OPENINGS AROUND FIRE-PLACE

section with the addition of a steel flitch plate (fig. 1j). Strength is thus achieved along with a reduction in the depth of the beam. Flitched joints are especially useful in alteration work or where depth is restricted.

The ends of floor joists and rafters are often notched over plates to obtain satisfactory support. Cogging consists in taking a small portion out of the underside of one timber crossing another in order to secure and level the two. It also assists in keeping the two timbers in position. Cogging was frequently used in the past, when timbers tended to vary in section owing to poor preparation and there was a correspondingly greater need for leveling.

A number of special joints are used in floor construction, especially where it is necessary to form a trimming. A trimming is a framing formed in a floor (or roof) for, e.g., a staircase well or skylight, or to run a floor around some obstacle into which it is either not possible or not permitted to fix timbers, such as a fireplace (see fig. 2). Most of these special joints are housed joints.

The end of one timber cut so as to leave one-third of its thickness forms a tenon, and the piece of timber which is to be joined to it has a mortise or slot cut through it to receive the tenon. The two are then pinned or nailed together to form a joint. This joint is used for preventing sliding movement between two members. The tusk tenon joint is a more complicated version used in flooring; it is provided with a neding arrangement so that the joint can be kept tight at all times.

A birdsmouth joint is formed when it is required to secure a timber which is at an angle to another which is level in order to prevent slipping. It is commonly used at the feet of roofing rafters (see fig 3).

Mitres and dovetailing are mostly used in joinery work, but may be used by carpenters in the lining of openings or trimmings.

Floors.—*Suspended Ground Floors.*—The use of solid concrete ground floor construction is now quite popular but up to 1939—and afterward for certain work—the suspended timber ground floor has been used (see fig. 4). A concrete slab is laid over the area of the building between the walls. Its function is to seal off the ground, prevent the growth of vegetation or entrance of vermin and provide a level surface on which the supporting walls for the ground floor may be laid. Since no clear space is required under the floor, it is the normal practice to use joists of small section, either 2 × 3 in. or 2 × 4 in., supported by brick "sleeper" walls. These walls, which are one brick thick, are built in honeycomb form for the efficient circulation of air and may be spaced between 3 to 6 ft. apart according to the size of joist used. A timber wall plate,

BRIAN SAGEGAR

FIG. 1. — FLITCH JOINTS

BRIAN SAYEGAR

FIG. 3. — TIMBER FRAMED CONSTRUCTION

usually 2×3 in. or 2×4 in., rests on top of the brick support and carries the joists, which are usually spaced 16 in. apart. A damp-proof course, *i.e.*, a layer of material impervious to moisture, must be inserted immediately under the wall plate so that any moisture that may find its way through the concrete and up the brickwork will be checked before it reaches the timber floor.

Good ventilation of the space between the timber floor and the concrete is essential; it is usually provided by placing perforated air bricks in the outer wall of the building and so arranging them that a current of air passes through the underfloor space.

There is danger of fungus attack on the timber forming a suspended ground floor if the precautions mentioned above are not taken. The air is liable to be damp, and if the ventilation is not efficient the moisture content of the timber may become such that in the presence of the spores fungus decay may take place (see **DRY ROT**).

If the timber is well seasoned and the damp-proof course and ventilation effective, it should not be necessary to treat the timbers with preservative, although this is frequently done as an added precaution. It is, however, advisable to treat the ends of any timbers which are in contact with wall plates or which for any reason must be built into brickwork. Good practice requires that timbers should not be built into walls unless this is absolutely unavoidable.

The main advantage of a suspended timber floor at ground level is its resilience, but from the point of view of thermal insulation it has considerable drawbacks. The boarding laid over joists is

usually tongued and grooved to prevent draft and dust entering the room. Even when this has been done, however, drafts often occur, especially when some shrinkage of the timber has taken place. Since underfloor ventilation is essential for suspended floors, it follows that there must be considerable heat loss, and the insulation efficiency of a boarded floor on joists with good underfloor ventilation is seldom as high as that of a solid concrete floor with suitable covering.

Suspended ground floors of this type are not suitable for carrying heavy loads, and their use is confined to houses and smaller public buildings.

Timber-Joisted Upper Floors.—This familiar construction is used for light loads and small spans and, like the suspended ground floor, mainly for buildings of domestic scale and in conjunction with load-bearing brick walls. The joists are usually spaced 16 in. apart, and the depth is selected according to the span, the joists being 2 in. in thickness. Three-inch-thick joists are used where it is required to carry extra load, as is the case with a trimming joist. The joists are covered with hardwood or softwood planks and lined underneath with plaster, boarding or other suitable finish. The rule-of-thumb method for calculating the depth of a timber joist is to divide the span, in feet, by two and add two to the quotient to give the depth in inches. This will obviously sometimes result in the joist selected being unnecessarily deep, and there are published tables of joist sizes related both to span and spacing which, being drawn up on a basis of calculation, will offer some economy in the amount of timber used. Alternatively the floor may be designed in accordance with normal engineering practice for its special conditions and loadings. As the depth of a joist increases (with the span) the cost of the timber becomes relatively higher; it is not economical to increase the depth of timber joists over about nine inches. If spans requiring more depth than this are to be covered with a timber-joisted floor, it is necessary to introduce an intermediate support in the form of a strengthened timber or steel beam, thus reducing the size of the common joists (see fig. 1). Further economy also follows in that in order to secure clear heights, a double floor of this type requires less over-all height in the building.

Fig. 5 shows the principal joints and fixing methods used in upper floors constructed of timber. The joists may be supported at the wall by means of pressed steel hangers or spiked to, or notched over, timber plates. Joists may also be built into the brickwork, in which case it is usual to rest them on a steel strip. The building in of joist ends of upper floors is less objectionable when they rest on the inner leaf of a cavity wall, but building in should be avoided in solid wall construction and under no circumstances should wood plates be built into brickwork or masonry

BRIAN SAYEGAR

FIG. 5.— UPPER FLOOR CONSTRUCTION SHOWING METHODS OF SUPPORTING JOISTS AND FORMING OPENINGS

Upper floors are not normally ventilated, and built-in should be treated with a suitable preservative. Where chimneys pass through timber floors, a trimmed opening must be formed so that no timber is built in near the flues, and all structural timber should be kept 1½ in. away from brickwork protecting flues unless the brickwork is at least 9 in. thick.

Water and gas pipes and electricity conduits are for convenience often run through the first floor, and braces may be provided between the joists to support them. Wherever possible, these pipes and conduits should run parallel with the joists, but if it is necessary to carry them through a joist this should be done by boring through the centre of the joist and not by notching the top. If notching is done, it should be near the point of bearing and not at the centre of the span.

Herringbone strutting, shown in fig. 5, should be used to steady the joists against lateral movement whenever the length of the joists exceeds 50 times the thickness.

An ordinary timber floor of this type with three-fourths inches of plaster forming the ceiling is rated as fire-resisting for one-half hour. Any longer resistance period, such as two hours, which is normally demanded for public buildings, will require a concrete floor of some kind.

Sound *Insulation in Timber Floors.*—The acoustic insulation of a normal timber floor is not good, but can be considerably improved by pugging (see fig. 6). Pugging consists of filling the space below the boards and between the joists with a material such as dry sand, lightweight concrete or lightweight material manufactured for this purpose. The improvement in sound insulation depends directly on the amount of material used, and in some cases the weight of the pugging may necessitate an increase in the size of the floor joists. Pugging reduces both air-borne and impact noises. Another method of insulation is the use of a floating floor. In this, the floor boards are nailed not to the structural joists but to battens placed between them. The load is carried from the boards to the joists via a glass silk quilt. Wood floors may be floated on concrete subfloors by the same method. A floating floor may also be used in conjunction with pugging. (See *ACOUSTICS OF BUILDINGS.*)

Roofs.—Floors and roofs form the bulk of the carpenter's construction work. The traditional pitched roof with various coverings (tiles, thatch, wood shingles, etc.) still remains the most commonly used method of covering houses and similar small buildings (see fig. 7).

The carpenter's framework will be influenced in its design both by the weight and type of the covering to be used and by the span to be covered. The weight of the roof covering is transmitted by means of boarding or battens or both to the common rafters, which are the key members in the design of the roof. They are usually placed about 16 in. apart, span from the eaves to the ridge of the roof and are usually of timber of small cross section, either 2 × 3

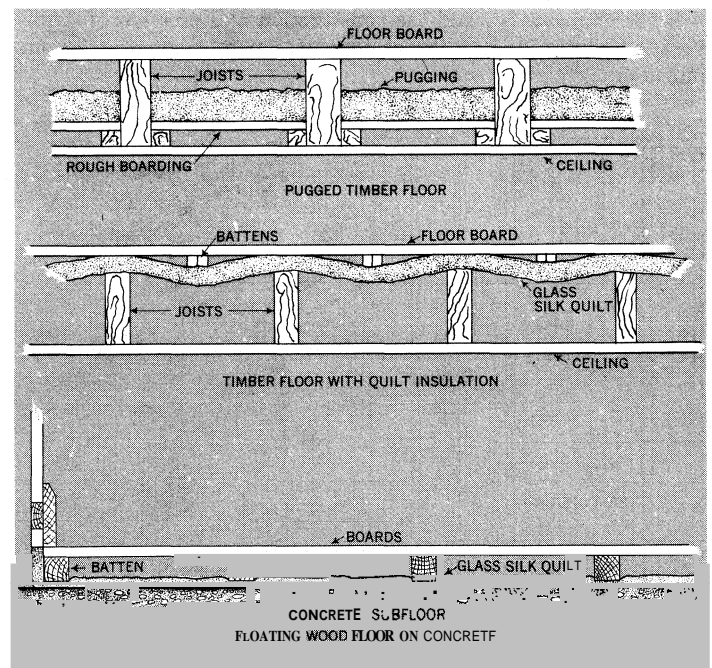

in. or 2 × 4 in. In small roofs the common rafter may be all that is required, but as the length of the rafter increases it is necessary to provide it with intermediate support to prevent sagging. If suitable support can be found (on the cross wall or above partitions, for example), a purlin, running horizontally and at right angles to the rafters, is introduced at the mid-point of the rafter span to give extra support. Light ceiling joists are also required; these span from wall to wall and are secured to the feet of the rafters.

Where no walls or partitions are available to give support to purlins, or for any reason a large clear span is required (as in a hall, for example), it is necessary to use a truss. A truss is an independent framed unit spanning from wall to wall on which the purlins can be carried. The traditional method was to use king-post or queen-post trusses (see *ROOF*). These use a large amount of timber and are in consequence very heavy; for these reasons they are rarely used today. Instead, the rule-of-thumb design methods for trusses have been displaced in favour of design by calculation. For this, the timber must first be stress graded, and calculations must then be made in accordance with the known loads and stresses which the members will have to carry. The result is that, while much smaller members are in general being used, the timber is used more efficiently. Standard designs have been produced for various spans and slopes, and the trussed rafter roof and the trussed purlin roof have entirely displaced the older and heavier trusses. By using specially laminated and formed beams and portal frames it is possible to construct timber roofs of virtually any span, but such work is outside the scope of what is normally understood by the term carpentry.

Framed Partitions.—Framed timber partitions for the subdivision of rooms and similar requirements have been in use for centuries and are still quite popular, especially in the construction of homes. Traditionally, they consisted of oak posts secured at the foot and head and plastered on both sides. Essentially this arrangement is still used, except that the framing is normally of softer timber (see fig. 8).

The timber frame, which is usually constructed of light members, consists of uprights or studs fixed to headplates and soleplates. The fixing may be by spiking or screening or by mortise joint. Intermediate horizontal members, called noggings, are also inserted for stiffening, for special fixings such as skirtings or for carrying cupboards or fittings.

The spacing between the studs is determined by the nature of the job and also by the dimensions of the covering to be used, but

BRIAN SAVEGAR

FIG. 6.—INSULATION OF TIMBER FLOORS

FIG. 7.—TIMBER ROOF CONSTRUCTION

is likely to be about 18 in. In addition to lath and plaster or plasterboard covering, insulating fibreboards, plywood, hard boards, veneered boards or plastic impregnated sheeting may be used.

Buildings With Timber Framework.—The principles outlined above for the construction of partitions may be satisfactorily combined with the design of roofs and floors to produce a completely timber-framed building. They are particularly suitable where it is required to use a light cladding, *i.e.*, a nonload-bearing covering, either of timber or of some other material, and a light roof. It may be necessary to pay particular attention to the thermal insulation of the walls; this may be improved by the incorporation of a quilt of glass wool or a suitable insulating fibreboard.

Carpentry in Temporary Work.—As mentioned earlier! the carpenter is frequently called upon to erect temporary timberwork for the assistance of other tradesmen during the course of building construction. This temporary work falls principally into three main groups: timbering for demolition and excavation work; the provision of centring for the construction of arches and vaults in brick or masonry; and the construction and erection of formwork or shuttering for the casting of concrete columns, beams and floors.

FIG. 8.—TIMBER FRAMED PARTITION

Timbering for Excavation.—Where trenches are required to be excavated on a building site for foundations, drains or the construction of basements, it is usually necessary, in order to prevent earth from falling and to safeguard those working below, to support the sides of the excavation by timbering (see fig. 9). The arrangement and the amount of timberwork needed depends on various factors—the depth, the condition of the ground and the width of the trench. Vertical timber boards called poling boards, which may be spaced at intervals in firm ground or set closely butted if the ground is loose or waterlogged, are set in contact with the earth. The poling boards are held in place by horizontal timbers called walings, and struts are then driven tight between the walings across the trench.

FIG. 9.—TIMBERSHORING FOR EXCAVATION

Centring for Arches.—For simple brick arches of a flat, segmental or cambered outline; the centre is formed by cutting a piece of timber to the required curvature; when made in this way the centre is called a turning piece (see fig. 10). It is supported

FIG. 10.—CENTRING FOR ARCHES

in the opening on props with folding wedges which allow not only easy adjustment but the removal of the centre after the arch has been completed. Where arches have a width over six to nine inches, the centre is constructed on two or more ribs set parallel to each other with their top edges conforming to the curvature of the intrados of the arch to be built.

The main consideration in the design and construction of a centre is that it shall remain rigid and not alter in shape or form during the building of the arch. The tendency, especially in the case of arches over a considerable span, is that as the building of the arch around the centre proceeds, the weight of the superimposed masonry tends to compress the centre at the haunches and in so doing forces up the crown. The reverse tendency is experienced when the weight is put on the crown as the arch nears completion. The ribs in a large centre must be built up to the required outline from small sections of timber, and it is essential that these be adequately jointed together and supported by braces and struts to insure that distortion cannot take place. In heavy arches or vaults, it is usual to design the centre to allow for distortion of this kind so that the final form which the centre assumes under load is the correct one.

The various ribs are connected together by laggings; *i.e.*, small pieces or strips of wood which actually carry the brickwork or stonework. The laggings are placed close together for brickwork

but are spaced out for heavier masonry so that the workman may use wedges for close adjustment of the heavy arch voussoirs.

Formwork.—Formwork or shuttering is the term applied to all wooden molds used for the casting of concrete. The special considerations in the design of formwork are that it must adequately support the weight not only of the concrete but also of the men placing it and the load of hand or mechanical ramming. In addition, it must be designed so that it can be erected, taken down and if necessary re-used during the progress of the work. Formwork is used mainly in foundations, columns, beams and floors. The sides and bottoms of formwork are constructed of boarding which may in some cases be specially lined with plywood or hard board, the boarding being supported and stiffened with cleats and uprights or walings to prevent distortion (see fig. 11).

Beam forms may be constructed in various ways. It is usual to arrange the formwork so that the centring at the sides of beams can be removed without disturbing the centring supporting the underside. This is because the side timbers may be removed as soon as the concrete has set, in a matter of 24 hours, but the concrete is not ready to support considerable weight for several weeks. The formwork for a long lintel, shown in fig. 11, is similar in principle to that used for beams.

CARPET: see RUG AND CARPET.

CARPETBAGGER, slang term for an unwelcome stranger coming with no more property than he can carry in a hand satchel (carpetbag), to exploit or dominate a region against the wishes of some or all of its inhabitants. The term was used in the United States to describe speculative bankers in the early settlements in the west. Gen. Ulysses S. Grant used the carpetbag as a symbol for the northern cotton speculators who traded with the enemy along his lines in the Mississippi area during the American Civil War. In U.S. politics the term came into widespread use as an epithet for northern Republican politicians or financial adventurers who in the Reconstruction period that followed the Civil War used the recently enfranchised Negroes as a means of obtaining office or fortune in the southern states. Not all of them were evil. There were among them idealists concerned with freedom and education as well as adventurers seeking state offices or opportunities for financial gain. (Jo. D.)

CARPET MANUFACTURE. This article deals with hand and machine methods for making carpet. Included among the hand, or oriental, methods are those for producing tapestry, Persian, Turkish, Caucasian, Indian and Chinese carpet. The machine methods discussed include those for making velvet, Wilton, Axminster, chenille, tufted and knitted carpet. For information on the history, classification and appearance of the various types of rugs and carpets, see the article RUG AND CARPET. Many of the techniques used in the manufacture of carpets by machinery

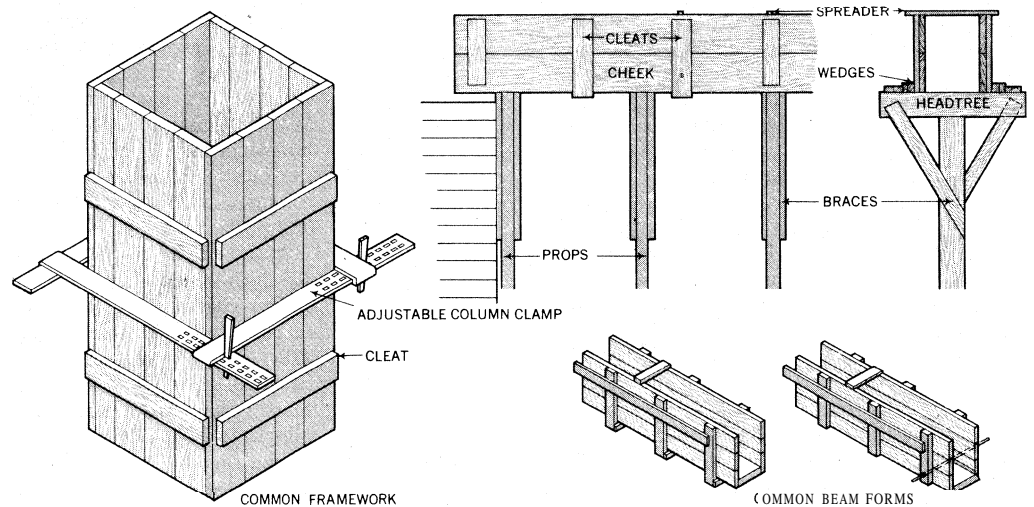

FIG. 11.—FORMWORK FOR CONCRETE LINTEL AND CONCRETE COLUMN

have their origin in hand craftsmanship. The earliest machinery employed hand power and water power to duplicate processes originally done by hand. Some carpet materials, used thousands of years ago, are still in use. Carpets have been produced by hand since the Assyrian and Babylonian empires and are still made by hand in the orient. Machine-made carpets, since they cost less to produce, replaced the hand-made types for general use many years ago. Commerce continues, however, in new, semiantique and antique oriental carpets.

HANDMADE CARPET

Ancient Origins.—Handmade carpets have been a part of the development of most civilizations. From the use of animal skins by primitive tribes to the creation of highly complex and beautifully designed silk tapestries by artists of Italy and France, the relative technical and artistic advancement of a culture could be measured by the craft of rug making. Oriental cultures have left the most lasting influence on carpets, and the term oriental has long been synonymous with the art of handcrafting carpets. North American and South American Indians developed the art to an advanced state early in their history and continued to make carpets of designs traditional to the history of their culture. The Navaho rug made by the North American tribe became one of the best known of the American Indian rugs. (See NAVAHO: Arts.)

Hooked, braided and embroidered rugs have been made in European countries and particularly by colonials of European origin since 1725. These carpets served the colonists' needs exclusively except for the rare importation of oriental types by wealthy landowners or merchants.

Early Materials.—Native materials were used in the first handmade rugs. Sheep were raised in most areas, and wool became the most widely used fibre. Silk was used in the east. Other animal hairs, such as those of the goat, horse, camel, alpaca and llama, were employed where they were available. Rags salvaged from discarded clothing were used for braided and hooked rugs. Cotton, jute and later some linen were used as the base of the carpet and to anchor its surface. The first dyestuffs were derived from vegetable matter. The design of these carpets reflected the experience of the weaver or the lore or history of his people. Most designs became classic and were used by generation after generation.

Oriental Carpet.—Iran (Persia), Turkey, India, Egypt and the Caucasian region have long been the centres of oriental carpet production. Various carpets with individual characteristics are identified with the town or area in which they are made. The best-known Persian types are Kerman, Ferraghan, Kurdistan, Sehna and Isfahan. Recognized Turkish carpets are Ghiordes, Kulah, Oushak and Ladik.

Production Methods.—These carpets are produced on hand looms. The warp or lengthwise yarns are wound on top and bot-

tom beams or poles. The width of the beams determines the width of the carpet. The beams are supported by upright pillars, and the yarns are stretched vertically. Weavers, often members of one family, sit in front of the frame and by hand tie row after row of pile tufts into the warp stretched on the frame. Pieces of yarn for the pile are cut about two inches in length; each pile piece is knotted around two warp threads according to the paper design in front of the weaver. As each row or part of a row is

finished, two weft threads are put in, one in the shed formed between the front and back halves of the chain (*i.e.*, the front and back strands of warp yarn) and a second in an alternate shed formed when the weaver pulls the back half of the chain temporarily in front of the front half. The second weft is put in straight, the first one loose, zig-zag or vandyked, so as to fill up the back of the carpet and also to avoid the tendency toward lateral contraction. The weft is forced down into place by a heavy fork or beater. This interlocking of warp and weft with the tuft forms the weave of the carpet and has been imitated more or less in all mechanically woven carpet fabrics.

Two kinds of knot (fig. 1) are employed: (1) the Ghiordes or Turkish, and (2) the Sehna or Persian. In the Ghiordes knot the tufts of yarn appear in pairs between two warp threads; in the Sehna knot each tuft end appears singly between a pair of warp threads. In either case the tufts do not stand up vertically to the plane of the fabric but lie over obliquely toward the starting end of the carpet, forming a characteristic feature of handmade carpets.

Designs and Colours.—Certain designs and colours have characterized oriental carpets from each producing region. Some of the best-known Persian designs and the carpets in which they were used are as follows. The Herati design used in Ferraghan. Sehna, Khorasan and Mahal rugs consisted of a series of rosettes, each series between two long, curved leaves. The resemblance of the leaves to the form of a fish caused this pattern to be called the fish pattern. Alternate rows of rosettes were enclosed in diamond-shaped devices. This design was set off by a dark blue background and bordered by a palmette or lotus design. The Guli Hinnai pattern was used especially in Ferraghan carpets and consisted of rows of small yellow plant shapes united by many flowers in diamond arrangements. The pear design was favoured by the makers of Sehna, Saraband and Shiraz rugs. It is actually a pear form but was thought to have represented a bend in the Ganges river, or a river in Kashmir. This design spread to India and the Caucasian regions, where it was used in shawls as well as in carpets. Other marks of Persian rugs were leaf, bud and flower motifs, and animal designs. Patterns were ordinarily flowing and graceful as opposed to geometric. Colours were shaded and used in harmonious tones.

Carpets from Asia Minor used the brightest colours and often put strongly contrasting colours next to each other in designs. Strong rectangular lines were evident. Animal designs were not used, perhaps because of the weavers being Muslims. The two best-known carpets in this group were the Ghiordes and Kulah. The Ghiordes rugs excelled over all other rugs in Asia Minor and equaled the best in Persia. Prayer rugs, with the entrance to a mosque as their principal figure, were bordered by intricate designs. The Kulah rugs were similar but were coarser in weave, had higher pile and usually had narrower borders.

Caucasian rugs were predominantly geometric in design with patterns of elongated stars and octagonal devices bordered by barber poles and latch hooks. Strongly contrasting colours, reds, blues and yellows predominating, were separated by strips of latch hook ribbons. Only the Ghiordes knot was used. The Kabistan became the best known of this group.

FIG. 1.—PRINCIPAL KNOTS USED TO TIE PILE YARN IN HAND-WOVEN CARPETS: (LEFT) GHIORDES, OR TURKISH. KNOT; (RIGHT) SEHNA, OR PERSIAN, KNOT

Turkoman carpets were made by nomadic tribes that roamed from the Caspian sea to the China border. No other group held more firmly to designs and colours through the years. The finest example of their work is the Tekke rug, more popularly known as the Bukhara. The field of the Tekke was a dull red divided into oblongs with octagonal shapes centred at the intersections of the lines forming the oblongs. Red, black and white were the main colours used. Often the webbing of the base, sometimes up to 12 in., of these carpets was left exposed at the ends.

India.—Princes of India imported Persian rug makers during the 16th century to teach the art to the people; consequently, Indian rugs are similar in design to Persian rugs. In the 17th century India began weaving operations in prisons; this competition with the caste weavers led to a decline in quality. Rugs from northern India were of better quality than those from the south, where wool was scarce and cotton and jute were often substituted for pile yarns. The Agra and Mirazapur are typical Indian rugs.

China.—Chinese rugs, which have become popular in Europe and America, received their character from an exchange of weavers with central Asia. During the late 17th century, the emperor K'ang Hsi and later his grandson Ch'ien Lung gave great impetus to rug making. Chinese rugs were scarcely known outside China until the Boxer rebellion and did not reach wide popularity until after World War I. Exports were heavy until the Chinese Communists stopped shipments.

Chinese rug designs date back to the 12th century and were taken from porcelains and paintings typical of early Chinese culture. Colours used were blue, yellow, white, red and black. No more than three or four colours were used in a single rug, and large areas of monotonous were typical. Symbolism was drawn upon heavily for design inspiration—the swastika, for example, symbolized good luck; the five-clawed dragon was originally reserved for the royal court but later was used generally; flowers represented seasons. Cloud bands were found only in these rugs, sometimes singly and sometimes in clusters. Chinese rugs were made with deeper pile than any other handmade rugs.

Tapestry Weave.—Another kind of hand weaving is the tapestry method, wherein the coloured weft threads, wound upon wooden needles, are threaded around and between the warp ends, leaving a flat or slightly ribbed surface. Since a tapestry carpet lacks a tufted pile, it does not make a luxurious carpet, even though a fine pitch (number of warps per inch) can be employed and the richest and most delicate effects of design and colour obtained. Carpets of this type have long been made at Les Gobelins, Paris, Aubusson and Beauvais in France and Tournai in Belgium. This work of producing tapestry carpet is slow and required great skill; the product therefore is expensive. (See TAPESTRY.)

MACHINE-MADE CARPET

Beginnings.—For several centuries preceding the Industrial Revolution carpets were manufactured in Europe and the British Isles by skilled handicraftsmen; prices were high and sales few. During the Industrial Revolution the British and later the Americans created a modern system of carpet manufacture, the British developing a systematized factory production on a sizable scale even though manufacturing was done entirely with hand looms. The carpet industry in the United States started by adapting the British system on a more modest scale and was largely a home industry organized by agents who also sold the small amount of carpets produced. Most sales were made in the major cities. At the time the United States began to make carpet, the basic styles and weaves had already been developed in Europe; their names were taken from the cities where they originated, such as Axminster, Wilton, Kidderminster, (all in England) and Brussels (Belgium). These weaves, with some variations, were copied in the United States.

By 1830, the use of carpets had become widespread in the eastern part of the United States and several factories had been established in New England, New York and Pennsylvania, although British carpets dominated the U.S. market. The U.S. industry was not able to compete successfully with the greater skill and lower

BY COURTESY OF THE SMITHSONIAN INSTITUTION
 FIG. 2.— POWER LOOM DESIGNED BY ERASTUS B. BIGELOW; USED FOR WEAVING TWO- OR THREE-PLY, INGRAIN CARPET

costs of British labour. During this period imports of British carpets into the U.S. averaged 660,000 sq.yd. a year and usually exceeded the total output of the U.S. carpet factories. This situation led the management of U.S. mills to encourage the development of power equipment. Spinning and other yarn-preparing processes had been mechanized by this period, but it was the invention of the power loom by Erastus B. Bigelow in 1841 that truly revolutionized the industry. Bigelow had previously invented a lace-making machine and was commissioned to develop power equipment for carpet making by the Lowell Manufacturing company of Boston. Bigelow's first loom was for ingrain carpet, but he later developed power-driven looms for Wilton, Brussels and tapestry carpets. The Axminster loom was invented by Halycon Skinner in 1876 and perfected a few years later by Alexander Smith. The Axminster loom copied the technique used in hand tufting carpets but was a new mechanical principle. Previous power looms had merely added power operation to the principle used in hand looms.

The power loom with its cost-cutting advantages soon came to be used in other technically advanced countries. Industries developed in Belgium, France, Germany and Canada. In Britain the already established industry was quick to adapt the power loom, and this industry continued to grow as the chief exporter of carpet while the U.S. industry, which came to be the largest in the world, sold exclusively in its home market.

Types of Machine-Made Carpet.—During the 19th and early 20th centuries, the types of carpet construction in widest use were the Brussels and ingrain, including an inexpensive variety of ingrain known as Venetian. In the late 1800s Axminster construction became popular and was the most widely used process from early in the 1900s until 1950. The Brussels type was replaced by the modern Wilton, and the ingrain carpet dwindled in popularity early in the 20th century. Tapestry carpets, also in wide use in the 19th and early 20th centuries, came to be known as velvet. Construction of the velvet and modern Wilton types remained constant without particular change until the tufted process, in which the pile is sewn into a prewoven back as opposed to weaving the entire carpet, was developed during the 1930s. Another recent innovation has been the development of a process of manufacture that fabricates the backing and pile in one continuous operation by means of the knitting principle. Chenille, a deep-piled luxury carpet, is still manufactured on a small scale.

Until the early 1900s all machine-made carpet was manufactured in widths of either 27 or 36 in. From that time loom widths gradually became wider, and the "broadlooms"—those over 12 ft.

in width—accounted for an ever-increasing portion of total production. In recent years 12-, 15- and 18-ft. widths have become most prevalent, although there is some production in 9- and 6-ft and 54- and 27-in. sizes.

Regardless of the type of construction used in manufacturing carpet, the preparation of its component parts closely follows the processes used generally in manufacturing all textile products. Most carpet manufacturers buy already prepared yarns for backing. Many mills that produce woven carpet spin their own surface yarns; many manufacturers of tufted carpets, however, buy all of their yarns and prewoven backing from other manufacturers.

All woven carpets have certain manufacturing characteristics in common. (See WEAVING: *Weaving Machinery*.) The warp (lengthwise) yarns are called "chain," and the weft (crosswise) yarns are called "shot." Additional weft strands placed in the body of the carpet to provide extra bulk or to secure pile yarns are termed "stuffer" yarns.

Velvet.—The velvet loom loops warp strands over raised wire strips to form the pile of the carpet. The wire strips are inserted across the loom in banks of 15 or more with loops being formed over one, two or three strips. As each row of pile loops is completed the wire strip at the front is automatically withdrawn and reinserted at the back for the next row of loops. If the wire has a knife edge that cuts the pile loop, a cut pile velvet is created. If the wires are smooth and the loop is not cut, an uncut or loop pile velvet is created. Most carpet known as twist carpet is created by using this method. Usually two or three beams of warp yarn are used. One beam feeds the basic warp yarn that binds the carpet together, another beam supplies the pile yarn and a third beam may be used for the stuffer yarns. The velvet loom is used mainly for solid colour carpets; it can, however, weave carpets in varied colours. One method is to form the pile yarn by twisting together two or more yarns of different colours. These are known as moresque yarns and produce a mottled colour effect. Another method uses two sets instead of one set of lengthwise yarn. This provides an additional weave shed through which a yarn of a second colour may be woven.

Wilton.—The Wilton loom operates on the same basic principle as the velvet loom but has greater versatility because of its Jacquard mechanism. (See WEAVING: *The Jacquard Machine*.)

FIG. 3.— METHODS OF MANUFACTURING WOVEN CARPETS

Up to six different colours of pile yarn may be used and the appearance of each of these colours in the surface of the carpet may be controlled to create the desired design. When a colour does not appear on the surface, it is buried in the back of the carpet. In addition to variations in colour, wide variations in texture also can be woven by this mechanism. Pile height can be adjusted to form scrolls and other patterns, and cut and uncut surfaces may be achieved. The Wilton process can produce highly intricate patterns. The Jacquard mechanism is controlled by punched cards that determine which yarns will be moved in position for looping over wires. The complete design is punched on a series of cards, which in turn are set together and travel as on a continuous belt around the Jacquard mechanism over the loom. As the cards move past a mechanism in the loom, the pile yarn that is to appear on the surface is selected. The cards, as they rotate, control each repeat of the pattern. A 15-ft. Wilton carpet may require as many as 4,800 different cards to complete a 36-in. repeat of the design in the finished carpet. Another form of Wilton weave is the double-face Wilton in which two fabrics are woven simultaneously, with the pile yarn passing backward and forward between the upper and lower cloths. A knife moving to and fro across the front of the loom cuts the pile yarns between the two cloths, thereby producing two separate carpets.

Axminster.—Axminster carpets can be woven on three different types of loom: the spool Axminster loom, the gripper Axminster loom or a combination of these two, the spool-gripper Axminster loom. The spool Axminster loom, unlike the velvet and Wilton looms, draws its pile yarns from small spools that have been wrapped with various coloured yarns to match the pattern to be produced. These spools, which are arranged across the width of the loom, are locked together in a frame and each frame represents one row of tufts across the carpet. Each strand of yarn taken from a spool forms a single pile tuft. As each frame of spools moves into position, it is automatically lowered so that the ends of the yarn strands are inserted between the warp threads in the loom. After insertion the shuttle shoots the weft yarn across the shed and a comb curls the ends of the surface tufts under the weft and back up between the warp strands. Another pass of the shuttle binds the looped strands in place, and a knife resembling a nipper cuts the strands from the spools, leaving the two ends of each strand protruding upward to form the pile tuft. The next spool frame then comes into position and the one used rotates until it again reaches the weaving position. This process inserts each pile tuft separately, thus simulating the technique of hand weaving. Axminster is the only weaving method that can give a different colour for each individual tuft in a pattern repeat, and it has no limitations as to the complexity of design. However, the preweaving preparations for complex designs is extensive, so that this method does not lend itself to other than extended production of the same design.

The gripper Axminster process was developed in Kidderminster, Eng., about the beginning of the 20th century. The variety of colour obtainable is a little greater than with the Wilton, though not as great as with the spool Axminster process; but short runs can be woven economically since the spool setting process is eliminated. In the gripper loom a series of vertically sliding carriers, equal in number to the number of tufts across the width of the carpet, are raised or lowered by a Jacquard mechanism. Each carrier has eight (or sometimes more) apertures, through which pile yarns from bobbins behind the loom are threaded. The movement up or down of a carrier, according to the operation of the Jacquard, brings the desired colour yarn opposite a gripper. The grippers are beaklike instruments, one to each carrier, that rotate about a shaft so that when they are in the upper position they are able to grip the tufts protruding from the carriers. A sliding knife cuts the tufts, and the grippers rotate backward and downward to insert the tufts between the ground warps. The tufts are then fastened around the weft and bound by a succeeding shot in the same way as in the spool Axminster.

The advantages of both types of Axminster loom have been combined in the spool-gripper loom. This is essentially a spool loom that uses a gripper mechanism for inserting the tufts. so

that it is possible to obtain, at one and the same time, the variety of colour and design characteristic of the spool Axminster, together with the economy of the gripper.

Chenille.—Chenille carpets are produced by a two-loom operation. The pile surface is woven into a blanket on one loom and then is cut in long furry strips. The second loom weaves the back of the carpet and at the same time forms a shed through which the prewoven strips are inserted, brushed into place and secured. Expert hand labour is required for this process, which has been used only to produce luxurious carpets. Any pattern, colour or shape up to 30 ft. in width can be woven by the chenille method. It is often used for custom-designed carpets.

Tufted Carpet.—The tufting process differs from other basic production methods in that it uses a needle instead of a weave action to form the pile of the carpet and uses a prewoven backing for the basic construction. As the backing moves through the tufting machine, a bank of needles as wide as the carpet inserts individual tufts of pile yarn into the backing. The sewing mechanism locks the tufts in place; later a coating of latex is applied to further secure the tufts. The yarn is supplied to the needles through tubes from cones of yarn set on a large rack or creel back of the machine. Each needle is supplied by an individual cone, which is connected in turn to a "magazine" or "feeder" cone. When all the yarn is used on one of the first cones, a magazine cone takes over automatically so that a continuous flow of yarn is maintained. Machine widths vary from 36 in. to 18 ft. The commonest machine widths are 12 and 15 ft. During the first years this method was in operation narrow machines were used and solid colour loop pile carpet was produced. Electronic and mechanical controls were then developed that made it possible to produce carpet with varying heights of pile and texture design; tweed designs have been achieved by using moresque yarn or pile yarns of different colours.

Knitted Carpet.—Knitted carpet is produced by bringing together the backing yarn, the locking yarn and the pile yarn in one operation by three different sets of needles simultaneously. This is an adaptation of the knitting principle used in the manufacture of many other textile products; either flat or circular knitting machines may be employed. Knitted carpets are usually made of loop construction in either solid or varied colours. The varicoloured effects are created by using moresque yarn or different coloured yarns in a manner similar to that used for velvet or tufted carpets. The height of the pile may be varied, and the knitting machines can achieve textured designs. Both cut and uncut pile can be produced.

Finishing Processes.—The finishing processes for woven and knitted carpets are similar. After the carpet comes from the loom it may be sheared to insure evenness of the pile, steamed to impart a bloom to the finished product, inspected for missing tufts or other imperfections and trimmed and cut to the proper size for shipment. If the carpet has been manufactured in rug units, it may be bound or fringed at the ends. Back sizing or latex is applied to many woven carpets.

Tufted carpet is subjected to the same processing, but it also may be piece dyed if it was not manufactured from pre-dyed yarns. Additional backing fabric may be added and one or two coats of latex applied to the back.

A layer of foam rubber is attached to the back of some woven, knitted and tufted carpets; this obviates the necessity for using padding under the carpet and facilitates the seaming and installing of the carpet when it is used wall-to-wall.

A small volume of thick pile are made with hand-carved designs, which are created with a hand-shearing machine. Special design effects are sometimes created in custom-made rugs with a hand-tufting machine.

Raw Materials.—Carpets were made of natural fibres exclusively until World War II, when man-made fibres began to come into an ever-expanding use.

Wool.—Wool has continued to be the principal raw material for surface yarns. It was always the chief fibre used in woven carpets and is now used extensively in tufted and knitted carpets and rugs. In the 1950-60 decade, the U.S. carpet industry used an

average of 135,000,000 lb. of wool annually. Wool traders distinguish between carpet wool and wool for wearing apparel. Carpet wool is obtained from native, unimproved breeds of sheep and is coarser and more wiry than wools used for making wearing apparel. Argentina and New Zealand are the principal sources of carpet wool, but considerable quantities also come from Pakistan, Iraq, Syria and India with small quantities from some European countries. China was a major exporter of carpet wools at one time but wool exports were halted when the Communists assumed control.

Cotton and Man-Made Fibres.—The high price of wool following World War II encouraged the use of cotton as a surface fibre for machine-made rugs and also fostered the use of man-made fibres. After a short while cotton consumption leveled off at approximately 6% of the total carpet fibre consumption. The chief man-made fibres in use in the early 1960s included rayon, nylon yarn, filament nylon, acrylics and modified acrylics. These fibres have been especially developed for the carpet industry and differ from fibres of the same type used for other textile products. Since many of them have proved highly suited for carpets, and, since the world supply of carpet wool is limited, more man-made fibres probably will be used for carpets in the future.

Materials for Backing.—Materials used for carpet backing include those also used for surface yarns and in addition jute, craft cord, cotton and some man-made fibres. Jute yarn is produced principally in India and Pakistan, where the jute is grown, with some spinning being done in Europe and the United States. Twisted craft cord yarns were developed in the United States and are used instead of jute in weaving and knitting and to some extent in tufting. Most prewoven backing for tufted carpets is made of jute and is manufactured in India. Millions of pounds of cotton yarn and some man-made fibres also are used.

The World Carpet Industry.—After about 1950 the carpet industry grew considerably throughout the world.

United States.—In the United States, production increased annually after 1950, with virtually the entire output consumed in the home market. Annual production exceeded 150,000,000 sq.yd. in the early 1960s; the wholesale value of the annual product exceeded \$650,000,000. The annual consumption of broadloom carpet per household rose from just under 2 yd. in 1950 to 2.8 yd. in 1960. The use of carpet in commercial establishments and institutions expanded rapidly until by the early 1960s it was commonplace in stores, hotels, motels, theatres, office buildings and churches; it also was sometimes used in schools and libraries. The ability of carpet to prevent and absorb noise, its relative ease of maintenance and its aesthetic appeal led to its wide commercial use.

Tufted carpet was the leading type in the U.S. market in the early 1960s and represented two-thirds of total carpet production. Axminster production dropped from approximately one-half of the total in 1950 to about one-tenth, and during the same period Wilton and velvet production also decreased. Woven and knitted carpet accounted for approximately one-third of the total production at the start of the 1960s.

The U.S. consumer's acceptance of solid colours, tweeds and simple textures contributed to the popularity of tufted carpets and the decline of the Axminster weave. Highly complex texture designs in solid colours remained popular and were found in Wilton, velvet and knitted constructions. Oriental rugs and machine-made rugs of traditional and period designs have continued to be of limited interest. Custom-designed rugs and carpeting in woven and tufted constructions became more popular and influenced mass-produced carpets.

Great Britain.—The British industry ranked second in size after the United States in the early 1960s; in Great Britain, traditional weaves and designs remained popular. Annual production exceeded 62,000,000 sq.yd., valued at nearly £90,000,000. Of the carpet produced in Great Britain, more than 50% was Axminsters, 20% was tufted and 15% was Wiltons. Sales in the home market more than doubled between 1951 and 1960, totaling about 23,000,000 sq.yd. in 1951 and more than 55,000,000 sq.yd. in 1960, or slightly more than 1 sq.yd. per person. Exports were sent prin-

cipally to other members of the commonwealth, with Australia being by far the largest buyer. Several British manufacturers established or helped to establish carpet factories in Australia, Canada, New Zealand and South Africa.

Canada.—The Canadian industry manufactures approximately one-half of the carpet consumed in Canada; the remainder, except for small amounts brought in from the United States, is imported from England, Belgium and Japan. Canadian plants produce all the woven types with the exception of chenille. Tufted carpets were being produced by some of the plants, and a few new mills were producing tufted carpets exclusively. The Canadian industry was not producing for export in the early 1960s.

Belgium.—The Belgian industry grew remarkably after World War II and became the world's third largest producer and a major exporter of woven carpets. Exports in some years have exceeded 80% of the total production. Chief importers of Belgian carpets have been the United States, Great Britain, Canada, African countries and other European countries. Belgian woolen carpet production was chiefly Wilton and velvet, although Belgian factories also manufactured large amounts of woven cotton carpet, principally inexpensive rugs of traditional design that were particularly popular in the United Kingdom.

Japan.—The Japanese machine-made carpet industry came into existence after World War II when machinery for making Wilton and velvet carpets was imported. The Japanese have become important exporters of Wilton and velvet carpets to the United States, Canada and some European countries. Virtually all carpet made in Japan is exported. Some Axminster equipment was being used in Japan, and tufted carpet was produced on a small scale.

Other Countries.—Carpet industries also exist in Europe in Denmark, France, the Federal Republic of Germany and the Netherlands. Central and South America had not become large carpet consuming areas by the early 1960s. Mexico had a small woven industry, and small plants were located in various places in South America. The near east continued to manufacture and export hand-made rugs, but no machine-made carpet industry developed there. (P. M. J.)

CARPI, GIROLAMO DA (1501–1556), Italian painter and architect whose principal scene of activity was Ferrara, was born in Ferrara and died there. He was a pupil of his father, Tommaso, then of Garofalo. He had a particular admiration for Correggio, several of whose works he copied. He was also influenced by Parmigiano and slightly by Raphael, but chiefly by Dosso Dossi. As a young man he visited Parma and Modena and worked in Bologna; in the church of S. Martino Maggiore in the latter city he painted an altarpiece with the "Adoration of the Magi" (1530). In 1540 he entered the service of Ercole d'Este, duke of Ferrara. His works for the Este family include an allegory representing "Opportunity and Patience" (1541, Dresden) and three frescoes—"Vintage," the "Triumph of Ariadne" and the "Triumph of Bacchus" (all at Ferrara). He also painted portraits. As an architect he is stated by G. Vasari to have prepared designs for a large number of Ferrarese private houses, and he worked on the restoration of the Castello after it had been damaged by fire in 1554. (M. W. L. K.)

CARPI, UGO DA (1479/181–1532), Italian painter and print-maker, the first Italian practitioner of the art of the chiaroscuro woodcut, was born in Carpi and was active in Venice and Rome. Many of his chiaroscuros are after drawings by Raphael and Parmigiano. His claim to the invention of this process has long been contested. Hans Burgkmair and Lucas Cranach were known to have practised it in the north before 1510, whereas there is no definite evidence of Ugo's work in chiaroscuro until 1516, when he appealed to the Venetian senate for protection from his imitators. None of his paintings is extant.

CARPINI, JOANNES DE PLANO (c. 1180–1252), a Franciscan friar and traveler, the first noteworthy European traveler in the Mongol empire and the author of the earliest important western work on central Asia, was born in Umbria, probably at Piano della Magione (formerly Pian di Carpini) near Perugia. The date of his birth is not known, but he was a contemporary and disciple of St. Francis of Assisi. By 1220 he was

a member of the Franciscan order and subsequently took a leading part in Franciscan teaching in northern Europe; he held successively the offices of *custos* ("warden") in Saxony and of *minister* ("provincial") of Germany, and afterward of Spain, perhaps also of Barbary and of Cologne. He was in Cologne at the time of the great Mongol invasion of eastern Europe and of the disastrous battle of Siegnitz (April 9, 1241).

Fear of the Tatars had not abated when four years later Pope Innocent IV dispatched the first formal Catholic mission to the Mongols, partly to protest against their invasion of Christian territory and partly to gain reliable information about their numbers and their plans; there may also have been the hope of alliance with a power who might be invaluable against Islam. At the head of the mission, the pope placed Friar Joannes, then already more than 60 years of age.

On Easter day, 1245, Carpini set out. He was accompanied by Stephen of Bohemia, another friar, who was left behind at Kiev. After seeking counsel of Wenceslaus, king of Bohemia, the friars were joined at Breslau by Benedict the Pole, another Minorite, appointed to act as interpreter. The mission entered the Tatar posts at Kanev. Thereafter the Franciscans crossed the Dnieper, the Don and the Volga. On the Volga stood the *ordu*, or "camp," of Batu, the supreme commander on the western frontiers of the Mongol empire and the conqueror of eastern Europe. Carpini and his companions, with their presents, had to pass between two fires before being presented to Batu at the beginning of April, 1246. Batu ordered them to proceed to the court of the supreme khan in Mongolia; accordingly on Easter day, April 8, 1246, they began the second and more formidable part of their journey. Their bodies were tightly bandaged to enable them to endure the excessive fatigue of their great ride through central Asia. Their route was across the Ural (Yaik) river and north of the Caspian sea and the Aral lake to the Syr-darya (Jaxartes) and the Muslim cities which then stood on its banks; then along the shores of the Dzungarian lakes and thence to the imperial camp of Sira Orda (*i.e.*, the "yellow pavilion") near Karakorum and the Orkhon river. They reached their destination on July 22, after a ride of about 3,000 mi. in just over 106 days.

On arriving at Sira Orda, the Franciscans found that the interregnum which had followed the death of Okkodai, the imperial ruler, had ended. His eldest son, Kuyuk, had been designated to the throne; his formal election in a great *Kurultai*, or "diet of the tribes," was witnessed by the friars along with more than 3,000 envoys and deputies from all parts of the Mongol empire. On Aug. 24 they were present at the formal enthronement at the near-by camp of the "Golden" Ordu and were presented to the supreme khan. They were retained until November and were then dismissed with a letter for the pope; this letter, written in Mongol, Arabic and Latin, was little more than a brief imperious assertion of the khan's role as the scourge of God. The friars suffered greatly on their long winter journey homeward and did not reach Kiev until June 9, 1247; they were welcomed as risen from the dead by the Slavonic Christians. Subsequently they delivered the khan's letter and made their report to the pope who was still at Lyons.

Immediately after his return, Carpini recorded his observations in a large work variously styled in the manuscripts extant—*Historia Mongalorum quas nos Tartaros appellamus* and *Liber Tartarorum*, or *Tatarorum*. He divided his treatise into eight chapters on the country, climate, customs, religion, character, history, policy and tactics and on the best way of opposing them; in a ninth chapter he described the regions traversed. He added four name lists: of the peoples conquered by the Mongols, of those who had successfully to his time (1245–47) remained unconquered, of the Mongol princes and of witnesses to the truth of his *Historia*, including several merchants trading in Kiev. His *Historia* discredited the many fables concerning the Tatars current in western Christendom. Its account of Tatar customs and history is probably the best treatment of the subject by any medieval Christian writer; only on geographical and personal detail is his book inferior to that written a few years later by William of Rubruquis (*q.v.*) or Rubrouck. Carpini's companion,

Benedictus Polonus, also left a brief account of the mission, taken down from his dictation. Not long after his return, Carpini was installed as archbishop of Antivari in Dalmatia and was sent as legate to Louis IX. He died on Aug. 1, 1252.

For a long time the *Historia* was only partially known through an abstract in the great compendium of Vincent of Beauvais (*Speculum Historiale*), made a generation after Carpini's own and first printed in 1473. R. Hakluyt (1598) and P. Bergeron (1634) published portions of the text, but the complete work was not printed until 1839: M. D'Avezac (ed.) in *Recueil de voyages et de mémoires*, vol. iv. Geographical Society of Paris.

CARRACCI, the name of three Italian painters, born at Bologna and blood relations, who possessed markedly individual artistic personalities and were major influences in Italian painting from the end of the 16th century. AGOSTINO CARRACCI (1557–1602), the more cerebral, and his brother ANNIBALE (1560–1609), the truer artist, were at first led by their cousin LODOVICO (1555–1619), a pupil of Prospero Fontana. Mannerist influences at Bologna persisted less in the styles of the two younger men, although Denis Calvaert had his effect on Agostino, and B. Passerotti on Annibale's early genre and portraiture. Tours of northern Italy developed their precocious talents, visits to Venice and to Parma being of particular significance. Agostino was the first to imbibe Venetian art. To Annibale is mainly attributed the rediscovery of Correggio, forgotten outside Parma for a generation. But the mystery of Lodovico's devotional works, and the aristocratic sentiment of his portraits, were unmatched by either cousin. He alone comprehended the tender feeling of the art of Federigo Barocci and mastered the poetry of night. Treatment of landscape in his early works was of importance for Bartolomé Esteban Murillo. His "Martyrdom of S. Angelo" (*c.* 1598) anticipates Francisco de Zurbarán. He became the leading master of the Accademia degli Incamminati, a school which was to include Guido Reni and Domenichino.

Each Carracci evinced his individuality in a monumental painting for an Emilian church. In S. Gerolamo della Certosa, Bologna, Lodovico's "Preaching of the Baptist" (1592) hung opposite Agostino's almost contemporaneous masterpiece, "The Last Communion of St. Jerome," which was to inspire altarpieces both by Domenichino and Rubens. Annibale's "Madonna of St. Matthew" (1588) for S. Prospero, Reggio, glowing with Venetian colour, manifests two persistent characteristics of his genius combined: the noble, classicizing strain in the Correggesque angel seated in the foreground, and the genial and bucolic in the simulated stone enrichment of the Madonna's plinth, a swag of fruits and a harpy. These last, though painted in grisaille, convey those sensations of warmth and colour which radiate from his capital successes, decorations of palace rooms.

In Bologna, the friezes of Palazzo Fava (1584) and Palazzo Magnani (1588–91) were frescoed by the three in concert. In Palazzo Magnani the frieze of Roman history, designed by Annibale, initiates ordered and airy landscape as a principal subject. In heroic landscape Domenichino and Nicolas Poussin were Annibale's heirs. In 1593, with his stupendous proto-baroque "Charity of St. Roch" still unfinished, Annibale was summoned south by Cardinal Odoardo Farnese to decorate his Roman palace. Having decorated the Camerino (study) there, he was joined (1597) by Agostino in his greatest task, the frescoing of the Galleria ceiling (1597–1603/4) with love fables. This was the noblest achievement in the metropolis since Michelangelo's overpowering display in the Sistine chapel. A triumph of classicism tempered with humanity, it became a feeding ground for the baroque imagination of Rubens and Bernini.

Agostino left (1600) to work for Ranuccio Farnese in Parma, where he died. Misinterpretation of Faberio's oration at his funeral occasioned the legend that the Carracci set an eclectic program. Their brilliant renewal of art, however, was made pos-

sible by observation of nature. study and revision of poses from life, and boldness of scale in draftsmanship. Such working methods enabled them to profit by visual knowledge won of past masters by drawing and printmaking. Engraving was not an important activity for Lodovico. But it formed a major part of Agostino's total production. his prints after Tintoretto and Titian being of especial significance. Annibale's "Holy Family" of 1590 and "Jupiter and Antiope" of 1592 were prints evidently appreciated by Rembrandt; and his two engravings on silver. "The Christ of Caprarola" of 1598 and the "Drunken Silenus" (for the Farnese dish) rank among the most beautiful and influential designs of the period. Annibale, ill-requited by Cardinal Farnese, died in Rome after four years of melancholic sickness and intermittent production. Lodovico continued painting until 1619.

See Catalogues of "La Mostra dei Carracci" (1956). (ML. J.)

CARRANZA, BARTOLOMÉ DE (BARTOLOMÉ DE MIRANDA) (1503–1576), Spanish Dominican theologian, archbishop of Toledo, unjustly imprisoned for nearly 11 years by the Spanish Inquisition, was born at Miranda, Navarre. He entered the Dominican order in 1520 and had a brilliant scholastic career. As Charles V's envoy he attended the Council of Trent and preached there. In 1546 Carranza published his *Summa conciliorum* and his *Controversiae quattuor*, an important study of the authority within the church of tradition, scripture, the pope and the councils, forestalling the work of Melchor Cano (*q.v.*). He also held positions of responsibility in the Dominican order. In 1554–57 he was in England, as adviser to Philip II at his marriage to Mary I, and in 1557 Philip named him archbishop of Toledo and primate of Spain; he attended the deathbed of Charles V in 1558. In that year he published his *Comentarios sobre el catechismo christiano* and on suspicion of Lutheranism in that work he was arrested by the Inquisition on Aug. 22, 1559.

The accusations of urging Bible reading for lay persons, writing theology in the vernacular and suspected "illumination" were in line with the fears of the time. Though the Council of Trent in 1563 declared his work sound, Philip and the Inquisition would not yield, mainly (it seems) for reasons of political prestige. Pius V called him to Rome in 1567, but he was not acquitted until April 14, 1576, when he was sent to the Dominican priory of the Minerva. He died there 18 days later, on May 2. Carranza was a man ahead of his time and a pioneer of historical theology. It remains strange that one so esteemed for wisdom and goodness should have been kept so long without redress, especially when the final verdict was for his innocence.

CARRANZA, VENUSTIANO (1859–1920), president of Mexico, was born on Dec. 29, 1859, in Cuatro Ciénegas, Coahuila, the son of a landowner who was active in civil and military affairs. Carranza planned a professional career but was forced by eye trouble to abandon his studies. After 1887 he became active in local and state politics. At various times he served as municipal president, state deputy, state senator, temporary governor, national deputy and national senator. Pres. Porfirio Díaz (*q.v.*) intervened to prevent Carranza's election as governor in 1910, and Carranza therefore joined the Madero revolution (1910–11). After Madero's triumph he became provisional governor of Coahuila. Soon he was elected governor and was in that position in 1913 when Madero was overthrown and assassinated by Gen. Victoriano Huerta's forces. As the duly elected governor, Carranza insisted that he, not Huerta, represented the popular will and he assumed the leadership of a revolutionary movement to overthrow Huerta. His "Constitutionalist" army, including such figures as Pancho (Francisco) Villa (*q.v.*) and Álvaro Obregón (*q.v.*), forced Huerta to flee in July 1914.

Within four months after Huerta's overthrow, a split among the victors brought on a new civil war, with Villa and Emiliano Zapata the most important leaders opposed to Carranza's provisional government. By mid-1915 Obregón's successful campaign against Villa assured a Carranza victory. Carranza was hailed as "First Chief" and continued to act as provisional president. At the

Querétaro constitutional assembly in late 1916, the fundamental difference between Carranza's 19th-century liberalism and Obregón's welfare state philosophy became apparent. Carranza was forced to accept reluctantly some constitutional provisions that were contrary to his philosophy and that he did not seriously try to effectuate when he became constitutional president on May 1, 1917. Aside from domestic disturbances by Villa and Zapata, Carranza's term was characterized by serious financial problems and political unrest brought on by his reluctance to institute far-reaching reforms. He also had serious diplomatic problems with the United States, generally revolving around the protection of American interests. He maintained Mexico's neutrality in World War I.

Carranza's term was due to expire Dec. 1, 1920. The most plausible candidates were generals whose political philosophy differed materially from Carranza's, and he therefore chose a civilian, Ignacio Bonillas, to succeed him. When it became obvious that Carranza intended to force Bonillas' election, Obregón and his friends started a revolution in April 1920. By early May the president, forced to abandon Mexico City, started for Veracruz; hemmed in, defeated and virtually abandoned, he began an arduous horseback trip to the north, but on the night of May 20–21 he was ambushed and killed at Tlaxcalalongo, Puebla, by the forces of Rodolfo Herrera. See also MEXICO: Independent Mexico.

(C. C. CV.)

CARRARA (CARRARESI), a medieval Italian family who ruled first as feudal lords in the countryside of Padua and then as despots in the city. The basis of their power was land, and they first appear (1027) as well-endowed members of the rural gentry. Subsequently they acquired rights of jurisdiction either as counts or as holders of episcopal fiefs. Thus by the 12th century they had built up a considerable dominion, centred on Carrara, a village and castle (*castellum*) near Padua, from which the family took its name. This lordship, however, soon dissolved! partly through family disunion, but mainly because of conflict with the local commune at Carrara and still more with the urban commune of Padua. In the 13th century the castle and jurisdiction of Carrara were ceded to Padua, where the family was obliged to take up residence.

The Carraresi then transferred their ambitions to Padua itself and, by exploiting the feuds of urban politics first as Ghibelline and then as Guelph leaders, were able to found a new and more illustrious dominion. It began with the election of Jacopo da Carrara as perpetual captain general of Padua in 1318 but was not finally established, with Venetian help, until the election of his nephew Marsiglio in 1337. Meanwhile, Padua had been under the nominal rule of imperial vicars (1320–28) and then of the Della Scala. From c. 1348 the Carrara were themselves imperial vicars.

For approximately 50 years the Carraresi ruled with no serious rivals except members of their own family. Marsiglio was succeeded without incident by Ubertino (1338–45), but Marsigliello, who succeeded Ubertino, was deposed and murdered by Jacopo di Niccolò (1345–50). Jacopo was then murdered by Guglielmino and succeeded by his brother Jacopino di Niccolò (1350–55), and Jacopino in turn was dispossessed and imprisoned by his nephew, Francesco il Vecchio (1355–87). The Carrara court was one of the most brilliant of the time. Ubertino in particular was a patron of building and the arts, and Jacopo di Niccolò was a close friend of Petrarch.

The lordship of Padua, however, though it extended to Belluno and Feltre (1361) and to Treviso (1383), was too small and finally too unpopular to survive the cupidity of greater neighbours, especially Venice and the Visconti of Milan. Francesco il Vecchio, reversing the family policy, inclined to the Visconti against the Venetians and formed an alliance (1385) with Gian Galeazzo Visconti against the Della Scala, who were backed by Venice. His policy was ill-conceived: though Verona was taken, the Visconti promptly formed a further alliance with Venice itself and the Este for the conquest of Padua. Francesco had to surrender his dominions (1388) and died a prisoner of the Visconti (1392). Meanwhile his son Francesco Novello, who had also been forced

to surrender because of dissension in the city, had made peace with Venice and in 1390 recaptured Padua. On Gian Galeazzo's death in 1402, Francesco Novello also seized Verona and tried to take Vicenza. The result was war again, with the Venetians. First Verona, then Padua fell (Nov. 1405); Francesco and two of his sons (Francesco and Jacopo) were conveyed to Venice and there put to death in 1406 for conspiracy with Venetian traitors. Francesco's third son, Marsiglio, was killed by the Venetians after an unsuccessful attempt on Padua in 1435.

CARRARA: see MASSA-CARRARA.

CARREL, ALEXIS (1873–1944), French surgeon, biologist and sociologist, who was awarded the Nobel prize in physiology and medicine in 1912 for his work in developing a new method for suturing blood vessels, a method which made it possible to perform blood transfusion safely and laid the groundwork for further studies of transplantation of arteries, veins and organs. He was born at Ste. Foy-lès-Lyon on June 28, 1873, received his medical degree in 1900 and for two years was prosecutor at the University of Lyons. He began there his experimental researches, and continued them in 1905 at The University of Chicago. In 1906 he was appointed to the staff of the Rockefeller Institute for Medical Research in New York, becoming a member in 1912. His work on blood vessels won him the Nobel prize. He also studied the preservation of tissues outside the body and its application to surgery. This work led him to investigate the conditions of tissues when they are living actively outside the organism. Returning to France in World War I, he helped to devise the Carrel-Dakin treatment for wounds, by means of which many lives were saved and countless amputations avoided (see DAKIN'S FLUID). At the same time, with Lecomte du Noüy and other collaborators he studied the laws of the cicatrization of wounds. After 1919 at the Rockefeller institute he developed new techniques for the cultivation of tissues and organs in vitro.

In 1941 he promoted in France the Fondation Française pour l'Étude des Problèmes Humains, where under his management all human problems were studied scientifically with a view to reaching synthetic conclusions of practical application. Carrel died in Paris on Nov. 5, 1944.

Among his publications are: *Man, the Unknown* (1935); *The Making of Civilized Man* (1937); *The Prayer* (1948); *The Culture of Organs* (with C. A. Lindbergh; 1938); *Journey to Lourdes* (1950); *Reflections on Life* (1952).

(JN.-M. C.)

CARREÑO DE MIRANDA, JUAN (1614–1685), Spanish court painter, was born in Avilés, Asturias, on March 25, 1614. He went as a youth to Madrid, where he is said to have been a pupil of Pedro de las Cuevas and Bartolomé Román. A follower of Velázquez, he painted frescoes in the royal palace under his direction, and after his death was appointed painter to the king (1669) and court painter (1671). His many portraits of the queen mother, Mariana of Austria, and the young King Charles II followed the tradition of Velázquez' court portraits. His style and religious compositions were also much influenced by Van Dyck. He died in Madrid in Oct. 1685, leaving several followers.

CARRERA, JOSÉ MIGUEL (1785–1821), leader in the early struggle for the independence of Chile, first president of that country and one of the few Latin-American revolutionary leaders who had visited the United States, was born in Santiago on Oct. 15, 1785. Trained in the Spanish army, fighting against the French invaders, he returned in 1811 to Chile, where his espousal of independence and republicanism won him quick popularity. Supported by his brothers Juan José and Luis, he assumed the leadership of the revolt against Spain; by a *coup d'état* in 1811 he placed himself at the head of the national government and later the same year made himself dictator. He reorganized the national army and the public finances, created the National Institute and inaugurated the first newspaper, but his instability and thirst

for power introduced into the independence movement discordant notes which soon led to internecine strife and permitted the Spaniards to restore royal rule in Chile. Bernardo O'Higgins (*q.v.*) was elevated to the leadership of those forces opposing Carrera and his brothers. In 1813 Carrera was removed from power by the junta in favour of O'Higgins, but early in 1814 he regained control. During the ensuing invasion of Spanish forces from Peru, Carrera and O'Higgins were defeated at Rancagua (Oct. 1814). Carrera fled to the protection of Gen. José San Martín (*q.v.*) in the province of Mendoza, Arg. San Martín sided with O'Higgins, however, and Carrera sought aid against his opponents, first in Buenos Aires and then in 1815 in the United States. On his return to Argentina in 1816 he was not allowed to continue into Chile. This circumstance and the death of his brothers at the hands of the followers of San Martín moved him to lend his military experience to the provincial chiefs in their sporadic revolts against Buenos Aires. He was eventually betrayed by his own men, captured and shot at Mendoza on Sept. 4, 1821. A controversial figure throughout his life, he remains the subject of acrimonious debate among Chilean academicians. (J. J. J.)

CARRERA, RAFAEL (1814–1865), dictator of Guatemala, was born in Guatemala City, Oct. 24, 1814. He had no formal education and remained illiterate all his life, but rose by revolution to become general of the army, protector of the church and president of the republic. With the support of the Indian peasantry and the lower clergy, Carrera overthrew the state government of Guatemala in 1837 and again in 1839. In the latter year he brought about the secession of Guatemala from the United States of Central America, proclaimed it an independent republic and established a dictatorship that lasted for a quarter of a century. In 1854 elections were abolished and Carrera was named president for life.

This regime, which was at once military, theocratic and personal, destroyed liberalism in Guatemala and union in Central America. It helped expel adventurers from Nicaragua led by William Walker (*q.v.*), thwarted two attempts by Mexico to annex Guatemala and set limits to the territorial expansion of neighbouring Belize (British Honduras). The atrocities and reactionary policies of Carrera's government were partially offset by a greater measure of political peace, economic progress and racial equality. He died April 4, 1865. His successor, Gen. Vicente Cerna, whom he appointed, kept the regime intact only until 1871. (M. L. M.)

CARRHAE, BATTLE OF. Carrhae (Harran, now a small village in southern Turkey), in northern Mesopotamia, was the site of the defeat of a Roman army by the Parthians in 53 B.C. War was precipitated by the triumvir M. Licinius Crassus who wanted a military reputation to balance that of his partners, Gnaeus Pompeius and Julius Caesar. With seven legions, but insufficient cavalry, in 54 he invaded Mesopotamia, which in 53 was defended by a Parthian noble of the Suren family (whose personal name is not known). Learning that Surenas was in the desert east of the Euphrates river, Crassus boldly left the cover of the river and struck out toward Carrhae; this move has been condemned by some as rash, yet if Seleucia on the Tigris river was his ultimate objective, he had to cross open country at some time. Suddenly the Parthians were upon him, with a force of 1,000 cataphracts (armoured knights) and 10,000 horse-archers. His troops were neither acclimatized nor adapted to desert warfare. While his son Publius in vain launched a covering attack with his cavalry, the main Roman forces had formed a square against the encircling Parthians, and vainly tried with their shields to cover both body and head against the incessant showers of Parthian arrows; Surenas' brilliant provision of a special corps of 1,000 Arabian camels, one for every ten men, enabled the Parthians to retire by sections and replenish their quivers. After dark Crassus did not risk a counterattack, abandoned 4,000 wounded, and withdrew to Carrhae. Lacking provisions, he was compelled by his demoralized men to negotiate, but was cut down by the Parthians in the attempt. About 10,000 Romans escaped, but the rest of Crassus' 44,000 men were either captured or killed. About 10,000 prisoners were later settled by the Parthians at Merv (*q.v.*) near the Oxus (Amu-Darya) river. At Carrhae the Parthians thus dealt a stun-

ning blow to Roman prestige in the east. The success of the mobile horse-archer, supported by cataphracts, foreshadowed future developments in Roman warfare in the east, while the death of Crassus had most serious repercussions on Roman political life.

See Plutarch, *Life of Crassus*, 20–25; for a theory of possible Roman survivors, H. H. Dubs, *A Roman City in Ancient China* (1957). (H. H. Sp.)

CARRIAGE, a passenger-carrying vehicle usually drawn by horses or other animals.

Origin and Early Development.— While it is not possible to determine the exact period at which wheeled, passenger-carrying vehicles were first used, archaeological evidence shows that a crude form had appeared in Sumer as early as 3500 B.C. By 2500 B.C. chariots were being used for military purposes in the middle east. These vehicles had two solid wheels made up of three or four triangular pieces of wood fitted together and bound by a wooden or leather rim, or felly, which was sometimes studded with copper nails. About 1500 B.C. solid wheels gave way to spoked wheels, which made the vehicles much lighter and faster. (See also **WHEEL**.) The chariot was drawn by two horses, over whose shoulders a wooden yoke, attached to a central pole, was placed.

At about the same time chariots appeared in Persia and Asia Minor, and by 1000 B.C. their use had extended into Egypt. Subsequently, chariots were adopted by the Greeks and the Romans for military and sporting purposes. (See also **CHARIOT**.) Primitive carts also were in use in the middle east and southern Europe by 1500 B.C., and funeral hearses have been found in excavations of the royal tombs at Ur, Kish and Susa. (See also **CART AND WAGON**.) The design of such vehicles remained comparatively crude, and it is doubtful that any important improvements were made until Roman times, when better roads and comparatively stable social conditions made travel less hazardous than it had been. The Romans constructed different types of wagons for carrying plunder, baggage or agricultural goods, as well as special carriages, such as the *pilentum* and the *carpentum*, and horse litters, or *basternae*, for ceremonial occasions. They were also responsible for a number of innovations, including tandem draft and metal horseshoes.

Middle Ages.— During the middle ages horse-drawn vehicles became commoner, but, since the Roman roads fell into disrepair and there was little traveling, development of the carriage was slow. There was some advance in the design of harness, however, including the introduction of the padded horse collar, which for the first time made possible the full use of the animal's tractive power. Concurrent similar developments in the middle east may indicate interchange of ideas between Europe and the east.

At the end of the middle ages the basic design of a carriage or cart consisted of a simple rectangular wooden platform with front and rear axles. In some carriages the axles were joined by a long pole, the perch, which at the back was fitted into the solid rear axle and at the front was inserted into the transom, a beam of wood placed above and parallel to the front axle. The front axle was connected to the transom by a strong metal pin that allowed the axle to swivel freely. The floor of the carriage was built up of wooden planks located between the axles, and the sides were made of wood and leather. A unique surviving example of this crude unsprung carriage, the forerunner of the stagecoach, is the 15th-century carriage of the emperor Frederick III in the Joanneum museum at Graz, Aus.

Development After the 15th Century.— The coach, which originated in Hungary in the 16th century, having evolved from the earlier basic design described above, was introduced into England by the earl of Arundel in 1580. It was an ornate vehicle with a painted and gilded body, a flat roof supported by decorated poles, and sides formed by curtains or leather screens. In later forms the body was suspended on leather straps from a wooden chassis—the first form of suspension system.

In the 17th century the gradual improvement of the roads, together with greater technical knowledge and craftsmanship, contributed to carriage development; for example, plate-glass windows were introduced in 1680. Carriage design became specialized, and general-purpose vehicles were replaced by carriages

designed specifically for short or long journeys or for use in towns. They increased in numbers until by the end of the 11th century the streets of London, Paris and Milan were crowded with vehicles; in 1662 Samuel Pepys estimated that there were at least 2,500 hackney carriages in London. The private carriage became a symbol of prestige.

About the end of the 18th century initiative in design and construction passed from the continent to England, where, during the following century, carriage building reached its zenith. In 1787 John Collinge invented an axle that carried a month's supply of oil; previously, oiling had been an almost daily task. In 1805 Obadiah Elliot patented a method of suspending carriages on elliptical springs, which, when used alone or in conjunction with the older C spring (described below), had a decisive effect on the design of carriages. Later Samuel Hobson reduced the size of carriage wheels and lowered the suspension system. All these improvements made carriages more comfortable, neater in appearance and easier to control.

Types in Use, 17th–19th Centuries.— The corbillard, four-wheeled with a flat bottom and half-open, curtained sides, was a popular carriage in France in the early 17th century. It was succeeded by the sociable, a low-slung carriage of German origin with two facing seats and an opening hood.

The *berlin* originated in Germany about 1660 but was adapted and improved in France. The body had a curved base that hung easily in leather braces suspended from metal strips bent into the shape of the letter C. These C springs absorbed much of the road shock, the berlin thus being one of the first vehicles to have good springs. It was constructed with two perches instead of the single perch formerly used. This made for greater safety, since the perch sometimes broke, and, as the two long poles afforded a certain amount of spring when weighted only in the middle, it also contributed to ease of movement. In appearance, the berlin was well-proportioned. Its four-wheeled, closed body carried four passengers sitting face to face in pairs. There was a box seat for the coachman and, at the rear, a platform where t o

grooms stood; it usually was drawn by four horses. There were numerous variations on the basic berlin design. A berlin with an especially light chassis, built for rapid travel, was known as a *diligence*. With the front seat omitted it was called a *berlin coupé*. The *vis-à-vis* was another type of berlin and carried two passengers sitting face to face.

The generic terms *coach* and *chariot* are applied to many varieties of vehicle. Specifically, during the 17th, 18th and 19th centuries, the coach and the chariot were carriages of similar design, the chariot being somewhat the smaller. The coach had seating accommodations for four people, who sat facing each other in pairs and generally was drawn by four horses. Either one or two pairs were used to draw the chariot, in which either one passenger or two sat on a single seat facing forward.

The *barouche*, *landau* and *landaulet* were large open four-wheeled carriages. The barouche had a folding hood, a high driving seat and was generally used in town. The landau and its smaller version, the landaulet, were distinguished by their hoods, which opened in the middle of the body and folded back to either end. These elegantly appointed vehicles were favourite town carriages in the 17th and 18th centuries.

For private travel over long distances the well-to-do often used the *Briska*, a four-wheeled Austrian carriage with a long body that was designed to give the passengers plenty of room.

The name *phaeton* refers to a family of vehicles, nearly all of which had speed and elegance. Light in construction, with no doors, high seating and large wheels, they were ideal for the gentleman driver. The first patent for a phaeton vehicle was granted in 1788. One of the most important types, the *mail phaeton*, introduced early in the reign of George IV, was the first fashionable two-horse vehicle designed to be driven by its owner. The *stanhope phaeton* was lighter than the mail phaeton; the *American spider phaeton*, like the *tilbury phaeton*, was used for horse-show work.

The *post chaise* originated as a two-wheeled French carriage specially designed for speed and comfort on long journeys. The four-wheeled version was copied and used extensively in England during the 19th century. Early examples were fitted with C springs, elliptical springing being introduced in 1804. An enclosed body accommodated two people comfortably on a single seat facing forward. A view of the surrounding country was obtained through large front and side windows. The post chaise generally was drawn by four horses controlled by two postilions and so had no coach box. Relays of horses were required, since the vehicle was employed in long-distance travel, and these were obtained from "posts" established along the route. The post chaise provided a faster and pleasanter method of public travel than did its contemporary the stagecoach; average speeds of up to ten miles per hour could be maintained. "If I had no duties and no reference to posterity," said Dr. Johnson, "I would spend my life in a post-chaise driving briskly with a pretty woman."

The *charabanc* originally was a four-wheeled vehicle, driven by its owner and used to carry guests to hunting expeditions and on excursions to the races. Early models had a high coach box and up to four rows of seats facing forward. In England it was pulled by two horses, though in France, where it originated, up to six horses

were used over rough country. Later the charabanc was modified for public transport. It was entered from the rear and had five or more rows of seats facing forward.

Two of the most important carriages introduced during the 19th century were the *brougham* and *victoria phaeton*. The former, first built for Lord Brougham, to his own design, in 1838, later became the most widely used town carriage. It had a rather heavy body suspended on Elliot elliptical springs and reached by a single step. The passenger seat, completely enclosed, faced forward. The brougham, the first four-wheeled vehicle meant to be drawn by one horse, was both safe and economical. When two horses were used, the coachman generally was accompanied by a groom.

The *victoria*, whose great popularity was attributable partly to the fact that it was Queen Victoria's favourite carriage, was a low, comparatively light, four-wheeled vehicle with a single forward-facing seat that could be covered with a large hood. Driven by a coachman from a high seat over the front axle, it was drawn by one or two horses. The most elegant victorias were finished in black with no ornamentation. Some types are still in use in Europe as horse-drawn cabs. The victoria was sometimes known under the slang name of *growler*, which was also applied to the brougham.

Two-Wheeled Vehicles.—The *gig* first appeared in Paris in the 17th century, and the basic design of this simple vehicle has been little modified. The first gigs had light, shell-like bodies attached to two long, curved shafts, and were drawn by one horse. Because of their high centre of gravity, they overturned easily; their popularity was attributed to the fact that they were light, fast and comparatively cheap. They were the forerunners of the *cabriolet* in France, the *whisky* or *chaise*, the *tilbury* and *stanhope gig* and the *dogcart* in England, and the *shay* in America. A gig drawn by two horses was called a *curricle*. The dogcart was originally a small one-horse carriage designed for shooting parties, with seats built high over lockers large enough to hold the gun dogs. It was found to be so safe and comfortable that its original purpose was forgotten; it was built in a great many different styles and frequently was used by women and children. The *stanhope gig*, carrying only two people and drawn by one horse, had a simple semicircular wooden seat, not unlike a rib chair, that hung on four springs; the *tilbury* was very similar. The *cabriolet*, a luxury carriage with, in some cases, a small rear platform for a groom to stand on, was introduced into England about 1815 and later modified in design and used for hire (*see below*).

Public Transport.—Carriages for hire, known as *hackney carriages*, first appeared in London in 1605 and grew so numerous that in 1634 their numbers were limited by act of parliament. All types of carriages were used. Later, *sedans* and *brouettes* (a sedan on wheels drawn by a man) were serious rivals, but these fell from favour in the beginning of the 18th century.

In the early 19th century a modified form of the *cabriolet* was introduced. This was a curious-looking vehicle in which the driver sat beside the passengers, who were shrouded in a hood that protected them from the weather and safeguarded their privacy. Although it was more unstable than the four-wheeled hackney, it was much faster and also more economical, since it was drawn by a single horse. The *cabriolet* was soon superseded by the hansom cab, but the popular form of its name, "cab," remained, being

used by extension to denote all forms of horse-drawn and motor vehicles plying for hire.

The two-wheeled, one-horse *hansom cab*, designed in 1834 by Joseph Aloysius Hansom, was an enclosed cab with a single forward-facing seat and a coach box perched high at the rear. Communication between the "cabby" and his fare took place through a small trap door in the roof. The entrance was close to the ground and the doors could be operated by the driver from his lofty seat. The hansom was particularly stable and easy to maneuver and was used widely in the latter half of the 19th century.

The *omnibus*, not unlike the charabanc in design, was first introduced into London in 1829. It was at first an enormous four-wheeled vehicle drawn by three horses abreast, this later being superseded by a narrower vehicle drawn by a pair of horses and carrying 14 passengers. In 1847 a seat was added along the centre of the roof. By the latter half of the 19th century the omnibus was a tolerably efficient form of transport, carrying 28 people at up to eight miles per hour.

Public transport outside the towns remained in a rather primitive condition until the 19th century. The *stagecoach*, which was introduced into England in 1640, replacing the older stage wagon, was a large, cumbersome vehicle, very heavy and usually unsprung. It had seats for six or eight passengers inside; second-class passengers sat in a large basket at the back and third-class traveled on the roof, clinging to a rail. The vehicle usually was vastly overcrowded and notoriously subject to difficulties and delays. Four or six horses were used and were changed at stages as much as 20 mi. apart; and average speed often was no more than four miles per hour. Various innovations were attempted, but there was little progress until the roads began to be improved in the early 19th century.

In 1784 the *mail coach* system, devised by John Palmer, was introduced. A four-horse diligence was used, driven by an armed coachman, accompanied by a guard, and drawn by four horses that were changed every six or eight miles and averaged eight miles per hour. The mails thus provided a quicker and safer method of travel than did the stagecoaches, which they gradually superseded. At first they carried only four passengers, but later accommodation was made for passengers in the boot and on the roof. Mail coaches were painted red, with the royal arms and the destination of the coach painted on the door panel.

The success and influence of the mail coach in Great Britain can be gauged by the fact that though only 80 new coaches were introduced in 1797 there were no fewer than 700 in general use throughout the country by 1835. After they were displaced by the railways, beginning in the 1840s, coaching was to some extent carried on as a sport by amateurs, especially in southern England and on the famous London-Brighton run. The end of the 19th century saw the foundation of the four-in-hand clubs that have carried on the art of coaching. (See also **DRIVING AND COACHING**.)

The *jaunting* car, first built in Dublin at the beginning of the 19th century, remained a purely Irish vehicle. Two-wheeled and open, it was drawn by a single horse. The passengers, usually four or six, sat sideways and back to back on a long seat that ran down the centre of the car. It was sometimes used also as a private carriage.

State Carriages.—Although carriage builders of the 17th, 18th and 19th centuries were concerned chiefly with producing lighter and more practical vehicles, carriages of great size and richness continued to be built for royalty and for the aristocracy. The influence of the early Hungarian and German state carriages spread to Italy, France, Spain and England, and state carriages of great magnificence were built, gilded, richly painted and ornamented. They are still sometimes used on state occasions. The English monarch's state coach, built in 1760-62 for King George III and painted by G. B. Cipriani, cost nearly £8,000. Its official description is as follows:

The whole of the carriage and body is richly ornamented with laurel and carved work, beautifully gilt. The length, 24 ft.; width, 8 ft. 3 in.; height, 12 ft.; length of pole, 12 ft. 4 in.; weight, 4 tons. The carriage and body of the coach is composed as follows:—Of four large tritons, who support the body by four braces, covered with red morocco leather, and ornamented with gilt buckles, the two figures placed in front of the carriage bear the driver, and are represented in the action of drawing by cables extending round their shoulders, and the cranes and sounding shells to announce the approach of the monarch of the ocean; and those at the back carry the imperial fasces, topped with tridents. The driver's foot-board is a large scallop shell, ornamented with bunches of reeds and other marine plants. The pole represents a bundle of lances; the splinter bar is composed of a rich moulding, issuing from beneath a voluted shell, and each end terminating in the head of a dolphin; and the wheels are imitated from those of the ancient triumphal chariot. The body of the coach is composed of eight palm-trees, which, branching out at the top, sustain the roof; and four angular trees arc loaded with trophies allusive to the victories obtained by Great Britain during the late glorious war, supported by four lions' heads. On the centre of the roof stand three bogs, representing the genii of England, Scotland and Ireland, sup-

porting the imperial crown of Great Britain, and holding in their hands the sceptre, sword of state, and ensigns of knighthood; their bodies are adorned with festoons of laurel, which fall from thence towards the four corners. The panels and doors are painted with appropriate emblematical devices; and the linings are of scarlet velvet richly embossed with national emblems.

The coach of the lord mayor of London, built a few years earlier, is only a little less resplendent.

United States.—Horses were introduced into America by the Spaniards, who also imported the first carriages. By 1660 carriages had arrived independently in New England, where the most widely used vehicle was the two-wheeled cabriolet; Italian *curricles*, also two-wheeled and driven by horses harnessed in tandem, became popular.

Public transport was provided by the *stage wagon*, a carriage with a long high body, large rear and smaller front wheels and drawn by four or six horses. It carried from 4 to 12 persons, who sat on wooden benches. The front was open and the sides were no more than a frame for leather curtains that were rolled up when the weather was suitable. All the passengers had to scramble over the driver's seat, and the wagons had a reputation, at any rate among European travelers, for being awkward and uncomfortable. By the end of the 18th century long-distance travel in the United States was developing along the same lines as that in Europe, and there were regular coaches between Boston, New York and Philadelphia. In 1792 a weekly mail route was established from the Washington district to the Maro district in Tennessee.

In the 19th century private carriages in the United States developed along lighter and racier lines than their European counterparts. The cabriolet was quickly modified; the *one-horse shay* (the word is a corruption of "chaise") appeared and then the light two-wheeled *dogcart*, the *rumabout* and the *buggy*, all designed to be pulled by one horse. The American buggy originated in India from a kind of one-horse gig with a hood to protect the traveler from the sun. In the United States it became a four-wheeled carriage with one seat fixed on a long shallow tray; its phenomenal popularity was rivaled only by that of the *wagon*, which was similar in construction but had two or more seats. Buggies were light, comparatively inexpensive and traveled easily over rough roads. They were so commonly used that in 1910 Ralph Strauss wrote, "the tourist in America will come away with the impression that there is hardly a family on the continent that does not possess at least one buggy or wagon." There were many local variations: of structure, as in the *bike wagon* of the middle west; and in name, as in Massachusetts, where a two-seater wagon was known as a *bargee*. Other favourite vehicles were the four-wheeled *surrey*, whose seats were arranged like those in a wagon except that they were not on a tray, and the four-wheeled *station wagon*, a covered carriage that carried two passengers and a footman and was famed for its comfort.

In 1822 a New York coach-maker named Miln Parker began building *volantes* for the Cuban and Mexican markets. These vehicles were a type of gig, the body being perched upon two very high wheels. The great demand for these light carriages made the carriage-building industry of the United States the largest in the world. In 1810 there were 28 factories engaged in coachbuilding in New York alone, and later in the century carriages were exported to South America, Australia and other countries.

Vehicles Using Manpower.—The *litter* was a bed or couch mounted on poles. In Greece or Rome it was carried by slaves but during the middle ages it was

adapted so that it could be harnessed to horses, for use by invalids and ladies of noble birth. In the 16th century the horse litter was gradually replaced by the coach. Litters borne by men were forerunners of the *sedan chair*.

At the end of the 15th century the sedan chair consisted simply of a chair with metal clasps for poles at either side. By 1700 the chair was mounted on a platform, covered by a leather roof and enclosed with curtains of velvet, damask or canvas. As the construction became more substantial, privately owned chairs became richly ornamented with baroque moldings and gilt and were often painted by prominent artists. Sedan chairs for hire remained modest in appearance but were so popular in London and Paris that for a time they were a serious rival to hackney carriages. Sedans began to go out of fashion in the early 19th century.

The *ricksha* is a light two-wheeled carriage that has two shafts, seats two passengers and is drawn by a man. Until the 1950s it was commonly used in the far east and in some cities in south-eastern Africa. In the 18th century it appeared in Europe as the *brouette*, which, like the sedan chair, enjoyed a brief vogue as a hired vehicle.

Collections.—The principal collections of carriages are at the Suffolk Museum and Carriage House, Stony Brook, Long Island; the Science Museum, London; the Musée de la Voiture au Château de Compiègne, near Paris; the Museu Nacional dos Coches, Lisbon; the Schonbrunn palace, Vienna; and the Schloss museum, Berlin.

CARRICKFERGUS, a seaport and borough of County Antrim, N. Ire., on the northern shore of Belfast lough, 9½ mi. N.E. of Belfast. Pop. (1961) 10,187. The name, meaning "rock of Fergus," commemorates King Fergus who was shipwrecked off the coast c. 320 A.D. Because of the strategic position of Carrickfergus castle, the town played a large part in the history of Ireland. The castle, in a perfect state of preservation, is of outstanding archaeological interest as a notable relic of the Norman period. The parish church of St. Nicholas was built by John de Courci at the end of the 12th century and is renowned for the C'chester monument (1625) in the north transept. The castle was besieged and taken by Edward Bruce in 1315. Under Charles I many Scottish Covenanters settled there to avoid persecution. In the Civil Wars, from 1641, Carrickfergus was one of the chief places of refuge for the protestants of Antrim, and in 1642 the first presbytery held in Ireland met there. It was later held by partisans of James II, but it surrendered in 1689 to the duke of Schomberg and in 1690 William III landed there on his expedition to Ireland. In 1760 the castle was taken by a French squadron under François Thurot and held for seven days. John Paul Jones entered Belfast lough in the "Ranger" in 1778 and defeated the English naval vessel "Drake." Elizabeth I gave the town a charter, which was confirmed by later monarchs. The corporation, however, was superseded in 1840 by a board of municipal commissioners. Carrickfergus was a parliamentary borough until 1885, a county of a town until 1898 and the county town of Antrim until 1850. Borough status was regained in 1949, and after World War II the population doubled. Local industry consists of a large viscose rayon factory, flax spinning mills, bleach works, printing and dye works, wrought-iron works and sheet-metal works. Rock salt, found in Triassic sandstone, is worked in the form of brine.

CARRICKMACROSS (CARRAIG M'ACHAIRE ROIS), a market town in County Monaghan, Republic of Ireland, 57 mi. N.N.W. of Dublin by road. Pop. (1956) 2,001. There are remains of an Elizabethan castle, destroyed in 1641. Carrickmacross is an agricultural centre and produces industrial alcohol from potatoes. Carrickmacross lace made the town famous and is still produced to a small extent, notably at the convent of St. Louis.

CARRICK-ON-SHANNON (CARA DROMA RÚISG), a market town and the county town of Leitrim, Republic of Ireland, is 101 mi. N.W. of Dublin by road. Pop. (1956) 1,530. It is situated

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART, GIFT OF J. PIERPONT MORGAN, 1922
FIG 5—ITALIAN SEDAN CHAIR, ABOUT 1730

on the upper Shannon near Loughs Gara, Key, Allen and Bofin, the area being a fishing centre. It is an assize town and has some river trade. Part of the town, in Killukin parish, is in County Roscommon.

CARRICK-ON-SUIR (CARRAIG NA SIÚIRE), a town on the banks of the Suir, lies 98 mi. S.W. of Dublin in County Tipperary, Republic of Ireland. Pop. (1961) 4,667. A town of Danish origin beside the wooded foothills of the Comeraghs, it has two bridges spanning the Suir connecting with its southern suburb Carrickbeg in County Waterford. Carrickbeg has narrow, hilly streets and a parish church believed to be the only 14th-century church still used in Ireland.

Ormonde castle, seat of the Butlers, begun in 1309, was fully restored after 1960. Margaret, daughter of the 7th earl of Ormonde, married Sir William Boleyn of Blickling and her granddaughter, Anne Boleyn, is said to have been born in the castle. (See BUTLER.)

In the 19th century Carrick-on-Suir was a flourishing industrial town, manufacturing furniture, boots, cotton and woolen goods. The American Civil War and the industrial revolution spelled doom for these industries. The population dropped from about 11,000 to 5,000 at the beginning of the 20th century. The chief industries are now tanning and leather manufacture; more than half the finished products are exported. (S. B. C.)

CARRIER, JEAN BAPTISTE (1756-1794), French Revolutionary terrorist, notorious for his atrocities against counter-revolutionaries at Nantes, was born at Yolet, in Haute Auvergne, on March 16, 1756. In 1792 he was chosen to represent Cantal in the Convention. He was already known as one of the influential members of the Cordeliers club and of that of the Jacobins. In March 1793 he took part in establishing the Revolutionary tribunal. After a mission into Normandy in July, Carrier was sent into Brittany in August. There he received orders to secure Nantes against the insurgents of the Vendée. Arriving on Oct. 7, he established a tribunal and formed a body of desperate men, the *Compagnie Marat*, to destroy in the swiftest way the crowds of prisoners in the jails. The formality of trial was soon discontinued, and the victims were sent to the guillotine or shot or cut down in the prisons en masse. He also had large numbers of prisoners put on board vessels with trap doors for bottoms, which were then sunk in the Loire. These *noyades* of Nantes made Carrier notorious, and he was recalled by the committee of public safety on Feb. 8, 1794. He took part in the Thermidorian attack on Robespierre, but was himself brought before the Revolutionary tribunal in November and guillotined on Dec. 16, 1794.

H. Carrier (ed.), *Correspondence of Jean-Baptiste Carrier . . . During His Mission in Brittany, 1793-1794* (1920).

CARRIER, a transporter of passengers or goods for compensation or without charge, by water: land or air. Carriers are commonly divided into three groups: those that transport passengers only, those that transport goods only and those that transport both. Carriers of goods are subdivided into common carriers and contract carriers. Common carriers of passengers and of goods are those which "hold themselves out" to serve all.

Common carriers of passengers, whether by boat, rail, motor vehicle or air, are regulated with respect to equipment, routes, schedules and fares. They are bound to serve all who would be patrons without discrimination, to protect passengers from improprieties of others and to avoid negligently injuring them. Such carriers are, except as modified by statutes, insurers of passengers' baggage against loss or damage.

While taxicab operators are common carriers, they are generally regulated as to equipment and charges but not as to routes. They must obtain permission to operate on the public streets, in the form of "certificates" or "franchises."

Common carriers of goods are also generally required to operate on fixed routes and schedules. Their charges are regulated, but they are entitled to charge rates sufficiently high to provide a fair return upon the value of the property with which they serve the public. No person may undertake such service in the United States

without first obtaining a "certificate of convenience and necessity" from the commerce or public utilities commission of the state or states in which operations are to be carried on. If interstate business is done, it is subject to regulation by the Interstate Commerce commission.

The contract carrier of goods by truck is not restricted to serving on fixed routes and at regulated rates. Generally speaking, it is free to contract such times, routes and charges for transportation as may be acceptable to shippers. However, in some locations contract carriers are restricted as to rates, routes and schedules, and they may be excluded from certain termini for the purpose of protecting common carriers of goods from competition when that is essential to the public welfare.

At common law the common carrier of goods was bound to serve for a "reasonable reward" and to carry all goods for which he had space. He was an insurer of goods entrusted to him, but was not liable if they were lost by act of God or the king's enemies or by reason of an inherent defect of the goods. The English Common Carriers' act relieved such carriers of liability for the loss of goods above a specified value unless their full value was disclosed and unless an added charge based on such value was paid. This specified value to which liability was limited has been several times increased. Similar rules apply with respect to some commodities in the United States under state and federal statutes and regulations.

Transportation by air is regulated in the United States under the Civil Aeronautics act and in Great Britain under the Carriage by Air act. Similar legislation is common throughout the world.

See also PUBLIC UTILITIES; INTERSTATE COMMERCE; for carriage of goods by sea, see AEFREIGHTMENT. (C. M. U.)

CARRIER. Many persons who recover from apparent or inapparent infections continue to harbour the causative microbes in their bodies after they have recovered from the disease. Such persons are termed carriers. Though the carrier has become immune to the harmful effects of the germs, the latter are capable of producing disease in other human beings to whom they may be transferred. Although this article is concerned only with human carriers of disease germs, it should be pointed out that many diseases are transmitted by animal or insect carriers. These infections include typhus fever, yellow fever, tularemia, brucellosis (undulant fever) and others. The first direct evidence of the existence of carriers was provided in 1893 by W. P. Dunbar, working with Robert Koch, who during a cholera epidemic in Hamburg showed that not only did convalescent patients harbour cholera bacilli but persons who had not been ill also excreted the germs in their feces. The habitat of microbes associated with the carrier state may be the alimentary tract, the respiratory tract or, as in malaria and homologous serum hepatitis, the blood.

It has been believed that some carriers may be capable of transmitting infection to others even though they have not been infected themselves. Studies carried out in the second quarter of the 20th century indicated, however, that ostensibly symptomless carriers who are able to transmit infection have probably had biological contact with the microbe concerned and have suffered an inapparent infection that led to the carrier state.

Not all carriers are equally capable of disseminating infection. For example, new cases are more likely to occur from contact with nasal carriers of hemolytic streptococci or staphylococci than from contact with throat carriers. The personal habits of a carrier undoubtedly play a role in determining whether or not the germs he harbours will be transferred to another human being. Unprotected coughs and sneezes are potential hazards. Also, since microbes carried in the nose, throat or intestines are often present on the hands in large numbers, careless use of the hands tends to propagate disease. Thus, cooks and food handlers are in a position to disseminate infectious diseases. Concurrent epidemics of scarlet fever and streptococcal sore throat caused by bacteria dispersed from the nose, and epidemics of typhoid fever spread by bacteria harboured in the small intestine or gall bladder, have been traced to common, single sources among cooks and food handlers.

The following diseases are known to be spread by human carriers: pneumonia, scarlet fever, streptococcal sore throat, epi-

demic meningitis, diphtheria, impetigo, typhoid fever, dysentery, cholera, whooping cough, gonorrhoea, syphilis, a form of jaundice called homologous serum hepatitis or infectious hepatitis, poliomyelitis, amebic dysentery and, in part, malaria. Other diseases, particularly some of the virus infections, may later prove to be transmitted by human carriers.

Formerly, isolation was the only practical means of dealing with carriers. After the discovery of antibiotics, however, the body could be rid entirely of the causative microbes of some diseases by drug treatment. In certain infections, discussed below, enough was known about various aspects of the carrier state in the early 1960s to warrant special comment.

Typhoid and Paratyphoid Carriers.—The germs are harboured in the small intestine or the gall bladder and discharged in the stools; a few carriers are chronic and may harbour the microorganisms for years or even a lifetime. Typhoid and paratyphoid fever are spread by the direct contamination of food or water supply with the specific germ.

One famous carrier in New York city, who became known as "Typhoid Mary," worked as a cook under various assumed names, moving from household to household and from institution to institution. She was finally apprehended and detained until her death 23 years later, 31 years after she was first recognized as a carrier.

Antibiotics proved disappointing in the treatment of typhoid carriers. The growth and dissemination of the germs in a carrier is often inhibited by chloramphenicol as long as this drug is given, but since the drug does not eliminate the germs from the intestine or the gall bladder they grow again when treatment is discontinued. In the course of time most carriers undergo spontaneous cure.

Dysentery.—In bacillary dysentery bacteria persist in the lower part of the intestines. They are excreted intermittently as a rule. Treatment of these carriers was unsatisfactory in the early 1960s, though success was sometimes claimed following the use of sulfonamide drugs or oxytetracycline.

In amebic dysentery carriers, the parasites that live in the large intestine pass into a resistant resting state during which they are encysted. These cysts do not multiply but remain quiescent until they are carried by food or water into the intestinal canal of another person, when the actively growing state is resumed with a resultant attack of dysentery. Many but not all carriers can be cured by drug treatment.

Cholera.—The cholera germ persists in the upper part of the intestines and the condition is similar to that in the typhoid carrier. The germs are excreted from the bowels only.

Diphtheria.—In this disease the germs are present in the throat and nose, and infection is spread directly from one person to another, either by coughing, sneezing, etc., or by contamination of drinking vessels. The carrier state is usually not so persistent in diphtheria as in typhoid fever. Young children are more likely to become carriers than adults. In the throat the germs are found in the tonsils, while in the nose they are associated with a chronic inflammatory condition.

Many persons harbour harmless bacteria that closely resemble diphtheria bacilli. Therefore, when diphtheria bacilli are found in the nose or throat of a supposed carrier, it is necessary to test them in the laboratory to prove that they are capable of causing disease.

Most diphtheria carriers can be successfully treated with penicillin.

Epidemic Meningitis.—The meningococci, the germs that cause this disease, are carried in the back of the throat. Surveys showed that many ostensibly normal persons are carriers of meningococci. During epidemics the carrier rate may rise to as high as 90%. Though it was believed in the early 1960s that coughing and sneezing were the chief modes of spread, this had never been directly authenticated. Epidemics are likely to occur where people are crowded together, as in boarding schools and military barracks.

A great advance in the control of meningococcus carriers was made during World War II when it was discovered that the carrier state could be eliminated by a few days' treatment with sulfadiazine.

Streptococcal Infections.—Hemolytic streptococci, the bac-

teria that cause scarlet fever and most cases of tonsillitis, are harboured in the noses and throats of sick and convalescent patients and of persons who have suffered inapparent infections. The bacteria are present in large numbers in the nasal discharges of about a third of the carriers and are found on the hands, on the clothing and in the environment of such persons. Despite much research carried on during World War II and thereafter, the precise pathway that streptococci take from the nose of the carrier to the throat of the susceptible person was not elucidated.

Penicillin in proper dosage effectively eliminates the streptococcal carrier state. It was found during epidemics in military installations that penicillin given for a few weeks to all personnel would control the vast majority of carriers and stop an epidemic.

Pneumonia.—The pneumococci, the germs that cause most cases of pneumonia, are carried in the throats of convalescent patients and in many normal throats. It was generally believed that the pneumococci were transferred from the carrier to the patient by coughing. It is not ordinarily practical to look for pneumococcus carriers, but when they are discovered they can usually be successfully treated by penicillin.

Poliomyelitis.—Research during the 1940s and 1950s demonstrated that poliomyelitis virus is excreted in the stool. The carrier may be a person with the active disease or someone who has contracted an inapparent infection but continues to shed virus in the feces. The amount of virus excreted in the feces varies considerably from one carrier to another. There was no effective drug treatment for poliomyelitis carriers in the early 1960s.

Malaria.—Where malaria is endemic many persons harbour the malarial parasites in their bodies for months or years, particularly inside the red blood corpuscles. In other human infections spread by insects, the insect must bite the patient during the active stage of his disease in order to transmit the infection to another human being. Malaria can be transmitted via the appropriate mosquito vector, or by direct transfusion of the carrier's blood into a human donor. The mosquito that bites the carrier transfers the malarial parasites, in a changed form, to another person via the bite. The human malarial carrier can be rid of his parasites by a few days' treatment with the drug chloroquine.

CARRIERA, ROSALBA (1675-1757), Italian painter, owes her fame to the art of pastels which she made stylish. She was born in Venice, Oct. 7, 1675, and died there April 15, 1757. She became first known for her miniature portraits on snuffboxes. Sovereigns and important personages going through Venice frequently had her paint their portraits. Augustus II the Strong, king of Poland, bought from her no less than 40 pastels for his Dresden collection. The great collector and financier Pierre Crozat, during a trip to Venice, encouraged her to go to Paris. She did so in March 1720, accompanied by her family, became the idol of the French capital and painted 36 portraits, among them one of Louis XV as a child. She became a member of the Royal academy in 1720 and the next year, returned to Venice. When she went to Vienna in 1730, the empress became her protectress and pupil. After 1750 her sight failed. Her art flattered

the refined and affected taste of her time

CARRIÈRE, EUGÈNE (1849–1906), French painter and lithographer, known for his scenes of domestic intimacy, was born at Gournay, Seine-Maritime, on Jan. 17, 1849, of Flemish-Alsatian parentage. He lived first at Strashourg, moving to St. Quentin in 1868. The pastels of Maurice Quentin de La Tour aroused his interest, and in 1870 he entered the Paris École des Beaux-Arts. Taken prisoner in the 1870 war with Germany, his enforced stay at Dresden enabled him to see the gallery there. Returning to Paris, he studied under Alexandre Cabanel (1872–76). After 1877, his wife recurs frequently as the model in his family groups and pictures of maternity. At first influenced by the colour of Rubens and Velázquez, by 1890 his art developed a distinctive character; figures appear shrouded in a pearly mist, sharp chiaroscuro is replaced by delicate predominantly gray tonalities and soft modeling. Among the distinguished literary and artistic personalities whom he painted were his friends Alphonse Daudet, Anatole France and Paul Verlaine (1891; acquired Luxembourg 1910). Carrière taught, and practised sculpture and lithography.

Carrière died in Paris on March 27, 1906. Retrospective exhibitions were held in Paris at the Galerie "Art Nouveau" (1892) and at the Galerie Bernheim (1903).

See G. Seailles, *E. Carrière, Essai de biographie psychologique* (1910); *Mercure de France* (1909—letters and writings); E. Fauré, *E. Carrière, peintre et lithographe* (1908). (D. L. Fr.)

CARRILLO DE SOTOMAYOR, LUIS (1583–1610), Spanish poet, was born at Córdoba, of a noble family. As a naval officer he served in the Mediterranean against the corsairs. His verse shows some of the stylistic complexities and imagery associated with Gongorism (so-called after Luis de Gongora; *q.v.*) and he wrote a treatise, on poetic learning, *Libro de la erudición poética* (mod. ed., 1946), to justify his methods. Much of his poetry has, however, real rather than historical value: sonnets, *canciones*, fine *romances* describing action at sea and an ambitious *Fábula de Acis y Galatea*. His work was published by his brother Alonso (1611).

See the modern edition by Dámaso Alonso (1935). (C. C. SH.)

CARRINGTON, RICHARD CHRISTOPHER (1826–18; j), English astronomer, who investigated the motions of sun-spots, by which he determined the elements of the sun's rotation and made the important discovery of a systematic drift of the photosphere, causing the rotation periods of spots to lengthen with increase of solar latitude. The son of a brewer at Brentford, he was born in Chelsea, London, on May 26, 1826, and educated at Trinity college, Cambridge. He was astronomical observer in the University of Durham (1849–52), and in 1853 established an observatory of his own at Redhill. There he devoted three years to a survey of the zone of the heavens within 9° of the north pole, the results of which are contained in his *Catalogue of 3,735 Circumpolar Stars*.

Carrington died on Nov. 27, 1875.

CARROCCIO, the war chariot of the medieval republics of Italy. A rectangular platform on wheels, drawn by oxen, it carried the city's standard, trumpeters and also an altar, at which priests held services before battle. Its loss in battle was regarded as an irretrievable humiliation. The earliest recorded instance of its use is by the Milanese in 1038. The Florentine *carroccio* was usually followed by a smaller vehicle bearing the *martinella*, a bell to ring out military signals. In peacetime the *carroccio* was in the keeping of some great family distinguished for its services to the state.

CARROLL, ANNA ELLA (1815–1894), a member of a Protestant branch of the distinguished Carroll family of Maryland, was born on Aug. 29, 1815, at Kingston Hall, Somerset county, Md. She has been called a "military genius" and a "great unrecognized member of Lincoln's cabinet." The first appellation is based upon her plan of strategy for the Tennessee campaign of 1862, which was in fact the plan followed by Gen. U. S. Grant, and the second

upon her valuable services as a pamphleteer on behalf of the policies of Abraham Lincoln as war president. Prior to her service on behalf of President Lincoln, she had become interested in politics and was influential in the American party. It has been well said that Anna Carroll, who died in Washington, D.C., on Feb. 18, 1894, was one of the most influential American women of her time.

See Hollister Noble, *Woman With a Sword* (1948). (E. E. R.)

CARROLL, CHARLES (1737–1832), U.S. political leader and signer of the Declaration of Independence, was born at Annapolis, Md., Sept. 19, 1737. He was educated in French Jesuit colleges, studied law at Bourges, Paris and London, and in Feb. 1765 returned to Maryland. There he took possession of an estate called Carrollton in Frederick county (hence his signature "Charles Carroll of Carrollton," to differentiate himself from relatives also named Charles), but he lived at Doughoregan Manor just west of Baltimore. Before and during the American Revolution he was a patriot leader, serving on committees of correspondence, committees of observation, the committee of safety and the provincial convention (1774–76). From 1776 to 1779 he sat in the continental congress, rendering important services as a member of the board of war, and signing on Aug. 2, 1776, the Declaration of Independence. In 1776, with Samuel Chase, Benjamin Franklin and his cousin the Rev. John Carroll, he was sent by the continental congress to Canada in a fruitless effort to persuade the Canadians to join the cause of the 13 colonies. From 1777 until 1800 he was a member of the Maryland senate, and from 1789 to 1792 a member of the U.S. senate. After the formation of parties he was a staunch Federalist. After 1801 he lived in retirement, his last public act being the formal ceremony of starting the construction of the Baltimore and Ohio railroad (July 4, 1828). He died at Baltimore, Nov. 14, 1832, the last surviving signer of the Declaration of Independence. He exercised powerful influence, particularly among his Roman Catholic coreligionists, and he used it to secure the independence of the colonies and to establish a stable central government.

(W. D. Ho.)

CARROLL, JOHN (1735–1813), American Roman Catholic prelate, first Catholic bishop in the United States, was born at Upper Marlborough, Md., Jan. 8, 1735. He was educated in Flanders and ordained priest in 1769, becoming professor of philosophy and theology at the Jesuit colleges in Liège and Bruges, Belg. After his profession in the Society of Jesus in 1771 he toured Europe for two years as tutor to an English nobleman. The suppression of the Jesuits by the papal brief of July 21, 1773, forced his flight to England whence he returned to Maryland in the spring of 1774. In 1776, at the request of the Continental Congress, he accompanied Benjamin Franklin, Charles Carroll and Samuel Chase on a mission to secure the aid or neutrality of Canada during the Revolution. Thereafter he served St. John's chapel, Forest Glen, Md., and organized the Select Body of Clergy. When the American church became a distinct body Carroll was made the superior of the mission on June 5, 1784, to Franklin's gratification. In 1786 he induced the select body to authorize a Catholic academy (now Georgetown university); on Sept. 14, 1789, he was made bishop. Consecrated at Lulworth castle, England, Aug. 15, 1790, he held his first synod in Baltimore in Nov. 1791. In the same year he founded the Sulpician seminary in Baltimore, and in 1796 he helped found the Baltimore Library company, serving as its president until 1815. With George Washington's aid Bishop Carroll secured federal funds for Catholic missionaries to the Indians of the west. In 1804 he received jurisdiction over the Danish West Indies and the next year became administrator of the diocese of New Orleans. With the erection of four new sees in 1808 (Boston, New York, Philadelphia and Bardstown, Ky.) Carroll became archbishop, receiving the pallium on Aug. 18, 1811. Together with Benjamin Latrobe he planned the Baltimore cathedral, whose cornerstone he laid on July 7, 1806. A staunch patriot, he initiated the public Prayer for the Civil Authorities of Our Country; he tirelessly defended religious liberty from the pulpit and in the press. He died in Baltimore, Dec. 3, 1815.

CARROLL, LEWIS: see DODGSON, CHARLES LUTWIDGE.

CARROT (*Daucus carota*), an herbaceous, generally biennial plant of the family Umbelliferae (*q.v.*) that produces an edible taproot. Most of the edible carrot consists of much enlarged taproot; the uppermost part is enlarged hypocotyl, tissue that developed from that part of the plant stem below the seed leaves of the seedling. In a section of root an outer zone or cortex and a central zone of "wood" and pith are clearly visible. A large proportion of cortex is desired because its tissues are more tender and richer in stored foods, carotene and flavour than tissues of the centre.

Carrot is native to Afghanistan and neighbouring lands. Wild carrot has become distributed as a weed in Europe, the U.S. and other temperate lands. Carrots were cultivated in the Mediterranean region before the Christian era; in Germany, France and China by the 13th century; and by about 1600 were grown in fields and gardens in England. The earliest colonists brought them to America. They are now extensively grown throughout the temperate zones. Appreciation of the value of carotene (provitamin A) in the diet greatly stimulated production and use of carrots as a common vegetable in the U.S. after 1920.

Normally, in the first season only an erect rosette of doubly compound, finely divided leaves develops above ground, the edible carrot and attached roots below. After a rest period at temperatures near freezing, large branched flower stalks arise two to six feet tall. Ends of the main stalk and branches bear large compound umbels of tiny white to pinkish flowers. The so-called seeds are one-seeded halves of tiny spiny fruits called schizocarps. Seeds as purchased for planting have had the spines removed.

Among common varieties root shapes range from globular to half-long to long, with lower ends blunt to long-pointed. In America only roots with orange-coloured flesh are popular. White-, yellow- and purple-fleshed varieties are known. Orange skin colour is most desired; green shoulders and red and purple skin occur.

Carrots require cool to moderate temperatures and so are grown in the warmer regions only in the autumn, winter and spring. They require deep, rich soil. Crusted or packed heavy soil interferes with emergence of the delicate seedlings. As formerly grown, carrots required much hand labour for removal of excess seedlings and weeds from the rows. Modern machines sow the seeds thinly in bands to give room for plant development without need for thinning. Weeds are largely controlled by spraying the fields with Stoddard solvent when the carrot plants are small. Stoddard solvent kills most weeds without injuring the carrots, largely eliminating weeding. See also VEGETABLE.

See H. C. Thompson and W. C. Kelly, *Vegetable Crops* (1957). (V. R. B.)

CARSHALTON, an urban district (1894) in the Carshalton parliamentary division of Surrey, Eng., lying about 12 mi. S. of London and 3 mi. W.S.W. of Croydon by road. Pop. (1961) 57,462. The first part of the name is said to derive from "cress." The place, mentioned in 7th-century records, appears in the Domesday Book under the name Avltone, the origin of the second part of the name. In the south of the district is the Oaks park and late 18th-century mansion owned by the earl of Derby, which gave its name to the Oaks horse race. Parts of the parish church of All Saints date back to the 12th century, but it has been several times altered, notably in 1893. In the park of Carshalton house (18th century), there is a brick-built grotto. Springs rise there which supply one of the heads of the Wandle river and which form an expanse of ornamental water near the church in the centre of the district. The main industries of Carshalton include the making of plastics (especially polyvinyl acetate), chemicals and paper goods.

CAR SICKNESS, a form of motion sickness evoked by the motion of an automobile. See MOTION SICKNESS.

CARSON, CHRISTOPHER ("KIT") (1809-1868), U.S. frontiersman, Indian agent and soldier, was born in Madison

county, Ky., on Dec. 24, 1809. As an infant he was taken by his family to Boone's Lick district, Mo., a frontier region subject to Indian forays. Carson received no formal education and not until late in life did he learn to read and to write a few words. At the age of 15 he began a brief saddler's apprenticeship in Franklin, Mo., but before a year passed he ran away from his master and joined the 1826 Santa Fe caravan. While at Taos, N.M., the youthful "Kit" became associated with the experienced trader Ewing Young through whose connections Carson began his remarkable career as a professional frontiersman.

He accompanied John C. Frémont on his exploring expeditions of 1842, 1843-44 and 1845-46. During these years Carson tended to make his home at Taos, where in 1843 he married Maria Josefa Jaramillo. Bent's Fort was frequently a place of employment for Carson and at times he served as hunter for this trading post.

As a member of Frémont's 1845-46 expedition, Carson found himself in the midst of California's Bear Flag revolt and involved with Mexican War activities. While carrying some official reports to Washington he encountered Gen. Stephen W. Kearny's California-bound army of the west. The general ordered Carson to retrace his steps to serve as an army guide and scout. In an ensuing battle between Mexican lancers and Kearny's forces at San Pascual, it was Carson who, by eluding the enemy, managed to convey a distress call to American naval forces at San Diego which came to Kearny's rescue.

During the American Civil War Carson served the federal cause in the southwest and was brevetted a brigadier general of volunteers. Thereafter he resumed his earlier activities as Indian agent with headquarters at Taos. He was holding this position when he died on May 23, 1868, at Fort Lyon, Colo. Carson was a soft-spoken, likable man and a leading frontiersman. His exploits contributed much toward the settlement of the west.

CARSON, EDWARD HENRY CARSON, BARON (1854-1935), British statesman and lawyer, famous politically as the "uncrowned king" of Ulster, who organized and successfully led resistance to the British government in its attempts to introduce Home Rule for the whole of Ireland. He was also acknowledged to be one of the greatest advocates, though not a profound lawyer, ever to have practised in the Irish and English courts. Although he was to become the champion of the northern province, Carson was a southern Irishman by birth and upbringing. He was born in Dublin on Feb. 9, 1854, the son of a civil engineer. Both his parents were Protestants. He was educated at Portarlinton school and Trinity college, Dublin, and after graduating studied law and was called to the Irish bar (1877). There he quickly made his name, becoming a queen's counsel and bencher of the Dublin King's Inns in 1889. Early in his career he came to distrust the Irish Nationalists, who were to be his lifelong opponents.

Carson was made counsel to the attorney general for Ireland when A. J. Balfour became Irish secretary in 1887, and later became senior crown prosecutor for Dublin. This put him into the thick of the highly dangerous work of enforcing the 1887 Crimes act. He entered into this with zest, getting convictions for agrarian and other outrages and needing in the process the constant protection of armed detectives. Appointed Irish solicitor general in 1892, he entered parliament as a member for his old university in the general election of that year. He was soon recognized at Westminster as an outstanding debater and his attacks on Gladstone's Home Rule bill were conducted with force and wit. He was called to the English bar in 1893 and became an English queen's counsel in 1894.

He did not take political office in England until after the general election of 1900, when he joined the Unionist ministry as solicitor general and received a knighthood. Through the late 1890s and the first years of the 20th century he was at the height of his powers as a barrister. No man of his generation—and few of any other—could so sway a jury or win over a reluctant judge. He could be

devastating, as in his cross-examination of Oscar Wilde, and he could be sympathetic and understanding. He had an intuitive sense of what was going on in the mind of a witness and his conduct of a case was always helped by his striking appearance. Tall and lean, he had a hatchet-shaped face and eyes that seemed to bore through an opponent. High pressure of legal briefs did not lead him to neglect parliamentary duties. He was to the fore whenever Irish affairs came up, throwing his decisive weight against any proposal to weaken the links between Great Britain and Ireland. When Walter Long retired from the leadership of the Irish Unionists (1910), Carson took his place. He might have succeeded Balfour as leader of the Conservative party, being mentioned as one of the several candidates, but he refused to compete, preferring to devote his energies to the cause of Ulster. This soon became a full-time task. In 1912 H. H. Asquith, having succeeded in depriving the house of lords of the right of veto, felt that the road was clear for the passage of a Home Rule bill. Throughout the years immediately before World War I Carson fought against this threat, as he saw it, to the political and religious liberties of Ulster. He stood like a colossus in the way of the Liberal ministry and it failed to get around him. He had no hesitation in appealing to force of arms, no less than to reason. He would hurry from the house of commons, where his speeches were of tremendous effect, to Belfast, where he was equally effective in rousing the Protestants of the northern countries to a mood of defiant and confident resistance.

Carson was determined that Ulster should never submit to the domination of a Southern Irish parliament at Dublin. He was the principal agent in raising a force of volunteers who openly drilled in preparation for taking the law into their own hands if Home Rule were established. At first Carson was laughed at as "an elderly lawyer" playing at soldiers, but the solemn Covenant of Resistance to Home Rule (1912), signed by many thousands of Ulstermen, and the setting up of a provisional government in Belfast in 1913 proved that the Orangemen meant business. The Liberals had to climb down and make more and more concessions to the North, leading ultimately to the complete exclusion of the six counties of Ulster from the operation of Home Rule.

During World War I the progress of the Irish settlement was interrupted. Carson was appointed attorney general in 1915, but resigned soon afterward because he was dissatisfied with the government's conduct of the war. In Lloyd George's coalition government of 1917 he became first lord of the admiralty, and in July 1917 was appointed a member of the war cabinet without portfolio. After the war he gave up his seat for Dublin university and was returned for the Duncairn division of Belfast. In 1921 he took a life peerage as Baron Carson of Duncairn on being appointed lord of appeal in ordinary—an office which he held until 1929, bringing to it his clear mind and ripe experience. He did not hold that this judicial position precluded him from expressing trenchant opinions on politics and he vigorously rebutted the charges made against him on this score by his old friend Lord Birkenhead. Carson died at Minster, Kent, on Oct. 22, 1935, and was given a state funeral in Belfast.

See Edward Marjoribanks and Ian Colvin, *The Life of Lord Carson*, 3 vol. (1932-36); H. Montgomery Hyde, *Carson* (1953). (A. P. Ry.)

CARSON CITY, the capital city of Nevada, U.S., 30 mi. S. of Reno. is the smallest state capital in the United States. The name is derived from Christopher ("Kit") Carson, famous frontiersman. Established in 1858 as a rival of Genoa, Nevada's first permanent settlement, it was made the seat of Carson county, Utah territory, effective blarch 1, 1861, and on the following day the Territory of Nevada was created by the U.S. congress. On Nov. 25, 1861, Carson City became the territorial capital and on Nov. 29 was made county seat of the newly designated Ormsby county. When Nevada acquired statehood in 1864, Carson City became the seat of the new state government (although Virginia City was at that time the centre of population). Carson City was not incorporated until 1875.

Mormon agriculturalists who settled in the Eagle valley area influenced the development of the city, as did wagon and stage routes over nearby Sierra Nevada passes into California. In 1859

discovery of silver in the Virginia City area 15 mi. N.E. rapidly expanded Carson City's economy. At nearby Empire, on the Carson river, mills treated the ore of the Comstock Lode, brought down from Virginia City by the Virginia and Truckee railroad which maintained extensive shops at Carson City. Along with the Comstock, the Virginia and Truckee declined and in 1950 was completely abandoned. For coining the immense silver output of the Comstock, the federal government established a mint at Carson City which later became the Nevada State museum. Also there is the capitol, state library and the State Orphans' home. Two miles east is the state prison; a federal Indian school was established at Stewart, three miles south.

At an elevation of 4,678 ft., Carson City enjoys a dry, invigorating climate. Twelve miles west, in the Sierra Nevada ranges, lies beautiful Lake Tahoe with surrounding ski resorts and gambling casinos: which are legalized institutions in Nevada. Thirty miles north is Reno, reached by the Three Flags highway.

For comparative population figures see table in NEVADA: Population. (A. J. Pr.)

CARSTARES (CARSTAIRS), WILLIAM (1649-1715), Presbyterian minister and leader of the Scottish Church at the time of the Revolution Settlement, was born at Cathcart on Feb. 11, 1649, and ordained in exile in Holland. During the reign of Charles II he was twice arrested for subversive activities in England and Scotland. At the time of the Rye House plot he confessed his complicity under torture in Edinburgh but was allowed to return to Holland, where he became minister to an English-speaking congregation at Leiden (1685) and chaplain to the prince of Orange. He won the trust of the prince, and his guidance was invaluable during the course of the Settlement. On the accession of Anne he settled in Scotland as minister of Greyfriars, Edinburgh, and principal of the university. He was four times elected moderator of the general assembly. The safeguarding Act of Security in the treaty of union (1707) was largely his work. He spent his last years fighting the Tory ministry's efforts to undermine that act, especially by two acts of 1712, one restoring patronage and the other legalizing Episcopalian worship. He died in Edinburgh on Dec. 28, 1715. Of the leaders of the Church of Scotland he was the most politically minded, but his deepest concern was for the Christian welfare of the land.

See R. H. Story, *Character and Career of W. Carstares* (1894).

CARSTENS, ASMUS JAKOB (1754-1798), German portrait and historical painter, who did much to infuse a classical spirit into the arts of the late 18th century, was born in Schleswig on May 10, 1754, and was active in Copenhagen, Liibeck, Berlin and Rome. A leader of the later school of German historical painting, Carstens disparaged prosaic naturalism and admired the work of Giulio Romano, Leonardo da Vinci, Raphael and Michelangelo. Many of his subjects were taken from the literature of antiquity.

In 1795 a great exhibition of his work was held in Rome, which aroused heated controversy among the theorists but gained him so many supporters that he remained there until his death on May 26, 1798.

CARTAGENA, Caribbean seaport of Colombia, is the capital of the department of Bolivar. Pop. (1961 est.) 179,250. The city is situated on the northern end of the Bay of Cartagena, which has only one navigable entrance. Boca Chica, far to the south of the city. The climate is tropical and generally humid. The old walled sections of Cartagena are divided between a peninsula and the island of Getsemani, but the city now spreads over the islands of Manga and Manzanillo (site of the airport) and the mainland below La Popa, a hill 552 ft. in height. In the old section the streets are narrow and picturesque; there are found the ornate cathedral, the beautiful church of San Pedro Claver, the Palace of the Inquisition, the main plaza and the university (housed in a former monastery).

In 1533 Pedro de Heredia founded the city which later became known as Cartagena de Indias to differentiate it from the Cartagena in Spain. After the middle of the 16th century great fleets stopped annually at Cartagena to take on gold and other products of northern South America for convoy to Spain. The city became

BY COURTESY OF STANDARD OIL CO. (N.J.)

16TH-CENTURY FORTRESS OF SAN FELIPE DE BARAJAS. CARTAGENA. COLOMBIA

a centre for the Inquisition and a major market for Negro slaves. Beginning in the 16th century Cartagena was increasingly fortified by heavy walls, and fortresses such as the towering San Felipe de Barajas were built near the city, at points on the shore of the bay and on both sides of Boca Chica. Fortification was needed to withstand attacks by such corsairs as Robert Baal, Martin Côtes, John Hawkins and Francis Drake.

In 1697, as local conflicts gave way to international wars, a great French force under the Baron de Pointis and Jean Baptiste Ducasse took the city and almost destroyed it after a 20-day siege. The restored and strengthened bastion was more successful in 1741 when it held out against a large naval squadron under the English admiral Edward Vernon.

Cartagena had to depend upon the Magdalena river for communication with the interior. By 1650 the Dique canal, an improved natural channel between the port and the river, had been opened. Often silted up, it was never fully satisfactory, but it helped to maintain Cartagena as the chief colonial port of northern South America.

On Nov. 11, 1811, the province of Cartagena declared its independence from Spain, and years of war followed. In 1815 the "Heroic City," as Bolivar christened it, was taken by the Spanish general Pablo Morillo after an estimated 6,000 inhabitants had perished. In 1821 it was retaken by patriot forces.

In the early national period Cartagena continued as Colombia's leading port, but was always handicapped by inadequate connections with the interior. By the 1840s it was declining both in population and commerce. The Dique, in disuse since the independence wars, was reopened from 1848-52 and again in 1879-88. By then it was Barranquilla (*q.v.*), situated on the lower Magdalena river, that began to rise, capturing much of Colombia's commerce. Cartagena's trade revived primarily as the result of the completion of a railroad to Calamar on the river in 1894. But Barranquilla had already gained the lead which it still maintains on the north coast.

Cartagena's population was less in 1905 than it had been in 1834. The city later experienced a steady growth—from 51,382 in 1918 to 111,291 in 1951—and trade volume improved. Among the causes for this were dredging of the bay, modern port works completed in 1933, another reopening of the Dique, and the laying of a sewage system in the 1940s. But probably most significant was the exploitation of great petroleum fields in the Magdalena river valley after 1917, and the pipeline completed from the main oil centre, Barrancabermeja, to the Bay of Cartagena in 1926. Since that time Cartagena has been the chief oil port of Colombia. However, Barranquilla, and Buenaventura on the Pacific coast, handle most of Colombia's chief export, coffee. Cartagena's manufactures include sugar, tobacco products, cosmetics, textiles and leather

goods. Thousands of Colombian and foreign tourists visit Cartagena annually.

(T. E. N.)

CARTAGENA (CARTHAGENA), a city and episcopal see of southeastern Spain, in the province of Murcia (*q.v.*), on the Mediterranean sea, is the terminus of a branch railway from the city of Murcia. Pop. (1950) 110,979 (mun.). Standing on an easily defended natural harbour, it is the chief naval base of Spain with an arsenal and dockyards ranking with those of El Ferrol and San Fernando near Cádiz. The city, on a small lowland at the north end of the bay, is fairly modern and uninteresting except for remnants of old walls and a castle. On the northeast a fertile valley gives access to the interior but on the west, southwest and southeast the port is surrounded by high mountains. The harbour, the largest in Spain after that of Vigo and the finest on the east coast, is a deep, spacious bay, dominated to seaward by four hills, crowned with forts, and approached by a narrow entrance guarded by batteries and a torpedo station. The outer bay is sheltered by the island of Escombrera, the ancient Scombraria ("mackerel fishery"), 2½ mi. S., and the harbour by a breakwater on its eastern side. On the northwest lie the Arsenal basin, often regarded as the original harbour of the Carthaginians and Romans, and the naval shipbuilding yards, with dry and floating docks. There are valuable mines near the town, producing lead, silver-lead, zinc, iron, copper and sulfur, and a mineral railway from Los Blancos, passing through the chief mining and smelting district of La Unión 6 mi. E. of the town, runs on to the quay in Cartagena harbour. The city exports some of the ores and also has important smelting works. Other manufactures include glass and esparto fabrics.

The industrial and commercial progress of Cartagena was considerably hindered during the first half of the 19th century by the prevalence of epidemic diseases, the abandonment of the arsenal and rivalry with the neighbouring port of Alicante. Its sanitary condition, though remaining defective, was improved by the drainage of the adjacent Almaraz marsh, and after 1870 Cartagena advanced rapidly in size and wealth. The opening of the railway enabled it to compete for a time with Alicante and revived the mining and metallurgical industries, while the coast and land defenses were modernized and new quays, docks and other harbour improvements were added. As a naval station Cartagena suffered severely in 1898 from the maritime disasters of the Spanish-American War but, after the decree of 1908 ordering the Spanish navy brought up to date, considerable naval construction went on in the port. As a general commercial port Cartagena was adversely affected after the beginning of the 20th century by the increasing importance of Barcelona, Málaga and Alicante on the same coast. It exports some olive oil, dried fruits and esparto grass and ordinarily imports coal, coke and machinery from Great Britain, timber from the United States and dried codfish from Norway and Newfoundland, but it is above all a mineral port. Even this activity was somewhat reduced after the establishment in 1898 of an independent port at Portmán, a mining village on a sheltered bay 11 mi. E.

History.—Cartagena was founded about the year 227 B.C. by the Carthaginian Hasdrubal, probably on the site of a much older town, and was called (by the Romans) Carthago Nova or New Carthage to distinguish it from Carthage in Africa. It lay opposite the Carthaginian territory in Africa and was early noted for its harbour. Its silver and gold mines were the source of great wealth to the Carthaginians and later to the Romans. In 209 B.C. it was the scene of a notable exploit of military history by Publius Cornelius Scipio (*q.v.*; later surnamed Africanus). Displaying an acute strategic instinct, he made a direct attack on this main Carthaginian base in Spain in spite of the presence of Hannibal in Italy. His capture of the city, with its harbour and silver mines, paved the way for the expulsion of the Carthaginians from Spain. The city continued to flourish under the Romans, who made it a colony with the name Colonia Victrix Julia Nova Carthago. In A.D. 425 it was pillaged and nearly destroyed by the Goths. Cartagena was a bishopric from about 400 to 1289, when the see was removed to Murcia. Under the Moors it became an independent principality, which was destroyed by Ferdinand II of Castile in 1243, restored by the Moors and finally conquered by James I of Aragon in 1269. It was rebuilt and fortified by Philip II of Spain

(1527-98) for the sake of its harbour. In the War of the Spanish Succession it was occupied by Sir John Leake in 1706 and by the duke of Berwick in 1707. On Nov. 5, 1823, it capitulated to the French. Cartagena took part in the revolutionary movement of 1844 and in 1873 was bombarded by the Spanish fleet under Admiral Lobo. The city was occupied by government troops on Jan. 12, 1874. It was the loyalist naval base during the civil war of 1936-39.

CARTAGO, a city of Costa Rica, 12 mi. S.E. of San José on the Inter-American highway at an altitude of 4,765 ft. above sea level, and capital of the province of the same name. Pop. (1960 est.) 17,776. The city is located on the Meseta Central, a fertile region of volcanic origin with mild climate. Earthquakes are not uncommon, and one in 1910 destroyed almost the entire town including the Central American Peace palace, home of the Central American Court of justice. The basilica of Our Lady of the Angels, patroness of Costa Rica, with its famous black madonna, is a much frequented place of pilgrimage. Cartago was founded in 1563 by Juan Vázquez de Coronado, and was the capital of Costa Rica during the Spanish colonial period. In 1823, two years after independence, the capital was moved to San José. Although poor and backward, Cartago and its surrounding area were believed to be rich by Spain's enemies, and frequent attacks by pirates were fought off in the 17th century.

Cartago province (area 1,004 sq.mi.; pop. [1960 est.] 145,503) contains the town of Turrialba, centre of the world-famed Inter-American Institute of Agricultural Sciences which maintains a vast experimental farm to study methods of increasing food production in Latin-American nations. The chief product of the province is coffee, and Cartago city is an important marketing centre. (T. L. K.)

CARTAN, ÉLIE JOSEPH (1869-1951), French mathematician who greatly developed the theory of groups begun by Bvariste Galois and contributed much to the theory of subalgebras, was born at Dolomieu, Isère, on April 9, 1869. Having entered the École Normale Supérieure in 1888, he became a lecturer at the University of Montpellier in 1894. There, working along the lines of W. Killing, he produced findings on the determination of simple groups.

He pursued the study of the structure of continuous groups introduced by M. S. Lie; and examined theories of equivalence and their relation to the theory of integral invariants, mechanics and the theory of relativity. Moving to the University of Lyons in 1896, he worked on linear associative algebra, developing general theorems based on the work of Benjamin Peirce of Harvard and exhibiting the Dedekind subalgebra of F. G. Frobenius. In 1912 Cartan became a professor at the Sorbonne, Paris, where he at first taught differential and integral calculus, and later (1924-40) higher geometry.

Although a profound theorist, Cartan was able to explain concepts to the ordinary student with clarity and comparative simplicity. He became a member of the Académie des Sciences in 1931, and a fellow of the Royal society in 1947. Cartan died in Paris on May 6, 1951.

Among his works are *La Géométrie des espaces de Riemann* (1925); *La Thdorie des groupes continus et des espaces généralisés* (1935). His *Oeuvres complètes* were published in Paris, in five volumes, from 1952 to 1955.

CART AND WAGON. A cart is a two-wheeled vehicle whose origin is bound up with that of its four-wheeled counterpart, the wagon. Carts and wagons became the common inheritance of Europe in the Late Bronze Age, having first come into use in ancient Mesopotamia where four-wheeled wagons or war chariots were used in the 3rd millennium B.C. Vehicles found in the Protodynastic cemetery at Kish, possibly dating shortly after 3000 B.C., are funerary wagons or hearses with solid, copper-bound wheels.

BY COURTESY OF OSLO UNIVERSITY (OLDSAKSAMLING)
VIKING WAGON. 9TH CENTURY. TAKEN FROM THE GRAVE MOUND AT OSEBERG. NOR.

Sumerian pictographs indicate that these early vehicles have some relation to sledges, from which they might possibly be derived, but the earliest models and painted representations on pottery illustrate a high-backed four-wheeled wagon of small chassis drawn by oxen.

Wagons of basically similar design were in use throughout the middle east by the early 2nd millennium B.C. and had reached Syria, Crete and the Anatolian plateau. In the steppes of central Asia, however, and in the Indus valley, where wheeled vehicles had been in use from the closing centuries of the 3rd millennium, it was the two-wheeled cart that was favoured. Model carts from Chanhudaro in the Indus valley are small and rather cubical in body and have two oxen yoked to the draft pole. The chassis of these early Indus carts consisted of two concave beams with three horizontal crossbars of wood. Holes in the long beams were sockets for upright stakes which held the wickerwork body in position. Wheels were solid with half-moon openings, and in structure these prehistoric carts differed little from modern peasant carts of Sind.

Among the nomads of the Asian steppes the covered wagon, models of which are found in Syria and Assyria from the 3rd millennium, was used for family transport, while farther west and into Europe, high-sided wagons were in use. The model from Budakalász in Hungary closely resembles Syrian model wagons of the 2nd millennium. Models of covered wagons from graves in the Kalmyk steppe dated c. 1250 B.C. are structurally similar to 5th-century B.C. models of Scythian wagons from Kerch and to the reconstructed Scythian ceremonial cart preserved in a tomb at Pasirik in the Siberian mountains. Two-wheeled carts of a type surviving in modern Anatolia were used for family transport by the "sea peoples" who in the early 12th century B.C. invaded Egypt, where previously the cart was unknown.

The small two-wheeled canopied carts used for personal transport in the Indus valley probably remained long in use, and in the last few centuries B.C. they reappear in China, with canopy or umbrella, as the chief means of personal transport.

In Greece and Rome farm carts with solid wheels were in use where conditions allowed, although the heavier four-ox wagon was used in the Etruscan area. Solid wheels discovered in Late Bronze Age contexts in Europe are more suitable for farm carts than any other form of vehicle, although spoked-wheel wagons were already in use in Europe by that time. In Greece the spoked-wheel cart in use for rural transport of people and goods is often illustrated on vase paintings.

Under the Roman empire both solid and spoked-wheel carts were in use in all the Mediterranean lands and western Europe. Carts in use at mid-20th century in Spain, Sardinia, Bosnia, Anatolia and even central Italy preserve the structure of carts used in Roman days. Structurally they can be divided into two types:

with the body sitting on the axle (Spain and Latium, Italy) or on the draft pole (Anatolia, Sardinia). It was the former type, a small affair drawn by mules, that was introduced at the Spanish conquest to the American continent, where formerly wheeled vehicles were unknown.

Pompeian wall paintings show that by the 1st century A.D. small carts drawn by goats or dogs were provided with shafts. In China shafts were being used on large bullock carts by the 2nd century A.D., and this innovation spread more rapidly in the far east than in the west. Carvings of shafted carts of the 3rd and 4th centuries A.D. are rare in Europe, and the first example from the British Isles dates from the 8th century.

Little is known of the structure of vehicles in the dark ages, but the earliest medieval manuscripts illustrating farm vehicles show little apparent advance on Roman models. Both shafts and draft poles were in use, but rarely is there evidence that either shaft or pole could swing horizontally or vertically or move in one piece with the axle as could the draft pole of the 1st-century Celtic wagons from Djebjerg, Den., or of the late Roman leatherhooded traveling coaches.

In the 14th century appear carts consisting of a long frame like a broad ladder carried on a pair of large wheels, basically like the Welsh dray in use until modern times. Traction of these carts: as in Wales and Orkney until modern times, was by traces attached to a beam at the front.

Besides the horsecart and the oxcart in use in Europe for agriculture, small carts such as the tinker's cart in Britain and the Irish jaunting car are still used for personal transport.

In the United States the Conestoga wagon; so-called because it was first built in the Conestoga valley of Pennsylvania, came into general use late in the 19th century in the pioneer movement across the Alleghenies. Its descendant, the prairie schooner, was used first in the Santa Fe trade and later by emigrants moving west to the Pacific coast in the 19th century. In modern U.S. usage the term wagon is also applied to automobiles—such as beach and station wagons—used both for passengers and light freight transport; in South Africa they are called ranch wagons: or shooting breaks—the latter from their use in hunting. The four-wheeled, horse-drawn wagon remains in use in rural areas of the United States, Canada and other countries.

CARTE, RICHARD D'OYLY (1844–1901), English impresario who successfully managed the first productions of the operas of W. S. Gilbert and Arthur Sullivan, was born in London on May 3, 1844. After some experience in his father's musical instrument business, Carte opened a concert and lecture agency and became manager of the Royalty theatre, London (1870). In 1875 he presented there *Trial by Jury*, a dramatic cantata in which Gilbert and Sullivan had successfully collaborated at Carte's instigation. Carte then formed the Comedy Opera company (1876) to produce other operettas at the Opéra Comique in the Strand. The success of *H.M.S. Pinafore* (1878) ended the necessity for this syndicate and Carte, Sullivan and Gilbert continued as partners. Carte later opened the new Savoy theatre (1881), the first London theatre to have electric lighting, where for many years the Gilbert and Sullivan operettas enjoyed immense popularity.

A less successful venture was the building of a Royal English Opera house, for which Sullivan wrote *Ivanhoe* as the opening attraction (1891). This attempt to establish serious English opera on a permanent basis collapsed and Carte sold the house to Sir Augustus Harris, who turned it into the Palace theatre. Carte died in London on April 3, 1901. His touring companies, which had secured copyright of the Gilbert and Sullivan operettas, were continued in Britain and the United States by his heirs.

CARTE. THOMAS (1686–1754), English historian, whose works remain useful source books because of his use of original documents. was born at Clifton-upon-Dunsmoor, Warwickshire, in 1686. A staunch Jacobite, he acted as secretary to Francis Atterbury (*q.v.*), after whose fall in 1722 he lived in exile for six years. His *History of the Life of James, Duke of Ormonde* (1735–36) is of value for its collection of manuscripts, letters and official documents. At the threat of a Jacobite rebellion in 1744 he was arrested for a short time. His *A General History of England* (1747–55) was based on a closer study of documentary sources than earlier histories but it was attacked by the anti-Jacobites because of its account of a cure of the king's evil by the Old Pretender, and this, and its tedious style, prevented popular success. Carte died at Abingdon, Berkshire, on April 2, 1754. His valuable collection of historical papers was eventually acquired by the Bodleian library, Oxford.

CARTEL. In economics, this term denotes an organization of independent firms or individuals for the purpose of exerting some form of restrictive or monopolistic influence on the production or sale of a commodity or group of commodities. If the members of the organization are firms domiciled in one country only it is referred to as a domestic cartel; if they are located in different countries the organization is known as an international cartel. The most common forms of control are created for the regulation of prices or output: or division of marketing areas.

Early History.—In the first treatise on cartels, by the German economist F. Kleinwaechter, these organizations were compared with medieval artisan guilds. There was some truth in this comparison, for some German cartels were combinations of small producers. However, cartels in Germany and elsewhere soon embraced some of the largest and most powerful producers. These combinations were quite dissimilar to medieval guilds and more closely resembled the mining and trading combines set up under royal or imperial authority by the Fuggers and their contemporaries. Combinations of cartel-like form are at least as old as the middle ages, and some writers allege to have found cartels even in ancient Greece and Rome.

The word "cartel" was not used to describe business combinations until 1879, when it was applied by a liberal deputy of the German *Reichstag*, E. Richter, to a group of producers in the iron industry who dumped their commodities abroad while keeping domestic prices high as the result of a mutual agreement and were enabled to do so because of tariff protection.

German Cartels.—The cartel has been the most common form of monopolistic organization in Germany in modern times. German cartels are usually horizontal combinations of producers (*i.e.*, of firms which turn out competing goods). Sometimes they may also embrace vertical integration (*i.e.*, firms which form integrated enterprises, extending into raw material production, intermediate goods and finished commodities). These organizations are sometimes called "trusts" in Germany, but they are not identical with C.S. trusts. An especially important form in Germany were the so-called *Interessengemeinschaften* which consisted primarily in a pooling of profits. The famous I. G. Farben was such a combination, but other famous *Interessengemeinschaften* were founded in the mining and electrical fields and in the manufacture of iron and steel and their products. The electrical Siemens-Schuckert concern, the Vereinigte Stahlwerke (United Steelworks) and later, in the 1930s, the Hermann Goring works were cartels of this type. They were all vertical and horizontal combinations of producers and resembled closely some large U.S. monopolies in the chemical, electrical and iron industries.

Though some of the early German cartels were formed soon after the Franco-German War (1870), a strong impetus to combination, notably of small and medium-sized producers, was given by Germany's increasing desire to conquer foreign markets in the decade before World War I. These producers profited from tariff protection that enabled them to keep domestic prices high and to

sell at a loss abroad. During World War I the German government encouraged cartelization as a means of facilitating the allocation of war orders. At the end of the war in 1918 cartels emerged, therefore, stronger than ever, especially in the heavy industries, and by 1926 it was estimated that about 75% of the German coal and coke output and 79% of the German steel output was controlled by them. In the chemical and electrical industries, as well as in some mining fields, especially the production of alkali, cartel control was even greater.

In view of the vast economic power which these cartels could wield, a decree "against the misuse of monopoly power" was issued in 1923. This so-called "cartel decree" was enacted originally with an intent similar to that of U.S. antitrust legislation. Actually, however, it did not combat cartels but tended to foster them. It did attempt to prevent secret clauses in cartel agreements by stipulating that verbal contracts "which lay down obligations in regard to production and marketing, conditions of business, the nature of price fixing or price lists" were invalid. The decree also set up a cartel court, which was charged with jurisdiction in cartel matters, and stipulated that a cartel could be dissolved if its continued existence or its business practices were against the public interest or seriously damaged consumers or some other section of the German economy.

German practice in regard to cartels varied. During the 1920s the government was not friendly to them, and in 1925-27 some were even dissolved. With the coming to power of the Nazis, cartels were favoured, and in some industries compulsory cartelization was successfully attempted. The reasons were the same as those that induced the German government in World War I to favour cartels. Cartels made easier the transformation of the German economy to war production. With the defeat of Germany in World War II the Allied occupation powers drafted a bill outlawing cartels and other forms of restraint of trade, but there was strong opposition to this law among Germans who favoured a law that would permit cartels to exist but would punish abuses of cartel power. After the end of the occupation the bill outlawing cartels was dropped and legislation against abuses was introduced into the *Bundestag*. There was opposition even to this legislation; counter-proposals were made and the debate on cartel legislation continued from 1951 to 1957. A law was finally passed in 1957 that outlawed various forms of "restriction of competition," but exempted from control certain cartel agreements; e.g., export cartels. In general, the 1937 was stricter than the 1923 cartel decree but was not basically different from it. Its main additional differences were that it took due account of Germany's involvement in the European common market and that it incorporated some of the ideas derived from U.S. antitrust legislation.

Cartels in Other Countries.—The German example was followed in other European countries. Not only did combinations in restraint of trade of various sorts develop, but a number of countries enacted legislation patterned after the German cartel decree. Such a law was passed in Norway, for example, in 1926, and drafts for similar laws were submitted in the Czechoslovakian, Polish and Hungarian parliaments in 1929. In Denmark a "trust" law was also in force but it did not provide for as extensive a supervisory authority as the German or Norwegian laws. In Great Britain the rules of common law with regard to monopoly, and in France the provisions of the Commercial code seem to have been considered sufficient to deal adequately with the problems raised by cartels and cartel-like organizations.

International Cartels.—International cartel agreements were first concluded in the period between World Wars I and II and attracted a great deal of attention during the latter war, since U.S. firms had entered into cartel agreements with German firms, and this was thought to influence war production. Whereas domestic cartels may sometimes be concluded by many small producers, international cartels are normally concluded between firms each of which enjoys a monopoly position in its country's industry. They are combinations of giant firms and hence may, in extreme cases, achieve total or almost complete monopolization of an industry on a world-wide basis. They sometimes wield such great economic power as to be able to prevent governments from implementing

national economic policies. Most international cartels, especially those in which German firms were partners, were dissolved during World War II, but some continued to exist, and trends were under way in the 1950s in the chemical and allied fields to revive some of the old cartel agreements.

Economic Aspects.—The main reason usually advanced for the establishment of cartels is the existence of "ruinous" competition. It is alleged that this causes profits in an industry to be too low, and cartelization is said to provide a solution by distributing fair shares of the total market among all competing firms. This often maintains inefficient firms in an industry and prevents adoption of cost-saving technological advances that would result in prices to the benefit of the consumer.

The most common practices employed by cartels in maintaining and enforcing their monopoly position are the fixing of prices, the allocation of sales quotas or exclusive sales territories to each member firm or the guarantee of a minimum profit to each member. These arrangements are often buttressed by agreements concerning conditions of sale, rebates, discounts, etc.

With increasing differences of efficiency and profitability among the various firms within a cartel, the cartel becomes, however, increasingly unstable. Although it can eliminate competition on the market, at least temporarily, it does not eliminate competition within itself. The larger and more powerful firms within the cartel will try to influence policy in their interest and may be opposed by weaker member firms. In some cases it may benefit a firm to withdraw from the combination and compete against it. Though a cartel tends to establish a high degree of price stability as long as it lasts, cartelized industries have experienced violent price fluctuations which accompanied periodic breakdowns of the cartel. Only when the government buttresses it and acts as an arbiter—as was done in Nazi Germany—can a cartel maintain long-lasting stability of prices and market conditions.

Wherever government support is absent, member firms have sought to strengthen the stability of cartels. In international cartels this need has been felt especially strongly, for the various partners are located in and subject to the jurisdiction of various countries. Among methods intended to strengthen stability and, simultaneously, to increase the monopoly power, have been allocation of exclusive sales territories to the various members and patent pools combined with cross-licensing of patents among members. In addition, agreements often contain provisions for penalties and sanctions against a firm which breaks the rules of the cartel, or they may provide for the establishment of a head office (usually located in a "neutral" country) which arbitrates disputes and may impose fines. The chief factor determining stability, however, is the common interest of all member firms in exploiting a monopoly position which the combination helps maintain.

Regulation and Control.—One of the most thorny problems of economic policy has been the control and regulation of international cartels. Since different governments view cartels in different lights, some supporting and others combating them with different degrees of vigour, and since the various partners of an international combination fall under different national laws affecting their constitution, duties and privileges, it is difficult to arrive at a uniform policy with regard to international regulation. Among the measures proposed are compulsory registration of international agreements, the conclusion of international treaties in regard to patents and trade-marks on which cartel power may be based and the conclusion of treaties outlawing the establishment of domestic cartels, especially those operative in export markets. Other suggestions include the conclusion of an international agreement outlawing the practice of allocation of markets or sales quotas and the establishment of an international supervisory organ with powers somewhat akin to the German cartel courts. This last proposal was contained in the draft for an International Trade organization (ITO), but the charter of the organization was not ratified. The U.S. may apply unilaterally its antitrust laws against cartels operating within its boundaries, though U.S. courts may lack jurisdiction in cases in which all participating firms in an international cartel are domiciled abroad. See also MONOPOLY; COMPETITION, ECONOMIC.

CARTER, ELIZABETH (1717-1806), English writer, and one of the group of literary "bluestockings" who gathered around Mrs. Elizabeth Montagu, was born at Deal, Kent, Dec. 6, 1717, the daughter of a learned cleric who taught her Latin, Greek and Hebrew. She was not a precocious child, but she persevered. nith an industry that affected her health, studying also French, German, Italian, Portuguese, Arabic, astronomy, ancient geography, ancient and modern history and music, as well as the housewifery that caused Dr. Johnson to say "My old friend, Mrs. Carter, could make a pudding as well as translate Epictetus from the Greek, and work a handkerchief as well as compose a poem." In 1734 some of her verses, signed "Eliza," appeared in the *Gentleman's Magazine* and it was through its founder that she met Dr. Johnson. Her *Poens Upon Particular Occasions* were published in 1738 and *Poens on Several Occasions* in 1762. It was her translations, however, which ensured her reputation. In 1749 she undertook her most considerable work, a translation of *All the Works of Epictetus Which Are Now Extant*, published in 1758. It was an immediate success and its value can be judged by Johnson's comment of a celebrated scholar that he "understood Greek better than any one whom I have ever known except Elizabeth Carter."

Her letters to her many friends (the Montagus, with whom she traveled on the continent, Lord Bath, Catherine Talbot, Archbishop Secker, Edmund Burke, Samuel Richardson, Horace Walpole, Hannah More) show her to have been a woman of sound sense as well as learning, and some humour.

She died in London, Feb. 19, 1806.

CARTER, HOWARD (1873-1939), British Egyptologist and water-colourist, discoverer of the tomb of Tutankhamen (*q.v.*), was born in Swaffham, Norfolk, Eng., and educated privately. At the age of 17 he joined the staff of the Egypt Exploration fund as a draftsman and received training in archaeological surveying under Sir W. M. Flinders Petrie and others. He engaged in excavations on behalf of the fund until 1899, when he became inspector general of the antiquities department of the Egyptian government. From 1902 he supervised the excavations of Theodore M. Davis in the Valley of the Kings and found the tombs of Tuthmosis IV and Hatshepsut. Subsequently, when working in collaboration with Lord Carnarvon (*q.v.*), Carter discovered many tombs, among them those of Amenhotep I and Tutankhamen, during the years 1907-23. He died in London, March 2, 1939.

He gave an account of his discoveries in *The Tomb of Thoutmôsis IV* (with P. E. Newberry, 1904), *The Tomb of Tutankh-Amen* (with A. C. Mace, 1923-33) and in contributions to various archaeological journals. (W. R. D.)

CARTER, MRS. LESLIE (born CAROLINE LOUISE DUDLEY) (1862-1937), C.S. actress, associated a number of years with David Belasco (*q.v.*), was born in Lexington, Ky., on June 10, 1862.

She made her stage debut in *The Ugly Duckling*, at the Broadway theatre, New York city, in 1890. Mrs. Carter played the leads in Belasco's *The Heart of Maryland* (1895-98), *Du Barry* (1901) and *Adren* (1905). After leaving Belasco in 1906 her chief successes were in *Camille*, *The Second Mrs. Tanqueray*, *The Gay Lord Quex*, *The Circle* and *Madame X*. She died Nov. 13, 1937. (S. W. H.)

CARTERET, SIR GEORGE (c. 1610-1680), English politician and proprietor of American colonies, was born probably in 1610 and reared on the isle of Jersey. He became a naval captain, then vice-admiral and lieutenant governor of the island. He made it a royalist stronghold and refuge during the English Civil

War, privateered in the royalist cause, and thereby won a knightship and baronetcy. After the capture of the island in 1651 by a parliamentary force, he went into exile in France.

Returning to England at the Restoration in 1660, Carteret became a powerful official: treasurer of the navy, privy councilor, vice-chamberlain of the household and member of parliament. Censured by parliament for laxity in account keeping, he gave up the treasurership of the navy in 1667, but subsequently held other important governmental posts.

In 1663 he was one of the eight proprietors to whom the king granted Carolina in North America. The following year the duke of York assigned to him and to John, Lord Berkeley, the American colony of New Jersey, named in his honour. Frictions in the colony and disappointing financial returns led Berkeley to sell out to Quakers in 1674. With them Carteret agreed upon a division of the colony in 1676, he keeping East Jersey. His heirs sold East Jersey to William Penn and other Quakers two years after his death in 1680. See also NEW JERSEY: *History*. (W. R. SL.)

CARTERET, JOHN, LORD: see GRANVILLE, JOHN CARTERET, EARL.

CARTESIANS, the name given collectively to the propagators and continuators of the philosophy of René Descartes (*q.v.*); alternative names for them current in France in the 1670s were Cartistes and Descartistes.

Some of them, who only repeated what Descartes had already stated, laid themselves open to the reproach that they rejected the principle of authority while still depending on the authority of Descartes, and much play was made of the anagram "Cartesius-Sectarius." against which the German Cartesian JOHANN CHRISTOPH STURM (1635-1703) protested in *De Cartesianis et Cartesianismo brevis dissertatio* (1677).

HEKRICUS RENERI (1593-1639) may have been lecturing on the Cartesian method at Utrecht in the Netherlands just before he died. For Henricus Regius, see below. Other early exponents in the Netherlands were JOANNES DE RAEY (1622-1707; *Clavis philosophiæ naturalis*, 1654) and ADRIAAN HEERCBOARD (1614-61; *Meletemata philosophica*, 1659), who introduced the new theses in scholastic form, just as JACQUES DU ROURE did in France (*La Philosophie établie sur des principes évidents*, 1654; *Abrégé de la vraie philosophie*, 1655). Commentaries on the *Meditations* were produced by JOANNES SCHOTAX (1643-99; *Exegesis*, 1687, and *Analysis exegetica*, 1688) and CHRISTOPH WITTICH (1625-87; *Annotationes*, 1688). Wittich, who worked first at Nijmegen, then at Leiden, showed more originality in his *Consensus veritatis in Scripturn divina . . . cum veritate philosophica a R. Cartesio detecta* (1659), in which he considered the application of Cartesian rationalism to Calvinist theology—as also did other Dutch Cartesians, such as BALTHASAR BEKKER (1634-98; *De philosophia cartesiana*, 1661), ABRAHAM HEDANUS (1597-1678) and Spinoza's friend LODERIK MEYER (*Philosophia Scripturae interpres*, 1666).

There were also several Germans teaching Cartesianism in the Netherlands: ALEXANDER ROELL (1653-1718; *Institutiones philosophicæ de theologia naturali*, 1662, and *De recta ratiocinatione*, 1683) at Franeker; RUARDUS ANDALA (1665-1727); and TOBIAS ANDREAE (1604-74) at Groningen, the opponent of Regius and the teacher of Johann Clauberg (*q.v.*). In Germany itself Cartesianism was expounded not only by Clauberg but also by DAXIEL LIPSTORP (1631-84; *Specimina . . .*, 1653). ANDREAS PETERMANN at Leipzig and JOHANN EBERHARD SCHWELING at Bremen wrote in defense of Cartesianism against Daniel Huet's *Censura* (1689), which also provoked defenses from Schotan and from BURCHARD DE VOLDER in Holland and from P. S. Régis (see below) in France. In Switzerland the system was professed by JEAN ROBERT CHOUET (1642-1731), a French refugee from Saumur at Geneva, while another French Calvinist, ÉTIENNE CHAUVIN (1640-1725), was publishing the first Cartesian dictionary, *Lexicon rationale* (1692).

Regius.—Long before all the above-mentioned adherents came forward, HEKRICUS REGIUS (Henri Le Roy, or de Roy; 1598-1679) had incurred the wrath of Cisbert Voet and others by teaching on Cartesian lines at Utrecht. Descartes himself first supported Regius, then disavowed him, so that it may be asked whether

Regius can be called a Cartesian or not. His *Fundamenta physices* (1646; augmented ed., *Philosophia naturalis*, 1654) and his *Explicatio mentis humanae* (1647) propound a mechanistic theory without any allowance for "substantial forms" and follow Descartes on mechanics and astronomy. Moreover, Regius made use of some then unpublished writings of Descartes on physiology, supplementing their findings with his own medical observations. On the other hand he reverses the Cartesian order of investigation, which gave the primacy to metaphysics, and, by presenting the soul as a mode of the body and the senses as the source of all our ideas, destroys the Cartesian proofs of the existence of God.

Regius, a mechanist and an empiricist, was quite as original as Arnold Geulincx (*q.v.*), who also owed much to Descartes. Benedictus de Spinoza, on the other hand, had already a wholly distinct philosophy of his own when he wrote his exposition, *Renati des Cartes principiorum philosophiae pars I et II* (1663).

The Early Editors and the Augustinian Tradition.—The editions of Descartes's posthumously published writings gave rise to more activity. CLAUDE CLERSELIER (1614–84) wrote prefaces for the *Lettres*, three volumes (1657–67), and for the *Traite' de l'homme* (1677), the latter work being also prefaced by the Dutchman FLORENT SCHUYL (d. 1669) and annotated by La Forge (see below) in 1664. The Oratorian NICOLAS JOSEPH POISSON (1637–1710) edited the *Traite' de mécanique* and the *Abrégé de musique* in 1668 and used some unpublished material of Descartes's youth in his commentary on the *Discours de la methode* (1670). A long extract from the manuscript of the *Regulae ad directionem ingenii*, a work not printed until 1701, was included by the great Antoine Arnauld and Pierre Nicole in the Port-Royal Logic (1662).

A new feature of Cartesianism appeared in these texts, namely stress on the agreement between Descartes and St. Augustine of Hippo. The Oratorian ANDRÉ MARTIN (1621–95), under the pseudonym "Ambrosius Victor," produced his *Philosophia christiana*, six volumes (1653–71), by cleverly marshaling excerpts from St. Augustine's writings according to the order and principles of Cartesian procedure—though when he arrived at the theory of animals as machines he had to admit that St. Augustine himself had still believed animals to have souls (vol. 6).

Animal Automatism.—The theory of animals as machines was much debated. Pierre Bayle (*q.v.*), in the article "Rorarius" in his *Dictionnaire* (1692), gives a long list of attacks on it and ironically expresses regret that a theory so convenient to Christian teaching should be so improbable. Bayle, whose *Système de philosophie* had been markedly Cartesian, was by this time a thorough skeptic. Animal automatism, however, was defended not only by Poisson and "Ambrosius Victor," but also by Rohault (see below; second *Entretien*), by Geulincx in his posthumous *Brutum Cartesianum* and by the Franciscan missionary ANTOINE LE GRAND (d. 1699), of Douai, who went to live in England and there published *De carentia sensus et cognitionis in brutis* (1675; he also published a Cartesian *Institutio philosophiae* in 1675 and an *Apologia pro Des Cartes* in 1679).

Yet another defender of animal automatism was ANTOINE DILLY, a priest of Embrun, whose *De l'âme des bêtes* (1676) was a counterblast to *De la connaissance des bêtes* (1672) by the Jesuit IGNACE GASTON PARDIES (1636–73). The latter work, however, itself incurred some suspicion of Cartesianism, as the first part, expounding the theory of animal automatism, was better than the critical part. In his mechanics and in his optics, however, Pardies is closer to Christiaan Huygens (*q.v.*) than to Descartes, and Huygens, whose father had been a personal friend of Descartes, had very soon shaken off all Cartesian influence, his studies on centrifugal force and on the finite velocity of light being completely destructive of Cartesian physics.

Rohault.—JACQUES ROHAULT (1620–72), Clerselier's son-in-law, is the best of the Cartesian physicists. He corrects Descartes on points of detail by means of ingenious experiments and gives an original account of capillary action. His *Traite' de physique* (1672) went through several editions in a short time and was translated into several languages (Samuel Clarke annotated the first English version). Rohault also published *Entretiens sur la philosophie* (1671), discussing the main objections to the Cartesian

explanation of transubstantiation and to the theory of animal automatism.

CLAUDE GADROIS (c. 1642–78) based his *Système du monde* (1675) largely on Rohault's work. His *Discours sur les influences des astres selon les principes de M. Descartes* (1671), however, shows a curious originality in suggesting a mechanistic explanation for telepathy and for certain influences of the stars.

Cordemoy.—GÉRAUD DE CORDEMOY (c. 1620–84) shows more originality than any other Cartesian on the subject of the general principles of physical theory. He introduces a new atomism into the mechanistic system of the Cartesians by linking unity and substantiality: matter is homogeneous but contains a multiplicity of bodies each of which is an indivisible substance (*Le Discernement de l'âme et du corps*, 1666; *discours* 1). The principle of inertia and the divine origin of everything reduce interaction between bodies to a simple correspondence (see OCCASIONALISM), and the same applies between soul and body; belief in the existence of bodies must be a matter of faith. Even so, Cordemoy does not abandon the notion of finality or purpose that Descartes derived from the real unity of body and soul: God warns us by means of sensations of what is useful or harmful to us, as it is vital for us to apprehend objects at a distance. A vast language of perceptible messages is thus built up, and Cordemoy, in his *Discours physique de la parole* (1668), develops the theory of signs—natural in the expression of the passions, conventional in language—language being the unique phenomenon that assures us of the existence of others as thinking beings and not as machines. These two slight works, together with a *Lettre* on animal automatism (1668), constitute Cordemoy's entire philosophical output.

La Forge.—LOUIS DE LA FORGE (d. shortly after 1666), a native of La Flèche who practised medicine at Saumur, began in 1664 by annotating Descartes's *Traite de l'homme* in the light of recent discoveries, such as that of the chyle by Jean Pecquet. His *Traite' de l'esprit de l'homme* (1666) serves as a continuation of the unfinished work of Descartes. For this, La Forge makes use of all the hints to be found scattered throughout the books and the correspondence of Descartes, stressing those of his formulas which point the way to the occasionalist account of the soul-and-body relationship. He is most daring where he poses the question of the state of the soul separated from the body after death, Descartes having only affirmed its natural incorruptibility.

Régis.—None of the continuators of Descartes took much interest in ethics. The only Cartesian work exclusively devoted to that subject is *L'Art de vivre heureux* (1667), sometimes questionably attributed to the Oratorian CLAUDE AMELINE (1635–1708), which is a juxtaposition rather than a synthesis of provisional precepts taken from the *Discours* and from the letters of Descartes. Ethics, however, is the subject of part 4 of *Le Système de philosophie* (1690), published by PIERRE SYLVAIN RÉGIS (1632–1707) after he had made his name lecturing in southern France and later in Paris. A great compiler, Régis is the chief exponent of a complete Cartesian system with empirical tendencies. Part I of his book, dealing with logic, borrows something from Port-Royal but something also from Pierre Gassendi. Part 2, dealing with metaphysics, insists that in this life the soul can act and know only in dependence on the body (Régis moreover inclines to faith rather than to reason for his expiation on the state of the soul after death). This empiricism likewise has features reflecting Gassendi, but it also owes something to the Benedictine Cartesian ROBERT DESGABETS (d. 1678), who published little but whose manuscripts (preserved at Épinal) emphasize how thought depends on the soul-and-body union—in particular the feeling of duration, as only bodily movements can call forth the notion of succession. In part 3 of the *Système*, on physics, Régis makes use of E. Mariotte's recent experiments and also, for anatomy and physiology, of those of M. Malpighi, N. Steno and A. van Leeuwenhoek, but he preserves all the mechanistic principles of Descartes (even including the instantaneity of light) and rejects Gassendi's atomism. Part 4, on ethics, devotes much space to natural inclinations and to self-love (*amour-propre*) and finally discusses absolute power as the guarantor of the state; it thus owes more to Hobbes and to Spinoza than to Descartes.

Later Developments.—His tendency to empiricism brought Régis into conflict with Nicolas Malebranche (*q.v.*). As Malebranche in fact made a new synthesis of Cartesian rationalism with revealed Christian dogma, he was not a Cartesian in the strict sense. For this reason his theory of ideas assimilated to eternal essences and seen directly "in God" was attacked by Régis, Desgabets and, especially, Arnauld.

The thesis of the creation of the eternal truths by God was hardly taken up at all by the Cartesians. Leibniz—who was rather an adversary than a follower of Cartesianism—says that Poiret alone took it up. In fact not only Desgabets but also PIERRE CALLY (*c.* 1630–1709) did so. The latter making essences depend on God's will in his *Universae philosophiae institutio*, 2 vol. (1695). PIERRE POIRET (1646–1719), a Calvinist theologian from Metz who died at Rijnsburg in the Netherlands, regarded the thesis as an acknowledgment of God's total transcendence, but if the first edition of his *Cogitationes rationales de Deo, anima et malo* (1677) is Cartesian, his later writings discard all the rational elements as superficial and uphold pure mysticism.

Bossuet and Fénelon (*qq.v.*) were not influenced by Cartesian thought. In many writers, however, it is hard to distinguish between the Cartesian and the Malebranchian influence: for instance the Oratorian BERNARD LAMY (1645–1715; *Entretiens sur les sciences*, 1683); the Benedictine FRANÇOIS LAMY (1636–1711; *De la connaissance de soi*, 6 vol. 1694–98); the abbé DE LANION (pseudonym Guillaume Wander; *Méditations sur la métaphysique*, 1684); RENÉ FÉDÉ; *Méditations métaphysiques*, 1683); the Italian Franciscan MICHELE ANGELO FARDELLA (1650–1718; *Universae philosophiae systema*, 1691, *Logica*, 1696, and *Animae humanae natura ab Augustino detecta*, 1698); MELCHIOR DE POLIGNAC (1661–1742), who published his *Anti-Lucrèce* in verse; and even the solipsist CLACDE BRUNET (*c.* 1660–1740), who maintained that things existed only insofar as he thought of them. In the 13th century, when Cartesianism had become a bulwark of antimaterialist thought and was being attacked by the Encyclopédistes, the abbé JOSEPH ADRIEN LELARGE DE LIGNAC (*d.* 1762) still acknowledged Descartes and Malebranche as his masters, but his *Éléments de métaphysique fire's de l'expérience* (1753) and his *Témoignage du sens intime* (1760) are often close to J. J. Rousseau's philosophy of existence and sometimes foreshadow Maine de Biran. In Italy the Savoyard cardinal HYACINTHE GERDIL (1718–1802) likewise used Cartesian arguments against materialism. Conversely, La Mettrie's *L'Homme-machine* (1747) reflects the mechanistic side of Cartesianism cut off from the spiritual. By this time, however, the Cartesian stage in the history of philosophy had been passed.

CARTHAGE, one of the most famous cities of antiquity, was founded on the north coast of Africa by the Phoenicians of Tyre and, according to the Sicilian historian Timaeus, in 814 B.C. Today it is a residential suburb of the city of Tunis (*q.v.*). The significance of its Phoenician name *Qartladasht* ("new town") is not precisely known, but according to ancient historians Carthage was founded by the Phoenicians after nearby Utica at the mouth of the Bagradas river (modern Medjerda), and after Gadir (Cadiz) in southern Spain, both of which, according to Velleius Paterculus were founded about 1100 B.C. Traditionally the "new town" of Carthage was so called because it succeeded the "old town" of Utica.

Various traditions concerning its foundation were current amongst the Greeks, who called the city Karchedon, but the Roman tradition is better known because of Virgil's *Aeneid*. This

tells of the city's foundation by the Tyrian princess Dido who fled from her brother Pygmalion, the name of a historical king of Tyre. The inhabitants were known to the Romans as *Poeni*, a derivation from the word *Phoenikes* (Phoenicians), whence the adjective Punic is derived.

Date of Foundation.—The dates of the foundations of Cádiz, Utica and Carthage were probably inflated by the Carthaginians themselves, for they do not agree with the archaeological data. In the case of Carthage, which has been extensively if not systematically explored, nothing earlier than the last quarter of the 8th century has been discovered, a full century later than the traditional foundation date. Dating of the earliest Carthage tomb groups is provided by the presence of proto-Corinthian cups which cannot be earlier than the last quarter of the 8th century B.C. Besides the material from tombs, there are stratified deposits of pottery in an area southeast of the Byrsa, the low hill which dominates the city site. In which were buried the cremated remains of children sacrificed to the Carthaginian goddess, Tanith (Tanit). This area, known as the "precinct of Tanith" in a locality now called Salammbô, has a stratification which covers most of the city's Punic history and can be divided into three periods: 814?–700 B.C., 700/650–350 B.C., 350/300–146 B.C. The beginning of the lowest stratum, here given the traditional historical date, can, however, only be dated by the presence of proto-Corinthian *kofylai* (cups) which are a century later at least. Nor can a deposit of pottery apparently related to the Ionian and Cumaean geometric style made on the virgin soil of this precinct and undoubtedly the earliest pottery hitherto found at Carthage be given a date earlier than about i20 B.C.

Concerning the foundation of Carthage there is a further relevant problem. A town called Qarthadasht was also founded by the Phoenicians at Citium (Kition) in Cyprus. It is mentioned in Assyrian tribute lists of Sargon II (*c.* 720 B.C.) and was a tributary city of Hiram II of Tyre as early as 758 B.C. Josephus records that Citium broke away from Elulaios of Tyre and was refounded by him as Qarthadasht, and it therefore seems possible that it was the Citium-Qarthadasht which was founded about 814 B.C. by Dido, whose other name Elissa means "Cyprus," and that the traditions of its foundation were later transferred to north African Carthage, a "new town" in relation to Citium.

Site of the City.—The site chosen in the centre of the shore of the Gulf of Tunis was admirable from every point of view. The triangular peninsula on which Carthage was built is covered with low hills and backed by the Lake of Tunis with its safe anchorage and abundant supplies of fish, and was easily defensible. The promontory of the city is protected on the north by Cape Carthage and the heights of the modern village of Sidi-bou-Said. On the south the peninsula is connected to the mainland by a narrow strip of land between the gulf and the lake which is broken by a channel at La Goulette connecting the two. The distance between Cape Carthage and La Goulette is about 6 mi.

The **Byrsa**.—The ancient citadel was on a low hill overlooking the sea. This is known as the Byrsa, a word probably Punic in origin but equated in ancient times to the Greek *bursa* (an oxskin), whence arose the story of Dido's claim to all the territory she could encircle by an oxskin. When her claim was granted she cut the skin into strips and hence encompassed enough space to build her city. It is on the Byrsa, now crowned by the cathedral of St. Louis and the monastery of the White Fathers and known as the Hill of St. Louis, that some of the earliest tombs have been found. For the rest of the town there is only one place name preserved by ancient historians and that is Magara. What or where this was is unknown, but according to Cornelius Nepos the name could be referred to the town lying below the Byrsa. Of domestic and public buildings nothing remains.

Burial Traditions.—From the earliest times both cremation and inhumation were used in the graveyards, implying the same mixed cultural tradition as found on the Phoenician coast. Both skeletons and cremation urns were placed either in stone sarcophagi or in small but carefully built chambered tombs. This multiplicity of burial traditions recurred throughout the history of Punic Carthage.

HISTORY

Colonization and Expansion. — The foundation of Carthage was closely followed by the establishment of other Phoenician cities in the west Mediterranean over which Carthage gradually gained control. Chief of these was Motya, an island city on the west Sicilian coast near Marsala, which according to Diodorus was founded by Carthage. In Sicily the arrival of Greek colonists in the 8th century B.C. caused the Phoenicians to curtail their interests in the island. According to Herodotus the Phoenicians withdrew to the western settlements of Panormus (Palermo), Soloeis (Solonto) and Motya (Mozia). Archaeology has confirmed the truth of this information. There were also a number of Phoenician cities in Sardinia, the majority of which were probably independent foundations.

The first major territorial expansion of Carthage in Sicily took place under the generalship of Malchus in 550 B.C. He succeeded in capturing half of the island before turning his attention to Sardinia. There, in an attempt to spread Punic domination over the eastern part of the island as well as over the south and west, which were already settled by Phoenicians, he was defeated by the Sards. The latter had in all probability allied themselves with the Phocæan Greeks who were anxious to prevent Punic interests spreading too far northward into their own commercial preserves. Rivalry between Greek and Carthaginian in western seas came to a head in 535 at Aleria (Alalia) off the coast of Corsica. There the Phocæans won a doubtful victory over the Carthaginians and their Etruscan allies. The first treaty between Rome and Carthage in 509 B.C. forbade the Carthaginians access to Italy with which they had close trading contacts and Carthage never again showed any desire to interfere with the Greek program of colonization of Liguria and southern France. Malchus' successor, however, Mago (q.v.), the first member of the Barcid house to come to power at Carthage, made certain of continued Punic domination in Sardinia and is said to have wrested the Balearic Islands from the Phocæan Greek sphere. In the Balearics, however, Carthage had already established a strong colony in the island of Iviza which Diodorus says was founded 160 years after the foundation of Carthage; i.e., in 654 B.C. Nothing of so early a date has been found in the numerous tombs near the present town of Iviza. There is in fact nothing much earlier than Mago's own day. Punic remains in Minorca and Majorca are limited to pottery, but Port Mahon supposedly derives its name from Mago. It was also probably under Mago that the first Punic colonies outside Gibraltar were planted on Iberian soil.

Apart from Utica, none of the Phoenician cities of the African mainland are as early as Carthage, but at Sousse (ancient Hadrumetum) on the eastern coast of Tunisia a burial ground is known of the early 6th century. Other settlements in Tunisia and Algeria, at Acholla, Tipasa, Gigthi and Gouraya, begin largely in the 5th century B.C. Farther to the west a trading station was founded on the small island of the coast near Oran and others followed (Andalouses, Mersa M...

tured Messana (Messina), defeated Dionysius and laid siege to Syracuse. Again a peace was patched up, Carthage re-establishing the surviving Motyans at Lilybaeum (Marsala). But Dionysius began war again in 383. After his defeat Sicily was divided between the Greeks and the Carthaginians at the Alìco river. In 367 Dionysius began war for the fourth time and, although he died in the course of it, campaigns were carried on against the Carthaginians by his successors, Dionysius II, Timoleon and Agathocles. Agathocles in 312–311 carried the war into north Africa and besieged Carthage which was then handicapped by the conspiracy of Bomilcar, but the Greek army was eventually defeated and driven out. After the death of Agathocles the Carthaginians re-established their supremacy in Sicily, and Mago even offered assistance to Rome against the invasion of Pyrrhus (q.v.). In 277 B.C. Pyrrhus prepared to sail for Africa and bring Carthage to submission, but he was compelled to return to Italy. Because of his intervention in west Mediterranean affairs, however, Carthage lost its opportunity to dominate Sicily completely.

Religion. — The narrative may here be interrupted by a brief account of the religion of Phoenician Carthage and of its political, cultural and commercial life.

Very little is known of Punic religion except that to the Greeks and Romans it was abominable because of its brutality and human sacrifices. The burials in the precinct of Tanith are certainly those of children sacrificed to the goddess Tanith and the god Baal Amon, although there is only one figural representation of such a sacrifice taking place, a gravestone which depicts a priest offering a human child. The god Moloch, who was supposed to have images of metal containing furnaces in which human victims were burned alive, is perhaps a Greek invention coined from MLK, a type of Punic sacrifice (cf. biblical "molech").

Tanith, whose full name *Tanit pene baal* means "Tanith, face of Baal," was the chief goddess of Carthage and is represented on innumerable monuments by her symbols of a disk and crescent moon and by the shape of a triangle surmounted by a crossbar and circle. She is equivalent to the Phoenician Astarte and has some of the aspects of the Egyptian goddesses Isis and Hathor. Punic representations of her show her wrapped in double pairs of wings and wearing the Hathoric disk and horns.

The role and iconography of Baal Amon in the early period are unknown. Representations of male deities are rare at Carthage, but from the 3rd century B.C. onward he was represented as a bearded figure with ram's horns. With him was associated Eshmun, a god of the Phoenician homeland, to whom a large temple was built on the Byrsa.

There were probably a number of other small gods but chief of these was the Baal of Carthage and Tyre who bore the title Melkarth (city king). A number of representations reveal him as a bearded figure wearing a tall conical cap and carrying an oriental type of ax.

During the greater part of Carthage's history, temple architecture probably followed Greek patterns. A Punic temple tariff found in Marseilles lists the prices of various animals which could be purchased from the temple for sacrifice and also refers to temple prostitutes, recognized adjuncts of Phoenician temples.

sacrifice of animals played a considerable part in Punic religion, especially in connection with funerary customs. Bones of small rodents were frequently interred with the

rich oligarchy of the city. Important matters governing the affairs of the city were decided by a larger council of 300 members. All citizens of Carthage, other than slaves, were able to elect members to this latter council, but only members of the oligarchy were available for election. Members of the council of 30 and the *suffetes* were elected by the council of 300. The "oligarchy" was not, however, a closed group: members of the public who were able to show a certain property qualification, of an extent unknown, probably automatically became members of it.

The financial affairs of the city were in the hands of a board of 100 ex-magistrates and officers. Continued re-election to this board formed of it a kind of permanent and professional fiscal body. One of its main responsibilities was the payment of the numerous mercenaries employed in the Carthaginian armies.

Cultural Life.—The standard of cultural life enjoyed by the Carthaginians was probably far behind that of the larger cities of the classical world, but when the Romans sacked Carthage in 146 B.C. they found libraries of extensive literature in Punic. Timaeus also states that Rings Hiempsal and Juba II of Mauretania were interested in Phoenician letters and collected libraries. Of Punic literature, however, all that has survived is the knowledge that a certain Mago wrote a book on agriculture and that Hanno wrote an account of his voyage to west Africa. In the visual arts the Carthaginians were completely tasteless. Their own cultural background was mixed and their artistic abilities devoted to copying the ideas of others, usually the worst ideas, and making serviceable mass-produced goods. Neither the mass-produced pottery nor terra cottas or the surviving bits of jewelry show any appreciation of design and some are frankly hideous. Although at least one Carthaginian sculptor enjoyed a moderate fame in ancient times, no surviving work shows even outstanding ability at modeling or drawing.

Commerce.—It was toward commerce that Punic interests were turned. In Roman times, Punic beds, cushions and mattresses were regarded as luxuries and Punic joinery and furniture were copied. Much of the revenue of Carthage came from its exploitation of the north African and south Spanish silver mines, begun as early as 800 B.C. Lead and silver were also obtained from Sardinia, pitch from Iviza and esparto grass from the Valencian coast. In the Atlas mountains the Carthaginians found the same cedars and junipers which had made the homeland Phoenicians rich. Olives and dates were exported in amphorae to Italy and Gaul, while the city's colonies traded in humbler commodities such as salt and salt fish. The rich fauna of the African hinterland were available for export to the Roman circuses and the trade in African ivory was Carthage's monopoly. At different periods imports included Greek and Etruscan pottery and Egyptian amulets and beads.

The Punic Wars.—(For a full account of these wars see PUNIC WARS.) The First Punic War (264–241 B.C.) was fought by Carthage for the defense of its Sicilian possessions and for its supremacy in the Tyrrhenian sea. After Rome's final victory at the Aegates Islands (241 B.C.) Carthage desired to disband its forces, but the mercenaries claimed their arrears of pay and, on being refused, revolted under Spendius and Matho, pillaged the suburbs of Carthage and laid siege to the city itself. The genius of Hamilcar Barca raised the siege; the mercenaries were cut down "defile of the axe."

Carthage then undertook the conquest of Spain. It lasted nine years up to the date of Hamilcar's death. His son-in-law, Hasdrubal, concluded with Rome a boundary boundary Carthage's northern boundary. Hasdrubal's death in 228 B.C. led to the Third Punic War.

Carthage was able to borrow large sums from the Egyptian Ptolemies and Hannibal built up a strong army equipped, on Ptolemaic lines, with elephants.

Although stripped of its African possessions and having lost its fleet in this war Carthage soon revived and, now with a population of about 700,000 (according to Strabo who gives the only figures on the city's population) never ceased to inspire alarm at Rome. The Numidian prince, Masinissa (*q.v.*), rival of Syphax and a Roman protégé, took advantage of a clause in the treaty of 201 B.C. which forbade Carthage to make war without the consent of the Roman senate, to extend his possessions at the expense of Carthage. In response to a protest from Carthage an embassy including M. Porcius Cato the Censor was sent to inquire into the matter, and Cato was so impressed with the resources of the city that on returning to Rome he never made a speech without concluding with the warning "Carthage must be destroyed."

At this time the popular faction in Carthage, which was turbulent and exasperated by the bad faith of the Romans, expelled the Numidian party and declared war in 149 B.C. on Masinissa who was victorious at Oroscopa. Rome then intervened. The Third Punic War lasted three years, and after a heroic resistance the city fell in 146 B.C. The last champions of liberty entrenched themselves under Hasdrubal in the temple of Eshmun. The Roman troops were let loose to plunder and burn. The site was dedicated to the infernal gods, and all human habitation throughout the ruined area was forbidden.

Roman and Christian Carthage.—A quarter of a century after this destruction the Roman senate entrusted C. Gracchus and Fulvius Flaccus with the foundation of the Colonia Junonia on the site (122 B.C.). It lasted only 30 years and was ill-omened from the start, so that the senate finally abrogated the law governing its foundation. Pursuing the last supporters of Pompey, Julius Caesar visited the site and the proposal for a new foundation was taken up by Lepidus during the second triumvirate. Caesar sent there a number of landless citizens and in 29 B.C. Augustus sent a body of *togati cives* and centred the administration of the African province there. Henceforth it became known as Colonia Julia Carthago and the new colony set about acquiring a prosperity which was soon to rank it with Alexandria and Antioch. Pomponius Mela and Strabo describe Carthage as one of the wealthiest and most populous cities of the empire and Herodian puts it second only to Rome. Carthage shared also in the vicissitudes of imperial succession and supported the revolt of Clodius Macer, legate of Numidia in A.D. 68, and proclaimed Piso, governor of Africa, as emperor at the accession of Vitellius (A.D. 69).

Carthage became a favourite city of the emperors, though none resided there. Hadrian, who greatly embellished it, was keen to call it Hadrianopolis. Antoninus Pius gave the city its chief baths. Commodus changed its name to Alexandria Commodiana Carthago and Caracalla added to Julia, Aurelia Antninniana. Of its history under the later emperors but from the mid-3rd century the city

ever. captured by Maxentius and strangled. About A.D. 311 there arose the Donatist heresy, supported by 270 African bishops. At the synod of Carthage in A.D. 411 this heresy was condemned owing to the eloquence of Augustine. Two years later the Carthaginian sectaries even ventured upon a political rebellion under the leadership of Heraclinus, who proclaimed himself emperor and actually dared to make a descent on Italy itself, leaving his son-in-law Sabinus in command at Carthage. Being defeated he fled to Carthage where he was put to death (A.D. 413). Donatism was followed by Pelagianism and these religious troubles were not settled when in May A.D. 429 the Vandals, on the appeal of Bonifacius, governor of Africa, crossed the Straits of Gibraltar and invaded Mauretania. Gaiseric appeared in A.D. 439 before the walls of Carthage. He entered almost without a blow and gave over the city to plunder. From this time Carthage became, in the hands of the Vandals, a mere pirate stronghold. Vandal remains are limited to coinage and jewelry. Once, in A.D. 470, the fleet of the Eastern empire under the orders of Basiliscus appeared in the Bay of Carthage, but Gaiseric succeeded in setting fire to the attacking ships and from the Byrsa watched their entire annihilation.

Under Gaiseric's successors Carthage was still the scene of many displays of savage brutality, though Thrasamund built new baths and a basilica and the city enjoyed a final period of economic prosperity. Gelimer, the last Vandal king, was defeated at Decimum by the Byzantine army under Belisarius, who entered Carthage unopposed (A.D. 533). The restored city now received the name of Colonia Justiniana Carthago; Belisarius rebuilt the walls and entrusted the government to Solomon.

At length the Arabs, having conquered Cyrenaica and Tripolitania (A.D. 642), and founded Kairouan (A.D. 671), arrived before Carthage. In A.D. 697 Hasan ibn Noman, the Ghassanid governor of Egypt, captured the city almost without resistance. But the patrician Ioannes retook the city and put it in a state of defense. Hasan returned, defeated the Byzantines again; and decreed the entire destruction of the city. In A.D. 698 Carthage finally disappears from history. Once again only does the name appear, in the middle ages, when the French king Louis IX, at the head of the 8th crusade, disembarked there on July 17, 1270, and founded a shrine. For the history of the site from its final destruction until modern times the only sources are the Arab geographers and the early medieval traveler Victor da Vita.

ROMAN AND CHRISTIAN CITY

Roman Carthage was not fortified until barbarian invasion threatened in A.D. 425, when walls were built by Theodosius II. The outline of these walls is not certain, but traces of a number of fortification walls have been found which were designed to prevent invasion from the *ligula*, the tongue of land between the gulf and the lake. It also appears that the Byrsa was separately fortified. Under Hadrian an aqueduct 138 km. long was built. Part of it is still standing with its arches 40 m. high. There also survive parts of Carthage's two ports.

The Romans adorned the Byrsa with a large temple dedicated to Juno, Jupiter and Minerva, and near it stood a temple to Aesculapius (Asclepius). On the area of the Byrsa overlooking the sea stood an open-air portico, a largely ornamental building, from which elaborate statues of Victory and Abundance, the finest Roman sculptures at Carthage, have survived. On the slopes of the Byrsa a temple was dedicated to the family of Augustus. Besides sharing the temple on the new Capitol, Juno-Caelestis had a special temple beside the sea in front of the Byrsa. Between them lay a temple of Saturn. A Serapeum lay at Douïmès and a temple of Demeter between Bord Djedid and Ste. Monique. There also existed in an unknown locality a temple of Memoria.

On the periphery of the town east of the Byrsa lay the Odeon designed for musical performances. Of this there are few remains and more survives of the nearby theatre constructed by Hadrian in the early 2nd century A.D. The amphitheatre modeled on the Roman coliseum and capable of seating 80,000 people lay to the

northeast. In this St. Perpetua and St. Felicity were martyred in A.D. 203. Over to the west lay the Circus. The site of a stadium mentioned by Tertullian is unknown. Several public baths served the city. The largest were the baths of Antonius (2nd century) at Bord Djedid in the locality called Dermech. Also important are the baths of Gargilus, where in A.D. 411 conferences between the Catholic and Donatist bishops took place, but no ruins correspond to the baths built by Justinian in honour of Theodora.

The Christian buildings within the city, apart from a few Vandal structures, are all Byzantine. The largest basilica is at 31r Knissa which was rebuilt in the 6th century on the site of an earlier basilica. Probably the earliest surviving Christian structure is the small basilica near the Antonine baths which might be that of St. Peter built by Justinian. Certainly churches existed in the 3rd-4th centuries but of these no traces remain not even of the primatial basilica where St. Augustine preached. From an inscription it is known that there was a basilica of the Theotokos (Mother of God) on the Byrsa and the basilica of Honorius was probably near the temple of Caelestis, but the site of the basilica of Faustus is unknown. Of the earlier basilicas, one dedicated to the Blessed Martyrs at the foot of the hill on which the Odeon stands was perhaps the most beautiful. Its surviving mosaics, the earliest Byzantine mosaics, incorporate the names of unknown martyrs. The relics of the martyrs St. Perpetua and St. Felicity were kept in the confessional of the basilica dedicated to them at Mcidfa and the inscription placed above their tomb was discovered there in 1929. St. Cyprian, who was responsible for their cult, was himself commemorated by three churches.

Much that is known of the antiquities of Carthage—Punic Roman and Christian—is due to the presence of the White Fathers, the enthusiasm of Cardinal Charles Lavigérie (*q.v.*) and the work of Père Alfred Delattre in the closing years of the 19th century. Besides the antiquities here mentioned others are to be found in the Musée Lavigérie de Carthage, the Musée Archéologique de Carthage (Direction des Antiquités de la Tunisie), the Musée du Bardo, Tunis, the British museum, the Musée du Louvre and the Leiden Museum of Antiquities. Punic antiquities are also to be found in the museums of Algiers, Constantine, Cádiz, Iviza, Barcelona, Mozia and Cagliari.

CARTHAGE, a city in southwestern Missouri, C.S., seat of Jasper county: is 17 mi. N.W. of Joplin and 148 mi. S. of Kansas City. It is noted for its Burlington limestone quarries, the largest of their kind in the world. Established in 1842, the city, like ancient Carthage for which it was named, was once completely destroyed. In 1863 Confederate guerrillas, angered by a Union garrison, razed the town. It was rebuilt in 1866 and chartered as a city in 1873.

The municipally owned electricity and water plant is a model of small-town public utilities operation. Carthage is the trade centre for an agricultural area producing strawberries and other small fruits, poultry and dairy products. The manufacture of clothing is the most important industry except the quarrying and finishing of limestone. Operation of the lead and zinc mines, once important in the area, is no longer profitable.

For comparative population figures see table in MISSOURI: *Population*. (E. R. St.)
