In the modern corporation the salaried manager is both a fiduciary and a skilled specialist. Under these circumstances a professional attitude is likely to develop, and indeed "business statesmanship" is the accepted ideal.

Self-government in Business.—The functional specialization of salaried corporate managers provided the initial impetus toward the self-regulation of business through codes of ethics. As loyalty to function succeeded loyalty to firm or industry, purchasing agents, advertising managers, credit managers and others began to organize themselves into associations and to adopt codes of ethics modeled upon those of medical and legal practitioners. Considerations essentially professional in character began to displace unqualified acceptance of the profit motive, as modern financial institutions and practices converted profits into salaries and dividends and so dulled the profit motive in a new generation which

was not accustomed to thinking of pecuniary advancement in terms of capital gains.

Codes of ethics encompassing whole industries followed naturally from the early tendencies of functional specialists toward professional organization. After World War I the trade-association movement developed rapidly, and the activities of the trade associations directed toward formulation of industry-wide codes of fair competition were greatly stimulated by the Federal Trade commission (*q.v.*). During the period 1919–25 misrepresentation of quality, commercial bribery and similar practices were widespread in U.S. business; competition forced the low standards of the unethical minority upon all who wished to survive. The Federal Trade commission arranged informal meetings of representatives of affected firms at which proposed standards of ethical conduct and definitions of unfair practices were drafted. The commission submitted these proposals to the industry and used them for the promotion of ethical standards of business conduct and as a guide in the selection of defendants for prosecution under the Clayton Anti-trust act and Federal Trade Commission act. After 1925 these meetings were formalized and further developed as "trade practice conferences" through which the Federal Trade commission co-operated with business in the development of codes of business ethics on a much broader scale.

The codes formulated through the trade practice conferences were supported by the moral and legal power of the Federal Trade commission and were taken much more seriously by violators than the earlier codes which could be enforced only by such extralegal sanctions as the trade associations themselves were able to impose. The co-operative attitude of the commission, the enforceability of codes drafted under its supervision, and the erroneous notion that the commission's blessing amounted to a suspension of the antitrust laws encouraged the formulation of increasingly broad codes which had the effect of eliminating competition while purporting to make competition fair. Costing systems tending to encourage price uniformity, uniform terms of sale, basing-point systems, perpetuation by artificial means of traditional marketing institutions and channels, prohibitions of sales below cost and the like began to be required by the codes. The self-regulation which the business community was so eager to practise threatened to develop into cartelization, and in 1930, after the department of justice questioned the legality of some of these code provisions, the Federal Trade commission drastically modified the trade practice conference procedure. Business confidence in the government-supervised code device was badly shaken and the popularity of the trade-practice conferences declined. Agitation for alteration of the antitrust laws took the place of the conferences, but business pressure for self-regulation did not produce results until the National Industrial Recovery act (NIRA) became law in 1933.

This abortive experiment in industrial self-government lasted only two years; in 1935 the United States supreme court held it to be an unconstitutional delegation of the legislative power of congress. During the life of the NIRA the antitrust laws were suspended to permit trade associations and other industry representatives to draft comprehensive codes of fair trade practice which would have the force of law upon their approval by the president. These codes regulated the wages and hours of labour in such a way as to "spread the work" and maintain consumer purchasing power during the economic depression which the law was designed to ameliorate. They also commonly allowed co-operative industrial price fixing and production control and generally tended toward rapid and extensive cartelization of business and almost total abandonment of the competitive ideal which theretofore had characterized U.S. economic policy. Insoluble conflicts of interest developed, and the impracticability of the plan had become quite apparent by the time the supreme court ended it.

After the demise of the NIRA public policy toward business regulation gradually reverted to the traditional competitive basis, with restraint of trade and monopoly controlled by the antitrust laws; business codes designed to regulate unfair methods of competition still were encouraged within the limitations of the antitrust laws. The Federal Trade commission's trade practice conferences were continued on a modest scale for the purpose of maintaining

competition on a satisfactory plane, and the commission's power to control unfair methods of competition directly was strengthened through supplementary legislation. Trade associations continued to assist the commission to discover and prosecute violations of law and to encourage ethical standards of competition on the part of members of their trades.

Industrial self-government had a full and fair trial in the United States and was found to be a practicable policy only within narrow limits and for specialized purposes. It was a useful technique for the efficient and economical accomplishment of certain desirable purposes, but it failed to eliminate unfair competition and threatened competition itself. Self-regulation was found practicable under U.S. conditions only within the basically competitive framework established by the antitrust laws and subject to such direct regulation of business practice as might be required under particular circumstances. Experience during World War II and the postwar transition period supported this conclusion: self-regulatory business codes proved useful for certain purposes, but direct control of a quite drastic sort was essential to the achievement of national objectives.

Business Codes as Law.—The trade practice conference device tends to give business codes the force of law. In a broader sense, it may be said that, though the law controls business, business makes the law. The standards and practices of the business community tend in time to become formalized as rules of law. The common law of commerce, including but not limited to the law merchant, and the statutory codifications and extensions of this law, are but the crystallization and restatement of business experience: law is the broadest business code.

BUSINESS CYCLE, a general fluctuation in the economy of a country that relies chiefly on private enterprise to organize the production and distribution of goods. Such a fluctuation is characterized by expansions that occur at approximately the same time in nearly all aspects of economic life—the earning and spending of income, industrial production, employment, trade (both domestic and foreign), security market activity and the prices of both commodities and securities—followed by similarly general contractions.

In simplest terms it is an alternation of prosperity and depression, or recession. Some branches of activity whose long-term rate of growth is very rapid continue to expand during general contractions, but usually at a reduced pace. The rise in unem-

ployment that accompanies depressions is the gravest social evil of business cycles.

In Great Britain and the United States, business cycles have succeeded one another in a virtually continuous round since at least the end of the 18th century. In other countries, evidences of cyclical fluctuation begin with their industrialization at various times in the 19th century. In the United States, business cycles characteristically have required between three and five years to run their course. Few have been shorter; a few somewhat longer. In European countries, cycles have been somewhat longer on the average and their duration less regular than in the United States.

Most business contractions are mild, but some have been very serious. The table below shows how different has been the impact of contraction. Even mild contractions, however, hit some branches of industry hard. The durable goods industries are a notable example. In such sectors, many workers lose their jobs even when the economy at large is little disturbed.

Among the serious contractions, the depression that began in 1929 was the worst economic catastrophe of modern times. In the United States, which was among the hardest hit of all countries, total output declined over 30% between 1929 and 1932. In the latter year, 25% of all workers were unemployed, and even in 1940, although employment had risen by 9,000,000, over 8,000,000, amounting to nearly 15% of an increased labour force, were still unable to find jobs.

Minor Cycles.—Because their characteristics are somewhat different, economists distinguish business cycles with mild and short contractions from those that include severe or protracted depressions. In the first group, often called minor cycles or recessions, almost the entire decline in output during contractions can be traced to a reduction in consumers' purchases of automobiles, furniture and the like (consumer durables), in business purchases of machinery and equipment (producer durables), and, most of all, to a decline in the volume of goods which business firms add to their stocks or inventories (inventory investment). Although in the United States these categories make up no more than 15% of total output on the average of good years and bad, they usually account for 80% or more of the declines in output during minor contractions.

The decline of inventory investment alone accounts for a major share of the total decline during minor contractions. The goods added to stocks normally make up far less than 1% of total output. Near the peaks of minor cycles, however, it will often happen that 3% or more of total output is intended for building up stocks. Near the troughs, on the other hand, businessmen will be content to fill 3% or more of their sales by drawing down inventories. The difference implies a drop of 6% or more in production which is very large compared with the total decline of output. In minor contractions, therefore, well over half the decline in total output typically results from a change-over from building up inventories in the boom to selling them off in the downswing.

The successive expansions and contractions of income, production and employment have a cumulative character which derives in the first place from the interaction of changes in incomes and

changes in consumer expenditures. Economists call this interaction the multiplier process.

An increase in incomes, however earned, encourages a larger volume of consumer expenditures.

The consequent increase in sales leads to increased production and, if there are unemployed, more men are put to work. The level of income earned thus rises still more and drives the process on to second and higher rounds. In contractions, the process is reversed.

The multiplier process tends to be self-limiting because consumer expenditures usually rise

or decline by much less than the change in the community's total income, the difference representing a change in the sums taken by taxation, retained by corporations out of profits or saved by consumers. The stimulus which any single change in income flow gives to the consumer goods industries is, therefore, transmitted with steadily diminishing force and tends to die out. The forces of expansion or contraction, however, gain renewed strength from coincident changes in inventory investment and business purchases of durable equipment; but it is also through these categories of investment that the forces which tend to reverse the direction of the business tides usually act.

Consider, first, inventory investment. Business firms seek to maintain a fairly constant ratio between inventories and sales or output. The volume of goods available for sale at any time, however, reflects the level of production decided upon, or the level of orders placed, sometime earlier. Consequently, at the beginning of expansion, an upturn in demand usually finds the current flow of production inadequate. Since business firms satisfy at least part of the increment in demand by drawing down inventories, the desired balance between inventories and sales is temporarily upset. This gives a strong stimulus to business firms to place larger orders or to expand production, partly to meet the increased volume of sales, partly to replenish inventories and partly to accumulate stocks to accommodate the higher level of sales. At first, the attempts to build up stocks are partially self-defeating. For the multiplier process set in motion by the expansion in employment also enlarges income and sales. For a time, therefore, stocks remain unduly low; the pressure to expand employment persists and helps to drive the economy to higher levels. After a time, however, the rise of demand slackens and manufacturers and distributors gradually overcome their inventory deficiencies. This may stop the expansion or actually depress business. Purchases and orders are now required only to meet the current level of sales, whereas formerly they also included amounts destined to be added to stocks. This difference is sometimes large enough to cause cuts in employment and the process then goes into reverse. In any event, it retards the growth of incomes and so makes the economy more vulnerable to a downturn initiated by other causes. When orders and sales do fall, business finds it cannot dispose of all it has produced. Stocks pile up, and the attempt to liquidate unwanted inventories combines with the multiplier process to drive the economy downward.

The inventory-adjustment and multiplier processes, however, do not work alone. Business expansion also activates investment in plant and equipment. The expansion of demand makes production capacity in many lines inadequate. It also causes profits to rise rapidly and widely. This strengthens the faith of businessmen in the future. It encourages old firms to carry out expansion plans and new firms to enter business. The increase in profits also encourages capital expenditure by facilitating financing; profits retained by business can be used for capital expenditure; and high profits create a favourable market for securities in which large corporations find it easy to float stock. At the same time, the rise in profits improves the credit standing of most firms and encourages banks and others to lend more freely.

As with inventory investment, the expansion of expenditures on durable capital is gradually checked. With intensified activity, prices of labour and materials rise. This tends to raise production costs, lower profit margins and discourage some firms from making investments. Other firms are put off by higher prices of machinery and buildings. Still others find that the demand for additional financing has driven up interest rates and made credit harder to obtain. In some industries, the pressure to expand capacity is reduced by the completion of plant and equipment ordered earlier in the boom, while in others the same thing occurs when the rate of growth of demand has slowed down. These developments sometimes actually can bring about a downturn in capital goods production. But even if its expansion is merely checked, the economy becomes more vulnerable to recession stemming from the inventory-adjustment process. When a downturn starts, business investment in durables is reduced, thus aggravating the general contraction.

In addition to the factors already considered, foreign trade plays a part in the cyclical process. It is especially important for countries like Great Britain that export a large portion of their output and import a large portion of the goods they fabricate or consume. Dependence on a market for exports involves such countries in the rising or declining fortunes of their foreign customers. When countries which are heavy importers suffer a contraction of income they naturally reduce their purchases abroad.

The process by which contractions gather force, slow down and finally give way to expansions is similar to that by which expansions first gain strength and later weaken. No contraction, however, is the exact mirror image of expansion. The chief reason is that expansions swim with the tide of long-term economic growth while contractions must breast it. Moreover, no full cycle is the identical twin of any other. Wars and civil disorder, speculative movements, the changing economic policies of governments, the accidents of harvests and the vagaries of foreign demand act to disturb the course of cyclical fluctuations in many unpredictable ways. Thus the mechanism as well as the observable features of business cycles change from occasion to occasion, a fact which has so far thwarted attempts at accurate business forecasting.

Major Depression.—Neither the characteristics nor the causes of the more serious contractions are as well established as those of the minor contractions. Some deep depressions seem to be of the class to which the minor movements belong. Others, however, display certain distinctive features which suggest that they constitute a separate class of disturbances. The latter are not only more than normally deep, they also last longer than minor recessions. Depressions may be of extended duration either in the sense that business activity declines without interruption for several years or in the sense that recoveries, if they occur, fail to bring the economy back to full employment levels or do so only briefly.

Long, severe contractions occurred in the United States in the years 1837–43, 1873–78, 1882–85, 1892–96 and 1929–32. Severe, short contractions occurred in 1857–58, 1907–08, 1920–21 and 1937–38. The minor contractions in each country have tended to run to some extent independently of business cycles in other countries but the severe depressions have usually been nearly world-wide in scope.

Apart from widespread unemployment, the distinctive features of depressions that were long as well as severe were serious declines or protracted cessations of growth in construction activity, declines in population growth and labour force growth, and great reductions in international capital movements. In the United States and in many other countries, financial panics, involving a collapse of security prices, the failure of commercial and investment banks, and the suspension of payments against bank deposits, were also characteristic of these episodes, as well as of some of the shorter severe depressions. (See PANIC.)

Two sorts of explanations have been offered for these occurrences. They are sometimes attributed simply to accidental combinations of unfavourable circumstances. In this view, each serious depression has its own particular origins. Among the causes suggested are inadequacy in the rate of growth of the money supply, hoarding and scarcity of credit brought on by financial panics, overinvestment in industry or real estate, and fortuitous declines in the investment opportunities afforded by technological advance or population growth. Another view holds that protracted depressions are the systematic outcome of a cyclical or quasi-cyclical process—a long wave in economic growth. These waves are attributed by some to the great swings observed in urban building activity, or in urban building activity in association with a similar fluctuation in the construction of transport facilities. The theoretical and empirical links in these proposed cyclical chains, however, are not yet clearly established. The significance of the long wave theory of serious depressions is, therefore, still uncertain.

Stabilizing Influences in Modern Economics.—In recent decades the evolution of economic life and certain changes in institutional arrangements and governmental policies have combined to reduce the vulnerability of economic activity to serious contractions. Examples from the United States will serve to illustrate a class of developments experienced in many countries.

One set of changes has served to weaken the impact of the multiplier process; the chain of reactions remains but the responses are less strong. Thus when business falls off, the incomes of the unemployed are partially protected by the payment of unemployment insurance benefits. Secondly, the incomes of business investors are better cushioned against sharp declines in profits because corporations keep dividend payments far more stable than their profits. Thirdly, taxes on corporate and personal income, which take a much larger share of all incomes, work in the same direction. When earnings decline during business contractions, income taxes decline also. Thus both corporate and personal incomes after taxes decline less than earnings before taxes. As a result, corporations are better able to maintain dividends and capital expenditures in the face of a decline in profits, and households are better able to maintain consumption expenditures. The result is a net gain for economic stability, for a larger portion of the shock of declining earnings is assumed by government, especially the federal government, which can better sustain expenditure when revenues decline than can private individuals or corporations.

The United States is also better armed against financial panic than it used to be, not only through the federal reserve system (*q.v.*), which can enlarge bank reserves at need, but still more through the Federal Deposit Insurance corporation, which provides a government guaranty of bank deposits. A large-scale run on banks and, therefore, a breakdown of the banking system, is no longer a practical possibility in the United States.

The U.S. Employment act of 1946 declared that it is ". . . the continuing policy and responsibility of the Federal Government to use all practicable means . . . to promote maximum employment, production and purchasing power. . . ." To meet this responsibility, the government, acting in part through the federal reserve system, has tried since 1946 to stabilize private expenditures or to offset their fluctuations by a variety of measures. These efforts have included control of the money supply, of rates of interest and terms of lending, especially on residential mortgages, acceleration or retardation of government expenditures and changes in tax rates. The success of these measures in helping to cope with the comparatively short and mild recessions of the post-World War II period is a matter of some dispute. It seems clear, however, that the U.S. government, like many other governments, is prepared to counter the danger of severe depression, should it arise, by large increases in government expenditures, by tax cuts and by measures to increase the money supply and reduce the cost of finance.

Not all the changes of recent decades are potentially stabilizing. In particular, the fluctuations of military expenditures under the pressures of the "cold war" may be a disturbing factor of considerable importance. On balance, however, the developments sketched above give promise that business contractions in the future will be less violent, at least on the average, than they have been in the past. While intervals of retarded growth and, therefore, of undesirably high unemployment rates may yet be experienced, it seems much less likely that serious depression should be suffered for protracted periods.

BUSINESS LAW, also called commercial law or mercantile law, is the body of law that governs commercial transactions and business organizations. Business law is studied at universities and at colleges or schools of business administration. The latter institutions approach business law as an essential element in the

professional training of business executives (whereas the law schools are primarily concerned with the training of practising lawyers), and often stress the connection of this branch of law with the economic, financial, managerial and sociological aspects of business.

Anglo-American business law traces its origins to the law merchant (*q.v.*), which was finally incorporated by Lord Mansfield, English chief justice, into the common law during the 18th century. Many important treatises on commercial law were published in that and the following century of which those of the French jurist R. J. Pothier (1699-1772), *Traité des obligations* (1761) and *Traité du contrat de vente* (1762); of the English lawyer Lord Blackburn (1813-96) on the Contract of Sale (1845) and of Judah P. Benjamin (1811-84) on the Law of Sale of Personal Property (1868) may be mentioned. Benjamin was an American lawyer who became a member of the Confederate government during the American Civil War and at the end of the war took refuge in England where he was admitted to the bar and published his famous treatise. In many countries business law or some branches of that subject are codified.

As an academic specialty business law developed after World War I as an integral feature of the modern U.S. school of business. In Europe and Great Britain periodicals specializing in business law provide a forum of discussion for those interested in the development and progress of this branch of law; the oldest of these periodicals is the German Zeitschrift *für das Gesamte Handelsrecht und Konkursrecht*, founded by Levin Goldschmidt in 1858; others are the French *Revue Trimestrielle de Droit Commercial*, the Italian *Revista di Diritto Commerciale* and the British *Journal of Business Law*. The American Business Law association includes most of the leading U.S. authorities on the subject and devotes itself to the advancement of business law through regional and national meetings and scholarly publications.

Business law includes two chief subdivisions: business transactions and business organization. The cornerstone of business transactions is the law of contracts (see CONTRACT), which deals with legally enforceable business agreements and the rules governing their negotiation, interpretation and performance. The fundamental principles of contract law are applied to such specialized topics as sales of goods, commercial paper (promissory notes, bills of exchange, checks, bonds and shares, etc.), debtor-creditor relations and insurance. (See SALE OF GOODS; COMMERCIAL PAPER; INVESTMENT PAPER; DEBTOR AND CREDITOR LAW.)

The law of business organization, as distinguished from the law of business transactions, pertains to the various legal forms in which capital may be organized for the purpose of conducting business transactions. Chief among these are the sole proprietorship, the partnership and the limited liability company or corporation. The principles of the law of agency, which establish rules enabling a person or business organization to act through agents or servants, underlie the entire field and, second only to contracts, constitute a primary element of business law. See COMPANY; CORPORATION; PARTNERSHIP; AGENCY.

BUSIRI, AL- (Arab., SHARAF-AL-DIN MUHAMMAD AL-BUSIRI) (c. 1212-c. 1294), Arabian poet of Berber extraction, won fame which is due almost wholly to his poem *al-Burdah* ("The Poem of the Mantle"). He was born in Egypt about 1212 and died in Alexandria about 1294, but lived for many years in Jerusalem and Arabia. His famous poem was written in Mecca and is in praise of Mohammed who cured the poet of paralysis by appearing to him in a dream and wrapping him in a mantle. Even in the poet's lifetime the poem was regarded as sacred. Its verses are used as amulets; it is employed in the lamentations for the dead; it has been frequently edited and made the basis for other poems, and new poems have been made by interpolating four or

six lines after each line of the original.

See Eng. trans., *The Scarf*, by Faizullah Bhai (1893); C. Brockelmann, *Geschichte der arabischen Literatur*, vol. i, pp. 264–267 (1898).

BUSIRIS, in Greek legend, an Egyptian king, son of Poseidon and Lyssianassa. After Egypt had been afflicted for nine years with famine. Phrasius, a seer of Cyprus, arrived in Egypt and announced that the end of the famine would not take place until a foreigner was yearly sacrificed to Zeus. Busiris began by sacrificing the prophet and continued the custom by offering a foreigner on the altar of the god. It is here that Busiris enters into the circle of the myths of Hercules, who had arrived in Egypt from Libya and was seized and bound ready to be killed and offered at the altar of Zeus in Memphis. Hercules burst his bonds and, seizing his club, slew Busiris with his son Amphidamas and his herald Chalbes. This exploit is often represented on vase paintings from the 6th century B.C. and onward, and the legend is referred to by Herodotus and later writers.

Although some of the Greek writers made Busiris an Egyptian king and a successor of Menes, about the 6th of the series and the builder of Thebes, those better informed by the Egyptians rejected him altogether. Various esoteric explanations were given of the myth, and the name not found as a king was recognized as that of the tomb of Osiris. Busiris is here probably an earlier and less accurate Grecism than Osiris for the name of the Egyptian god Usire. All shrines of Osiris were called *P-usiri* (Busiris), but the principal city of the name was in the centre of the Delta, capital of the ninth (Busirite) nome of lower Egypt. The name Busiris in the legend may have been caught up merely at random by the early Greeks, or they may have vaguely connected their legend with the Egyptian myth of the slaying of Osiris (as king of Egypt) by his mighty brother Set, who was in certain aspects a patron of foreigners. Phrasius, Chalbes and Epaphus (for the grandfather of Busiris) are all explicable as Grecized Egyptian names, but other names in the legend are purely Greek.

The sacrifice of foreign prisoners before a god, a regular scene on temple walls, is perhaps only symbolic for the later days of Egyptian history, but foreign intruders must often have suffered harsh treatment at the hands of the Egyptians, in spite of the generally mild character of the latter.

(F. LL. G.; X.)

BUSKEN HUET, CONRAD (1826–1886), the greatest, and also one of the liveliest, Dutch literary critics of his time, was born at The Hague, Dec. 30, 1826, of an old French Protestant family. He studied theology at Leiden and became pastor of the Walloon chapel at Haarlem, but resigned because of his modernist views. He turned to literary criticism, and from 1862 to 1865 was an editor of the influential literary magazine, *De Gids*. After many disappointments, he left Holland for the Dutch East Indies where he worked as a journalist, and for the last years of his life lived in Paris, where he died, June 1, 1886.

As a critic, Busken Huet took C. A. Sainte-Beuve and Georg Brandes as his guides, and sought to bring Dutch literature into closer touch with other European cultures. He wrote brilliantly about the Dutch classics, about the minor Dutch poets, and about both the classic and modern literature of other countries. He castigated some of the Dutch writers of his own time severely for their narrowness and dullness. Busken Huet collected his most important critical writings in 25 volumes entitled *Litterarische Fantasiën en Krieken*: they are still read with enjoyment for their style and acute perception. His history of Dutch culture in the 17th century, *Het land van Rembrand* (1882–84), remains a classic.

See C. G. N. de Vooy, *Busken Huet* (1949).

(J. C. B. C.)

BUSKERUD, a fylke (county) in south central Norway, extends 130 mi. northwestward from Oslo fiord to the mountains of Hardangervidda in the centre of the country. Area 5,718 sq. mi.; pop. (1959 est.) 166,786. Caledonian rocks in thrust masses form high peaks (Hallingskarv, 6,342 ft.) over a plateau of altered Cambro-Silurian schist (3,230 ft.) giving summer pastures for the valley farms. The schist is deposited on Pre-Cambrian bedrock into which the deep forested valleys of Hallingdal

and Numedal are cut. In the eastern part of the fylke the schist lowland of Ringerike forms a basin containing a lake, Tyri fiord, which is drained by the Drammen (Dramselva) river to Oslo fiord. The lowland districts contain 75% of the population. Drammen (administrative headquarters of the fylke) on Drammen fiord and Hønefoss in Ringerike are industrial and commercial towns; several pulp and paper mills are located along the Drammen river. At Kongsberg (pop. [1959 est.] 9,499) silver mines were worked from 1624 to 1937. The eastern lowlands are agricultural districts, fruit, vegetables and corn being grown. The Oslo-Bergen railway follows Hallingdal; the Oslo-Stavanger railway goes via Drammen and Kongsberg with a branch line through Numedal. (L. H. HG.)

BUSONI, FERRUCCIO BENVENUTO (1866–1924), Italian musician who attained fame as a pianist of brilliance and intellectual power, but was also an important composer. The son of an Italian clarinetist and a pianist of German descent, Busoni was born at Empoli, Tuscany, April 1, 1866. Taught by his mother, he appeared as a child prodigy and later completed his studies in Vienna and Leipzig. In 1888 he became professor of pianoforte at Helsingfors (Helsinki), and from there he moved to Moscow and later to the United States. From 1894 to 1914 he lived in Berlin, conducting a series of orchestral concerts containing music by his contemporaries and making concert tours devoted mainly to Bach, Beethoven and Liszt. During World War I he retired to Zürich, conscious of the pull between his Italian nationality and his affinity with German music. This dichotomy affected him also as a composer, his music being compounded of romantic fervour controlled by an austere intellect and Latin brilliance and clarity. His most ambitious work was the unfinished opera *Doktor Faust*, based not on Goethe but on earlier versions of the Faust legend. It was completed by his pupil, Philipp Jarnach, and performed in Dresden (1923). Two other short operas, *Arlecchino* and *Turandot*, composed at Zürich, attempted to revive the *commedia dell'arte* in modern form. Busoni's pianoforte works include an immense *Concerto* with choral finale, six sonatinas, which contain the essence of his musical thought, and the great *Fantasia Contrappuntistica* on an unfinished fugue by Bach (two versions: 1910: one version, 1912; fourth version for two pianos, 1921), which sums up his lifelong experience of Bach's music. In 1920 he returned to Berlin, where he died on July 27, 1924.

BUSS, FRANCES MARY (1827–1894), founder of the North London Collegiate School for Girls and associate of Dorothea Beale (*q.v.*) in her work for girls' secondary education; was born in London in 1827. She attended a school in Camden Town, London, and, after teaching there for a short time, taught with her mother in a school in Kentish Town. In 1848 she attended lectures with Miss Beale at Queen's College for Ladies, also teaching in her mother's school. This was moved to Camden street and in 1850 became the North London Collegiate School for Ladies. After its recognition as a public school for girls (1871), the word "Ladies" in the title, became "Girls." This school served as a model for the high schools of the Girls' Public Day School trust.

Miss Buss appeared before the Schools Inquiry commission in 186j and testified to the need for girls' secondary schools. With the assistance of funds from the Brewers' and Clothworkers' companies, she was able to move the North London Collegiate school to other premises, and to open the Camden Girls' school in 1871.

She believed in a sound intellectual training for girls and encouraged them to take examinations, supporting the foundation of women's colleges at the universities and the improvement of teachers' training. She founded the Association of Headmistresses in 1874 and was its first president (1874–94), being succeeded by Miss Beale. Miss Buss died in London on Dec. 24, 1894.

BUSSACO (BUÇACO), a mountain in Portugal, rises steeply above the coastal plain north of the valley of the Mondego to

1,801 ft. Luso (pop. 1950, 2,561), a small spa, is the nearest railway station. The hotel on Bussaco is contiguous with the modest buildings of a Carmelite monastery founded in 1628. The famous state forest, surrounded for ten miles by a 10-ft. wall and protected in the past by various papal edicts, contains exotic cypresses, cedars and eucalyptus, as well as many mixed European and Mediterranean species, including Portuguese oaks. It is also the site of a famous victory of the duke of Wellington over the French under Marshal André Masséna (Sept. 27, 1810).

(J. M. Ho.)

BUSSUM, a town in the province of North Holland, Neth., on the shore of the IJsselmeer, 24 km. (15 mi.) E.S.E. of Amsterdam. Pop. (1957 est.) 38,064. Bussum is a garden suburb of Amsterdam and is connected to it by railway. It has several public parks, an important chocolate factory and a television studio. Bussum, originally part of the ancient town of Naarden, became an autonomous town in 1817. There is a modern town hall.

(A. P. V.)

BUSSY, ROGER DE RABUTIN, COMTE DE (called BUSSY-RABUTIN) (1618-1693), French soldier and writer, a member of the Académie Française but known chiefly for his urbane and malicious *Histoire amoureuse des Gaules*, was born at Epiry in Burgundy on April 13, 1618. An army officer from the age of 16, he served quite diligently in many campaigns. In 1644 he purchased the lieutenant-colonelcy of the light cavalry commanded by the duc d'Enghien (Louis II de Bourbon, prince de Condé in 1646); and in 1645 he succeeded his father as king's lieutenant of the Nivernais province. In the period of the Fronde, when Condé was arrested (1650), Bussy joined the rebels demanding his release; but on his release Condé, for personal reasons, made Bussy resign his lieutenant-colonelcy (1651). Bussy then offered his services to the government for the final war against Condé and the Spaniards. His new commanding officer, Turenne, found him too much given to frivolous versification. Bussy, however, bought the rank of lieutenant-colonel general of the light cavalry of France in 1653.

Meanwhile Bussy had been acquiring a worldly reputation. In 1641 he was imprisoned in the Bastille for five months because his regiment had misbehaved while he was absent with a lady; in 1648, after his first wife's death (1646), he tried to abduct a rich widow, to whose family he had eventually to pay damages; after his second marriage (1650), he still pursued other ladies, with varying success; and in Holy Week 1659 he attended a party at Roissy which was later supposed to have been an outrageous orgy. Apart from all this, he was accepted as a critic by Parisian literary society; and finally he was persuaded to put five of his scandalous stories about court ladies into writing. These stories constitute the authentic *Histoire amoureuse des Gaules*, manuscript copies of which were being circulated in 1663. Then, in 1664, Louis XIV read Bussy's short *Maximes d'amour* (in verse) with approval; and early in 1665 Bussy became a member of the Académie Française. Within a few weeks of this a secretly printed text of the *Histoire amoureuse* was published, without Bussy's consent.

This provoked extreme indignation. Bussy was sent to the Bastille for 13 months and then exiled to his Burgundian estates. There he remained for the rest of his life, save for rare intervals when he could show himself in Paris or at Versailles. His enemies made his situation worse by satirizing the royal family in spurious supplements to the *Histoire amoureuse*; and Bussy's former association with Nicolas Fouquet, the disgraced finance minister, was not forgotten. Bussy in exile devoted himself to family affairs, to a voluminous correspondence and to writing his memoirs. He died at Autun on April 9, 1693, in a Christian spirit.

The *Histoire amoureuse* is a masterpiece of elegant and witty narrative, reflecting the piquant grace of a well-informed courtier's intimate conversation. The letters of Bussy bear comparison with those of his cousin Mme. de Sévigné, to whom many of them are addressed. His memoirs are uneven, in parts vivacious, in parts preoccupied with military detail or official communications.

BUSTARD, the common name for medium to large game birds of the family Otidae, constituting the suborder Otides in the order Gruiformes, typified by the cranes and rails. The family comprises about 11 genera and 23 species, confined to the old world. The best known is the great bustard, *Otis tarda*, largest European land bird, males reaching as much as 32 lb., with four-foot length and eight-foot wingspread. It is found in grain fields and open steppes from central and southern Europe to central Asia and Manchuria. Both sexes are similar in colour, being grayish barred with black and brown above, whitish below; the male is stouter, and has whitish bristly feathers at the base of the bill. Being wary, the great bustard is difficult to approach, running swiftly when endangered. On land it assumes a stately gait; on the wing, it displays a relatively slow but powerful and sustained flight. The spring courtship ceremonies are characteristic: the cock's head is bent back almost touching the uplifted tail, the white quill feathers of the forearm are exposed and the throat pouch is inflated. Two or three eggs, olive blotched with brown, are laid in a shallow excavation sheltered by low vegetation.

ERIC HOSKING

GREAT BUSTARD (OTIS TARDA)

The little bustard, *Otis tetrax*, ranges from western Europe and Morocco to Afghanistan. The bustards of south Africa are known as paauw, the largest being the great paauw. *Ckoriotis kori*; *C. arabs* is found in Morocco and northern tropical Africa south of the Sahara; *C. australis*, in Australia, where it is called turkey; and *C. nigripes*, in northwest India. The family also includes the following: *Spheotides indica*, common over India; *Houbaropsis bengalensis*, occurring from eastern India to Indochina; *Chlamydotis undulata*, of the deserts and high plateaus of north Africa and southwest Asia; and a number of species (belonging to the genera *Neotis*, *Eupodotis*, *Lophotis* and *Lissotis*) common in desert, savanna and thornbrush country over Africa south of the Sahara.

(G. F. Ss.; X.)

BUSTELLI, FRANZ ANTON (1723-1763), modeler of porcelain figurines for the factory of Symphenburg (near Munich, Bavaria), was born at Locarno, Switz., in 1723. Nothing is known of his early life or training. Bustelli worked for Nymphenburg from 1754 to 1763, when he died. His characteristically graceful models became recognized as the most excellent porcelain sculpture of the rococo. Bustelli respected the limitations of the material even in his detailed works. Their rich colours on the milky white porcelain of Symphenburg grant them unrivaled charm. Bustelli's most famous subjects are Harlequins, Columbines, Chinese, cupid-like children, and groups such as the "Tea Party." Bustelli figurines of the period are very rare and valuable; his models are still reproduced by the factory in Nymphenburg.

See George W. Ware, *German and Austrian Porcelain* (1952).

(Hs. H.)

BUSTO ARSIZIO, a town in Varese province, Lombardia. Italy, 33 km. (20½ mi.) N.W. of Milan. Pop. (1957 est.), 57,962, commune. The church of Sta. Maria di Piazza (1517), designed by Bramante, contains works of G. Ferrari, B. Luini and others. The baroque cathedral church of S. Giovanni (1630) designed by F. M. Richini has a belfry dating from 1418 and contains the "Cristo Morto" (1623) of D. Crespi and frescoes (1769) by B. Bellotti. The library of the chapter is rich in ancient manuscripts, incunabula and liturgical volumes. The town is a centre of the cotton industry. There is an airport at Malpensa (10 km. or 6.2 mi.).

See P. Bondioli, *Storia di Busto Arsizio*, 2 vol. (1937-54); G. Rossi, *Cinquant'anni di vita cotoniera* (1956).

BUTADES OF SICYON (fl. c. 600 B.C.?), wrongly called **DIBUTADES**, the first Greek modeler in clay. The story is that his daughter, who loved a youth at Corinth, where they lived, drew upon the wall the outline of his shadow, and that upon this outline her father modeled a face of the youth in clay and baked the model along with the clay tiles which it was his trade to make. This model was preserved in Corinth until Mummius sacked that town. He is also said to have invented a mixture of clay and ruddle, or to have introduced the use of a special kind of red clay.

BUTADIENE is a hydrocarbon of industrial importance as the major constituent of synthetic rubber. It was first produced commercially by Germany during World War I from acetylene. Before World War II the only U.S. production was a minor quantity obtained as a by-product. When natural rubber imports were stopped by the war an emergency program was undertaken in 1942 which resulted in construction of production capacity of approximately 1,000,000 tons per year by 1945. This corresponded to almost twice the prewar consumption of rubber. The plants were government owned and for raw materials used ethyl alcohol for 40% of the production and butenes from petroleum and natural gas for the remainder.

With the resumption of natural rubber importation into the United States in 1946, excess butadiene capacity was held in stand-by condition and the most efficient plants were operated under government contracts. In 1954-55 the government plants were sold to private industry and an expansion program was initiated to increase production from petroleum and natural gas. Production from alcohol is generally not attractive except in emergencies because of higher production costs. Although new chemical uses were being developed, synthetic rubber continued to consume approximately 90% of the U.S. butadiene production.

At atmospheric conditions butadiene exists as a colourless gas but is condensed to a liquid either by cooling to -4.4°C . (24°F .) or by compressing to 2.8 atm. at 25°C . (77°F .). The gas is 1.86 times heavier than air, while the liquid has a specific gravity of 0.627 at 15.5°C . (60°F .). Butadiene has the chemical structure $\text{CH}_2\text{:CHCH:CH}_2$ and is the lowest member of the conjugated diolefin series. It is the high chemical activity of the conjugated diolefin structure that is responsible for the importance of butadiene in chemical synthesis. Under suitable conditions, particularly in the presence of an oxidizing catalyst, butadiene molecules combine with each other or with other highly reactive compounds such as styrene or acrylonitrile to form plastic or solid polymers of high molecular weights. (See *RUBBER: PRODUCTION AND MANUFACTURE: Synthetic Rubber*.) Many other additional compounds are readily formed. The chemical activity of butadiene leads to difficulties in its manufacture and handling. At elevated temperatures and pressures it polymerizes to 4-vinylcyclohexene-1, which is a stable liquid boiling at 127°C . In the presence of air or other sources of oxygen, butadiene peroxides are formed which catalyze polymerization to plastic or solid materials. Such peroxidized solids may decompose with explosive violence and their formation in storage is prevented either by exclusion of oxygen or by the use of suitable oxidation inhibitors. (K. M. W.)

BUTANE belongs to the series of paraffinic hydrocarbons found in natural gas and in crude petroleum; it is formed in large quantities in the cracking of oil to produce gasoline. It occurs in two isomeric forms: n-butane and isobutane. The chemical formula of butane is C_4H_{10} .

The butanes present in natural gas are separated from the large quantities of lower-boiling constituents such as methane and ethane. The butanes thus obtained and freed from lower-boiling gases have a sufficiently low vapour pressure (2-4 atm.) at ordinary temperatures to enable them to be shipped safely in tank cars or in cylinders. The production of liquefied butanes separated from natural gasoline in the United States in the early 1960s was over 1,000,000,000 gal. of n-butane and over 300,000,000 gal. of isobutane. The amount of butanes consumed in the United States in the early 1960s in motor fuels was over 900,000,000 gal.

Butanes present in the refinery gases are usually admixed with large proportions of butenes; the latter, being more reactive, are converted to high-octane gasoline or to chemical derivatives. The

butanes remaining from this reaction are either added to gasoline to increase its volatility or used as raw material for the manufacture of aviation gasoline.

Butanes can be separated into iso- and n-butane by means of fractional distillation. The former boils at -11.7°C . and freezes at -159.6°C .; the latter boils at -0.5°C . and freezes at -138.3°C . n-Butane can be transformed commercially to isobutane. Isobutane reacts with olefins in the presence of hydrogen fluoride or sulfuric acid to form an alkylate which is a constituent of high-octane gasoline. This reaction was responsible for the production in the early 1960s of more than 10,000,000 gal. of octanes.

Butene (C_4H_8), also called butylene, belongs to the series of olefinic hydrocarbons. It occurs in four isomeric forms as shown in the table.

Name	Freezing point $^{\circ}\text{C}$.	Boiling point $^{\circ}\text{C}$.
n-Butene	-185.3	-6.3
cis-2-Butene	-138.9	3.7
trans-2-Butene	-105.5	0.0
Isobutylene (methylpropene)	-140.3	-6.0

The first three isomers are classified as normal butenes.

Butenes are formed during the cracking of oil to produce gasoline; they can also be prepared commercially by the catalytic dehydrogenation of butanes. Butenes undergo all the characteristic reactions of olefins. The major part of the butenes is utilized for the production of octanes, which are important constituents of aviation gasoline. This is done either by causing the butenes to react with isobutane or by polymerizing butenes to form octenes (C_8H_{16}), which on hydrogenation yield octanes (C_8H_{18}). Butenes, on treatment with water in the presence of catalysts, are transformed to secondary and tertiary butyl alcohols, which are important commercial solvents. n-Butenes on dehydrogenation form butadiene, which is the main starting material for the manufacture of synthetic rubber. Isobutylene, on treatment with catalysts and minor amounts of diolefins at temperatures below -40°C ., polymerizes to a spongelike material called butyl rubber, which is used for the production of high-grade tire tubings.

(H. Ps.)

BUTE, JOHN STUART, 3RD EARL OF (1713-1792), British politician, the "dearest friend" of George III, whose accession caused him to be thrust briefly into political prominence, was born in Edinburgh on May 25, 1713, son of James, 2nd earl, and of Lady Anne Campbell, daughter of the 1st duke of Argyll. He was educated at Eton and succeeded to the earldom (created in the peerage of Scotland for his grandfather, Sir James Stuart, in 1703) on his father's death in 1723. He married Mary, daughter of Edward and Lady Mary Wortley Montagu, in 1736, and after her father's death (1761) Bute controlled his wife's large fortune. He was elected a representative peer for Scotland in 1737, but not in the following parliaments, and appears not to have spoken in debate. In 1738 he was made a knight of the Thistle. For several years he lived in retirement in Bute, engaged in agricultural and botanical pursuits, and from the quiet obscurity for which his talents and character entirely fitted him he was drawn by a mere accident. He had resided in England since the rebellion of 1745. In 1747, a downpour of rain having prevented the departure of Frederick, prince of Wales, from the Egham races, Bute was summoned to his tent to make up a whist party; he immediately gained the favour of the prince and princess, became the leading personage at their court at Leicester house and in 1750 was appointed by Frederick a lord of his bedchamber. After Frederick's death in 1751 his influence in the household increased. Bute became the constant companion and confidant of Frederick's son George, heir apparent, over whom he exerted a strong personal influence. He took part in the negotiations between Leicester house and William Pitt, directed against the duke of Newcastle, in 1755 and in the conferences between Pitt and Newcastle in 1757 which led to their taking office together.

On the accession of George III in 1760, Bute became a privy

councilor, groom of the stole and first gentleman of the bedchamber, and though without a seat in parliament or in the cabinet he was the only man who enjoyed the king's complete confidence. George III immediately proceeded in his attempt to accomplish his long-projected plans, the conclusion of the peace with France, and the ejection from power of his grandfather's ministers. His policy was followed with skill and caution. Great care was shown not to alienate the old ministers in a body, which would have raised up under Pitt's leadership a formidable party of resistance, but advantage was taken of disagreements between them concerning the war, of personal jealousies and of the reluctance of the old statesmen who had served the crown for a generation to identify themselves with active opposition to the king's wishes. They were all discarded singly and isolated, after violent disagreements, from the rest of the ministers. Bute succeeded Lord Holderness as secretary of state for the northern department on March 25, 1761, and Pitt resigned in October on the refusal of the government to declare war against Spain.

On Nov. 3, 1761, Bute appeared in the house of lords, where he had not been seen for 20 years, in his new capacity as first minister. Though he had succeeded in disarming all organized opposition in parliament, the hostility displayed against him in the nation, arising from his Scottish nationality, his character as the king's favourite, his peace policy and the resignation of the popular hero Pitt, was overwhelming. He was the object of numerous attacks and lampoons. He dared not show himself in the streets without the protection of prize fighters, while the jack boot (a pun on his name) and the petticoat (representing George's mother, the princess of Wales) were continually being burned by the mob or hanged upon the gallows. On Nov. 9, while proceeding to the Guildhall, he narrowly escaped falling into the hands of the populace, who smashed his coach, and he was treated with studied coldness at the banquet. In Jan. 1762 he was compelled to declare war against Spain, though now without the advantages which the earlier decision urged by Pitt could have secured, and he supported the war, but with no zeal and no definite aim beyond the obtaining of a peace at any price and as soon as possible.

In May 1762 Bute succeeded the duke of Newcastle as first lord of the treasury. In his eagerness for peace he conducted on his own responsibility secret negotiations for peace with France through the comte de Viry, the Sardinian minister, and the preliminary treaty was signed on Nov. 3 at Fontainebleau. A parliamentary majority was secured with the aid of Henry Fox, who became leader of the house of commons. The definitive peace of Paris was signed on Feb. 10, 1763, and a wholesale proscription of the duke of Newcastle's party was begun, in which even insignificant adherents incurred the vengeance of the court. Later, Bute roused further hostility by his cider tax, an ill-advised measure producing only £75,000 a year, imposing special burdens upon the farmers and landed interest in the cider counties, and extremely unpopular because it extended the detested system of taxation by excise, regarded as an infringement of popular liberties. At length, unable to contend any longer against the general animosity displayed against him, fearing for the consequences to the monarchy, alarmed at the virulent attacks of the *North Briton* and suffering from ill-health, Bute resigned on April 8, 1763.

He still for a time retained influence with the king, but George Grenville (whom he recommended as his successor) insisted on possessing the king's whole confidence, and on the failure of Bute in Aug. 1763 to procure his dismissal and to substitute a ministry led by Pitt and the duke of Bedford Grenville demanded and obtained Bute's withdrawal from the court. He resigned accordingly the office of privy purse and took leave of George III on Sept. 28. He still corresponded with the king and returned to London in 1764, but in May 1765, after the duke of Cumberland's failure to form an administration, Grenville exacted the promise from the king which was kept faithfully that Bute should have no share and should give no advice whatever in public business and obtained the dismissal of Bute's brother from his post of lord privy seal in Scotland. Bute continued to visit the princess of Wales, but on the king's arrival always retired by a back staircase. He spoke against the government on the American question in

Feb. 1766 and in March against the repeal of the Stamp act. In 1768 and 1774 he was again elected a representative peer for Scotland but took no further part in politics, refusing, in 1778, to have anything to do with the abortive attempt to effect an alliance between himself and Pitt, now earl of Chatham.

He traveled in Italy and determined on "retiring from the world before it retires from me." He died in London on March 10, 1792, and was buried at Rothesay in Bute. Thrust into high office and great influence at a critical moment in British history, Bute proved to have little grasp of realities. He loved the theatrical and lacked the ability or balance of judgment to overcome political animosities by wise government.

BUTE, the most important, though not the largest, of the islands constituting Buteshire (*q.v.*) in the Firth of Clyde, Scot., about 18 mi S.W. of Greenock and 40 mi. by water from Glasgow. Pop. (1951) 12,547. It is bounded on the northeast, north and northwest by the picturesque Kyles of Bute, the narrow winding strait which separates the island from Argyllshire; on the east by the Firth of Clyde, and on the south and southwest by the Sound of Bute, about 6 mi. wide, which divides it from Arran. Its area is 47 sq.mi., its length 15½ mi., and its breadth from 4½ to 1 mi.

Its highest point, Kames hill, in the north, is 875 ft. This part of the island is composed mainly of the metamorphic rocks of the eastern Highlands, mica schists, interrupted by a belt of clay slate; the south of the island consists mainly of Upper Old Red Sandstone, with many intrusive igneous rocks.

The name of the island is variously derived from the Erse, *both*, a "cell," in allusion to St. Brendan's foundation there in the 6th century, and from the Gaelic *Ey Bhiod*, "the island of corn," in reference to its fertility. Stone monuments, barrows, cairns and cists, with the remains of ancient chapels, attest its early settlements. Bute was probably first colonized by the vanguard of Scots who came over from Ireland.

Because of its pleasant scenery, sandy bays, mild climate and lower rainfall than occurs over much of the western coast, added to its fertile soil and proximity to the Clyde estuary, the island is relatively populous and a residential and holiday resort for the Scottish industrial belt and other centres of population in the British Isles. Mount Stuart, a modern Gothic mansion, is a seat of the marquess of Bute. About two-thirds of the island is arable, the main crops being oats, turnips and swedes and, in the southern part of the island, early potatoes. Many burns (streams) drain the island, and there are six lochs among which the biggest, Loch Fad, about 1 mi. S. of Rothesay and stretching south-southwest for 2½ mi., was the source of the power used in the Rothesay cotton-spinning mill, the first of the kind erected in Scotland. The island is well served by steamers, including a vehicular ferry, from Wemyss Bay to the chief port and old royal burgh of Rothesay (*q.v.*).

There is also a vehicular ferry across the Kyles of Bute from Colintrave to Rhubodach (Rudhabodack), enabling heavy goods to be conveyed by road.

See J. K. Hewison, *Isle of Bute in the Olden Time*, two volumes (1894-95) (A. H. Wb.)

BUTENANDT, ADOLF FRIEDRICH JOHANN (1903-), German biochemist who shared the 1939 Nobel prize in chemistry with Leopold Ruzicka. He was given the award for his work on sex hormones but was forbidden by the German (Nazi) government to accept. Born at Bremerhaven-Lehe, March 24, 1903, Butenandt studied chemistry at Gottingen and graduated there in 1927. As a *Privatdocent* he worked in the laboratory of A. Windaus, winner of the 1928 Nobel chemistry prize for research in sterol chemistry. In 1929, almost simultaneously with E. A. Doisy in the U.S., Butenandt isolated estrone, one of the hormones responsible for sexual development and function in

females. In 1931 he isolated and identified androsterone, one of the male sex hormones, and in 1934 progesterone, a hormone produced by the corpus luteum that plays an important part in the female reproductive cycle.

He carried out much research on the chemistry and interrelationships of the sex hormones and on the possible carcinogenic properties of some of these substances. The large-scale production of cortisone stemmed largely from Butenandt's work on hormones.

Butenandt was professor of chemistry at Danzig (1933–36), director of the Kaiser Wilhelm institute of biochemistry in Berlin (1936–45), director at the Max Planck Institute for Biochemistry, Tübingen, Ger. (1945–56) and director of the Max Planck Institute for Biochemistry, Munich (from 1956). (W. J. Bp.)

BUTES, the name of three figures in Greek mythology and legend.

1. Butes, a son of Boreas. Having killed his brother Lycurgus, he was compelled to flee from Thrace to Naxos, where he lived by piracy. On one expedition he captured Coronis, a handmaiden of Dionysus, whom he took as his wife; but Dionysus drove him mad, so that he jumped into a well and perished.

2. Butes, son of Pandion of Athens, brother of Procne, Philomela and Erechtheus (*q.v.*). He married his niece Chthonia, but when her father, Erechtheus, was compelled by the Delphic oracle to sacrifice one of his daughters in order to repel the attack of Eumolpus and the Eleusinians, Chthonia was killed and her sisters committed suicide. Butes was priest of Athena and Poseidon, and in historical times an altar dedicated to him was to be seen in the Erechtheum.

3. Butes, the Argonaut who succumbed to the lure of the Sirens. Jumping from the ship and swimming toward their island, he was saved by Aphrodite, who bore him to Sicily where he became by her the father of Eryx. (T. V. B.)

BUTESHIRE, an insular county of southwestern Scotland, consists of the islands of Bute, Arran, Great Cumbrae, Little Cumbrae, Holy Island (not to be confused with Lindisfarne), Pladda and Inchmarnock, all lying in the Firth of Clyde between Ayrshire on the east and Argyllshire on the west and north. Land area 218.3 sq.mi.

Physical Features.—The Highland boundary fault passes through Bute where the Old Red Sandstone in the south abuts sharply upon the higher schists in the north of the island (highest point 911 ft.). In Arran, although the fault cannot be traced, the same contrast exists between the southern part and the northern part, which is the only mountainous area in the county, rising to 2,867 ft. Arran has a large variety of rock formations and is regularly visited by students of geology. The climate of Buteshire is temperate; snow is infrequent and seldom lies for more than a few days except in the mountains of Arran. The soil, mostly light and fertile loam near the shore, generally turns toward clay inland which can nevertheless yield excellent crops when properly drained. Fauna include red deer, roe deer, weasels, stoats and others. An area of land in Glen Diomhan, a steep-sided post glacial gorge in Arran extending to 24 ac., is a nature reserve.

History.—Excavations have revealed evidence of human habitation from the Neolithic period and at Dunagoil, Bute, there is a fine vitrified fort of the Iron Age. There are remains of numerous chapels of the early Christian period. St Blane, who was born on Bute (6th century), built a chapel near Dunagoil where a ruined church still stands. Rothesay castle, Bute, which goes back to Viking times and was used as a royal residence by Robert II and Robert III of Scotland, was burned down in 1685 and is now an ancient monument, as is Lochranza castle on Arran. Brodick castle, where Robert the Bruce lived for a time before the battle of Bannockburn and which was once the residence of the duchess of Montrose, is now administered by the National Trust for Scotland.

Population and Administration.—The population of Buteshire in 1961 was 15,129. There are two small burghs: Rothesay (7,656) (*q.v.*), the county town, and Millport (1,592), on Great Cumbrae. Buteshire unites with North Ayrshire to return one member to parliament. Ayrshire and Buteshire form a sheriffdom,

courts being held weekly in Rothesay and when required in Lam-lash, Arran. Police courts are held in Rothesay and in Millport, Great Cumbrae, and justices of the peace sit occasionally in Rothesay and Lam-lash. There is a district council for each of the three main island groups. Arran, Bute and the Cumbraes.

Industries and Communications.—Agriculture and the tourist trade are the main industries in the county, although fishing is of some importance. The staple crops are oats, hay, turnips and potatoes, while cattle and sheep are reared and milk is sent from Bute and Xrran to the mainland. Many people from the industrial belt of Scotland and the industrial towns of northern England spend their vacations in Buteshire. There is regular steamship communication for passengers and cars between the county ports of Rothesay, Millport and Brodick and the mainland ports of Wemyss Bay, Gourock and Fairlie (or Ardrossan). There is also a regular ferry service for vehicular and passenger traffic across the Kyles of Bute between Rhubodach, Bute, and Colintraive, Argyll. See also ARRAN; BUTE; CUMBRAES, THE.

See J. E. Reid, *History of the County of Bute (1864)*. (A. H. Wb.)

BUTLER, the name of a family famous in the history of Ireland. The Butlers alone, among the families of the Norman conquerors, could rival the Geraldines, their neighbours, kinsfolk and often their mortal enemies, and until 1688 the effective government of Ireland was usually in the hands of one of the two families (See IRELAND: History).

The Butlers are descended from THEOBALD WALTER (d. c. 1206), whose office of hereditary chief butler (or botiller) of Ireland gave the family its name. Theobald, a nephew of Ranulf de Glanville, Henry II's justiciar, rose in the king's service through his uncle's influence, although he never attained the eminence of his brother, Hubert Walter, archbishop of Canterbury. He may have accompanied Henry II to Ireland in 1171, and certainly went there with the king's son John in 1185. His services on that expedition were rewarded with large grants of land, in Ormonde (now part of County Tipperary) and elsewhere. He made his Irish home at Arklow, where he founded a monastery. The date of his appointment as chief butler to the lord of Ireland is uncertain, but after the Irish expedition he spent most of the rest of his life in England in John's service (from 1194 to 1199 he was sheriff of Lancashire, where he also had large estates). Toward the end of his life he returned to Ireland.

His descendants steadily increased the family's influence in Ireland, adding to their possessions by judicious marriages. EDMUND (d. 1321), 6th butler, was justiciar of Ireland during Edward Bruce's Scottish invasion of 1315 and was afterward granted the castle and manors of Carrick, Macgriffyn and Roscrea with the title of earl of Carrick, which, however, he apparently never used. His son JAMES (c. 1305–38) married in 1327 Eleanor de Bohun, a granddaughter of Edward I. The marriage further increased the power and prestige of the Butlers, and because of it James was created earl of Ormonde in 1328.

From the time of the 1st earl, the Ormondes served in the chief offices of the government of Ireland as deputies, lords lieutenant, lords keeper and lords justice. They fought in the king's wars both at home, against the native Irish, and overseas, and unlike their enemies, the Geraldines, they remained loyal to the English crown. JAMES (1331–82), 2nd earl (the Noble Earl), was four times governor of Ireland. His son JAMES (d. 1405), 3rd earl, increased the territorial influence of the Butlers, in particular acquiring the castle of Kilkenny, which became the family seat. JAMES (c. 1392–1452), 4th earl (the White Earl), was famous not only as a warrior, but as a scholar and antiquarian. He won his spurs in France with Henry V and then fought for him in Ireland. His best known battle was at the red moor of Athy in 1420 against the wild O'Mores, when, according to legend, the sun stood still for three hours until the English had won.

JAMES (1420–61), 5th earl, son of the White Earl, lived mainly in England, and was given an English peerage as earl of Wiltshire in 1449. He took an active part in the Wars of the Roses on the Lancastrian side, both in politics, after his appointment as high treasurer in 1455, and in the field. But he was taken prisoner by the Yorkists after the battle of Towton in 1461, and shortly after-

ward was executed at Newcastle. On his death the earldom of Wiltshire became extinct and his Irish title and estates were forfeited by the act of attainder (1462) against him and his two brothers. However, Edward IV recognized the 5th earl's brother JOHN (d. 1478) as 6th earl of Ormonde some time before the attainder against him was annulled in 1475. John was a famous scholar, and spoke every European language. Edward admired him greatly and employed him as ambassador to several foreign courts. He was succeeded by his brother THOMAS (d. 1515), 7th earl, who also remained at court in England, and was sent as ambassador to France and to Burgundy. He died in 1515 without male issue. His daughter, Margaret, married Sir William Boleyn, and their younger son, Thomas, was the father of Anne Boleyn.

While the earls of Ormonde lived in England, the influence of the family in Ireland had declined, especially as it had no recognized head there. But SIR PIERS BUTLER (c. 1467–1539), 8th earl (the Red Earl), cousin of the 7th earl, claimed the title in 1515, seized the estates and revived the Butler influence. He fought for the English against the rebel Irish lords, especially the Kildare Geraldines, and in 1522, styled as the pretended earl of Ormonde, he was made lord deputy of Ireland. In 1528, renouncing his claim to the earldom of Ormonde, he was made earl of Ossory, and Sir Thomas Boleyn was made earl of Ormonde. Then in 1538, Piers was given the earldom of Ormonde as a new creation. However, his son and successor, JAMES (c. 1496–1546), 9th earl (the Lame), lord treasurer of Ireland since 1532, who had been made Viscount Thurles in 1536, was confirmed in the possession and precedence of the ancient earldom by act of parliament in 1544. James died, poisoned, at Ely house, London, on Oct. 28, 1546. Another son of Piers, Richard, was in 1550 created Viscount Mountgarret, a title which is still held in the Butler family.

James's son THOMAS (1531–1614), 10th earl (the Black Earl), was brought up a Protestant at the English court after his father's death. He returned to Ireland in 1554 and was appointed lord treasurer there in 1559. In the rebellions of the Irish he threw his great influence on the English side, but he was equally zealous in prosecuting his private feud with the Desmond Geraldines. The earl of Desmond finally rose in open revolt in Dec. 1579, and Ormonde was appointed military governor of Munster in 1580 to put down the rebellion. He was able to pacify Munster after Desmond's death in 1583. Appointed lieutenant governor in 1597, he suppressed the rebellion of the O'Neills and the Burkes. His nephew, WALTER BUTLER of Kilcash (1569–1633), 11th earl, who had fought with him in Ireland, succeeded to the title, but his claim to the estates was disputed by Sir Robert Preston, the husband of the 10th earl's daughter Elizabeth. Refusing to submit to the arbitration of James I, Walter was imprisoned in 1617 and deprived of the palatinate rights in Tipperary which had been held by the family for three centuries. However, after his release in 1625 he recovered most of his estates. His grandson and successor, James (see ORMONDE, JAMES BUTLER, 1st Duke of), the most famous of all the Butlers, regained the rest of the Ormonde estates by marriage with his cousin Elizabeth Preston.

James's son THOMAS (1634–1680), earl of Ossory, "the terror of foreign nations and the glory of his own," who served Charles II as soldier and ambassador, died before his father, who was succeeded by his grandson (see ORMONDE, JAMES BUTLER, 2nd Duke of).

The Ormonde estates and titles were forfeit by the 2nd duke's attainder in 1715, but his brother CHARLES (1671–1758) was allowed to buy back the estates in 1721. A supporter of William III, Charles had been given an Irish title as earl of Arran in 1693, and an English one as Lord Butler of Weston in 1694. On his death these titles became extinct, as did the dukedom and marquessate of Ormonde. The earldom was claimed by descendants in Ireland of the brother of the 1st duke, but the attainder was only reversed by the Irish parliament in 1791, when JOHN BUTLER (1740–95), 17th earl, was confirmed as earl of Ormonde and Ossory and Viscount Thurles. John's son WALTER (1770–1820), 18th earl, gained an English title as Lord Butler of Lanthony in 1801, and was made marquess of Ormonde in 1816, but these titles died with him. He sold one of the ancient privileges of the Butlers, the right to the

prisaige of wines in Ireland, to the English government for £216,000. His brother JAMES (1774–1838), 19th earl, was made Baron Ormonde of Lanthony in 1821, and the Ormonde marquessate was revived for him in 1825. These titles were retained by his descendants, down to JAMES ARTHUR NORMAN (1893–), 6th marquess, who succeeded his brother in 1949.

Other branches of the Butler family also gained honours and titles, although the Ormonde lines were the most distinguished. A descendant of the 1st earl of Ormonde's brother was made Viscount Ikerrin in 1629, and one of his successors was made earl of Carrick also, in 1748. Sir Thomas Butler of Chaier, or Chaierdomn-Eske, a descendant in an illegitimate branch of the family, was made Baron Caher in 1543. The title fell into abeyance on the death of the 2nd baron in 1561, but was revived in 1583, after the surrender of their rights by the heirs general, for Sir Theobald Butler (d. 1596). It became extinct in 1858 on the death of Richard Butler, 13th baron and 2nd viscount Caher, and 2nd earl of Glengall. A descendant of the 3rd earl of Ormonde, COUNT WALTER BUTLER (d. 1634) gained fame and a title on the continent. A dragoon officer in the Thirty Years' War, he served for a time under Albrecht von Wallenstein, but in 1634, distrusting him and doubting his loyalty, he planned and carried out Wallenstein's murder. In memory of his services, the imperial title of Butler von Clonebough, genannt Haimhausen, count of the Holy Roman empire, was revived in 1681 for a kinsman.

BUTLER, ALBAN (1710–1773), English Roman Catholic hagiologist, author of the celebrated *Lives of the Saints*, was born in Northampton on Oct. 24, 1710. He was educated at the English college, Douai, France, where after ordination in 1734 he held successively the chairs of philosophy and divinity. In 1749 he returned to England but later became president of the English college at St. Omer, France, where he died on May 15, 1773. Butler's chief book, *The Lives of the Fathers, Martyrs, and Other Principal Saints*, 4 vol. (1756–59), a sound critical work of its period, which went through many editions, was drastically revised by H. Thurston and D. Attwater (*Butler's Lives of the Saints*, 4 vol., 1956), to bring it up to date in both content and treatment.

See C. Butler, *An Account of Alban Butler (1800)*; J. Gillow, *Bibliographical Dictionary of English Catholics*, vol. 1 (1885).

BUTLER, BENJAMIN FRANKLIN (1818–1893), U.S. lawyer, soldier and politician, was born at Deerfield, N.H., on Nov. 5, 1818. He was educated at Waterville (later Colby) college, Waterville, Me., was admitted to the Massachusetts bar in 1840 and soon became a prominent lawyer in Lowell, Mass. An active Democrat, he served in the Massachusetts house of representatives in 1853 and in the state senate in 1859, distinguishing himself as a champion of the rights of labour and of naturalized citizens. In 1860 he attended the Democratic national convention at Charleston, S.C., but withdrew from it and joined the pro-southern faction that nominated John C. Breckinridge.

When the Civil War broke out, Butler strongly supported the Union. As a brigadier general of the Massachusetts militia, he commanded the troops that occupied Baltimore, and, in May 1861, was promoted to the rank of major general in command of Ft. Monroe, Va. There he refused to return fugitive slaves on the ground that they constituted "contraband of war," an interpretation which was later upheld by his government. He lost the engagement at Big Bethel in June, 1861, but achieved a success two months later when he captured the forts guarding Hatteras inlet.

Early in 1862, Butler took command of the land forces which accompanied Farragut's expedition against New Orleans. The city fell late in April, and from May to December Butler ruled it with an iron hand. He executed a citizen who had torn down the U.S. flag, undertook sanitary measures to prevent an outbreak of yellow fever, and confiscated the property of Confederate sympathizers. In order to end the indignities inflicted upon his soldiers, he published his famous order no. 28 in which he threatened to regard any female molesting his troops "as a woman of the town plying her avocation." Partially because of difficulties arising from his relations with foreign consuls, he was recalled in Dec. 1862.

As commander of the army of the James in 1864, Butler permitted himself to be bottled up at Bermuda Hundred, Va., and was

generally unsuccessful in operations before Richmond and Petersburg. After the failure of an expedition against Ft. Fisher, N.C. he was relieved of command in Jan. 1865.

From 1867 to 1875 and again from 1877 to 1879, Butler served in the house of representatives as a Republican. An outspoken proponent of radical reconstruction and a manager of the impeachment trial of Andrew Johnson, he became one of President Grant's chief supporters in congress after 1868. But because of his sympathy with the inflationary greenback movement, he lost the confidence of prominent members of his party. In 1878 he broke with the Republicans, and, after two unsuccessful attempts, was elected governor of Massachusetts as a Democrat in 1882. Defeated for a second term, he bitterly opposed Cleveland's nomination for the presidency. In 1884 he became the standard bearer of the People's party, which included remnants of the Greenback Labor party and the Anti-Monopoly party, but failed to win a single electoral vote.

An able lawyer, Butler was often accused of corruption, but the charges against him were never proven. His flamboyant advocacy of the rights of workers, women and Negroes called attention to the necessity of many reforms, and he performed a valuable service by rallying the Democrats to the national cause in 1861. He died at Washington, D.C., on Jan. 11, 1893.

BUTLER, HENRY MONTAGU (1833–1918), famous headmaster of Harrow school and master of Trinity college, Cambridge, was born at Gayton, Northamptonshire, on July 2, 1833, the son of George Butler, dean of Peterborough and a former headmaster of Harrow. H. M. Butler was headmaster from 1859 to 1885. At first he was opposed by an old-fashioned staff, but through his tact and firmness, public spirit and devotion to the school he overcame their opposition. During his term of office the report of the Clarendon commission was issued; many of the reforms recommended by the commission were already being tried out by Butler.

A brother-in-law of Sir Francis Galton, he was in sympathy with the scientific thought of the period, and science was officially recognized as a subject in the school curriculum. When E. E. Bowen was appointed to the staff, Butler supported him in the creation in 1869 of a modern side, or division, with the proviso that only boys with a satisfactory record in classics should be admitted. He also encouraged the traditions of the school. He was a great lover of music, and during his headship the cycle of Harrow school songs written by Bowen was completed. In 1885 Butler became dean of Gloucester, but this did not diminish his interest in Harrow, and in 1901 he was elected a governor of the school.

While master of Trinity college (1886–1918), Butler formed a link between religious bodies of different types and showed great interest in classes for working men. It was at Cambridge that he met Albert Mansbridge, the founder of the Workers' Educational association. Butler also began the annual reunion of Trinity scholars and was vice-chancellor of the university for the year 1889–90. He died at Cambridge on Jan. 14, 1918.

BUTLER, JOSEPH (1692–1752), English bishop of Durham and moral philosopher, was born on May 18, 1692, at Wantage, Berkshire, of Presbyterian parentage. As a boy he was sent to the dissenting academy of Samuel Jones at Gloucester and later to Tewkesbury. While there Butler became dissatisfied with Presbyterianism and resolved to join the Church of England. In 1715 he entered Oriol college, Oxford, and after taking his degree, three years later, was ordained deacon and priest. In 1736, after several previous posts, Butler was appointed clerk of the closet to Queen Caroline. In 1737 the queen died. Her recommendation of Butler to the favour of her husband led to his appointment in 1738 to the bishopric of Bristol. Two years later Butler was pre-

sent to the deanery of St. Paul's and in 1746 was made clerk of the closet to the king. In 1750 he accepted the see of Durham. He died on June 16, 1752, at Bath, and was buried in Bristol cathedral. According to his wishes, all his manuscripts were burned after his death. Butler never married.

Butler's reputation rests chiefly upon two printed works, the *Fifteen Sermons* (1726) and the *Analogy of Religion* (1736). In the former he set forth his moral philosophy, arguing the case for ethics primarily from reason rather than from revelation and basing his arguments upon the nature of man and of the world rather than upon the divine imperative. The *sermons*, although written earlier than the *Analogy*, did not come into their own as a classic in ethical theory until a century or so after the author's death. The *Analogy of Religion, Natural and Revealed, to the Constitution and Course of Nature*, by contrast, did much to shape the history of the Christian apologetics during the 19th century. It is aimed at deism and proposes to defend the doctrine of immortality and the need for revelation against deistic rationalism. In support of both these tenets Butler argues that a sound use of reason does not contradict but at the least supports faith in divine revelation and in human immortality.

Of the many editions of the *Analogy* the best are those by W. Fitzgerald (1860), containing a valuable biography; by W. E. Gladstone (1896), the second volume containing the *Sermons* as well; and by J. H. Bernard (1900), which also includes the *Sermons*.

BUTLER, JOSEPHINE ELIZABETH (1828–1906), English social reformer, chiefly remembered for her efforts to combat prostitution, was born at Milfield Hill, Northumberland, on April 13, 1828. She was the daughter of John Grey, an agriculturist, and was of Huguenot descent through her mother Hannah Annett. After her marriage (1852) to George Butler, later canon of Winchester, she settled in Liverpool (1866) where she began to work for the rehabilitation of prostitutes. She became involved at an early stage in the campaign against the Contagious Diseases acts, which had been passed in 1864, 1866 and 1869 to prevent the spread of venereal diseases in garrison towns and naval stations. These acts permitted the arrest of suspected women by special police, required compulsory medical examination by justices' order and detention in hospital if found affected. In 1869 Mrs. Butler organized the Ladies National Association for Repeal, and the "Protest of the Ladies," which, signed by notable women including Florence Nightingale and Harriet Martineau, was published in the London *Daily News* and initiated the abolitionist crusade. Urging that the acts deprived the most defenseless class of its constitutional rights and failed as public health measures, Mrs. Butler agitated for their repeal by numerous publications (notably *The Constitution Violated*, 1871), by appealing directly to working men, by intervention in elections and by organizing debates in parliament. A royal commission (1870–71) and a select committee of the house of commons (1879–82) were obtained to investigate their operation. The acts were suspended in 1883 and repealed in 1886. Mrs. Butler told the story of the campaign in *Personal Reminiscences of a Great Crusade* (1896).

She also influenced European governments against licensed brothels and state regulation of prostitution. Victor Hugo, Mazzini and Garibaldi were among her continental, and William Lloyd Garrison among her American, supporters. She founded the International Abolitionist federation, which held its first world congress in Geneva (1877). She revealed the licensed brothel as the market for the white-slave traffic and sale of children for infamous purposes.

An early suffragist, Mrs. Butler worked also for equal educational and economic opportunities for women. She died at Wooler, Northumberland, on Dec. 30, 1906.

BUTLER, NICHOLAS MURRAY (1862-1947), U.S. educator, publicist and Nobel laureate, was born at Elizabeth, N.J., on April 2, 1862. He was educated at Columbia college, where, under the influence of Pres. F. A. P. Barnard (*q.v.*), he decided to prepare himself for a professional career in education. After completing his undergraduate work in 1882 he continued at Columbia as a graduate fellow in philosophy, taking the Ph.D. degree in 1854. A year in Berlin and Paris completed his formal education.

At the age of 23 Butler embarked upon an active career destined to put him in touch with the leading educators and statesmen of his time. He was appointed an assistant in philosophy at Columbia in 1885 and rose to a full professorship within five years. In 1890 he became the first dean of the faculty of philosophy, and in 1901 he acceded to the presidency of the university, a post he held until his retirement in 1945. Under his leadership Columbia grew from a provincial college into a cosmopolitan university of world renown.

As a young man Butler boldly criticized the schools and colleges of his day. He attacked antiquated pedagogical methods and sharply assailed what he called "the old dogma of formal education." As president of the Industrial Education association he played a central role in the founding of the New York College for the Training of Teachers, subsequently Teachers college. Columbia university Later, however, he turned his criticism against pedagogical reform itself, steadfastly defending the "great tradition" in education and lashing out against vocationalism and behaviourism as the "new barbarism."

For more than a half-century Butler was active in the Republican party, serving frequently as a delegate to its national conventions. He was also a vigorous advocate of improved international understanding, sharing with Jane Addams the Nobel peace prize for 1931. Butler died on Dec. 7, 1947, in New York city.

His *Across the Busy Years*, two volumes (1939-40), contains a bibliography of his published works.

See Edward C. Elliott (ed.), *The Rise of a University*, vol. ii (1937) (L. A. C.)

BUTLER, SAMUEL (1612-1680), English poet, satirist and author of *Hudibras*, son of a Worcestershire farmer, was baptized at Strensham, in that country, on Feb. 8, 1612. Educated at the King's school, Worcester, he obtained employment as a clerk with a Mr. Jeffereys and later in the household of the countess of Kent at Wrest, Bedfordshire, where he had access to a fine library and met the great scholar John Selden, whose secretary he is said to have been for a time. He then passed into the service of Sir Samuel Luke of Cople Hoo, a rigid Presbyterian, a colonel in the parliamentary army and scoutmaster-general for Bedfordshire. In his service Butler must have had abundant opportunities of studying at firsthand the motley collection of cranks, fanatics and scallywags who attached themselves to the Puritan army, and whose antics were to form the subject of his famous poem. At the Restoration he obtained a post as secretary to Richard Vaughan, earl of Carbery, lord president of Wales, who made him steward of Ludlow castle, an office which he held from Jan. 1661 till Jan. 1662. At this time he is said to have married a woman with "a competent fortune" which was however dissipated by "being put out on ill securities."

The first part of *Hudibras* appeared anonymously in an edition dated 1663, which was apparently on sale at the end of 1662. Samuel Pepys bought a copy on Dec. 21, but could find no wit in "so silly an abuse of the Presbyter knight going to the wars." However he repeatedly testifies to its immense popularity and there is no doubt that it had a very great success. Charles II delighted in it and it was said that

He never Eat nor Drank nor Slept
But *Hudibras* still near him kept.

A spurious second part appeared within the year and this apparently determined the poet to bring out the authentic second part, licensed on Nov. 7, 1663, and published in 1664. The first two parts were reprinted together in 1674 with "The Heroical Epistle of Hudibras to Sidrophel." In 1677 an injunction was issued by the king to protect Butler's rights against piratical printers, and in 1678 a third (and last) part of *Hudibras* was pub-

lished. According to John Aubrey, the biographer, when the first part of *Hudibras* appeared, the king and the lord chancellor Clarendon sent for Butler and "promised him great matters" but these promises do not seem to have materialized, though Charles is said to have given him £300. In the latter part of his life he seems to have been attached to the suite of George Villiers, 2nd duke of Buckingham, whom he probably accompanied on an embassy to France in 1670, and he is said to have been a member of the team which helped the duke in the composition of *The Rehearsal* (1671) and to have acted as his secretary when he was chancellor of Cambridge university. Butler died Sept. 25, 1680, and was buried in the churchyard of St. Paul's, Covent Garden. There seems little doubt that he died a poor and disappointed man, who, at the end of an apparently successful literary career, in the words of his contemporary, John Oldham, "found nothing left but poverty and praise" Aubrey, who knew Butler well, describes him as "of a middle stature, strong sett, high coloured, a head of sorrell hair, a severe and sound judgment: a good fellowe."

Hudibras is the most memorable burlesque poem in the English language. Its hero is a Presbyterian knight who goes "a-colonelling" with his squire Ralpho, an Independent. They constantly squabble over religious questions and in a series of grotesque adventures are shorn up as ignorant and wrongheaded, cowardly and dishonest. Butler derived his story from Cervantes and the burlesque method (making everything as "low" and undignified as possible) from Scarron. However, his brilliant handling of the octosyllabic metre, his witty, clattering rhymes, his delight in strange words and out-of-the-way learning, resembling in some respects both Rabelais and James Joyce, and his enormous zest and vigour produce effects which are entirely original. The story and characters in *Hudibras* are of little importance. Its strength lies in the fact that it is the first English satire to make a notable and successful attack not on personalities but on ideas. Butler's real enemies are not so much the Puritans as fanaticism, pretentiousness, pedantry and hypocrisy. His famous description of the militant Presbyterians is an unforgettable deflation of the spirit of religious intolerance:

Such as do build their Faith upon
The holy Text of *Pike* and Gun;
Decide all Controversies by
Infallible *Artillery*;
And prove their Doctrine Orthodox
By Apostolick *Blows* and *Knocks*:
Call Fire and Sword and Desolation
A *godly-thorough-Reformation*, . . .

His description of the doctrine of the Inner Light is a fine example of "metaphysical wit" harnessed to serve the new skeptical rationalism of the age of Kewton and Locke:

'Tis a Dark-Lantern of the Spirit,
Which none see by but those that bear it:
A Light that falls down from on high
For Spiritual Trades to couzen by:
An *Ignis Fatuus* that bewitches
And leads Men into Pools and Ditches . . .

There is lyrical beauty as well as burlesque in *Hudibras* and the description of the rising of the moon is as fine as anything of the kind in Andrew Marvell or Thomas Carew:

The *Moon* pull'd off her veil of Light,
That hides her face by day from sight,
(Mysterious Veil, of brightness made,
That's both her lustre, and her shade).

The pictures of low life in the poem are, perhaps, the most notable things of the kind in English poetry between John Skelton and George Crabbe, with both of whom Butler has a certain affinity.

He attacked pretentiousness and pedantry wherever he found it. In "The Elephant in the Moon" (1676) he mocked the solemnities of the scientists of the newly founded Royal society and in "Repatees between Puss and Cat at a Caterwalling" the absurdities of the rhyming heroic tragedies. His ode *To the Happy Memory of the Most Renowned Du Val* (1671) is an amusing skit on the fashionable "pindaric" odes. Other poems are ascribed to him in an edition of his *Posthumous Works in Verse and Prose*, three volumes (1715-17), but some are undoubtedly spurious. Butler's papers, now in the British museum,

London (Add Mss. 32. 625–626). passed at his death into the hands of his friend William Longueville and were left untouched till Robert Thyer edited from them *Genuine Remains in Verse and Prose of Mr. Samuel Butler*, two volumes (1759). This collection included more than a hundred prose "Characters," which show Butler as a master of vigorous, incisive, racy prose and an artist in the Theophrastian "character" not inferior to John Earle or the contributors to Sir Thomas Overbury's famous collection. The study of "A Duke of Bucks" is a satiric analysis of the character of the 2nd duke of Buckingham which does not suffer much even by comparison with Dryden's famous "Zimri" in *Absalom and Achitophel*.

BIBLIOGRAPHY.—The best modern edition is the *Collected Works*, ed. by A. R. Waller and R. Lamar, 3 vol. (1905–28); *Poetical Works*, ed. by R. B. Johnson, 2 vol. (1893) contains important bibliographical information. Editions of *Hudibras*, besides those mentioned above, appeared in 1704 (containing the first *Life* of Butler), in 1726 (illustrated by Hogarth), in 1744 (2 vol., ed. by Zachary Grey, with a copious and learned commentary) and a new edition by J. S. Wilders (1961). The *Poetical Remains* (1827) were based on Thyer's *Genuine Remains*.

BUTLER, SAMUEL (1835–1902), English satirist, novelist, essayist and critic, one of the most original and many-sided writers of the late Victorian age. The son of the Rev. Thomas Butler, and grandson of Dr. Samuel Butler, headmaster of Shrewsbury school and later bishop of Lichfield, he was born at Langar rectory, Nottinghamshire, on Dec. 4, 1835. After six years at Shrewsbury he went to St. John's college, Cambridge, where in 1858 he was bracketed 12th in the classical tripos. His father wished him to be a clergyman and he actually went as far as to do a little slumming in a London parish by way of preparation for Holy Orders. But the whole current of his highly independent and heretical nature was carrying him away from everything his father stood for: home, church and Christianity itself—or what Christianity had appeared to mean at Langar rectory. After an unpleasant altercation with his father he left Cambridge and the church and all home prospects, and emigrated to New Zealand, where (with funds advanced by his father) he set up a sheep run in the Canterbury settlement.

When Darwin's *Origin of Species* came into his hands, soon after his arrival in New Zealand, it took him by storm; he became "one of Mr. Darwin's many enthusiastic admirers," and a year or two later he told a friend that he had renounced Christianity altogether. Yet, as it proved, Christianity had by no means finished with Butler. For the next 25 years it was upon religion and evolution that his attention was mainly fixed. At first he welcomed Darwinism because it enabled him to do without God (or rather, without his father's God). Later, having found a God of his own, he rejected Darwinism itself because it left Him out. Naturally, therefore, he antagonized both the church and the orthodox Darwinians, and spent his life in a lonely, "Ishmaelitic" situation. To the *New Zealand Press* he contributed several articles on Darwinian topics, of which two—"Darwin Among the Machines" (1863) and "*Lucubratio Ebria*" (1865)—were later worked up in *Erewhon*. Both show him already grappling with the central problem of his later thought: the relationship between mechanism and life. In "Darwin Among the Machines" he tries out the consequences of regarding machines as living organisms competing with man in the struggle for existence, and so likely to win that they must at once be destroyed. In the "*Lucubratio*" he takes the opposite view, that machines are extracorporeal limbs; and that the more of these a man can tack on to himself the more highly evolved an organism he will be.

Having doubled his capital in New Zealand, Butler returned to England (1864) and took the apartment in Clifford's Inn which was to be his home for the rest of his life. In 1865 his *Evidences for the Resurrection of Jesus Christ . . . Critically Examined* appeared anonymously. For a few years he studied painting at Heatherley's art school, and tried to convince himself that this

was his vocation. Until 1876 he exhibited occasionally at the Royal Academy. One of his oil paintings, "Mr. Hatherley's Holiday" (1874), is in the Tate gallery, London, and his "Family Prayers," in which the ethos of Langar rectory is satirically conveyed, is at St. John's college, Cambridge. Later he tried his hand (in collaboration with H. Festing Jones) at musical composition, publishing *Gavottes, Minuets, Fugues, and Other Short Pisces for the Piano* (1885), and *Narcissus*, a comic cantata in the style of Handel—whom he rated high above all other composers—in 1888: *Ulysses: an Oratorio* appeared in 1904. It was typical of Butler to use his native gifts and mother wit in such exploits, and even in literature, his rightful territory, much of his work is that of the shrewd amateur who sets out alone to sling pebbles, small but lethal, at various Goliaths of the Establishment. "I have never," he once said, "written on any subject unless I believed that the authorities on it were hopelessly wrong." Hence his assault on the citadels of orthodox Darwinism and orthodox Christianity; hence, later, his attempt to prove that the *Odyssey* was written in Sicily by a woman (*The Authoress of the Odyssey*, 1897), and his new interpretation of Shakespeare's sonnets (*Shakespeare's Sonnets Reconsidered and in Part Rearranged*, 1899).

Erewhon (1872) made whatever reputation Butler enjoyed in his lifetime as a writer; it was the only one of his many books on which he made any profit worth mentioning, and he only made £69 3s. 10d. on that. Yet it was received by many as the best thing of its kind since *Gulliver's Travels*—that is to say, as a satire on contemporary life and thought conveyed by the time-honoured convention of travel in an imaginary country. The opening chapters, based upon Butler's recollections of the Upper Rangitata mountains, are in an excellent narrative style, and the description of the hollow statues at the top of the pass, vibrating in the wind with unearthly chords, makes a highly effective transition to the strange land beyond. The landscape and people of Erewhon are idealized from northern Italy; its institutions are partly Utopian and partly satiric inversions of our own. Butler's two main themes, religion and evolution, appear respectively in the "Musical Banks" (Churches) and in the chapters called "Some Erewhonian Trials" and "The Book of the Machines." The Erewhonians have long ago abolished machines as dangerous competitors in the struggle for existence, and by punishing disease as a crime they have produced a race of great physical beauty and strength.

The Fair Haven (1873) is an ironical defense of Christianity, which, under the guise of orthodox zeal, nevertheless undermines its miraculous foundations. Butler was dogged all through life by the sense of having been bamboozled by those who should have been his betters; he had been taken in by his parents and their religion; he was taken in again by his friend Charles Pauli, who returned neither the money nor the friendship he accepted from Butler for years, and by the companies of another friend, Henry Hoare (in which he invested and lost money); life itself, and the world, sometimes seemed to him a hollow sham. Was Darwin himself, his saviour from Langar, now to prove a fraud as well? This was the suspicion that dawned upon him while writing *Life and Habit* (1878), and envenomed the series of evolutionary books that followed: *Evolution, Old and New* (1879), *Unconscious Memory* (1880) and *Luck or Cunning* (1887). Darwin had not really explained evolution at all, because he had not accounted for the variations on which Natural Selection worked. Where Darwin saw only chance, Butler saw the Lamarckian effort on the part of creatures to respond to felt needs. He conceived creatures as acquiring necessary habits (and organs to perform them) and transmitting these to their offspring as unconscious memories. He thus restored teleology to a world from which purpose had been excluded by Darwin; but instead of attributing the purpose to God he placed it within the creatures themselves as the Life Force.

Many regard *The Way of All Flesh* (published 1903, the year after Butler's death) as his masterpiece. It certainly contains much of the quintessence of Butlerism (though the *Notebooks*, of which H. Festing Jones published a selection in 1912, are necessary to supplement it). This largely autobiographical novel tells

with ruthless wit, realism and lack of sentiment, the story of Butler's escape from the suffocating moral atmosphere of his home circle. Ernest Pontifex stands for his early self and Overton for his maturity: Theobald and Christina are his parents. Towneley and Alethea represent "nice" people (Alethea was partially modeled on his friend and critic Miss Savage)—people who "love God" in Butler's special sense of having "good health, good looks, good sense, experience, and a fair balance of cash in hand." The book was influential at the beginning of the anti-Victorian reaction, and Butler was saluted by G. B. Shaw as "the greatest English writer of the latter half of the nineteenth century." He died in London, on June 18, 1902.

Other works of Butler, not mentioned above, include *Alps and Sanctuaries of Piedmont* (1882); *Ex Voto: An Account of the Sacro Monte or New Jerusalem at Varallo-Sesia* (1888); *The Life and Letters of Dr. Samuel Butler*, 2 vol. (1896); *Erewhon Revisited* (1901); *God the Known and God the Unknown* (1909); *The Humour of Homer, and Other Essays* (1913).

BUTLER, a city of Pennsylvania: U.S., the seat of Butler county, is about 30 mi. N. of Pittsburgh. It is built on a site once owned by Robert Morris, American Revolutionary War financier, and is named for Gen. Richard Butler. It was founded in 1800, incorporated as a borough in 1503 and made a city in 1917.

Oil, natural gas, limestone, coal and iron are plentiful in the vicinity. Manufacture of steel, chemical, glass, food, lumber, metal, mine and paper products together with extensive agriculture give diversified employment to the region. For comparative population figures see table in PENNSYLVANIA: *Population*.

(C. c. G.)

BUTLEROV, ALEXANDER MIKHAILOVICH (1828-1886), Russian chemist, best known for his studies of organic compounds, was born Aug. 25, 1828, near Kazan. With a Moscow doctorate (1854) he joined the Kazan university faculty. In 1868 he transferred to St. Petersburg. Butlerov studied with E. Mitscherlich, F. A. Kekulé, C. A. Wurtz, A. W. Von Hofmann and A. W. Williamson. His contributions included the first synthetic sugar and tertiary alcohol, proof of the impossibility of free methylene, formaldehyde polymerization and special studies in connection with hexamethylenetetramine, zinc alkyls, pinacolone and isomeric hydrocarbons. Giving full credit to Kekulé, he introduced the word "structure" into organic chemistry in a text on structural theory. He was an honorary member of many scientific societies! and was one of the first honorary members of the American Chemical society. He died Aug. 5, 1886, in Biarritz. (V. Bw.)

BUTO, the Greek form of ancient Egyptian P-Udjo (older form Per-Wedjoyet), "house of (the goddess) Udjo," is the name of several towns in Egypt, the most important being the modern Tall al-Farain in the northwestern delta. Stephen of Byzantium wrongly applies the name of the town, Buto, to the goddess herself: by all other Greek authors she is identified with Leto and called by this name. The town, where the cult of the goddess had its origin, was the capital of a lower Egyptian kingdom in pre-historic times, and retained some religious importance even after the unification of the country, as did the goddess, who remained a tutelary deity of lower (northern) Egypt. She was usually depicted as a cobra (uraeus) entwined round a papyrus stem, or as a part of the diadem on the head of the Pharaoh, whom she protected against enemies. According to a later tradition she was nurse to the infant god Horus whom Isis bore on the floating island of Chemmis near Buto, and saved Horus from his treacherous uncle, the god Setekh. It was this myth that reminded the Greeks of the story of Leto and Apollo on Delos and led to the identification of Udjo with Leto (*q.v.*).

The temple and oracle at Buto were much admired by Herodotus (ii. 155). (J. Cy.)

BUTT, DAME CLARA ELLEN (1873-1936), English contralto known for her performances of ballads and oratorios. Born at Southwick, Sussex, Feb. 1, 1873, she was a pupil of Daniel Rootham and J. H. Blon-er in England, of V. A. Duvernoy and J. Bouhy in Paris and of Etelka Gerster in Berlin. She made her debut in 1892 in London as Ursula in Sir Arthur Sullivan's cantata *The Golden Legend*. She possessed a powerful contralto voice and a commanding personality and was admired especially in the oratorios of Handel and Mendelssohn. She also became popular as a ballad singer in Britain and abroad, notably in Sir Edward Elgar's "Land of Hope and Glory," written at her suggestion, and Samuel Liddle's "Abide with Me." Elgar wrote for her his song cycle *Sea Pictures*, and she inspired the part of the angel in his *Dream of Gerontius*. In 1900 she married the baritone Robert Kennerley Rumford, with whom she gave joint recitals. In 1919 she made one of her few appearances in opera, taking the title role in the production at Covent Garden of Gluck's *Orfeo*, conducted by Sir Thomas Beecham. In 1920 she was created a dame of the British empire for her services to music in World War I. She died at North Stoke, Oxfordshire, Jan. 23, 1936.

See W. Ponder, *Clara Butt* (1928).

BUTT, ISAAC (1813-1879), Irish lawyer and Nationalist leader, who inaugurated the Home Rule movement, was born at Glenfin, Donegal, on Sept. 6, 1813, the son of the rector of Stranorlar. He was educated at Trinity college, Dublin, where in 1833 he helped to found the *Dublin University Magazine*, and in 1836 was appointed professor of political economy. He was called to the Irish bar in 1838 and was made a queen's counsel in 1844. Butt was a staunch supporter of the union between Great Britain and Ireland, and his eloquence, knowledge of economic affairs and great legal abilities made him one of the most influential opponents of Daniel O'Connell (*q.v.*). But his faith in the system of a joint legislature for Great Britain and Ireland was shaken by the government's failure to take effective action in the face of the great Irish famine of the 1840s.

Butt had for years urged a radical reform of the Irish system of land tenure which at that time gave no security to tenants and enabled landlords to increase rents exorbitantly by subdividing the uneconomic small holdings. Experience of the famine convinced him that even the most urgent Irish needs received little attention at Westminster and that some form of native parliament in Ireland was indispensable. In 1848 he undertook the defense of the leaders of the Young Ireland movement when they were charged with high treason as a result of their abortive insurrection that year. Later, between 1865 and 1869, he became the chief defending counsel for the Fenian leaders.

Butt was elected Liberal-Conservative member of parliament for Youghal in 1852 and retained the seat until 1865. During this time his views became increasingly liberal. In May 1870 he propounded a policy calling for a national parliament for Ireland (subordinate to the imperial parliament at Westminster) and formed the Home Government association. He was, if not the originator of the term "Home Rule," the first to make it an effective political slogan (see IRELAND: *History*). When, in 1871, he was again elected to parliament—on this occasion for Limerick—he found he could count upon the support of 57 Home Rule members in the house of commons. The national agitation revived quickly under his leadership, but the movement soon found a more dynamic and younger leader in Charles Stewart Parnell, who began to organize systematic obstruction of parliamentary business at Westminster. Butt disapproved of the obstructionists' provocative and disruptive methods, but with his influence declining and in failing health, he was unable to control them and was soon displaced in favour of Parnell. He died in Dublin on May 5, 1879.

See T. de Vere White, *The Road of Excess* (1946). (D. G.)

BUTTE, a city of Montana, U.S., on the western slope of the continental divide; the seat of Silver Bow county. Butte early became known as "the richest hill on earth." Placer gold discovered in 1864 produced \$1,500,000 by 1869. Silver was first successfully treated in 1875. Its production declined markedly after the price dropped in 1893. Copper production in Butte began in

1882 and by 1900 represented 50% of the nation's output. Zinc had almost equaled the value of copper in annual output by the second half of the 20th century. Lead and manganese were other important products.

The city of Butte was laid out in 1866 and incorporated in 1879. It grew slowly until the railroads reached it in the 1880s. Butte's early history was closely linked with the "war of the copper kings," William A. Clark, Marcus Daly and F. Augustus Heinze (*see MONTANA: History and Government*). The decline in mining and the increased use of machinery caused the population to decrease after 1940 (for comparative population figures *see* table in *MONTANA: Population*). In an effort to relieve the chronic instability of the economy the Anaconda Copper Mining company in 1952 adopted a 20-year plan, the Greater Butte project. This was followed in 1955 by the beginning of open-pit operations in the Berkeley mine. Butte's strong labour organizations have been nationally important.

The city continued to be the railroad and wholesaling centre for western Montana. Its Memorial hospital is widely used in the area. The Montana School of Mines opened in Butte in 1900. Diversified industries include a packing plant, a large stock sales yard and an elemental phosphorus plant. To the west of the city is Big Butte, a sharp conical peak from which the city takes its name.

(M. G. BU.)

BUTTE (BUTE) (Fr. *butte*, "a hillock or rising ground"), a flat-topped hill surrounded by a steep escarpment from which a slope descends to the plain. The term is sometimes used for an elevation higher than a hill but not high enough for a mountain. The butte capped by a horizontal platform of hard rock is characteristic of the arid plateau region of the western United States. *See* also MESA.

BUTTER. As the term is used most commonly, butter is the yellowish or whitish fat of cow's milk as flocculated or solidified by churning. The commercial product contains not less than 80% and as much as 85% milk fat, 12% to 16% water, about 2% salt (mostly added) and about 1% milk curd. The fat consists of glycerides of perhaps eight acids, among them oleic, stearic, palmitic and butyric. The recognized high food value of butter depends predominantly on high food energy, approximately 716 cal. per 100 grams, plus high vitamin A value of about 3,300 international units (annual average) per 100 grams and substantial amounts of vitamin D. Protein is low, as are vitamins other than A and D, but about 20 mg. of calcium and 16 mg. of phosphorus are present per 100 grams. The colour of butter is caused by the carotene and other fat-soluble pigments in the fat globules of milk.

When or where man first learned to concentrate this small portion of milk and to utilize it as a semistorable and high energy food is unknown, but presumably it was in the prehistoric stages of animal husbandry. Certainly it has long been used and relished by man as a spread and as a cooking fat. Butter is the favourite edible fat of the peoples of northern Europe, North America and Oceania and some other places to which Europeans have migrated in numbers. Much of the production is restricted to those areas, but some other areas, particularly India, make considerable use of it. Much of Indian consumption is of a semifluid, clarified form called ghee.

In all, about one-third of the world's milk production is devoted to buttermaking. Estimated world butter production in the early 1960s was about 9,500,000,000 lb. annually, which was, however, about 10% less than the average in the years preceding World War II. The United States was the world's largest producer with an annual output exceeding 1,400,000,000 lb., followed by the Soviet Union with a production about 5% less than the U.S.; west Germany with 725,000,000 lb.; France, 650,000,000 lb.; and Australia and New Zealand, each with about 450,000,000 lb.

In the United States butter was first made on farms. The pioneers who went west to take up grain farming soon realized the value of cattle in the maintenance of soil productivity and built up sizable herds as quickly as possible. When this led to the production of butter in excess of the farm family's require-

ments, the surplus was disposed of either to neighbours for cash or to the village store in exchange for necessary commodities.

Enterprising persons saw an opportunity for commercializing buttermaking. The first creamery established in the United States was built by R. S. Woodhull of Campbell Hall, Orange county, New York, in 1856. Other creameries sprang up in various sections of New York and gradually moved westward to the Great Lakes and beyond.

The change of butter from a farm to a factory commodity is mirrored in the statistics of the United States department of agriculture. In the year 1850 the United States produced 313,-345,566 lb. of butter, all farm-made. In 1910 the country's output was 1,706,000,000 lb., 60% of which was made in commercial plants. In the early 1960s, about 1,250,000,000 lb. of creamery butter and 150,000,000 lb. of farm butter were being manufactured annually in the United States.

The first creameries purchased whole milk from the farmers and separated it by letting the milk stand until the cream rose to the top. Then either the cream was skimmed from the top or the skim milk was drawn from the bottom. With the introduction of a farm-sized mechanical separator in 1890, however, the farmer was able to market his butterfat in the form of cream rather than as whole milk. The development of the Babcock test by S. M. Babcock in the same year enabled the creamery to give the farmer a cash return on the actual fat delivered rather than on the amount of whole milk.

The first neighborhood factory handled only a few hundred pounds of butter a day; by the early 1960s the small creamery had an average annual output of about 250,000 lb. of butter, marketed through the city wholesale dealer or jobber. In a few cases a number of small creameries organized a co-operative marketing agency. A few single factories had an annual production of approximately 15,000,000 lb., and a few companies with a series of 15 or 20 creameries were manufacturing more than 60,000,000 lb. of butter in a year.

Milk as it comes from the cow ranges from a low of approximately 3% to a high of about 6% butterfat. Good butter production must begin with the milk cow—her health and her diet affect even the final flavour of the butter (*see* DAIRY INDUSTRY). The care the milk receives, particularly as to noncontamination with bacteria or odours and rapid cooling after milking, is most important.

Butter is made as follows: As quickly as the milk is separated the cream is cooled. The cream is delivered to the creamery, where it is graded according to at least two classes, sweet and sour. If sour, the acidity is standardized to about 0.25% lactic acid by the use of a carbonate or a lime. Then it is pasteurized, and if ripened cream butter is to be made a pure culture of *Streptococcus lactis* is introduced to start the desirable souring process. If sweet cream butter is to be made no starter is added. The best storage butter is made from unripened or sweet cream. After pasteurization and ripening the cream is held overnight and then is churned, washed, salted and worked in the combined churn and worker. The market requirements determine the amount of colour and salt that are used.

The butter is compressed in bulk containers and then or later is cut into rectangular blocks of 1 lb. or $\frac{1}{4}$ lb. weight and packaged for retailing. Various continuous-process methods, by means of which butter can be produced in a continuous flow rather than in batches, were under development in the early 1960s.

In the early 1920s congress authorized the U.S. department of agriculture to set up a federal butter-grading and inspection service that would enable buttermakers and dealers to have an inspector examine commercial lots of butter and issue official certificates of grade.

Such grading did not become compulsory, however. The grade is based on aroma, taste, body or texture, colour and salt. The grades, based on a scoring of all factors, range from a high of 93 score through the much more usual and very acceptable 92 score, to 90 to 89, to cooking-grade butter. Grading has been particularly well developed and high quality obtained in countries such as Denmark and New Zealand, which serve an export market.

In England and Wales, the voluntary grading scheme operated by the National Association of Creamery Proprietors received 100% support of the producers.

About one-fourth of U.S. milk production ordinarily is used for butter. Eighty per cent of U.S. butter is manufactured in the west north central and east north central regions, with Minnesota, Iowa and Wisconsin the leading states. From more than 2,800 manufacturing plants it is sold mostly as produced to central market wholesalers, butter marketing co-operatives, chain stores, large dairy corporations and meat packers. These primary receivers distribute nearly half through their own outlets. Nearly 90% of the butter tends to bypass the wholesale "open markets" of Chicago and New York city. Spot markets are found in those cities as part of the mercantile exchanges, as are butter future markets. Those of Chicago are more active.

Butter was rationed in most major consuming countries during World War II and in some of them even into the early 1950s. In part this was because of the general food situation, but in the United States, in spite of increased milk production, a larger share of the total was consumed as whole milk and used for manufacturing. Military procurement rose to 312,000,000 lb. in 1944 and exports to 107,000,000 lb. in 1943. Civilian consumption per capita declined from more than 17 lb. per year prewar to 8.3 lb. in 1958. Competition with margarine became more severe as laws were relaxed in the postwar period. In 1958 New Zealand had the world's highest per capita consumption of butter of 42.7 lb., followed by the Republic of Ireland with 39.9 lb.

During the years 1933-41 the U.S. government engaged in butter price-stabilization programs, purchasing about 270,000,000 lb. From late 1942 until mid-1946 ceiling prices were in effect on butter, with a subsidy of five cents per pound. Butterfat came under the provisions of the Steagall amendment and so was supported at 90% of parity for two years after the official ending of hostilities. After 1949 the Commodity Credit corporation supported milk and butter prices through offers to purchase butter and other manufactured dairy products.

International trade in butter in 1958 set a post-World War II record but was 7% less than before the war. New Zealand exported 174,000 tons, or 30% of the world total; Denmark was second with 113,000 tons, or 20%.

BUTTERCUP, various plants, also called crowfoots, which bear bright-yellow, broadly cup-shaped flowers. Among the best known are the tall or meadow buttercup (*Ranunculus acris*), two feet to three feet high, n-ith stiffly erect stems; the creeping buttercup (*R. repens*), which spreads by runners; and the bulbous buttercup (*R. bulbosus*), one foot high, with the stem thickened at the base into a bulb. These plants, all Eurasian and abundant in the British Isles, have become widely naturalized in North America.

Among native American species are marsh buttercup (*R. septentrionalis*) and California buttercup (*R. californicus*). The turban or Persian buttercup (*R. asiaticus*) is widely cultivated for ornament. See RANUNCULUS.

BUTTERFAT, the fatty constituent of cows' milk. Butter, which is a solid emulsion containing fat, water, curd, milk sugar and inorganic salts, is melted and allowed to settle; the clear butterfat rises to the top and is separated by decantation. It does not become rancid as readily as butter, for the albuminous curd and the water present in the latter favour the growth of the organisms which promote rancidity. Butterfat is manufac-

tured chiefly in India and Egypt; before World War I it was also prepared in Siberia (whence it was exported to Turkey) and to a less extent in Germany (*Schmelzbutter*). In India, where it is prepared in large quantities, butterfat is known as ghee; it is commonly mixed with the milk fat of the buffalo, while in Egypt the chief adulterants are the milk fats of sheep and goats. In the latter country the fat is termed *samna*. Butterfat occupies a unique position among the natural animal fats because it contains considerable amounts of the glycerides of the water-soluble fatty acids—butyric, caproic, caprylic and capric acids. The Reichert-Meissel (Reichert-Wollny) value, which is a measure of the amount of these acids, is a valuable characteristic in butterfat analysis.

Especially characteristic is the presence of butyric acid, which is absent from coconut and palm-kernel oils, from which butterfat is distinguished also by its smaller content of lauric acid. See also BUTTER; OILS, FATS AND WAXES.

BUTTERFIELD, WILLIAM (1814-1900), English architect, was born in London on Sept. 7, 1814. Articled first to a Westminster builder, he later spent three years with a Worcester architect, acquiring a taste for Gothic. In 1843 he became connected with the Cambridge Camden society, a High Anglican group who wished ecclesiastical architecture to conform to the Oxford reformers' liturgy.

Butterfield, who built nearly 100 churches, provided the desired settings, but built in an astringent manner using red brick, roughly sawn timber and a harsh, abrupt disposition of masses, qualities linking him with the Pre-Raphaelites. His most ornate church is All Saints', Margaret street, London (1849-55); others include St. Matthias', Stoke Newington (1851-53), and St. Alban's, Holborn (1859-63), in London; a church at Babbacombe, Devon (1867-74), and in 1891-92, St. Augustine's, Bournemouth, Hampshire. His few secular works include Keble college, Oxford, mostly complete by 1870; its variegated brick banding is characteristic of all Butterfield's works.

He died in London on Feb. 23, 1900.

BIBLIOGRAPHY.—J. Summerson in *Architectural Review*, xcvi (Dec. 1945), and *Heavenly Mansions* (1949); N. Pevsner, *London, Except the Cities of London and Westminster* in the "Buildings of England" Series (1952). (D. C. T. T.)

BUTTERFISH or DOLLARFISH (*Poronotus triacanthus*), a deep-bodied, spiny-rayed fish with a long dorsal and anal fins and a forked tail, caught along the Atlantic coast of North America from Nova Scotia to Florida. The delicate flavour is especially well developed when the fish is fried in butter until lightly browned. Its maximum length is about 12 inches. Because of its bright, silvery, rounded appearance it is sometimes called the dollarfish.

Spawning occurs off-shore in deep water during the summer. The adults then congregate in loose schools over mud bottom in shallow water. The eggs hatch in about two days and the young often gather under jellyfish.

The name butterfish is also applied to various other fishes of the Stromateidae family and to species of blenny. (C. H. U.)

BUTTERFLY AND MOTH. The butterflies and moths together form a single order of insects; in fact, few languages even make a distinction between them. This group is the Lepidoptera—a term derived from the Greek meaning "scale-wing," in reference to one of the most distinctive features of the order. The name was proposed by Linnaeus in 1733 and has been retained by all naturalists after him.

This article is divided into the following sections:

I. General Structure

1. Head
2. Thorax
3. Wing Veins
4. Legs
5. Hearing Organs
6. Abdominal Segments

II. Development

1. Eggs
2. Caterpillars
3. Food of Caterpillars
4. Silk Production
5. Pupa or Chrysalis

III. Natural History

1. Sexual Difference
2. Seasonal Forms
3. Departure From Usual Life History
4. Sound Production

IV. Distribution and Migration

1. Geographical Distribution
2. Migration
3. Geological Distribution
4. Economic Importance

V. Classification

- A. Suborder Jugatae (Homoneura)
- B. Suborder Frenatae (Heteroneura)
- C. Macrolepidoptera

I. GENERAL STRUCTURE

At least 100,000 species were described by the early 1960s. Lepidoptera are among the most familiar and easily recognizable insects and have long been popular objects for study and collecting, largely because of the great beauty of coloration shown by so many of the species, together with the interest that is afforded by following their transformations. Their most easily observable characteristic is the scaly covering of the wings, body and appendages, which comes off on the fingers as a dust when these insects are handled. Examined under a microscope this dust is seen to be composed of minute scales of definite forms. Most Lepidoptera also possess a coiled "tongue" (proboscis) in front of the head.

Metamorphosis is complete. The larvae are caterpillars usually having eight pairs of legs. The pupae generally have their appendages more or less glued down to the body and are then said to be obtected; they are usually enclosed in a silken cocoon or in an earthen cell.

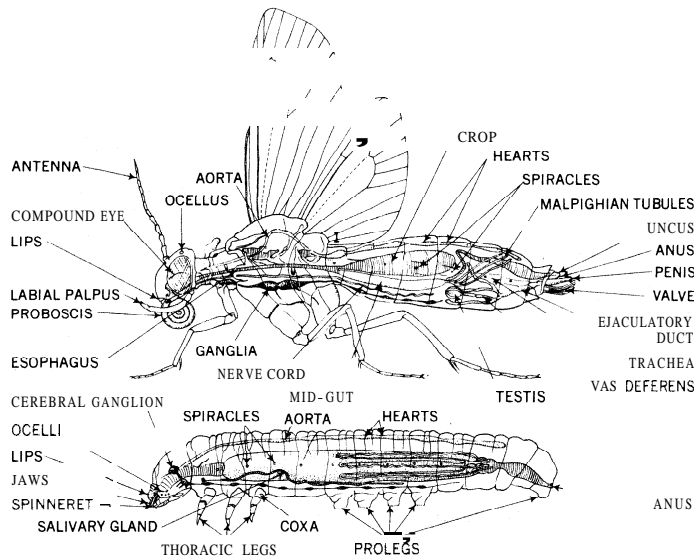

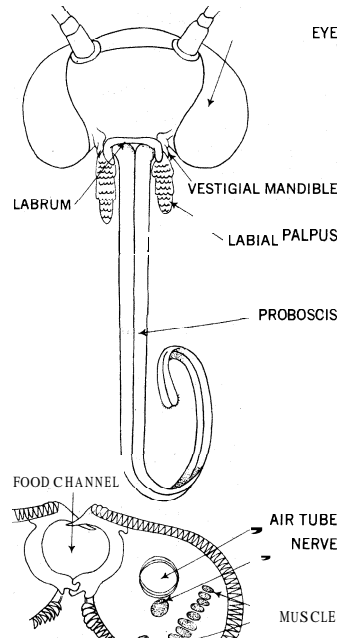

FIG. 1.—(TOP) BODY PLAN OF BUTTERFLY OR MOTH. LEFT WINGS, RIGHT LEG AND NERVOUS SYSTEM OF HEAD NOT SHOWN. RIGHT WINGS REDUCED. (BOTTOM) BODY PLAN OF CATERPILLAR

1. Head.—The head is small and subglobular in shape with the compound eyes well developed; a pair of simple eyes (ocelli) is often present on the vertex. The antennae are many-jointed: in numerous moths they are threadlike, in others they bear comb-like processes and are said to be pectinate, a development that is most pronounced in the males; among butterflies the antennae terminate in a club or knob.

The mouth parts (fig. 2) are nearly always adapted for sucking, with the mandibles reduced to vestiges or entirely wanting. The maxillae have their two galeae greatly elongated and interlocked to form the proboscis, a sucking tube through which the food is imbibed; it is coiled up like a watch spring when at rest, but extended straight out when sucking nectar from flowers. Maxillary palpi are generally reduced or absent, and the labium is represented by a small plate generally bearing prominent three-

BY COURTESY OF THE EDITOR OF THE AMERICAN NATURALIST

FIG. 2.—(TOP) HEAD-ON VIEW OF MOUTH PARTS OF MOTH (BOTTOM) HIGHLY MAGNIFIED CROSS SECTION THROUGH PROBOSCIS

longitudinally striated and there are often tiny cross striae or connecting bars between the striae. Each scale has a very complex structure of chitinous bars forming a grating in three directions and revealed only by the electron microscope. When spaced at the proper distance (half the wave length of the light concerned) these bars produce brilliant interference colours. Peculiar scales known as androconia are found in the wings of the males of certain Lepidoptera; in some cases they occur in "brands" or patches and physiologically they are glandular structures that secrete an odour often very characteristic for particular species. The wings of a side are linked together by a coupling apparatus which exists in several forms (fig. 4). In the primitive swift moths a finger-like process (jugum) of the forewing grips and overlaps the base of the hind wing when the insect is in flight. In most moths a group of stiff setae, forming the frenulum, arises from the base of the hind wing and passes beneath the forewing, where it is retained in position by a catch (retinaculum); in the male the setae of the frenulum are usually fused into a single stout bristle, but in the female they remain separate. Among some moths and in butterflies there is no frenulum, and the humeral lobe at the base of the hind wing is greatly developed and projects some distance beneath the forewing, where it is held in position.

3. Wing Veins.—For practical purposes the wing veins may be thought of as a loop, enclosing the discal cell (fig. 4) from which a series of branches radiate to the margins, with one free

FIG. 3.—WING SCALES. (A) FROM MOTH OF THE FAMILY URANIIDAE; (B) FROM FRITILLARY BUTTERFLY (ARGYNNIS) SHOWING ARRANGEMENT OF SCALES AND EMPTY SOCKETS FROM WHICH SCALES HAVE BEEN REMOVED. (BOTH ENLARGED)

jointed palpi. In some Lepidoptera the mouth parts are rudimentary and no food is taken in the adult stage, while at the other extreme in certain hawk moths the proboscis is more than six inches long and adapted for probing the deeply seated nectaries of tubular flowers. In a few cases the proboscis bears toothed spines at its apex, and those moths which possess this feature are able to lacerate the rind of fruits and suck the juices within.

2. Thorax.—The thorax has its first segment small and usually collarlike, but often bearing lateral processes (patagia) that are characteristic of the order. The mesothorax is large and carries a pair of well-developed plates (tegulae), which often overlap the bases of the wings. In almost all species the metathorax is small and inconspicuous above.

The wings are membranous and clothed with modified hairs termed scales; in many species almost every transition between flattened hairs and broad scales can be detected under a micro-

scope (fig. 3). Most scales are

FIG. 4—WING VENATION OF MONARCH BUTTERFLY (DANAUS PLEXIPPUS)

vein (subcosta) in front and one to three veins (anals) behind it. The original Comstock system (used in this article), the earlier system still sometimes used to designate the main veins, and the Herrick-Schaeffer number system correspond as follows:

Comstock	Earlier System	Herrick-Schaeffer
	Main veins	
Subcosta (Sc)	Costal (C)	12
Radius (R)	Subcostal	
Media (M)	
Cubitus (Cu)	Median	
1st anal (1stA)	"The fold"	1c
2nd anal (2dA)	Submedian (SM)	1b
3rd anal (3dA)	Anal (hind wing)	1a
	Branches	
5 radials (R ₁ to R ₅)	5 subcostals	11-7
1st medial (M ₁)	Upper radial (UR)	6
2nd medial (M ₂)	Lower radial (LR)	5
3rd medial (M ₃)	Upper median (M ₃)	4
1st cubital (CU ₁)	Middle median (M ₂)	3
2nd cubital (Cu ₂)	Lower median (M ₁)	2

In the hind wing, where four radials are absent in higher moths and butterflies, Herrick-Schaeffer numbers the surviving radial vein seven, and subcosta eight.

4. Legs.—The legs characteristically have five-jointed tarsi; the forelegs bear a modified upper spur (the epiphysis), the middle legs two end spurs and hind legs both upper and end spurs. In many butterflies the forelegs are unused and reduced; in a few geometrid moths, the hind legs.

5. Hearing Organs.—The great majority of Lepidoptera carry organs for the perception of vibrations, frequently with resonating structures in the form of air sacs and tightly stretched membranes. Their position is characteristic of the group. In the Noctuoidea this tympanum is on the thorax below the base of the hind wing; in the Geometridae and most Pyralididae at the base of the abdomen, below; and in the nymphalid butterflies in the swollen base of the subcostal vein, etc.

6. Abdominal Segments.—Ten abdominal segments are pres-

AFTER IMMS GENERAL TEXTBOOK OF ENTOMOLOGY
FIG. 5—WING VENATION OF A JUGATE MOTH (MNEMONICA SUBPURPURELLA)

ent in the Lepidoptera, but the sternum of the first is degenerate or modified into the tympanum, and the last two are transformed into the external organs of reproduction. The fundamental structures of the male and their modifications are of major importance in classification. In the female the ovipositor is never valvate as in primitive insects, but takes many forms, lobed, telescopic, or hard, serrate and piercing, adapted to the manner of laying eggs. In all but a few primitive families there are two reproductive openings, one for copulation and the other for laying eggs.

II. DEVELOPMENT

1. Eggs.—The eggs of Lepidoptera are generally of one of two types. They may be ovoid or flattened with the long axis horizontal; or upright, spherical or hemispherical with the horizontal axes equal. Both types may have the shell (chorion) sculptured in various ways, and in the upright eggs of many butterflies the shell exhibits a beautiful cell-like structure divided by longitudinal ribs. The number of eggs laid is variable and a single female may deposit up to a thousand or more. Some of the swift moths and the antler moth (*Charaeeas graminis*) merely drop their eggs at random among the herbage upon which the future caterpillars feed. The lackey or tent caterpillar moths (*Malacosoma*) lay their eggs in necklacelike rings around twigs, whereas the garden white butterflies (*Pieris*) place them singly or in small groups on the undersides of leaves and the brown-tail moth (*Euproctis chrysorrhoea*) lays them in masses covered with hair derived from the anal tuft at the extremity of the body.

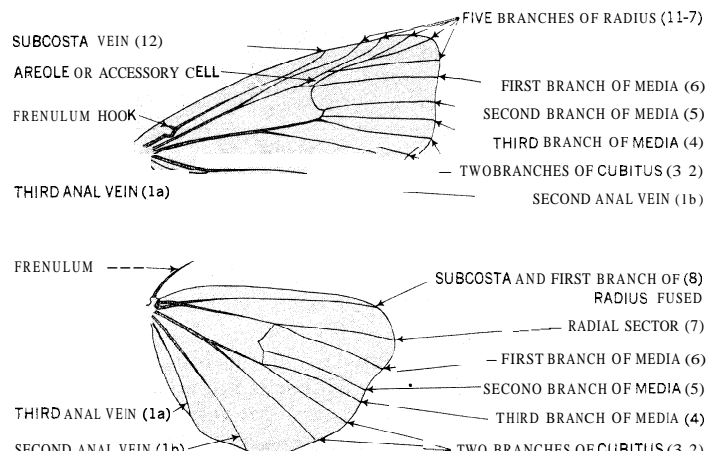

FIG. 6—WING VENATION OF NOCTUID MOTH (LITHACODIA APICOSA) NUMBERS IN PARENTHESES INDICATE HERRICK-SCHAEFFER SYSTEM OF DESIGNATION (See TEXT)

2. Caterpillars.—The larvae are known as caterpillars, which are characterized by the presence of three pairs of jointed, clawed legs on the thorax and a variable number of abdominal feet, which are short, fleshy outgrowths provided with a series of hooks or crochets on their grasping surfaces. These abdominal feet consist typically of five pairs, but in the geometer or looper caterpillars they are present only on the sixth and tenth segments.

The head in caterpillars is a firmly chitinized capsule which carries six simple eyes on either side and a pair of very short antennae. The jaws (or mandibles) are large and strong, while the maxillae are small and inconspicuous; the labium bears a median tube (spinneret) which receives the ducts of the spinning glands. The latter are the modified salivary glands and they produce the silk used in forming the cocoon; in many cases these glands are very long, and in the silkworm are about five times as long as the whole caterpillar.

Along the sides of the body nine pairs of spiracles are found and they appear as small dots, often easily seen.

Caterpillars are armed or protected in various ways either by virtue of their structure or of their behaviour. Some, such as those of tiger moths, are densely hairy, and in the vaporer moths (*Orgyia*) these hairs are grouped into conspicuous tufts and brushes. Certain caterpillars are efficiently protected by so-called urticating hairs which are very fragile and bristle with needlelike

lateral points. Their irritating properties are in part caused by mechanical action, but chiefly by a poisonous secretion; most

people who handle hairy caterpillars of various types experience the effects of such hairs on the skin. In North America and also in the tropics there are caterpillars armed with true poison spines, which are tubes fed with the secretion of special glands in the skin. Such spines are capable of inflicting painful stings and evidently secure for their possessors considerable immunity from attack. Some notodontid caterpillars can also throw a jet of formic acid, and many have poisonous body fluids.

Among butterflies, the caterpillars of the tortoise shells and other species of *Vanessa* and of fritillaries are armed with spiny nonpoisonous outgrowths of the body, and very much the same

LYNWOOD M. CHACE FROM NATIONAL AUDUBON SOCIETY

FIG. 8.—WING VENATION AND PATTERN OF BLACK SWALLOWTAIL BUTTERFLY (*PAPILIO POLYXENES ASTERTIUS*)

sort of armature is found in caterpillars of the great emperor moths (*Saturniidae*). In hawk moth larvae there is usually a single horn near the extremity, while many other caterpillars are entirely smooth or only slightly hairy.

A very large number of caterpillars protect themselves by feeding only at night; others form cases or webs, or mine into the tissues of leaves, while numerous tortricids roll leaves into tubular retreats. There are, again, others which obtain a measure of protection by close resemblance to their surroundings. Thus, many geometrid or looper caterpillars bear such a very close resemblance to a midrib of a leaf or to a small twig as to render detection a matter of great difficulty. The larvae of some of the hawk moths bear a resemblance to portions of foliage, their diagonal lateral stripes being believed to simulate the effects of light and shade. The caterpillars of the moth *Anarta myrtilli*, with their intricate green pattern, are hardly discernible among the heather upon which they live.

The experiments of E. B. Poulton showed that the reflection of light from the immediate surroundings produces a nervous response on the part of the caterpillar which results in a physiological change in the accumulation of the pigment. Thus larvae of the red underwing moth, when subjected to green surroundings, become bluish-green and in a darkly-coloured environment become bluish-gray. Similarly looper caterpillars, if so placed when young, become dark brown among dark twigs and green if placed among leaves.

3. Food of Caterpillars.—Caterpillars feed almost entirely upon the higher plants, and there is probably not a single family of the latter which does not serve as food for one or more species.

Among the very few caterpillars that are carnivorous are those of some of the lycaenid butterflies. The caterpillars of the large blue (*Lyceena arion*), after feeding upon wild thyme, finally enter ants' nests and prey upon the grubs; those of the North American *Feniseca tarquinius* feed upon aphids. Many other Lycaenidae of the old-world tropics have similar habits. In the Mediterranean region and southern Asia species of the noctuid genus *Eublemma* devour scale insects; this habit generally may be considered beneficial, but it becomes seriously injurious when the lac insect and the cochineal insect are attacked.

Certain other caterpillars are cannibalistic, notably those of the common European moth *Calymnia trapezina*, but this habit is by no means exclusive and such larvae are also regular devourers of

ALEXANDER B. KLOTS

FIG. 9.—FEMALE YUCCA MOTHS (*TEGETICULA ALBA*), IN YUCCA FLOWER. PLANT IS DEPENDENT ON THESE MOTHS FOR CROSS-POLLINATION

foliage. Some additional instances of unusual feeding habits are given in the section devoted to the economic importance of Lepidoptera.

Actual parasites are still rarer, but include the family Epipyropidae and the young larvae of *Cyclotorna* (family uncertain, perhaps Tineidae) on Fulgoridae; a pyralid, *Bradypodicola* (*Cryptoses*) on the hair of the three-toed sloth; a pyralid, *Sthenauge parasiticus* on saturniid caterpillars of the genus *Automeris*; and *Euclementia bassettella*, a gelechioid of uncertain family, in scale insects of the genus *Kermes*.

The latter is the only one markedly modified for parasitism, having very sharp mandibles, although a similarly modified larva of unknown habits was found in the nests of African termites

4. Silk Production.— The production of silk by caterpillars has already been referred to; it is used for several purposes and the best known is for the formation of the cocoon. The latter attains its greatest perfection in those families which include the silkworm moth (*Bombycidae*) and the emperor moths (*Saturniidae*); in other cases, as in the tiger moths and tussock moths, the cocoon is much less dense and the silk often intermixed with hairs derived from the larva that formed it.

Sometimes foreign material largely replaces a cocoon and the silk is utilized to draw together leaves to form a pupal shelter or

AUTHENTICATED NEWS

FIG. 11.— HICKORY-NERVED DEVIL (*CITHERONIA REGALIS*), LARVAL STAGE OF REGAL MOTH. FEEDING ON LEAVES

to cement soil particles into a compact earthen cell, as in many hawk moths (*Sphingidae*) and owl moths (*Noctuidae*).

Among many butterflies the cocoon is reduced to a slight pad, to which the cremaster is hooked, and perhaps a thread encircling the body of the pupa; in such cases these exposed pupae are protected by their close colour resemblance to their surroundings.

Silk is also used by caterpillars as a "life line" which is run out through the spinneret as quickly as it is secreted, and by means of this device such creatures elude their enemies or save themselves when blown off or shaken from their food plants, by remaining suspended by the thread until the danger has passed.

Other caterpillars, when young, are gregarious and secrete guiding threads over their food plant, which enable them to maintain their foothold; others go a stage further and construct communal webs, within which they feed, gradually dispersing and becoming solitary as they grow older.

5. Pupa or Chrysalis.— The pupa in the majority of Lepidoptera is of the obtected type with the appendages glued down to the body, which therefore presents a hard compact appearance. Such pupae have little or no power of movement of the abdominal

segments and remain in a fixed position, being attached by the cremaster to the cocoon, or to a silken pad in the case of many butterflies. (The cremaster consists of a group of hooks or a prominent spine at the caudal extremity of the body and is formed from the last dorsal shield, overlying the vent in the larva.)

Obtected pupae are found in all the higher groups, from the Pyralicoidea to the butterflies and in some Tineae.

Among the lower groups, the pupae are termed incomplete; they have the appendages partially free from the body, instead of being soldered down, and the abdomen has several of the segments freely movable. The latter feature, aided by girdles of spines, enables such pupae to work their way out of the cocoons or burrows and come to the surface to allow for the exit of the perfect insect. Except in the Pterophoridae the cremaster is absent or but little developed. In the Micropterygidae the pupae closely resemble those of the caddis flies (*q.v.*; Trichoptera), and are of the free type, with all the abdominal segments movable and the appendages entirely free from any secondary attachment to the body.

Functional mandibles are present which enable these pupae to bite their way through the cocoons when the time for emergence of the moths approaches. In some moths a special fluid secreted from the mouth serves to soften or dissolve the silk of the cocoon (formic acid in *Schizura concinna*); in many of these and in others there is a sharp hook at the base of the wing, which is used to cut the silk. Certain moths have special spines or ridges on the face, which serve to break open the cocoon or break a way up through hard, dry soil. Facial spines are notably developed in arid countries.

III. NATURAL HISTORY

As adults Lepidoptera feed principally upon nectar, which they derive from flowers, and, among other sources of food, honeydew and overripe fruit. Decaying fruit, for example, is attractive to the red admiral (*Vanessa atalanta*) and certain other butterflies, whereas the purple emperor (*Apatura iris*) is well known to visit carrion.

Certain flowers are more attractive to Lepidoptera than others, and in Europe the flowers of jasmine, honeysuckle, valerian, heather, ivy, sallow, syringa, privet, petunia and ragwort are much visited by moths, whereas butterflies are especially partial to bramble, thistle and butterfly bush (*Buddleia*).

Butterflies and certain moths are diurnal insects, but the majority of the members of the order are crepuscular (twilight active) or nocturnal, among them some tropical butterflies, especially Satyrinae, Brassolinæ and a few skippers. Some moths fly both by day and at night; others are seldom known on the wing before midnight. After dark almost the whole of the Noctuidæ are attracted to the moth collectors' sugar mixture.

During the winter, in cold and temperate lands, most Lepidoptera hibernates either as larvae or pupae; some, such as the hairstreak butterflies, overwinter as eggs, while certain of the

Vanessae and other butterflies, along with a number of moths, pass the dormant season as adults. Many Lepidoptera are double-brooded in that two complete life cycles are passed through in the year; others, given a sufficiently high temperature, may pass through four or five generations in that period, particularly species infesting stored grain, meal, etc.

1. Sexual Difference.—The sexual differences in Lepidoptera are often well marked; in some families the antennae are finely branched (pectinated) in the males and simple in the females, or these organs may be pectinated in both sexes, but much more pronounced in the males. The special sensory organs located on the antennae are greatly developed where those appendages are highly pectinated, and give to the males their remarkable power of finding their mates.

The phenomenon known as assembling is especially prevalent in the so-called Bombyces as well as in some other moths, and is believed to be of the nature of an olfactory response. The females apparently emit an odour attractive to the opposite sex, and under favourable conditions a freshly emerged female will attract many males, which fly up to her against the wind.

In many Lepidoptera the sexes differ greatly in size and coloration, as for example in the gypsy moth; among the Lycaenidae the males of numerous species are brilliant blue and the females of a brownish hue. In the tropical Papilionidae the sexes are often totally different in coloration as well as in exhibiting differences in form.

Other examples of sexual dimorphism are shown by those moths whose females are either wingless or have the wings reduced to useless vestiges, the males being fully winged. This peculiarity occurs in distantly related families and was consequently independently evolved. Notable examples are found in the bagworm moths (Psychidae), vaporer moths (*Orgyia*) and in about one-half dozen genera of geometrid moths.

2. Seasonal Forms.—Another interesting feature is the occurrence of different seasonal forms among certain butterflies: these are so different in coloration that they were regarded as separate species until their relationships were worked out. One of the best known examples is the European *Araschnia levana*, whose spring form is known as *levana* and whose summer form was first described under the name *prorsa* as a different butterfly. In the tropics certain species occur in definite wet season and dry season forms.

The North American swallow-tail *Iphiclides marcellus* has three distinct seasonal forms. Those which emerge from overwintered pupae in the early spring are of the form *marcellus* and those that appear somewhat later are of the form *telamonides*; the summer butterflies, produced from eggs laid the same season, are different from either of the spring forms and are of the type named *lecontei*.

There are, again, other butterflies, such as the African *Papilio dardanus*, which have several and

quite different forms in the female that closely mimic other species of Lepidoptera. For a discussion of this and other cases of polymorphism see MIMICRY.

Extensive experiments were conducted by A. Weismann, F. Merrifield, M. Standfuss, E. Fischer and others upon the effects of temperature on seasonal and other types of coloration. Thus Weismann showed that when pupae destined to produce the summer form *prorsa* of *Araschnia leana* were kept at a low temperature they gave rise to the form *levana* or to a form intermediate between it and *prorsa*. By raising the temperature it proved exceedingly difficult to change the form *levana* into *prorsa* and in most cases it was a failure. Weismann concluded, therefore, that the species was a northern one and that the form *levana* was the older and more constant, and that *prorsa* was a later acquired form, and consequently more readily influenced.

By the application of cold, individuals of *Aglais urticae* indistinguishable from the northern variety *polaris* were produced; also, pupae of the summer form of *Pieris napi* when placed on ice gave rise to the winter form of that butterfly.

By raising temperature to the proper level and applying it at the susceptible period it was possible to change the female coloration of two butterflies, *Parnassius apollo* and *Gonepteryx rhamni* into that of their respective males.

3. Departure From Usual Life History.—Among the most remarkable departures from the usual life history prevalent in Lepidoptera is that shown by the Indo-Australian lycaenid butterfly *Liphya brassolis*, whose larva is flattened and covered by a hard cuticle, devoid of evident segmentation. It is found in association with the ant *Oecophylla smaragdina* and is believed to prey upon the brood of the latter, its hard covering serving as a protection against the ants. Pupation occurs in the old larval skin which forms a puparium loosely enclosing the chrysalis. The newly emerged butterfly is covered with loosely attached white scales, over its more permanent orange and brown scales, which serve as protection against the ants, since they fall off readily and cause those insects evident discomfort if they adhere to them.

Another very interesting moth is the North American yucca moth (*Tegeticula*), the females of which have the maxillae provided with a long tentacle specially adapted for collecting the pollen of yucca flowers. After collecting a large mass of pollen she inserts her eggs deep into the ovary of a flower, usually other than that from which the pollen was gathered. After egg laying she then thrusts the pollen into the stigmatic opening of the flower. By means of this provision the development of the seeds upon which the larvae feed is ensured and any not so devoured secure the perpetuation of the yucca.

A third example is afforded by aquatic moths of the genus *Acentropus*. The young larvae live submerged in mines that they excavate in the leaves of water plants; as they grow older they form tunnels of spun leaves, and the submerged pupa is enclosed in a similar shelter. The female moths are dimorphic: the long-winged forms are aerial, whereas those with reduced wings are aquatic,

using their rudimentary wings for swimming.

4. Sound Production.—A few Lepidoptera possess a capacity for sound production. The death's-head moths (*Acherontia*) were long known to emit a shrill chirping note. The method of its production was much discussed and it is believed to be caused by the forcing of air through the proboscis. The caterpillar also was noted to produce sharp cracking notes resembling those emitted during the discharge of successive electric sparks; in this case the sound is produced by bringing the mandibles forcibly together.

Several moths are able to stridulate, and in certain Agaristidae the male has a corrugated area beneath the costa of the forewings, and the membrane in that area is distended to form a resonator. It is suggested that the clicking sound observed is caused by the ridged area on the forewings rubbing against the spurs on the legs during flight.

IV. DISTRIBUTION AND MIGRATION

1. Geographical Distribution.—Lepidoptera have a range practically co-extensive with that of flowering plants and are only absent from the remote and inhospitable regions around the poles. Among butterflies it is interesting to note that at least 46 species extend within the Arctic circle and some range as far north as latitude 80°; but, on the other hand, no resident butterfly is known from too cloudy Iceland. In the antarctic, latitude 50° is about their most southerly limit, which is reached by a species of fritillary found on an island near Cape Horn.

Some species of Lepidoptera are almost world-wide and exhibit migratory tendencies, notable examples being the hawk moth *Celerio lineata* and the butterfly *Vanessa cardui*, the latter being found in all the continents except South America. Several noctuid moths, notably *Agrotis ypsilon*, are cosmopolitan. The blue butterfly *Lampides boeticus* occurs over all the warmer parts of the old world to Australia as well as reaching remote islands in the Atlantic, Pacific and Indian oceans. In some cases human agencies were possibly partially responsible for the wide range enjoyed by such insects by the introduction of suitable food plants in regions where they did not previously exist.

J. A. WILSON

FIG. 17.—MOTTLED UMBER MOTH (*ERANNIS DEFOLIARA*): (LEFT) MALE; (RIGHT) NORMAL WINGLESS FEMALE

Although many of the largest families of Lepidoptera are cosmopolitan, certain others are limited to definite areas of the globe. Among moths the Xyloryctidae are most at home in Australia, the Lacosomidae are confined to the western hemisphere and the Megalopygidae have few species elsewhere. Among butterflies, the subfamilies Ithomiinae, Brassoliniinae and Heliconiinae of the Nymphalidae are confined to tropical America, and Acraeinae are mainly centred in Africa.

The richest fauna of Lepidoptera, as in most orders of insects, is found in the tropics, and Brazil probably yields more species of butterflies than any other part of the world. More than 600 species were stated to have been taken within an hour's journey of the city of Para alone. Some idea of this wealth of species will be gathered when it is mentioned that only 70 species are recorded from the British Isles.

2. Migration.—Some species of Lepidoptera have a marked capacity for migrating from one region to another, either individually or in swarms. In North America great companies of the monarch butterfly (*Danaw plexippus*) form in parts of Canada and the northern U.S. and fly southward in early autumn, wintering in a zone extending from Florida to southern California; the scattered survivors straggle north in the spring. Southern populations in Argentina and Brazil migrate similarly, but the tropical populations are sedentary.

In Ceylon C. B. Williams mentions that about 69 out of a total of 234 species of butterflies known in Ceylon were recorded as taking part in migratory flights. The latter occur at the beginning and at the end of the northeast monsoon and proceed in various directions. At times these flights seem to bear some correlation with seasonal changes, and it was suggested that they originate owing to the drying up of the food plants, but the data is insufficient for drawing reliable conclusions.

The painted lady (*Vanessa cardui*) moves northward in spring in north Africa and south Europe, invading most of central and northern Europe as far as Iceland; individuals found in countries such as England and Germany are entirely emigrants from the south, and in some years they fail to appear.

Migratory swarms of Lepidoptera were often recorded from far out in the ocean. In one case a swarm of the weak-flying moth *Utetheisa pulchella* was observed at sea nearly 1,000 mi. from its nearest known habitat. Solitary individuals of various species often fly on board ship at a great distance from land, and are chiefly those of wide geographical range.

3. Geological Distribution.—No undoubted fossil Lepidoptera are known before the commencement of the Tertiary period (about 70,000,000 years ago), although it is probable that the primitive Jugatae existed at an earlier epoch. Butterfly remains are known from the Eocene and Oligocene of North America and a few moths were described from Baltic amber. As a whole, knowledge of the fossil history of Lepidoptera is very scanty, which perhaps is scarcely surprising considering the delicacy of structure exhibited in so many of the species.

4. Economic Importance.—In the caterpillar stages a large number of species of the order are injurious to crops and forest trees. Among the Hepialidae the subterranean larvae are destructive to grass roots and in Australia those of *Leto* and *Charagia* bore into the solid wood of trees. Other wood borers are found in the families Cossidae, including the goat and leopard moths, Xyloryctidae and Sesiidae. The Tineidae include the cosmopolitan clothes moths, *Tinea pellionella*, *Tineola bisselliella* and *Trichophaga tapetzella*, which are destructive in houses, their larvae attacking wool, hair, carpets, feathers and dried skins. Among the Gelechiidae are the Angoumois grain moth (*Sitotroga cerealella*) which attacks wheat, maize, etc.; *Pectinophora gossypiella*, the most serious lepidopterous enemy of the cotton plant, found in many lands; and *Hypatima pulverea* which is destructive to lac cultivation in India. In the Yponomeutidae the diamondback moth (*Plutella maculipennis*) is one of the widest distributed of all moths and very destructive to cruciferous vegetables. The great group known commonly as the tortricids include many species harmful to fruit trees, and its most notable representative is the codling moth (*Cydia pomonella*) of the

apple; *Tortrix viridana* is a serious defoliator of the oak in Europe, and species of *Evetria* are very injurious to conifers. Mention needs also to be made of the oriental peach moth (*Laspeyresia molesta*) which, from 1916, became a dangerous enemy of plum, cherry, peach and apple in the U.S., where it is believed to have been introduced from Japan.

Of the Pyralididae the cosmopolitan *Pyralis farinalis* forms silken galleries among stored corn and flour; corn borers (*q.v.*) are dangerous pests in several countries. In the Crambinae the borer moth (*Diatraea saccharalis*) is also a chief pest of sugar cane in the Gulf states and tropical America. Among the Phycitinae are two moths infesting stored foods, viz., the cosmopolitan Mediterranean flour moth (*Ephestia kuhniella*), which is troublesome in flour mills, and the Indian-meal moth (*Plodia interpunctella*), which is a pest of almonds, groceries and other stored goods. Both species became practically world-wide through commerce.

Among the Noctuidae, larvae of *Agrotis*, *Noctua* and other genera are known as cutworms which feed at night, cutting off crop plants before they are very far grown. The army worm (*q.v.*; *Leucania unipuncta*), found throughout the U.S. east of the Rocky mountains and also in other countries, appears in some years in vast numbers in the caterpillar stage. The name is given from the fact that when these larvae have destroyed the vegetation in the area where the eggs were laid they advance in army-like swarms to other fields.

In Europe the antler moth (*Charaas graminis*) behaves in a similar fashion, and a serious outbreak in Great Britain took place in 1917. The Lymantriidae include several well-known defoliators of forest and shade trees, as was previously mentioned; while among the Geometridae, group the looper caterpillars of many species are injurious to fruit trees and bushes.

In contrast, certain Bombycidae and Saturniidae are commercially valuable in yielding silk. The common silkworm moth (*Bombyx mori*), which belongs to the first mentioned family, is native to China and was introduced into many countries. The usual food of its caterpillars is the leaves of the mulberry and the silk produced is of the highest quality. Among the Saturniidae several eastern species yield lower grades of commercial silk, and the varieties of the latter, known as shantung, tussore, eria and muga silks, are produced by species of *Antheraea* and *Philosamia*. (See SILK AND SERICULTURE; SATURNIID MOTH.)

Very few other Lepidoptera are in any sense useful to man, except the showy coloured species which are utilized for ornamentation or mounted for purposes of display. Mention need also be made of the caterpillars of a few species which prey upon aphids or scale insects, and thereby confer benefit by destroying noxious and pestiferous forms of insect life.

V. CLASSIFICATION

The first scientific arrangement of Lepidoptera was that of Linnaeus in 1758. He divided them into three genera, *Papilio*, including the butterflies, *Sphinx* and *Phalaena*. The first and last were subdivided into named groups similar to modern subgenera. His subdivisions of *Papilio* were abandoned, but his *Sphinx*, *Phalaena Noctua*, *Geometra*, *Pyralis*, *Tortrix* and *Alucita* correspond roughly to the modern families Sphingidae, Noctuidae, Geometridae, Pyralididae, Tortricidae and Pterophoridae. His *Bombyx* is represented by many families of generally stout, and often weak-tongued and sluggish moths, still loosely referred to as the "Bombyces"; and his *Tinea* to a similar series of families of small, slender, broad-fringed and soft-scaled moths often called Tineae, or loosely, Tineidae.

The moths are also divided into Microlepidoptera or "Micros," comprising the first groups discussed below (including or excluding the Pyralididae), except those whose build and habits cause them to be classed as "Bombyces"; and the "Macros," including the Lepidoptera above the Pyralididae. Another common subdivision of the higher moths is according to the position of vein media-two (M_2); if this arises low down, so that it is more or less clearly a branch of the cubital stem, at least in the forewing, the moths are called Quadrifidae; if independent, so that the cubitus

appears to have only three branches, they are called Trifidae. These two terms are also used for the two main subdivisions of the family Noctuidae, basing the names in this case on the condition of the hind wing.

The following arrangement is based on that in W. T. M. Forbes's *Lepidoptera of New York and Neighboring States*.

A. SUBORDER JUGATAE (HOMONEURA)

Venation of forewings and hind wings similar, vein R with four or five branches in both pairs of wings; forewings provided with a jugum

Of the half-dozen families forming this suborder of jugate moths, only three are found in the north temperate zone, and they are not closely related.

Micropterygidae.—This is a family of very small moths, usually brilliantly coloured and flying by day, with a digestive system suited to eating pollen, well-developed mandibles, and no sucking tongue. The wings are much like the following family, and also the pupa, but the eggs are laid externally on mosses and liverworts in wet places, on which the larvae feed exposed. The chief northern genera are *Micropteryx* and *Epimartyria*, with the more primitive *Sabatina* in New Zealand.

Eriocraniidae.—The Eriocraniidae are strictly nectar feeders, with a short but spirally coiled tongue like higher moths; the last segment of the abdomen is modified into a piercing ovipositor, by which the eggs are laid in the tissue of leaves, and the larvae, which are unique in structure, feed as leaf miners on woody plants—birch, chestnut, hazel, etc. The pupa, which is formed in the ground, has enormous crossed mandibles like a caddis fly pupa, with the help of which it digs its way to the surface before the moth emerges. *Eriocrania* and *Mnemonica* are the chief genera.

Hepialidae (Swifts or Ghost Moths).—The Hepialidae contrast with the two preceding, being "Bombyces" in build. They have no functional mouth parts, and in the north temperate species no spurs on the tibiae. They are medium, large or even gigantic moths, and are most widely represented in Australia. The larvae are borers, most frequently in woody plants, although the ghost moth of Europe (*Hepialus humuli*) works in the roots of herbaceous plants.

B. SUBORDER FRENATAE (HETERONEURA)

Venations of forewings and hind wings markedly different; the hind wing showing only a single free radial vein (or two in a very few primitive types); jugum absent, frenulum normally present

This suborder is generally taken to include the enormous residue of Lepidoptera including the remaining moths and all the butterflies and skippers; but butterflies have a long history of their own, and have some right to be considered a third suborder (the Rhopalocera), marked by the combination of loss of the frenulum and clubbed antennae, with the sensory area practically limited to the club; they also have differences in the pupal tracheation (R_{4+5} arising before R_1) and in the egg and larva.

Many of the families can be grouped into superfamilies, but the relationships of others are still uncertain. The following analysis takes early stages as well as adults into consideration, and tries to take a middle position in the delimitation of families, subdividing less than the Washington but more than the Vienna school.

The two families listed below appear to be world-wide, but are generally neglected in Europe and North America.

Incurvariidae.—The family Incurvariidae (or Adelidae, including the Prodoxidae) is the most primitive of frenate families and has the general structure of the Tineidae, but still preserves the piercing ovipositor of the Eriocraniidae. The larvae are borers or seed feeders and most frequently live in portable cases (e.g., *Adela*). The most curious habit is that of *Tegeticula* (see above, *Departure Front Usual Life History*).

Nepticulidae.—The Nepticulidae are a degenerate family of minute moths, and are the smallest of Lepidoptera, some having a wing expanse of only three millimetres. Most of them are leaf miners, usually forming serpentine mines. These two families

appear to be world-wide, but generally are neglected except in Europe and North America.

SUPERFAMILY ZYGAENOIDEA (SLUG CATERPILLARS)

Moths of bombycine build, frequently with proboscis degenerate; with complete venation, including a vein through the cell (the actual base of media) and the first anal preserved; caterpillars very stout and sluglike; pupae short, stout and thin-skinned, dorsally covered with fine spinules

The pupa is an extreme of the so-called "incomplete" type, with most of the segments movable, and capable of emerging from the cocoon with the aid of a pumping motion of the abdomen, before the mouth emerges.

The group is extremely primitive also in venation and thoracic structure, but biologically occupies the same place as the higher (unrelated) bombycine families. Many of the larvae possess sucking disks on the prolegs, in addition to, or in place of the usual hooks. The pupae are in silken cocoons, made of distinctive flat, ribbonlike silk, and are usually provided with a lid or trap door for the emergence of the pupa.

Zygaenidae (Leaf Skeletonizer Moths).—The Zygaenidae include the burnets and foresters. They fly slowly and by day, and are almost limited to the old world. *Zygaena* includes many European kinds, generally black with pale or crimson spots and frequently with blue or green iridescence; the Chalcosiinae dominate in the oriental region, where many enter into Miillerian mimetic groups; in *Himantopterus* the hind wings are drawn out into long filaments. America has only a few dull blackish species.

Limacodidae (Slug and Saddleback Caterpillars).—This is a large and world-wide family (but relatively few in Europe), adapted to wet climates. The curious sluglike larvae have the head completely drawn into the body, and the prolegs replaced by eight pairs of suckers, without hooks. The majority have spines, and some sting severely like nettles, but a few, like the two European species, are smooth.

Megalopygidae (Flannel Moths).—In the Megalopygidae the larvae have prolegs, and the suckers are also lengthened into false prolegs, seven or eight pairs in all; they also have irritant hairs, and some sting severely. Their distribution is curious, being limited to America and North Africa.

AUTHENTICATED NEWS
FIG. 18.—SADDLEBACK CATERPILLARS (SIBINE STIMULEA). POISONOUS SPINES ARE PRESENT IN TUFTS

Epipyropidae (Planthopper Parasites).—The Epipyropidae may be considered an appendage of this superfamily. They are most unusual for Lepidoptera in having a parasitic larva, living externally on nymphs of planthoppers (Fulgoridae). The larva is sluglike, but the moth is more like a psychid (see *Psychidae*, below) than a zygaenid. The few species are found in the U.S., Japan, China and the tropics, but are best represented in Australia. The curious Australian genus *Cyclotorna* may also be related. Its larva is a parasite on Fulgoridae only when young, then undergoes a drastic change of structure and finishes its life as a social parasite in ants' nests. The moth looks more like an unusually smooth tineid (see *Tineidae*, below).

SUPERFAMILY TINEOIDEA

This heading may serve to group a varied and ill-defined mass of families more or less related to the Tineidae. Typically the head is rough, maxillary palpi long and folded, labial palpi clumsily shaped and bristled, larva with setae four and five (the two below the spiracle) wide apart, and pupa incomplete, but slender and rather well chitinized. But this structure is only a norm, from which there is divergence in all directions.

Tineidae (Clothes Moths and Others).—The Tineidae are a varied family of small moths, whose larvae are mostly scavengers or fungus feeders; one species, discovered in Florida in 1943,

makes a gall on *Helianthus*; the notorious clothes moths are included, but no normal leaf feeders are known. Many larvae, like one of the clothes moths (*Tinea pellionella*), live in portable cases. A few are reported as predacious.

Psychidae (Bagworm Moths).—The bagworm moths cover every possible range of structure from almost normal Tineidae to large heavy-bodied types generally considered "Bombyces." In the higher forms the male body is heavy, the wings small but strong, and frequently almost transparent; the female is degenerate, ranging from types which are active crawlers, with fully developed legs and antennae but no wings or mouth parts, to maggotlike creatures with no appendages, and only a tuft of hair-scales on the end of the body to show their lepidopterous origin. These latter never leave the cocoon, but are fertilized within it, and lay their eggs in the pupa shell. All the larvae form portable cases of silk, usually covered with bits of leaves or other vegetable fragments.

The psychids are best represented in the temperate old world, but very few inhabit Great Britain. In the eastern U.S. the most famous is the bagworm *Thyridopteryx ephemeraeformis*. It is an advanced type, the male with black body and transparent wings, the female maggotlike, and feeds on many trees, both evergreen and deciduous. It is sometimes a serious pest on shade trees, especially in the suburbs of cities and in parks, reaching its northern limit not much above New York city.

Families Related to the Preceding Groups.—In other more or less related families mention may be made of the trumpet miners (*Tischeria*, Tischeriidae), and the ribbed-cocoon makers (*Bucculatrix*, Lyonetiidae) which are leaf miners when young but later skeletonize leaves. The Gracilariidae have a hypermetamorphosis, the young larvae being sap-feeding leaf miners, with thin knifelike mandibles suitable only for slashing open plant cells and sucking the juices; the late larvae more normal in structure, although lacking the fourth pair of prolegs. *Phyllonorycter* are blotch miners of this type, but in about half the species the larva does not feed after its change of structure.

SUPERFAMILY YPONOMEUTOIDEA

Yponomeutidae (Ermine Moths and Others).—The Yponomeutidae have an obtect pupa (*i.e.*, with the wings soldered to the first four segments of the abdomen, so that only the following segments, if any, are movable, and the pupa unable to progress out of the cocoon). But they still have an unusually large metathorax, and the larva has several series of hooks on the prolegs. The small ermine moths (*Yponomeuta*) have white wings dotted with black, and the larvae are gregarious in a web. *Plutella maculipennis* is the widespread diamondback moth, whose larva is injurious to plants of the cabbage family. It is sometimes made a separate family, Plutellidae, marked by straight maxillary palpi.

Aegeriidae (Sesiidae) (Clearwing Moths).—The Aegeriidae (Sesiidae) comprise the clearwing moths, distinguished by the absence of scales over the greater part of the wings, and the fact that the fore- and hind wings are locked together by a special series of spines (like the Hymenoptera).

Many bear a remarkable resemblance to wasps, bees or ichneumon flies, and fly like them in the sunshine. Their larvae are stem or wood borers, but usually do not bore deeply in larger limbs. Several are serious pests, such as the currant borer (*Ramosia tipuliformis*); the squash borer (*Melittia satyriniformis*, with its many tropical relatives); and the peach-tree borer (*Sanninoidea exitiosa*).

SUPERFAMILY GELECHIOIDEA

Moth of normal tineoid type but with smooth head, minute maxillary palpi of folded type. Larva with setae four and five close together; pupa obtect, more or less flattened

This is a very large and well characterized group, the two families Gelechiidae and Oecophoridae each containing about 3,000 species. In these two families, and also the Xylorictidae, Stenomidae, etc., the wings are ample, the hind wing broad and the venation complete, but in the Cosmopterygidae and Lavernidae the hind wings are reduced to a thread, bearing an enormous

fringe. Most are plant feeders—leaf rollers, seed eaters, borers—but there are some scavengers, especially in the Blastobasidae, and the isolated genus *Endrosis* is a stored food pest. Many are pests, but the pink bollworm of cotton (*Pectinophora gossypiella*) and the Angoumois grain moth (*Sitotroga cerealella*), both Gelechiidae, are perhaps most notorious.

The individual families are frequently world-wide, but the Oecophoridae and Xylorictidae are best developed in Australia, the Stenomidae in South America, and the Blastobasidae in America.

Possibly related to these families are the case-bearers, *Coleophora*, whose larvae are at first leaf miners and later live in portable cases.

SUPERFAMILY TORTRICOIDEA

Soft-scaled moths with venation complete or nearly so; the cell commonly divided by the preservation of the base of media, first anal preserved in at least one pair of wings, head commonly somewhat rough, labial palpi blunt and maxillaries rudimentary. Larva with setae four and five close together; pupa incomplete and heavily spined

This is a varied-looking group, but strongly linked together by the very similar early stages, the great majority of the larvae being borers, and the rest (part of the Tortricidae) leaf rollers or folders.

The more normal members are "Micros" but the Cossidae are traditional "Bombyces" and include, so far as bulk goes, the largest of moths. The Castniidae are almost identical in larva and pupa, and similar in venation, having preserved first anal and the lower fork of the base of media, like the Tortricidae; but they are butterflylike in their colouring, habits and clubbed antennae, and were formerly often rated as butterflies. There is little doubt that they are actually related to the ancestor of the butterflies.

Tortricidae (Leaf Roller Moths).—The Tortricidae are smallish moths, with thin wings, often very broad at the base, giving them the shape of a bell when the wings are folded. There are a good many injurious species, among them the codling moth (*Carpocapsa pomonella*; see CODLING MOTH) and oriental fruit moth (*Laspeyresia molesta*).

There are two subfamilies (raised to families by some). The Tortricinae, without a fringe of hair along the base of vein cubitus of the hind wing, have leaf-rolling larvae, among them several injurious apple leaf rollers in America and the well-known, bright green, oak-feeding *Tortrix viridana* of Europe. The Eucosminae possess a fringe, and include all the injurious boring and fruit feeding species, as well as a few leaf rollers, such as the hydrangea leaf roller, *Exartema ferriferanum*.

Phaloniidae.—The Phaloniidae are several hundred rather humped-looking moths, with the first anal vein wholly lost, and cubitus-two arising much nearer the end of the cell. They are obscure and little known, all borers, mostly in herbaceous plants.

Cossidae (Carpenter Moths and Others).—These are primitive-looking, very heavy moths, with the mouth parts and leg spurs much reduced, but venation very complete, with forked base of medial vein in the cell, and a well-marked areole. All the larvae are borers, many of them in hardwood, and several are serious pests of forest and shade trees. Best known are the leopard moth of Europe, now established at several places on the Atlantic coast of the U.S. (*Zeuzera pyrina*); goat moth of Europe (*Cossus cossus*); carpenter moths of the U.S. (*Prionoxystus robiniae* and *macmurtrei*); red coffee borer of eastern Asia (*Zeuzera coffeae*); and coffee borer of the West Indies (*Xyleutes personalis*).

LYNWOOD H. CHACE
FIG. 19.—LEOPARD MOTH (*ZEUZERA PYRINA*)

Castniidae.—The Castniidae include a small number of bright coloured, day-flying moths from tropical America, several from Australia and a couple from Indo-Malaysia. The adults are remarkably skipperlike both in looks and habits, but the scales are very loosely attached to their powerful wings, like the Tortricidae, and the larvae are cossidlike borers, although in monocotyledonous plants. One very large species is a pest, boring in the trunks of palms; and other species bore in *Heliconia* (bush banana) and orchids. The eggs of the Castniidae and typical Cossidae are upright and sculptured, like the butterflies, and unlike the *Zeuzera* group and most Microlepidoptera.

SUPERFAMILY PYRALIDOIDEA

Hind wings with veins Sc and R¹ closely parallel or fused beyond the point where R leaves the cell (with few exceptions); first anal vein commonly preserved in hind wing only; tongue commonly scaled at base, like most of the preceding moths; tympanum commonly present, facing forward at ventral base of abdomen. Larva with only two setae on the wart before the first spiracle (like the following moths), with setae four and five close together; pupa obtect

This group has a very distinct array of forms, halfway between the "Micros" and the higher types, and usually disowned by specialists in both. There are more than 10,000 species, mostly of the enormous family, with a few hundred representing one-half dozen other families.

Pyralididae (Pyralid Moths).—These moths are distinguished by always having the characteristic arrangement of subcosta of the hind wing, and two or more radial branches of the forewing strongly stalked (that is, arising as a single vein from the discal cell and then separating before reaching the margin) or totally united. The first anal vein is rarely preserved in the forewing (subfamily Schoenobiinae), or lost in the hind wing (Chrysauginae).

The family is divided into a dozen subfamilies, or by some authors is made a smaller number of separate families, treating most of the following groups as families. The Pyraustinae (or Pyraustidae) contain nearly one-half of the kinds, and more than one-half the specimens received from tropical collectors, and include many of the most beautiful of moths, such as the large, pale green *Siga liris* of South America, nearly three inches across the wings; the widespread tropical bean pest, *Maruca testulalis*; and the black and white grape leaf folder of the U.S. (*Desmia funeralis*), with its many tropical relatives. The latter form retreats by folding parts of grape leaves into tunnels (see also CORN BORER).

Among the Pyralididae are the most completely aquatic of caterpillars, many of whom form portable cases in which they swim from plant to plant. Caterpillars of several species of *Nymphula* (Nymphulinae, or considered part of the Pyraustinae) live wholly under water and breathe by tracheal gills. *Acentropus niveus* (Schoenobiinae), which is common in Europe, is now known from the St. Lawrence area. The meal moth (*Pyralis farinalis*, Pyralidinae), which is widely distributed through commerce, the Mediterranean flour moth and Indian-meal moth (*Anagasta* or *Ephestia kuhniella* and *Plodia interpunctella*, Phycitinae) and *Corsyra cephalonica* of the Galleriinae represent widespread and important pests of stored foods.

Thyrididae.—The Thyrididae have always lost both first anal veins, and usually have no veins of the forewing stalked. They are almost limited to the tropics, but have a few primitive types in which subcosta and radius of the hind wing are still widely separated (*Thyris* and *Dysodia*) in the temperate zone of both hemispheres. The larvae are stem borers, and often make slender galls.

Carposinidae.—The Carposinidae are a curious little family, which E. Meyrick thought to represent the ancestor of the pyraloids. The larvae are unique and maggotlike, with the last pair of spiracles very large and turned back like a maggot. They live in juicy fruits and one is injurious to plums in China and Japan.

Hyblaeidae.—The Hyblaeidae are much like the thyrids, but have enormous maxillary as well as labial palpi, and have preserved a slender first anal vein in the hind wing. They are a very

small family, but include the injurious teak leaf roller (*Hyblaea puera*), widespread in the tropics. Some Hyblaeidae have the smallest heads of any known Lepidoptera.

Pterophoridae and Orneodidae (Featherwings or Plume Moths).—The plume moths, or featherwings, belong to two families and represent the Phalaena Alucita of Linnaeus. The Pterophoridae have the hind wing almost invariably divided into three feathers and the forewing more or less cleft. They include several hundred species and are world-wide.

The Orneodidae are also world-wide, but rather few, and are represented by a single rare species in the U.S. They have each wing cleft into six feathers, and therefore are called the 20-plumes, or many-plumes.

C. MACROLEPIDOPTERA

The remaining families constitute the Macrolepidoptera or "Macros." In them the maxillae are never scaled and the maxillary palpi never well-developed; the wings never have a well-developed base of the median vein, nor first anal vein, although there may occasionally be vestiges; and their scales are always firmly attached. The larvae never have but two setae on the tubercle in front of the first spiracle, and the two setae just below the abdominal spiracles are never as closely associated as in many of the preceding types; the pupae are always obtect, with the wings soldered to the first four segments of the abdomen, and only capable of a squirming motion if any. In this series the trifid or quadrid condition of the wing veins, and the frequent loss of the frenulum, are important characters, although less than was formerly supposed. In the following subdivision more weight is put on larval characters and the auditory organ.

SUPERFAMILY URANIOIDEA

Tympanum sexually dimorphic; on second segment of abdomen, facing backward in male, forward in the female. Venation much as in the Saturnioidea, but with all radial branches present and the last one closely associated with first media

Uraniidae and Epiplemididae.—The Uraniidae are among the most brilliant and butterflylike of moths. Many are brilliant black and green, and tailed like a swallowtail; but others are brown, and there is a large, old-world, white group forming the transition to the Epiplemididae. The Uraniidae lack the frenulum entirely, the white annectent types merely show a base, while the Epiplemididae have a normal frenulum. The latter are inconspicuous types, and not limited to the tropics, although absent from Europe. The odd genus *Epicopeia*, from eastern Asia, shows striking mimicry of the aristolochia swallowtails of the same region.

SUPERFAMILY SATURNIOIDEA

Tympanum absent. Trifidae with at least one radial branch lost, the last one widely separated from the first medial. Hind wing always without frenulum; with subcostal vein leaving the cell abruptly near the base and not again approaching it. Antenna usually unscaled

This group of large or very large and beautiful moths is most popular with the amateur, both because of their beauty and the ease with which they are reared. Most of them are tropical, but a fair number are found in temperate North America and several in the warmer part of Europe. The Saturniidae are also of great economic value to man, for they include all the so-called "wild" silkworms (see SILK AND SERICULTURE; SATURNIID MOTH). Aside from a few South American forms they belong to two families, which are well contrasted, but intergrade completely.

HUGH SPENCER FROM NATIONAL AUDUBON SOCIETY

FIG. 20.—LUNA MOTH (ACTIAS LUNA)

Saturniidae (Giant Silkworm Moths).—The Saturniidae are silk spinners; the moth

has four branches on each segment of the male antenna; the forewing has the first two branches of media grouped together, and the hind wing has only one anal vein.

Citheroniidae (Royal Moths).—In the Citheroniidae, which are almost wholly American, there are only two branches on each segment of the male antenna, the second media arises free, and there are two anals in the hind wing. But the group which contains the io, and many other American moths, is intermediate; they are also marked by the caterpillars being densely covered with branching nettle spines, and processionary in habit when young.

Doubtful Members.—The Lacosomidae are an isolated and purely American family that may have some relation to the saturniids. They are instantly recognized by the very wide space between the third and fourth branches of radius. The caterpillar is unique in habits, forming a portable case with two similar round doors, one of which is blocked by the caterpillar's head when withdrawn, the other by a circular leathery patch on the end of the tail.

SUPERFAMILY BOMBYCOIDEA

Tympanum absent. Moths with more normal radial system, frequently with all branches preserved; subcosta separate from cell at base, then again connected to it, so as to enclose a small humeral cell. Caterpillar densely covered with fine hair, which may be microscopic or conspicuous

Bombycidae (Silkworm Moths).—The true Bombycidae are a very small group, mainly from eastern Asia, and are famous only for including the Chinese silkworm, probably the most important to man of all Lepidoptera. They are Trifidae, with a tendency to lose the frenulum, and have naked-looking caterpillars with a horn on the tail much like the sphinxes.

Lasiocampidae (Tent Caterpillar Moths).—The Lasiocampidae are quadrids with the frenulum totally lost, and include the injurious tent or lackey caterpillars and the lappets.

SUPERFAMILY DREPANOIDEA

Tympanum on first abdominal segment, pointing backward. Moths with subcosta and radius associated beyond the cell, like the pyralids and sphinxes. Caterpillar with end of body raised and last pair of prolegs somewhat reduced or lost

This is a small group, including the Thyatiridae, which are noctuidlike Trifidae (except one Australasian genus) and the Drepanidae, or hooktips, which are geometerlike Quadrididae. The oriental genus *Cyclidia* or *Euchera* makes the link.

SUPERFAMILY GEOMETROIDEA

Tympanum on the venter of the first abdominal segment, facing forward, as in the Pyralididae. Trifidae with perhaps a few exceptions; subcosta of hind wing sharply bent at base and connected to base of frenulum by a short brace vein, then again approaching or fusing with cell

Geometridae (Measuring Worms and Others).—The superfamily practically consists of the enormous family Geometridae, the inchworms or loopers, with more than 10,000 species. The caterpillars are peculiar in

LYNWOOD M. CHACE FROM NATIONAL AUDUBON SOCIETY

FIG. 22.—TOMATO HORNWORM (*PROTOPARCE QUINQUEMACULATA*): (TOP) LARVA WITH HORN AT POSTERIOR END; (BOTTOM) MOTH

having lost all but the last two pairs of prolegs, so that they must travel by a series of loops. Most important are the cankerworms or winter moths, whose males fly in the frosty weather of late autumn or early spring, while a large proportion of the species have wingless females, who crawl up the trunks of trees to lay their eggs. Some authors divide the Geometridae into about six families: distinguished by points in the venation.

SUPERFAMILY SPHINGOIDEA

Tympanum absent. Very heavy swift-flying moths, with subcosta and radius of hindwing closely parallel beyond end of discal cell and connected by a heavy cross vein (really a free bit of R₁). First segment of palpus enormous, edges of abdominal segments with a series of fine spines

Sphingidae (Sphinx or Hawk Moths).—The caterpillars were the original "sphinxes" because of their way of resting with the front of the body raised high. Most of them are armed with a single strong horn on the tail (eighth segment of abdomen). The moths are called hawk moths from their swift hovering flight, and many of them have very long maxillae, with which they can feed from deep-tubed flowers without alighting. They are believed to be the chief pollenizers of such flowers as petunias and orchids. Although the Sphingoidea consists essentially of Sphingidae, it appears likely that the very small Asiatic and African family Brahmaeidae is related (Jordan). They have the same thorax and venation, but are saturniids in appearance and larval characters.

SUPERFAMILY NOCTUOIDEA

Tympanum on the thorax under the base of the hind wing, facing down and back, often protected by a hood attached to the abdomen. Hind wing with subcosta closely parallel to cell or fused with it for more or less of its length, but rarely beyond. Egg of upright type, with sculpture centring about the top; larva with hooks on prolegs not alternately of two lengths

This is a varied but well-defined group, usually divided into a number of families which, however, are thoroughly linked by transitions. The first three families are trifids, and have the tympanum facing down; they were often widely separated, but

BUTTERFLIES OF NORTH AMERICA

1. Pearl crescent (*Phyciodes tharos*); most of United States and Canada. 2. Spring azure (*Lycaenopsis argiolus*); most of North America. 3. Tiger swallowtail (*Papilio glaucus*); most of North America. 4. Aphrodite fritillary (*Speyeria aphrodite*); United States and southern Canada. 5. Gray hairstreak (*Strymon melinus*); most of United States and southern Canada. 6. Mustard white (*Pieris napi*); most of Canada and northern United States. 7. Common sulphur (*Colias philodice*); most of North America. 8. Red admiral (*Vanessa atalanta*); most of North America, Europe. 9. Fiery skipper (*Hylephila phylaeus*); central United States southward into tropics. 10. Checkered skipper (*Pyrgus communis*); southern Canada and most of United States. 11. Monarch or milkweed butterfly (*Danaüs plexippus*); central Canada southward to Argentina. 12. Meadow fritillary (*Boloria toddi*); southern Canada to Colorado and Virginia. 13. Comma anglewing (*Polygonia comma*); eastern North America southward to North Carolina and Kansas

(Note: Right-hand side of each specimen shows underwing coloration)

PAINTED BY MARJORIE LETHAM, THE AMERICAN MUSEUM OF NATURAL HISTORY, NEW YORK CITY

BUTTERFLIES OF EUROPE

1. Small heath (*Coenonympha pamphilus*); Europe and north Africa to central Asia. 2. Grizzled skipper (*Pyrgus malvae*); Europe to central Asia. 3. Small copper (*Lycaena phlaeas*); Europe, Asia, North America. 4. Apollo (*Parnassius apollo*); most of Europe and northern Asia. 5. Swallowtail (*Papilio machaon*); most of Europe, northern Asia and northern North America. 6. Heath fritillary (*Melitaea athalia*); Europe to central and northern Asia. 7. Painted lady (*Vanessa cardui*); cosmopolitan. 8. Orange tip (*Anthocharis cardamines*); Europe to central Asia. 9. Peacock (*Nymphalis io*); Europe to central Asia. 10. Small white or European cabbage butterfly (*Pieris rapae*); Europe, northern Africa, northern and central Asia; North America (introduced). 11. Wall (*Parrarge megera*); Europe, Asia Minor. 12. Grayling (*Eumenis semele*); Europe and western Asia. 13. Camberwell beauty or mourning cloak (*Nymphalis antiopa*); most of Europe, central Asia and North America. 14. Common blue (*Polyommatus icarus*); Europe, north Africa, northern Asia. 15. Brimstone (*Gonepteryx rhamni*); Europe, northern Africa, northern and central Asia. 16. Comma skipper (*Hesperia comma*); northern Europe, Asia and North America

(Note: Right-hand side of each specimen shows underwing coloration)

EXOTIC BUTTERFLIES

1. *Thecla phaea*; Guatemala to Ecuador. 2. *Euselasia zena*; Amazon. 3. *Heliconius elevatus*; South America. 4. *Kallima limborgi*; southern Asia. 5. *Colotis evippe*; western Africa. 6. *Ordothoptera priamus*; Australia, New Guinea, Moluccas, etc. 7. *Perophalma tullius*; new world tropics. 8. *Eurema proterpia watsonia*; Arizona to Argentina. 9. *Morpho rhetenor*; central and northern South America. 10. *Acraea peneleos*; Africa

(Note: Right-hand side of each specimen shows underwing coloration)

show all other characters of the Noctuoidea.

Notodontidae (Prominent~).—The Notodontidae, or prominents, frequently have the last pair of prolegs of the caterpillar raised and not used, or even modified into slender processes, as in the puss moths, *Cerura*, *Dicranura*; others have a gland under the neck from which they can throw a jet of formic acid several inches, such as the red hump (*Schizura concinna*) in the U.S. and *Anurocampa mingens* in South America.

Diopsideae.—The tropical American Diopsideae differ only biologically, being slender, brilliantly coloured day-flyers. Many of them enter mimicry associations.

Thaumetopoeidae.—The Thaumetopoeidae or processionary caterpillars of the old world have masses of nettle hairs, and the female moth has a large tuft on the end of the abdomen, the hairs of which are plastered over the egg mass. A Madagascar species of the genus *Anaphe* is a source of wild silk.

Lymantriidae (Tussock Moths).—The Lymantriidae (formerly called Liparidae) or tussock moths also have many species with nettle spines and hairy-tufted females, such as the brown-tail, gold-tail and satin moths, but they are quadrifids with an upright tympanum. However, the caterpillars of the gypsy (see GYPSY MOTH) and tussock moths are not poisonous.

Noctuidae (Owlet Moths and Underwings).—The Noctuidae contain about 15,000 species, and as a family are hard to define technically, but can usually be recognized by their stout bodies, relatively inconspicuous colouring and well-developed mouth parts and heads. Technically they possess ocelli and have subcosta fused to the cell of the hind wing for a short distance near the base. They are divided into many subfamilies, of which the trifid ones (with second media of hind wing weak and widely separated from third media and cubitus) usually have stout, normal-looking caterpillars which pupate in the ground and often live at or beneath the surface of the ground (the cutworms or surface caterpillars). Others feed in fruits and seed pods, like the boll-worm or corn-ear worm, *Heliothis zea*, while many feed on leaves. In the quadrifid subfamilies all are leaf feeders, most of them well off the ground, and the caterpillars have rather generally lost one or two pairs of prolegs, so that they loop like a geometer when they walk, but less perfectly. Most of these latter spin cocoons. The venational figure is of an intermediate type.

JOHN H. GERARD
FIG. 24.—CORN EARWORM (*HELIOTHIS ZEA*): (LEFT) CATERPILLAR EATING CORN; (RIGHT) MOTH

Arctiidae (Tiger Moths and Others).—The Arctiidae include the tiger moths. Their caterpillars are the woolly bears, and are densely covered with tufts of stiff, barbed hair; in the American subfamily Phegopterinae some of these tufts are long and pencil-like, causing them to be known as tussocks, like the similar lymantriid caterpillars. The rattlebox moth (*Utetheisa ornatrix*) is of interest, since the North and South American races blend like proper races of a single species where they meet in the West Indies, while in the zone from Kansas to Texas they meet but remain distinct.

Euchromiidae.—The Euchromiidae (Syntomidae, Amatidae) comprise about 2,000 species, mostly brilliantly coloured, day-flying moths, the great majority of them South American. They are distinguished by the loss of Sc of the hind wing as a distinct vein, and the single European genus (*Syntomis* or *Amata*) has lost the tympanum.

Agaristidae (Forester Moths).—The Agaristidae are hardly distinct from the Noctuidae, but their slightly clubbed antennae cause them to be mistaken often for butterflies. Some of the males of this superfamily can make loud rattles or squeaks, such as *Euchontha* in the Diopsideae; *Heliocheilus paradoxus*, a North American noctuid; *Thecophora fovea*, a European one; and some Agaristidae.

SUPERFAMILY PAPILIONOIDEA (BUTTERFLIES)

Antennae clubbed or swollen at their apices and a frenulum wanting
The Papilionoidea, or butterflies, can readily be separated from the moths, or remainder of the Lepidoptera, by the above-mentioned characters and it is noteworthy that clubbed antennae are also found in certain moths, but in such cases the frenulum is present.

Hesperiidae (Skippers).—The most primitive family of butterflies are the Hesperiidae, or skippers, which have all the veins in the forewings arising separately from the cell. They derive their popular name from their erratic darting flight which is different from the more sustained movements of other butterflies. Their affinities are not wholly clear, but they are probably related to the Castniidae (see above). The two chief subfamilies of the Hesperiidae form a very large and world-wide series, but the Pyrrhopyginae are tropical American; the Megathyminae, southern North American; the Ismeninae, old world, chiefly tropical; the primitive Trapezitinae, Australian. The Australian genus *Euschemon* forms a subfamily of a single species, and is the only butterfly with a frenulum.

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY
FIG. 25.—GLASSWING BUTTERFLY (*HAETERA PIERA*)

In the remainder of the butterflies certain of the veins of the forewings do not arise separately from the cell.

Papilionidae (Swallowtail Butterflies).—The swallowtails are large insects, mainly tropical; the majority have tails to the hind wings and they are among the most magnificent of all insects. The forelegs are fully developed in both sexes and the hind wings have only a single anal vein. The larvae are smooth or provided with tubercles, and there is a dorsal retractile scent organ or osmeterium on the prothorax; the pupae are attached head upward, by means of a girdle of silk and a cremaster. The genus *Papilio* is world-wide and the species *P. machaon* is the sole English member of the family. The apollo butterflies (*Parnassius*) are alpine, with translucent wings, and their pupae are exceptional in being enclosed in a loose web among leaves.

Pieridae (Whites and Sulphur Butterflies).—The Pieridae include the whites, yellows and orange tips; the forelegs are fully developed in both sexes and these insects differ from the Papilionidae in having two anal veins to the hind wings. The cabbage white (*Pieris rapae*), common in many parts of the world, is one of the few injurious butterflies, its larvae being destructive to

cabbage and related plants. The larvae have fine velvety hair and the pupae have a single horn to the head and are suspended upright by a girdle of silk and a cremaster.

Lycaenidae (Blues, Coppers and **Hairstreaks**).—The Lycaenidae have the forelegs normal in the female but the tarsi are shortened in the male, with one or both the claws absent; the antennae are nearly always ringed with white and a white rim encircles each eye. They are mostly rather small butterflies, often with metallic colours above and spotted beneath. Their larvae are very short and almost sluglike and the pupae are devoid of spiny processes.

Erycinidae.—The Erycinidae, or Lemoniidae, are closely related to the Lycaenidae and have the forelegs in the male useless for walking, but they are normally developed in the female. The family is essentially South American: only a few species occur in the U.S., while the Duke of Burgundy fritillary (*Nemeobius lucina*) is the only well-known European representative.

Nymphalidae (Brush-Footed Butterflies).—The Nymphalidae are the largest family of butterflies, and number more than 5,000 species; they have the forelegs in both sexes reduced and useless for walking.

Among the various subfamilies, the Nymphalinae include the peacocks, tortoise-shells, admirals, fritillaries and emperors; as a rule they have spiny caterpillars and the pupae hang head downward, only supported by a cremaster. The Satyrinae include the heaths, graylings, meadow browns; they are mostly sombre-coloured and their larvae are smooth, feeding usually upon grasses. The Danainae are only numerous in warm countries! but one of the best known species is the monarch (*Danaus plexippus*) of North and South America. Several of the other subfamilies are found mainly in South America, including the splendid metallic blue Morphinae.

See IKSECT; ENTOMOLOGY; see also Index references under "Butterfly and Moth" in the Index volume.

BIBLIOGRAPHY.—The standard bibliography is *Lepidopterorum Catalogus* (published by Junk), about half completed when interrupted by World War II.

Descriptive Works: North America: J. H. and A. B. Comstock, *How to Know the Butterflies*; W. J. Holland, *Butterfly Book*, rev. ed. (1931), *Moth Book* (1914); A. B. Klots, *A Field Guide to the Butterflies of North America* (1951); W. T. M. Forbes, *Lepidoptera of New York and Neighboring States*, memoir 68, Cornell University Agricultural Experiment Station (1923). Europe: R. South, *Butterflies of the British Isles*, 3rd ed. (1941), and *Moths of the British Isles*, 2 vol., 3rd ed. (1939); E. Meyrick, *Revised Handbook of British Lepidoptera* (1927); J. W. Tutt, *British Lepidoptera*; E. B. Poulton, *The Colours of Animals* (1890); A. G. Mayer, *Bull. Mus. Comp. Zool. Harv.*, vol. 29 (1896); B. N. Schwannwitsch, "Studies Upon the Wing-Pattern of Catagramma . . ." *Trans. Zool. Soc. Lond.*, vol. 21, pt. 2, pp. 107-284 (1930). For migration see C. B. Williams, *The Migration of Butterflies* (1930); C. B. Williams et al., *Trans. R. Ent. Soc. Lond.*, pp. 101-280 (1942). For geographical distribution, A. Pagenstecher, *Die Geographische Verbreitung der Schmetterlinge* (1909); K. Holdhaus in Schroeder's *Handbuch der Entomologie*, vol. ii, pp. 592-1058.

Other literature on the order is mentioned in A. D. Imms, *General Textbook of Entomology*, 3rd ed. (1934) and *Recent Advances in Entomology*, 2nd ed. (1937). (A. D. I.; W. T. M. F.)

BUTTERFLY FISH, the common name of the family Chaetodontidae; these are laterally compressed, brilliantly coloured fishes of tropical seas with, as their Latin name indicates, bristlelike teeth. Young butterfly fish have a collar or sheath around the head and neck; they lose this collar as they mature. The brilliantly coloured adults are easily seen as they dart among coral reefs. Black spots (ocelli) often occur on the tail or fins. Their habit of pointing toward potential danger may help conceal them. Few exceed 8 in. in length and they seldom are used for

food. As do many other tropical fishes, butterfly fishes often have toxins in the viscera and occasionally in the muscles. (C. H. U.)

BUTTERFLY WEED (*Asclepias tuberosa*), a North American plant of the milkweed family (Asclepiadaceae), known also as pleurisry-root, orange-root and orange milkweed. It is native to dry fields from Maine to Ontario and Minnesota and southward to Florida, Texas, Arizona and Chihuahua. The butterfly weed is a stout, rough-haired perennial, with long horizontal roots. The usually erect, somewhat branching stem, 1 ft. to 3 ft. high, is very leafy throughout, and about midsummer bears numerous clusters of bright orange flowers. Unlike most milkweeds, this plant has a very scanty milky juice. The root once was used in medicine, especially for pulmonary affections.

J. HORACE MCFARLAND CO.

BUTTERFLY WEED (ASCLEPIAS TUBEROSA)

Butterfly weed is often planted in wild gardens and is sparingly grown as a border plant.

BUTTERMILK, the liquid residue after removing the butter from cream by the churning process. It consists mainly of water, some 90%, together with milk sugar, about 5%, and casein, about 3%. In addition it contains small quantities of butterfat and lactic acid: To the latter, which is formed during the ripening of the cream, buttermilk owes its slightly acid taste. In North America until about 1900 buttermilk was used chiefly for feeding pigs, especially in the leading dairy districts, but, because of its healthful and nutritious qualities, it later became widely popular as a beverage.

In the United States and Canada it is extensively bottled or packaged in cartons for the market and sold at dairies, grocery stores, delicatessens, soda fountains and restaurants. In some sections, most of the buttermilk sold commercially is "cultivated." Certain bacteria are added to skimmed milk to produce fermentation. The resulting product is somewhat thicker than natural buttermilk, but is in other respects similar. See DAIRY INDUSTRY; MILK.

BUTTERNUT, the tree and fruit of the North American white or long walnut, *Juglans cinerea*, a native of rich woods from New Brunswick to North Dakota and south to Georgia and Arkansas, although not abundant below the latitude of Pennsylvania and Iowa. The nut is oblong-cylindrical with jagged, hard shell. The kernel has a pleasing flavour and is popular in confections and baked goods. Butternut wood is used for furniture. This name is also sometimes used for certain nuts of South America, as the Brazilnut and souari nut. See also WALNUT.

BUTTERWORT, the popular name of a small insectivorous plant, *Pinguicula vulgaris*, which grows in wet, boggy land. It is an herb with a rosette of fleshy, oblong leaves, one to three inches long, lying flat against the ground, of a pale colour, and with a sticky surface. Small insects settle on the leaves and are caught in the viscid secretion. This, like the secretion of the sundew and other insectivorous plants, contains a digestive enzyme which renders the nitrogenous substances of the body of the insect soluble and capable of absorption by the leaf. In this way the plant obtains nitrogenous food by means of its leaves. The leaves bear two sets of glands, the larger borne on usually unicellular stalks, the smaller almost sessile. When a fly is captured, the viscid secretion becomes strongly acid and the naturally incurved margins of the leaf curve still further inward, rendering contact between the insect and the leaf surface more complete. The plant is widely distributed in the north temperate zone, extending into the arctic zone. In North America it ranges from the high northern tundras southward to Newfoundland, New York, Minnesota, Montana and British Columbia. The butterwort belongs to the bladder-

wort family (Lentibulariaceae), which comprises various other carnivorous plants. See UTRICULARIA; CARNIVOROUS PLANTS.

See also F. E. Lloyd, *The Carnivorous Plants* (1942).

BUTTERWORTH, GEORGE SAINTON KAYE (1885–1916). English composer of the post-Elgarian nationalist revival, was born in London, July 12, 1885. He was educated at Eton and Oxford, and later for a short time at the Royal College of Music, London. He was a close friend of Ralph Vaughan Williams and Cecil Sharp, whom he helped in the collection and arrangement of folk songs and dances. He shared Vaughan William's interest in A. E. Housman's poems, some of which he set in two cycles of songs. One of these songs provided the theme for his best-known work, the orchestral rhapsody *A Shropshire Lad* (1912). He was killed in the battle of the Somme on Aug. 5, 1916, shortly after gaining the military cross for gallantry. (Co. MA.)

BUTTONBUSH (*Cephalanthus occidentalis*), a North American shrub or small tree of the madder family (Rubiaceae; *q.v.*), called button willow and also honeyballs in California. It grows in swamps almost throughout North America and in Mexico and Cuba. In the northern parts of its range it is a shrub 3 to 12 ft. high, but in southern Arkansas and eastern Texas it attains a height of 40 to 50 ft., with a straight trunk a foot in diameter. It bears ovate, entire, pointed leaves and small, fragrant, creamy white flowers in globular stalked heads about an inch in diameter. In the northeastern states the buttonbush is sparingly cultivated as an ornamental plant.

BUTTONS, formed pieces of solid material, usually circular, perforated with sewing holes or furnished with a shank, and used to fasten together two parts of a garment by being sewed or otherwise attached to one part and passed through loops or holes (buttonholes) in the other. The term is also applied to a wide variety of buttonlike objects.

Ancient Types.—The tunic, or chiton, of both the ancient Greeks and the Etruscans was fastened at the shoulders with buttons and loops. The chlamys of the Etruscans, a short semicircular mantle, was also fastened with buttons and loops, although the oblong Greek chlamys was fastened with a brooch.

In medieval Europe, garments were chiefly fastened with brooches, clasps and points, or laces, until the 13th century, when buttons came into a prominence that brought about the passing of sumptuary laws limiting their use. The sporting of buttons by persons of low degree was described as a scandal. Despite moral criticism and legal restrictions, however, buttons gained in favour until, in the 14th century, they were worn, both as ornaments and as fastenings, from the elbow to the wrist and from the neckline to the waist.

Cost was a continuing check on such luxury materials as gold, silver and ivory, and the wearing of buttons made from them was an indication of rank and wealth. Handsome and expensive buttons were also made of copper and its alloys. Until the 18th century, manufacture of gold, silver and copper buttons was governed by the guilds dealing with the specific metals; the buttons produced were beautiful-examples of the metalsmith's art. Such buttons were frequently embellished with insets of ivory, tortoise shell and jewels.

More commonly used were buttons of wood and bone. Button forms of these materials were also used as foundations for fabric-covered buttons. Coarse thread-buttons were made by repeatedly drawing the thread over a wire ring.

Pewter, Brass and Steel.—During the 17th and 18th centuries, buttons were molded or stamped from pewter, the familiar metal of the age. During this period, brass buttons also became popular as fastenings for both military and civilian dress. These were cast in molds in which ornamental and distinguishing designs were incorporated. A favoured button of the 18th century was made of calamine brass, produced by heating copper and calamine together. Before the close of the century, multiple molds supplanted single molds, and button output was considerably increased.

A sand mold was also developed. This device consisted of a two-part wooden box containing in both sections a firm mixture of sand, water and molasses. Button-shaped holes were made in

the sand by the pressure of a mold pattern that consisted of individual button forms joined to metal arms and which was placed between the sand surfaces when the box was closed, the sand surfaces being lightly dusted with powdered chalk to prevent their adhering together. After the pattern was removed, molten metal, introduced through an opening in the box, traveled along the channels made in the sand by the pattern arms and entered the individual molds. The buttons were finished on a lathe and then friction-polished by being tumbled together.

The bright, costly cut-steel button, made by attaching polished steel facets to a steel button blank, was introduced by Matthew Boulton, an English manufacturer, about the middle of the 18th century. In France, the facets of the cut-steel button were elaborated by delicate openwork designs. During the first quarter of the 19th century, a less costly but highly attractive stamped steel button in an openwork pattern made its appearance.

Brass buttons gilded by dipping them in an amalgam of mercury and gold achieved great popularity during the 19th century. Five grains of gold were allowed to a gross of buttons. The button blanks were cut from rolled sheets of brass and finished on a lathe. Shanks were soldered in place. The buttons were marked single, double or triple gilt according to the number of times they were treated with the mercury and gold compound. Frequently these gilt buttons bore die-struck or hand-chased ornamentations.

B. Sanders, a Danish manufacturer who went to England after the bombardment of Copenhagen by Lord Nelson in 1801, introduced the two-shell metal button during the first quarter of the century. The shells were thin metal disks with turned edges. Two shells were united by crimping the edges together, with a small piece of cloth or pasteboard enclosed. Another Sanders innovation, originating with the manufacturer's son, was the canvas shank.

Other Improvements.—By the third decade of the 19th century it became possible to produce fabric-covered buttons by mechanical means. Animal horn had been used as button stock since the latter part of the 18th century; during the 19th century animal hoofs were also utilized. Horn and hoof material, plasticized by heat, can be cut, dyed and molded. Buttons were also made of ceramics and glass. Porcelain buttons, charmingly decorated by hand-painting or by the transference of designs in coloured inks from thin tissue papers, became, in the main, a French specialty. Production of coloured glass canes used in button manufacture was largely centered in Czechoslovakia although Paris was the recognized centre of manufacture. The Japanese developed a ceramic button that they hand-painted in traditional motifs of great charm and delicacy. The Chinese also produced a button of unusual interest that consisted of an intricately carved thickness of vermilion lacquer on a wood base. Attractively decorated and lacquered papier-mâché buttons enjoyed a wide popularity during the second half of the 19th century.

Buttons of "Pearl" and "Ivory."—The pearly shells of sea mollusks were early turned to some account in button making. It was with the advent of mechanical methods of production, however, that pearl buttons took an outstanding place in the industry. Button blanks were produced by revolving tubular saws from shell separated into its component layers by treatment with a nitric acid solution. By a second process sewing holes were bored, and an engraved decoration was mechanically applied by a third. At first only sea shell was used, but in the 1890s an American manufacturer, J. F. Boepple, began to avail himself of the ready and abundant supply of fresh-water shells found along the Mississippi river and its tributaries. Although less iridescent than sea shell, fresh-water shell nevertheless represented a useful and profitable source of material. By modern advanced methods of production a single machine can perform all the functions required to produce the completed button from the blank in one operation. Surface irregularities are removed from the finished buttons by tumbling them in rapidly revolving drums.

Vegetable ivory buttons, which first appeared about the middle of the 19th century, are made from the meat of corozo nuts, the fruit of a palm indigenous to South America. By manufacturing methods similar to those employed in the production of pearl but-

tons, vegetable ivory buttons are made from thick slices of nut meat that has been cured in kilns and dried.

Plastics and Resins.—Plastics, such as cellulose, casein and polystyrene, and the polyvinyl resins have been added to the materials from which buttons are manufactured. Molding machines can produce from 50,000 to 250,000 plastic buttons in a 24-hr. period. Buttons can be molded by compression from plastics introduced in a powdered form. They can also be molded by an injection process in which plastic material, heated to a flowable consistency, is forced into individual molds through small openings. Sewing holes are provided for in the molds. Plastic buttons are often intricate in design and are produced in a wide variety of brilliant colours.

BUTTRESS, in architecture, the term given to a mass of masonry projecting from the face of a wall, either to strengthen the wall or to resist the side thrust of an arch, roof or vault. The part of the buttress which receives the thrust is called an abutment.

Buttressing began, tentatively, with the great state constructions of the later Roman empire—baths, basilicas and the like. However, the Romans, and the Byzantines who followed them, preferred wherever possible to combine buttresses with crosswalls, and developed no special architectural treatment for them. It was not until the Romanesque period that external buttresses of large size began to appear—first as mere pilaster strips, then as engaged columns, and finally as projecting masses of masonry with a steep slope at the top to shed water.

As naves came gradually to be roofed with ribbed or groined vaults, in the Gothic period, the tremendous concentration of thrusts at each bay necessitated an entirely new study of the buttress problem. The result was the flying buttress—most spectacular, perhaps, of all Gothic structural innovations. Technically, the flying buttress is an arched strut which transmits the thrust of an arch or vault across an open space, commonly a side aisle or a chapel. The typical Gothic flying buttress consisted of a half arch abutting at its apex, against the nave wall and at the outer end against the vertical mass of the buttress proper, which was usually weighted by a heavy pinnacle. Where the nave wall was of great height, as at Beauvais cathedral, two, or even three, half arches,

one over the other, formed the flying buttress.

In later Gothic architecture elaborately sculptured buttresses were an outstanding feature; but with the revival of Roman building practices during the Renaissance, their importance steadily diminished. In modern architecture, where masonry vaults are seldom found, buttresses have reverted to being mere wall strengtheners, treated in the simplest possible manner. See also ARCHITECTURE; ARCH AND VAULT; ARCHITECTURAL ENGINEERING; GOTHIC ARCHITECTURE. (AN. G.)

BUTUNG, an island S.E. of Celebes, Indon., one of a group which includes Butung, Muna, Kabaena and Wowoni. Butung strait, between Butung and Muna (port, on the east coast. Raha), is narrow and difficult to navigate, but beautiful. Butung is 95 mi. long; the area is 1,759 sq.mi. It has an axial chain of limestone hills (highest point Kepala-Ogena, 3,740 ft.) and is thickly forested. Pop. (1957 est.) 302,347. The coast people are mostly Muslim Buginese, but the interior also has pagan peoples. There are traditionally three classes: descendants of nobles, free inhabitants and slaves. They carry on weaving and copperwork, but are chiefly trading sailors and fishermen, and their well-built prahus traverse all the seas of the archipelago. Houses are built of wood, on piles, and sometimes villages are in shallow water off shore, with approach by a bamboo causeway. Butung formerly had a reputation for piracy, and on the south coast the old pirate haunt of Wasumba is still to be seen, surrounded by thick walls of coral blocks, not far from the village of Wabula. Butung comes under the jurisdiction of South Sulawesi (Celebes), but there is a local sultan, whose *kraton*, or fortress, at Wabula is on a steep hill. Teak is found, and is used for boatbuilding; coconuts are grown, and there is some trade in copra and a kind of small dried fish; a few of the inhabitants engage in pearl-dealing. Butung yields much natural asphalt. Its port is Labuantobelo, at the north end of the island. The administrative centre is Baubau in the southwest. Japan occupied the island in World War II. (J. O. M. B.)

BUTYL ACETATES. This collective term is applied to the acetic acid esters of *n*-butyl alcohol, isobutyl alcohol and secondary butyl alcohol. The butyl acetates are colourless, neutral, mobile liquids having pleasant fruitlike odours. Their commercial importance depends upon their great solvent power for nitrocellulose and for other film-forming compounds used in the lacquer and varnish industries. The acetic acid ester of tertiary butyl alcohol is extremely difficult to prepare and has no commercial importance.

Normal butyl acetate is the standard medium evaporating solvent of the lacquer industry. The commercial product contains 90%–92% *n*-butyl acetate and 8%–10% of *n*-butyl alcohol. Its use in lacquer formulations imparts low viscosity, good flow-out and high resin compatibility characteristics. The butyl acetates of commerce contain 90% butyl acetates and 10% butyl alcohol. Principal users were the manufacturers of lacquers, enamels, patent leathers, linoleum and celluloid products. Pure *n*-butyl acetate boils at 126.1° C.; it is lighter than water, since its specific gravity at 20°/4° C. is 0.882.

Secondary butyl acetate is not as good a lacquer solvent as *n*-butyl acetate. Its evaporation rate is approximately 1.8 times as fast as *n*-butyl acetate. It therefore has a greater tendency to cause blushing of the lacquer films. Its primary use is as a substitute for *n*-butyl acetate. The boiling point is 111.5° C., specific gravity at 20°/4° C. is 0.869.

Isobutyl acetate imparts slightly lower viscosity characteristics than does *n*-butyl acetate to nitrocellulose lacquers. It boils at 117.2° C. and has a specific gravity at 20°/4° C. of 0.875. The commercial product contains 90%–100% ester and 0%–5% isobutyl alcohol. Its evaporation rate is approximately 1.5 times that of *n*-butyl acetate. (D. G. Z.; N. C. S.; X.)

BUTYL ALCOHOLS, a class of organic compounds, of which four members are known: normal butyl alcohol, secondary butyl alcohol, isobutyl alcohol and tertiary butyl alcohol. They have the formula C₄H₉OH. All but tertiary butyl alcohol find extensive use as solvents for lacquers. They are also used extensively in the manufacture of various esters. Tertiary butyl alcohol is used mostly in the manufacture of derivatives. These alcohols are

slightly viscous liquids with penetrating odours. They are somewhat poisonous if taken internally but can be handled with safety if ordinary precautions are taken.

Normal butyl alcohol (butanol) is made commercially by fermentation of corn or molasses and also from acetylene by a series of reactions involving addition of water, condensation and reduction. Secondary butyl alcohol is ordinarily produced from butylene present in cracking gases from petroleum refineries by solution in sulfuric acid followed by reaction with water. Tertiary butyl alcohol is similarly produced from isobutylene. Isobutyl alcohol is made commercially by causing carbon monoxide and hydrogen to react at high pressure.

BUTYRIC ACID is the first acid in the fatty acid series to show structural isomerism (*q.v.*). There are two acids of the formula $C_3H_7.CO_2H$. Normal butyric acid or fermentation butyric acid is found in butter, as a hexyl ester in the oil of *Heracleum giganteum*, as an octyl ester in parsnip (*Pastinaca sativa*), and in the oil of *Eucalyptus perriniana* as n-butyl butyrate; it has also been noticed in meat juice, in perspiration and in excrement. The acid is an oily liquid of unpleasant smell, solidifies at $-19^\circ C$. and boils at $162.3^\circ C$.

Isobutyric acid, $(CH_3)_2.CH.COOH$, is found in the free state in carobs (*Ceratonia siliqua*) and in the root of *Arnica dulcis*, and as an ethyl ester in croton oil. It is a liquid of somewhat unpleasant smell, boiling at $155.5^\circ C$.

BUXACEAE, the boxwood family, a small group of evergreen plants with 6 genera and 30–60 species, mostly shrubs or small trees, in the warmer parts of both hemispheres. Representatives of the genus *Buxus*, known as boxwood (*q.v.*), are highly prized for garden hedges and borders; certain species of *Pachysandra* (*q.v.*) are used as ground covers.

BUXTEHUDE, DIETRICH (c. 1637–1707), Danish organist and composer of church music. The exact date and place of Buxtehude's birth are not known. His father came from Oldesloe and was organist at Helsingborg from about 1638 to 1641 and at Helsingor (Elsinore) from about 1642 to 1671. Nothing is known of Buxtehude's youth, but it can be assumed that his musical education at least was given him by his father. Buxtehude was organist at St. Mary's, Helsingborg (1657–58), and at St. Mary's, Helsingor, from 1660. In 1668 he went to St. Mary's, Lubeck, Ger., and remained there for the rest of his life. With the duties of organist he combined those of *Werkmeister*, a post similar to a *bursar's*. In the same year he married Anna Tunder, the daughter of his predecessor, Franz Tunder. It is not known that Buxtehude journeyed outside Liibeck, though visits by organists to one another were common at this time. In 1703 he was himself visited by Handel, who hoped to succeed him, but marriage with one of Buxtehude's five daughters was a condition; in 1705 Bach also found this condition unacceptable. Buxtehude died at Lubeck on May 9, 1707, and was buried in St. Mary's on May 16.

The duties of the St. Mary's organist included, as well as writing the usual incidental service music, composition for public festivals and for marriages and funerals of the great merchant families of Liibeck. Buxtehude left a considerable amount of vocal and instrumental music, much of which was not recovered until the 20th century; much more certainly remains lost.

Buxtehude's instrumental music is simple and pleasing; it is always well constructed but rarely aims at technical virtuosités. The most important and influential part of it is that for organ, which includes toccatas, preludes and fugues, chaconnes, pieces based on chorales, and a *passacaglia* to which that of J. S. Bach in C minor (Bach *Werke Verzeichnis*, 582) is clearly indebted. The preludes are generally brief and, with one exception, are unlike those of Bach in having no thematic connection with the much longer fugues that follow them. The form of these fugues often consists of several sections contrasting in rhythm and tempo, rather than of a progressive contrapuntal development. Here Buxtehude may have been influenced by the somewhat similar form of Jan Sweelinck's keyboard fantasias. A few short fugues in simple counterpoint are, however, also among Buxtehude's work. The pieces based on chorales include a number of simple chorale preludes with the decorated melody placed in a high register and

in counterpoint with an independent part on the pedals, and also several long works in which the chorale text is treated with such technical elaboration that the result is a kind of instrumental motet. This extended chorale treatment seems to have been confined to northern Germany; Nikolaus Bruhns, a pupil of Tunder and Buxtehude, is among the other organists who have left examples.

Little of Buxtehude's harpsichord music remains but much is known to be lost, including a suite illustrating the planets. A suite of dances, which is extant, is of special interest for Buxtehude's use of the hymn-tune *Auf meinen lieben Gott* for his theme. Among his secular music are a number of sonatas for various combinations of two or three stringed instruments with continuo. Fourteen of these were published in two parts at Hamburg in 1696 as the composer's Opus 1 and 2.

Most of Buxtehude's vocal music consists of church cantatas, in the history of which he is an important figure, although the influence of his vocal work was less widespread than that of his organ music. Over 100 cantatas are extant, composed in a great variety of forms, of which only the main groups will be mentioned here. All are imbued with a devout simplicity that contrasts strongly with the elaborations of their Bachian successors. It is uncertain whether they were composed for services or for "concert" performance; the latter seems more likely. It is possible that some were written for the famous *Abendmusiken*, concerts of mixed vocal and instrumental music held in St. Mary's in the late afternoons of the five Sundays before Christmas. A few programs of these, including the 1700 series, are known, but no extant work by Buxtehude is mentioned.

The cantata texts are rarely liturgical. The Bible, the hymn-book and sacred verse of the time are their main sources. Latin texts are used for about 30, which include a set of seven based on a poem by St. Bernard on the seven last words from the cross. The settings are of three main kinds: (1) Those for solo voice with continuo and with or without string *ritornelli* between stanzas. These cantatas have formal affinities with the secular *Arien* of such composers as Adam Krieger; (2) for choir, either unaccompanied or with organ continuo, and sometimes a group of strings to provide an overture (also known as *sinfonia* or *sonata*), instrumental comments and brief interludes during the cantata; (3) for soloists and choir, often with continuo and a group of instruments as in (2). A more extended work, on the Last Judgment, was discovered in 1927 and has been termed an oratorio; it is a succession of arias for soloists or chorus with instrumental *ritornelli*. These are for strings instead of the brass, which might have been sometimes expected.

See a collected edition of Buxtehude's works that was begun in 1925, Ugrino ed., vol. vii (1937). See also W. Stahl, *Dietrich Buxtehude* (1937). (C. P. Co.)

BUXTON, SIR THOMAS FOWELL (1786–1845), English philanthropist, chiefly remembered for his work for the campaign to abolish slavery, was born at Castle Hedingham, Essex, on April 1, 1786, and was educated at Trinity college, Dublin. In 1807 he married Hannah Gurney, sister of Elizabeth Fry. He entered the brewery of Truman, Hanbury and company in 1808, became a partner in 1811, and soon had the whole concern in his hands. In 1818 he published his able *Inquiry into Prison Discipline*. The same year he was elected M.P. for Weymouth, a borough he represented till 1837. In the house of commons Buxton worked for the abolition of slavery in British colonies, taking over the leadership of the agitation in 1822. He was not entirely satisfied, however, with the abolition act of 1833, which included some clauses to which his better judgment was opposed. Although his health was giving way, he continued his interest in social work, including prison conditions on the continent. He was made a baronet in 1840, and devoted himself to a plan for ameliorating the condition of African Negroes. The failure of the Niger expedition of 1841 was a blow from which he never recovered. He died at his home in Norfolk on Feb. 19, 1845.

Buxton's *Memoirs* (1848), with selections from his correspondence, were edited by his third son, Charles Buxton (1823–71), a member of parliament who consistently advocated humane and liberal policies, especially for the colonies. (A. BRI.)

BUXTON, a municipal borough, holiday resort and spa in Derbyshire, Eng., 38 mi. N.W. of Derby by road, is situated in the centre of the Peak District (*q.v.*) National park. Pop. (1961) 19,236. Area 9.9 sq.mi. Standing between 1,000 ft. and 1,100 ft. above sea level, Buxton is the highest market town in England. Situated in a basin protected by hills of grit and limestone rising to 1,810 ft. at Axe Edge, it lies on the river Wye (a tributary of the Derwent), which in the Pavilion gardens disappears underground from a waterfall. The mineral waters of Buxton, which are tasteless and odourless, have long enjoyed a great reputation and were known and used by the Romans, who called the place *Aquae Arnemetiae* and whose roads connected it with Derby, Edale and Manchester. After the departure of the Romans the baths seem to have been long neglected, but were rebuilt and again frequented in the 16th century. Later the church of St. Anne (1625) acquired fame for the cures effected. At the close of the 18th century the duke of Devonshire, lord of the manor, spent large sums of money on improvements in the town. The Crescent was built during 1780–86 in the Doric style by John Carr, and in its Pump room the drinking of the mineral waters is still practised, although the chalybeate spring is no longer used. The thermal mineral water rises from the springs at a temperature of 82° F. and is much used at the municipal physical treatment centre, where it is superheated for the treatment of rheumatic diseases and non-rheumatic complaints affecting muscles, joints and nerves. There are numerous public and private baths, open the year round, some of which have a sustained tonic effect; treatment is also given at the Devonshire Royal hospital.

Buxton has a repertory theatre, and drama, music and cricket festivals are held annually. The public museum contains archaeological and natural history collections. A traditional annual event is the Wells Dressing festival which also takes place in the surrounding villages.

Buxton has a few light industries, including the making of brake linings, and limestone is quarried nearby. In the neighbourhood are Poole's cavern, a dripstone cave; Diamond hill, so called from the quartz crystals in its rocks; and Chee tor, a 300-ft. cliff on the bank of the Wye. Arbor Low, 9½ mi. S.E., is a "henge," a stone circle of the Bronze Age. (D. B. A.)

BUYER. As commonly used in the business world, a buyer is the authorized purchasing agent for some other individual or for a business firm. On the stock exchange, a buyer or broker is an individual or a firm legally invested with the power to buy stocks and bonds upon orders from purchasers. Large department stores, composed of a great number of departments, have a buyer at the head of each department. These buyers, whether men or women, are employed by the store owner to buy on the market, for the store's account such articles as are required to keep their departments running and meet the anticipated demands of customers. It is the duty of each buyer to select the best quality goods at the lowest possible price, and to undersell corresponding departments in other stores whenever possible.

In commercial and manufacturing establishments, an important procurement and buying function is undertaken by the purchasing agent who is responsible for buying the raw materials and supplies needed for the firm's operations. He is sometimes referred to as the "buyer." To perform his duties effectively a buyer or purchasing agent must become familiar with all possible sources of goods and materials as well as with their characteristics. He endeavours to supply goods of the desired quality when needed, at favourable costs, and to maintain a minimum inventory. (O. R. G.)

BUYIDS, a Persian dynasty (945–1055 A.D.) whose homeland was Dailam in the Elburz uplands in northern Iran. Their eponym was Abu Shuja' Buya, who had three sons, Ali, Hasan and Ahmad. Ali, having been appointed governor of Karaj about 930 by the Dailamite leader Mardawij ibn Ziyar, seized Isfahan while Hasan and Ahmad took Fars and Kerman during 935–936. In Dec. 945 Ahmad entered Baghdad, the caliph's capital. After obtaining the title of Amir al-Ümara and Mu'izz al-Dawla for himself, and those of 'Imad al-Dawla and Rukn al-Dawla for Ali and Hasan respectively, Ahmad deposed the caliph al-Mustakfi in Jan. 946 substi-

tuting al-Muti'. Henceforth until 1055 the Buyids controlled the Abbasid caliphs. On Ali's death (in 949 or 950) Rukn al-Dawla became head of the family, his son, Adud al-Dawla ruling Fars, but the family co-operation broke down after Mu'izz al-Dawla's death in 967. By 977 Adud al-Dawla ruled over Fars, Iraq and Kerman. He was the dynasty's most enlightened prince, celebrated for his public works including the amir's dam (Bendameer) still standing near Shiraz. After his death in 982 the ebb of the dynasty's power was expedited by fractious Turk and Dailamite subordinates until only Baghdad remained under their control. The last Buyid ruler, al-Malik abu Mansur, was deposed by Togrul Beg the Seljuk, in 1055. The significance of the Buyids is that they provided, between the Arab invasion and that of Sunni Turks, a purely Persian and Shi'ite entr'acte in Iran's history. In their time popular and passionate observance of certain Shi'ite festivals, still maintained, was inaugurated, and visits to the Shi'ite holy places, Najaf and Karbala, in Iraq assumed significance.

See V. Minorsky, *La Domination des Dailamites* (1932); article "Buwayhids or Buyids" in *Encyclopaedia of Islam*, 2nd ed. (1960). (P. W. A.)

BUYS, PAULUS (1531–1594), Netherlands patriot, the leading statesman of the province of Holland from 1572 to 1585, was born at Amersfoort in the province of Utrecht. He became pensionary of Leiden in 1561 and advocate of the province of Holland in 1572. In close touch with the exiled prince of Orange, William the Silent, he prepared, together with others, the rising of the greater part of the province in 1572 (see NETHERLANDS) and particularly the adhesion of Leiden to the cause of the rebels. In 1573 he became a member of the council of nine which assisted William, but his efforts to make him count of Holland and Zeeland were cut short by the murder of the prince (1584). After this he resigned his office (1585), partly in protest against the temporarily prevailing policy of seeking help from France, and retired to his native province of Utrecht. Having always advocated an English alliance, he was one of the negotiators of the treaty of Westminster with Elizabeth I (Aug. 20, 1585). A member of the council of state under the governorship of the earl of Leicester, he soon came into conflict with the earl, mainly because of the latter's favouring the democratic Calvinists and alienating the liberal urban aristocracies. With the connivance of Leicester he was arrested by the Utrecht democrats in July 1586, and held prisoner for six months. He died at IJsselstein on May 4, 1594.

See W. van Everdingen, *Het leven van Mr. Paulus Buys* (1895); L. J. Rogier, *Paulus Buys en Leicester* (1948). (A. G. J.)

BUYS BALLOT'S LAW, in meteorology, takes its name from Dutch meteorologist C. H. D. Buys Ballot who first stated the law in 1857. The law states that in the northern hemisphere a person standing with his back to the wind has high pressure on his right and low on his left; in the southern hemisphere, the low pressure area would be on the right. Strictly speaking the law states that the angle between the wind and the pressure gradient is a right angle. This is almost exactly true in the free atmosphere though not at the surface, where the angle is usually less than 90°. The law is not applicable in equatorial regions. (See WIND: General Winds.)

CHRISTOPH HENDRIK DIDERICUS BUYS BALLOT (1817–1890), was born at Kloetinge, Zeeland, Neth., on Oct. 10, 1817. He was director of the Royal Netherlands Meteorological institute from 1854 until his death. He derived the law empirically, unaware that it had already been deduced on theoretical grounds some months earlier by the U.S. meteorologist William Ferrel, whose priority he later acknowledged. He died on Feb. 3, 1890. (WR. BR.)

BUZĂU, a town of Rumania, situated on the Buzău river, 97 km. (60 mi.) N.E. of Bucharest, is the administrative centre of a district of the same name in the Ploesti region. Pop. (1956) 47,101. Lying between the Carpathian mountains and the fertile lowlands of southeastern Rumania, it is important as a railroad junction and as a market for petroleum, timber and grain. Industries include woodworking, textile, alcohol and building materials manufactures and wineries.

Archaeological excavations in the vicinity revealed vestiges of Thracian and Gothic settlements. The first historic mention of the town is a reference to the Buzău fair in a document of 1431. In the town are the ruins of the cathedral, built in the 15th century and renovated by the Walachian ruler Matei Basarab in 1640.

BUZZARD, the name applied in England to large hawklike birds of the genus *Buteo* and in North America to various new world vultures (family Cathartidae), especially the turkey vulture (*Cathartes aura*) (see VULTURE). In North America *Buteo* species are called buteos, "buzzard hawks" or simply hawks.

CY LA TOUR
RED-TAILED HAWK (*BUTEO JAMAICENSIS*), A NORTH AMERICAN BUZZARD HAWK OR BUTEO

True buzzards, or buteos, occupy a subfamily (Buteoninae) of the family Accipitridae. When in flight they can usually be distinguished from other birds of prey by their broad wings and expansive, rounded tails. When hunting they customarily soar gracefully for hours but in direct flight the wingbeats are slow and heavy. The plumage of most species is essentially dark brown above and white or mottled with brown below. The tail and underside of the wings usually are barred. However, there is much variability of pigmentation, and a melanistic colour phase commonly occurs. Buzzards customarily prey on small mammals and beetles and only occasionally attack birds. Carrion is also eaten. The nest is a large, substantial structure of sticks lined with softer materials and usually is placed in a tree or on a cliff. The whitish eggs (two to five) are blotched or spotted with brown.

The best-known species, the common buzzard (*B. buteo*), is found from Scandinavia south to islands of the Mediterranean. The rough-legged buzzard (*B. lagopus*), so named because of its feathered tarsus, breeds at high latitudes in both hemispheres and winters south to the Adriatic sea and southern parts of the United States. Other species range over much of Eurasia and north Africa.

BYBLIS, a heroine of Greek mythology who fell in love with her brother Caunus. He fled when she disclosed her passion, and she, wandering after him, was transformed into a weeping fountain named for her. This myth, originally connected with Aphrodite worship in Asia Minor, became a popular romantic tale with the Hellenistic writers and with Ovid. (E. R. R. E.) (H. W. P. A.)

BYBLIS, a genus of carnivorous plants belonging to the family Byblidaceae. There are two species inhabiting western and north-western Australia. They grow in somewhat drier localities than other carnivorous plants found in the same general environment. Byblis is a low perennial, herbaceous except at the somewhat woody base, and produces long, slender, linear leaves armed with sessile glands, which have a digestive function: and numerous stalked glands, which secrete mucilage. This entraps small insects. The whole operation of catching and digesting prey appears to be similar to that in *Drosophyllum* (*q.v.*), from which Byblis differs in having mucilage and digestive glands of much simpler structure. See also CARNIVOROUS PLANTS. (F. E. L.)

BYBLOS (mod. JUBAYL or JEBEIL; biblical GEBAL), an ancient town on the coast of Lebanon and possibly the oldest continuously inhabited town in the world with monuments pertaining to Amorite, Hyksos, Phoenician, Greco-Roman and medieval periods. Its biblical name is sustained in the small Lebanese town on the site which lies 17 mi. N. of Beirut and south of Tarabulus esh-Sham (Tripoli). Because of its significance as the chief harbour for the export of cedar and other valuable wood to Egypt, it early became a great centre of trade, called Kubna in ancient Egyptian and Gubla in cuneiform inscriptions. The Greek name

Byblos goes back at least to Mycenaean times, and papyrus received its early Greek name (byblos, byblinos) from the fact that it was exported to the Aegean through Byblos. Hence the word "Bible" is derived from Byblos as "the (papyrus) book."

Systematic excavations were begun there by Pierre Montet in 1921, 60 years after the first scratching by Ernest Renan (*q.v.*). In 1926 Maurice Dunand resumed the work and continued it for many years with great success. One totally unexpected result of the excavations was to show that the Byblos of the Late Bronze and Iron ages must have been submerged in the Mediterranean by some historically unrecorded earthquake.

Byblos was occupied as early as the Neolithic Age, and during the 4th millennium there were two successive Chalcolithic settlements, the second of which was already very extensive. A flourishing city stood there through the entire Bronze Age. Egyptian monuments found on the site, including many inscriptions, attest close relations with the Nile valley during every dynasty from the 1st to the 6th.

Egyptian mentions of Byblos, its cedar trade and shipping, begin in the available hieroglyphic sources at the outset of the 4th dynasty and continue into the 6th, toward the end of which the city was destroyed by an unknown invader. In the 21st century B.C. a native prince, Abishemu, left a small obelisk with an Egyptian inscription of historical interest. During the 12th dynasty Byblos again became an Egyptian dependency, and the chief goddess of the city, Baalat ("the Lady"), was admitted into the Egyptian pantheon. In the Amarna Age the prince of Byblos, Rib-Adda, declared that his city was just as Egyptian as Memphis; the cuneiform letters which he wrote to Egypt are several times as numerous as those from any other Syro-Palestinian vassal. After the collapse of the New Egyptian empire in the 12th century B.C. Byblos became the foremost city-state of Phoenicia, as is known from the report of Wen-amun, an Egyptian envoy to the Byblian prince Zakar-Baal.

Byblos has yielded nearly all known early Phoenician inscriptions, chiefly from the 10th century B.C.; the earliest datable text is on the famous sarcophagus of Ahiram (discovered by Montet in 1922). By that time, however, the Sidonian kingdom, with its capital at Tyre, had become dominant in Phoenicia and Byblos never recovered its relative importance though it flourished into Roman times.

The crusaders captured the town in 1103 and called it Gibelet, but lost it to Saladin in 1189. The imposing citadel, still standing, is essentially a crusader work.

See P. Montet, *Byblos et l'Égypte* (1928); M. Dunand, *Fouilles de Byblos*, vol. i-iii (1937 et seq.), *Byblia Grammata* (1945). (W. F. A.)

BYDGOSZCZ (Ger. BROMBERG), a town in northern Poland, capital of Bydgoszcz województwo (province). Pop. (1960) 231,500.

Bydgoszcz lies on the border of agricultural Kujavia (Kujawy) and wooded Pomerania (Pomorze). It is a junction of water and rail communications on the Brda river (a tributary of the Vistula) and on the Bydgoszcz canal (25 km. or 15½ mi. long) which links the Vistula basin with that of the Oder. After the building of this canal in the 18th century, Bydgoszcz developed more rapidly than any other town in the *województwo*. The importance of the canal increased after World War II, when the mouth of the Oder became Polish territory. By the early 1960s Bydgoszcz was the most important inland port in Poland. It was also a railway junction for lines including the Prague-Baltic line and the line linking Upper Silesia with the Baltic coast. Bydgoszcz was the most important industrial centre of the province and has chemical, metallurgical (machinery), timber (sawmills, furniture), printing, tanning and clothing factories. It has two theatres and a concert hall.

Referred to in historical documents as a 13th-century frontier castle between Kujavia and Pomerania, Bydgoszcz suffered greatly during the wars with the Teutonic knights. It obtained town rights in 1346. Transferred to Prussia after the first partition of Poland in 1772, it was returned to Poland by the treaty of Versailles.

BYDGOSZCZ *województwo*, a province in northern Poland, was

formerly part of historic Pomorze (*q.v.*). Pop. (1960) 1,706,200; area 20,798 sq.km. (8,030 sq.mi.). Moraine elevations, with numerous lakes, form the circumference of the region, while the central sector is the broad Torun-Gorzow valley used by the Vistula, Notec and Brda rivers. Old geological formations (Paleozoic and Mesozoic) form an anticlinal embankment lying in a southeast-northwest direction, where Poland's richest deposits of salt, clay and lime occur. These minerals were used in development of the chemical industry and the spas of Ciechocinek with its radioactive saline springs, and Inowroclaw. The high standard of cultivation in the district gives high yields per acre, although the soils are poor except for the marshy black earth regions in Kujavia and the Vistula region.

See M. Kielczewska-Zaleska, *Województwo bydgoskie* (1952); Instytut Bałtycki, *Pamiętniki*, vol. xliii (1948); W. Winid, *Kanał bydgoski* (1928). (K. M. Wl.)

BYELORUSSIA: see BELORUSSIAN SOVIET SOCIALIST REPUBLIC.

BYLAW, a regulation made by a subordinate authority, such as a public or private corporation, association or society, for the government of its internal affairs or its dealings with others. In the United States the term is usually restricted to rules made by a private corporation for the regulation of internal matters. The power to make such rules is vested in the shareholders but may be delegated to the directors either by statute or charter. Bylaws commonly deal with such matters as the calling of shareholders' and directors' meetings or the qualifications and duties of officers. Bylaws are not enforceable if they conflict with the charter, statutes or public policy. Thus a bylaw cannot unduly restrict the right of shareholders to inspect the books of the corporation. Directors and officers are bound by the bylaws and hold office subject to their provisions. In contradistinction to British usage, the term bylaw does not include municipal ordinances. (See also CORPORATION: Corporation Law.) (X.)

England. — In England, bylaw designates either (1) a regulation made by a common-law corporation, one of whose legal privileges is the power to make regulations for the government of its members, or (2) a regulation made by a statutory corporation which, unlike the former, has no power to make such regulations unless it is expressly conferred upon it. Thus a municipal corporation, which is always a common-law corporation created by charter, has an inherent power to make such bylaws, while a statutory corporation, a term which includes other local authorities and statutory undertakers, always has its power defined by statute. In practice, however, the common-law power of municipal corporations to make bylaws is rarely used, and borough councils rely on specific authority to make bylaws conferred by various general acts relating to local government, public health, etc.

The procedure relating to the making and confirmation of bylaws by local authorities outside London was reviewed by the Local Government and Public Health Consolidation committee in 1933, and on their recommendation a single code of procedure was enacted by the Local Government act, 1933, in substitution for earlier provisions which differed in various ways. A similar code was enacted in respect of the metropolitan authorities in the London Government act, 1939. Bylaws made under these codes do not have effect until they are confirmed by the minister of the crown specified in the statute conferring the power of making bylaws. Before application for confirmation is made, public notices must be given and copies of the bylaws made available for public inspection. Copies may also be purchased by members of the public.

The minister may confirm or refuse to confirm any bylaws submitted to him and may fix the date on which they are to come into operation. Confirmed bylaws must be kept available for inspection by the public, and copies may be purchased on application to the local authority. Bylaws may be made for limited periods, and some acts (*e.g.*, the Public Health act, 1936, as regards building bylaws) empower the minister to require a local authority to make bylaws satisfactory to him and, in their default, to make bylaws himself on their behalf. The bylaws of statutory undertakers usually require the approval of a government department; *e.g.*,

railway bylaws are subject to disallowance by the minister of transport and civil aviation.

There is an important difference between statutory instruments and bylaws, in that the latter may be quashed by the courts, even when they are otherwise legitimate, on the mere ground that they are "unreasonable" (*i.e.*, oppressive or repugnant to the common law or statute) or that they are uncertain in their terms. The courts have, however, laid down an important principle that in the exercise of their power to declare a bylaw "unreasonable" they will extend more latitude to the interpretation of bylaws made by local authorities than to that of bylaws made by "profit-making companies," which "the courts must scrutinize jealously" (see *Kruse v. Johnson*, 1898, 2 Q.B. 91, the leading case on the subject).

It is a rule of law that when the power to make bylaws exists, whether at common law or by statute, there is also the power to enforce the bylaw by pecuniary penalties (see *Hall v. Nixon*, 1875, L.R. 10 Q.B. 159). It is usual, however, for any statute giving power to make bylaws to prescribe maximum penalties on summary proceedings, special penalties being frequently provided for offenses which continue after conviction or after a reasonable time allowed by the magistrates' court. It was suggested in *Salt v. Scott Hall*, 1903, K.B. 245, that although a bylaw may be reasonable in its general operation, the subject is protected against its oppressive enforcement by the rule that the magistrates are not bound to convict in every case of infringement of a bylaw that comes before them. The magistrates have power under s. 7 of the Criminal Justice act, 1948, if they think the circumstances warrant it, to grant the defendant an absolute or a conditional discharge.

In addition to the summary prosecution of offenses, where a breach of a bylaw also constitutes an infringement of public rights or public interests, an injunction may be granted at the suit of the authority general.

A local authority has no power to relax or waive the requirements of its bylaws unless such power is expressly conferred by the bylaws themselves or by statute; *e.g.*, s. 63 of the Public Health act, 1936, which enables a local authority with the consent of the minister of housing and local government to dispense with compliance with building bylaws in a case where their strict application would be unreasonable.

The Interpretation act of 1889 provides that a statutory power to make bylaws includes a power to rescind, revoke, amend and vary them, a fact which, as the court observed in *Kruse v. Johnson*, means that a local authority can always, under the pressure of the public opinion of the locality, be compelled to alter them if they are unpopular or unnecessary. (E. J. O. G.)

BYNG, JOHN (1704–1757), British admiral, who was executed in 1757 for failing to do his utmost to relieve Minorca from attack by the French the previous year, was the son of George Byng, Viscount Torrington, himself a distinguished admiral who destroyed the Spanish fleet off Cape Passaro in 1718. His son entered the navy that year, becoming a rear admiral in 1745. In 1755, on the eve of the Seven Years' War, it was feared that the British Mediterranean base at Minorca would be attacked. Byng was sent out to save the island, but by the time he arrived (May 1756) a force under the duc de Richelieu had landed and was besieging Ft. St. Philip. Byng engaged the French fleet, under the marquis de La Galissonnière, which covered this operation, but faulty tactics allowed the French to break off the action with little damage. At a council of war held afterward, Byng decided that his force was insufficient to renew the attack or relieve the castle. He therefore returned to Gibraltar, leaving Minorca to its fate. This failure aroused a storm of anger in England. The government under the duke of Newcastle tried to escape blame by having Byng arrested and court-martialed on board his own flagship at Portsmouth. He was acquitted of charges of disaffection and cowardice, but was found technically guilty of neglect of duty in battle. Under the recently revised Articles of War the members of the court had no alternative but to condemn him to death, although they never expected their sentence, which was accompanied by a strong recommendation for mercy, to be carried out. But

the mob clamoured for a scapegoat and most of the ministers were determined to save themselves by sacrificing Byng. He was therefore shot on board the "Monarque" in Portsmouth harbour on March 14, 1757. Shortly before his death he said: "They make a precedent of me such as admirals hereafter may feel the effects of"—a remark which is echoed in that of Voltaire in *Candide* that in England it was found necessary from time to time to shoot an admiral "pour encourager les autres."

See W. C. B. Tunstall, *Admiral Byng* (1928). (C. C. L.)

BYNG, JULIAN HEDWORTH GEORGE BYNG, 1ST VISCOUNT (1862-1935), British field marshal, who was a distinguished commander during World War I and later became governor general of Canada, was born at Wrotham Park, Barnet, on Sept. 11, 1862, the son of the 2nd earl of Strafford. He joined the 10th Hussars in 1883, served in the Sudan expedition (1884) and the South African War (1899-1902), and in 1912 took command of the British troops in Egypt. During World War I he commanded, successively, the 3rd cavalry division in France (1914), the cavalry corps (1515), and the IX corps at Gallipoli. As commander of the Canadian corps in France (from May 1916), he was responsible for the capture of Vimy ridge in April 1917, and as commander of the 3rd army (from June 1917) he carried out the surprise tank attack on Cambrai in Nov. 1917. He was very popular when governor general of Canada (1921-26), but in 1926 was unintentionally the cause of a constitutional crisis. He was a successful commissioner of police in London from 1928 to 1931, disarming his critics and carrying through a number of reforms. Byng, who had been made a baron in 1919 and a viscount in 1926, was, despite his retirement, given his field marshal's baton in 1932. He died in Essex on June 6, 1935. (R. G. TH.)

BYNKERSHOEK, CORNELIS VAN (1673-1743), Dutch jurist, was born at Middelburg, Zeeland. He studied law at Franeker, Friesland, and was called to the bar at The Hague. In 1703 he was appointed a member of the supreme court of Holland and Zeeland, of which he became president in 1724. In that position he enjoyed great prestige, but his judicial career did not prevent him from publishing a large and varied number of works of legal scholarship.

His writings on Roman and Dutch municipal law are important, but his fame rests chiefly on what he did for the development of international law on positive lines. To a greater extent than any of his predecessors in this field he took actual usage, as appearing from ordinances issued by the States-General or other governments and from treaties concluded between Christian states as the basis of his studies. On questions like the sovereignty of the seas, the legal position of ambassadors, private property in war time, prizes, neutrality, contraband, blockade, his opinions have always been regarded as carrying great weight and have exercised considerable influence.

BIBLIOGRAPHY.—Bynkershoek's principal works in the domain of international law are *De dominio maris* (1702), *De foro legatorum* (1721), *Quaestiones juris publici* (1737). Complete editions of his works were published after his death, one at Geneva in 1761, and another at Leiden in 1766. See O. W. S. Numan, *Cornelis van Bynkershoek* (1869); J. Delpech, in *Les fondateurs du droit international* (1904); Coleman Philipson, in *Journal of the Society of Comparative Legislation* (1908).

BYRD, RICHARD EVELYN (1888-1957), celebrated pioneer aviator and navigator and foremost antarctic explorer of the second quarter of the 20th century, made important contributions to transatlantic flying and was first to command and navigate flights over the earth's north and south poles. He was born Oct. 25, 1888, at Winchester, Va., the brother of the U.S. senator Harry F. Byrd. When he was 12 years old Richard Byrd made an unescorted trip around the world. He attended Shenandoah Valley Military academy, Virginia Military institute and the University of Virginia before entering the U.S. Naval academy, where he graduated in 1912. After three years of active service, he was retired because of leg injuries which he had sustained while participating in sports at the naval academy. Shortly thereafter he was readmitted into naval aviation, however. Byrd received pilot training but soon gravitated to administrative positions. He received the rank of commander in 1926 after his north pole flight

and of rear admiral in 1930 after his south pole flight. He was instrumental in the development of naval aviation reserves, the bureau of aeronautics and numerous congressional bills benefiting naval personnel and interests. During World War II he served on the staff of the chief of naval operations and, among other duties, evaluated Pacific islands as operational sites. His talent for organization and administration and his influence and skill in public relations led him to serve in many important government, patriotic and humanitarian capacities.

At the close of World War I Byrd developed plans and navigational aids for the first NC flying boat transatlantic flights but was deprived of a place in the principal aircraft. He also assisted with dirigibles built for transatlantic crossings. He later aided Charles A. Lindbergh with navigational training and the use of his specially extended runway for his Atlantic flight. Shortly afterward, on June 29, 1927, Byrd with three companions left New York on a multiple-engine crossing of the Atlantic, with the first official mail service and a pay load of 800 lb. Fog prevented landing at Paris, and the plane was ditched off the coast of France on July 1 after 42 hours and exhaustion of the fuel supply.

Byrd's polar career began in 1924 when he had command of a small naval aviation detachment with Commander D. B. MacMillan's arctic expedition to western Greenland, based at Etah. Controversy over the success of those early U.S. flights over Greenland and Ellsmere Island led Byrd to prove his points by organizing a private expedition to get his plane, the *Josephine Ford*, to Kings Bay, Spitsbergen. On May 9, 1926, he and his pilot, Floyd Bennett, flew over the north pole.

With that success and his transatlantic flight a year later Byrd became an international hero and had little difficulty finding support for an antarctic expedition. In late Dec. 1928 he established Little America at the Bay of Whales, Antarctica, with 42 men. On Nov. 29, 1929, he and three companions flew over the south pole. He also discovered the Rockefeller and Edsel Ford mountains and the western portion of Marie Byrd Land, named by him in honour of his wife.

Five years later he returned to Little America with a 56-man wintering party, extended exploration of Marie Byrd Land and continued scientific observations. In 1934 he spent the polar winter alone in a tiny hut at Bolling advanced base, 123 mi. south of the main base. This was man's farthest south and Antarctica's first and only inland habitation for the next 21 years. Carbon monoxide fumes nearly cost him his life before his unrequested relief arrived after five months.

Byrd's three subsequent antarctic trips were in summer seasons while serving as director of U.S. government expeditions. For brief periods on each trip he continued personally to take an active part in exploration. At the request of Pres. Franklin D. Roosevelt he took command of the U.S. antarctic service, which was terminated after the first year because of the approach of World War I. Bases were located at Little America and Stonington Island, Palmer peninsula. Byrd's discovery of Thurston peninsula greatly decreased the length of unexplored coast of the continent.

After World War II he served as officer in charge of Naval Task Force 68—Operation "Highjump," a 4,000-man, multi-unit summer season effort (1946-47) to photograph the antarctic coast from the air. Byrd flew into Little America on one of the six R4D aircraft launched by jet assist from the deck of the aircraft carrier "Philippine Sea" north of the ice pack about 700 mi. from the camp. He made a second flight over the south pole and took part in several other flights. In 1955 Byrd was made officer in charge of U.S. antarctic programs, the senior authority for government antarctic matters. He accompanied Naval Operation "Deep Freeze I" aboard the newest and most powerful icebreaker "Glacier" on its maiden voyage and took his last exploratory flight over the heartland of Antarctica and once again over the south pole on Jan. 8, 1956.

Byrd died March 11, 1957 in Boston, Mass., and was given full honours at Arlington National cemetery. Short of kings and heads of state, few men in their lifetime received more honours or greater acclaim than he. His books are *Skyward* (1928), *Little America*

(1930), *Discovery* (1935), and *Alone* (1938). He also contributed a number of articles to *National Geographic* magazine.

See Charles J. V. Murphy, *Struggle, the Life of Commander Byrd* (1928); F. Green, *Dick Byrd, Air Explorer* (1928). (P.L.A.S.)

BYRD, WILLIAM (1543–1623), the greatest English composer of the age of Shakespeare, was born in 1543, possibly in Lincolnshire. Of his origins and early life virtually nothing is known. He was a pupil and protégé of Thomas Tallis (*q.v.*), and this suggests that he may have belonged to the same family as the Thomas Byrd who was, like Tallis, a member of the Chapel Royal under Edward VI and Mary Tudor. Byrd's first authenticated appointment was as organist at Lincoln cathedral (Feb. 27, 1563). In 1572 he moved to London to take up his post as a gentleman of the Chapel Royal, where he shared the duties of organist with Tallis.

The close personal and professional relationship between the two men had important musical consequences. In 1575 Elizabeth I granted them a joint monopoly for the printing, publishing and sale of music, as well as for the importing of music and the printing of music paper. The first work under their imprint appeared in that year—a collection of *Cantiones Sacrae* dedicated to the queen; of the 34 motets it contained, Tallis contributed 16 and Byrd 18.

In 1577 Byrd moved to Harlington, Middlesex, where he and his family lived for the next 15 years. As a devout and lifelong Catholic he probably preferred the greater privacy of living outside London. Yet in spite of his close social contact with many other Catholics, some of whom were certainly implicated in treasonable activities, his own loyalty to the government was never questioned.

In 1585 Tallis died, and in the following year Byrd's first wife, Juliana. These sad events may have prompted him to set his musical house in order, for in the next three years he published four collections of his own music: *Psalmes, Sonets, and songs of Sadnes and pietie* (1588), *Songs of sundrie natures* (1589) and two further books of *Cantiones Sacrae* (1589 and 1591). The two secular volumes were dedicated respectively to Sir Christopher Hatton, the lord chancellor, and to Lord Hunsdon, the lord chamberlain and first cousin to the queen. Both volumes of motets were dedicated to prominent Catholics: the earl of Worcester, a great friend and patron of Byrd's, whose loyalty to the crown was unimpeachable, and Lord Lumley, who was now again in favour after being deeply implicated in the Ridolfi plot (1571). Also in 1591 a manuscript volume of Byrd's keyboard music was prepared for "my ladye Nevell" (probably Rachel, wife of Sir Edward Nevill), while many more keyboard pieces found their way into the volume known as the Fitzwilliam virginal book, copied by another well-known Catholic, Francis Tregian, during his imprisonment in the Fleet.

In 1592 or 1593 Byrd moved with his family to a property at Stondon Massey, Essex, and despite prolonged litigation he lived there for the rest of his life. At the accession of James I the Catholics' prospects temporarily brightened, and this probably prompted Byrd's next three publications. In his collection of three Masses (*n.d.*) and two books of *Gradualia* (1605, 1607) he attempted to provide singlehanded a basic liturgical repertory, comprising music for the ordinary of the Mass and for the proper of all main feasts. It is significant that the dedicatees of both books of *Gradualia* were prominent Catholics ennobled within the first years of James's reign: the earl of Northampton and Lord Petre of Writtle, another close friend of Byrd's. One further publication came from Byrd, the *Psalmes, Songs and Sonnets* of 1611, containing English sacred and secular music. Byrd died on July 4, 1623.

Byrd's musical stature can hardly be overrated. He wrote extensively for every medium then available except, it seems, the lute. His virginal and organ music brought the English keyboard style to new heights and pointed the way to the achievements of John Bull and Giles Farnaby, Orlando Gibbons and Thomas Tomkins. In music for viol consort he also played an extremely important role, pioneering the development of the freely composed fantasia, which was to become the most important form for

Jacobean and later composers. Although he admired Italian madrigals and as a publisher helped introduce them to England, Byrd's own secular vocal music is distinctly conservative; much of it is conceived for the old-fashioned medium of solo voice accompanied by viol consort, later abandoned by the English madrigalists, with Thomas Morley (Byrd's pupil) at their head.

Byrd's religious beliefs did not prevent him from composing a great deal of church music to English words, most of which has survived only in manuscript. Although this is of generally high quality it cannot be denied that Byrd maintained his highest consistent level in his Latin sacred music. Of this, the 1589 and 1591 sets of *Cantiones Sacrae* (mostly designed for the private edification of the Catholic circles Byrd moved in, and therefore unrestricted by liturgical considerations) have an intensity unrivaled in England and a breadth of scale unknown on the continent. Although the *Gradualia* are necessarily more concise and superficially more similar to the work of G. P. da Palestrina and T. L. de Victoria, with which Byrd was well acquainted, closer examination reveals their real individuality as well as an astonishingly consistent level of inspiration.

BIBLIOGRAPHY.—*The Collected Works of William Byrd*, ed. by E. H. Fellowes (1937–50); and a more scholarly edition of the sacred works in vol. 2, 7 and 9 of *Tudor Church Music* (1921–). See also E. H. Fellowes, *William Byrd*, 2nd ed. (1948). (J. J. N.)

BYRD, WILLIAM OF WESTOVER (1674–1744), a Virginia planter, satirist and writer of diaries which give an intimate picture of colonial life on the southern plantations, was born March 28, 1674, in the James river plantation home of his father, also William Byrd, Indian trader and slave importer. The boy went to school in England, traveled in Holland and studied law in the Middle Temple. After he was admitted to the bar in 1695, he returned to Virginia, but two years later was again in London as colonial agent. Almost all his youth was thus spent in England, where he was intimate with Sir Robert Southwell, president of the Royal society, John Campbell! 2nd duke of Argyll and other members of the aristocracy and literati. He was a member of the Royal society.

In 1705, after his father died, Byrd returned to Virginia to manage a large estate. Through marriage he became allied to some of the most powerful Virginia families. He was receiver general, as his father had been, and like his father was a colonel of the county militia. In 1708 he was made a king's councilor, an appointment he held for life. He spent the years 1715 to 1726 (except for a trip home in 1720–21) in England, part of the time as colonial agent. He was the spokesman of the large planters against Gov. Alexander Spotswood. Then he returned to the colony for the last time, to lead the busy life of a planter and a member of the ruling clique. He built a great house at Westover, the estate of his father, on the James river, experimented with crops, founded the city of Richmond, collected the largest private library in the colonies (4,000 volumes), and acquired some 179,000 ac. Byrd was twice married; he was survived by four daughters and a son, William Byrd III. He died at Westover, Aug. 26, 1744.

Byrd's "History of the Dividing Line," a witty, satirical account of a 1728 survey of the North Carolina-Virginia boundary, for which he was appointed one of the commissioners, is a classic of colonial literature, as are accounts of similar expeditions, "Journey to the Land of Eden" and "A Progress to the Mines," published in *The Westover Manuscripts* (1841). Byrd kept a less literary but very revealing diary in shorthand, three portions of which have been discovered, transcribed and published. The earliest known diaries of any length for the southern colonies, they illuminate the domestic economy of the great plantations.

Woodfin and Marion Tinling (eds.), *Another Secret Diary of William Byrd of Westover, 1730–1741, with Letters and Literary Exercises, 1696–1726* (1942); Louis B. Wright and Marion Tinling (eds.), *William Byrd of Virginia: the London Diary, 1717–1721, and Other Writings of William Byrd* (1958). See also R. C. Beatty, *William Byrd of Westover* (1932). (M. R. T.)

BYROM, JOHN (1692–1763), *English poet and inventor of a system of shorthand*, was born at Kersal Cell, near Manchester, on Feb. 29, 1692. He was educated at Trinity college, Cambridge, where he was elected fellow in 1714. He then went abroad, ostensibly to study medicine; in view of his Jacobite leanings his journey may have been political. On his return to London in 1718 he taught his own method of shorthand and was elected a fellow of the Royal society in 1724. He died in London on Sept. 26, 1763.

Byrom's first poem, "Colin and Phoebe," appeared in the *Speculator* (Oct. 1714), and his collected *Miscellaneous Poems* were published in 1773. His poems are lively and show ingenuity in the use of rhyme, which is particularly telling in his poetic epigrams. A high churchman, and a follower of William Law, many of whose prose works he paraphrased in verse, thus winning praise from John Wesley, he also wrote some forceful hymns, the most famous of which is the Christmas hymn, "Christians awake, salute the happy morn." His diary gives interesting portraits and letters of the many great men of his time whom he knew intimately. Although his system of shorthand (*The Universal English Shorthand*, 1767) was soon superseded, it marked a stage in the development of shorthand.

See Sir A. W. Ward (ed.), *The Poems of John Byrom*, Chetham society (1894–95); R. Parkinson (ed.), *The Private Journal and Literary Remains of John Byrom*, Chetham society, 4 vol in 2 (1854–57); H. Talon (ed.), *selections from the Journals and Papers* (1950).

BYRON, GEORGE GORDON (NOEL) BYRON, 6TH BARON (1788–1824), *English poet and satirist, a colourful figure whose poetry and personality captured the imagination of Europe*. His name became a symbol for the deepest romantic melancholy on the one hand and for the aspirations of political liberalism on the other. Renowned as the "gloomy egoist" (Childe Harold) during most of the 19th century, he is now more generally esteemed for the satiric realism of his *Don Juan* and the facetious wit of his letters.

The poet's grandfather, second son of the 4th Lord Byron, was an admiral in the British navy and his father was the handsome and profligate Capt. John Byron who first seduced and later married the marchioness of Carmarthen. On the death of his first wife (who bore him a daughter Augusta), the captain married Catherine Gordon of Gight, an only child of a proud Scottish family that traced its ancestry to James I of Scotland. Mrs. Byron, after following her husband to Paris while he squandered most of her fortune, returned to England, where her son was born with a clubfoot on Jan. 22, 1788, at 16 Holles street, Cavendish square, London. She took her child, George Gordon, to Aberdeen, where they lived in lodgings on a meagre income. Her husband died in France in 1791. The boy, who early developed an extreme sensitiveness to his lameness, attended the Aberdeen grammar school. His nurse, May Gray, helped to awaken precocious passions in him when he was only nine. This experience and a quite different one—his idealized love for his distant cousin Mary Duffat about the same period and a similar feeling for his cousin Margaret Parker—shaped his parallel and paradoxical attitudes toward women through the rest of his life.

In 1798, at the age of ten, George Gordon inherited the title and estates of his great-uncle, the "wicked" Lord Byron. His mother proudly took him to England. The boy fell in love with the ghostly halls and spacious grounds of Newstead abbey, which had been presented to the Byrons by Henry VIII, and he and his mother lived in its ruins for a while. The young Byron was tutored in Nottingham by a Mr. Rogers and his clubfoot was doctored by a quack named Lavender who tried to straighten it. John Hanson, Mrs. Byron's attorney, rescued the boy from the pernicious influence of May Gray, the tortures of Lavender and the uneven temper of his mother. Hanson took him to London, where Dr. Matthew Baillie prescribed a brace and later a special boot for his foot and then sent him to Dr. Glennie's school at Dulwich in the autumn of 1799.

In 1801 Hanson took his protégé to Harrow. Byron's first years were marked by battles with the boys and quarrels with the masters, but later his friendships with younger boys fostered a ro-

mantic attachment to the school. It is possible that these friendships gave the first impetus to his sexual ambivalence, which became more pronounced at Cambridge and in Greece. Dr. Drury, the headmaster, won his confidence and encouraged his participation in the "Speech Day" recitations that stimulated Byron's early ambition to become a parliamentary orator. Byron spent the summer of 1803 with his mother at Southwell, near Nottingham, but he soon escaped to Newstead and stayed with his tenant, Lord Grey, while he courted his distant cousin, Mary Chaworth, at nearby Annesley hall. This first adolescent love kept him from returning to Harrow in the autumn, and when Mary, already engaged, grew tired of "that lame boy," he indulged his grief by writing melancholy poetry and she became the symbol of idealized and unattainable love.

Byron took "super-excellent" rooms at Trinity college, Cambridge in the autumn of 1805 and piled up debts at a rate that alarmed his mother. But after indulging in the conventional vices of the undergraduates, which did not much engross him, he spent his time with a few favourites and with a devoted chorister. John Edleston, for whom he developed "a violent, though pure, love and passion." After the first term Byron indulged in dissipations in London that put him farther in debt. He returned in the summer of 1806 to Southwell where he gathered his early poems in a volume privately printed in November with the title *Fugitive Pieces*. The following June his first published poems, *Hours of Idleness*, appeared. When he returned to Trinity for the autumn term he formed a close friendship with John Cam Hobhouse, who stirred his interest in liberal Whiggism. At the beginning of 1808 he entered into "an abyss of Sensuality" in London that threatened to undermine his health as well as his finances. A sarcastic critique of his *Hours of Idleness* in the *Edinburgh Review* caused him to revise a Popean satire he had begun and to add some lines on Francis Jeffrey, the supposed reviewer (it was actually Henry Brougham). In the autumn he regained possession of Newstead from his tenant, furnished some of the empty halls and entertained his friends there. On reaching his majority in Jan. 1809, he took his seat in the house of lords, published his satire anonymously as *English Bards and Scotch Reviewers* and then embarked with his friend Hobhouse on a grand tour.

The travelers sailed on July 2, 1809, on the Lisbon packet, crossed Spain to Seville and Cádiz and proceeded by Gibraltar to Malta. There Byron fell in love briefly with Mrs. Spencer Smith and almost fought a duel on her account. Byron and Hobhouse next landed at Préveza in western Greece and made an inland voyage to Janina (Ioannina) and later to Tepelene in Albania to visit the cruel but mild-mannered despot Ali Pasha. On their return Byron began at Janina an autobiographical poem (Childe Harold) which he continued during the journey to Athens where they arrived on Christmas day. They lodged with a widow, whose daughter, Theresa Macri, Byron celebrated as "The Maid of Athens." In March 1810 he sailed with Hobhouse for Constantinople by way of Smyrna and while becalmed at the mouth of the Hellespont, Byron visited the site of Troy and swam the channel from Sestos to Abydos in imitation of Leander. After two months in Constantinople, Byron returned to Athens and Hobhouse went back to England. Byron's sojourn in Greece made a lasting impression on his mind and character. After visiting Veli Pasha at Tripolitza (Tripolis) he took lodgings in a Capuchin monastery in Athens where he formed a friendship with Nicolo Giraud, a young boy who taught him Italian and to whom he bequeathed £7,000 in his will of 1811 (later changed). He bathed in the sea, made a journey to Sounion—which inspired his "Isles of Greece"—and delighted in the sunshine and the moral tolerance of the people.

Byron arrived in London on July 14, 1811, and his mother died on Aug. 1 before he could reach her at Newstead. He was further shocked to learn that John Edleston, the beloved choir boy, had died in his absence. He poured out his grief in a number of poems to Thyrza. During the autumn he met Thomas Moore and Samuel Rogers who brought him into the Holland house circle. On Feb. 27, 1812, he made his first speech in the house of lords on the frame-breaking bill, going beyond even the radical Whigs in his

humanitarian plea for the Nottingham weavers. At the beginning of March *Childe Harold's Pilgrimage* was published by John Murray and took the town by storm. Byron was lionized in Whig society. The handsome poet with the clubfoot, curly auburn hair, pale face and pouting lips, who had bared his soul in the melancholy verses of *Childe Harold*, was swept into a liaison with the passionate and eccentric Lady Caroline Lamb, daughter-in-law of Lord and Lady Melbourne. Although her open defiance of conventions shocked him and he was ultimately repelled by her reckless indiscretions, the scandal of an elopement was barely prevented by Hobhouse. Byron took consolation in the "autumnal charms" of Lady Oxford who encouraged his political radicalism.

During the summer of 1813 Byron apparently entered into intimate relations with his half sister Augusta Leigh. His confidante, Lady Melbourne, encouraged his flirtation with Lady Frances Webster as a diversion from this dangerous liaison. The agitations of these two love affairs and the sense of mingled guilt and exultation they aroused in his mind are reflected in the Oriental tales he wrote during the year, *The Giaour* and *The Bride of Abydos*. He "spared" Lady Frances while "Platonism" still prevailed, but it was not so easy to break with Augusta. The affair went on through the winter and summer of 1814, while his emotions found vent in the gloomy and remorseful Oriental tales, *The Corsair* (which sold 10,000 copies on the day of publication) and *Lara*.

Seeking escape in marriage, in September he proposed to and was accepted by Lady Melbourne's niece: Anne Isabella (Annabella) Milbanke, only child of Sir Ralph and Lady Judith (née Noel) Milbanke. She had met Byron at Melbourne house in 1812 and had intrigued him by her innocence and her serious conversation. He had proposed to her through Lady Melbourne when he was trying to extricate himself from the affair with Caroline Lamb. She refused but later renewed the correspondence that led to the second proposal. The marriage took place at Seaham, the home of the Milbankes near Durham, on Jan. 2, 1815. After a honeymoon "not all sunshine," the Byrons settled in a large house at 13, Piccadilly terrace, London, in March. Delays in negotiations to sell Newstead left them financially embarrassed and before long bailiffs were in the house. Byron escaped to Murray's parlor where he met Walter Scott, and to the Theatre Royal in Drury lane, where he had become one of the subcommittee of management with his friend Douglas Kinnaird. Augusta had come for a visit to Piccadilly terrace and Byron, exasperated by debts, irritated by Annabella's humourless sensitivity and liberated by drink, talked wildly and hinted at past sins.

Lady Byron gave birth to a daughter, Augusta Ada, on Dec. 10, and on Jan. 15 she left with the child for a visit to her parents. Two weeks later Byron received word from her father that she would not return to him. The reasons for her decision were never given and rumours began to fly, most of them centring on Byron's relations with Augusta. When the rumours grew, Byron signed the legal separation papers, parted fondly from Augusta and went abroad, never returning to England.

After visiting the field of Waterloo, which inspired some stanzas of a new canto of *Childe Harold*, he followed the Rhine into Switzerland. At the Villa Diodati near Geneva he was closely associated with Shelley and his entourage which included William Godwin's daughter Mary, and Godwin's step-daughter by a second marriage, Claire Clairmont, who had insinuated herself into a liaison with Byron before he left England. A boat trip to the head of the lake with Shelley gave Byron material for his "Prisoner of Chillon." He completed the third canto of *Childe Harold* at Diodati (published Nov. 18, 1816). Madame de Stael, whom he visited at Coppet, tried to effect a reconciliation between him and his wife, but was rebuffed by Lady Byron. At the end of the summer the Shelley party left for England, Claire carrying Byron's illegitimate daughter (born Jan. 12, 1817, and named Allegra by Byron). A tour of the Bernese Oberland with Hobhouse provided the scenery for *Manfred* (published June 16, 1817), the Faustian poetic drama which reflected Byron's brooding sense of guilt and remorse and the wider frustrations of the romantic spirit doomed by the reflection that man is "half dust, half deity, alike unfit to sink or soar."

On Oct. 5 Byron and Hobhouse left Diodati for Italy. After a stop in Milan they arrived in Venice on Nov. 10. Byron was not disappointed in the seagirt city, which had always been, he wrote, "(next to the East) the greenest island of my imagination." He took lodgings in the Frezzeria in the house of a draper with whose dark-eyed wife, Marianna Segati, he proceeded to fall in love. He studied Armenian at the monastery of S. Lazzaro and occasionally attended the *conversazioni* of the Countess Albrizzi, "the de Stael of Venice." In May he joined Hobhouse in Rome and rode over the ruins gathering impressions which he recorded in a fourth canto of *Childe Harold* (published April 28, 1818). At a summer villa at La Mira on the Brenta he also wrote *Beppo*, a rollicking satire on Italian manners. There he met Margarita Cogni, wife of a baker, who followed him to Venice and eventually replaced Marianna Segati in his affections. When he leased the Palazzo Mocenigo on the Grand canal in May 1818, she became his housekeeper. His descriptions of the vagaries of this "gentle tigress" are among the most entertaining passages in his letters from Italy. During the summer he completed the first canto of *Don Juan* (cantos i and ii published July 15, 1819), a picaresque verse satire in the manner of *Beppo*, with more pointed references to his own experiences. Claire had sent his illegitimate daughter Allegra for him to raise and was continually annoying him with admonitions. The sale of Newstead abbey to his school friend Thomas Wildman in the autumn for £94,500 finally cleared most of his debts, which had risen to £34,000, and left him with an income of £3,300. And since he had come abroad his yearly earnings from writing had averaged more than £2,000.

Shelley and other visitors in 1818 had found Byron grown fat, with hair long and turning gray, looking older than his years, and sunk in sexual promiscuity. A chance meeting with the Countess Teresa Guiccioli in April 1819 changed the course of his life. In a few days he fell completely in love with Teresa, who was only 20 and married to a wealthy and eccentric man nearly three times her age. Byron followed her to Ravenna and later in the summer she accompanied him back to Venice and stayed at his villa at La Mira until her husband called for her. In October Byron presented Thomas Moore, who came for a visit, with the manuscript of his memoirs, which Moore sold to Murray for 2,000 guineas but which was burned at the insistence of Hobhouse and Murray after Byron's death. Byron returned to Ravenna in Jan. 1820 as the accepted *cavalier servente* of Teresa. He won the friendship of her father and brother, the Counts Ruggero and Pietro Gamba, who initiated him into the secret revolutionary society of the *Carbonari*. In Ravenna he was brought into closer touch with the life of the Italian people than he had ever been in Venice. He gave arms to the *Carbonari* and alms to the poor. It was one of the happiest and most productive periods of his life. He wrote there *The Prophecy of Dante*; cantos iii, iv, and v of *Don Juan*; the poetic dramas *Marino Faliero*, *Sardanapalus*, *The Two Foscari* and *Cain* (all published in 1821); and his satire on Southey, *The Vision of Judgment*. When Teresa's father and brother were exiled for their part in an abortive uprising and she, now separated from her husband, was forced to follow them. Byron reluctantly removed to Pisa where Shelley had rented the Casa Lanfranchi on the Lung Arno for him. He arrived on Nov. 1, 1821, having left his daughter Allegra in the convent at Bagnacavallo near Ravenna where, despite the protests of Claire, he had sent her to be educated.

Byron paid daily visits to Teresa, whose father and brother had found temporary asylum in Pisa. Suspected and watched by government spies as a dangerous revolutionary, he made no friends among the natives. His associates included a circle gathered around Shelley: Edward Williams, Thomas Medwin, John Taaffe, Edward John Trelawny and Capt. Daniel Roberts. Byron commissioned Roberts to have a boat, the "Bolivar," built for him. The death of his mother-in-law, Lady Noel, in Jan. 1822 gave him an additional income of £3,000. By the terms of the will he henceforth took the name of Noel Byron. The comfortable routine into which he had settled was broken in March by an unfortunate affair ending with the stabbing of a dragoon by one of Byron's servants. Close upon this came word of the death of Allegra in the

convent on April 20. Shelley had rented a house on the Bay of Lerici and Byron leased the Villa Dupuy near Leghorn for the summer, taking Teresa and the Gambas with him.

There Leigh Hunt found him on July 1 when he arrived from England to join with Shelley and Byron in the editing of a new periodical. Shelley came from Lerici to help install Hunt and his family in the lower floor of Byron's Casa Lanfranchi. At the same time the Gambas were expelled from Tuscany, and Byron returned with Teresa to Pisa. The drowning of Shelley on July 8 left Hunt entirely dependent on Byron who had already "loaned" him £250 for his passage and furnished an apartment for him and his family. Byron found Hunt an agreeable companion but their relations were somewhat strained by Mrs. Hunt's moral condescension and by the depredations of her six uninhibited children. Byron contributed his *Vision of Judgment* to the first number of the new periodical, *The Liberal*, which was published in London by Hunt's brother John (Oct. 15, 1822). Byron was writing new cantos of *Don Juan*. At the end of September he moved his entire household to Albaro, a suburb of Genoa, where the Gambas had found asylum and had taken a large house, the Casa Saluzzo, for him. Mary Shelley had leased another house nearby for herself and the Hunts.

Byron's interest in the periodical had waned, but he continued to support Hunt and to give manuscripts to *The Liberal*. After a quarrel with Murray, Byron gave all his later work, including cantos vi to xvi of *Don Juan*, *The Age of Bronze* and *The Island*, to John Hunt. Restive in the domesticity of his life with the countess Guiccioli and longing for the opportunity for some noble action that would vindicate and redeem him in the eyes of his countrymen, Byron seized eagerly the offer from the London Greek committee, which came in April 1823, to act as its agent in aiding the Greeks in their war for independence from the Turks. He prepared to take supplies and money to the scene of the struggle. In the meantime the arrival in Genoa of the countess of Blessington and her party turned his thoughts nostalgically to England. His last weeks in Italy were made hectic by quarrels with Leigh Hunt and Mary Shelley and by the emotional strain of the final parting from Teresa.

On July 16. Byron left Genoa on a chartered ship, the "Hercules," accompanied by Trelawny and the young Count Pietro Gamba. They arrived at the Ionian island of Cephalonia on Aug. 2, and Byron settled in the village of Metaxata near Argostoli to await developments. After a trip to Ithaca, he tried to forward the floating in London of a loan for the Greeks. He was avidly wooed by the Greek factions, all eager for his cash and influence. Finally he sent £4,000 of his own money to activate the Greek fleet and then sailed for Missolonghi on Dec. 29 to join Prince Alexander Mavrokordatos, leader of the forces in western Greece.

With tremendous energy he entered into the plans to attack the Turkish-held fortress of Lepanto. He employed the firemaster William Parry to prepare artillery and took under his own command and pay the Suliote soldiers, reputedly the bravest of the Greeks. In addition he made efforts to unite eastern and western Greece by effecting a reconciliation of the factions. But a serious illness on Feb. 15, 1824, followed by the usual remedy of bleeding weakened him at the same time that an insurrection of the Suliotes opened his eyes to their cupidity. Though his enthusiasm for the Greek cause was undiminished, he had thenceforth a more realistic view of the obstacles and was often depressed. He was also suffering from the emotional strain of an unequal friendship with Loukas Chalandritsanos, a Greek boy, whom he had brought as a page from Cephalonia and to whom he addressed his last agonized poems including his lines on completing his 36th year. He still fixed his hopes on the Greek loan and the uniting of the dissident parties. He was planning to attend a conference with Odysseus and other leaders at Salona when, drenched by a sudden downpour during his daily ride, he contracted a fever which was aggravated by the bleeding insisted on by the doctors. After a painful and pathetic illness of ten days, he died on April 19, 1824. Deeply mourned throughout the land, he became a symbol of disinterested patriotism and a Greek national hero. His body was carried back to England and, refused burial in Westminster abbey, was depos-

ited in the vault of his ancestors in Hucknall Torkard church near Newstead.

On close examination the paradox of Byron's character resolves itself into understandable elements. Disappointment at the failure of the dreams of his youth, magnified by sensitivity to his lameness, made him keenly aware of the imperfection of reality, and his belief in inevitable human frailty, imbibed from early Calvinistic training, was never quite dissipated by later skepticism. A spoiled only child revolted by the crudities of his mother's temper, longing for an ideal love and disillusioned by a premature sexual experience, he alternated between a deep-seated melancholy and mockery of the disparity between real life and the unattainable ideal. A feminine quality impelled him not only toward sexual ambivalence but also toward showing that facet of his nature most congenial to each of his friends. To Hobhouse he was the facetious companion, humorous, cynical and realistic. To Edleston, and to most women, he could be tender, melancholy and idealistic. But his weakness was also his strength. His chameleonlike character was engendered not by hypocrisy but by sympathy and adaptability, for the side he showed was a real if only partial revelation of his true self. And that "mobility" of character noted by Lady Blessington permitted him to savour and to record the mood and the thought of the moment with a sensitivity denied to those tied to the conventions of consistency.

Byron's work, more patently autobiographic than that of any of his contemporaries, even among the self-revealing romantics, displays both the melancholy inspired by the imperfections of life and the irony attending the unmasking of the hypocritical face of reality. In fact, the *Weltschmerz* of *Childe Harold* and the satiric realism of *Don Juan* are but two sides of the same coin. In the former Byron ran the gamut of the moods of romantic despair. In *Don Juan* he was concerned with the same disparity between real and ideal, but in the main he shows it in its comic or at least sardonic aspects. And yet there are enough Childe Harold-like passages in the poem to remind the reader that the one mood easily melts into the other.

It is well to remember that Byron was born in the 18th century. An admirer of Pope from his school days, he modeled his first important poem, *English Bards and Scotch Reviewers*, on the *Dunciad*. And a degree of hard-headed 18th-century rationalism tempered much of his work, particularly his satires. It is probable that this leaven prevented Byron from succumbing, even in his highest flights of romantic idealism, to transcendental vagaries or German mysticism. He had a natural contempt for "metaquizzical" poets like Wordsworth, and he wished that Coleridge would "explain his explanation."

Byron was diverted from his satiric-realistic bent by the success of *Childe Harold*. He followed this up with the Oriental tales, which reflected the gloomy moods of self-analysis and disenchantment of his years of fame. In *Manfred* and the third and fourth cantos of *Childe Harold* he projected the brooding remorse and despair that followed the debacle of his ambitions and of his life and loves in England. But gradually the relaxed and freer life in Italy opened up again the satiric vein, and he found his forte in the mock-heroic style of the Italian satirists Berni, Casti and Pulci. The ottava rima, which he first used in *Beppo*, was easily adaptable to the digressive commentary, and its final couplet was ideally suited to the deflation of sentimental pretensions. In the successive cantos of *Don Juan*, which he at first intended only "to be a little quietly facetious upon every thing," but which he soon took more seriously as "a versified Aurora Borealis" reflecting all his mobile moods, Byron constructed his masterpiece, distilling it from his own varied experience and observation of life. "Almost all *Don Juan* is real life, either my own, or from people I knew," he wrote his publisher. Yet, for the most part, except in the castigation of Southey and a few others, the poem transcends the bitterness of personal feelings. In his most unified and sustained mock-heroic poem, *The Vision of Judgment*, he rose to good humour even when satirizing Southey. The mockery of the laureate's fulsome praise of George III is less digressive than Byron's other satires and at times it reaches sheer brilliance.

In the main, Byron's historical dramas were successful only

insofar as the protagonists reflected aspects of his own personality. Though all the dramas are provided with characters whose speeches are replete with Byronic philosophy and confession, *Sardanapalus* is perhaps the most self-revealing. The Assyrian king, steeped in luxury and indolence, effeminate and slothful, rises to heroic action as Byron saw himself doing in defense of Italian freedom. *Cain* gave ample scope to Byron's philosophical and religious skepticism and speculation and caused a furor among the orthodox. It convinced Goethe that Byron's true bent was to dramatize the Old Testament.

Byron was a superb letter writer, conversational, witty and relaxed. An increasing number of his letters made available for the first time in the 20th century have contributed to the growth of his literary reputation. Among his most entertaining epistles are those to Lady Melbourne, Hobhouse and Douglas Kinnaird and his letters from Italy to his publisher John Murray and to Thomas Moore. With an admirable incisiveness, whether dealing with love or poetry, he cuts through to the heart of the matter. His apt and amusing turns of phrase make even his business letters fascinating.

Chew, *Byron in England, His Fame and After-fame* (1924), includes an extensive bibliography of Byroniana; Chew's chapter, pp. 138–183, on Byron in *The English Romantic Poets, a Review of Research*, rev. ed., by Thomas M. Raysor (1956), is a critical bibliography of Byron scholarship. (L. A. M.)

BYRON, JOHN (1723–1786), British admiral, whose account, published in 1768, of a shipwreck in South America was to some extent used by his grandson, the poet, in *Don Juan*, was born on Nov. 8, 1723, the second son of the 4th Baron Byron. In 1741 he was a midshipman on board the "Wager" when she was wrecked off the coast of Chile during George Anson's voyage round the world. After unparalleled hardships Byron eventually reached a Spanish prison and was repatriated in 1745. He was appointed to the command of the frigate "Dolphin" in 1764 and sent out to the Pacific ocean in an attempt to discover the supposed southern continent, but he did not have the temperament of an explorer and only made a fruitless circumnavigation lasting 22 months.

Appointed governor of Newfoundland in 1769, he reached flag rank in 1775 and became vice-admiral in 1778. In 1779 he lived up to his nickname "Foul-weather Jack" when, in command of a fleet sent to relieve British forces in America, he encountered one of the worst Atlantic gales on record. As commander in chief of the West Indies he fought an inconclusive battle with the comte d'Estaing off Grenada that year. He died in England on April 10, 1786. (C. C. L.)

BYTOM (Ger. BEUTHEN), a Polish town in the Katowice *województwo* (province) in Upper Silesia. Pop. (1960) 182,500.

Situated on the old trade route between Wrocław (Breslau) and Cracow in a mining district (lead, zinc) that was early exploited in the 12th century, the town has developed over a long period. It is a large industrial centre, with coal mines, foundries and factories. It lies on the railway between Wrocław, 120 mi. to the northwest, and Cracow. The Silesian opera house and museum are situated there.

Bytom was the capital of the Bytom castellany, which was separated from the Cracow territories in the 12th century, and incorporated in Silesia. From 1282 it was capital of the independent dukedom of Bytom, whose ruler acknowledged vassalship to the king of Bohemia in 1289. Like Bohemia, Bytom came under the Habsburgs until Austria was forced to yield it to Prussia in 1742. Germany kept it after the 1921 plebiscite, though 68% of the population of the Bytom *powiat* (district) had voted for unification with Poland (see SILESIA). During World War II Bytom, then in the extreme southeast of Upper Silesia, was a centre of the Polish underground movement in Germany. It became Polish after the war.

NOWY BYTOM (New Bytom) lies between Bytom and Katowice. It was allotted to Poland as a result of the 1921 plebiscite. Classed as a town in 1951, Nowy Bytom had 84,000 inhabitants in 1958. (K. M. Wl.)

BYTOWNITE (named from Bytown, now Ottawa, Ont.), a rock-forming mineral of the plagioclase group of feldspars. See FELDSPAR.

BYZANTINE ARCHITECTURE is the architecture that was developed under the Eastern Roman empire from the time of Constantine in the 4th century to its fall in the 15th century. Offshoots of this style in Russia, the Balkans, along the east coast of Italy and elsewhere are frequently included in the term. The first part of this article deals with the general historical development of Byzantine architecture; specific discussions of its development in Armenia and in Russia will be found later in the article and in ARMENIAN ART and RUSSIAN ARCHITECTURE.

(The development of architecture in western Europe during this period is discussed in ROMANESQUE ARCHITECTURE and in GOTHIC ARCHITECTURE, and that of the preceding period in ROMAN ARCHITECTURE. ISLAMIC ARCHITECTURE is also pertinent. Background material will be found in BASILICA; MOSQUE; ARCHITECTURE; and ORTHODOX EASTERN CHURCH.)

The Byzantines, named from Byzantium, which became the East Roman imperial capital in 330 (its name was then changed to Constantinople), actually called themselves Romaioi. The cultural heritage that this implies is particularly strong in archi-

ecture, for many practical ideas developed by the Romans survived, and are in use today. The ancient dominance of Old Rome, which favoured architectural uniformity, was then in decline, and a new opportunity was offered for imaginative designers in the east. Syria at the time was prospering on oriental trade flowing through Antioch, and artistic ideas, following the same route, suggested piquant structural and decorative combinations, with novel proportions, in a wide variety of buildings which were nevertheless very Roman and very influential.

As may be learned from the long-abandoned dead cities of Syria, the excellent local limestone was used, along with wooden roofing and flooring. The upper floors in structures of importance were formed of long thin slabs of cut stone carried on diaphragm arches. The best example is the vast monastery and church (the latter an octagon with four basilican church arms) at Kalat Seman near Antioch, Turk. (459). There are indications that Armenian medieval architecture was derived from this region, but Syrian architecture came to its real flowering under Byzantine and Persian influences after the Arab conquests (7th century).

Period of Transition (330–527).—A stupendous civic monument, indicative of the new importance of Constantinople, was the Great wall (413–447). The expansion of the city drew craftsmen from many regions, and they made significant changes in Roman architectural practice. Perhaps with Anatolian precedent, masonry-faced rubble walls replaced puddled concrete with studded facing (often of triangular brick). Tile and brick, similar to modern varieties, were used in effective new ways, doubtless under oriental influence, which also transformed late Roman architectural ornament. In decoration, boldness of modeling gave way to new effects gained by softer profiling and sophisticated lacelike surface treatments (e.g., the church of St. John Studion, Constantinople, 463). Exteriors were plain, but marble sheathing and mosaic were lavished on the interiors, as in the mausoleum of Galla Placidia, Ravenna, Italy, about 450,

Following the general demolition of churches by Diocletian (303–304), the Edict of Milan (313) brought church architecture to major importance. As a rule the early Christians had only one church in a city and this had to be rebuilt on the scale of the chief local civic monuments. To meet this need, the imperial architects created the dignified wooden-roofed Christian Roman columnar basilica, with nave and aisles, early in the 4th century. Memorials and small shrines were soon built with vaulting, and it was not long until major church buildings were built, as Roman civic structures had been, with permanent masonry vaulting. However,

traditional Roman vaulting had been developed for civic, not church, building; its application to church building met great difficulties. New types of construction had to be evolved, which, with their appropriate canons of proportions and decoration, determined the Byzantine and Gothic styles.

About A.D. 480 Anatolian architects developed the domed basilica, having barrel vaulting in the aisles and also in the nave except for a square area, with suitable piers, at its head. This area was brought up to a circle by pendentives (sometimes also squinches) each arching inward and upward from a corner to support a quarter of the circular circumference under a dome. Domes were built in the clever oriental manner as thin shells of brickwork, saving weight and allowing generous illumination through a circle of windows (e.g., St. Sophia, Thessalonica, 6th century). The Byzantines learned to combine domes with other vaults and developed them in original, practical ways; e.g., the "domed cross" elements (fig. 1, 2). Much of the character of Byzantine work was due to the resulting opulent rounded interior effects with a minimum of heavy, obstructive supports. (See ARCH AND VAULT; DOME.)

The First Golden Age (527–726).—This period began with Justinian's reign in Constantinople. His first church there, SS. Sergius and Bacchus (523–527), was a vaulted octagon with aisles and galleries, the culmination of early Christian experiments with round, polyfoiled and polygonal plans. This church inspired S. Vitale in Ravenna (526–547) and ultimately the Carolingian cathedral of Aix-la-Chapelle (Aachen), Ger. (c. 790–805).

Two Anatolians, Anthemius of Tralles and Isidorus of Miletus, created the masterpiece of Byzantine architecture in the patriarchal cathedral of Hagia Sophia (Holy Wisdom), Constantinople (532–537, perfected 558–563 by Isidorus the Younger). A splendid narthex or vestibule has nine doors leading to the church proper. The scheme of the church proper was based on the domed basilica, though the 107-ft. domed area, with immense pendentives, was extended by two systems of hemicycles, and domes were cleverly used to vault the aisles and lateral galleries. This command of structural means marked the maturity of the Byzantine style. No later Byzantine building matched Hagia Sophia in size or in the superb ordering of its interior space. Its domed surfaces produced remarkable acoustical effects, which greatly enhanced the traditional sung liturgy of the Eastern Church.

Other remarkable buildings in Constantinople were the cruciform domed Church of the Holy Apostles (536–546), and, during and after Justinian's time, great works on the Sacred palace.

Beginning in Justinian's time it became customary in the Eastern Church to divide the sanctuary from the nave by a low thin wall pierced by two lateral doors and the ceremonial central or "holy" door, directly in front of the altar. In early Christian times the altar itself had been screened from view at the consecration by curtains hanging from the canopy or baldachin. The new arrangement was much more convenient for Byzantine services, which had become more elaborate, and required a larger number of clerics. Also, it heightened the sense of otherworldliness and mystery.

Venerated pictures, consecrated and technically called icons, were soon displayed on the separation wall, which thus came to be called the iconostasis. All churches of the Eastern rite still use the iconostasis. An image of the Saviour as teacher or judge is usually seen at the right of the central door, and a corresponding image of the Holy Mother and Child at the left, with the icon of the dedication of the church just beyond. The archangels Michael and Gabriel are usually placed on the lateral doors. The Annuncia-

AFTER K. J. CONANT, "A BRIEF COMMENTARY ON EARLY MEDIEVAL CHURCH ARCHITECTURE"
 FIG. 3.—"FIVE-SPOT" OR QUINCUNX CHURCH, A CHURCH TYPE OF THE SECOND GOLDEN AGE BASED ON THE DOMED CROSS ELEMENT

tion and the Saviour as the great archpriest usually appear on the central door, with the Last Supper in an upper row of icons, just above. This upper row, extending in both directions, regularly has icons of the apostles or of the great feasts of the church. Popular among the subjects which fill out the main row of icons are John the Baptist, St. Nicholas, and the equestrian saints George and Demetrius.

In Slavic lands the *ikonostas* usually has several upper registers, with many saints; often it reaches the full height of the sanctuary.

The Iconoclastic Period (726–867).—The period during which icons were forbidden in the Byzantine church was not very productive in architecture. Nonfigural mosaic work was used in both palaces and churches; a fine Byzantine example still exists at the Great mosque of Damascus (8th century).

The Second Golden Age (867–1204).—Inaugurated by Basil I, this period was fecund in the creation of interesting, practical church types, rich effects of decorative masonry and sophisticated iconographical schemes. Mosaic began to give way to fresco painting on the church interiors. Sea Ekklesia (Sew church), Basil I's palace church in Constantinople (881?), was the prototype of the Byzantine and Slavic princely churches of the middle ages. Characteristically, they have an animated silhouette, due to their five-spot plan: an arrangement of five domes with a large one in the middle and a small one at each corner of the building, over the chapels and a gallery (fig. 3).

The patriarch Photius, who dedicated Nea Ekklesia, was responsible for the character of the new posticonoclastic icons, churchly pictures of strictly defined theological content. In his time a remarkably influential set of dogmatic mosaics was introduced into the Church of the Holy Apostles in Constantinople. The apse had the Holy Mother and Child, the central dome the Pantocrator ("Lord of All") (represented by the lineaments of His Son); the other domes had the Transfiguration, Resurrection, Ascension and Pentecost, with a multitude of figures—heavenly, prophetic, apostolic and hieratical—in orderly array on the less important surfaces. This church was copied at St. Mark's, Venice, with similar decoration (1063–13th century; see fig. 2[C], diagram for both churches).

The most familiar Byzantine church type was created in the second golden age. With apses at the east, the main block was oblong, having corner vaults at a relatively low level enclosing a cross of barrel vaulting, which formed the intermediate step to a dome on pendentives and drum carried high in the middle of the building. Since four slender supports (usually columns) were set under the dome to sustain the whole middle part, this type of church has been called the four-column type (fig. 4).

The Athonite subtype was developed about A.D. 1000 on Mount Athos by adding an apse at each end of the transept of a four-column church, to accommodate the monastic antiphonal choirs. The church of the Theotokos (c. 1050) at the monastery of Hosios Lukas in Greece is a good example of the simple four-column church. The beautiful main church of this monastery, dated about 1013, represents the squinch type, so called from the straddling corner arches which aided the transition from the square plan of a rather cubical central space to the characteristic broad, rather flat dome above. The square was extended by four narrow arms, forming a cross, with smaller vaults on two levels at the corners of the church.

Later Periods.—The Latin domination (1204–61) was a period of unqualified disaster for the Byzantines, and the empire was so weak during the Byzantine Renaissance (1261–1453) that little building was done. Traditional types were maintained, usually with slender proportions, sometimes with contamination from western art, as in the church of the Pantanassa

monastery at Mistra near Sparta (1445). Under the Turks the chief Byzantine churches, including Hagia Sophia, became mosques, and when the Turks built new they were inspired by Byzantine originals, though the decoration and many minor features were drawn from Muslim works in Persia and Egypt. There was a considerable increase in the Greek population during the 18th century; since the Christians were not allowed to build conspicuous or imposing buildings, they revived the ancient wooden-roofed basilica. Little remains of Byzantine architecture in Asia, but the Balkans are rich in late examples, which have characteristic patterned wall work. Fortifications and palaces exist at Istanbul. Mistra and on Mount Athos where there are interesting domestic and conventual structures, old and new.

The kingdom of Serbia was active in church building during the 11th–14th centuries. The monasteries at Decani (c. 1327) and Gracanica (c. 1320) and the church of St. Clement at Ochrida with its patterned brick walls are particularly interesting.

After the War of Independence (1821–33), the Greeks revived medieval Byzantine types. In modern times Greek congregations have used traditional forms in cathedrals all over the world.

Armenia.—Armenia, which became Christian in 303, shows clearly its architectural contacts with early Christian Palestine, Syria and Anatolia. It was a stone-building area, where walls and vaulting of rubble were faced with fine cut stone. In the First Period of Bloom (7th–8th centuries) very interesting and original combinations were made using round, quatrefoil, octofoil, polygonal and domed basilican forms, all building up to handsome domes, usually on squinches, polygonal on the exterior. Exterior arcading was used. A fine example near Echmiadzin is Surb Hripsimé, Vagarshapat (618).

The Second Period of Bloom (10th–12th centuries) produced elegant variations of older types, taller and more expressively formed, as in Holy Cross church (915–921), Akhtamar, Lake Van. This church, exceptionally, has calligraphic exterior sculptures. By 989 the architect Trdat, at Ani cathedral, was using pointed arches and ribbed structure resembling 12th-century French Romanesque work. But no development comparable to workaday Gothic vaulting ensued, because the Armenians preferred to use the ribs in centralized vaults with multiple intersections (as at Haghbat, 11th century). Later work shows Persian influence.

The Turkish conquest (11th century) proved to be a catastrophe for the Armenians and their architecture. Nearby Georgia, more fortunate, remained Christian. Excellent church designs resembling Armenian work still exist there (example, the Cathedral of Mtskhet, 11th century). The great age is the 11th and 12th century, but the style has continued in use down to the present.

Russia.—Russia, a wood-building country, had strong traditions which definitely modified the Byzantine architecture that came in with Greek churchmanship (989). The first Russian churches (about 940) doubtless resembled the traditional rustic chapels—log cabins axially extended by a porch and a chancel. Elaborate gables, and perhaps spire forms, began with St. Vladimir's cathedral of Kovgorod ("Our Lady of the Thirteen Roofs," 989). Eventually octagonal spire churches were built with log walls of primeval timber, capped by pyramidal tent-roofs, occasionally reaching nearly 200 ft. in height. This form was taken over into masonry at Kolomenskoye, 1532; the famous Church of Basil the Beatified on the Red square, Moscow, 1555–60, is actually a bundle of domed spire churches in masonry, with many *kokoshniki* (ex-

terior transition arches).

Church architecture in masonry began with St. Vladimir's Tithe church in Kiev (991), which was, or soon became, a five-spot arrangement—a typical middle-Byzantine princely church. This theme was carried along by the Russians together with the single-domed church (as at Pskov), but with relatively heavy, simple masonry and constantly increasing Russian character. Thus the cathedral of Kiev (1037–c. 1100), though embellished with Byzantine frescoes and mosaics, had an extraordinary group of 13 (later 19) tall domes.

The new cathedral of Novgorod (1045–12th century) early had helmet-shaped and onion domes (really light outer shells—often painted or gilded—protecting domes of ordinary profile from the wet and snowy climate). These new shapes rapidly became universal; they are an unmistakable feature of Russian churches.

Classic equilibrium between the Byzantine and the Russian was achieved in the five-domed cathedral of Vladimir (1158–89) and nearby churches; there are interesting Byzantine frescoes and sculptures of Armenian or Lombard inspiration. This development was throttled by the Tatar invasion (1240). When it was revived, as Ivan III built the Moscow Kremlin (1475–16th century), Italian influence was strong. Renaissance and Baroque motives joined in making the later works extraordinarily complex, with the Byzantine reminiscences reduced, often, to the five-spot arrangement of decorative onion domes or spire clusters.

BYZANTINE ART is rooted in the Greek region of the Eastern Roman empire: it is a Christian art inspired by the church; and it is an imperial art closely bound up with the court. These three factors determine its nature and its history. In this article it is considered to have taken shape at the end of the 4th century (though some scholars would place its beginnings later), by which time it comprised the three essential elements that characterized it throughout its history.

There are three major periods in the history of Byzantine art. The first goes up to the period of the iconoclastic dispute, which marks a profound break, lasting from 726 to 843, during which artistic activity seems to have waned. The second and most brilliant period, that of the Macedonian and Comnenian dynasties, ended in 1204 when Constantinople was captured by the crusaders. The third period, corresponding to the reign of the Palaeologan dynasty, lasted until the fall of the city to the Turks in 1453. Byzantine art did not however disappear entirely with the end of the empire, for it continued to develop in the Orthodox countries that were not occupied by the Turks, particularly Russia, and it survived even on the Greek mainland and on the islands. But its real history ends with the history of the Byzantine empire.

Byzantine art, like western medieval art, derives from Greco-Roman art. But while in the west there was a break in continuity between the end of antiquity and the middle ages, the transition in the Greek near east was imperceptible. Nevertheless, Byzantine art stands out clearly from the art that preceded it. The latter had tended, throughout its history, toward the imitation of nature, idealizing it but never transforming it. Byzantine art, al-

though retaining many of the formulas of its predecessor, modified them and subordinated them to a new ideal; in contrast to the natural world it reveals a heavenly one where the laws of nature do not obtain. An increasing stylization in figure painting and abandonment of the "naturalistic" formulas of Greco-Roman art are the expression of this tendency.

The religious content of this new art was determined by Christianity, which furnished most of the themes of Byzantine iconography. Nevertheless, in one important matter it maintained its connection with antique art. It continued the tradition of imperial iconography, which since Augustus had had for its object the exaltation of the emperor and of the empire.

The changes in technique are no less important. Freestanding sculpture, the favourite technique of Greek and Roman art, was soon abandoned for mosaic, that "painting for eternity" which took its place. The sumptuary arts, sculpture in ivory, jewelry and goldsmith's and silversmith's work and costly fabrics, were developed and attained a brilliance never before achieved. The richness and fineness of the material surpassed the harmony of the forms.

FIRST PERIOD

Mosaics.—It is not merely by chance that from the beginnings of Byzantine art the most representative works should have been in mosaic. This technique, because of the intensity of the colours and the glancing play of light over the cubes of glass and marble, surrounds the figures represented with an air of mystery that painting has never been able to evoke. Inside the churches the believer finds himself transported into another world, that of the Christian hereafter.

The principle groups of Byzantine mosaics of the 5th, 6th and 7th centuries are to be found at Salonika (Greece) and Ravenna (northern Italy). Those at Salonika, though less well preserved, are probably closer to the lost works of this period in Constantinople. The mosaics in St. George's church (formerly an imperial mausoleum) take first place by reason both of date (end of the 4th or middle of the 5th century) and of artistic quality. Below the immense dome of the building, which was covered with a mosaic of the Ascension now lost, are fantastic architectural compositions in the Greco-Roman style among which stand the figures of saints in mosaic. The emerald greens, the azure blues, the reddish purples of the state robes and the buildings stand out against the gold background, their brilliance making a telling contrast with the asceticism of the heads. The mosaic in the Church of Hosios David, dating from the end of the 5th century, reveals a less hierarchic style which has affinities with 4th-century Christian art. The decorative mosaics in the soffits of the arches in the Paraskevi church (Eski Jami), also of the 5th century, continue the antique, naturalistic style. Those of St. Demetrius, the chief church in Salonika, were partly destroyed by fire just after they had been uncovered in 1918. They dated from the 5th to the 7th century and showed the evolution of the style which, emerging from illusionism, was becoming rigid and linear.

At Constantinople itself few remains of the mosaics of this first period have been preserved. Those of Hagia Sophia, dating from the 6th century, show a very simple form of decoration. A remarkable mosaic pavement probably of the time of Justinian I, although it has also been attributed to the first half of the 5th century, covers one of the entrances to the destroyed Great Palace. Scenes of country life, the hunt and the circus are juxtaposed without division. They are classical in style, issuing more directly than the church mosaics from Greco-Roman tradition.

Farther east, two 7th-century mosaics on Cyprus (Panagia Angeloktistos at Kiti and Panagia Kanakaria) and one of the Transfiguration in the Convent of St. Catherine on Mt. Sinai dating from the reign of Justinian I reveal a style found again at Ravenna.

Ravenna is the most westerly outpost of Byzantine art. An imperial city from 404 to 476 and an important centre until the 7th century, it has preserved intact the greatest number of 5th- and 6th-century works. The Italian tradition can still be observed in the mosaics in the mausoleum of Galla Placidia and the baptistry of the Orthodox, both of the 5th century. But the mosaics

executed under the Ostrogoth king Theodoric (493–526) and later are brilliant examples of the Italo-Byzantine style. The mosaics in the church of S. Apollinare Nuovo belong to two periods. Some were executed under Theodoric and reveal, for the first time in the west, the majesty of the art of the capital. The others, two long ranks of men and women saints: more vivid in colour and more elegant in form, date from the middle of the 6th century. The masterpiece among the Ravenna mosaics is the decoration of the choir of S. Vitale (540–547). The most celebrated mosaics of this are the processions of the emperor Justinian I and of his wife Theodora, in which immobility of the figures, all seen from the front despite the movement of the processions toward the apse, the astonishing realism of the heads, the dazzling richness of the colours, create an impression at once of solemnity and intense life. At S. Apollinare in Classe a symbolic representation of the Transfiguration covers the vast apse.

At Porec (Parenzo) on the Istrian coast there is a mosaic in the apse (mid-6th century) of the Virgin and Child enthroned between two archangels and six saints, which appears to have been executed by mosaic workers from Ravenna. A little later Byzantine influence becomes apparent in some of the mosaics in Rome. The hieratic style of the east characterizes those in the apses of S. Venanzio near St. John Lateran, of S. Stefano Rotondo, of Sta. Agnese (all three of the 7th century) and of Sta. Prassede (9th century). Some fragments of the mosaics of a chapel of Pope John VII (705–707) and the frescoes in Sta. Maria Antiqua in the Forum of the same period are very classical in style, less Byzantine than those mentioned above. It is not known whether this style derives from Constantinople or from one of the other important Greek cities of the east.

Sculpture.—The Greco-Roman iconographical tradition is more apparent in sculpture than in mosaic, but little of it remains. The base of the obelisk of the emperor Theodosius I (probably 392) in the Hippodrome at Constantinople represents the emperor with his two sons and coemperors presiding at the circus games. In Ephesus (Asia Minor) a series of statues of dignitaries, probably local, date from throughout the 5th century. At Barletta (southern Italy) a colossal bronze statue of an unidentified emperor is not earlier than the 5th century.

The subjects of all these works are traditional, but the style reveals some new characteristics. The realism of the features contrasts with the immobility of the figures, which is of a piece with the rigid drapery of the robes. At Ravenna a considerable number of Christian sarcophagi adorned with reliefs date from the early 5th to the 7th century. They evolve from a style at once realistic and classical toward an austere symbolism and highly simplified forms.

Manuscript illumination.—The Greek illuminated manuscripts of the 6th and 7th centuries reveal the penetration of the "Byzantine" style already defined and the continuance of the antique tradition. The Dioscorides in the National library in Vienna, written and illuminated at the beginning of the 6th century for a noble lady of Constantinople, can be attributed with certainty to a workshop of the capital. Three others, the Vienna Genesis (6th century) in the same library, the Rossano Gospels (southern Italy) and the fragments of the Sinope Gospels (Paris, Bibliothèque Nationale) both 6th-7th century, may be Constantinopolitan work or may derive from Asia Minor or Syria (Antioch). They are sumptuous manuscripts in gold writing on purple parchment.

Many of the narrative and genre scenes of the Vienna Genesis are full of life and of a truly Hellenistic charm. In the two Gospel manuscripts, however, the story is told in an austere style related to that of the mosaics. The few surviving leaves of the Cotton Bible (British museum, London) furnish several examples of 6th-century Alexandrine art. The Rabula Gospels, a Syrian manuscript (dated 586) written by the monk Rabula in northern Mesopotamia and now in the Laurentian library, Florence, can be distinguished from Greek work only by its language and textual variations. An illustrated secular manuscript, the Iliad in the Ambrosian library, Milan, has been attributed to a 6th-century Constantinopolitan workshop.

The interest of these illuminations is as much iconographical as stylistic. Their numerous illustrations of Old and New Testament scenes are for many subjects the only surviving evidence from which to reconstruct the earliest Christian iconography.

Sumptuary Arts.—The sumptuary works of art created for display by the court and the aristocracy are particularly characteristic of the taste of this epoch. Ivories, gold and silver objects, and fabrics are to be found in most of the great collections of Europe and America.

Ivories.—Diptychs form the largest group, falling into three categories: consular Christian and imperial. Both leaves of consular diptychs bear the portrait of a consul opening the circus games. Imperial and Christian diptychs are generally bigger, both leaves being composed of five panels, the central one bearing the image of the emperor or empress, of Christ or the enthroned Virgin, surrounded by narrative scenes. In the best works, like the Barberini diptych in the Louvre and the diptych of the consul Anastasius (517) in the Bibliothèque Nationale, Paris, the low relief reveals great sensitivity for the slightest variations of surface. Maximian's throne at Ravenna, probably executed there between 545 and 553 for bishop Maximian, though it has also been thought to come from workshops of Constantinople, Alexandria or Antioch, is the most important example, despite its mutilated condition, of ivory sculpture of this period. (See also IVORY CARVING)

Fabrics.—The fabrics of the earliest Byzantine period cannot yet be classified either geographically or chronologically. Many have been found in the dry soil of Egypt at Akhmim and Antinoë and are now in the great collections of Europe and America. Others are still preserved in the treasuries where they were used as wrappings for precious relics. Woven from silk (e.g., the shrouds of St. Victor, St. Columba and St. Loup in the treasury of Sens cathedral, France), or wool, they were either portions of appliqué work for vestments, or great decorative pieces such as hangings to go over doors or between pillars, or altar cloths faintly decorated with Christian or secular subjects. The influence of the east (Sassanian Persia, central Asia and perhaps even the far east) is apparent in the motifs (e.g., winged griffons) and in the style.

Silver.—The silversmith's work that is still preserved was for the most part intended for liturgical use. An important 6th-century group of patens was discovered in Cyprus (the greater part is now in the Metropolitan Museum of Art, New York city). They are decorated with scenes from the life of David in a highly classical style. Similar treasures—for instance, those of Homs and Hama, now partly in the Louvre, Paris—have come from Syria, although Syrian origin is not thereby established. These pitchers, basins and patens are distinguished by the refined simplicity of the decoration, which sometimes consists only of a dedicatory inscription. In contrast, the 6th-century Syrian Riha paten (Washington, D.C., Dumbarton Oaks collection) showing the communion of the apostles is more forceful and cruder in style. One of the most important pieces of Byzantine silversmith's work is the Antioch chalice (Metropolitan museum, 6th century). Its openwork reveals the extraordinary skill of the craftsmen. The Vatican treasury possesses a silver cross, a gift from the emperor Justinian II (565–578) and his wife, of which the style and iconography resemble that of contemporary coinage. A whole series of 7th-century silver plates adorned with mythological subjects, mostly in the Hermitage museum, Leningrad, show a return to the Greco-Roman style and to subjects of the 2nd and 3rd centuries.

GOLDEN AGE

During the period from mid-9th century to 1204, Byzantine art attained its zenith. Masterpieces were created in every technique; the style, full of grandeur and subtlety, spread beyond the confines of the empire.

Mosaic.—Mosaic was still the principal art. The customary architectural form of Byzantine churches since the 10th century, a cross inscribed within a square crowned by a dome above the crossing, sometimes surrounded by smaller domes on the arms of

5. Ivory panel carved in bas-relief, from the throne of Saint Maximian (6th century) in the cathedral, Ravenna
6. Ivory panel depicting Romanus II. and his wife, Eudocia. About A.D. 945. From the Cabinet des Medailles, Paris
7. Leaf of an early ivory diptych representing the Archangel Michael

the cross, lends itself perfectly to mosaic decoration not only on the walls but also on the vaults; the lower part of the walls was covered with multicoloured or inlaid marble.

Iconography and style had been profoundly altered by the iconoclastic controversy. All secular subjects or genre detail were now rigorously excluded, and decoration was reduced to a minimum. Figures of Christ and the saints, bare of ornament and ranged in a severe order dictated by theological considerations, stand out against a uniform gold background. The liveliness of the figures is intensified by the contrast between the relative opacity of the coloured cubes and the translucent gold background.

The Pantocrator, a majestic half-length portrait of Christ, Lord of the world, was generally represented on the central part of the dome, surrounded by angels and prophets. In the squinches at the angles of the dome and on the upper walls the events of Christ's earthly life were displayed in the cycle of church festivals. The Virgin and Child was enthroned in the principal apse. Figures of the saints were ranged under the arches and along the lower part of the walls above the marble facing.

Surviving examples of this scheme are to be found chiefly in Greece. The church of Hosios Lucas in Phocis is the oldest (beginning of the 11th century), followed by the Nea Moni on Chios and the church of Daphni near Athens (end of 11th century). At Daphni the elegance and physical beauty of the figures echo the sweetness of the expressions, while at Hosios Lucas a solemn gravity prevails and at Nea Moni the style is cruder, the scenes more dramatic.

The mosaics of St. Sophia at Salonika are older, dating from the 9th century (though perhaps the Virgin and Child in the apse belongs to the end of the 8th century) and therefore reveal several differences in style and iconography: the figures are squatter and the Ascension instead of the Pantocrator adorns the cupola as in the earlier church of St. George.

In Hagia Sophia at Constantinople there are a number of fine mosaics dating from the 9th to the 14th century: Leo the Wise prostrated before Christ between busts of the Virgin and the archangel Michael above the central door of the narthex; Constantine the Great and Justinian I before the Virgin and Child enthroned (end of the 10th century) above the south door of the entrance to the narthex; another magnificent Virgin and Child enthroned between two archangels (dated variously between the 10th and 14th centuries) in the principal eastern apse; imperial portraits of the 11th and 12th centuries at the eastern end of the south gallery. These mosaics show the evolution in the capital of a style that developed from an illusionism close to the antique toward the portrayal of the attenuated, two-dimensional figures of the middle ages.

Byzantine mosaic of the golden age had an influence far beyond the frontiers of the empire. Remarkable examples executed by Byzantine masters are to be found in the church of St. Sophia (11th century) at Kiev in Russia and in Italy. At St. Mark's, Venice, the style of the capital is progressively transformed by Italian masters. In Sicily, on the other hand, in the Martorana (1140) and the Palatine chapel (1143) at Palermo, and in the churches of Cefalù (1148) and Monreale (1182), the Norman princes tried, not always with success, faithfully to reproduce the models of the capital.

Manuscript Illumination.—The flowering of the arts after the iconoclastic controversy is particularly apparent in the illuminated manuscripts of which magnificent 10th- and 11th-century examples still exist. The return to antique models characterizes their style even more than that of the mosaics. The imitation of Greco-Roman works is sometimes so faithful that some of these manuscripts, for instance the Joshua Roll in the Vatican library, were for a long time attributed to the 5th or 6th century. The Bibliothèque Nationale in Paris owns the most outstanding of them: sermons of Gregory of Nazianzus (9th century; Paris, Grec. 510), a psalter (10th century; Paris, Grec. 139) and sermons of John Chrysostom (11th century; Coislin. 79), decorated with imperial portraits whose majesty and subtle detail are in no way inferior to monumental painting. The 11th- and, more particularly, the 12th-century manuscripts are more refined in style; the

figures are more slender, the backgrounds of unrelieved gold. In some cases the rich and subtle ornamentation reveals Muslim influence.

Sumptuary Arts.—Like manuscript illumination the sumptuary arts reached their zenith under the Macedonian and Comnenian emperors. Cloisonné enamels of this period later served as models to the west in that technique. Two crowns in the museum at Budapest, one of Constantine Monomachus (1042–55), the other of St. Stephen of Hungary (dated 1071–74), are remarkable for a series of cloisonné enamel plaques with figures representing Christ between two apostles, emperors and empresses, and two dancers. An object of primary importance in the treasury of St. Mark's, Venice, is the *Pala d'oro*, a gold altar covering adorned with figures of saints and cloisonné decoration in 12th-century Italo-Byzantine style. This treasury contains numerous other Byzantine objects in gold adorned with precious stones: pyxes, ewers, chalices and patens ranging from the 10th to the 14th century.

Ivories.—Those that bear imperial portraits or Christian subjects (scenes from the life of Christ and of the saints) are stylistically quite close to the mosaics. The Byzantine masters knew how to unite the delicacy of the lesser arts and the grandeur of the monumental style. Two masterpieces in Paris are the Harbaville triptych (10th century) in the Louvre and an ivory of Christ crowning the emperor Romanus II and his wife Eudocia (959–963) in the Bibliothèque Nationale. Some reliquaries and some boxes designed for secular use depict religious subjects or Greek and Roman mythological scenes. (See also IVORY CARVING.)

Fabrics.—Authentic Byzantine fabrics of this period are rare, but some magnificent examples in silk carry inscriptions citing the names of Byzantine emperors (Basil II, 976–1025; Constantine VIII, 1025–28) and bear the date of manufacture. Examples are the fabric decorated with lions from Siegburg, Ger. (921–923); another lion fabric divided between the museums of Dusseldorf, Berlin and Krefeld (976–1075); and a piece of fabric at Aachen (c. 1000) decorated with elephants. The oriental style that characterized the fabrics of the first Byzantine period is maintained in this craft and is even accentuated under the influence of Arab models.

THIRD PERIOD

Toward the end of the 12th century monumental painting was losing its vigour. In the 13th, and still more in the 14th century, Byzantine art was profoundly altered, although it did not undergo so radical a change as western art of the same period. It remained to the end the art of the Orthodox Church, which dictated its themes and determined the smallest detail of the iconography.

Some new subjects—for instance, extended cycles from the life of Christ and of the Virgin, and numerous lives of the saints—are introduced in this period. The figures are much more numerous and more realistic, the action is often dramatic, extensive landscape and architectural backgrounds are imitated from the antique and after the 14th century perhaps also from Italian models. The number of works still preserved is naturally much greater than from the preceding period and it is possible to mention only the most important of them.

Mosaic and Painting.—Mosaic was no longer the chief technique among the arts; fresco became increasingly important and in the second half of the 14th century completely supplanted mosaic. Neither is the superiority of the Greek world (Greece and Constantinople) as marked as hitherto. In the Balkans, and above all in Yugoslavia, the evolution of painting may be studied in an uninterrupted series of masterpieces stretching from the 12th to the 15th century.

In Constantinople mosaics and fine frescoes in the Kahrie Jami (church of the Saviour in Chora), a mosaic in the gallery of Hagia Sophia representing the Deesis (*i.e.*, Christ between the interceding figures of the Virgin Mary and John the Baptist), in which Christ has a grave beauty and the technical execution is of exceptional delicacy, and mosaics in the Pammacaristos church all date from the early 14th century. They are characterized by rich harmonies of colour, numerous narrative themes and slender

figures with varied expressions.

In Greece the mosaics in the church of the Twelve Apostles at Salonika are of the same period, perhaps even from the same school, as the mosaics of the Kahrie Jami, while the Pantocrator mosaic in the church at Arta (Greece) belongs to the end of the 13th century. At Kastoria (near the Albanian-Yugoslav border) dozens of churches and chapels still contain Byzantine frescoes ranging from the end of the 12th to the 15th century. At Mistra, a ruined Byzantine town near Sparta, and on Mt. Athos, numerous churches still possess 14th- and 15th-century frescoes, of which those in the Metropolitan church, the Peribleptos and the Pantanassa at Mistra and in the Lavra and Dochariou on Mt. Athos are the most important.

The religious paintings of Yugoslavia are the work of several schools. In Macedonia the 12th-century paintings in Nerez and in the cathedral of St. Sophia at Ohrid (Ochrida), and the late 13th-century paintings in St. Clement at Ohrid, are Greek in origin and style; the latter, which are particularly well preserved, are the work of two painters, Eutyches and Basil, who signed their work. The vigour of expression and the dramatic power of numerous scenes from the life of Christ are comparable with the contemporary frescoes of Giotto, although there is no discernible influence in either direction. At Prizren and in the nearby convent at Decani and at Gracanica, 14th- and 15th-century frescoes cover the walls and vaults.

In Serbia the Byzantine contribution is particularly apparent in the early 13th-century paintings in the church of St. Nicholas in Studenica. Later it wanes and elegance gives place to powerful realism which makes the frescoes of Milesevo (1230-36) and above all of Sopocani (c. 1256) the most remarkable works of Serbian art, and indeed of 13th-century Byzantine art in general. The statuary of the great French cathedrals may have influenced the Serbian artists who painted these frescoes.

Sumptuary Arts.—The sumptuary arts continued to be practised in this later period, but these luxury crafts—enamel, sculpture in ivory and goldsmith's work—are far removed from their old perfection. Only in embroidery, worked chiefly in convents, was work of great merit still produced. The ornamentation of consecrated cloths (*epitaphioi*) to cover the altar and the altar vessels and of liturgical vestments gave occasion for the display of a copious religious imagery, and some examples, such as the dalmatic in the Vatican (early 15th century), are not inferior to the best contemporary monumental painting. The earlier pieces, dating from the second half of the 14th and the beginning of the 15th century, were imitated up to the 19th century.

ART OF THE ICON

An icon in the wider sense of the term is any representation of holy personages or scenes, but the word is here used in its narrower sense of portable representations only. The icon is believed to represent the actual features of the person concerned, hence the repetition, throughout many centuries, of the same iconographical type.

The oldest icons still preserved (6th century) are in the monastery of St. Catherine on Mt. Sinai, at Kiev and at Sta. Francesca Komana in Rome. They are little tablets of wood painted in encaustic. One of the most celebrated icons, Our Lady of Vladimir (in the State Tretyakov gallery, Moscow), dating from the first half of the 12th century and doubtless the work of a great artist of Constantinople, had a considerable influence on Russian icon painters, of whom Andrei Rublev (15th century) is the best known. The rare 12th- and 13th-century works are distinguished by great spirituality, fine draftsmanship and a most subtle use of colour; among them are the head of Christ from the church of the Dormition in Moscow, and St. Demetrius, both in the Tretyakov gallery, Moscow. Later, following the evolution of monumental painting, the style becomes more banal and admits popular elements. The icon is the only form of Byzantine art that has effectively endured into modern times.

BYZANTINE EMPIRE. The Byzantine or east Roman empire was in essence the Roman empire in its medieval form; and its early beginnings can already be discerned in the reign of Constantine the Great, who profoundly influenced the course of European and imperial history. There was no break in continuity, for the Roman imperial tradition and Hellenistic civilization continued to be essential elements of the Byzantine polity. But Constantine's adoption of Christianity and his foundation of Constantinople marked a new epoch.

The empire of the *Rhomaioi* with its emphasis on its Greek heritage was to be a Christian empire centred in the eastern half of the Mediterranean. The foundation of Constantinople provided an admirable base for the administration and defense of the eastern and Balkan provinces, as well as a first-rate centre for international trade.

During its long life of 1,130 years the Christian empire had various roles; in particular, it acted as the defender of Europe against the great powers of western Asia and it introduced the young Slav peoples of the Balkans and Russia to Christianity and the heritage of the Greco-Roman world. It faced a continuous succession of enemies on its northern frontier in Europe—Germanic, Slav and Turkic peoples—and in the case of the Slavs and Bulgars had to accept them as permanent inhabitants in the Balkans. It also observed perpetual vigilance in the east, where it was in almost continuous conflict with the powers which successively inherited the dominion of Cyrus and Darius. From this point of view the external history of the empire was marked by four great struggles, each with a different Asian power: with Persia, ending c. 630 in the victory of Constantinople; with the Muslim Arabs, who ceased to be formidable in the 11th century; with the Seljuk Turks, in the 11th and 12th centuries; and with the Ottoman Turks, who emerged triumphant by the 15th century. It should, however, be emphasized that from the 11th century onward the hostility of certain Latin powers, notably the Normans and then Venice, culminating in the Latin capture of Constan-

tinople in 1204, was a strong contributory factor in weakening the empire's resistance to the Turks.

Up to the middle of the 11th century the Byzantine empire was in actual strength and prestige the first power in Europe, and under the Comneni it still had considerable authority in the 12th century. And until the rise of the Italian maritime cities it was supreme in commerce. Throughout the medieval period until its capture by the Latins in 1204, Constantinople was in fact the foremost city in the Christian world. But the significance of the Byzantine empire consisted in far more than mere political strength. As the heir of antiquity it was undoubtedly superior in civilization and was largely responsible for introducing the rest of Europe to its Greek heritage. The needs of the Christian church gave fresh impetus to creation in building, the visual arts and music, and to a lesser degree in literature.

This account of the Byzantine empire is treated as follows:

I. HISTORY

A. CHRISTIAN ROMAN EMPIRE; BARBARIAN MIGRATIONS

By their administrative and financial reforms Diocletian and Constantine immeasurably strengthened the empire. Its vast extent made subdivision essential, but Diocletian's experiment of two Augusti and two Caesars proved a failure; after Constantine I had destroyed his last rival and restored peace, he remained sole ruler for the rest of his life. On his death his son Constantius ruled the eastern part with its capital at Constantinople, and Constantians (after the death of Constantine II in 340) governed the western half, only to be killed by the usurper Magnus Magnentius in 350. Constantius then defeated Magnentius and was left the only sovereign of the whole empire.

Constantine the Great had firmly supported the Christian church in its pronouncement against heresy, but after his death Arianism openly rent the imperial house. The Arian Constantius, who had no children, was succeeded by his cousin Julian (361-363), who openly attempted to revive paganism. He was, however, killed

fighting against Persia, and the eastern struggle was temporarily suspended by a treaty negotiated by his successor, the Christian Jovian (363-364), whereby the empire renounced territory in Mesopotamia as well as its claims in Armenia.

This period was also characterized by wars against the Germans, who were pressing against the northern frontiers. Pushed forward by the Huns (see GOTHS; HUNS), the Visigoths crossed the Danube; at the battle of Adrianople (378) Valens, ruler of the eastern half of the empire, was defeated and killed. This signal victory marked a new stage in the relations between Roman and German. Theodosius the Great temporarily saved the situation by his arrangement with the Goths whereby Visigoths and Ostrogoths were allowed to settle in the Balkan provinces as foederaui. The efforts of a series of exceptionally able and hard-working rulers had thus preserved the empire intact throughout the 4th century, but the dangers which they weathered were fatal to their weaker successors in the western half of the empire. After the death of Theodosius I (395) the empire, now ruled by his two sons, was still regarded as a unity, but the tension between the east (under Arcadius) and the west (under Honorius) developed into antagonism verging on hostility, and in the west many provinces were rapidly lost to the Germans (see ROME: Ancient History).

After the death of Honorius' nephew, Valentinian III (455), the Theodosian dynasty ended in the west, and the authority of the western emperors who succeeded him in rapid succession barely extended beyond Italy. In 472 the western throne was usurped by Romulus Augustulus, set up by the general Orestes against the legitimate Augustus, Julius Nepos, who was acknowledged by the eastern emperor. But in 476 this temporary government was overthrown by a Germanic military revolution headed by Odoacer, who appropriated part of the soil to his German soldiers and founded an Italian kingdom under the nominal supremacy of the emperor at Constantinople, who, however unwilling, recognized Odoacer's position after the death of Nepos in 480.

The very different fate of the eastern provinces shows the extent to which the strength of the empire lay in the east. These provinces were more populous and presented greater obstacles to the invaders, who followed the line of least resistance. But it was of considerable importance that for the greater part of this period the empire was able to maintain at least intermittent peace with its great eastern rival. The struggle with Persia, terminated in 364 by the peace of Jovian, was not renewed on any scale until the beginning of the 6th century. It was of even greater importance that the eastern rulers pursued a wise policy both in internal and in foreign affairs. Under the weak Theodosius II (408-450) the government was ably conducted by his ministers and by his sister Pulcheria. His reign was important for the Armenian question. Theodosius I had agreed to a division of this buffer state into Roman and Persian spheres of influence, Persia having much the larger. The Sassanian government persecuted the Christians and tried to suppress the use of the Greek language, but the government of Theodosius II intervened on behalf of the Christians and war broke out which was ended by a treaty in 422. The Byzantines also officially supported the translation of the Bible into Armenian (the Armenian alphabet had just been invented), thus facilitating the development of the Christian church there and initiating numerous translations from the Greek which ensured the connection of Armenia with European rather than oriental culture (see ARMENIAN LITERATURE). This reign is also distinguished by the building of the great land walls of Constantinople, by the foundation of a university there in 425, and by the collection of the imperial laws in the Codex Theodosianus, which is a mine of information on the social condition of the empire (see ROMAN LAW).

In the second half of the 5th century in the east, as in the west, the empire had to face renewed inroads from the Germans, and during the reigns of Marcian (450-457) and Leo I (457-474) the government of Constantinople was largely under the control of the Alan leader, Aspar. Leo I however called in the hardy native warriors of Isauria in south Asia Minor. Strong anti-German feeling drove out Aspar, and the Isaurian chief Zeno married Leo's daughter and took control, first as co-emperor with his son Leo II and

886-912	Leo VI the Wise or the Philosopher	1449-53		
912-913	Alexander			

Vandal power had declined and the able general Belisarius (*q.v.*) won back Africa in a single expedition in 533. In Italy the Ostrogothic kingdom was rent by internal dissension and weak rule after the death of Theodoric (526), but its conquest was long drawn out, partly because of the rise of the Gothic leader Totila. Begun in 535 by Belisarius, the conquest was completed by Narses, but not until 555. The corner of southeast Spain was also won from the Visigoths so that the Romans again commanded the western straits. At the same time Justinian was engaged in a series of Persian wars with Kavadh and then his successor Khosrau I. Justinian also had to protect the Danube against the Slavs and Bulgars who constantly threatened the Balkan provinces and he spared no expense in strengthening fortifications. In addition he had an extensive building program of public works and churches.

Justinian, inspired by his high conception of the imperial office and well served by his generals and administrators, was a great conqueror, a great lawgiver, a great diplomat and a great builder. He was also the protector and leader of the church. His legal work alone, or the building of Hagia Sophia, the "great church" of Constantinople, would be sufficient to justify his title of "the Great." His name is always associated with that of the gifted Theodora (*q.v.*), an actress of dubious fame in her early life, who shared his throne. Their mosaic portraits are preserved in the contemporary church of San Vitale at Ravenna. Theodora possessed great political influence, and the fact that she was a champion of the monophysites, while Justinian was devoted to orthodoxy, did not affect their good relations, even though until her death in 548 she secretly favoured heretics who were publicly condemned. The monophysites were particularly strong in Syria and Egypt, provinces which were hostile to Roman rule, and Justinian failed to devise any ecclesiastical compromise which would conciliate them without alienating the rest of the empire. In view of his Italian policy it was particularly important for him not to have any break with Rome.

Justinian's attempt to restore the imperial boundaries made severe demands and was not permanently successful. But it did at least reintroduce Roman rule into the north African provinces for more than a century, and it was from north Africa that help was sent to save Constantinople in its hour of need in the early 7th century. Justinian renewed direct links between Italy and Constantinople which were not broken until the Norman conquest of the last remaining Byzantine provinces in the 11th century. At the same time he held his own against the Persians on the eastern frontier and successfully asserted Byzantine influence in the important territory of Lazica (see COLCHIS) in the southeastern Black sea area. (See also JUSTINIAN I.)

During the half-century after Justinian's death the empire had to cede ground on the west and the north and was attacked by the Persians on the east. In 568 the Lombards invaded Italy and soon established themselves in the north and centre of the peninsula, though the empire still retained important areas linking Ravenna and Rome, as well as the south Italian lands. In the north the Avars, a Turkic people who had advanced from the Caspian, took possession of Pannonia and Dacia and formed an empire, consisting of Slav and Bulgar subjects, which endured for about 60 years. Their chief occupation was to invade the Balkan peninsula and extort tribute and ransoms from the emperors. So far as the Avars themselves were concerned, these incursions had no permanent significance, but the Slavs who overran the provinces did more than devastate. These years saw the beginning of the Slav settlements which changed the ethnic character of the peninsula and infused fresh blood into the Byzantine empire. Slavs occupied Moesia and a large part of Macedonia, even close to Thessalonica (Salonika), which they besieged but never took; they penetrated southward into Greece and settled in parts of the Peloponnesus. They occupied the northwestern provinces, which became Croatia and Serbia, as well as the hinterland of the Dalmatian coast. In the northern part of the peninsula the Slavs remained dominant, but in Greece they were eventually assimilated. At the same time that the Lombards and Slavs were invading the empire, it was engaged in its perennial warfare with Persia. Maurice (582-602), who had ably organized the exarchates of

then as sole emperor. A further threat from the Ostrogoths in the Balkans was met by diverting them to Italy, where their leader Theodoric founded a kingdom which was, in its constitutional aspect, a continuation of Odoacer's regime. Theodoric, like Odoacer and Alaric, held the double position of German king and Roman official. He was magister *militum* as well as rex. His powers were defined by capitulations which were arranged with the emperor Anastasius I in 497 and loyally observed. The right of legislation was reserved to the emperor, and Theodoric never claimed it; but for all practical purposes he was independent. Thus by the end of the 5th century the east had successfully warded off the Germans, while the western provinces had virtually been lost to them.

B. JUSTINIAN AND HIS IMMEDIATE SUCCESSORS

The conception of the empire as a single unit still firmly persisted, and in the 6th century Justinian I (527-565) made a bold attempt to recover the lost western provinces. He had already dominated imperial policy under his uncle Justin I (518-527) and he sponsored the repudiation of the monophysite policy (see ΜΟΝΟΦΥΣΙΤΕΣ) of Anastasius I (491-518), thus enabling the resumption of ecclesiastical relations with Rome. The proposed expeditions against the Ostrogoths in Italy and the Vandals in north Africa afforded him the opportunity of delivering native Catholic Christians from their pro-Arian Germanic rulers. The

Ravenna and Carthage, was able to make an advantageous treaty with Persia, and he secured the alliance of Khosrau II by helping him to dethrone a usurper. Maurice himself was deposed and killed by Phocas, during whose incompetent reign (602–610) the eastern provinces were overrun by the Persians, and the Balkans by the Slavs.

C. THE HERACLIANS

The tyrannical and unsuccessful rule of Phocas ended in 610 when the exarch of Africa sent his son Heraclius with the African fleet to Constantinople. Phocas was deposed and killed and the coronation of Heraclius on Oct. 3, 610, inaugurated a dynasty whose work during the 7th century was to save the empire from disintegration and to lay the foundations of medieval Byzantium. Heraclius found the Balkans and Greece overrun by the Slavs and Avars; Asia Minor, Syria and Egypt by the Persians. The desperate nature of the situation and also the appeal which the west still made are shown by Heraclius' proposal to transfer the imperial capital from Constantinople to Carthage. This was keenly opposed in Constantinople and Heraclius therefore abandoned the idea. He set about restoring morale in the capital and in the provinces. Most of the Balkans and Greece was at the time virtually lost to the Slavs and Bulgars, and Heraclius and his immediate successors concentrated on the territory which was still under imperial control in Asia Minor. These provinces were now grouped into large themes or military zones, each under a single military governor (*strategos*) to whom the civil administrators were responsible. This system was gradually extended throughout the 7th and succeeding centuries as the Byzantines recovered control over their Balkan and Greek provinces and then expanded their eastern frontier. Within the themes soldiers were given inalienable grants of land on condition of military service which passed from father to eldest son. This provided an efficient and relatively inexpensive native army and strengthened the class of small independent farmers. New developments also occurred in the central administrative departments which were to characterize the middle as distinct from the early Byzantine period (see Administration below).

Partly as a result of these changes, partly by reason of able diplomacy, Heraclius and his successors were able to defeat the Persians and at least hold back the Arabs on the eastern front. In the early years of Heraclius' reign the Persians had made spectacular advances. Syria was invaded; Antioch and Damascus fell, and in 614 Jerusalem was captured and the holy cross was carried off to Ctesiphon. The conquest of Egypt followed. Armenia was successfully attacked, and the victorious Persians advanced into Asia Minor. By 627, however, Heraclius, who had now gained as an ally the powerful khan of the Khazar kingdom in the north Caucasus and lower Don-Volga regions, was able boldly to take the offensive. In Dec. 627 he defeated the Persians at Nineveh, and in 628 drove Khosrau from Dastagerd. The murder of the Persian king in the spring of 628 was followed by a peace treaty by which all Byzantine territory was restored, and in 629 Heraclius in person restored the holy cross to Jerusalem.

This victorious affirmation of Christian imperial rule did not, however, secure the eastern provinces. From 634 onward the Byzantines were challenged by the rising forces of Islam (see CALIPHATE; MOHAMMED). Weakened by the bitter struggle with Persia and handicapped by the political and religious hostility of its provinces in Syria, Palestine and Egypt, Byzantium was forced to cede ground. The Arab caliph Omar advanced into Syria in 634, and by 636 had conquered it, having defeated the Byzantines at Yarmuk (636). Palestine was next subjected, and the Arabs then drove into Persia. Byzantine Mesopotamia and Armenia (639–640). By 646 Egypt had been finally lost and the Arabs were penetrating into the north African provinces and into Asia Minor, while the growth of an Arab fleet under Mu'awiya I, governor of Syria, brought the loss of Cyprus, Rhodes and Cos and constant raids on the Aegean islands and coast. Civil war among the Muslims enabled Constans II to make peace in 659, and from his base in Sicily he was concentrating on offensives against the Lombards in south Italy and the Arabs in north Africa when he

was assassinated (668). His successor, Constantine IV (668–685), had to face renewed attacks on Asia Minor under Mu'awiya I, now caliph. These culminated in the siege of Constantinople (674–678). The Byzantines withstood the attacks and their victory was followed by an advantageous peace with the Muslims. This was the first of the three decisive checks on Arab advance into Europe during this period (the others were the second siege of Constantinople in 718 and the defeat at Poitiers in 732); it was therefore an event of world significance.

The second major problem of the Heraclian era was the Slav occupation of the Balkans which from the 7th to the 9th centuries also extended into Greece. The defeat of the Avars besieging Constantinople in 626 had resulted in revolt against their domination, first by the Slavs and then by Bulgars north of the Black sea and the Caspian sea. Henceforth the Avars were not a factor in Byzantine politics, and a fresh influx of Slavs (the Serbs and Croats) settled in the Balkans, apparently with Heraclius' consent, though there was evidently little substance to later claims that Byzantine suzerainty was at this time recognized by the Slavs. The Balkans and Greece were dominated by the Slav settlers and these regions were known by the Byzantines as the "Slavinias." Fully occupied in defending the empire against the Muslims, the Heraclians could only give occasional attention to the Slavs. In 658 Constans II attacked the "Slavinias," probably in Thrace and Macedonia, compelling them to acknowledge his suzerainty. A number of Slavs were taken prisoner and settled in Asia Minor and incorporated into the army.

Under Constantine IV some of the Bulgar tribes from the north of the Black sea moved southwest under 'pressure from the Khazars, and one band under Asparukh settled round the Danube mouth, dominating the Slavs already there and forming a state which was to become far more dangerous to Byzantium than the "Slavinias." Constantine IV's expedition against the Bulgars in 680 failed and it was not until 1018 under Basil II Bulgaroctonus that their principality in the northeast Balkans was finally incorporated into the empire.

Justinian II in 688/689 led an expedition against the Slavs in Thrace and Macedonia and succeeded in making his way into Thessalonica, which had remained in Byzantine hands though surrounded by Slav-occupied lands. Captured Slavs were again settled in Asia Minor and the claims of Byzantine overlordship asserted. But by the end of the 7th century effective Byzantine control in Greece and the Balkans was confined to Thrace and central Greece (Hellas) where the imperial government had set up the theme organization in the latter years of the century.

The 7th century thus saw the emergence of the middle empire as distinct from the early Byzantine empire. The provinces of Egypt and Palestine and Syria, as well as north Africa, were lost to the Muslims. The Lombards retained northern and central Italy, while Byzantine control over the exarchate of Ravenna was precarious—only in south Italy did it maintain its hold for several centuries to come. In the Balkans the Slavs and Bulgars, though they were eventually brought under Byzantine influence and to some extent control, were the predominant factor. Further, the Slav occupation created a barrier between Byzantium and the Latin west which probably did more to interrupt communications than did Arab piracy in the Mediterranean. In spite of the obvious interest of 7th-century emperors in Italy and Africa, the ties between the Greek east and the Latin west were being continually loosened, and it was clear that Justinian I's policy of restoration had failed. But a smaller and more manageable empire emerged. Reorganized by the Heraclians and revitalized by the vigorous Slavs, it stood as an effective barrier against Islam until the mid-11th century.

D. THE NORTH SYRIAN DYNASTY (ISAURIANS)

The last of the Heraclians, Justinian II, lost his throne in 711, and after a series of struggles the commander of the Anatolikon theme, Leo III, took control in 717. He and his family were associated with the policy of iconoclasm which brought them into discredit with later generations as heretics. But both their administrative and their foreign policies carried a step further the

constructive work of the Heraclians. In 726 Leo III issued the *Ecloga*, a legal handbook which was to take the place of the more cumbersome *Corpus iuris* of Justinian and incorporated changes in customary law since Justinian's day. In spite of being the work of a heretic emperor, this manual was an important influence in the future development of Byzantine, as well as Slav, law. The main change in administration was the reorganization and subdivision of certain of the overlarge Heraclian themes in Asia Minor. The western region of the Anatolikon theme was made into the new Thraceseon theme. At some time between 710 and 732 the maritime theme of the Carabisiani was subdivided into the theme of the Cibyrraeots and the drungariate (later the theme) of the Aegean sea. By the middle of the 8th century Crete had also been organized as a theme.

The imperial religious policy had important political repercussions. In forbidding the veneration of icons the iconoclast emperors had considerable support in Asia Minor and from the army, but they roused the European provinces and incurred the implacable opposition of Rome. It was probably during Leo III's reign that the provinces of Calabria, Sicily and Illyricum (the western Balkans and Greece) were transferred from Roman jurisdiction to that of the patriarch of Constantinople, though not with papal acquiescence. At the same time the Byzantine position in north and central Italy weakened owing to Lombard encroachments, and in 751 Bari, the seat of the exarch, was lost. Both the danger of the Lombard advance and the rift with Constantinople caused the papacy to look west instead of east for help, with the consequence that the Carolingians became a major factor in Italian politics. Byzantine authority in Italy survived only in the southern provinces which it kept until these fell to the Normans in the 11th century.

Though Byzantium lost ground in the west and at the peripheries in the south and east, it held its own against the Arabs in Asia Minor. At the opening of Leo III's reign the capital was once more invested (717–718), but with the help of the Bulgars under Khan Tervel the Byzantines forced the Muslims to lift the blockade. In Asia Minor the perpetual Arab raids were checked by a series of campaigns and a signal victory at Acroinon (740), while the Byzantine allies, the Khazars, proved invaluable in stirring up trouble for the Arabs in the Caucasian and Armenian districts. The conflict between the Omayyads (Umayyads) and Abbasids and the removal of the caliph's capital from Damascus to Baghdad in 750 also temporarily created a situation favourable to Byzantium. Constantine V (741–775) was able to take the offensive, but his attacks in north Syria, Armenia and Mesopotamia did not result in permanent acquisitions; Cilicia and the Taurus region also remained in Arab hands until the 10th century. But the main core of Asia Minor, the stronghold of medieval Byzantium, had been secured.

In the Balkans the Byzantine position was precarious and the chief enemy was the expanding Bulgar state now threatening Thrace. The Bulgars were checked in a series of campaigns undertaken by Constantine V. Both naval and military operations were successful, culminating in the victory of 763 at Anchialus on the Black sea. Internal conflicts in Bulgaria brought a temporary respite, and war was only resumed after the accession of Telerig in 770. During the last years of his reign (773–775) Constantine V was again campaigning in the Balkans, but, though Telerig was defeated, the Bulgars remained hostile and unsubdued.

Leo III and Constantine V were the outstanding rulers of the north Syrian dynasty. Despite their iconoclast policy they showed their recognition of the essential needs of the empire by their constructive internal administration and by their concentration on the two key problems of the Balkans and Asia Minor. Unfortunately their successful military policy was not continued during the last quarter of the century under Leo IV (775–780) and his wife Irene (797–802) together with their son Constantine VI (780–797). Leo IV's short reign was marked by a policy of procrastination in religious matters. On his death, Irene took control as Constantine VI was a minor. She strongly opposed iconoclasm, and in 787 the use of icons was restored at the seventh ecumenical council held at Nicaea (see COUNCIL).

Neither Irene nor Constantine VI succeeded in organizing successful military resistance to the Bulgars and the Arabs. Irene appears to have deliberately weakened the army, which was known to be iconoclast in sympathy, and she played for popularity by remitting taxes needed for the expenses of defense. Consequently the Muslims again raided far into Asia Minor, and the imperial forces in the Balkans were defeated by the Bulgars who successfully demanded the payment of tribute. In the west the diminishing prestige of the Byzantine empire in Italy was reflected in Pope Leo III's coronation of the Carolingian Charlemagne as emperor in Rome on Dec. 25, 800. This symbolized the separation of what had once been the eastern and western halves of a single empire, and, though the western assumption of imperial authority was indignantly repudiated by the east, it remained a fact which in practice had to be accepted. Byzantine claims to universal rule were thus successfully challenged.

On the deposition of Irene in 802, financial economy and imperial defenses were the main concerns of Nicephorus I (802–811). As a former logothete of the treasury he was well fitted to stabilize finance. His measures for the protection of the soldier-farmer and his colonization of districts in Thrace and Macedonia made it possible to take the offensive against Bulgaria and to strengthen Byzantine control in the south Balkans and in Greece. Though Nicephorus actually lost his life in a campaign against the Bulgar ruler Krum (811), the gradual re-establishment of Byzantine control is reflected in the extension of the theme organization. About the end of the 8th century and beginning of the 9th, themes of the Peloponnesus, Macedonia (which included part of western Thrace) and Cephalonia were probably established, and soon afterward Dyrrachium and Thessalonica. In spite of temporary setbacks the administrative and military work of the iconoclast emperors, particularly Leo III and Constantine V, was to bear fruit in the steady expansion of Byzantine authority and prestige from the mid-9th century onward, not only in the Balkans but also on the eastern frontier. Because these rulers were heretics, their solid achievements were often glossed over by Byzantine historians.

E. AMORIANS AND MACEDONIANS

The attempts of Leo V (813–820) and the early Amorians Michael II (820–829) and Theophilus (829–842) to revive iconoclasm failed, and under Michael III (842–867) a new era was inaugurated. Iconoclasm was finally renounced in 843 and the able administrative, cultural and foreign policy of Michael III's regents and generals, and his uncle Caesar I Bardas, was continued by the blacedonian dynasty established by Basil I on the murder of Michael in 867.

1. Relations With the Slavs.—One of the most pressing problems was the penetration of the Balkans by the Slavs. Both Rome and Constantinople sent missionaries to the south Slavs, but by the end of the 9th century it was clear that Slavs had been won for the Orthodox Church and drawn into the orbit of Byzantine civilization, partly as a result of the able work of the scholar missionaries Cyril and Methodius. For Byzantium it was a matter of urgent policy to establish some control over the young Slav principalities, particularly Bulgaria, which by the end of the 9th century was expanding west and south. The Bulgar ruler Simeon took advantage of the unwarlike Leo VI and the minority of his son Constantine VII and in 913 threatened Constantinople. Simeon failed to take the capital and he came to terms with the regents whereby he was crowned *basileus* of Bulgaria and his daughter was to marry Constantine VII. He was, however, subsequently outwitted by the Byzantine co-emperor Romanus I Lecapenus (920–944), and after his death in 927 a period of peace followed. During the last quarter of the 10th century the Bulgars again threatened the empire and there was the further menace of Kievan control in Bulgaria. This time the problem was solved by conquest. John I Tzimisces (969–976) drove out the Russians, captured the Bulgarian ruler Boris, abolished the Bulgarian patriarchate and incorporated eastern Bulgaria into the Byzantine empire. During Basil II's reign (976–1025) an attempt to revive the Bulgarian kingdom in western Macedonia with Ochrida (Ohrid) as its capital was made by Samuel, a Macedonian of Armenian

stock. He was defeated by Basil II, whose ruthless campaigns earned him the title of "Slayer of the Bulgars" (Bulgaroctonus). Thus by 1018 Bulgaria was completely absorbed and its patriarchate replaced by a virtually autonomous archbishopric.

The Russians, like the Balkan Slavs, were indebted first to the missionaries and then to the ecclesiastics of the Orthodox Church. They also came into contact with Byzantium first as raiders, then as traders, allies and mercenaries. In 860 they first attacked Constantinople, and it is from this period of Photius' patriarchate that Byzantine missionary work among the Russians dates. In 907 Prince Oleg of Kiev led an expedition to Constantinople and in 911 a commercial treaty was signed between the Russians and Byzantines. An attack on the Bosphorus in 941 was decisively defeated by the Byzantine general John Curcuas. In 944 Prince Igor of Kiev advanced to the Danube and was bought off by money and a new commercial treaty. Friendlier relations were inaugurated by the newly baptized regent princess Olga of Kiev, who visited the imperial court at Constantinople in 957. Her son Svyatoslav's attempt to establish his ascendancy in Bulgaria failed, and under Vladimir, not yet a Christian, the Russians allied with Basil II in 988. A Russian (Varangian) contingent remained in Byzantine service and in 989 Vladimir was rewarded by the hand of Basil's sister Anna. This marriage symbolized the ecclesiastical and cultural links between the two countries. Vladimir and his people formally adopted Christianity and the new Russian church developed with the help of the Byzantine patriarchate.

2. Success Against the Muslims.—On the eastern front and in the east Mediterranean from the mid-9th century on the Byzantines, in spite of intermittent setbacks, successfully took the offensive. In 863 the Muslims under the emir of Melitene were annihilated when they attacked the Armeniakon theme. Under Basil II's generals the Byzantines penetrated into the Euphrates territory. But during the early 10th century the empire was occupied by the struggle against Bulgaria, and Leo of Tripoli was able to ravage the Asia Minor coast and in 904 to sack Thessalonica. With the accession to power of the able Romanus I and the defeat of Bulgaria, the Byzantines under the leadership of generals such as John Curcuas, Nicephorus Phocas and John Tzimisce began their spectacular advance into Mesopotamia and Armenia, and then into Cilicia, Syria and Palestine. In 934 Melitene fell to John Curcuas, who advanced into Mesopotamia (943) and then captured Edessa. In alliance with Baghdad and Egypt, the Byzantines pushed home their attack on the formidable Hamdanid emir of Mosul and Aleppo, Saif-ud-Daulah. In 960–961 Nicephorus Phocas took Crete and advanced in Cilicia and north Syria. In 962 Aleppo surrendered, though it did not remain in Byzantine possession. Under Nicephorus, now emperor, Cyprus was occupied (965), Antioch fell (969) and Aleppo was taken. John I Tzimisce penetrated further into Mesopotamia and drove south through Syria into Palestine. Although he took Nazareth he did not reach Jerusalem, nor did he establish the Byzantine position in Palestine. But by the beginning of the 11th century the measure of the Byzantine advance can be seen in the establishment of new themes in the east—Melitene, that of the "Euphrates cities" (later named Edessa), Mesopotamia, Taron, Teluch and particularly Antioch, the seat of the patriarchate. To these Basil II added Armenian and Caucasian territory over which he had established control—the themes of Vaspurakan, Theodosiopolis and Iberia. He also arranged for the Armenian kingdom of Ani to lapse to Byzantium on the death of its reigning king, Yovhannes-Smbat. This remarkable expansion on the eastern front was due partly to imperial statesmanship and military brilliance and partly to factions among the Muslim rulers, but also to the desire for further expansion which spurred on the Byzantine landed families of Asia Minor.

3. Events in Italy.—By contrast, the Byzantines made little advance in the west. They retained their province of Longobardia in south Italy (Apulia and Calabria), but by the end of the 10th century they had lost Sicily to the Muslims. They were aware of Italian problems, though priority had to be given to the Balkans and the east. Although Syracuse had been lost to the Muslims in 878, during Basil I's reign, the general Nicephorus Phocas the elder

began a successful offensive and reinforced the Byzantine position in south Italy. In spite of the troubles connected with the patriarch Photius (*q.v.*) relations were maintained with the papacy. During the 10th century the political situation was affected both by the German intervention in Italian affairs and by Otto I's assumption of the imperial title first claimed by Charlemagne. Nicephorus II, on the crest of his eastern successes, rejected out of hand Otto I's offer of a marriage alliance. John I Tzimisce more prudently came to terms; though he did not recognize any German claim to Byzantine territory in south Italy, in 972 he sent Theophano (probably his niece) as wife for Otto II. Neither Otto II nor Otto III achieved any real success in their attempts to consolidate their hold on Italy, while their contemporary Basil II strengthened his position by reorganizing the Byzantine provinces in south Italy under the control of a single governor, the catapan. Basil was preparing to take the offensive against the Arabs in Sicily when he died in 1025.

4. Home Affairs.—Byzantine prestige abroad during the years 842–1025 was paralleled by achievements at home. Under Basil I and Leo VI commissions were set up to revise the legal system, and during the latter's reign the Byzantine legal code known as the Basilica (*q.v.*) was issued. Under the patronage of Caesar Bardas the university of Constantinople was revived. Countless scholars, such as Photius and Leo the mathematician in the 9th century or Constantine VII and his circle in the 10th century, carried on and developed cultural traditions of ancient Greece and of medieval Byzantium. In purely domestic affairs one striking feature of the 10th century was the imperial agrarian policy designed to keep in check the power of the great landed families ("the powerful") and to bolster up the smallholders ("the poor"), many of whom held their land on condition of hereditary military service. Romanus I and Basil II were the chief promoters of legislation to prevent smallholders from being bought out by "the powerful." But even Basil II with his policy of ruthless severity toward the aristocracy was unable to ensure any permanent security to the small farmers who in the past had been a source of manpower for the army and navy.

F. IMPERIAL DECLINE; NORMANS AND SELJUK TURKS

Certain aspects of Byzantine life continued to develop as long as the empire lasted; there was no break in Byzantium's cultural and religious life either now or in the later middle ages. The achievements of its monasticism and its spirituality, its art and literature, reflect its continued vitality in these fields, particularly in the 11th century. But in other respects both at home and abroad the years 1025–81 mark the beginning of political decline. After Basil II there was no ruler who could compare with him in stature until the accession of Alexius I Comnenus in 1081. The Macedonian dynasty petered out with his two elderly and incompetent nieces Zoe (d. 1050) and Theodora (d. 1056). It proved difficult to enforce earlier agrarian laws against the magnates, and under Zoe's first husband, Romanus III, the law making the rich responsible for the taxes due from unworked land was repealed. Her second husband, Michael IV (1034–41), was a moderately competent general, but her third husband, Constantine IX Monomachus (1042–55), took little part in military activities.

After the death of Theodora in 1056 the disastrous struggle between the court aristocracy and the military families was accentuated. Except for the short reigns of Isaac I Comnenus (1057–59) and Romanus IV Diogenes (1068–71) the civil party held the field, usually with disastrous results. Extravagance led to unfortunate expeditions, such as debasement of the coinage, which set in under Constantine IX Monomachus and perhaps even earlier, while the civil service was expanded at considerable cost particularly under Constantine X Ducas (1059–67), who is also said to have filled the senate with artisans and traders. More disastrous still, the civil party's fear of the military families led to deliberate neglect of imperial defenses. Further, within the military party there was a marked antagonism between the Asian and European troops which on occasion prevented united action against the civilians.

Unfortunately this internal struggle coincided with the appear-

ance of new enemies on all fronts. The conquest of Bulgaria had brought the Byzantine frontier to the Danube and the empire now felt the full force of attacks from the tribes to the north, particularly the Pechenegs (Patzinaks), who proved a scourge in the Balkans until their final defeat by Alexius I in 1091. In the Bulgarian provinces themselves there was discontent and sometimes rebellion, while the Bogomil heresy of these regions spread south into the very capital itself (see *BOGOMILS*). In the western Balkans the growing Slav principalities became increasingly difficult to control, particularly Croatia and Zeta (see *CROATIA*; *SERBIA*), and aware of the strength of their position and the weakness of Byzantium under the Ducas emperors (1059–78) the rulers of these two states even turned to the papacy and received their crowns from Gregory VII.

It was particularly important for Byzantium to retain control of, or at least diplomatic relations with, the west Balkan rulers because of their proximity to western powers. During the 11th century the Byzantine hold on its south Italian provinces steadily deteriorated in spite of some success during the 1140s under the brilliant general George Maniaces. The death blow to Byzantine authority came not from the Arabs or the Lombards but from the Normans, who established themselves in south Italy from the mid-11th century onward. In 1059 they forced the papacy to recognize them and by 1071 they had taken Bari and pushed the Byzantines out of the peninsula. Shortly after they mastered Sicily, and then turned eastward and attacked the mainland of Greece in the early years of Alexius I.

Simultaneously the Byzantine frontier on the east was subjected to intermittent attacks from the Turkic peoples who had gained control over the caliphate of Baghdad (see *SELJUKS*). Throughout the 11th century there were raids and infiltration. In 1068 Romanus IV, who came from a Cappadocian military family, with difficulty mustered an army to stem the Turks. By now they controlled Syria, the Armenian lands and were seriously devastating the central provinces of Asia Minor. The Seljuk leader Alp Arslan defeated Romanus IV at Manzikert (*q.v.*; *Malazgirt*), north of Lake Van, in 1071, aided by treachery among the Byzantine troops. Alp Arslan was, however, willing to come to terms with the empire and to maintain the status quo, but when Romanus was deposed and blinded by the civil faction at Constantinople the proposed treaty fell through. A member of the Seljuk house established himself in the heart of Asia Minor as the sultan of Iconium (Konya) or Rum, and the Turkish rivals of the Seljuks, the Danishmends, set up the principality of Melitene in northeast Asia Minor. This marked the end of Byzantine control over the whole of Asia Minor. Neither the Comneni nor later emperors could recover more than a fraction of the provinces which had formed the heart of the medieval Roman empire.

G. THE COMNENI, THE ANGELI AND THE CRUSADES

The accession of Alexius I Comnenus (1081–1118) put an end to the struggle between the military and civil parties and inaugurated a period of almost a century during which the statesmanship of father, son and grandson temporarily restored imperial prestige. But even the powerful Comnenian dynasty, itself belonging to a landed military family, could only delay the final decline, and even so it had to use those elements in the polity which the more powerful rulers of the Ricedonian period had tried to check. From now on the empire was characterized by the increasing predominance of the military aristocracy as well as by strong separatist tendencies.

Alexius' main concern was to drive back the Seljuk Turks from Asia Minor, to maintain some control over the growing Slav principalities in the Balkans and to expel the ambitious Normans of south Italy from his western provinces. His army and navy were seriously depleted and his finances low. But he succeeded in coming to terms with Suleiman, the sultan of Rum, virtually recognizing the *status quo*, and he obtained mercenaries from this source. He enlisted the help of the Venetian navy at the cost of trade privileges. Thus reinforced, he turned against the Normans who were advancing from Dyrrachium (*Durazzo*). But the withdrawal of the Normans after the death of Robert Guiscard

in 1085 halted the duel between Norman and Greek, which continued intermittently throughout the 12th century.

Alexius' temporary lull, achieved by astute diplomacy supported by military campaigns, came abruptly to an end when the situation was radically changed by the first crusade (see *CRUSADES*). Alexius indeed asked the west for help against the Turks, but what he wanted was troops to serve under him. The Latin feudal armies, however, who set out against the infidel in 1096 acted independently, in spite of the Byzantine emperor's attempt to exact oaths of allegiance and to assert his right to former imperial territory. From the outset the Holy Land was their goal. There and in Syria they set up independent principalities, introducing a further complication into east Mediterranean politics. For Byzantium it was essential to begin by expelling the Seljuks and Danishmends from Asia Minor. Instead it had to deal with the petty intrigues of a disunited Christian front in Syria and Palestine; the most bitter blow of all was the establishment of the Byzantines' archenemy Bohemund, son of Guiscard, in Antioch, which had been regained for the empire in the late 10th century and only comparatively recently lost to the infidel. Bohemund, forced to return to Italy for help, spread false stories of Alexius' treachery toward the crusaders, and then in 1107 he turned once again to attack the Greek provinces of the empire. Defeated by Alexius, he was forced by the treaty of Devoll (1108) to recognize Byzantine overlordship and to agree to the re-establishment of a Greek patriarch in Antioch. But Tancred, acting as regent in Antioch, refused to implement this treaty.

Alexius' prestige steadily grew. In the Balkans he held the balance between Rascia and Zeta, and strengthened his position by marrying his son John to a Hungarian princess. In 1091 he decisively crushed the marauding Pecheneg (Patzinak) bands who periodically ravaged the lands south of the Danube. In western Asia Minor he regained ground and checked further aggression by playing off one Muslim power against the other. At home Alexius' main problems were of defense and finance. Here he was unable to reverse the developments of the 11th century. He attempted to check debasement and inflation but apparently only at the cost of devaluation which specially hit the poorer classes. He continued to grant frequent immunities, sometimes in the form of the *pronoia* or the *charisticium*, thus strengthening further the magnates at the expense of the central authority (see *Administration* below). For defense he relied mainly on mercenaries and the Venetian navy.

The main lines of Alexius I's policy were continued by his son John II Comnenus (1118–43) and his grandson Manuel I (1143–80). It was essential to watch, and, if possible, come to terms with, the Normans of Sicily, to win over the papacy by holding out hopes of patching up the ecclesiastical rift of 1054 (see *The Church* below), and to gain allies among the Italian cities. At the same time growing Serbian power had to be controlled and Hungary's interests south of the Danube checked if possible by diplomatic advances or even military force. In the east the main aim was the re-establishment of Byzantine control over the Norman principality of Antioch.

John II in spite of some reverses exercised a measure of control over Rascia, and in 1128 forced Hungary to come to terms with him. He allied with the German emperor Conrad III and the Pisans as a counterpoise to Roger II (crowned king of Sicily in 1130). Though he was not able to reduce the extensive trading privileges of Venice, he balanced this by confirming similar concessions granted to Pisa by Alexius I. In Asia Minor he defeated the emir of the Danishmends (1132–35) and reconquered Little Armenia in the southeast (1136–37). He then advanced on Antioch and asserted his rights of suzerainty (1137). He evidently intended to make good this claim and then to advance south, but he died unexpectedly in 1143.

Manuel I, faced by hostility from Norman Sicily and Norman Antioch and by the disturbances caused by the unfortunate second crusade (1147), counterattacked with boldness and originality, while keeping open the door to any possible alliance. He drove off the Norman invasion of Greece and Corfu (1147–49). He married his daughter (and at that time heiress) Mary to the heir-

apparent (later Béla III) of Hungary, cleverly gaining certain Balkan lands claimed by Hungary which he retained after the marriage had fallen through. He was a firm ally of Conrad III, and when this German ruler was succeeded in 1152 by Frederick I Barbarossa. Manuel still hoped to maintain this understanding. For a time he even attempted a military offensive in south Italy, but had to withdraw and come to terms with Sicily in 1158. He maintained cordial relations with the papacy, again holding out the bait of ecclesiastical reunion and playing on Alexander III's fear of Barbarossa and his antipope. He relied too on the help of Pisa and Genoa, bought with trading concessions, and used the general Byzantine resentment at the arrogance and privileged position of Venetian merchants to organize a concerted attack on them throughout the empire (1171) which incensed the republic and was one of the underlying reasons for the later attack of the fourth crusade. In the east, Manuel continued his father's policy in Cilicia and Antioch, but he was not able successfully to organize either Christian or Muslim resistance to the growing menace of Saladin, and his own defeat by the Seljuk Killij Arslan II of Iconium at Myriocephalon in 1176 greatly shook his own position which was now openly challenged by Barbarossa.

Manuel himself had been open to Latin influence and, though maintaining Byzantine imperial tradition, had freely used Latins within the empire; it is even maintained that he had a deliberate policy of invigorating Byzantium with an infusion of Latin blood. But on his death the anti-Latin feeling of the populace and the weakness of the empire were only too apparent. The regency of the Latin empress-mother, Mary of Antioch, for her young son Alexius II (1180-83) was speedily ended by a terrible massacre of all Latins in Constantinople. Alexius himself was overthrown by his cousin Andronicus I Comnenus (1183-85), an able and unscrupulous man who attempted in vain to check the power of the magnates and to restore the effective control of the central government. He thus lost the support of the military families, and his brutal methods (though in a good cause) made him hated. Hungary under Béla III regained its lost Balkan lands; the Serbian Stephen Nemanya repudiated Byzantine overlordship; the Normans of Sicily once again attacked the western provinces, took Thessalonica and advanced on Constantinople; and Isaac, the Comnenian governor of Cyprus, declared himself independent.

Andronicus was brutally killed by a Constantinopolitan mob and from 1185 to 1204 the Angeli took control. This short-lived dynasty was ineffective in the face of internal disorder and external hostility. Extortion and oppression crept back into the administration and the dominance of the landed magnates continued unchecked. Under two local leaders, Peter and Asen, the Bulgarians and Vlachs seceded to form the second Bulgarian empire. The German contingent of the third crusade, led by Frederick Barbarossa, passed through the Balkans, allying with Byzantine enemies and even threatening the capital itself. Isaac II Angelus (1185-95) staved off Barbarossa and came to terms with Stephen Nemanya. He was, however, blinded and deposed by his brother Alexius III, who took control until 1203. Isaac's son Alexius IV appealed to the west for help, thus giving Byzantine enemies the pretext for the Latin capture of Constantinople (1204) and the partition of an empire which they had long feared and coveted.

H. THE LATIN EMPIRE

The commercial ambitions of Venice, the mistrust between Latins and Greeks engendered by the crusades, the papal desire to reunite the churches of Rome and Constantinople, western covetousness of Byzantine wealth and even of Greek ownership of Christian relics—such reasons account for the deliberate diversion of the fourth crusade from Jerusalem to Constantinople, ostensibly to restore Isaac II and his son Alexius IV as puppets of the crusaders. Alexius III was driven out in 1203, but Isaac and Alexius IV, unable to fulfill their promises to the western powers and most unpopular with their anti-Latin Byzantine subjects, were in turn deposed by Alexius V. This incited the crusaders to take the city by assault and Alexius V fled. Constantinople was sacked by the victors, and many manuscripts and works of art perished or were seized by the looting westerners. The

architect of the Latin empire was the doge Enrico Dandolo, who ensured that Venice should have a major share in the spoils. The Latin emperor, Baldwin I, was from the outset too ineffective to establish any real control over the Latin principalities which were set up in Greece and the islands, and in Thrace and Thessalonica.

Three Byzantine states emerged from the wreck. Even before the fourth crusade separatist tendencies were reflected in the rising kingdom of Trebizond (modern Trabzon; see *TREBIZOND*), founded on the shores of the Black sea with the help of Georgia by members of the Comnenian family who continued to rule there until their final conquest by the Turks in 1461. In western Greece Michael Angelus set up the despotate of Epirus which in the course of the 13th century was to lose much of its territory before Latin, Serbian and Nicene attacks. In Asia Minor a third Greek state was founded by Theodore Lascaris, the son-in-law of Alexius III. Both Epirus and the Lascarid rulers claimed to be the true successors of the displaced imperial rulers. At the same time the able Bulgarian John Asen II also made a bid for the capital.

Theodore I Lascaris had been crowned emperor by a patriarch in 1208, and at Nicaea his court continued the Byzantine imperial traditions. By skilful diplomacy he consolidated and enlarged his kingdom. His successor and son-in-law, John III Vatatzes or Ducas (1222-54), continued Theodore's work and secured the predominance of the Lascarid kingdom. He practically drove the Latins out of Asia Minor and he regained a foothold in Europe. Cleverly allying with John Asen II, Vatatzes struck at the weakened Latin empire and also at the rule of the Angeli in Thessalonica and Epirus. In Asia Minor he further secured his position by alliances with Trebizond and Iconium. Theodore II Lascaris (1254-58) lacked his father's statesmanship, and on his death control was seized by Michael Palaeologus, ostensibly as regent for the young John IV (1258-61). Michael reaped the fruits of Lascarid policy and captured Constantinople in 1261. There he was crowned Michael VIII and founded the dynasty which was to rule until the final fall of the empire in 1453.

Michael's restored empire consisted of the Nicaean lands of northwest Asia Minor, the capital, most of Thrace and Macedonia, with some of the islands, as well as control over Epirus; as the result of his victory at Pelagonia (1259), he also gained certain strategic fortresses in the Peloponnesus. His main problems were inadequate resources for a policy of expansion and a new enemy in Charles of Anjou, the successor of the Normans and Hohenstaufen in south Italy. But Michael was a diplomat in the best Byzantine tradition, and he adroitly met the Angevin coalition of western powers by allying with the papacy, once again promising the reunion of the two churches which was actually attempted at the second Council of Lyons (1274). As usual this union between Rome and Constantinople was violently repudiated by the Greek clergy and people, and again Charles of Anjou prepared for an attack on the empire only to be foiled by bitter Sicilian hostility which in 1282 came to a head in the Sicilian Vespers (*q.v.*) and the establishment of the Aragonese house in the island. Michael VIII had a hand in these events and an understanding with Peter of Aragon.

I. DECLINE OF THE EMPIRE

After the downfall of Charles of Anjou no powerful Latin enemy ever again threatened the restored Byzantine empire, but its position nevertheless steadily worsened and it was menaced first by a vigorous Serbian kingdom and then by the Ottoman Turks (see *SERBIA*; *TURKEY*). Internally the empire was hampered by civil wars and by diminishing resources as well as by local and separatist feeling. Andronicus II (1282-1328) could not prevent the deterioration of the situation in Asia Minor, where as a result of the 13th-century Mongol invasions the sultanate of Rum had given way to a number of small emirates. These attacked the Byzantines by land and sea and by 1326 the Ottomans had established their capital at Brusa (Bursa) in Bithynia dangerously near to Constantinople. Andronicus had also to endure the inroads of the Catalans, originally called in as mercenaries, who had become the rulers of an independent principality in Greece. From the end of Andronicus II's reign onward civil war

and bitter family quarrels continued intermittently until the 15th century. First Andronicus II was forced to abdicate by his heir and grandson, Andronicus III (1328–41), and then dissension arose between the able Cantacuzenus (crowned co-emperor as John VI in 1347) and the young John V Palaeologus (1341–91). These were not merely political or personal struggles, but on either side different social classes and religious parties were ranged, and the partisans did not hesitate to support their own cause by allying with foreign powers, Muslim as well as Christian. John VI, who had married his daughter to John V (1348), was largely responsible for increasing the imperial hold on the Peloponnese and in Thessaly; this was achieved by an appanage system which was continued by the Palaeologan rulers after John Cantacuzenus' abdication in 1354.

During the second half of the 14th century Byzantine possessions in Thrace and Macedonia steadily diminished. The danger from the powerful and ambitious Serbian ruler Stephen Dushan, who apparently hoped to found a new Roman empire of Serbs and Byzantines, was averted by his early death and the subsequent disintegration of his greatly enlarged kingdom, which had included Thessaly and Macedonia (though not the city of Thessalonica), as well as Epirus and Albania. On the other hand this meant that there was no one Christian leader able to give a strong lead against the rapidly encroaching Ottomans. Adrianople in Thrace became the capital of Murad I and Bayazid I. The Ottomans defeated the Slavs at the battle of Kosovo (1389) and the western crusaders at Nicopolis (1396); Bulgaria was virtually under Ottoman control; Thessaly and the Morea (*i.e.*, the Peloponnese) were constantly raided. Political rifts and religious dissension prevented the Greek and Latin Christians from any united effort, and Byzantine resources alone were hopelessly inadequate. Neither Manuel II's courageous but pathetic tour of western capitals, nor the unexpected lull following Bayazid's defeat at the battle of Ankara (1402), could save the Byzantine empire. The Byzantine emperors were in fact Ottoman vassals.

The situation became critical with the accession of the sultan Murad II; the capital was more closely invested and frequent attacks were made on the comparatively flourishing despotate of the Morea, where a member of the Palaeologan family ruled from Mistra. In desperation John VIII (1425–48) turned once more to the papacy. He himself, with the patriarch and other representatives of the Orthodox Church, took part in the Council of Ferrara-Florence (*q.v.*; 1439) and the union was agreed upon. Once again it was repudiated by the Greek rank and file, and it also bitterly antagonized the Slav churches. In any case Pope Eugenius IV could not have mustered any western military force capable of retrieving the situation for the Byzantines. An army led by the Hungarian king was crushed by the Turks at Varna (1444).

In April 1453 Murad II's successor, Mohammed II, began a close blockade of Constantinople by land and sea. Constantine XI, with the loyal support of the Genoese, defended the city bravely, but it was finally stormed on May 29–30. Shortly after, the Ottomans made themselves masters of the Peloponnese and of Trebizond, and by the end of the 15th century they had set up their successor-state. Constantinople, magnificently rebuilt, became the capital of their empire; at the same time it remained the centre of Christian Orthodoxy which survived under Ottoman domination.

II. GOVERNMENT

A. IMPERIAL AUTHORITY

1. Emperor.—With Diocletian the principate of Augustus had become undisguisedly an absolute monarchy, and this constitution prevailed to the end. There is virtually no constitutional history in the proper sense of the term in the Byzantine empire. The monarchical system remained in all its essential points unchanged, and presents a remarkable example of an autocracy of long duration which perfectly satisfied the ideas of its subjects. No attempt was made to alter it—to introduce, for instance, a limited monarchy or a republican government; all revolts and conspiracies were aimed at the policies of particular autocrats, not at autocracy

itself; generally they only represented sectional antagonisms and personal ambitions, though often combined with opposition to tyranny. The emperors inherited a deeply rooted instinct of legality as a tradition from old Rome; and this respect for law which marked their acts, along with the generally good administration of justice, was a safeguard of the monarchy. They were supreme in legislation, as well as in the administrative and judicial spheres; but they were on the whole moderate in wielding legislation as an instrument of policy. There were however recognized constitutional principles which it would have been exceedingly difficult for the emperor to override.

Election.—The elective principle, inherited from the republic, was never changed. A new emperor had to preserve the formality of election by the senate and acclamation by the people and army. The succession never became automatic. But even Augustus had indirectly introduced the dynastic principle. Theodosius the Great, by causing his two sons, Arcadius and Honorius, to be elected Augusti in their infancy, practically elevated the dynastic idea into a constitutional principle; henceforward it was regarded as in the regular course that the son born to a reigning sovereign should in his infancy be elected Augustus. After the acceptance of Christianity the electors were regarded as expressing by their acclamation the will of God.

Religion.—When in the course of the 4th century the position of Christianity was assured, it followed that the profession of that religion would in future be a necessary qualification for election to the throne. This was formally and constitutionally recognized when the coronation of the emperor by the patriarch of Constantinople was introduced. The first emperor to be crowned in this way was Leo I (457–474), and from the 7th century on it was customary for this ceremony to be performed in Hagia Sophia. Originally the patriarch acted as the representative of the electors, but the ceremony gradually took on increasing ecclesiastical significance. The emperor, who was regarded as the protector of the church and the guardian of orthodoxy, had to make a profession of faith. Anastasius I is known to have made a statement recognizing his obligations to his electors, and by the 9th century there was in existence a regular coronation oath binding the new sovereign to keep the Christian faith and traditions.

Personal Sovereignty.—The sovereignty of the emperor was personal, not territorial. In this respect it always retained the character which it had inherited as the offspring of a Roman magistracy. Hence no Roman territory could be granted by the emperor to another power. For instance, the western emperor Conrad III could promise to hand over "Italy" (*i.e.*, certain Italian lands) to Manuel Comnenus as the dowry of his promised bride, but it would have been constitutionally illegal for Manuel to have made such a promise to any foreign prince; a Byzantine emperor had no right to dispose of the territory of the state. The Palaeologan custom of granting appanages to members of the imperial family were not a concession to western custom but the only way of governing widely scattered lands in a period when the central authority at Constantinople was weakened and in financial straits.

2. Senate.—While the senate of Rome generally lost its importance and at last became a mere municipal body, the new senate of Constantinople for a time preserved its position as an organ of the state. For the imperial elections it was constitutionally indispensable, and it was able sometimes to play a decisive part when the throne was vacant—its only opportunity for independent action. The abolition, under Diocletian's system, of the senatorial provinces deprived the senate of the chief administrative function which it exercised under the principate; it had no legislative powers, and it lost most of its judicial functions. It was, however, still a judicial court; it tried, for instance, political crimes.

In composition it differed from the senate of the principate. The senators in the 4th century were chiefly functionaries in the public service, divided into the three ascending ranks of *clarissimi*, *spectabiles* and *illustres*. The majority of the members of the senatorial order lived in the provinces, forming a provincial aristocracy, and did not sit in the senate. Then the two lower ranks

ceased to have a right to sit in the senate, which was confined to the *illustres* and men of higher rank (patricians). The senatorial order must therefore be distinguished from the senate in a narrower sense. The latter did on occasion have considerable influence as a consultative assembly, and its political weight was increased by the fact that the inner council of imperial advisers was practically a committee of the senate.

Its power was greatly diminished by the 10th century, but it did play a more important part when the civil party was in power during the 11th century.

3. People.—The memory of the power which had once belonged to the *populus Romanus* lingered in the part which the inhabitants of New Rome, and their representatives, played in acclaiming newly elected emperors, and in such ceremonies as coronations. In the 6th century the factions ("demes") of the circus. Blues and Greens. appeared as political parties, distracted the city by their quarrels and broke out in serious riots. On one occasion they almost shook the throne (the "Nika" revolt, 532). The emperors finally quelled this element of disturbance by reorganizing the factions and assigning them a definite quasi-political position in the public ceremonies in the palace and the capital where they were responsible for the "acclamations."

4. Court Ceremonial.—The court ceremonial of Constantinople, which forms such a marked contrast to the ostentatiously simple establishments of Augustus and the Antonines, had in its origin a certain constitutional significance. It was introduced by Aurelian and Diocletian, probably not from any personal love of display but rather to dissociate the emperor from the army, at a time when the state had been shaken to its foundations by the predominance of the military element and the dependence of the emperor on the soldiers. It was the object of Diocletian to make the emperor independent of all, with no more particular relation to the army than to any other element in the state; the royal court and the inaccessibility of the ruler were calculated to promote this object.

The etiquette and ceremonies were greatly elaborated by Justinian and were carefully maintained and developed. The public functions, which included processions through the streets to various sanctuaries of the city on the great feast days of the church, supplied entertainment of which the populace never wearied; and it did not escape the notice of the rulers that the splendid functions and solemn etiquette of the court were an effective means of impressing the imagination of foreign visitors with the majesty and power of the emperor.

5. Co-emperors.—The imperial dignity was collegial. There could be two or more emperors (*imperatores*; Gr *basileis*) at the same time; edicts were issued, public acts performed, in their joint names. During the 4th and 5th centuries, when the administration of the eastern half was generally separate from that of the western, the imperial authority was also collegial. But after this period the system of divided authority came to an end and was never renewed. There was frequently more than one emperor, not only in the case of a father and his sons, or of two brothers, but also in the case of a minority, when a regent or commander in chief might get himself elected emperor (as did Romanus I, Nicephorus II or John I Tzimiscus). But one colleague always exercised the sole authority, was the real monarch, the "great" or "first" *basileus*; the other or others were only junior partners. Until the Palaeologan period the title "autocrator" was reserved for the senior emperor.

B. LEGISLATION

The history of the legislation of the Byzantine empire is distinguished by three epochs associated with the names of Justinian; Leo III; Basil I and Leo VI.

1. Justinian I.—For Justinian's legislation, see JUSTINIAN I.

2. Leo III.—Justinian's reign was followed by a period in which juristic studies appear to have been neglected. The 7th century, a time of internal and external crisis, is a period for which little has survived and it is not known how far the law of Justinian, which had been translated into Greek, was studied or understood. Practice at least was modified by principles in accord with the

public opinion of Christian society and influenced by ecclesiastical canons. In the Quinisext or Trullan council held at Constantinople in 692 in the reign of Justinian II numerous rulings were made, differing from the existing laws and based on ecclesiastical doctrine and Mosaic principles, and these were sanctioned as laws of the realm by the emperor. Certain surviving legal codes may belong to the late 7th or early 8th century, such as the "Farmer's law" (*Nomos georgicos*) and the "Rhodian sea law" (*Nomos Rhodion nauticos*). The period of the north Syrian rulers was certainly characterized by legislative activity.

In 726 the *Ecloga* was issued in the name of Leo III and Constantine V. Written in Greek, this "Brief Selection of Laws" marks a new era and reflects the changed ideas of the community; it may in fact be described as a Christian law book. In regard to the *patria potestas* increased facilities were given for emancipation from paternal control when the son came to years of discretion, and the paternal was to a certain extent replaced by parental control over minors. The law of guardianship was considerably modified. The laws of marriage were transformed under the influence of the Christian conception of matrimony; the institution of concubinage was abolished. Impediments to marriage on account of consanguinity and of spiritual relationship were multiplied. While Justinian had regarded marriage as a contract, and therefore, like any other contract, dissoluble at the pleasure of the parties, Leo III accepted the church view that it was an indissoluble bond. Ecclesiastical, as well as oriental, influence was written large in the criminal law, of which a prominent feature was the substitution of mutilation of various kinds for the capital penalty. Death was retained for some crimes, such as murder and high treason; other offenses were punished by amputation of, for instance, the hand or nose, and the tendency to avoid capital punishment increased. The same spirit, it may be noted, is apparent in the usual, though by no means invariable, practice of Byzantine emperors to render dethroned rivals or members of a deposed dynasty innocuous by depriving them of eyesight or forcing them to take monastic orders, instead of putting them to death. The church, which had its own system of penalties, exercised a great influence on the actual operation of criminal law, especially through the privilege of asylum (recognized by Justinian, but with many reserves and restrictions), which was granted to Christian churches and was admitted without exception in the *Ecloga*.

3. Basil I and Leo VI.—The last period of legislative activity under Basil I and Leo VI represents a reaction, in a certain measure, against the *Ecloga* and a return to Justinian. Basil aimed at a revival of legal studies which was to be based on the law books of Justinian or their Greek versions. These books were now treated somewhat as Justinian and his lawyers had treated their own predecessors. A handbook of extracts from the Institutes, Digest and Code was issued in 879 (*Procheiros nomos*, "law as it is"), to fulfill something of the same function as the Institutes. Then a collection of all the laws of the empire was prepared by means of two commissions, and completed under Leo VI. It was entitled the *Basilica* (*q.v.*). In many points (in civil, but not in criminal, law) the principles of the *Ecloga* were set aside in favour of the older jurisprudence. Thus Justinian's ordinances on the subject of divorce were revived, and there remained henceforward a contradiction between the civil and the canon law.

After this there was no legislation on a grand scale; but there was a marked revival of legal study under Constantine IX, who founded a new faculty of law in the reorganized university of Constantinople, and there were many learned specialists who wrote important commentaries, such as John Xiphilinus (11th century), Theodore Balsamon (12th century), Harmenopolus (14th century). The young Slav principalities in the Balkans were influenced by Byzantine legal codes; and modern Greece, although in framing its code it took the Napoleonic for its model, professes theoretically to base its civic law on the edicts of the emperors as contained in the *Hexabiblus* of Harmenopolus.

C. ADMINISTRATION

Three principles underlay the administrative reform of Diocle-

tian: the separation of civil from military functions; the formation of small provincial units; and the hierarchical structure which depended on the interposition of the vicar of a diocese and the praetorian prefect between the provincial governor and the emperor. This system lasted unchanged for three and a half centuries. The few unimportant alterations that were made were in harmony with its spirit, until the reign of Justinian, who introduced certain reforms that pointed in a new direction. He combined some of the small provinces into large units, undermining the hierarchical system by doing away with some of the dioceses and vicars, and placing in some cases military and civil authority in the same hands. These changes, some of which were soon canceled, would hardly in themselves have led to a radical change; but they prepared the way for an administrative revolution, brought about by stress of external necessities.

1. Themes.—In the 7th century all the energies of the empire, surrounded by active enemies, were centred on war and defense; everything had to give way to military exigencies, and a new system was gradually introduced which led ultimately to the disappearance of the old. The change began in Italy and Africa, at the end of the 6th century, where operations against the Lombards and the Berbers were impeded by the friction between the two co-ordinate military and civil authorities (masters of soldiers and praetorian prefects). The military governors were made supreme with the title of exarchs, and the civil authority was subordinated to them. The change is an index of the dangerous crisis through which these provinces were passing. In the east similar circumstances led to similar results. The Muslim danger threatening Asia Minor imposed a policy of the same kind. And so by the end of the 7th century the empire had been divided into eight great military provinces or themes: exarchate of Africa; exarchate of Italy; strategia of Thrace; strategia of Hellas; county of Opsikion (obsequium), including Bithynia, Honorias, Paphlagonia, parts of Hellespontus and Phrygia; strategia of the Anatoliki, most of west and central Asia Minor; strategia of the Armeniaki, eastern Asia Minor; strategia of the carabisiani (Gr. *carabos*, "vessel"), the naval theme including the southern coastland of Asia Minor, and the Aegean (see below, Defense). The lands of the old prefecture of Illyricum were not included in the system, because this part of the empire was then virtually outside Byzantine control owing to the Slav invasions. There military powers were committed to the prefect of Illyricum, whose actual sphere extended little beyond Thessalonica, which was surrounded by Slav tribes.

The changes in provincial organization in Asia Minor began under the Heraclians in the 7th century, who also extended this system to the European provinces. The system was further developed by their successors. Leo III, for instance, partitioned the dangerously large Anatolikon theme, and the western part became the Thraceseion theme; similarly he divided the Carabisian theme into the two themes of the Cibyrreots and the Aegean islands. This reorganization was greatly extended during the 9th and 10th centuries. As the frontiers expanded the conquered lands were incorporated into the empire, sometimes initially as military frontier zones (clisurarchies), later to become themes or duchies. In the early 10th century there were in Asia Minor Anatolikon, Armeniakon, Thraceseion, Opsikion, Bucellarion, Capadocia, Charsianon, Colonea, Paphlagonia, Chaldia and Optimaton; in Europe Thrace, Macedonia (both ranking with the Asian themes), Peloponnese, Nicopolis, Hellas, Sicily, Strymon, Cephalonia, Thessalonica, Dyrrachium, Dalmatia, Cherson and Longobardia; and the maritime themes of the Cibyrreots, the Aegean sea and Samos. The themes of Mesopotamia, Lycandus, Sebastea, Seleucia, Leontocomis and Cyprus (made into a theme by Basil I but then lost to the Arabs until its reconquest in 965), are mentioned in either the *De thematibus* of Constantine VII or in the 10th-century *Tacticon*. Further themes had been added by the mid-11th century, and even after the empire contracted the number of themes grew owing to a policy of subdivision.

The name theme (Gr. *thema*, "corps") denotes the military origin of these provinces. Their governors combined military and civil powers and they generally had the title of strategos,

though there were exceptions, such as the Opsikion, governed by a *comes*, or the Optimaton, by a *domesticus*. The old hierarchical system had disappeared, including the vicars and the praetorian prefect of the east (some of whose functions were merged in the prefect of the city) and no authority interposed between the emperor and the strategoi. But as the armies of the themes declined in importance from the late 10th century on, while the army of the tagmata came to the fore, so the chief civil official (the *krites* or praetor of the theme) emancipated himself from military control and became directly responsible to the central government at Constantinople. The central government did in fact exercise considerable control over provincial administration, particularly in financial matters, and it was always possible for provincials to appeal to the central courts for legal redress.

2. Central Administration.—In the central administration the heads of the great administrative departments retained the palatine character which belonged to most of them from the beginning. But over a millennium there were many changes in these offices, in their nomenclature and in the delineation of their functions. The following tendencies may be noted: an increase in the number of ministers directly responsible to the emperor, caused by subordinate offices in the administrative departments being raised to the rank of independent ministries and the creation of new offices, the old ones becoming merely titular; changes in nomenclature; substitution of Greek for Latin titles; changes in the relative importance and rank of the high officials, both civil and military.

The prefect (eparch) of the city controlled the police organization and administration of justice in the capital; he was president of the imperial court of justice in the emperor's absence, and, when the office of prefect of the east was abolished, he inherited the functions of that dignitary as judge of appeals from the provinces. But the *praefectus vigilum*, commander of the city guards, who was subordinate to him, became an independent officer, entitled the drungary of the natch, and in the late 11th century superseded him as vicepresident of the imperial court. The eparchy of Constantinople, originally one of the most important of civil offices, described by Michael Psellus in the 11th century as the equal of the emperor except for the purple, gradually declined in power, its functions passing to others, so that by the time of the Palaeologi the name only survived as a court title.

Instead of the quaestor of the sacred palace, whose duty was to draft the imperial laws and rescripts, there was in the 9th century a quaestor who possessed certain judicial and police functions and was far lower in the hierarchy of rank. It has been supposed that the later quaestor really inherited the duties of another officer, the quaesitor, who was instituted by Justinian. The office of quaestor survived until the Latin conquest, but by the later middle ages had become only a title of rank.

The master of offices (*magister officiorum*), who supervised the departments in the palace and was master of court ceremonies, also performed many functions of a minister of foreign affairs, was head of the imperial post (*cursus*) and of the corps of imperial couriers (*agentes in rebus*). This ministry disappeared, probably in the 8th century, but the title was retained as a dignity at least until the end of the 9th. The most important functions, pertaining to foreign affairs, were henceforward performed by the logothete of the drome. In the 12th century this minister was virtually the chancellor of the empire, but after the Latin conquest his office seems to have disappeared and to be simply a title of rank. Under Andronicus II the title of the first minister was that of the grand logothete.

The two chief financial ministers of the early Byzantine period were the *comes sacrarum largitionum* and the *comes rerum privatarum*, though the *annona*, the provincial tax, was controlled by the praetorian prefect who had indeed also tended to appropriate from the *rec privatae* and *largitiones*. When the praetorian prefecture lost its importance, different financial arrangements were made. From the 7th century onward there were new and independent financial departments controlled by logothetes. Other financial officials were named secretici or *chartularii*, and the chief financial officer was the sacellarius, sometimes called the grand

sacellarius. The head of the imperial chancery was the *protoasecretic*, an office usually filled by a legal official.

The employment of eunuchs as high ministers of state was a feature of the Byzantine empire from the end of the 4th century. It was laid down as a principle (A.D. 900) that all offices were open to them, except the prefecture of the city, the quaestorship and the military posts which were held by "domestics." There were also at that time eight high posts which could only be held by eunuchs, of which the chief were the *parakoimomenos* (grand chamberlain) and *protovestarios* (master of the wardrobe).

The orders of rank (which must be distinguished from titles of office) were considerably increased in later times. In the 4th and 7th centuries there were the three great classes of the illustres, spectabiles and *clarissimi*, and above the illustres a small, higher class of patricians. In the 9th century a different system is found, the number of classes being largely augmented, and the nomenclature different. Instead of epithets, such as illustres, the names were titles which had designated offices; "patrician" alone survived. The highest rank was now the *magistri*; then the patricians in two classes, proconsular patricians and respectable patricians; below these were *protospatharii*, *dishypati* (i.e., *bis consules*), *spatharocandidati*, *spatharii* and other lower ranks. Whoever was promoted to one of these ranks received its insignia from the emperor's hand, and had to pay fixed fees to various court officials.

3. Justice.— In the provinces ordinary justice was administered by judges who were distinct from the governors of the themes and inherited their functions from the old provincial governors of Diocletian's system. In Constantinople higher and lower courts of justice sat regularly and frequently. The higher tribunals were those of the city prefect and the quaestor, before whom different kinds of cases came. Appeals reached the emperor through the bureau of petitions; he might deal with the case immediately, or might refer it to the imperial court of the "divine judges," which was instituted by Justinian. In the 12th century there were four imperial courts of justice in Constantinople, and in 1166 rulings on appeal were laid down by Manuel I. After the Byzantine reconquest of Constantinople Michael VIII set up a single imperial court, and further changes introduced by Andronicus II in 1296 and Andronicus III in 1329 show the growing power of the church. Two of Andronicus III's four "chief justices of the Romans" were clerics. There were also the ecclesiastical courts to which certain cases involving the laity were reserved, such as marriage, or cases in which the defendant was a cleric. This close association of church and state continued to the end, and indeed the distinction between ecclesiastical and civil jurisdiction grew increasingly blurred.

4. Finance.— The Byzantine fiscal system, like the administration of justice, was inherited from the late Roman empire. One main source of revenue was the land. The direct taxes levied on this were the land tax proper and the *annona*, a tax on the products. The land tax (*capitatio terrena*) was based not on the yearly produce but on the capital of the proprietor, the character and value of the land being taken into account. In later times this seems to have become the *capnicon* or hearth tax, a capitation tax first mentioned in measures of Nicephorus I. In Diocletian's time the *annona* consisted of a combined poll tax and land tax, the *capitio-iugatio*. An important element in the Byzantine fiscal system was the *epibole*, whereby land which fell out of cultivation was compulsorily assigned to other landowners in the district who were obliged to pay the tax due from it as an additional charge. This responsibility was transferred to the rural community by the late 7th or early 8th century, as is evident from the "Farmer's law," though it was later reimposed on the powerful landowners by Basil II in the form of the *allelengyon*, but soon repealed by Romanus III. Whether this form of taxation, the *epibole*, or extra tax, did survive into the later period is a matter of controversy. The city population was also subject to direct taxes, such as the burdensome *auri lustralis* collatio, which was abolished by Anastasius I, who also made officials of the prefecture responsible for collecting city taxes in place of the inefficient *curiales*. Customs and excise duties were an important source of revenue throughout the middle ages and bore heavily on city populations.

In the countryside there were a number of additional burdens in the shape of labour services for public works, or the provision of military transport and billets, as well as the additional financial contributions exacted by the tax collectors or district officials.

With the development of the Byzantine civil service, fiscal administration was supervised by departments under the various logothetes, and the local taxes were collected by praetores, and sometimes farmed out, specially from the 11th century onward. Byzantine state expenditure was on a large scale and its diplomacy, defense and internal administration were only made possible by a highly complex monetary system.

5. Landed Property.— The history of landed property and agrarian conditions in the eastern empire is a somewhat controversial subject. Individual hereditary proprietorship was normally the rule, whether of the large estate with its cultivators attached to the soil, or the small freeholder depicted in the "Farmer's law." Conditional grants sometimes were made, such as the small farms given in return for hereditary military service (*stratiotica ktemata*) which may have been part of the reorganization undertaken by the Heraclian and subsequent dynasties. They were evidently a well-established source of recruitment in the middle Byzantine period and they featured prominently in the 10th-century legislation which attempted to prevent their being bought up by the powerful landowning magnates. Such measures failed, and from the 11th century on military holdings, if they can be so called, were of a different nature. From Alexius I's day grants were made in *pronoia*, sometimes in return for military service from the recipient, the *pronoiar* or "soldier," as he was often called. Originally a grant for life only, this had become hereditary by Michael VIII's reign. When lands were granted, or confirmed, to monasteries or laymen, the number of tenants (*paroikoi*) permitted on the estate was carefully stated because of the fiscal obligations of such tenants. An estate, whether imperial or private, would have not only its permitted number of *paroikoi* but also slaves and hired labourers; but existing evidence points to a surveillance over the *paroikoi* which grew stricter, particularly as both the labour problem and financial difficulties increased in the later middle ages.

D. DEFENSE

The general principle of the military defense of the empire in the 4th century consisted in large forces stationary on the frontiers, and reserve forces, stationed in the interior provinces, which could be moved to any point that was in danger. Thus the army was composed of the *limitanei*, frontier troops (under *duces*), and reserve forces (under *magistri militum*) of two denominations, *palatini* and *comitatenses*. In the 6th century the fundamental principles of the system were the same; but the cavalry had become a much more important branch of the service, and in the wars of Belisarius the *foederati*, barbarian mercenaries of various races, commanded by their own chiefs, played a great role. The peasants of Illyria and Thrace and the mountaineers of Armenia and Isauria in Asia Minor still supplied an important part of the army, but the number of barbarians (Vandals, Goths, Slavs, Arabs, etc.) was much larger. Solidity and a corresponding lack of mobility characterized at this time both cavalry and infantry; their great merit was straight and rapid shooting: Belisarius ascribed his success in Italy to the excellence of the archery.

Justinian carried out on the frontiers and in the exposed provinces a carefully devised and expensive system of defensive works. Fortified towns along the *limes* were connected by intervening forts, and at some distance behind was a second line of more important fortresses more strongly garrisoned which furnished both a second barrier and places of refuge for the inhabitants of the open country. There was an elaborate system of signals by which the garrisons of the frontier stations could announce not only the imminence of a hostile invasion but also the number and character of the enemy. In north Africa there are abundant remains of the forts of the 6th and 7th centuries, displaying the military architecture of the period and the general frontier system.

1. Army.— The disasters and losses of the 7th century led to a radical change in the military organization, and the division of

the empire into themes (see *Administration: Themes* above). The preponderant influence which Asia Minor won and retained until the 11th century is reflected in the military establishment, which at any rate until the mid-10th century mainly depended on the Asian provinces. The *strategos* of a large theme commanded a corps of 10,000, and the scheme of the divisions and subordinate commands has a remarkable resemblance to the organization of some of the armies of modern Europe.

The recorded scheme was probably not uniform in all the themes, and varied at different periods. The *thema* (corps) consisted of two *turmaï* (brigades) under *turmarchai*; the *turma* of five *banda* (regiments), each under a *drungarios* (colonel); the *bandon* of five *pentarchiai* (companies) under a *cometes* (captain). The *pentarchia*, containing 200 men, had five subdivisions under *pentecontarchai*; and there was a smaller unit of 10 men under the *decarches* (corporal).

Distinct from the military forces (*themata*) of the provinces were the forces (*tagmata*) stationed in or near the capital. The most important of these were the *scholae* and the *excubitores*. The scholarian troops were in early times under the master of offices, but subsequently their chief officer, the domestic of the schools, became the highest military commander in the empire. In war, when the emperor did not assume the chief command himself, he might entrust it to any commander, and he often entrusted it to the domestic. In the 11th century, after the conquest of Bulgaria, there were two domestics, one for the east and one for the west, and under Alexius I Comnenus the domestic of the west received the title "grand domestic." Under the Palaeologi the grand domestic was superior in rank to all other ministers.

Besides the scholarians and the *excubitores* (who had been organized in the 5th century), there were the regiments of the *hicanatoi*, the *arithmos* and the *numeroi*. The *numeroi* were foot soldiers. The *optimatoi*, also infantry, properly belonged to the same category, though they were constituted as a theme. The demes or corporations of Constantinople were partly organized as militia and were available for purposes of defense.

The great difference between this Byzantine army and that of the earlier empire is that its strength (like that of the feudal armies of the west) lay entirely in cavalry, which the successors of Heraclius and the north Syrian emperors developed to great perfection. The few contingents of foot were subsidiary. The army was maintained in Asia Minor, which was the great recruiting ground, by a system of military holdings of land (an extension of the old Roman system of assigning lands in the frontier districts to federate barbarians and to veterans). The conditions of the marauding expeditions and guerrilla warfare, continuously carried on against and by the Arabs in the 8th, 9th and 10th centuries, were carefully studied by generals and tacticians, and the theory of the Byzantine methods is set out in various military treatises including the *Tactica* of Leo VI based on the so-called *Strategicon* of Maurice.

The loss of a great part of Asia Minor to the Seljuks and the disorganization of the provinces which they did not acquire seriously weakened the army, and the emperors had recourse more and more to foreign mercenaries and barbarian auxiliaries. The employment of Russians had begun in the 10th century, and in 988 the Varangian (Russian) guard was formed. Under Michael IV the Norwegian prince Harald III Hardraade fought for the empire in Sicily and in Bulgaria. During the 11th century foreign mercenaries, including Turks, Normans and English, greatly increased in numbers and importance.

The keynote of the Byzantine army was efficiency, and nowhere is the immeasurable superiority of the civilization of the eastern empire to the contemporary states of Europe more apparent. The theory of military science was always studied and taught: constant practice, interpreting and correcting theories safeguarded it against pedantry; and a class of magnificent staff officers were trained who in the 10th century were the terror of the army. The particular tactics of the various foes whom they had to face were critically studied. There are extant various military textbooks, from the time of Anastasius I to that of Basil II, which set out their principles and methods. In this army there

was plenty of courage and distinct professional pride, but no love of fighting for fighting's sake, nor the spirit that in western Europe developed into chivalry. The Byzantines despised such ideas as characteristic of barbarians who had physical strength and no brains. The object of a good general, as Leo VI shows in his *Tactica*, was not to win a great battle but to attain success without the risks and losses of a great battle. The same author criticizes the military character of the Franks; paying a tribute to their fearlessness, he points out their want of discipline, the haphazard nature of their array and order of battle, their eagerness to attack before the word was given, their want of faculty for strategy or tactical combinations, their incapacity for operations on difficult ground, the ease with which they could be deceived by simple artifices, their carelessness in pitching camps and their lack of a proper intelligence department. These criticisms illustrate the contrast between a western host, with its three great "battles," rushing headlong at the foe, and the Byzantine army, with its large number of small units, co-operating in perfect harmony, under a commander who had been trained in military science, had a definite plan in his head, and could rely on all his subordinates for strict and intelligent obedience.

2. Navy.—Under the early empire, as Rome had no rival in the Mediterranean, it was natural that the navy and naval theory should be neglected. When Constantine the Great decided to besiege Byzantium by sea, both he and his opponent Licinius had to create fleets for the struggle. Even when the Vandals in Africa made transmarine conquests and became a naval power, the Romans did not seriously concern themselves with building an efficient navy. The Vandals harried their coasts; their expeditions against Africa failed. And even when the Vandal power was in its decline and Belisarius set forth on his successful expedition of conquest, his fears for the safety of his squadron in case he should be attacked at sea suggest that the Vandal fleet was superior to his. The conquest of Africa secured for Justinian I the undisputed command of the Mediterranean, but he did nothing for the naval establishment. It was not until the Arabs, aspiring to conquer all the Mediterranean coastlands, became a naval power that the empire was forced to organize an efficient fleet. This was begun by the Heraclians. The naval forces, designated as the *carabisiani*, were placed under the command of an admiral, with title of *strategos*. They consisted of two geographical divisions, each under a *drungarios*: the province of the Cibyræeots (probably named from the smaller Cibyra in Pamphylia) which included the southern coast districts of Asia Minor, and the Aegean province, which consisted of the islands and part of the west coast of Asia Minor. It was a new principle to impose the burden of naval defense on the coast and island districts. Distinct from these fleets, and probably organized on a different principle, was the naval contingent stationed at Constantinople. Leo III changed the naval administration, abolishing the supreme command, and making the Cibyræeot and Aegean provinces separate independent themes under a *strategos* and a *drungarios* respectively. The charge was due to two motives. There was a danger lest a commander of the whole navy should become overpowerful (indicated by the political role played by the navy before Leo's accession).

In this and the following reigns, the tendency was to neglect the fleet; the interest of the government was concentrated on the army. For a time this policy was prosecuted with impunity, since the Omayyad dynasty was growing weak, and then under the Abbasids, who transferred the capital from Damascus to Baghdad, the seapower of the caliphate declined. But the neglect of the fleet was avenged in the 9th century, when Crete and Sicily were wrested from the empire, the loss of south Italy was imminent, and Muslim squadrons sailed in the Adriatic—losses and dangers which led to a reorganization of the navy under Michael III and Basil I. After this reform the navy consisted of two main contingents: the imperial fleet stationed at Constantinople, and the provincial fleets, three in number, of the Cibyræeot theme, the Aegean theme and the theme of Samos. Naval service was also exacted from the European coastal themes, as the Peloponnese and Cephalonia. When the fleets acted together, the *drungarios*

of the imperial fleet usually took supreme command. The warships (Gr. *dromones*) were mainly biremes, but there were also ships with single banks of oars built for speed called galleys (Gr. *galaiai*). Pyrotechnic was an important department in the naval establishment; the manufacture of the terrible explosive known as liquid or sea fire (see GREEK FIRE) was carefully guarded as a state secret. The navy, active and efficient in the 10th century, is described by Cecaumenus, a military and perhaps therefore unprejudiced officer of the 11th century, as the glory of the empire. By the late 11th century Byzantine naval resources had however declined. Alexius I united the imperial and provincial fleets under the command of a grand admiral (*mezas dux*), but neither his efforts nor those of his successors could create a force capable of holding its own with the Italian maritime cities. On the contrary it was only with Venetian naval help that Byzantium repulsed Norman attacks and for this Venice exacted extensive commercial privileges which injured Byzantine trade and excited the jealousy of other Italian cities, particularly Genoa. In the Palaeologan period, though emperors, such as Michael VIII, appreciated the importance of naval power, they lacked resources with which to implement such a program and were virtually pawns in the hands of the maritime rivals Venice and Genoa.

E. DIPLOMACY

In foreign policy diplomacy was a weapon as important in the eyes of the Byzantine government as soldiers or fortifications. Peace on the frontiers was maintained not only by strong military defenses, but by skilful management of frontier peoples. In the Byzantine empire this kind of diplomacy was practised as a fine art and had certain underlying principles. One people was kept in check by means of another, and the imperial government fomented rivalry and hatred among them. Thus Justinian I kept the Gepidae in check by the Lombards, the Kutriguri by the Utiguri, and the Huns by the Avars. Subsidies were given to the peoples on the frontiers, in return for which they undertook to defend the frontier adjacent to them and to supply fighting men when called upon to do so. The chiefs received honours and decorations. Thus the Berber chiefs on the African border received a staff of silver encrusted with gold, white cloak, embroidered tunic, etc. More important potentates were invested with a costlier dress. In these investitures precedence was carefully observed. The chiefs thus received a definite position in the empire, and in some cases they were admitted to posts in the official hierarchy, such as that of patrician or master of the soldiers. They were extremely fond of such honours and considered themselves half-Roman.

Another mode of winning influence was to marry barbarian princes to Byzantine wives and to bring up their sons in the more civilized environment of the capital. Dissatisfied pretenders and defeated candidates for kingship were welcomed at Constantinople. Thus there were generally some princes, thoroughly under Byzantine influence, who at a favourable opportunity could be imposed on their compatriots. Methods of this kind had long been employed by the Roman government. Then with the imperial adoption of Christianity and the close connection between church and state, the mission field offered endless opportunities for the extension of Byzantine influence. Newly converted countries were brought into touch with the civilization and court of the empire, and this was maintained both by personal contacts in princely circles and through the ecclesiastical hierarchy, particularly the bishop, who would normally be appointed by the patriarch of Constantinople. Diplomacy of this kind was fostered not only by the central government but by local officials, who thus exercised considerable influence over neighbouring peoples or states (e.g., the catepan of Italy or the strategos of Kherson).

One particularly important state in the early middle ages was that of the Khazars, between the Caucasus and the Don, with which the empire had long maintained relations. Heraclius, to win its co-operation against Persia, promised his daughter in marriage to the khan, and later two Khazar princesses became Byzantine empresses, the wives of Justinian II and Constantine V. Their state steered skilfully between the contending influences of Islam

and Christianity, and their rulers avoided suspicion of partiality for either creed by embracing the religion of the Jews (c. 800). Commercial and political relations with the Khazars were maintained through the important outpost of the empire at Kherson in the Crimea, which had been allowed to retain its republican constitution under a president and a municipal board, though this freedom was limited by the appointment of a strategos in 833, a moment when the Khazars were seriously threatened by the Pechenegs (Patzinaks). The danger to be feared from the Khazars was an attack upon Kherson, and it seems probable that this was a leading consideration with Leo III when he married his son Constantine V to a Khazar princess. In the 9th century it was an object of the government to maintain the Khazars (whose army consisted mainly of mercenaries) against the Pechenegs; and hence, if it should become necessary to hold the Khazars in check, the principle was to incite against them not the Pechenegs but other less powerful neighbours, the Alans of the Caucasus and the people of "Black Bulgaria" on the middle Volga (a state which survived until the Mongol conquest).

In the 10th century it can be observed how the government conducted its foreign policy on carefully thought-out principles. The empire was then exposed to constant danger from Bulgaria, as well as to attacks from the Russians. The key to the diplomatic system, designed to meet these dangers, was the cultivation of friendly relations with the Pechenegs, who at that period did not menace the provinces by land or by sea and could be incited to act against Russians or Bulgarians. The system is explained by the emperor Constantine VII Porphyrogenitus in his *De administrando imperio*.

The policy had its dangers, and was severely criticized by one of Justinian's contemporaries, the historian Procopius. Concessions encouraged greater demands; the riches of the empire were revealed. It was a system which could not be permanently successful without military power behind it, and was not infallible, but in principle it was well-founded and proved of immeasurable value, particularly during the periods when the empire enjoyed great prestige.

For this systematic diplomacy it was necessary to collect information about the peoples whom it concerned. Ambassadors reported everything of interest they could discover, and sometimes information was provided by missionaries. Priscus left a famous graphic account of the embassy which he accompanied to the court of Attila, and there exists an account of an embassy sent to the Turks in central Asia in the second half of the 6th century, derived from an official report. Peter the Patrician, in Justinian I's reign, drew up careful reports of his embassies to the Persian court. When foreign envoys came to Constantinople, information was elicited from them as to the history and domestic politics of their own countries. Some of the accounts of the history and customs of neighbouring peoples in the *De administrando imperio*, furnishing numerous facts not to be found anywhere else, were derived from ambassadors who visited Constantinople. Diplomatic relations with the west were also important, and frequent embassies went to the rulers who established themselves in what had once been the western half of the Roman empire as well as to the Persian and then the Islamic courts. With the crusades and the influx of Latins and Turks into east Mediterranean politics the Byzantine foreign office and Byzantine gold had full scope for the diplomacy which had been exercised to such good effect in the early middle ages. Byzantine diplomacy, like the civil administration and military organization, showed considerable flexibility and proved capable of being adapted to the changing needs of more than ten centuries.

III. THE CHURCH

1. Position of the Emperor.—When Constantine the Great recognized Christianity and indeed accepted it as his own religion he inaugurated a new era in the history of the Roman empire. At first tolerated, then by the end of the 4th century the only permitted religion (though the proscribed paganism lingered on), the Christian church henceforth took its place in public as well as private life. Its rapid integration with the polity and the importance

accorded it were symbolized by the special position of the Christian emperor. He was regarded as the vicegerent of God on earth, and as such he had the special duty of protecting the church and of furthering its aims. He had the right of summoning general church councils and of presiding over them; his was the deciding voice in the appointment of the patriarch; he could inaugurate changes in the organization of sees or in episcopal status; and, particularly in the earlier middle ages, he tried to impose his will in doctrinal matters. It is especially this last which has given rise to the charge of caesaropapism. But in fact this is hardly justified. Even Justinian I himself clearly laid down that "the two gifts of God," the *sacerdotium* and the *imperium*, were two quite distinct spheres. The emperor, permitted as he was to enter the sanctuary and to communicate as priests and deacons did, never performed the priestly functions. When he tried, often for political ends, to impose his views in matters of faith against the will of the church, he was never permanently successful. Normally the emperor was the protector of the church and the guardian of orthodoxy, and the relation between church and state was one of close interdependence.

2. Ecclesiastical Divisions.— In the 4th century there were some Christian communities outside the Roman empire, but the greater part of Christendom lay within imperial bounds and ecclesiastical organization and ecclesiastical conferences were modeled on imperial administration and procedure. Dioceses were under bishops, provinces under metropolitans. Over them were the regional archmetropolitans, or patriarchs as they were called by the 6th century. These were originally the bishops of the three cities specially venerated for their Christian associations, Rome, Alexandria and Antioch, although also great metropolitan centres in the secular sense. During the 4th century Constantinople, as New Rome and the imperial capital of the eastern half, rose to prominence, and although not without bitter opposition, was accorded second place after Rome (381). This was confirmed in the so-called 28th canon of the ecumenical Council of Chalcedon (451). In the 5th century, the bishop of Jerusalem's claim to the title of patriarch was also recognized. After the Arab conquest of Egypt, Palestine and Syria, the patriarchs of Alexandria, Jerusalem and Antioch naturally played a less important role in Christian affairs and the lead was taken by Rome and Constantinople.

Political circumstances also led to different developments in the eastern and western halves of the Roman empire, and this was reflected in ecclesiastical relations between the two patriarchates. Leo III's transference of south Italy and Sicily, the western Balkans and Greece from Roman jurisdiction to the patriarchate of Constantinople, and rivalry in the missionary field, particularly among the Slavs, as well as differences of discipline, ritual and doctrinal emphasis, all helped to foster a situation which from the 11th century onward was acerbated by Latin political and economic ambitions.

The year 1054, when the patriarch Michael Cerularius and his followers were excommunicated by the papal legate Cardinal Hurbert, is often taken as marking the beginning of the existing schism between Rome and Constantinople. It was in fact not an excommunication of the Orthodox church as such, and the door was left open for reconciliation. But the Greeks were bitterly antagonized by such events as the Latin capture of Constantinople in 1204. Henceforth people and church stood together, and imperial pleas for reunion, such as were attempted at the Council of Lyons (1274) or the Council of Ferrara-Florence (1439), were scorned by the Byzantines. As their political power dwindled, so their national feeling grew, and one of the most fervent manifestations of this was their refusal to accept any reunion with Rome.

3. Doctrinal Issues.— A general council was by long custom the acknowledged method of dealing with ecclesiastical problems of doctrine and discipline. The first was called by Constantine the Great at Nicaea (325), and this set the pattern and demonstrated the strength of the links between church and state. The emperor summoned the general council and either he or his representative took the chair. Procedure was modeled on that of the senate, and

the emperor could intervene in debates if he wished. As the senior patriarch, the pope (or his legates) had the right of voting first. The decisions or canons of the council were confirmed by the emperor. It was in the general councils of the 4th to the 7th centuries that trinitarian and christological doctrine was defined (*see* COUNCIL). In the 8th and 9th centuries the doctrinal problem was primarily the iconoclast heresy settled at the second Council of Nicaea (787) and at a council held in Constantinople in 843.

After the rift with Rome in the 11th century, the Byzantine church still had its theological problems which were usually dealt with by the patriarch of Constantinople's standing synod, reinforced by metropolitans and autocephalous archbishops, including the eastern patriarchs. There were occasional cases of heretical error arising among educated scholars and churchmen, but the only instance of widespread heresy was Bogomilism, a form of the dualism which troubled Latin as well as eastern Christendom. The Bogomils (*q.v.*), who grew to strength in the Slav Balkans, spread into the Byzantine empire in the 11th and 12th centuries, and the heresy was never completely eradicated, especially in Bosnia. Byzantine theological discussions of the later middle ages (apart from the question of reunion) tended to centre in hesychasm, which had a long ancestry in Christian Greek spirituality (*see* HESYCHASM). This problem was debated in councils in the mid-14th century, and though it was in essence a matter for the church it had widespread political repercussions because of the secular affiliations of its supporters and opponents in an age of civil war. It also brought out the differing theological emphasis of the Greek and Latin churches. Generally speaking, the Byzantine people were bitterly antagonistic to the Latin church and to Latin thought, as their attitude to reunion shows, but there were notable exceptions. Some Greek scholars and churchmen availed themselves of the opportunity to read western writers, such as Thomas Aquinas, some of whose works were translated into Greek, and though most preferred Turkish domination to reunion a small minority traveled westward and entered the Roman church. Under Ottoman domination after 1453, the Byzantine church long remained the one bulwark of the Christian population.

4. Patriarch.— The head of the Byzantine church was the patriarch of Constantinople, who through force of circumstances was the dominating figure of eastern orthodoxy. He also exercised authority over the churches of the Slavs in the Balkans and in Russia. As head of the Byzantine church he had the right of crowning the emperor; as chief ecclesiastic he was widely influential. He could excommunicate the emperor, as happened when Leo VI was excommunicated because of his fourth marriage) or refuse coronation, as when John I Tzimisces was forced to agree to patriarchal conditions before he was crowned. During a minority the patriarch might act as one of the regents, as Nicholas Mysticus did in the early years of Constantine VII's reign. But normally his role in purely political matters was a subordinate one, though emperors obviously preferred a patriarch who would be likely to support their policy and took steps to ensure this. The patriarch was chosen by the emperor from three names submitted to him by the synod, and he could if he wished put forward a different name; if a patriarch once appointed proved intractable or unacceptable there were ways of contriving his resignation.

The patriarch was responsible for maintaining orthodoxy and discipline, and in both respects he normally had an ally in the emperor, who shared in conciliar activity and could supply the backing sometimes necessary to implement the canons. The emperors, particularly before the 10th century, issued their own edicts on points of doctrine, as for instance the *Ecthesis* of Heraclius on monotheletism (*see* MONOTHELITES), but such imperial intervention in matters of faith did not permanently alter orthodoxy as interpreted by the tradition of the church. Ecclesiastical administration was also the subject of innumerable imperial rulings, particularly insofar as concerned property, for the church was one of the most important landowners in the empire.

5. Other Clergy.— Subordinate to the patriarch was the hierarchy of metropolitans and bishops presiding over provinces and

dioceses. Autocephalous bishops were not subject to metropolitans and had no bishops under them. Metropolitans were at first chosen by the patriarch from three names put forward by the provincial bishops, then from the 10th century on by the standing synod of Constantinople. Bishops were chosen by the metropolitans from three names put forward by the provincial synod. The metropolitan presided over the provincial synod, which legislated on matters concerning the whole province and acted as a court of appeal against episcopal sentences. Bishops-elect, if married, had to separate from their wives and normally assumed the monastic habit; they were in fact usually chosen from the monastic ranks. They were responsible in their dioceses for pastoral work and administration of church property as well as for the clergy and monks. In legal matters certain cases were reserved to their courts, and they could act whenever a cleric was involved. Bishops were assisted by their diocesan clergy and had their own *curias*. Cathedral churches were served by special dignitaries; Hagia Sophia in Constantinople originally had five, then nine, great patriarchal officials. The clergy, except for bishops, could retain their wives if they had married before being ordained sub-deacon. Second marriage was disapproved of and precluded the possibility of ordination.

Pastoral work originally centred in the cathedral church in the town, but as Christianity spread other churches were founded in towns and in the countryside. Some (catholikai ecclesiai) were parish churches directly under the bishop who nominated their clergy; others (eukterioi oikoi) were chapels on private estates or even built by villagers. The founders of such chapels appointed the priest but had to get the bishop's consent for this as well as for the performance of certain sacraments. There were also the chapels in the many monasteries which did in fact also minister to the faithful laity, though this was not their primary function.

6. Finance. — The revenues of the church were derived largely from the gifts of the faithful which from the time of Justinian I were regarded as the property of the particular institution or church. They were administered by the priests responsible for the services under the foundation deed or by a steward (*oiconomus*) appointed by the bishop. Landed property often was granted out on lease in return for a yearly payment. It was regarded as inalienable, although imperial practice, particularly in the later middle ages, made inroads into ecclesiastical property. A canonicon or ecclesiastical tax from the laity and priests of both parish "catholic" churches and private chapels was assigned to the bishop and from the 11th century was made compulsory. Monasteries also paid this canonicon. Bishops normally would be responsible for the stipends of their cathedral clergy. The parish churches were provided for by the bishops and in the later middle ages from property reserved for this purpose. Founders of private chapels made their own arrangements for the maintenance of their own clergy. Many priests also worked their land and lived as *paroikoi* on estates. Priests also received the voluntary offerings of their parishioners, given for instance when some sacrament was performed.

7. Monasticism. — Side by side with the secular clergy were the monks, cenobitic and eremitic, and theirs was one of the greatest single influences in Byzantium, for it was in the contemplative life that Byzantines considered the perfect Christian life to be most nearly realized (see MONASTICISM).

8. Laity. — Within this ecclesiastical framework Byzantine men and women, lay and monastic, were instructed in the Scriptures and the traditions of the church, whether by the sermon of bishop or abbot (of which splendid examples have survived) or by the simple teaching of the parish priest. Above all they drew their strength from the sacraments, in which everyone shared alike and which were performed in a liturgical setting as impressive in the simplicity of the small country chapel as in the majestic ceremonial of Hagia Sophia in Constantinople.

IV. BYZANTINE SOCIETY

Byzantium was both a cosmopolitan and an aristocratic society. Its many different races found some kind of unity within the

framework of a Christian empire in the main deriving its administrative and cultural traditions from the Greco-Roman world, though not uninfluenced by oriental civilizations. The geographical situation of its capital, Constantinople, enabled it to command routes by land and sea between Asia Minor, the Balkans and western Europe, or leading to Russia, central Asia and beyond. It was the metropolis of Mediterranean economy certainly up to the end of the 12th century, and its gold coin, the nomisma, was the medium of international exchange until it was supplanted by the Italian cities, notably Venice and Genoa in the period after 1204. Constantinople drew considerable revenue from customs dues and from its own export trade, particularly of its highly prized materials and its works of art, such as ivories. Both industry and trade were under strict state control. In the countryside there were always large estates owned by important families (as the Ducas or the Phocas) and worked by serfs and slaves and other agricultural labourers, as well as tenant farmers. There were also villages recognized as taxable units, with a free peasantry working their own small farms, but this was a precarious life, subject to the depredations of the tax collector and the ravages of nature, and often had to be abandoned for the position of tenant on a large estate with obligations to a landlord in return for his protection. Conditions changed over the long history of Byzantium, but the landed magnate was always a powerful factor in provincial economic life as in the government of the state.

In the capital the civil service formed an essential element of the polity, though the interests of its higher members often clashed with those of the nobility. In this trained bureaucracy a young man without birth or family backing could rise to the influential upper ranks as an administrator or a court official. Byzantine society, certainly the middle and upper reaches, was well educated and aware of its continuity with its Greek past. The wealthier families had tutors for their children and there were some schools in the provinces. Teachers were available in the big cities, and Constantinople, to which the ambitious naturally gravitated, had its own university, founded as early as 425, providing higher instruction in a secular curriculum in which law and philosophy took pride of place. The church also had its schools, but the state had no need to depend on these for the provision of educated civil servants. Intellectual activity was equally assiduously promoted in imperial circles, and in the rare exceptions when this was not so (as in the case of Basil II) the fact was noted with disapproval. This interest grew rather than diminished as Byzantine political fortunes waned; the exiled Nicaean emperors were at pains to build up their libraries in Asia Minor, and, amid the stresses of civil wars and foreign dangers in the 14th century, protagonists such as John VI and Nicephoras Gregoras supported their respective points of view in lively and lengthy literary works.

Byzantium left an extensive and varied literature. Most of it is in a language somewhat artificially modeled on Attic Greek; much, especially letters and speeches, is in a highly rhetorical style. In some literary fields the Byzantines excelled. Their contemporary histories and memoirs, their writings on Christian spirituality, their lives, whether of saints or of secular figures, are often outstanding. Secular poetry was usually written in classical metre; the Byzantines did not excel in this field, though there are exceptions, such as the short poems in the Greek Anthology. Some of the finest Byzantine poetry was either liturgical or concerned with Christian spirituality and this was not in classical metre. (See GREEK LITERATURE: Byzantine Literature.) Inseparably allied to liturgical poetry was church music, where Byzantine achievements, only deciphered in the 20th century, can hold their own with comparable medieval western masterpieces (see BYZANTINE MUSIC).

Throughout the middle ages Byzantium influenced and conferred benefits upon its neighbours in varying degrees, and in certain respects that influence and indebtedness still continue. For much of the middle ages Greek was not understood in Latin Europe, but Latin translations of a number of Greek works were made, whether of ancient Greek or of Hellenistic authors, or of later Christian writers such as the desert fathers or Pseudo-

Dionysius. From the 12th century onward this work of translation was greatly accelerated, spreading via Hungary, Italy and Sicily, Spain and the Arabs; more westerners themselves gradually learned to read the Greek originals which by the early modern period were being eagerly studied in western Europe. An obvious debt was owed in respect of the masterpieces of ancient Greece, where texts could hardly have been continually copied and read without the interest of an educated Byzantine public. Another source of influence was art and architecture, both through the smaller objects such as ivory reliquaries, fine textiles and illustrated manuscripts which traveled as gifts to princely courts and as merchandise, and through the craftsmen trained in Byzantine ateliers who went to work in south Italy or Sicily or the Balkans (see *BYZANTINE ART*; *BYZANTINE ARCHITECTURE*).

The Byzantine state itself with its imperial and administrative traditions impressed contemporaries, not only the travelers from all parts who were continually passing through the capital, but particularly those Slavs who in the course of the middle ages learned how to build up their kingdoms in the Balkans and further afield in Russia. They profited by contact with the living imperial regime, from translations of its legal codes (also widely influential in Latin European countries), from marriage alliances which brought Greeks into their family and court circles, and above all from the church. Greek missionaries and then Greek ecclesiastics spread the Byzantine conception of a Christian polity with its close relationship between church and state.

The Byzantine empire in the middle ages performed a further duty. It acted as a bulwark against the Muslim upsurge which threatened Greco-Roman civilization. When Constantinople finally fell to the Ottomans, the western European kingdoms were strong enough to resist the advance of Islam in a way which might not have been possible earlier. And although the Balkan kingdoms and the Greek lands of the empire were for several centuries under Ottoman control, both Slav and Hellenic national consciousness was strong enough to survive together with the Orthodox Church. See also references under "Byzantine Empire" in the Index volume.

BYZANTINE LITERATURE: see GREEK LITERATURE.
BYZANTINE MUSIC. The term is used to describe the liturgical chant of the Byzantine Church down to the 16th century; it has survived in some monasteries to the present day. It has been preserved in a great number of manuscripts, mainly from the 10th to the 19th centuries, though a few have come down from the 9th and even the 8th centuries. The most interesting are those written before the end of the 14th century. Before the deciphering of the notation and the transcription of the main body of Byzantine liturgical chant in the second quarter of the 20th century, Byzantine music was believed to derive from ancient Greek music. This misapprehension was furthered by the fact that Byzantine theorists applied the speculations of Greek and Hellenistic mathematicians to their own chant, though according to Nicolas Mesarites, c. 1200, in his description of the church of the Holy Apostles at Constantinople the teaching of singing was in practice independent of Greek theory.

In fact Byzantine chant, like western chant, derives in the main from that of the Syro-Palestinian liturgy; which had inherited the practice of the Jewish synagogue, and is in no way connected with classical Greek music. The earliest example in style of Byzantine music is the famous Oxyrhynchus hymn to the Trinity (late 3rd century) that used to be considered as the last document of Greek

music. It is written on a strip of papyrus in the letter notation ascribed to Alypius.

Structure of the **Melody.**—The 20th-century deciphering of the notation and transcription of the chants led to the discovery of the principle of Byzantine musical composition. It is now seen that each melody consists of a number of melodic formulas. They are the archetypes from which the musician worked. His creative activity consisted in adapting the formulas to the text and in composing connecting passages. The formulas were divided into eight groups, each of which represented a certain mode (*Echos*). This principle of melodic construction was taken over from the Syrian Church. There it was the custom to sing in cycles of eight weeks a repertory of hymns in all eight modes, each week being assigned to a single mode. This custom derived from Gnostic calendaric speculations and can be traced back to Babylonian cosmology: it caused late Neoplatonic theorists to identify the Byzantine modes with the ancient Greek *echoi* and to attribute to each of the scales a certain quality of mood. These theorists overlooked the fact that in Greek scales the division into tones and semitones runs downward, whereas in Byzantine scales, as in medieval modes, it runs upward. The *Echos* theory of the Greek philosophers cannot, therefore, be applied to the Byzantine modes. At the beginning of a melody the mode was indicated by the Greek numerals, one to four, and their plagal correspondents.

Development of Notation.—Like western musical notation Byzantine notation is a system of neumes based in the main on the prosodic signs of the Greek grammarians. Its first phase is the "ekphonetic notation," designed to indicate the correct cantillation (chanting) of the lessons without giving any pitch; it occurs, fully developed, in 8th-century manuscripts and has remained unchanged. The earliest musical manuscripts date from the 9th century. In these the notation is primarily intended to guide the singers in performing correctly chants they have memorized. The signs indicated the rise and fall of the melody but not the exact intervals. They fixed the rhythmic nuances, and showed which signs ought to be accentuated, which prolonged and which shortened. When, in the 11th century, many of the old hymns were replaced by new ones it became necessary to give clearer indications. Some signs were added and others interpreted in a different way in order to mark the intervals. The third stage, beginning about 1200, was the adaptation of the approximate interval values into exact ones. Finally, at the beginning of the 14th century, supplementary signs were added in red ink to indicate the correction execution of groups of notes. Thus the system of Byzantine neumes was from the earliest times more precise than that of the Gregorian chant in indicating the rhythmic nuances of the melodies and, in its later stages, as precise as western staff notation in giving the size of the intervals.

The system, however, was a complex one. When, in the 17th and 18th centuries, the art of Byzantine chanting gradually decayed, the signs were no longer understood, and the neo-Hellenic notation introduced by Chrysanthus of Madytus in his *Theoretikon mega*: (1832) is an artificially simplified version for the modern printed hymnbooks.

Literal transcriptions can be made only from manuscripts written after 1200, because in these the exact pitch is clearly indicated. Yet it is obvious from the similarity between the later, more elaborate and the earlier, simpler notation that the shape of the syllabic melodies remained practically unaltered from the 10th to the 15th centuries whereas from the 13th century on the melismatic chants increased their coloraturas so abundantly that the words became incomprehensible and the original shape of the melodies could hardly be recognized.

Types of Hymn.—The earliest form of Byzantine hymn was the troparion, a short stanza inserted after each of the last six, or three, verses of a psalm. Composition of troparia independent of a psalm originated in the time of the emperor Leo I (457-474). Anthimus and Timocles are mentioned as the first hymn writers soon to be followed by a great number of poet-musicians who were the authors of innumerable troparia. In the 6th century Sophronius, patriarch of Jerusalem (634-638), wrote two cycles,

one for Christmas, the other for Good Friday, each consisting of 12 troparia.

In the same century a composite form appeared, the kontakion, a poetical homily, which in its content, poetical form and dramatic character derived from the three main forms of Syriac poetry. *mēmṛâ*, *madrâshâ* and *sôgithâ*. The greatest master of the kontakion was Romanos, a Syrian by birth who was inspired by the spirit of Syriac poetry but who wrote in Greek. Romanos went to Constantinople during the reign of Anastasius I (491–518) and composed several hundred kontakia. Romanos is possibly the poet-composer of the most famous hymn of the Greek Church, the Akathistos hymn for the feast of the Annunciation. The patriarch Germanus, celebrating the victory over the Arabs, who besieged Constantinople in 718. wrote a new proemium (introductory stanza) to the Akathistos, which from then on was also regarded as a hymn of victory. The kontakia are collected in the kontakarion. None of the surviving kontakaria is earlier than the late 13th century, and the melodies they contain are of a richly melismatic type. It is doubtful if they are the original melodies; for the words of the hymns, mostly by Romanos, are so important and of such sublime quality that they were certainly originally chanted in a simple way, as were the lessons. It is possible that there is a historical reason for the increase in ornamentation.

When, after the Trullan council (691–692), preaching became an obligatory part of the service, the kontakion, the sung homily, became superfluous and fell out of use. This is why the later kontakaria contain only the proemium and first stanza, not the whole kontakion. The Akathistos, however, has an exceptional position; all its 25 stanzas are still sung in the office of the feast of the Annunciation.

Toward the end of the 7th century a new form, the kanon, came into being. Though poetically inferior to the kontakion it was in its form and content such a perfect expression of Byzantine piety that kanon-singing holds an important place in the liturgy down to the present day. The first kanon writers, Andrew of Crete, John of Damascus and Cosmas of Jerusalem, came from the monasteries at Jerusalem; a second group, however, writing in the 8th and 9th centuries, belonged to the Studios monastery in Constantinople during the worst days of iconoclasm. There was also the nun Kasia (b. c. 810), a gifted poetess, famous for her monostrophic poems. In the 11th century, St. Nilus founded the monastery of Grottaferrata near Rome, and south Italian and Sicilian kanon-writing flourished for another century.

In the heyday of the Byzantine empire the office was so rich in hymns that a great orientalist speaks of the "ivy of poetry" that overgrew the liturgy.

Now that so great a part of Byzantine chant has been transcribed it has become clear that it is in no way inferior to western chant, and that it is no less impressive than Byzantine visual art.

Secular Byzantine Music.—Music also played a great part in the ceremonial life of the emperor. Wherever he went he was greeted by the "acclamations" of the two factions, the Blues and the Greens. Acclamations were chanted when he appeared at the hippodrome and when he and the patriarch went to church. Portable organs were carried in processions; they were played during meals and in the hippodrome; but they were never taken into the church.

BYZANTIUM (mod. ISTANBUL, in European Turkey), an ancient Greek city on the shore of the Bosphorus, occupying the most easterly of the seven hills of the modern city, was founded by Megarians about 657 B.C. It owed its continuing importance to its command of the grain trade from the Black sea and of one of the shortest passages from Europe to Asia. When the Persians advanced into Europe in 514 Byzantium came under Persian control, but remained restive and was liberated by the Greeks under the Spartan king Pausanias in 478. When Pausanias was officially discredited he occupied Byzantium, but was soon expelled by the Athenians (477). Byzantium then became a tribute-paying member of the Delian league. It joined Samos in revolt in 440, but was reduced without serious fighting. It revolted again in 412 after the Athenian defeat at Syracuse but was recovered by Alcibiades in 408. Lysander captured the town in 405 and installed a Spartan governor, but in 389 Thrasybulus expelled the pro-Spartan party and restored democracy and the Athenian alliance.

Byzantium joined the Athenian confederacy of 377, but revolted in 357 when Mausolus, ruler of Caria, stirred up the islands against Athens. When, however, Philip II of Macedonia advanced against it in 340 an appeal was made to Athens. The Athenians under Chares effected little against the Macedonians, but in the following year gained a decisive victory under Phocion and compelled Philip to raise the siege. The divine intervention of Hecate on this occasion was commemorated by the symbol of crescent and star stamped on Byzantine coins of this period (the device later adopted by the Turks).

During the reign of Alexander the Great, Byzantium was compelled to acknowledge Macedonian supremacy: after the decay of Macedonian power it regained its independence, but suffered from the incursions of Gallic tribes. The treasury was drained to buy off the Gauls about 270 B.C. and with the further imposition by the Gauls of an annual tribute of 80 talents, the Byzantines were compelled to exact a toll on all the ships which passed through the Bosphorus—a measure which the Rhodians avenged by a war in 219 in which the Byzantines were defeated, and forced to restore the freedom of the straits.

When Pontus and Bithynia together became a Roman province in Pompey's (Pompeius') settlement of 62 B.C., Byzantium ranked as a free city; under the early empire it was regarded as part of Bithynia but remained free until, having sought arbitration on some of its domestic disputes, it was subjected to the imperial jurisdiction and gradually stripped of its privileges. The emperor Claudius remitted the heavy tribute which had been imposed on it; but the last remnant of its independence was taken away by Vespasian. The city was besieged and taken (A.D. 196) by Septimius Severus in his campaign against Pescennius Niger; he destroyed it, demolished the famous wall and put the principal inhabitants to the sword. Severus afterward rebuilt a large portion of the town and gave it the name of Augustus Antonina. It had scarcely begun to recover its former position when, through the capricious resentment of Gallienus, it was once more sacked. From this disaster the survivors recovered so far as to be able to check an invasion of the Goths in the reign of Claudius II, and the fortifications were strengthened during the civil wars which followed the abdication of Diocletian. Diocletian had resolved to transfer his capital to Nicomedia; but Constantine, aware of the advantages that the situation of Byzantium presented, resolved to build a new city there on the site of the old and transfer the seat of government to it (A.D. 330). Renamed Constantinople (*see* ISTANBUL), it was the capital of the East Roman or Byzantine empire (*q.v.*).

See also references under "Byzantium" in the **Index** volume.

C THE third letter of the alphabet, corresponds to Semitic **ג** *gimel* (which probably derived from an early sign for "camel"), and Greek **Γ** *gamma*. Greek forms were **Γ, γ, Λ, λ**. From the last derived the round form **ϸ**, which occurs at Corinth and in the Chalcidic alphabet. Both **ϸ** and **ϸ** are found in the early Latin alphabet, as well as in Etruscan. The rounded form survived and became general, and the shape of the letter has since altered little. In certain medieval forms of writing the minuscule letter tended to become pointed; e.g., **ϸ**. Roman cursive forms are shown in the illustration to the right.

The sound represented by the letter in Semitic and in Greek was the voiced velar stop, represented in English by the "hard" g. In the Latin alphabet it came to represent the unvoiced velar stop (indicated in English by k as well as c), and was for some time, it appears, used for both the voiced and unvoiced sounds. This change is in all probability due to the Etruscan alphabet from which the Latin alphabet was derived, for a phonemic distinction between voiced and voiceless stops apparently did not exist in the Etruscan language. An early Latin inscription exists in which the word *RECEI* (probably an early dative form of rex "king") occurs, the letter C being still employed to represent the voiced sound. Finally a new symbol G was used for the voiced sound, and C displaced K as the representative of the unvoiced stop.

In modern English the letter represents two separate sounds: (1) the unvoiced velar stop as in the Latin alphabet; and (2) the unvoiced sibilant, identical with the sound represented by s in certain positions. The letter represents the sibilant when followed by any of the front vowels, e, i and y (e.g., in "receive," "cider," "cycle"); in all other cases (except before h) the velar (e.g., "call," "come," "clear," "crumb," "epic"). This is due to the palatalization of the velar in early medieval times before the front vowel, the stages of sound change being k > ti > ti > ts > s. The letter c was applied by French orthographers in the 12th century to represent the sound ts in English, and this sound developed into the simpler sibilant s. Gradually the use of the letter c to represent the velar before front vowels (for example, in the Middle English *cyng*) gave way to that of k, ambiguity being thus as far as possible avoided. The c takes the place of s in words such as "mice," "advice," in which s would represent a voiced sibilant (identical with the sound of z), and in words such as "practice" merely as a means of grammatical distinction. (See also ALPHABET.)

Before k the letter is often redundant (e.g., in "thick," "clock," etc.). The combination *ch* represents an unvoiced palatal affricate (ti), as in "church," except that in words of Greek origin it generally has the sound of k; e.g., in "chorus."

In chemistry, C is the symbol for carbon.

In music, C is the name of the third note of the musical alphabet, this note being at the same time one which has always occupied a peculiarly distinctive position, in that it is the keynote of what used to be called, from the fact that it contains no accidentals, the natural scale. Thus on the pianoforte it consists

entirely of white notes and hence has come to be regarded as the simplest and most fundamental of all keys. C is further one of the three notes (F and G being the others) which have served for centuries, in conjunction with the appropriate signs, to indicate the clefs. See MUSICAL NOTATION.

(J. W. P.)

CAAGUAZÚ, a department of east central Paraguay, stretches southward from the Cordillera de Amambay as a dissected watershed area between the Paraguay and Paraná rivers and as an extension of the Brazilian plateau. Area 8,345 sq.mi. Pop. (1960 est.) 95,276. Northern Caaguazú is a thinly peopled forest yielding wood and maté; the southwestern area is a savanna district growing tobacco, oranges and sugar, raising cattle and processing these products and petitgrain essence. Coronel Oviedo, the capital (pop. 8,298), is the centre of this agricultural area. It is linked with Asunción by an arterial road.

(G. J. B.)

CAAZAPÁ, a department of southern Paraguay, lies where the last forested hills of the Brazilian plateau reach the lowlands of the Tebicuary, a tributary of the Paraguay. Area 3,667 sq.mi. Pop. (1960 est.) 91,749. A population density of 25 per square mile is supported by an agricultural and pastoral economy in which oranges, sugar, petitgrain and leather are the principal products. Maté is gathered and timber extracted from the forests. Paraguay's principal railway, between Asunción and Encarnación, serves the lowlands and a branch line runs from Borja to Abai on the forest edge. The capital, Caazapá, was established in 1607 and is reached by a road from Villarrica.

(G. J. B.)

CAB: see CARRIAGE.

CABAL, a private organization or party engaged in secret intrigues, and applied also to the intrigues themselves (through the French *cabale*, from the Cabala [q.v.], a mystical interpretation of the Hebrew scriptures). In England the word was jealously used throughout the 17th century, with the alternative junto or cabinet (q.v.), to describe any secret and extralegal council of the king, more particularly the foreign committee of the privy council. The invidious meaning attached to the term was stereotyped by the coincidence that the initial letters of the names of Charles II's ministers, Clifford, Arlington, Buckingham, Ashley and Lauderdale, spelled cabal.

CABALA (KABBALAH, QABBALA; literally "tradition") denotes the developed forms of Jewish mysticism and theosophy from c. AD. 1200 and, in a less technical sense, the entire range of the esoteric doctrine of Judaism from the beginning of the Christian era. The term Cabala meant originally the non-Pentateuchal part of scripture and the oral traditions of Judaism. As a designation of Jewish mysticism it dates from about 1200. From Nahmanides (1194-1270) onward the Cabalists (mequbbalim) refer to themselves also as "those knowing grace," the Hebrew word for "grace" (hen) being read as an acrostic for "secret science" (*hokhma nistara*). Older terms are "mysteries of the Torah" (*sitre tora*, raze tora), "masters of the mystery" (ba'ale ha-sod), "men of faith" (*anshe emuna*), "those who understand" (*ha-maskilim*; cf. Dan. xii, 10), etc.

Cabala is essentially an oral tradition in the sense that initiation into its doctrines and practice requires a personal guide, if only to avoid the dangers inherent in the mystical experience. It is also

understood as a "tradition" in the sense that it claims to represent the esoteric part of the oral Torah revealed by God to Moses or the original revelation to Adam. Jewish mysticism therefore regards itself as circumscribed, at least in theory, by the authority of tradition. Characteristic in this respect is the role played by revelations by the prophet Elijah, the archetypal figure of the guardian of tradition, in the charismatic experience of Jewish mystics.

Cabala comprises two aspects, viz., theoretical Cabala (qabbala *'iyyunit*) and practical Cabala (qabbala *ma'asit* or *shimushit*). The latter amounts, to all intents and purposes, to white magic, operating with the holy names of God in contrast to black magic, which uses demonic powers (witchcraft). Black magic is strictly prohibited in Cabala, but employment even of the holy names is damnable if intended for selfish ends. Warnings against the use of the divine names for the sake of magical power are repeatedly uttered. As early as the 2nd century A.D. the Mishnah condemns it (Abot i, 13): "He that makes use of the crown shall perish" (crown being a metaphor for the most holy name of God). This passage is quoted by many Cabalists. It is permitted, however, to employ the holy names for the purpose of contemplation and spiritual ascent. Abraham Abulafia's doctrine of the combination (*zeruf*) of letters stresses the pursuit of the inward path as distinct from magical power. But it is difficult to draw the line, and magical tendencies often prevail in cabalistic practice. Hayyim Vital emphatically points out the dangers involved in the use of magic formulas (*hashba'ot*), even for the sake of spiritual meditation. In certain Cabalists the borderline between white and black magic is somewhat blurred, especially in necromancy, exorcism and the writing and use of amulets. Cabala also is linked with many occult sciences, such as astrology, alchemy, physiognomy and chiromancy.

Cabala represents the irruption into normative Judaism of deep-seated but repressed mythical ways of thinking. Dissatisfied with the plain meaning of the traditional interpretation of Judaism, and repelled, in the 13th century, by the excessive rationalism of the philosophers, the Cabalists created a new dimension of religious depth in the very heart of Judaism. From the 16th century onward Cabala almost displaced Jewish philosophy until the 18th-century period of Enlightenment. In the popularized form it achieved in Hasidism (18th century) it held sway over large masses of Jews in eastern Europe.

Merkabah Mysticism.— The oldest form of Jewish mysticism arose as a kind of rabbinic gnosis within the circles of the teachers of the Mishnah in the 1st and 2nd centuries of the Christian era. In opposition to the radical dualism of heretical Jewish Gnosticism, however, it was careful to stress the unity of God. Its main concern was the mystical contemplation of the *Merkabah* (throne of God) described in Ezek. i. The statement (*Tosefta Megilla, iv*) "Many have preached about the Merkabah without ever having had a vision of it" indicates that the true mystics experienced ecstatic visions of the celestial hierarchies and the throne. The ascent of the visionary is described, in Gnostic fashion, as a perilous journey through the spheres of hostile planet angels with the help of magic seals. From about A.D. 500 the visionaries of the *Merkabah* are termed "descenders" to the throne (*yorde merkava*), indicating most probably the posture (putting the head between the knees) that, along with fasting and hymnody, induced the trance. The verse (S. of Sol. vi, 11) "I went down to the nut orchard" was held allegorically to refer to the contemplation of the *Merkabah*. (The medieval mystic Eleazar of Worms was to elaborate the image of the nut as a symbol of the "depth" of the Merkabah.) A famous passage from the earliest phase of *Merkabah* mysticism uses the term "garden" (*pardes*) as a synonym for the contemplation of the *Merkabah* when speaking of the "Four who entered the garden," Rabbi Akiba ben Joseph being the only one who emerged "in peace"—i.e., unharmed—from this experience. The Merkabalaz signifies in rabbinic mysticism what the pleroma or divine fullness means in Gnosticism. The texts describing the soul's descent are contained in the Hekhalot books (*hekkhalot* = "palaces"; i.e., the various celestial chambers), dating from the 3rd century. The Hebrew Book of Enoch belongs to the 5th to 6th centuries. The movement arose in Palestine but spread to Babylonia, whence its

documents found their way into Italy and Germany.

The original Gnosticism is still discernible in the figure of Metatron, which plays a considerable part in the Hebrew Book of Enoch and subsequent Cabala. As the highest angel he occupied a seat next to the throne of God. The Babylonian Talmud contains three references to Metatron. Heretical Jewish gnosis refers to him as the "lesser Yaho" (his original name having been Yahoel or Yoel), a term that reappears in the Coptic work *Pistis Sophia* (3rd century). Another highly Gnostic and barely Judaized doctrine is that of the "Measure of the Body" (*shū'ur qoma*), interpreting the body of the beloved in S. of Sol. v as the body of the Creator. The gigantic measurements and the splendour of the description—perhaps related to the mythical figure of the Iranian *Urmensch* (primordial man)—have parallels in Greek and Coptic texts of the 2nd and 3rd centuries. They aroused violent opposition in nonmystical circles but were regarded as symbols of profound mysteries by the Merkabah mystics.

From the period between the 3rd and 6th centuries dates the earliest speculative text of Jewish mysticism, the *Sefer Yezirah* ("Book of Creation"), describing the process of creation in terms of the ten primordial numbers (*sefirot*) and the 22 letters of the Hebrew alphabet, forming together the "32 secret paths of wisdom." The numbers are connected with the "living creatures" (angels) of Ezek. i and may go back to the "hyperessential numbers" of the Neoplatonist Proclus. The letters are applied to the three parallel worlds of man (*nefesh*), the planetary spheres (*'olam*) and the course of the year (*shana*). The book was attributed to the patriarch Abraham, and numerous commentaries were written on it. It gave a powerful impulse to theurgic Cabala.

Merkabah mysticism culminates in the bizarre *Sefer Bahir* ("Book of Clarity") edited in Provence in the 12th century and foreshadowing the doctrine of the *Sefirot* (divine potencies) in 13th-century Cabala. It interprets in midrashic fashion scriptural verses, rabbinic homilies and topics of Merkabalaz and *Yezirah* mysticism, and shows a marked magical tendency. Mystical interpretation of the divine commandments plays a considerable part in it. Typically Gnostic terms such as *ha-male* (pleroma) and *nezahim* (aeons) are introduced. One of its principal sources is the book *Raza Rabba* ("The Great Mystery"), which was imported from the east to Provence via Germany.

The Hasidim of Medieval Germany.— In the Hasidim (Devout, Pietists) of 12th- and 13th-century German Jewry in the Rhineland are met for the first time clearly defined individual Jewish mystics. Samuel the Hasid, his son Judah the Hasid (a great legendary figure) and Eleazar of Worms, all of them members of the Kalonymide family that had migrated from Italy to Germany, were steeped in the tradition of Merkabah mysticism and occult sciences. They were also under the spell of Neoplatonic thought as mediated by Abraham ibn Ezra and Abraham bar Hiyya. Above all, they derived inspiration from the conception of God found in the Hebrew paraphrase of Saadia's Book of Beliefs and *Convictions* (see SAADIA BEN JOSEPH), the influence of which is reflected in the superb hymns composed in this circle. The mystical presence of God is sought in humility and in the love of God rather than in ecstatic visions of the *Merkabah* type. The glory of God that appears in the *Merkabah* visions as occupying the throne is differentiated from a still higher inner glory or holy spirit, while God himself remains unrevealed. Yet there is a strong note of pantheism in the manner in which the immanence of God is expressed. The German Hasidim reflect the spiritual climate of their age and environment, which was saturated with popular mysticism and the cultivation of a personal spiritual life, illustrated, for example, by St. Francis of Assisi and the Order of Cluny. The excessive penitentiary practices advocated by the group also may be due to Christian influence. The main documents of the German Hasidim are the *Sefer Hasidim* (in two versions), a collection of stories, homilies and doctrines; and Eleazar of Worms's numerous tracts.

Rise of Cabala in Provence and Spain.— Of decisive importance for the development of Cabala were the Jewish mystics in Provence (second half of the 12th century) and Spain, particularly Gerona (c. 1200–60). The leaders of pre-Cabalistic Jewish mysticism in Provence, where the *Sefer Bahir* was edited, were Abra-

ham ben Isaac of Narbonne, one of the great rabbinic authorities of the time; his son-in-law Abraham ben David, famous for his glosses on Maimonides' Code of Laws (*Mishne Tora*); his grandson Isaac the Blind; and Jacob ha-Nazir of Lunel, who wrote a commentary on the prayers. Claiming revelations of the prophet Elijah, they initiated new Cabalistic doctrines. According to Shemtob ben Gaon (beginning of the 14th century), Abraham ben Isaac's Compendium of Cabala, though offering only hints to the initiated, already contained essential elements of the Sefirot doctrine beyond the stage found in the *Sefer Bahir*. The Sefirot are the "soul" and "inner life" of the hidden God, the transcendent Cause of Causes. The old Merkabah doctrine is said to refer only to the Creator aspect of God, not to his inner life. Of a more philosophical type are the small pseudographical tracts that emanated from another circle in Provence, named (by G. Scholem) the *Iyyun* circle after the *Sefer ha-Iyyun* ("Book of Contemplation"). Here Neoplatonic thought intrudes forcefully into a hitherto mainly Gnostic type of mysticism. The concept of emanation (*azilut*) is applied to the ten Sefirot, which are identified with the "intelligible lights" (the ten "separate intellects") of Islamic and Jewish Neoplatonism.

Neoplatonic speculation gains even greater importance in the circle of Gerona (Judah ben Yaqar, Ezra ben Solomon, Azriel, Jacob ben Sheshet and the celebrated Bible commentator and rabbinic scholar Moses ben Nahman or Nahmanides). According to Azriel, the difference between the Cabalists and Neoplatonists may be reduced to one of terminology. In his Commentary on the Ten Sefirot he sought to derive the principles of Cabala from Neoplatonic concepts. Ezra's Commentary on Canticles contains mystical interpretations of the "reasons of the divine commandments" (*ta'ame* ha-mizvot). Nahmanides' exegetical work is shot through with mystical references. In his immediate circle may be sought the origin of the highly influential *Sefer Temuna* ("Book of the Image"), which describes the 22 letters of the Hebrew alphabet as the image of God and evolves the theory that in each successive world period (*shemitta*) another of the seven lower Sefirot predominates. This mystical theory of history had a marked influence on later phases of Cabala and was invoked by the heretical theology of Sabbatianism (see *SABBATAI ZEBI*). Another important figure was Abraham Abulafia, the representative of prophetic (*i.e.*, ecstatic) Cabala, who elaborated a system of contemplative techniques. Though he was repudiated by the religious authorities of his time, and his numerous tracts were repressed by the Cabalists, his influence was nevertheless pronounced. Joseph Gikatila wrote his *Ginat Egoz* ("Nut Garden") under Abulafia's influence. Of a more Gnostic frame of mind are the two brothers Jacob and Isaac ben Jacob ha-Kohen, Todros Abulafia and Moses ben Simon of Burgos. These Cabalists introduced the doctrine of a separate realm of demonic emanations as a parallel to the holy Sefirot.

The **Zohar**.—All these variegated elements merged in the main work of Cabala, the *Sefer ha-Zohar* ("Book of Splendour"), which made its appearance in the 1280s. The Zoharic corpus of writings contains:

1. The Book Zohar proper; printed first in Mantua (1558–60) in three volumes, it discourses in homiletic fashion on the Pentateuch. Interspersed in the main text are a number of smaller and often disjointed tracts such as the *Sifra di-zeni'uta* ("Book of Concealment"); *Idra Rabba* ("The Greater Assembly") and *Idra Zutta* ("The Lesser Assembly"); the story of Saba ("the Old Man") dealing with the mysteries of the soul; the story of Yanuqa ("the Child") on the mysteries of the Torah; *Sitre Tora* ("Secrets of the Law"); sections of the *Midrash ha-Ne'elam* ("Mystical Midrash"); *Raya Mehemna* ("The Faithful Shepherd") offering cabalistic interpretations of the divine commandments.

2. The book *Tiqqune Zohar* (editio *princeps* also in Mantua, 1558) in 70 chapters, each beginning with a fresh discourse on the first word of the Torah.

3. The Zohar *Hadash* ("New Zohar") containing sections of (1) and (2) that were missing from the manuscripts of the first edition and were supplemented from manuscripts found in Safed.

All parts of the Zohar are attributed to Simeon ben Yohai (see *SIMON BEN YOHAI*), the celebrated 2nd-century teacher of the

Mishnah and a legendary figure of Jewish mysticism. Doubts as to the authenticity of this claim arose immediately on the appearance of the Zohar. Isaac ben Samuel of Acre visited Spain in 1305 in order to meet Moses de León of Guadalajara, who from 1280 onward had circulated copies of the Zohar. He was assured that De León possessed in his home the ancient original of this book, but De León died before he could fulfill his promise to show the original to Isaac. His widow subsequently denied the existence of an original text. The question has remained a mystery and given rise to a great deal of discussion among both Jewish and Christian scholars. In the 19th century A. Jellinek concluded from the close analogies between the Zohar and known writings of Moses de León that the author of the Zohar was none other than De León himself. His view was accepted by H. Graetz and subsequently was reconfirmed, after much initial hesitation, by G. Scholem. According to Scholem, Moses de León wrote first the *Midrash ha-Ne'elam* between 1275 and 1280 and completed the bulk of the Zohar between 1280 and 1286. The *Raya Mehemna* and the *Tiqqune Zohar*, on the other hand, were composed by some other Cabalists 10 or 20 years later in imitation of the Zohar proper. Between 1286 and 1293 De León published a series of minor works designed to propagate the doctrines of the Zohar, the last being the *Maskiot Kesef* ("Settings of Silver"). Scholem's theory is based mainly on linguistic evidence. Moreover, the Zohar reflects the conditions of Jewish life in Spain around 1280, and it employs theological and psychological doctrines current at that time. Its borrowings from the Geronese school and from Gikatila's *Ginat Egoz* are striking.

The Zohar is preoccupied with the theosophical description of the inner life of Divinity as expressed in the ten Sefirot; the destiny of the human individual; and the meaning of the divine commandments. The world of the Merkabah ranks lower than the ten Sefirot, and all interest now shifts to the higher plane. Beyond it human thought is unable to penetrate, and even within its compass the uppermost point of transition from the *Ensof* ("Infinite") to God's self-revelation defies all understanding.

The ten Sefirot are (1) *Keter Elyon* or "Supreme Crown," also called God's primordial Will, and *Ayin* ("Nothing"); (2) *Hokhma* or "Wisdom," identical with the "Beginning" (*reshit*) of creation and with Eden or the source of all blessings; (3) *Bina* or "intelligence," the "supernal Mother" and womb of the totality of all individuation. There follow the seven lower Sefirot, mystically represented by the seven days of creation; they contain (4) *Hesed* or "love"; (5) *Gevura* or "power," also called *Din* or "stern judgment"; (6) *Rahamin* or "compassion," also called *Tiferet* or "beauty"; (7) *Nezah* or "endurance"; (8) *Hod* or "majesty"; (9) *Yesod* or "foundation"; and (10) *Malkhut* or "kingdom," identical with the *Shekhina* (lit. "presence"—*i.e.*, of God) as a female, purely receptive potency, and with the *Keneset Yisrael*, the ecclesia of Israel conceived as the celestial archetype of the terrestrial people of Israel.

These Sefirot form the "world of union" (*alma di-yihuda*) as distinct from the lower world of created beings, which is a "world of separation" (*alma de-peruda*). The Sefirot constitute the mystical Tree or Upper Man and are meant to describe a real process of divine life overflowing into the entire creation. The pantheism inherent in this view presented a major problem to later Cabalists. Innovations of far-reaching significance are the introduction of male and female principles into the Sefirotic world, recalling the old Gnostic doctrine of pairs; and the concept of a holy union (*ziwuga qadisha*) or *hieros gamos* between the Sefirot, particularly between the first and the last. The harmony of the divine life is described in terms of the union between "the Holy one, blessed be he" and his *Shekhina*. The present unredeemed state of the world is explained as due to a rupture of that supernal union, and eschatological hope envisages the restoration of this union when God again will be "one" (*Zech. xiv, 9*). Evil arose by the breaking away of the "left side" of the Sefirotic world from its union with the rest, thus establishing the demonic "other side" (*sitra ahra*), the domain of Satan and impurity. Redemption means the restoration of all things to their pristine harmony, and can be aided by man's attachment (*devequt*) to God. From *devequt* flow pure and

holy actions, and the "upper roots" of holiness in the worlds above are thereby strengthened. In terms of man's individual destiny, the pious fulfillment of the divine commandments prepares for him the celestial garment (haluqa de-rabanan) with which to clothe his soul in the upper paradise after he has departed from the world.

Post-Zoharic 14th-Century Cabala.—Joseph Gikatila's *Sha'are Ora* ("Gates of Light") develops the *Zohar's* doctrine of the Sefirot by systematically linking the names of God and the divine commandments with the individual Sefirot. Gikatila also elaborates the meaning of the commandments in voluminous tracts. Of particular importance are the two pseudepigraphical works *Pelia* (on the first six chapters of Genesis) and *Qana* (on the commandments), which engage in vehement criticism of non-mystical rabbinic Judaism, following a trend already noticeable in the *Raya Mehemna*. Other Cabalists, such as Joseph ibn Waqar of Toledo, Nisim ibn Malka of Fez and Samuel ibn Matut of Guadalajara, seek to reconcile philosophy and Cabala.

16th-Century Cabalists of **Safed**.—The expulsion of the Jews from Spain (1492) led to a deepening of mystical yearning. In the circle of Jewish mystics in the little town of Safed in Upper Galilee occurred a great revival of Cabala that fully articulated these tendencies. Moses Cordovero, his teacher and brother-in-law Solomon Alkabez, Joseph Qaro, Eliezer Azikri and, above all, Isaac Luria and his pupil Hayyim Vital were the chief members of this group. Azikri's *Sefer Haredim* ("Book of the Godfearing") mirrors the mystical piety of the holy brotherhood Sukkat Shalom (Tabernacle of Peace) founded by the group. Joseph Qaro's mystical diary recording the revelations vouchsafed to him by his *maggid* or angel testifies to a charismatic experience that was not unique.

Cordovero, the profound theorist of Cabala, was soon eclipsed by Isaac ben Solomon Luria (*q.v.*), creator of the "new Cabala." His chief doctrines are (1) on *zimzum* (God's "retraction"); (2) on *shevirat ha-kelim* (the "breaking of the vessels"); and (3) on *tiqqun* ("restoration" of God's unity). The doctrine of *zimzum* teaches that God's first act of creation consisted in his retraction or withdrawal into himself in order to make room for the world. But a residue (*reshimu*) of the divine light remained in the primordial space created by his withdrawal, and from it and its mixture with the quality of stern judgment inherent in the act of withdrawal the world came into being. The process of creation was set in motion by the emanation of light from the *Ensof* forming first the primordial man (*Adam qadmon*) from which, in turn, the lights of the Sefirot burst forth in one total emanation. These lights had to be channelized in order to create a universe of differentiated beings and therefore were directed into special "bowls" (*i.e.*, the individual Sefirot). But under the impact the seven lower vessels broke, and from their shattered fragments the domain of evil arose. Now the lights of the Sefirot were organized in new configurations of "countenances" (*parzufim*), each revealing God under a different aspect. Of special interest to Luria is the "countenance" of the six lower Sefirot and its relation to the tenth Sefirah called Shekhina or Rachel. The fate of the Shekhina was of deep concern to him, and his peregrinations (*gerushim*) with his disciples in the vicinity of Safed on the eve of the Sabbath were meant as participations in the "exile of the Shekhina." *Tiqqun* signifies the restoration of the union of the Sefirot and the complete self-realization of God, a process in which man is destined to play a significant part.

The spread of Lurianic Cabala and its adoption by large numbers of Jews constitutes one of the major factors in 17th- and 18th-century Jewish history. It prepared the ground for the Sabbatian movement and the subsequent rise of 18th-century Hasidism.

(1946), *Reshit ha-Qabbala* ("The Beginnings of Cabala") (1948), *Jewish Gnosticism, Merkabah Mysticism, and Talmudic Tradition* (1960), *Zur Kabbala und ihrer Symbolik* (1960), and article "Kabbalah," in *Encyclopaedia Judaica*, vol. ix (1932); Leo Baeck, *Aus Drei Jahrtausenden*, pp. 243–289 (1958).

CABALETTA, originally an operatic aria based on a simple animated rhythm, and later the concluding section of an operatic

aria, usually at the end of an act. The term is derived from the diminutive of the Italian *cobola*, "a couplet." An early example is "Le belle immagini" in Gluck's *Paride ed Elena* (1770). In 19th-century Italian opera it signifies either a short aria in quick tempo with repeats, of which there are examples in the operas of Rossini, or a brilliant conclusion to an aria such as Violetta's "Sempre libera deggio" in Verdi's *La Traviata*. Anne's cabaletta in Igor Stravinsky's *The Rake's Progress* (1951) has the form of a short aria of a quick, uniform rhythm.

CABALLERO, FERNÁN, pseudonym of CECILIA FRANCIS-JOSEFA DE ÁRROM (1796–1877), Spanish writer, whose father, Nikolas Bohl von Faber (a German merchant married to an Andalusian and settled in Madrid), had stimulated interest in Spain's medieval and classical literature with his *Floresta de rimas antiguas castellanas* (1821–28) and *Teatro español anterior a Lope de Vega* (1832). She is famous for her defense of the traditional virtues of Spain—Catholic, monarchist, moral and rural—against the upsurge of 19th-century liberalism.

Born in Morges, Switz., Dec. 25, 1796, she went to Spain when she was 17. One of the earliest Spanish folklorists, she collected into many volumes, full of entertaining anecdotes, the language, superstitions and customs of the country people of Sevillian Andalusia. Of these, the most notable are *Cuadros de costumbres*, *Relaciones* and *La familia de Alvareda*. She claimed that in her novels also she was only a recorder of fact, but this cannot be accepted; research has discovered that in *Clemencia* (1852), one of her best novels, the rivalry for a lady's hand of a Frenchman and an Englishman is largely autobiographical.

Her best-known novel, *La Gaviota* (Eng. trans., *The Seagull*, 1867), was first published serially in *El Heraldo* (Madrid) in 1849. It is acclaimed, incorrectly, as the first realistic novel of Spanish customs. It describes the career of a selfish child of nature with a golden voice, whose life is ruined by success in the big city. Like her other novels, it is marred by its obtrusive morality and slow pace, but these are lightened by lively, sympathetic presentation of country people and their conversation.

Fernán Caballero died in Seville, April 7, 1877. She had been three times married, yet remained childless. She may well be remembered primarily as a remarkable woman, whose complex personality and intimate griefs are revealed in a voluminous correspondence, still largely unpublished. (R. F. B.)

CABAÑAS, third smallest department in El Salvador (area 423 sq.mi.), bordered on three sides by the deep Lempa valley, was established in 1873. The population was estimated at 102,103 in 1958. Although mostly rugged terrain, Cabañas ranks second in the country in production of rice, third in beans, and is significant in the production of corn, vegetables, livestock and cheese. Manufactures include distilled liquors and clay products, especially pottery from excellent clay deposits. Ilobasco (pop. 28,186) is noted for its miniature Salvadoran dolls. Sensuntepeque (altitude 2,471 ft.; pop. 28,791), 49 mi. by highway from San Salvador, is the departmental capital and leading pottery-manufacturing centre of the country. (C. F. J.)

CABANILLES, JUAN BAUTISTA JOSÉ (1644–1712), the last notable representative of the 16th- and 17th-century Spanish school of organ composers, was baptized at Algemesi, Valencia, Sept. 6, 1644. He spent his adult life as organist of Valencia cathedral. He was appointed on May 15, 1665, following the death of his predecessor and teacher, Jerónimo de la Torre, and, as his position required, was ordained a priest in 1668. He appears to have traveled little, although his reputation spread as far as France, where he is known to have played. He died at Valencia, April 20, 1712. His surviving works include a huge number of pieces for organ and other keyboard instruments: *tientos*, *tocatas*, *versos*, *pasacalles*, *gallardas*. While these contain many interesting features, for example the brilliant figuration of the *tocatas* and the dissonances of the *tientos de falsas*, Cabanilles was content to extend Renaissance techniques without wholeheartedly accepting the new baroque style.

See H. Angles, *Musici organici Iohannis Cabanilles Opera omnia*, only 3 vol. published (1927–36). (Jo. St.)

CABARRUS, FRANÇOIS (FRANCISCO), CONDE DE (1752–

1810), French financier, who gained prominence as a financial adviser of the Spanish king Charles III, was born at Bayonne in 1752. He originally settled in Madrid as a soap manufacturer. As adviser to Charles III, he devoted his considerable financial talents to the organization of a bank, to the formation of a company to trade with the Philippine Islands and to a reformation of the currency and taxation. But these measures were hindered by the death of Charles III in 1788, and Cabarrus spent two years in prison on a charge of embezzlement. Restored to favour, with the title of count, he was nominated Spanish ambassador to Paris, but the Directory raised objection to his appointment on the grounds of his French birth. Cabarrus took no part in the intrigues by which Charles IV of Spain was compelled to abdicate and his son deprived of the succession in favour of Joseph Bonaparte, but he became minister of finance under Joseph's government and held that post until his death at Seville on April 27, 1810. His daughter, Therese, was the famous Madame Tallien (see *TALLIES*: JEAN LAMBERT).

Cabarrus' works include *Memoria al Rey . . . para la extincion de la Deuda Nacional* (1783), and *Cartas . . . al Señor D. Gaspar de Jovellanos y . . . al Príncipe de la Paz* (1808; new ed., 1933).

CABBAGE, a biennial vegetable and fodder plant whose various forms are said to have been developed by long cultivation from the wild or sea cabbage (*Brassica oleracea*) found near the seacoast of various parts of England and continental Europe. The cultivated varieties, however, have departed widely from the original type, and they present marked and striking dissimilarities among themselves. The wild cabbage is a comparatively insignificant plant, growing one to two feet high, in appearance similar to charlock (*Brassica kaber*) but having smooth leaves. The wild plant has fleshy, shining, wavy and lobed leaves (the uppermost being undivided but toothed), large yellow flowers, elongated seed pod and seeds with conduplicate cotyledons. Although the cultivated forms differ in habit so widely, the flower, seed pods and seeds present no appreciable difference. The common horticultural forms of *Brassica oleracea* may be classified according to the plant parts used for food and the structure or arrangement of those parts: (1) leaves: loose or open foliage (kale and collards) and leaves folded into compact heads (large terminal heads, e.g., common cabbage and savoy cabbage; and small axillary heads, e.g., Brussels sprouts); (2) flowers and thickened flower stalks: flowers little or not modified (sprouting broccoli) and flowers much thickened and modified (cauliflower and heading broccoli); (3) stem much expanded to a bulbous structure (kohlrabi). All these forms intercross as readily as do varieties of a single form. Many distinct horticultural varieties of these several forms are commercially important.

All these forms of "cabbage" have succulent leaves that are free of hairs and covered with a waxy coating; in most of them the waxy coat gives the leaf surface a gray-green or blue-green colour. These plants grow best in mild to cool climates, tolerate frost, and some of them tolerate hard freezing at certain periods of growth. Hot weather impairs the growth and the eating quality of all of them. Only those forms grown for their flower parts are annuals; the others are biennials. After an initial period of growth the biennials must undergo a period of rest imposed by temperature below 45° F. before

flower parts can develop. Premature flowering brought about, in part, by untimely temperatures often is a cause of economic loss to growers. The edible portions of these plants are low in calorie value. They serve as sources of bulk, vitamins and minerals in the diet.

Kale (*Brassica oleracea* form *acephala*) produces a strong-growing rosette of long-petioled, elongated leaves with wavy to frilled margins. In a long growing season the main stem reaches

a height of two feet or more. In the United States the plant is usually harvested by cutting off the entire rosette before the stem has elongated, but in Great Britain and in Europe the individual lower leaves are usually removed progressively as the main stem elongates. Kale is grown mainly for autumn and winter harvest because cold improves its eating quality and its hardiness permits harvest of fresh greens after most fresh vegetables have become unavailable. Thousand-headed or Jersey kale is a different species a coarse, rapidly growing plant that may reach a height of eight to ten feet and is grown only for stock feed.

Collards (also *Brassica oleracea* form *acephala*) is another hardy, nonheading form of cabbage which is grown extensively as winter greens in the southern United States. The leaves are much broader than those of kale, are not frilled and resemble the rosette leaves of head cabbage. The lower leaves are commonly harvested progressively, the main stem reaching a height of two to four feet with a rosette of leaves at the top. The entire young rosette is sometimes harvested. Both collards and kale are primitive forms of cabbage similar to those used in ancient times in the Mediterranean region, where the species is believed to have originated.

Brussels sprouts (*Brassica oleracea* form *gemmifera*) produces tiny cabbage heads, about an inch in diameter, that form in the axils of the leaves along the much-elongated main stem. This plant is relatively new among food plants; it was first described in 1587 and apparently was developed in northern Europe about the 15th century or not long before. Because of its exacting climatic requirements, Brussels sprouts is little grown except in cool districts near the sea. Firm "heads" will not develop if the daily mean temperature is much above 55° F.

Head cabbage (*Brassica oleracea* form *capitata*) is by far the most important form of this species. Hard-headed cabbage, like Brussels sprouts, is a new crop plant that was developed in northern Europe during the middle ages. Soft-headed cabbages such as the savoy type are believed to be of southern European origin of an earlier time. Head cabbage is generally denoted by the simple term "cabbage," and is a major table vegetable in most countries of the temperate zone.

The heads of horticultural varieties of cabbage range in shape from pointed through globular to flat; from soft to hard in structure; through various shades of green, gray-green and magenta or "red," and from one or two pounds up to ten pounds and more in weight. They also differ in suitability for specific uses. The less hard varieties must be used more or less promptly after harvest for salads, in cookery or for the manufacture of sauerkraut: the very hard, late-maturing Danish type is suited to winter storage for later general use.

Some varieties, such as Early Jersey Wakefield, will tolerate winter temperatures as low as 0° F. when the plants are small, but most varieties will not.

The edible part of cauliflower (*Brassica oleracea* form *botrytis*) consists of a compact terminal mass of greatly thickened, modified and partially developed flower structures, together with their subtending fleshy stalks. As desired for food, this terminal cluster forms a firm, white, succulent "curd." The broad, much elongated leaves extend far above this curd. In most varieties the leaves of a plant must be tied together well above the curd, or broken over it, several days before harvest to prevent the discoloration of the curd by sunlight.

Heading broccoli is, in effect, a slow-growing winter type of cauliflower and indistinguishable from it on the market. In the United States both are marketed as cauliflower. Cauliflower is

very exacting in its climatic and cultural requirements.

Sprouting broccoli (also *Brassica oleracea* form *botrytis*) and cauliflower were both cultivated by ancient Mediterranean peoples. Despite the antiquity of sprouting broccoli and its popularity in Italy for centuries, it was not widely known in the United States until about 1925. The edible part of this plant is the unopened flower clusters and their subtending fleshy stems at the terminal of the main axis, from 2 to 4 ft. tall, and of the axillary branches. Large quantities are preserved by freezing in the United States as well as marketed fresh.

Kohlrabi (*Brassica oleracea* form *caulorapa*), first described in the 16th century, is another "cabbage" of recent European origin. Its most distinctive feature is the greatly enlarged stem just above the soil. It is best harvested for food when this enlargement is 2 to 23 in. in diameter. At this stage the enlargement is globular to slightly flattened, but if allowed to become old it becomes elongated. The flesh resembles that of turnip but is sweeter and milder. Kohlrabi is little grown for food except in kitchen gardens; in Europe it is grown for stock feed.

CABEIRI, an important group of deities, perhaps of Phrygian origin, worshiped over a large part of Asia Minor, on the islands nearby, particularly Lemnos and Samothrace, and in Macedonia and northern and central Greece, especially Boeotia. They were powers of fertility, perhaps originally indefinite in number; in classical times there appear to have been two male deities, Axiocersus and his son and attendant Cadmilus or Casmilus, and a less important female pair, Axierus and Axiocersa. These were variously identified by the Greeks with gods of their own pantheon (Hephaestus, Dionysus, Demeter and Kore, the Dioscuri, etc.). The cult included worship of the power of fertility, symbolized by the male organ of generation; there were also, as usual in mysteries such as these, rites of purification, which seem ultimately at least to have included insistence on moral purity; also initiation, presumably into the favour and intimacy of the gods. An obscure legend preserved by ecclesiastical writers says that there were three male Cabeiri, of whom two killed and beheaded the third.

They are often identified with the great gods of Samothrace (though not on Samothrace itself). There, as early as the 5th century B.C., their mysteries attracted great attention, and initiation was looked upon as a general safeguard against all misfortune, particularly against shipwreck. But it was in the period after the death of Alexander the Great in 323 B.C. that their cult reached its height, and initiation was sought not only by large numbers of ordinary pilgrims but also by persons of distinction. The island possessed the right of asylum or sanctuary. Excavation of the sanctuaries and the town proceeded systematically after 1938.

In 1888 interesting details as to the Boeotian cult of the Cabeiri were obtained by excavations of their temple in the neighbourhood of Thebes, conducted by the German Archaeological Institute. Two male deities were worshiped: Cabeirus, who is shown on many vases reclining, drinking, surrounded by vines and grapes—*i.e.*, in the guise of Dionysus; and a boy called simply *pais*, "boy." The Romans, who claimed Trojan descent, identified the Cabeiri with the *penates publici* (see PENATES).

CABELL, JAMES BRANCH (1879–1958), U.S. novelist and essayist, had a great vogue in the 1920s, followed by an equally pronounced eclipse in popularity. Born in Richmond, Va., April 14, 1879, of an old and distinguished family, he began writing fiction shortly after the turn of the century. His great acclaim did not arrive, however, until after the suppression of *Jurgen* (1919) on moral grounds. For a decade or more he was extravagantly praised, but in the 1930s his mannered style and his philosophy of life and art lost favour with both critics and public.

Of his more than 50 books, the best known were the 18 volume *Biography of Manuel*, which, besides *Jurgen*, included *Cream*

of the Jest (1917), *Beyond Life* (1919), *Figures of Earth* (1921) and *The High Place* (1923). Although he persistently avoided the literary convention of "realism" in these and his other books, his imaginary medieval province of Poictesme never concealed a septic view of human experience; and he remained, in H. L. Mencken's phrase, "the most acidulous of the anti-romantics." Cabell died May 5, 1958, at Richmond, Va.

Parrington, *Main Currents in American Thought*, vol. iii, pp. 335–345 (1930); Carl Van Doren, *James Branch Cabell* (1932); typical of the later, more hostile, critics are Alfred Kazin, *On Native Grounds*, pp. 230–235 (1942); Oscar Cargill, *Intellectual America*, pp. 495–503 (1941). For a return to the sympathetic view, see Edmund Wilson, "The James Branch Cabell Case Reopened," *The New Yorker*, pp. 129–154 (April 21, 1956). (J. R. Hk.)

CABER TOSSING, a Scottish athletic event which consists in tossing a caber, a straight, barked log from 13 to 18 ft. long, end over end. The caber is held vertically against either shoulder with the small end (4 to 6 in. in diameter) in the hands and the big end (10 to 14 in.) straight up. The toss is made after a 10- to 20-yd. run. According to Highland tradition, tosses are judged as to style and the straightness with which the caber falls in direct line from the contestant. Each meet has its own caber. If no one succeeds in turning it after three tries, a piece is cut from the thick end and the contest begins again.

In the United States, a lighter caber is thrown for distance and the run is shorter. There are no official standards as to weight, length or system of tossing. (F. S. T.)

CABET, ÉTIENNE (1788–1856), French Socialist and founder of a settlement at Nauvoo, Ill., was born at Dijon, France, in 1788, the son of a cooper. Rebellious against the regimentation of his work as teacher at a local school, he turned to law and practised in Dijon until 1820. He then settled in Paris and became director of the *Vente Suprême*, the local association of the revolutionary organization known as the *Carbonari*.

After taking part in the revolution of 1830 in France, he was made *procureur général* in Corsica but was soon dismissed because of his attacks on the monarchy in his *Histoire de la Révolution de 1830*. Elected to the chamber of deputies as a member for Dijon in 1831, he founded, in 1833, a journal, *Le Populaire*. Cabet was exiled in 1834 for criticizing the government and spent five years in London, where he was influenced by Sir Thomas More's *Utopia* and by the ideas of Robert Owen. On the amnesty of 1839 he returned to France; in 1839–40 his *Histoire Populaire de la Révolution Française de 1789 à 1830* was published, and in 1840 a novel, *Voyage en Icarie*. Six years later he published *Le Vrai Christianisme suivant Jésus Christ*.

Voyage en Icarie contained Cabet's theories on progressive taxation, obligation to work, old-age pensions and the divisions of the products of industry. The Icarian movement gained popularity in France and Cabet sought to put his ideas into practice. He contracted to buy, through agents of the Peters Land company, a tract in Texas supposed to comprise 1,000,000 ac. In March 1848, 69 Icarians landed in New Orleans to pave the way for 1,500 who were to follow. But the purchase proved to be only 100,000 ac. of poor soil. At length the advance guard abandoned the Texas location and returned to New Orleans. Cabet, meanwhile, had left France with almost 500 followers, undaunted by the news of the Texas misfortunes. His little force met what was left of the firstcomers at New Orleans in 1849. Some lost heart and returned to France, and all refused to go to the Texas site. Cabet then purchased the old Mormon settlement at Nauvoo, Ill., and led 280 settlers there to start Icaria. The Icaria settlement was at best a compromise, for Cabet was never able to put into practice many of his ideas. The population never exceeded 1,800.

In 1856 dissensions arose and, with 180 followers, Cabet left to found a new settlement, but died the same year on Nov. 8 at St. Louis, Mo. (B. M.)

CABEZA DE VACA, ALVAR NÚÑEZ: see NÚÑEZ CABEZA DE VACA, ALVAR.

CABEZÓN, ANTONIO DE (1500–1566), is supreme among Spanish composers for the organ. He was born at Castrillo de

Matajudios, near Burgos, on March 30, 1500, and, although blind from childhood, reached the peak of his profession as a keyboard player. In about 1521 he was studying in Palencia and in 1526 was appointed organist and clavichordist to the empress Isabel, in 1548 passing into the service of Philip II. Through the court he met the influential musicians, Tomás de Santa Maria, theorist and composer, and Luis de Narváez, the vihuelist, and he gained valuable experience on travels with the royal chapel to Italy, Germany and the Netherlands (1548–51), and to England and the Netherlands (1554–early 1556). Traces of his style may be observed in the music of Thomas Preston, organist of Windsor chapel at this time. Cabezón died at Madrid, March 26, 1566. His surviving music consists almost entirely of *tientos* (*i.e.*, *ricercari*), plainsong settings (for Mass and Office) and variations. A comprehensive collection ("for keyboard, harp, vihuela") was published in 1578 by his son, Hernando. Stylistically, his music is austere, lofty polyphony enlivened by controlled runs and ornaments.

F. Pedrell's *Hispaniae scholae musica sacra* (1894–98), vol. 3–4, 7–8, contains modern editions of Cabezón; see also S. Kastner, *Antonio de Cabezón* (1952). (Jo. Sr.)

CABINDA (KABINDA), a Portuguese possession (an exclave of Angola) on the west coast of Africa, lies north of the mouth of the Congo river. It is bounded by the Atlantic on the west, the Republic of Congo (formerly French Middle Congo) north and northeast, and Republic of the Congo (the former Belgian Congo), south and southeast. Its coast line is 93 mi. and its greatest width 70 mi. Pop. (1950) 50,506, of whom 734 were white and 659 mixed. Area 2,807 sq.mi. For administrative purposes Cabinda is a district of Angola, from which it is separated by the Congo river and a strip of the Congo territory, and is divided into two *concelhos*, Cabinda and Cacongo, and one circumscription, Maiombe. The inhabitants are Bantu Negroes, called Cabindas. They are intelligent, energetic and enterprising, and known as daring sailors and active traders. The Maiombe region is rich in forests, though transportation difficulties have hindered exploitation, and its beauty is an attraction to tourists.

Cabinda's busy trade has consisted mainly of timber, palm oil and kernels, cocoa and coffee. The area is favourable to the production of rubber, fruit and ivory. Alluvial gold is extracted and deposits of mineral and other phosphates have interested U.S. companies. In 1957 contracts were made for the prospecting and exploitation of petroleum. The district's chief town, Cabinda, is a seaport situated on the right bank of the small river Bele. Population of the town in 1950 was 11,129, including 355 whites. A second town and harbour is Lândana to the north. (A. A. G. P.)

CABINET, a governmental term denoting a body of advisers to a sovereign or chief executive. It has been an important element in nearly all countries where legislative powers have been vested in a parliament or congress, but it has taken markedly different forms in various countries, the two most striking examples being Great Britain and the United States.

GREAT BRITAIN

As a British constitutional term, the word "cabinet" originally signified a small room. Cabinet counsel came to mean secret counsel or advice and cabinet council the body of persons that gave such counsel.

Historical Development.—The cabinet in England derived from the privy council. In Tudor times, in order to facilitate the subdivision of labour, many standing and temporary *ad hoc* committees of the council were appointed, and the practice was continued under the Stuarts. One of these committees, usually called the foreign committee, gradually became of outstanding importance. On it sat the king's most intimate advisers and it debated the most serious affairs of state, domestic as well as foreign. Decisions were frequently reached in this committee before the subject of the decision had even been broached before the privy council, the functions of which were thus to a large extent usurped.

After the Restoration of 1660, under the auspices of the earl of Clarendon, much use was made of committees, particularly of an informal, secret committee for foreign affairs (which in fact dealt

with any matters requiring secrecy). On Clarendon's fall the precedent was followed by a standing committee of the privy council, called the committee for foreign affairs. This committee, because of the coincidence of the initial letters of the names of some of the members (Clifford, Ashley, Buckingham, Arlington and Lauderdale), has passed into history as the cabal.

By the reign of Anne the routine of "committee" and "cabinet" had become the accepted, but still unpopular, machinery of executive government: the committee, meeting as often as necessary throughout the week in the office of the senior secretary of state at the Cockpit in Whitehall, deliberated upon all business of government and prepared it for the sovereign, with whom final decisions would be taken, generally at weekly meetings, in her cabinet with the lords of the committee. By this time only formal business was transacted at meetings of the privy council. But George I, who spoke no English, from 1717 onward ceased to attend, and less and less frequently in the succeeding years did the lords of the committee come to the palace to wait upon a king who never appeared. The designation "the committee" was dropped. It was as "the cabinet," since that had been the title of the decisive body, that the executive was henceforth known.

Meanwhile, in proportion as the foreign committee and its descendants developed into the recognized executive of the nation, so did it tend to be composed more and more exclusively of the principal political officials. The numbers swelled from 6 or 7 under Charles II to 10 or 12 under Anne and reached 20 or more under the Georges. Not all of these were effective officials; they included borough magnates and the king's personal favourites. Such unwieldiness led naturally to the development of an inner cabinet, at first informal but after 1739 recognized and regulated. It consisted of the first lord of the treasury, the lord chancellor, the lord president and the two secretaries of state. It met at Sir Robert Walpole's house, as he became the king's "first minister," the first lord of the treasury and the effective master of the house of commons. This dual system, of inner (efficient) and outer (nominal) cabinets persisted until the inner cabinet, by gradual accretion of important office holders, displaced its outer shell. This stage was reached by 1783, when the younger Pitt formed his administration.

Throughout the 18th century the cabinet remained in an indeterminate position. It had a genuinely independent executive power but could neither flout the will of the commons nor forfeit the favour of the king. Thus Walpole resigned in 1742 when the commons pronounced against him after the election of the previous year. But his resignation did not involve, as it would now, a complete change in the administration. The success of George III in reasserting the crown's right to direct policy and to control ministries effectively checked for a period any tendency toward ministerial independence. The strongest prime minister of the 18th century, the younger Pitt, enjoyed his position primarily as a result of royal favour.

Thus although there were isolated instances of the crown accepting, against its inclination, the advice of ministers (*e.g.*, George IV's assent to Catholic emancipation in 1829) it was only the passage of the 1832 Reform bill that made possible the emergence of cabinet government today. Henceforth no cabinet could maintain itself unless it had the support of a majority in the house of commons, or could obtain a majority by dissolving parliament and appealing to the electorate. Obviously for both these purposes it must be united, and the most natural and solid basis for unity was party. Hence party government and cabinet government developed simultaneously.

Principles of Cabinet Government.—The cabinet may be described as a committee of privy councillors, with seats in parliament. The members are united by political principle and they profess unanimity in public under the leadership of the acknowledged head of the party commanding a majority in the house of commons. It is by this head, with the sovereign's assent, that they have been appointed to the control of the principal government departments, to act through him as the sovereign's sole advisers, and to be severally and jointly responsible to the sovereign, the prime minister, parliament and the people, for their individual and collec-

tive actions, so long as they are supported by a majority of the house of commons. Membership of the privy council provides, through the privy councilors' oath, the necessary formal basis of loyalty and secrecy. The passage of the Official Secrets act in 1911 imposed legal penalties for the publication of cabinet documents. Obviously cabinet deliberation would be robbed of its frankness and cabinet action of much of its authority if freedom of speech inside the cabinet were not married to silence about its proceedings outside, and the rules of secrecy have in the main been admirably preserved. Of course, at a certain point cabinet proceedings pass into history. We are no longer in much doubt about what passed in 19th-century cabinets; and eminent persons, like Lloyd George and Sir Winston Churchill, seem to have been granted generous latitude in the publication of cabinet memoranda in their memoirs. But in general the rule of secrecy means that at any given time students and the public are less well informed about the operations of the cabinet than about most parts of the machinery of government.

Cabinet members must have seats in parliament, both in order to defend their political actions, and to enable parliament to hold them to account. The Ministers of the Crown act, 1937, gives legal sanction to the obvious political necessity of distributing ministers in adequate proportions between the commons and the lords. It is essential that the prime minister should be in the commons and desirable that the finance ministers be there, too.

In ordinary times, members of a cabinet will obviously be members of the same party. Coalitions may occur, but experience suggests that in fact only war or other national emergency provides an adequate solvent for partisanship; the 1931 coalition soon lost unanimity of purpose and its short-lived experiment in "agreement to differ" over tariffs demonstrated the continuing validity of Lord Melbourne's principle of unanimity.

The doctrine of collective responsibility is the keystone of the cabinet arch. It implies an obligation on every member not to vote or speak against a cabinet decision and to support it in the division lobbies and in public. This in turn implies that important decisions shall normally be taken in full cabinet. Nevertheless, changes of policy may sometimes be announced without prior agreement. In such cases either the cabinet must disavow the spokesman (as Baldwin's cabinet disavowed Sir Samuel Hoare over the Hoare-Laval pact in 1935) and, as a corollary, the aberrant member must resign; or else the cabinet must close ranks behind the new policy and endorse it. In such circumstances the prime minister is in a particularly strong position. As leader of his party he enjoys especial authority in parliament and the country; as head of the cabinet he can require any hostile colleague's resignation. If he resigns, his cabinet falls with him and the right of advising the sovereign to dissolve parliament is his alone. (For details of the prime minister's powers see PRIME MINISTER, BRITISH.)

Relations With the Sovereign.—Because the full implications of the Reform act were not immediately grasped, Queen Victoria retained throughout her reign a degree of control over the cabinet that was logically incompatible with its position in the constitution. The sovereign's power is now restricted to the initial act of selecting an individual and inviting him to form a government. Whom he appoints, what policies his administration pursues, when he resigns or when he asks the sovereign to grant a dissolution—these are matters on which the prime minister, subject to the law of the land is entitled to have his own way.

Composition of the Cabinet.—Cabinets have grown in size as the responsibilities of government have expanded. Sir Robert Peel in 1841 had only 13 members in his cabinet but by 1900 the number rose to 20 and it has seldom dropped below this figure in normal times since. The problem has increasingly become how to include all the important departments and yet not make the cabinet too unwieldy. Certain departments are so pivotal that they obviously must be included, such as the foreign office and the treasury. The importance of others may rise and fall with the changing emphases of politics. But room may also have to be found for some ministers who are not heads of departments but whose counsel or debating strength is of value; they can either hold

sinecure offices, like the lord presidency, or serve without portfolio.

In war the needs of administration and execution take priority over those of politics. This has been reflected in the composition of wartime cabinets. Lloyd George in 1916 superseded H. H. Asquith's ordinary cabinet by one of five or six members only, none of whom, except the chancellor of the exchequer, had departmental duties. This inner circle of executives met daily, either by itself or, more frequently, in the company of whatever departmental head was operationally concerned with the business under discussion. Opportunity was also taken of visits to Britain by dominion prime ministers to invite them to attend cabinet sessions, and in 1917 Gen. J. C. Smuts was made a regular member. At the outset of World War II in 1939 Neville Chamberlain reduced his peacetime cabinet of 23 to one of 9, but, unlike Lloyd George, he included 5 members with departmental responsibilities, the 3 service ministers, the foreign secretary and the chancellor of the exchequer. It was not until the formation of Winston Churchill's coalition government in 1940 that cabinet numbers shrank to five, but it gradually expanded again and for most of the war stood at eight or nine. As the numbers increased the initial policy of basing the cabinet on nondepartmental ministers was abandoned.

Cabinet Committees and Secretariat.—The modern cabinet does much of its work through committees on which heads of departments not of cabinet rank frequently serve. The first formal committee to be instituted was the committee of imperial defense established in 1904. The prime minister was chairman and the committee contained, in addition to the ministers directly concerned with military matters, the three chiefs of staff. As the work of the committee expanded subcommittees developed to deal with detailed questions of manpower, supply, etc. In 1946, at the same time that a minister of defense was created, the committee's name was changed to the defense committee.

The home affairs committee was first set up in June 1918 to consider all questions of internal policy, but has become more of a legislation committee, concerned with the drafting of bills and the planning of parliament's work. It is for each government to decide on the committee structure most convenient for discharging cabinet business. The Labour government of 1945–51 developed an elaborate structure of almost 20 cabinet committees.

The cabinet was late in developing any secretariat of its own and for many years the only record of its proceedings was the confidential letter which the prime minister sent to the sovereign at the end of each meeting. The committee of imperial defense had had a modest secretariat ever since its inception and on the outbreak of World War I the obvious solution was adopted of taking over its staff, which became enlarged and was in 1916 placed under Sir Maurice Hankey as the first permanent secretary to the cabinet. Strict secrecy still governs all cabinet records but there is a great gain in the continuity and precision of cabinet action.

World War II led to the growth in 1940 of an economic section of the cabinet secretariat, which became a permanent part of the machinery of government in May 1944. Its duty is to measure and analyze economic trends and submit reports on them. There is also a central statistical office attached to the cabinet (also dating from 1940) whose job is to collect statistics from the departments.

The cabinet ordinarily meets in Sir Robert Walpole's house, No. 10 Downing street, which he bequeathed to the nation, and which prime ministers occupy to this day. For tables of the cabinets and ministers of English crown see MINISTRY, GOVERNMENT.

COMMONWEALTH OF NATIONS

The other countries of the commonwealth maintain cabinet systems closely related to those developed in the United Kingdom, though with local variations resulting from differences in political environment. The older countries, Canada, Australia, and New Zealand, base their cabinets on the U.K. model. India proceeded on much the same lines after independence. Ceylon is distinctive in having the conventions of the British cabinet system formally incorporated in its constitution. Pakistan, after an unsuccessful attempt to operate a system of parliamentary democracy, instituted what was virtually a system of military rule in

Oct. 1958, while Ghana showed marked signs of substituting the personal rule of the first premier Kwame Nkrumah for cabinet rule. The non-self-governing states of the commonwealth have in almost all cases an executive council under a governor and proceed in their evolution toward a full cabinet system along much the same path the British cabinet took in the evolution of its relations with the crown and parliament. (H. G. N.)

EUROPE

On the continent of Europe, as in Great Britain, the cabinet—frequently termed council of ministers—became an intrinsic part of parliamentary systems of government. In many European countries, however, the historical development of cabinet bodies and their functions within the complex of parliamentary institutions differed appreciably from British experience.

Cabinets of a recognizably modern form first appeared in Europe during the 19th century with the gradual spread of constitutional government. Monarchs had previously made use of members of their court circles for the exercise of various administrative functions, but as their own private servants. The establishment of constitutional rule brought in its train a new status for the king's ministers. This was in large part due to the creation of elected representative parliaments whose approval was needed for budgetary matters and legislative acts. Ministers now came to share with the king responsibility for the processes of government—their signature, for instance, was required on legislative acts—and it became their task to defend policy proposals in parliament. The choice of such ministers continued, however, to rest with the king and many monarchs who only reluctantly agreed to the adoption of forms of constitutional rule clearly hoped that the change would not seriously interfere with their selection either of individuals or policies.

Germany.—In some cases the weakness of parliamentary bodies did in fact leave a large measure of personal power either to the monarch himself or to the person of his choice. This was the case in Prussia under the constitution of 1850, for instance, where ministers—though they had the right to appear in either chamber and speak as often as they pleased—did not in practice resign on an adverse vote. Nor did ministers in that state develop the cohesion characteristic of a modern cabinet: there was a minister president, but he had no authority over his colleagues and could not compel them to adopt his views. Similarly, in the German empire power continued to reside principally with the emperor who either, as in the case of William II, himself undertook the direction of public affairs, or, as with William I, delegated its exercise to a minister of his choice—Bismarck. In neither case did the cabinet assume a decisive role. In Germany the exercise of governmental power did not become dependent on a vote of confidence given by the assembly until the creation of the Weimar republic after World War I, and then the fragmentation of political parties within the *Reichstag* gave rise to a long series of weak minority cabinets. Actual government devolved more and more upon permanent civil servants and many ministerial posts came to be filled by non-political experts, while political power shifted to the directly elected president to whom the constitution gave control over the army.

France.—In a number of other countries constitutional regimes gave place earlier to forms of government which gave much greater power to the cabinet, either through a process of formal constitutional change or by the gradual evolution of parliamentary practice. An example of the former was the French third republic (1870–1940) in which effective control of executive power was confined to the council of ministers who alone had responsibility for governmental acts. In the reaction against the second republic (1848–52) which, through its provision for the direct election of the president, had allowed Louis Napoleon to assume autocratic powers, the role of the president was greatly reduced. Elected by a joint meeting of the two houses of parliament, he was allowed to communicate with them subsequently only by message, though his ministers had the right of appearing in person and speaking. The constitution of the fifth republic, adopted in 1958, strengthened the powers of both president and premier. The president names the premier and cabinet members and in a dispute with the assem-

bly can dissolve the assembly and call for new elections. (See also FRANCE: *Government, Politics and Law*; MINISTRY, GOVERNMENT: *Continental Europe*.)

Italy.—In Italy cabinet government evolved without formal constitutional change within the framework established by the Piedmontese *statuto* of 1848. Although this did not explicitly require ministers to have parliamentary support, the tradition established by Cavour of ministerial responsibility toward a parliamentary majority was continued by his successors, and it was rarely that the king subsequently attempted to nominate members of his own private circle for the position of prime minister, as he had done in 1848–49. Royal interference in certain aspects of policy, particularly foreign affairs, continued through the 19th century but did not assume proportions such as to call in question the right of the council of ministers, sustained by a parliamentary majority, to govern. The republican constitution of 1948, which reintroduced parliamentary forms of government after the Fascist interlude, for the first time gave explicit constitutional sanction to the role of the cabinet, but this was a confirmation of pre-Fascist practice rather than an innovation. (See also ITALY: *Government, Law and Defense*.)

The Netherlands.—In the Netherlands the change from a constitutional regime to one in which the majority in parliament exercised a determining influence on the nature and composition of the government was also gradual. The Fundamental law of 1814 left the king still the determining force in government and down to 1840 William I ruled as an autocrat, his ministers being treated as his personal servants. His abdication in that year was occasioned by constitutional reform which introduced a degree of ministerial responsibility, but his successor continued to be the main source of his ministers' strength. It was not until the further reforms of 1848 that the way to full ministerial responsibility to parliament was opened up, when William II was obliged to agree to the conditions laid down by the person he nominated to form a cabinet—Rutger Jan Schimmelpenninck—who first assured himself of a parliamentary majority and a homogeneous cabinet before he took office. The ensuing period up to 1868 witnessed a continuing conflict between the king and parliament for control over successive ministries which culminated in the triumph of the elected assembly. (See also BELGIUM: *Administration and Social Conditions*; HOLLAND: *Government and Administration*.)

Sweden.—Sweden was an example of another country where the process was also gradual. After the 1840–41 *riksdag* the Swedish kings recognized the need for governments to co-operate with parliament, but for a long time they refused to subject themselves to it when making ministerial appointments. The conflict over this issue was often bitter but again it was resolved in favour of parliament, the creation of the Liberal-Social Democrat ministry of 1917 generally being accepted as the final culmination of this process. (See also SWEDEN: *Government, Justice and Defense*.)

Switzerland.—In their general form European cabinets resembled that in Britain, though that of the Swiss confederation remained a distinctive exception. Its federal executive is a body whose membership is fixed at seven, these being elected by the two chambers of the legislature in joint session for a period of four years—the full parliamentary session. The presidency of the confederation rotates annually among these seven members. (See also SWITZERLAND: *Government*.)

The Common Problem of Stability.—Elsewhere cabinets are formed by a person designated by the head of state, usually after consultation with party leaders and other prominent politicians. Except in Britain this process in Europe is frequently extremely laborious and lengthy. The Netherlands, because of the finely balanced political situation after World War II, saw some particularly prolonged attempts. In 1956 it took no less than 121 days to form a government and this followed on similar, if shorter, crises in 1952 (68 days) and 1951 (49 days). Several postwar Italian cabinets also had lengthy periods of gestation. That of Fernando Tambroni was confirmed in office early in 1960 after more than two months' intense maneuvering and even then it failed to command a true majority in the lower chamber.

Such difficulties arose because of the absence of parties strong enough by themselves to command stable majorities in parliament—a reflection of the much greater political fragmentation found in most continental European countries as compared with Great Britain. In all but a few continental countries coalition cabinets are the rule and tend to be much less stable than single-party ministries.

Both France and Italy have a particularly unhappy and continuing tradition in this respect. With the exception of the two French empires France had only two long-lived cabinets after 1789—those of the comte de Villèle (1822–28) and François Guizot (1840–48). During the remaining ten years of the July monarchy (1830–40) there were 14 cabinets and the third republic between September 1870 and June 1940 gave rise to no less than 110. The record of the fourth republic (Jan. 1947–May 1958) followed the same pattern—21 cabinets in office in addition to several others which, once formed, failed to receive parliamentary approval. Similarly, in Italy there were 67 ministries in the 74 years between 1848 and 1922 and 12 in the first 10 years of the republic (1948–58).

Although frequent changes of cabinet have not always reflected a basic political instability—the eight De Gasperi ministries between Dec. 1945 and Aug. 1953 being a case in point—it remains generally true that cabinets on the European continent have had much shorter lives than those in Great Britain and also much greater difficulty in the execution of their programs. Countries faced by such difficulties have had recourse to various constitutional devices to maintain some form of governmental continuity. Both the Netherlands and Italy from time to time resorted to cabinets whose task was limited to the carrying on of current business—“caretaker” ministries whose continuance in power depended on avoiding major political issues. Such was the case of the De Geer cabinet of 1926 in the Netherlands, which deliberately refrained from drawing up a political program; the 1960 Tambroni cabinet in Italy had a similar origin. In France and the postwar Federal Republic of Germany attempts were made to erect formal constitutional barriers against frequent cabinet crises provoked by adverse parliamentary votes. The most severe of these was the

provision in the German republic's Basic law (art. 67) that the *Bundestag* can express its lack of confidence in the federal chancellor only by electing a successor by the majority of its members—the so-called “constructive vote of no confidence.”

It is doubtful, however, whether the existence of this provision, by itself, explains the remarkable stability of cabinets in postwar Germany. There the personal political strength of Konrad Adenauer was the decisive factor, just as in other countries individuals of the stature of Alcide de Gasperi (or, earlier in the century, Giovanni Giolitti) succeeded in maintaining apparently impregnable parliamentary positions for long periods. In such circumstances cabinets sometimes became so transparently dependent on the power of a single person that accusations of dictatorship followed from frustrated members of the opposition.

Even such powerful individuals nevertheless remain subject to ultimate parliamentary support. This is not the case in presidential-type regimes that some countries resorted to after failing to maintain stable government with parliamentary regimes. The need for greater governmental stability was one of the powerful motives for the constitutional changes in France brought about by the fifth republic. The result in that case—which has been described as “a Hanoverian monarch masquerading as a Republican President” (P. M. Williams and M. Harrison, *De Gaulle's Republic*, Longmans, Green & Co., Inc., New York, N.Y., 1960.)—is a variation on a constant theme in European politics: the search for a form of executive power which can overcome the weaknesses so often displayed by cabinets dependent on parliamentary approval.

(R. Pr.)

UNITED STATES

In the United States, the president's cabinet is altogether different from the British cabinet. It is composed of the heads of the co-ordinate executive departments, but the members do not have seats in congress and their tenure does not depend on favourable votes on administration measures. The existence of the cabinet and its operation are matters of custom rather than law, for the cabinet as a collective body has no legal existence or power. The constitution contains no mention of and no provision for a

* = Date appointed. † After Sept. 1947 the secretary of defense represented the national military establishment.

cabinet. It does, however, assume, in incidental references, that congress will establish executive departments. One of these references says that the president "may require the opinion in writing of the principal officer in each of the executive departments, upon any subject relating to the duties of their respective offices." This language is all that remained of an attempt by some members of the Constitutional Convention to provide for a specific presidential advisory council. Some of the framers felt that the senate, with its powers to ratify treaties and confirm appointments, would function as an executive council. But the most important reason for the omission was the feeling among the delegates that the wisest course was to leave the president free to decide for himself where to go for advice.

George Washington inaugurated the practice of consulting regularly with his department heads as a group. In 1789 he wrote that the first three executive departments had been instituted because of "the impossibility that one man should be able to perform all the great business of the state." Quite naturally, he turned to his subordinates in the executive branch of the government for assistance, the more so since the senate, anxious to preserve its legislative independence in a system of separation of powers, was reluctant to act as an intimate advisory council to the president. From the outset of his administration Washington sought advice, in informal conversation and in writing, from the three secretaries and from the attorney general, an official who was not made a department head until later. In the period

†Recess appointment, Oct. 1958 to June 1959. Senate failed to confirm appointment

1791-92 he began as a matter of convenience to consult occasionally with this group of four on important and confidential matters of government policy. By 1793 the meetings had become settled practice. The term "cabinet" was first publicly applied to the group by James Madison in 1793, and in a few years it had become a matter of general usage.

Gradually, as administrative duties increased and different problems arose in the expanding nation, new executive departments were created by congress. The departments of state, treasury and war were established in 1789. The offices of attorney general and postmaster general, which were also created in 1789, did not rank as regular departments until 1870 and 1872 respectively. but the attorney general was considered a member of the cabinet from

the beginning and, upon the invitation of President Jackson, the postmaster general became a member in 1829. Other department heads became members of the cabinet as follows: the navy in 1798, the interior in 1849, agriculture in 1889, and commerce and labour in 1903; the latter department was divided in 1913 into two separate departments, that of commerce and that of labour. with separate heads. In 1947 the head of the reorganized national military establishment, the secretary of defense, became a cabinet member, while the secretaries of the departments under his direction—army, navy and air force—were not given cabinet rank. The cabinet was increased to ten members in 1953 when a department of health, education and welfare was created, and Oveta Culp Hobby became its head. She was the second woman to hold cabi-

net office, the first being Frances Perkins, who served as secretary of labour under Pres. Franklin D. Roosevelt.

Washington's habit of calling regular and frequent cabinet meetings began a tradition that has been followed by every succeeding president. But it is important to remember that the cabinet exists solely to help the president carry out his functions as the nation's chief executive. He is virtually free to use it or not to use it as he wishes. The president may consult with cabinet members before making a particular decision but the responsibility for making that decision is nevertheless completely his. If he does not choose to consult with cabinet members there is little they can do about it. A story is told about a disagreement in Abraham Lincoln's cabinet that found the president's viewpoint opposed by all the members of the group. Lincoln called for a vote and announced the results—"One aye, seven nays: the ayes have it." The story may not be true, but it illustrates the nature of the relationship between the president, who makes final decisions, and the cabinet, which only advises. Some presidents have relied on their cabinets a great deal and others have done so relatively little. The great variety in usage is accounted for by differences in the kinds of problems under consideration and, most importantly, by the differences in ability, temperament and working habits among individual presidents.

The cabinet meets regularly, usually once a week, at a time fixed by the president. Attendance at meetings has not, from the time Washington invited his attorney general, been restricted exclusively to those department heads who are of cabinet rank. Presidents have exercised their discretion in inviting to meetings, either on a regular or an occasional basis, other high government officials. A significant expansion in the number of such officials occurred under Franklin D. Roosevelt, Harry S. Truman and Dwight D. Eisenhower. The vice-president, for example, was more often invited to attend cabinet meetings, as was the U.S. representative to the United Nations. During the Eisenhower administration, for instance, the number of regular and equal participants at cabinet meetings was about 20.

The business of cabinet meetings is initiated either by the president or the members. Usually the meeting opens with some comments by the president, either presenting a problem for discussion or passing along information to the group. Depending on the nature of his remarks, a round-table discussion or individual comments will follow. Typical items of business include: presidential speeches that relate to the over-all policies of the administration, legislative proposals being prepared for presentation to congress, the state of public opinion on matters of current concern and reports by individuals on departmental activities of general interest to the group. When the president has finished with his business, cabinet members are given their chance to raise questions for consideration by the tradition of proceeding around the table. Usually the order of speaking has followed the order in which the departments were established—the secretary of state having the first opportunity and so on to the most recent addition to the group. The importance and success of cabinet sessions have varied greatly over the years. Some have been of help to the president; others have been more nearly a waste of time.

The cabinet, with a few early exceptions, does not take votes. The president may, on occasion, summarize a discussion and state what seems to him to be the general sense of the meeting. He may or may not announce his decision at the meeting. Cabinet transactions are, by public custom, kept secret. No formal or detailed records are kept. Information about them (except for occasional "leaks" to the press) comes mostly from the memoirs or reminiscences of former cabinet members. A notable exception occurred when a newspaperman was given, for use in his book, extensive notes taken in President Eisenhower's cabinet meetings. (Robert J. Donovan, *Eisenhower: the Inside Story*, 1956.)

President Eisenhower made several changes affecting his cabinet machinery in 1954. His previous experience in military organizations, where the emphasis was on regularized staff procedures, made him want to organize his political advisers in a similar system. He set up a cabinet secretariat (a secretary to the cabinet and one assistant) with responsibility for planning an agenda for

cabinet meetings and circulating in advance information on the items to be discussed. It also supervised the implementation of decisions reached at the cabinet table. The purpose of these arrangements was twofold; first, to try to cut down on the unplanned and haphazard nature which often characterizes cabinet discussions, and secondly, to try to increase the efficiency with which presidential decisions made in the cabinet meeting are carried out. The secretariat had some success in accomplishing these ends, mostly because the machinery suited the working habits of President Eisenhower. Other presidents, with different methods of decision-making, however, might not have found the secretariat as congenial or as helpful.

Many different factors enter into the president's selection of his cabinet. Ordinarily, all members are of the same political party as he. Some may be personal friends who are not well known to the public; others may be political leaders of national reputation. Normally, the group contains representatives from different sections of the nation. The desires of pressure groups may influence the selection of certain members. Farm groups, for example, will be interested in the appointment of the secretary of agriculture, business groups in the secretary of commerce, labour groups in the secretary of labour. Some men are chosen for their legislative experience; others are selected for their executive experience in government or in business. Still others will be men with special talents, whether lawyers, diplomats or party politicians.

While nominations to the president's "official family" must be confirmed by the senate, confirmation is normally given promptly and without objection. Only six nominees were rejected during the period from 1789 to 1960. Cabinet appointment is for the duration of the administration; however, the president may dismiss any member at pleasure, without approval of the senate. Dismissals are rare, but individual resignations have been fairly common. Department heads may also be removed by impeachment but such action is extremely rare. In 1876 impeachment proceedings were brought against Secretary of War William W. Belknap but he was not convicted.

Under the Presidential Succession act of 1886 the cabinet was given a special role in the event that both the president and vice-president died, resigned, were removed or were unable to serve. The members of the cabinet were next in line of succession, beginning with the senior member, the secretary of state. The Presidential Succession act of 1947 modified this procedure to place the speaker of the house of representatives and the president pro tempore of the senate ahead of the cabinet members.

The cabinet is only one of many sources of advice and assistance that the president may use in fulfilling his executive responsibilities. Under President Eisenhower, for example, questions of foreign policy were considered by the national security council, and cabinet business was restricted to domestic affairs. Since cabinet members are often more interested in their own particular departments than in the president's broad over-all problems, he must sometimes turn for advice to individuals and groups outside the cabinet.

CABINET FURNITURE is the term used to describe all the varied pieces of furniture whose chief use is for storage. Even migratory peoples who had little need for seat furniture developed portable cabinet furniture, and even in cultures, such as the Japanese, in which few specialized furniture forms have developed, storage pieces are to be found.

Characteristically, a piece of cabinet furniture must have a fixed frame with a movable panel. The simplest storage pieces are boxes and similar containers. A box is formed of six sides, one of which is a lid that opens to allow access; the lid may slide or it may be fastened with hinges, hasps or catches. Boxes have been made from hide, wood, bark, metal, paper products and ceramics, sometimes covered with leather or fabric. Other containers related to the box (barrels, crates, ceramic vessels) have been used for storage; clay vessels were commonly used in most ancient cultures.

A great variety of storage furniture evolved from the box. A box that is lifted off the floor on legs, for example, becomes a chest or cabinet. Such improvements as drawers (essentially boxes within a box), interior compartments and fall fronts led to the development of specialized furniture forms such as the chest of drawers and the desk. Storage areas sometimes are incorporated into seat furniture, producing dual-purpose pieces.

Not all cabinet furniture is movable. From antiquity the practice of making storage space a part of interior architecture has persisted; such pieces often have been constructed in cabinetwork, fitted into the structure of the building.

The rest of this article is a historical survey of the forms of cabinet furniture; for the development of furniture styles *see* FURNITURE.

ANCIENT WORLD AND FAR EAST

Some pieces of Egyptian cabinet furniture have survived, and other types are known from wall paintings and bas-reliefs. The nooden box was the dominant form, often painted with representations of rulers, deities and symbolic forms. The most imposing Egyptian boxes were the sarcophagi (*see* SARCOPHAGUS). Laminated wood often was used in making the tops and ends of these cases, thin riven layers of wood being pegged together, the grain of one layer perpendicularly to the grain of adjoining layers. The resulting product was highly durable. Some sarcophagi were decorated inside and out.

Actual pieces of cabinet furniture from the ancient near east have not survived, but such furniture is known from extant art. As in Egypt, the box was the standard form, ranging in size up to the very large containers in which the treasures of kings were stored. The boxes (which probably were made of wood) often were decorated with designs similar to architectural details.

Greek cabinet furniture is known both from surviving examples and from pictorial representations. The box was still the standard form, made of wood and often painted. Coffins made in the Crimea in the 4th century B.C. testify to the skill of Greek carpenters. The arched or gabled lids of these pieces were made from pegged laminated wood, much in the manner of the Egyptian sarcophagi. Decoration included applied stucco or terra-cotta ornament in relief, brightly painted, and marquetry of rare woods. Pottery boxes with removable lids also were used for storage; some extant examples are decorated with red-figured paintings, like those found on Greek table pottery.

Roman furniture is known from surviving pieces as well as from representations in fresco and vase paintings. Boxes varied in size up to large wooden chests for storing money and clothing. Treasure chests, also made of wood, covered with bronze plates or bound with iron, had hinged lids secured by heavy locks. Paintings of chests found at Pompeii show that the Romans were familiar with framed paneling; *i.e.*, panels filling in a rigid structural framework, fastened with dowels or pegs. Previously the size of a chest had been limited by the size of its surface planks; with the framed-paneling technique, however, larger surfaces, of lighter weight, could be assembled. Chests often were supported on lion feet. Wall paintings at Pompeii show cupboards, apparently attached to the walls, with paneled doors and, probably, shelves inside.

Chinese furniture is portrayed in very early paintings, and so little change in style has occurred through the centuries that the forms are difficult to date. Many Chinese boxes are made of hide, stitched at the corners, but Chinese boxes of black lacquer from the 8th century are preserved in the Shōsō-in (the imperial museum at Nara, in Japan). Cabinets, chests and desks were made in red and black lacquer. Cabinet pieces also were constructed of a variety of hardwoods, sometimes inlaid, lacquered or carved. Chests and large cupboards, masterpieces of careful joinery, were decorated with brass and bronze pulls, hinges and mounts. An important piece of furniture was the scholar's desk, sometimes a writing table with drawers, on high legs, sometimes a table with compartments and drawers extending down to the floor. Boxes and chests for storing books and writing equipment were used as supplementary desk furniture. Cabinet furniture in Korea was similar to Chinese.

Fewer specialized furniture forms were developed in Japan, and those were easily movable. The box, made from basketry, lacquer or wood, was standard, though with many variations. The stationary desk, evolved from the low table, was an extension from a bay window, with a writing surface and compartments for holding writing equipment.

EUROPE AND AMERICA

Middle Ages.—As late as the mid-12th century chests that were set up in churches to collect money were often mere tree trunks, hollowed out by chopping, chiseling or burning; lids, if they existed, were made of rough, heavy boards. Five massive and unique chests from the 12th century, preserved in the Valère Castle church in Valais canton, Switz., are constructed of wide timbers secured with broad-headed nails and stand on four heavy legs; they are decorated with elaborate chip carving and open Romanesque arches. Chests of the period sometimes were covered with leather, bound with iron straps or scrollwork, inlaid, carved or decorated with painted plaster reliefs, though more often they were undecorated. Easily transportable and readily procurable, chests were the most widely used pieces of furniture of the middle ages, in contemporary illuminations often seen arranged around walls, and used for both seating and storage.

When framed paneling came into general use at the beginning of the 15th century, in the Burgundian Netherlands, cabinet furniture design began to evolve rapidly, culminating in this era in the upright cupboard, usually containing shelves and sometimes doors. The drawer was an innovation of the 15th century, originating probably in Burgundy or Flanders as a small portable chest installed inside a larger piece of cabinet furniture. The *armoire*, a movable cupboard fitted with doors, shelves and sometimes drawers and most often used for storage of clothing, also probably developed during this period. The desk, a box fitted with a hinged lid and placed upon legs, also began its evolution during the middle ages. Dual-purpose furniture began to develop, chairs and tables sometimes containing compartments or drawers for storage.

Renaissance.—The Renaissance style in furniture, beginning in Italy, showed a strong architectural influence: the function of a piece often was subordinate to its design. The box persisted in an important form known as the *cassone*, a marriage coffer used for storing the household linens that formed an essential part of the bride's dowry. These magnificent coffers, with bold and massive feet shaped like lions, other animals or claws, were raised on low platforms. They were richly adorned with carving, gilding, intarsia or gesso, and commonly were painted inside and out with scenes from the Bible or classical mythology. The family arms often were emblazoned on the front. The desk evolved further; in some instances a slant-top box was put atop a frame, other examples contained drawers below a flat surface. Large storage cupboards, sometimes in plain walnut, sometimes painted and gilded, were widely used; painted cupboards were commoner in the early Renaissance, carved ones later. Cupboards contained shelves above, sometimes concealed behind small doors; a large open shelf in the middle; and shelves below, also concealed by doors. Very large cupboards were made in two pieces.

The style of the Italian Renaissance, of course, soon came to

affect the design of cabinet furniture in France and the Low Countries, though French furniture of the 16th century tended to be more delicate than the Italian. Chests remained an important form, their ornament often showing the influence of the designer Jacques Androuet du Cerceau. Cabinet pieces were inlaid with coloured woods, semiprecious stones, ivory, nacre and marble. Large cupboards were architectural in form. The armoire, which now came into wide use, was a tall, movable cupboard (the ancestor of the wardrobe) made in two sections, the top fitted with many small drawers, the bottom containing shelves, concealed behind one or two large doors, for storing clothing.

A cabinet piece common in Spain was the *vargueno*, a chest of drawers placed on a high wood and iron frame. Its drawers were concealed behind a fall front, strap-hinged with iron or bronze, which, when dropped, became a writing surface. The drawer fronts were often painted and the front sometimes was painted and inlaid with woods and ivory. The *vargueno* combined Moorish decorative elements with an essentially Renaissance structural form.

The furniture of England did not come under Italian Renaissance influence until about 1520, and even then the influence was seen mainly in superficial Italianate decoration on essentially medieval forms. Workmen from the continent brought with them new ideas, however, and by the middle of the 16th century an individual English style was beginning to evolve. Enrichment of flat surfaces by painting, inlaying or carving was characteristic. The chest remained an important cabinet piece, a well-known type being the Nonesuch chest, the front of which was decorated with a representation of Nonesuch palace in parquetry. Because of their resemblance to German chests inlaid with architectural scenes, it is believed that these were made in Germany or by German workmen. They were largely responsible for the popularity of inlaid furniture in England.

Toward the end of the 16th century the court cupboard began its evolution. This was a large piece, usually in two sections, each with open shelves, for the display of plate and other important possessions. The earliest examples had heavy, turned baluster supports and often were intricately carved. A chest with drawers began its evolution toward the end of the century. Desks generally were merely portable boxes placed on tables or frames.

Baroque.—The 17th-century baroque ideal, as reflected in furniture, required that a piece be conceived as a single unit, all its design elements contributing to a harmonious total effect. The play of light and shadow over the surface was an important design consideration, and broken pediments, heavy moldings and twisted columns were borrowed from architecture. The influence of the orient was strong during this period. Lacquer furniture, screens and boxes began to be imported into Europe from India and the far east, and panels and pieces of oriental lacquer were incorporated into case pieces made in Europe. By the end of the 17th century lacquer pieces imitating eastern products were being made in Europe. Tropical woods also were imported and used in furniture making. Italian cabinets and cupboards of walnut and ebony had heavy, richly carved framework and panels inlaid with marble and semiprecious stones, the entire piece being supported by heavy, turned legs, numbering four to eight. In Flanders massive cupboards with four doors, two above and two below, were made from oak, elaborately carved and inlaid. The linen-press, developed at this time in Flanders or Holland and usually made of oak, was a contrivance for pressing napkins, sheets and other linen articles.

During the late 17th and early 18th century André Charles Boulle (*q.v.*) designed and built cabinet furniture veneered with tortoise shell or exotic woods and inlaid with brass or ivory, and though other craftsmen executed pieces in the same style, Boulle's name is generally associated with this furniture. Boulle's case pieces included the cabinet, cabinet-on-frame, desk, chest of drawers and coffer. The workmanship was of the highest quality, and pieces often were embellished with heavy gilt mounts that protected the corners.

In England significant changes and developments in furniture design did not occur until after the middle of the 17th century.

The taste for oriental lacquers became widespread, and a process of imitating these works, called *japanning* (*q.v.*), was developed. In 1688 John Stalker and George Parker wrote *A Treatise on Japanning and Varnishing . . .*, which included patterns for designs as well as a description of the process. Cabinets-on-stands, japanned or with oriental panels incorporated, generally had two doors concealing numerous small drawers or compartments. The cabinet rested on a carved and sometimes gilded or silvered stand.

During the reign of William and Mary the taste of the Low Countries was brought to England by the court and the workmen they imported. The chest-on-frame, often called a highboy, a chest of drawers resting on a frame that held it above the floor, was an important form, commonly made of walnut wood. Drawer fronts were inlaid and surfaced with veneer made from walnut burl; drawer pulls shaped like teardrops, and engraved quatrefoil escutcheons, further ornamented the drawer fronts. The base of the chest had four or six trumpet-shaped, turned legs connected by flat stretchers. The dressing table, sometimes called a *lonboy*, a cabinet form closely resembling the lower section of the chest-on-frame, was made in one piece, and had drawers and trumpet-shaped legs and stretchers. Writing furniture was developed in a variety of forms. The chest with a desk enclosed, the latter fitted with pigeonholes and small drawers, was one of the most ingenious types.

At the beginning of the 18th century, during the reign of Queen Anne, another style influenced by the contemporary furniture of Holland came into fashion. Ornamentation was reduced to a minimum, and curved lines began to replace the square lines of the William and Mary period. The cabriole leg, derived from the curve of an animal's leg, adapted from classical styles, and terminating in a pad, trifold or ball-and-claw foot, became the standard furniture support. Stretchers, commonly seen on earlier pieces of cabinet furniture, were discarded. The chest-on-frame and dressing table remained standard forms, differing from their predecessors chiefly in their simplicity and in the use of the cabriole leg with no stretchers. The double chest of drawers, made in two parts with drawers above and below, was an innovation. In some pieces the drawers extended to the floor; others were elevated on short cabriole legs. The desk contained an inner compartment of pigeonholes and drawers, the front usually falling to form a writing surface; drawers were set in below and the whole rested on cabriole legs.

American colonial furniture in the 17th century varied from one region to another according to the nationality of the settlers, though English furniture design was predominant. The chest of drawers, chest-on-frame, dressing table and desk made in America were conceived in the forms of pieces being made in England, but, since there was a lag in the transmission of styles, America was always behind the current English taste. Some of the colonial pieces were of high style and as fine as anything made in London; others, made by less skilled craftsmen, had a naïve provincial quality.

Rococo.—France.—The rococo style—one of the leaders in which was Juste Aurèle Meissonier (*q.v.*), designer, architect, goldsmith and sculptor—characterized by great delicacy, movement and asymmetry, directly affected French furniture design only from about 1735 to 1765. The central features of the style were the use of the C-curve and the S-shape. With this were combined ribbons, trophies, floral and shell motifs. The cabriole leg was refined to great delicacy and lightness. Chinese themes were popular, and pagodas, waterfalls, birds and Chinese figures are common decorative motifs.

Charles Cressent (*q.v.*), a pupil of Boulle, was the leading exponent of the *régence* style, excelling in the quality of ormolu (brass made to imitate gold) mounts he applied profusely to furniture. During the *régence* period also marquetry of coloured woods began to replace ebony and ebonized woods.

The commode, derived from the late 16th-century Italian chest, was one of the most important furniture forms, developed in France between 1705 and 1710 and made in quantity by 1720. The commode contained three large drawers (the technical joinery problems involved in making large drawers having now been

overcome) running the width of the piece, with a row of smaller drawers above. The bombé or swollen shape was introduced at this period, the curvilinear form being incorporated into the body of the piece as well as applied to externals such as legs or tops. The sides and front of a *bombé* commode undulated in sinuous curves, and the drawers were generally so well fitted that only a hairline betrayed their existence. This form was adopted and further enriched by rococo cabinetmakers. Chinese lacquer panels or marquetry inlays were incorporated into the front of the bombé commode, the top was marble, and the corners and legs were covered by ormolu or silver mounts, the most celebrated makers of which were Jacques and Philippe Cafféri (see CAFFIERI).

The desk or *secrétaire*, another important form, was characterized by a drop front that, when dropped, served as a writing surface and, when closed, concealed small drawers arranged in rows; below was a door or doors concealing shelves or drawers. The tambour—a sort of flexible shutter made of thin strips of wood glued to cloth and running in a groove—which developed at this time was sometimes incorporated into the *secrétaire*. The movable bookcase, inlaid and mounted with ormolu, evolved during the Louis XV period.

The writing table, which began to appear at the end of the rococo period, usually had three drawers, the whole piece being supported on four cabriole legs. The top was covered with leather or coarse woolen cloth called *bure*, from which the French word for desk, *bureau*, was derived. A cartonnier or set of shelves or drawers sometimes formed an integral part of the *bureau*, but more commonly it was a separate piece set on the *bureau* top. The cylinder-top *bureau*, the original roll-top desk, was a development of rococo cabinet furniture. Incorporated into the front of this type of *bureau* was a sliding door of tambour construction that could be pulled back to reveal a set of drawers and shelves. Slides could be pulled out and used as writing surfaces. The cabriole legs of the *bureau* were ornamented with gilt mounts.

Cupboards had glass-paneled doors opening upon an interior fitted with shelves. The corner cupboard, originally intended for utilitarian purposes, by the middle of the 18th century had become an elegant piece of drawing room furniture. These cupboards, of the same height as the commode, were essentially triangular in shape, supported on three or four short legs, with marble or wooden tops; they were inlaid or decorated with lacquer and had elaborate metal mounts.

England.—In England during the early 18th century the influence of the continent could be observed in the furniture designed by the architect William Kent (*q.v.*). The essential lines of his pieces were classical, in keeping with the architecture of the Palladian houses they were designed to grace; the ornament was intricate, curvilinear and baroque. Kent designed chests of drawers, organ cases and desks as well as tables, chairs and room interiors.

Although there was resistance to rococo in England, by 1740 it had begun to appear. The commode remained an important form, varying from a simple chest containing three drawers to a piece that incorporated swell fronts with doors and drawers, the whole supported on elaborate cabriole legs. The chest-on-chest (highboy and tallboy), generally made in two sections, had drawers above and below. The clothes cupboard, a closely related form, had in its upper part doors, behind which were shelves or drawers, and in its lower part drawers. Both the chest-on-chest and clothes cupboard generally rested on four bracket feet.

Library furniture was developed in great profusion. The desk had several forms, the chief being the *bureau*-bookcase and writing or library table. The *bureau*-bookcase had a case with two doors (either glass-paned or solid) and interior shelves above; the bottom had a fall front (which formed a writing surface) concealing interior compartments and, below this, drawers. The feet were of the bracket variety, or the whole rested on cabriole legs, ornamented in the French (rococo), Gothic or Chinese style. The writing or library table, related to the French *bureau*, had a flat top utilized as a writing surface, an empty space in the centre below (which allowed a chair to be drawn up) with drawers on either side; sometimes these were wide enough to be used by two

persons, one on either side. The English bookcase was more strongly architectural than was the French model, having a pedimented top, a frieze above large doors that protected interior shelves, and doors or drawers below; sometimes a fall-front desk was incorporated into such a piece. The cabinet-on-stand often was constructed in the Chinese style, in imitation of a Chinese cabinet.

Mahogany was the favoured wood for English furniture of the period, having been first imported about 1720 and quickly replacing walnut. Much provincial furniture, however, was made from oak and yew, executed in a simplified version of the high style of the day.

Colonial.—France and England were the two most important countries in setting taste, and their influence was to be seen in almost all European countries. Colonial furniture showed the influence of the mother country. In America the English rococo was the dominant style, and Boston, Newport, New York, Philadelphia and Charleston produced mahogany furniture that ranked with the best made in London. The furniture of Boston, Philadelphia and Charleston was noted for its profuse decoration—indeed, the richness of the carving on Philadelphia case pieces has not been surpassed in American furniture—and strict adherence to London models; that of New York and Newport was plainer and more amply proportioned.

An important innovation in cabinet furniture was the block front, developed by the cabinetmakers of the Goddard and Townsend families (see GODDARD AND TOWNSEND) of Newport, R.I. The blocking was formed by the contrast of a raised area against a recessed area. The grain of the mahogany was accentuated and the play of light and shadow over the front produced a dazzling effect. The chest, chest-on-chest, desk and dressing table, when made with a block front, generally had little carving or other wood ornamentation.

Neoclassicism.—Early.—With the development of the neoclassic spirit in furniture design—in which the architect Robert Adam (*q.v.*) was one of the most important figures—the commode lost its serpentine shape and developed a semicircular front with veneered, inlaid or painted decoration. The bookcase retained much the same shape as its rococo predecessor, but classical decorative motifs were imposed. The wardrobe, desk, chest-on-chest and chest of drawers persisted in the new style.

One of the most important new developments was the sideboard, evolved from the side or serving table. Intended for use in the dining room, both for serving and for storing serving utensils, it contained drawers and compartments and had four or six tapered or turned legs. In some examples, at the rear of the wooden top there was a brass railing on which towels and napkins could be hung. Hepplewhite and Sheraton designed knife boxes, square or urn-shaped receptacles containing compartments for cutlery, to stand either on the sideboard or on pedestals beside it. A form associated with the sideboard and knife box was the cellaret ("little cellar"), a wooden box with zinc partitions holding ice; wine bottles were placed in it for chilling. The cellaret might be an integral part of the sideboard, concealed inside a drawer or compartment, or a separate box designed to be used near the sideboard. It usually contained a tap through which melt water could be withdrawn.

Many specialized case forms associated with personal grooming began to develop: dressing tables, wash stands and shaving stands containing ingeniously designed compartments that pulled out or folded back.

American furniture was much under English influence, and the books of Hepplewhite and Sheraton (*qq.v.*) were widely used by colonial craftsmen, who often constructed remarkably exact interpretations of the designs. Salem and Baltimore became important centres of furniture manufacture, the cabinet pieces made by Samuel McIntire of Salem being among the finest examples of American furniture of the period. Baltimore excelled in the production of painted furniture; on a background of red, black or white, colourful floral decoration was executed around panels on which were painted scenes from classical mythology. The New York cabinetmaker Duncan Phyfe produced the most highly indi-

vidual neoclassical furniture, utilizing a unique combination of classical elements.

In France, neoclassicism was beginning to be noticed by the middle of the century, but it was not seen in furniture design until the 1760s. At first, classical ornament was sparingly applied to essentially rococo shapes; then the curved shapes began to straighten and eventually became rectilinear. The bombk form disappeared from commodes and legs became straight, tapered and fluted. Marquetry, now of classical inspiration, was popular, as were ebony and oriental lacquer panels. Boulle marquetry, which had dropped out of fashion during the Louis XV period, was revived. French cabinet furniture forms were essentially rococo and less original than the English. The commode, *secr'taire*, bookcase and corner cupboard were important pieces.

The influence of the Louis XVI style was felt all over Europe, and excellent furniture in this style was produced in Germany, Denmark, Sweden and Italy.

Empire.—In the Empire style, which began to evolve at the end of the 18th century, few new cabinet forms were developed. The commode, severely rectilinear, with drawers or doors concealing shelves or compartments, remained a basic form. Commode tops were of marble or wood, and gilt mounts were used along with painted and inlaid decoration. The bureau now developed as a form separate from the *secr'taire*. Both were desks, the former a low piece related to the writing table, the latter a tall cabinet piece with a fall front. Tall chests of drawers, bookcases and corner cupboards were all characterized by heavy application of classical ornament.

In the United States the Empire style was widely adopted, New York being the great centre of cabinetmaking. Duncan Phyfe (*q.v.*) developed from neoclassicism to the severe classicism of the Empire; his case pieces of this period, heavy and ornately carved, lost the individual quality of his earlier products. Craftsmen who came to New York from Paris produced cabinet furniture that closely followed French models of the day. One of these was Charles Honoré Lannuier, whose case pieces are characterized by use of French gilt mounts and metal inlays.

Regency.—An important name associated with severe classicism or the Regency style in England is that of Thomas Hope (*q.v.*), who in 1807 published *Household Furniture and Interior Decoration*. His massive case furniture included bookcases, chests of drawers, commodes and desks. George Smith's *Cabinetmaker and Upholsterer's Guide* (1826) contained designs for sideboards, wardrobes, commodes, bookcases and *secr'itaires*, richly carved with classical ornaments and often touched with gilt. The inclusion in this work of a low desk called a lady's *secr'taire*, distinct from the large bookcase *secr'taire*, heralds the era of greater specialization that was to develop in the 19th century.

Biedermeier.—Provincial Biedermeier-style furniture, produced in Germany and Austria from about 1815 until the middle of the 19th century, was characterized by use of geometric shapes and by freedom from excessive detail. Typical cabinet pieces, made from fruit woods, mahogany, oak and birch, were chests of drawers, bookcases, commodes, desks and small toilet pieces, exhibiting gracefully curved lines.

Romanticism and Revivalism.—Gothic revival furniture (which had begun to appear in the late 18th century) was characterized by the use of the pointed arch and of ornaments derived from architecture; hence the feeling of the case pieces was primarily architectural and they were heavy in general appearance even though the ornamentation or tracery might be delicate. Among the important designers of furniture in this style was A. W. N. Pugin (*q.v.*), better known as an architect. Gothic revival furniture was more popular in England than in France; in the United States it remained in fashion until the middle of the century. Andrew J. Downing included Gothic interiors and furniture in his influential *Architecture of Country Houses* (1850), showing monumental sideboards, bookcases, chests of drawers and desks that combined a multitude of details from many sources.

A revived interest in the orient began to manifest itself during the first decade of the century; India and China were sources of inspiration for cabinet pieces made from bamboo and lacquer

or japanned panels, and Turkey and the near east inspired cabinet furniture made from dark woods and inlaid with mother-of-pearl and ivory. French revivals—Louis XIV, XV and XVI—were familiar, although not always accurate. The use of power machinery in the production of most of this furniture caused it to be coarse and to lose the qualities of individuality the originals possessed. Other revivals—Renaissance, Tudor, Norman, Italian, Elizabethan—produced new versions of the *cassone*, armoire, court cupboard and other pieces that were most unlike their models in the detail that was applied to them.

MODERN TRENDS

19th Century.—Innovations in cabinet furniture design began to appear around the middle of the 19th century. In New York city, John Henry Belter (generally in Louis XV style) made drawer fronts of laminated wood, which was stronger and allowed more intricate carving than did solid wood. A variety of storage pieces, from small boxes to commodes, was made from papier-mâché, sometimes inlaid with mother-of-pearl, painted or gilded. Mechanical furniture appeared, a single piece of which might serve several functions; in 1864 a portable camp chest that was a storage piece, chair, lounge and table was patented in the United States.

By the 1870s aestheticism, drawing its inspiration from the orient, especially Japan, became a dominant English trend, and the furniture it produced was light, delicate and based on straight lines. E. W. Godwin and Christopher Dresser were exponents of this style; Godwin's cabinets, bookcases and sideboards were light and simple in line. In the latter half of the century, the arts and crafts movement (*q.v.*) produced cabinet furniture that was free from the fussy detail of revival furniture. Some of the cabinets-on-stands designed by William Morris, although based on Gothic predecessors, showed a remarkable simplicity and restraint of line. The Globe-Wernicke sectional bookcases—which are considered the forerunners of modern "unit" furniture and which were developed toward the end of the 19th century and continued in use into the 20th—had glass doors that could be lifted and slid into the body of the case. Art nouveau (*q.v.*) was represented in furniture characterized by severe curvilinear surfaces and a use of asymmetric inlay and carving; leading designers of art nouveau cabinet pieces were Henry van de Velde, Victor Horta, Émile Gallé and Hector Guimard.

20th Century.—Throughout Europe and America simpler cabinet shapes began to appear. Handicraft traditions were allied to modern designs in many elegant and handsome variations, culminating in the Paris style of the 1925 Exhibition of Decorative Arts. At the turn of the century in the United States the arts and crafts movement was reflected in the Mission style, using predominantly oak wood, straight lines and heavy proportions. The early furniture designed by Frank Lloyd Wright, a leader in producing cabinet furniture, often built-in, that was harmonious with architecture, was related to that of the arts and crafts. In spite of arts and crafts, however, machine productions became a dominant factor in furniture design in the early part of the century, being advocated by such an influential institution as the Bauhaus (*q.v.*). Cabinet furniture made under this influence was undecorated, with highly polished wooden surfaces; Marcel Breuer, among others, designed furniture of this type to be used in his own architectural settings. By the 1940s Scandinavians were leaders in furniture design. Plywood was used in the construction of cabinet pieces by the Finnish designer Alvar Aalto; machine production introduced panel plastics into furniture construction in America, and molded plastics also were used in manufacture of drawer trays, a notable structural simplification. The trend toward making storage areas part of interior architecture has been dominant throughout the century, at the expense of cabinet work. Large wardrobes and sideboards in particular have tended to disappear from the selections of available cabinets.

CABLE, GEORGE W (ASHINGTON) (1844-1925), U.S. author and reformer, noted for novels and stories dealing with life in New Orleans, was born in that city on Oct. 12, 1844. His first books, *Old Creole Days* (1879), a collection of stories first published in *Scribner's Monthly*, and a novel, *The Grandissimes* (1880), marked Creole New Orleans as his literary province and were widely praised. These works recaptured in a delicate gallicized prose and with a whimsical play of imagination the picturesque scene and the tone of life in the old French-Spanish city. Yet they employed a realism new to southern fiction. Though Cable was the son of slaveholders and fought in the Confederate cavalry, he came to see slavery as a moral wrong and held the same view of attempts to deny the freedmen full public rights. Thus his early fiction draws strength and urgency from the overtones of moral condemnation in his handling of caste and class and authorized oppression, whether before or after emancipation. He used essays and public lectures to urge the cause of Negro rights, in the face of violent abuse in the southern press, and he published two collections of his social essays, *The Silent South* (1885) and *The Negro Question* (1890). He abandoned the effort only after race discrimination in the south had become entrenched. In 1885 he settled in Northampton, Mass. Novels set mainly in the south came from his pen until he was past 70, but though better constructed they lacked the freshness and charm and also the force of moral conviction that characterized his early books. Cable died in St. Petersburg, Fla., on Jan. 31, 1925.

See Arlin Turner, *George W. Cable: a Biography* (1936), which contains an extensive bibliography. (A. Tr.)

CABLE, originally a rope, made of hemp or other material, of relatively large diameter; the term subsequently was applied to the heavy chain used with ships' anchors. Although this article deals primarily with chain cable, the old usage whereby the length of a hempen anchor cable was 101 fathoms survives in the British naval measurement of a "cable's length," or one-tenth of a nautical mile. Wire rope, frequently referred to as cable, woven of many small wires, has generally superseded hemp cable in most engineering applications (see *WIRE: Wire Rope*; *ROPEWAYS AND CABLEWAYS*). Electric cables, composed of one or more insulated conductors, are used to carry electrical signals or power (see *CABLE. ELECTRIC*).

Chain anchor cables were adopted by the British navy after development in 1806-10 by Sir Samuel Brown, who later established works in south Wales for their manufacture. They are cleaner than hemp cables, are less susceptible to fouling and are less likely to be cut by rocks or damaged by enemy fire. Twisted links were suggested in 1813, and the stud—the crosspiece in each link to

FIG 1 — TWO LENGTHS OF CHAIN CABLE COUPLED BY A "JOINING SHACKLE" The end links (C) are made without studs in order to take the shackle. The adjacent links (B) are made larger to take the big studless links. The shackle (D) is shown. The bolt of the shackle is secured by a steel pin and lead pellet

FIG. 2. — MOORING SWIVEL. PUT IN THE CABLES OF A WARSHIP WHEN SHE IS RIDING BY TWO ANCHORS. TO PREVENT THE CABLES FOULING EACH OTHER AS THE SHIP SWINGS

prevent the chain from kinking—was introduced in 1816. In manufacturing iron chain cables, the bars are cut to the required length of link, at an angle for forming the welds and, after heating, are bent by machinery and welded, each link being inserted in the previous one before welding.

Iron chain cable has largely been replaced by cast-steel, high-strength welded steel and a forged steel known as Die-Lock (links locked together in dies). All three types have a high elastic limit and can withstand great shock. Die-Lock and welded-steel cables, being stronger and lighter than iron, are standard in the U.S. navy and widely used in the merchant marine. Distinguishing features of cast-steel chain are solid studs that are an integral part of the links and the absolute identity of each common link in the shot. Some types of high-strength welded-steel chain are constructed with alternate solid forged links that have integral studs, every other link having the stud welded in place. In Die-Lock chain the studs are also an integral part of the link, though they are split down the middle. A great advantage of cast-steel, Die-Lock and high-strength welded-steel chain

FIG. 3.—MOLD FOR CAST-STEEL CHAIN

FIG. 4.— OUTBOARD SWIVEL SHOT, DIE-LOCKED ANCHOR CHAIN

is that the studs cannot fall out, thus eliminating the pounding of the links one on another and the danger of kinking.

Chain cable is manufactured in lengths of 15 fathoms (90 ft.) known as shots, or in the British navy as "shackles of cable." Various types of connections are used to join the individual shots together and to connect the outboard end to the anchor and the inboard end to the chain locker of the ship. The U-shaped shackle and pin is not now as widely used as various types of detachable links. In general, these consist of interlocking or coupling plates held together by a stud and taper locking pin.

To indicate the amount of cable out, appropriate links are marked with white paint and with wire windings on the studs.

Ships ride to their cables by use of the brake band on the windlass or cable holder, using a chain stopper, guillotine or compressor. The cable is hove in by a power-driven windlass. (M. O'N.)

CABLE, ELECTRIC. Electric cables are usually used to transmit either power or information. An electric power cable transmits electrical energy from the point where the energy is generated to the point where it is used. The function of an electric communication cable is to transmit information, by electrical means, from one point to another. Descriptive terms, many of them self-explanatory, are frequently associated with the word cable, indicating its construction or use. Power cables may be described as bare (uninsulated), insulated, armoured, oil-filled, gas-filled, pipe type, or as dredge, service drop, vertical riser, etc. Communication cables are described as coaxial, telephone, telegraph, control, etc. The terms aerial, underground and submarine may refer to either power or communication cable. There is no clear distinction between an electric wire and an electric cable. Usually the former refers to a single, solid metallic conductor, with or without insulation, while the latter refers to a stranded conductor, or to an assembly of insulated conductors.

Power Cables.—Probably the simplest, as well as the most common, type of electric power cable is that which is suspended overhead between poles or steel towers. These cables consist of a number of wires, usually of copper or aluminum, twisted (stranded) together in concentric layers. Copper or aluminum is chosen for high electrical conductivity, while stranding gives the cable flexibility. Overhead cables are frequently subjected to severe mechanical stresses by high winds, or by the accumulation of sleet, or both. Because copper and aluminum do not possess high mechanical strength, alloys of copper or aluminum are sometimes used. Alloying increases the strength of the cable, at some detriment to its electrical conductivity. A more common solution of the problem is to include in the stranded assembly of a copper or aluminum cable a number of high-strength steel wires. The steel wires are protected from corrosion by a coating of zinc, copper or aluminum applied directly to the individual wires.

Many overhead cables, especially those operating at high voltages, have no insulating or other coverings. Cables operating at lower voltages frequently have coverings of asphalt-saturated cotton braid, Neoprene or polyethylene. These coverings offer some protection against electric shock to personnel accidentally contacting the line, and prevent short circuiting in case of temporary contact between the line and a grounded (earthed) object.

An equally important but less conspicuous type of electric power cable is installed in underground ducts, and is extensively used in cities where lack of space or considerations of safety preclude the use of overhead lines. The conducting element of such a cable is similar to that of the overhead cable, except that commercially pure copper or aluminum is invariably used (mechanical strength is not a problem underground), and the stranded conductor is frequently rolled to modify its shape and compactness, resulting in a cable of maximum electrical conductance and minimum size.

The conductors of any cable that is frequently or permanently in contact with grounded objects must be insulated throughout their length to withstand the full operating voltage. Cable insulations are usually thermosetting materials (natural rubber, silicone rubber, butyl, Buna S), thermoplastics (polyvinyl chloride, polyethylene), varnished cambric or oil-impregnated paper. Where high temperatures are encountered, insulations consisting wholly or partially of inorganic materials such as asbestos or fibre glass may be used. The thermosetting and thermoplastic insulations predominate for cables operating at 5,000 v. or less. Oil-impregnated paper insulation is usually used for cables of intermediate voltage, and is used almost exclusively for cables operating above 35,000 v. The required insulation thickness is dependent mainly on voltage, and may vary from about $\frac{1}{8}$ in. to 1 in.

The insulation of high-voltage oil-impregnated paper insulated cables must be maintained under pressure. Such cables are provided with longitudinal channels through which pressure is transmitted from pumps or other auxiliary equipment at the cable terminals. In an alternate design, the insulated conductors are installed in a steel pipe. The pipe is subsequently filled with oil which serves both as an insulating and a pressure-transmitting medium.

An insulated electric cable requires a covering over the insulation to protect it from mechanical abuse, moisture and other detrimental influences. A seamless lead or lead alloy tube (sheath) is extensively used as a protective covering for underground cables. For less exacting conditions, when greater flexibility is necessary, or for insulations less susceptible to moisture, protective coverings may be of nonmetallic materials, including impregnated fabric braids (in dry locations only), Neoprene, or one of the thermosetting and thermoplastic compounds already mentioned as insulations. Various combinations of metallic and nonmetallic materials are also used, the metallic part providing the primary moisture barrier and the other materials protecting the metallic part from damage, especially from corrosion. When exceptionally severe mechanical abuse is anticipated, additional coverings (armour) of saturated jute and steel tape, or of steel wire, may be applied as the final outer layer.

Some of the cables described above are suitable for overhead use, and such installations are common in suburban areas. The cables are rather heavy and have inadequate longitudinal strength; hence they are lashed to a high-strength cable (called a "messenger cable") which provides the necessary support. Telephone cables are also frequently installed overhead in a similar manner.

These overhead and underground power cables comprise a major portion of the electrical circuit from the generator to the point of utilization of the electric power. However, the balance of the circuit (and sometimes the entire circuit) may require specialized cables. Illustrative of these usages, and the special conditions to be met are: cables for steel mills, boiler rooms and electric furnace operation (high temperature); cables on mobile equipment (vibration); shipboard cables; cables in chemical plants (corrosion); submarine and mining cables (mechanical abuse); and portable cables for many uses (excessive flexing). Cables for use near nuclear reactors and in guided missiles and artificial satellites must withstand various types and intensities of radiation and extremes in temperature and pressure.

Communication Cables.—Cables used to transmit information are quite different from power cables, both in function and in design. Power cables are designed for high voltages and high current loads, whereas both voltage and current in a communication cable are small. Power cables operate on direct current or low-frequency alternating current. Telephone cables operate at higher frequencies, and coaxial cables used for radar, television and many other communication services may have to carry frequencies up to 10,000 mc. per second. A power cable usually has not more than three conductors, each of which may be 1 in. or more in diameter; a telephone cable may have several thousand conductors, the diameter of each being less than $\frac{1}{8}$ in.

The insulation of telephone cable is almost invariably of dry cellulose (in the form of paper tape wrapped around the conductor or paper pulp applied to the conductor) or of polyethylene. The insulation thickness is a few hundredths of an inch or less.

The conductors of a control cable are usually fewer in number, larger in size and more heavily insulated than those of a telephone cable.

A coaxial cable is a two-conductor cable in which one of the conductors takes the form of a tube while the other (smaller but also circular in cross section) is supported, with a minimum of solid insulation, at the center of the tube. Several of these coaxial units, along with other types of communication conductors, may be assembled within a common jacket or sheath. (For additional information on coaxial cable, see RADAR.)

Protective coverings for communication cables are similar to those for power cables. They usually consist of an aluminum or lead alloy tube, or a combination of metallic strips and thermoplastic materials.

The construction of long submarine cables for either telephone or telegraph service is somewhat different from that indicated above. Such cables usually have a single solid or stranded central conductor insulated with gutta-percha or polyethylene, over which may be applied a concentric outer conductor, followed by layers of asphalt or tar-impregnated jute roving and high-strength steel-wire armour. See also CABLE LAYING, SUBMARINE; ELECTRIC POWER: *Transmission*; INSULATING MATERIAL (ELECTRICAL); TELEPHONE; TELEGRAPH. (L. E. Fo.)

CABLE LAYING, SUBMARINE. Submarine cable is a transmission line of one or more conductors, suitably insulated and protected, for carrying electrical signals (telegraph, telephone, etc.) or electrical power under water. Its installation is called submarine cable laying.

Laying of the first successful transatlantic telegraph cable was completed on July 27, 1866, from Heart's Content, Newfoundland, to Valentia, Ire., by the famous steamship "Great Eastern." Since that time submarine telegraph cables have been laid all over the world.

Submarine telephony was well established early in the 20th century but was limited to short, unrepeatered cables laid in shallow water. (The repeater is an amplifier inserted in the circuit to maintain the strength and fidelity of the signal.) The first sub-

merged repeater installation was made in 1943 on a coaxial submarine telephone cable between Anglesey, Wales, and the Isle of Man. The first transoceanic telephone cable system, consisting of two submarine links, was completed in the mid-1950s, one link from Clarenville, Newfoundland, to Oban, Scot., and the other from Terrenceville, Newfoundland, to Sydney Mines! Nova Scotia. The great difference between the North Atlantic section of the system and all earlier transoceanic telegraph cables was the inclusion of submerged repeaters as an integral part of the cable and the use of two cables to provide a separate path for messages in each direction.

Cable Construction.— Submarine cables are made up of a core of one or more conductors, suitably insulated, which is covered and protected by layers of jute and armour. The conductors are usually stranded to improve flexibility and provide a conductive bridge across a possible break in any one of the elements. The core insulation must be able to withstand, without deformation or damage, the compressive and tensile strains to which it is subjected, and it must be electrically and physically stable after prolonged immersion.

Until the late 1920s a natural gum material called gutta-percha was used as insulation. Subsequently, improved substitutes, such as deproteinized rubber and polyethylene, were developed. The treatment and covering applied to the core of cables is varied to suit expected environmental conditions, but in any one cable run, the core is unchanged throughout its entire length. One or more layers of jute yarn is applied over the core to prevent damage by cutting action of the armour. The jute is given a chemical treatment known as cutching to guard against microbiological attack. Protection of the core insulation from marine borers may be provided by applying an overlapped thin metallic copper tape under the jute. Armour wires are applied over the bedding jute, followed by outer jute servings. All jute and armour applications are flooded with asphaltum tar compound.

The metallic elements of a cable are applied with a left-hand direction of lay to assure satisfactory handling characteristics. Directions of lay of the jute layers are similarly chosen. Fig. 1 shows the essential difference between the armour types employed and the approximate range of depths in which each is used. Mild-steel armour is used in the intermediate depths primarily to achieve weight and substance and thus withstand wear and damage. In deepwater cable, high-tensile steel armour is needed to withstand the strain of handling at great depths.

Cable-Laying Operations.— The selection of a route for a cable is guided by (1) the shortest route length; (2) adequate clearance for repairs; (3) minimum potential environmental damage; and (4) suitable terminal locations. To facilitate repair op-

FIG. 2.—H.M.T.S. "MONARCH" RECEIVING CABLE FROM DOCK AT NEWINGTON, N.H.

erations and avoid damage, cables are usually separated 15 to 20 mi. in deep water, but less separation is permissible as the water becomes shallower. To minimize the possibility of damage, cable routes are chosen so as to avoid fishing grounds, harbour areas, undersea canyons and mountains and areas where turbidity currents may occur. Turbidity currents are underwater landslides that are caused by earthquakes, floods or hurricanes. Sediment-laden water rushes down the side of an underwater slope carrying away anything in its path. It is essential to have the most detailed knowledge possible of the ocean floor along the route.

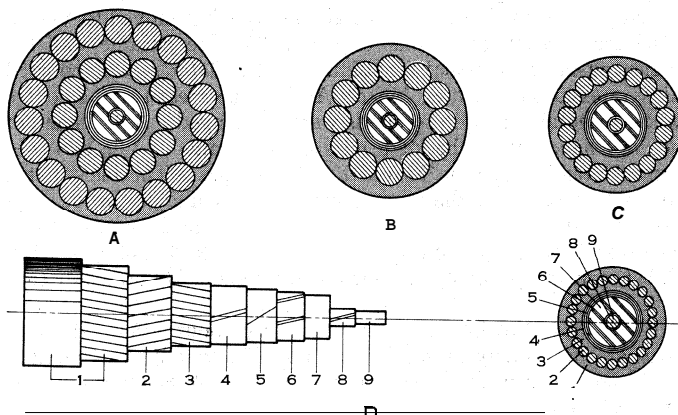

A typical cable-laying ship has an overhanging bow with three cable sheaves and a paying-out cable sheave on the stern. It is equipped with four steel cable tanks, each 41 ft. in diameter, with approximately 30,000 cu.ft. of coiling space in each. A watertight hollow steel cone is built in the centre of each tank to facilitate cable loading and laying. During loading, the cable is carefully coiled by hand, layer by layer, in the tanks in a clockwise direction from the outer edge toward the cone. The maximum capacity of the tanks is almost 2,000 mi. of deep-sea cable.

Two cable engines driven by electric motors are installed forward for use during pickup or laying. A single cable engine is fitted aft for use during laying. Dynamometers fore and aft provide measurements of cable tension.

Cable is laid at a ship speed of three to eight knots, and the selected cable route is followed as accurately as navigational facilities and techniques will allow. Cable is generally laid over the bow in shallow water to permit better control of the ship. In deepwater work, laying over the stern is preferable for lengths in excess of ten miles.

When laying over the stern, the cable is first led aft from one of the tanks along fair-lead blocks to the holdback gear (for pre-tensioning), and then given two to five turns over the cable engine drum depending on the weight of the cable and depth of water. From the drum, the cable passes through the dynamometer and then overboard through the after laying sheave. Drum braking is adjusted, within safe limits of cable tension, to provide for approximately 5% slack in deep water to allow for variations in the bottom and aid in later recovery during repairs. Less slack is required in shallow water. When laying over the bow, the same procedure is followed except that the cable is led forward and goes overboard through one of the bow sheaves.

Shore ends of cable are necessarily laid by barges and tugs or by the cable ship's boats. Usually the route to be followed is marked by buoys. The cable joining the shore ends is laid by the ship in sections depending upon the different types and lengths of cable required. Prior to splicing and during all cable-ship laying operations, the cable is under continuous test to detect

FIG. 1.—TYPES OF CABLES: (A-C) END VIEWS OF CABLES WITH MILD-STEEL ARMOUR AND (D) SIDE AND END VIEWS OF CABLE WITH HIGH-TENSILE ARMOUR

(A) for short runs, 2.68 in. diameter; (B) for depths to 350 fathoms, 1.84 in. diameter; (C) for depths from 350 to 700 fathoms, 1.40 in. diameter; (D) for depths greater than 750 fathoms, 1.21 in. diameter: (1) two servings impregnated jute, (2) 24 armour wires, (3) one serving cutched jute, (4) Telconax tape (gapped), (5) Tereido copper tape (overlapped), (6) six copper return tapes, (7) polyethylene, (8) three copper surround tapes, (9) copper centre conductor

faults that may occur during laying. Cable splicing may be done either in the factory or aboard ship. A splice must be so made that the spliced cable is electrically and mechanically equivalent to a similar, unspliced cable of the same length.

Cable Repairs.—In the repair of cables, the approximate location of the fault is initially determined from the shore terminals by electrical measurements which can be converted into distances. The cable ship then proceeds to the approximate position of the fault, lowers a grapnel to the bottom and drags it slowly back and forth until the cable is hooked by one of its protruding prongs. The speed of grappling depends on the depth of water, nature of the bottom and age of the cable. Cable ships generally carry different types of grapnels, each designed for use on a particular kind of bottom.

When grappling in great depths, strain on the cable frequently causes it to part. To avoid this, a special grapnel is used which, when it hooks the cable, will simultaneously cut it and hold the desired end. If a bight or loop of cable can be brought above the water, two ropes or chains are led over the bow sheaves and stoppered (fastened) to the cable, one on each side of the bight. The cable is then cut through with the stoppers holding each end of the cable. The cut ends are then bared and the cable is tested through to each terminal to determine in which direction the fault lies. Having determined the direction of the fault and its approximate distance, the repair crew seals and buoys the end of the good side of the cable. The ship then starts picking up cable over the bow in the direction of the fault, coiling the cable in one of the tanks. Strain on the cable is relieved by going ahead slowly on the engines and keeping the ship's head toward the cable. Cable is picked up at the rate of one to two miles per hour in deep water. When a sufficient amount of cable has been brought aboard to have passed the fault, the cable is again stoppered, cut and tested. If the fault has been removed and relaying over the bow is intended, the end of a sufficient length of good cable is led out of the cable tank around the forward cable drum and spliced on. When the splice is completed, the stopper is cast off and the good cable laid directly toward the position of the buoy on the other end. Arriving at the buoy, its mooring line and the

FIG. 3.—SCHEMATIC DRAWING OF THE CABLE GEAR ON THE H.M.T.S. "MONARCH"

cable end to which it is fastened are brought aboard over the bow sheaves with the picking-up gear. The ends are then spliced together and the bight of the cable slipped over the bow and dropped into the water.

CABLE TRANSFERS are transoceanic money payments arranged by cablegram. Similar international payments by land telegraph lines are usually called telegraphic transfers. Sometimes transfers between nearby countries—and even on rare occasions between Europe and America—are arranged by telephone. The person wishing to transfer the money pays the required amount to his own bank. This bank then sends a cablegram instructing its foreign branch or a correspondent bank in the foreign country to pay the money to the recipient. Commercial banks that do not themselves deal in foreign exchange can offer cable transfers through the agency of their correspondent banks, which are usually located in metropolitan centres.

The price, or rate of exchange, for a cable transfer payable in a foreign currency will vary with the fluctuations of the exchange market. A transfer may also be made payable in the currency of the payer. An importer in Chicago, for example, might remit payment to a European supplier in U.S. dollars. Cable transfers are usually payable upon the arrival of the cable, but sometimes payment is made on the following day. When funds are transferred between distant cities such as New York and London, consideration must be given to differences in time zones, banking hours, bank holidays and the time required for communication.

(H. G. GN.)

CABOCHE, SIMON (SIMON LE COUSTELIER) (fl. early 15th century), French agitator, by profession a skinner, led the Paris butchers in the riots that began in April 1413 and brought about the promulgation, in May, of the *Ordonnance cabochienne*, under the protection of John (q.v.) the Fearless, duke of Burgundy. This aimed at a radical reform whereby regularly constituted organs were to control all the administration and all official appointments. The butchers' excesses, however, caused the *bourgeoisie* to react, in August, in favour of John's rival Louis, duc d'Orléans, after whose entry into Paris the *Ordonnance* was torn up (Sept. 8). Caboché reappeared in Paris with the Burgundians in 1418, but never recovered his influence.

CABOT, GEORGE (1752-1823), U.S. politician and leader of the New England Federalists, was born in Salem, Mass., Jan. 16, 1752. After studying at Harvard from 1766 to 1768 he went to sea, gradually rose to become a shipowner and successful merchant, and retired from business in 1794. Throughout his life he was interested in politics, and as a contributor to the press and through his friendships exercised a powerful political influence, especially in New England. He was a member of the Massachusetts constitutional convention of 1779-80, of the state senate in 1782-83, of the convention which in 1788 ratified for Massachusetts the federal constitution and of the U.S. senate from 1791 to 1796. Cabot was president of the Hartford convention, a secret meeting called on Dec. 15, 1814, to express the opposition of the New England Federalists to the War of 1812. Its report of Jan. 5, 1815, attacking Pres. James Madison's administration and the war, aroused charges of lack of patriotism from which the party, already unpopular, never recovered (see FEDERALIST PARTY). Cabot died in Boston on April 18, 1823.

See Henry Cabot Lodge, *Life and Letters of George Cabot* (1877).

CABOT, JOHN (GIOVANNI CABOTO) (c. 1450-c. 1499), Italian (Venetian) navigator and explorer who, sponsored by Henry VII, king of England, voyaged in 1497 and 1498 to the northeast coasts of North America. The exact details of his life and of his voyages are still subjects of controversy among historians and cartographers.

John Cabot was born in Genoa about 1450, but moved to Venice and became a citizen of that city in 1476. He became well experienced in navigational techniques and in later years reported his impressions on visiting Mecca, Arabia, the great trading centre where oriental and western goods were exchanged. As a Venetian he must have known the intricacies of this trade, and he had presumably read of Asia in Marco Polo's writings. The idea that a sea route west across the ocean from Europe could secure oriental products at their source, and short-circuit the long, expensive routes and middlemen to the east, occurred to both Columbus and Cabot, and was probably current among speculative minds of that day.

Cabot moved to London with his family about 1484. His motives are not clearly known. It is possible that he had already envisaged a westward voyage, and came to seek English support. His plans probably differed from those of Columbus, for Cabot's course in 1497 and 1498 lay close to the 60° meridian which was, because of the earth's curvature, a much shorter route than Columbus' course across the 30° meridian. It was suggested that Cabot was aware of the advantages of the northern route and hence sought to promote his schemes in England, the most northerly commercial nation.

In 1496 Henry VII was on tour in western England, and on March 5 issued letters patent to Cabot and his sons authorizing

them to voyage in search of unknown lands, to return their merchandise by the port of Bristol and to enjoy certain privileges and obligations. The news of Columbus' successes on behalf of Spain was a spur to English action, and secured some support for Cabot from Bristol merchants.

John Cabot set sail from Bristol on May 2, 1497, in the small ship "Matthew," with a crew of 18 men. He proceeded around Ireland and then north and west and made landfall on the morning of June 24. Cabot went ashore, took possession of the land for the English king and unfurled both the English and Venetian flags. He reported on returning to Bristol in August that the land was excellent, the climate temperate, that brazilwood and silk probably grew there, and the sea was covered with fish which could be caught not merely by nets, but with weighted baskets lowered into the water. England's dependence on Iceland's fish could be ended. In the midst of an enthusiastic welcome he voiced his plans to return to his landing place, and from there to sail westward hugging the coast until he came to Japan (Chipangu), the source, as he thought, of spices, and gems.

It was never definitely established where Cabot made his first landfall, whether in Labrador, in Newfoundland or on Cape Breton Island. He named various features Cape Discovery, Island of St. John, St. George's cape, the Trinity Islands and England's cape. These may be, respectively, the present Cape North, St. Paul Island, Cape Ray, St. Pierre and Miquelon, and Cape Race, all in the area of Cabot strait.

After his first voyage Cabot received £10 as a gift from the king and an annuity of £20. He dubbed himself "the admiral," and found London and Bristol merchants ready to back another voyage. New letters patent were issued to him on Feb. 3, 1498. It is possible that he visited Lisbon and Seville in search of experienced navigators and officers.

His second expedition probably consisted of five ships and about 200 men. Soon after setting out in May 1498, one ship was damaged by storm and sought anchorage in Ireland; the others sailed westward on the latitude of northern Scotland. Scholars have pieced together the probable course of this voyage from quite diverse scraps of evidence. The ships were carried northwestward until the east coast of Greenland was sighted in early June. Cabot steered northeastward along the coast when mutiny and formidable ice obstructions at 67° 30' N. caused him to turn back southward along the coast. He passed the southern tip of Greenland and coasted on the eastern and western shores of Davis strait. There is evidence that he traded with natives on the Labrador coast. Continuing southward and eastward he did not discover the Gulf of St. Lawrence or the Bay of Fundy, but he did note the hook of Cape Cod. Finally, having failed to discover an oriental trade route and finding supplies running low, he turned back at the latitude of Chesapeake bay, and returned to England empty handed. The dreams of easy wealth were exploded; perhaps it was realized that a continent barred the way to Asia.

John Cabot drew his English annuity for 1499, and then disappeared from historical records. In spite of his fame and undoubted ability, he remains a shadowy figure. He may have been a more able navigator than Columbus, but his voyages did not lead immediately to empire building, and his exploits faded from memory.

Cabot's work of discovery was reinforced by the Portuguese explorer Gaspar Corte-Real. Cabot's son Sebastian was not independently heard of until May 1512.

CABOT, SEBASTIAN (c. 1476-1557), son of the Italian navigator, John Cabot (*q.v.*). Although Contarini, Venetian ambassador at the court of Charles V, affirmed that Sebastian Cabot was born in Venice, more recent evidence supports the belief that he was born in Bristol, Eng., probably in 1476. In 1496 John Cabot and his three sons, Lewis, Sebastian and Santius, were issued letters patent by Henry VII to fit out ships under the English flag to conquer, occupy and possess for England any lands they might discover in any part of the world. Sebastian may have ac-

companied his father in a ship named "Matthew" on the voyage of May 1497 that resulted in the discovery of Labrador or Newfoundland, then believed to be the China coast. This was the first discovery of the new world by any navigators sailing in the British service.

In 1512 Sebastian was employed as a cartographer by Henry VIII and accompanied the English army sent to the continent to aid Ferdinand of Aragon against the French. Because of his knowledge of the northeast coast of North America, he was given a commission in the Spanish navy with the rank of captain, and named to command an expedition in 1516. The death of King Ferdinand that year canceled the project, but Cabot's services were retained by Charles V. In 1518 Cabot was given membership in the council of the New Indies (Consejo de las Nuevas Indias) and appointed pilot major and official examiner of pilots.

Upon his return to England in 1520 he was offered command of an expedition that had been organized to explore Newfoundland. He rejected this proposal and instead assumed command of a Spanish expedition composed of three vessels, which left Seville in 1525 for the purpose of developing commercial relations with the orient. He was diverted from this objective by reports of fabulous wealth in the Rio de la Plata region of southern South America. After about three years of fruitless exploration he returned to Spain, where he was judged responsible for the failure of the expedition and was sentenced to four years' banishment. Nevertheless, he was pardoned by Charles V and restored to his old post of pilot major.

Edward VI then ascended the English throne and, recognizing the value of Cabot, offered him his old position in the English navy. He accepted the appointment in 1548 and was also granted a pension by the monarch. Cabot remained in England, and in the last years of his life, as governor of the Merchant Adventurers, he organized an expedition to search for a northeast passage to the far east. While this objective was not attained, and several naval disasters ensued, it contributed to the development of trade with Russia. Cabot died in London in 1557.

CABRAL, PEDRO ÁLVARES (1467 or 1468-1520[?]), Portuguese navigator widely known as the discoverer of Brazil, was born in 1467 or 1468 in Belmonte. He was not, in point of fact, the first European to reach this part of South America. A member of the lesser nobility, he was appointed commander of an expedition to India that left Lisbon on March 9, 1500. (The first such expedition, led by Vasco da Gama [*q.v.*], had returned to Lisbon in 1499.) Cabral's fleet sailed so far to the southwest, either to avoid the calms of the Gulf of Guinea or to carry out possible instructions from the king (who may have wanted to make sure that the sea route to India via the Cape of Good Hope lay entirely within the Portuguese sphere as defined by the treaty of Tordesillas of 1494), that on April 22, 1500, it sighted Monte Pascoal on the Brazilian coast. After a stay of ten days in Brazil, largely at Cabrália bay in the present state of Bahia, during which time some reconnoitring was done and two Masses were celebrated, the fleet sailed on to India.

After his return from the orient, Cabral led an uneventful life and died, probably in 1520. He was buried in Santarém, Port.

(M. CA.)

CABRERA, RAMÓN (1806-1877), Spanish Carlist general, who, after Tombs de Zumalacárregui, was the most famous commander of the first Carlist War and later became one of the party's most controversial figures, was born at Tortosa on Dec. 27, 1806. Although he took minor orders, he did not make the church his career but instead became involved in the Carlist risings after Ferdinand VII's death (1833). Fanatical and daring, he soon

dominated the leadership of the Carlist bands in Catalonia. He was nicknamed the "Tiger of the Maestrazgo" and inspired terror by his relentless cruelty, which rose to a climax after the liberals had shot his mother (1836). Cabrera, who gained several notable victories, including that of Morella (1838), for which he was created conde de Morella, refused to recognize the convention of Vergara which ended the war in the Basque provinces in 1839 and continued to hold out against forces under Baldomero Espartero in central Spain for nearly a year. In exile, first in France and then in England, he objected to Don Carlos' abdication (1845) in favour of his son, the conde de Montemolin, but from 1846 Cabrera again commanded Carlist bands in Catalonia. He retired from activity in 1849, disillusioned by the failure of these risings. Although the legend of his name led the Carlists to seek his advice and support after the September revolution in 1868, he had changed after marrying an English Protestant and settling down in England. He now advocated peaceful propagation of Carlist views and refused to accept offers to command Carlist forces when the civil war was renewed in 1872. He earned the execration of the party when, in March 1875, he advised them to desert the cause and to follow his example in recognizing Alfonso XII. He died in London on May 24, 1877. (C. A. H.)

CABRILLO, JUAN RODRÍGUEZ (JÃO RODRIGUES CABRILHO) (d. 1543), Portuguese navigator in the Spanish service, best known for his explorations of the west coast of the United States. Cabrillo arrived in Mexico in 1520, and participated in Cortes' siege of Mexico City in 1521 and in the conquest of Oaxaca, Tehuantepec and Guatemala. Leaving Navidad in northwest Mexico on June 27, 1542, he explored the Pacific coast of Lower California and continued northward to latitude 38° 31', discovering San Diego bay, Santa Catalina Island, and San Pedro and Santa Monica bays. He died Jan. 3, 1543, in the vicinity of the Santa Barbara channel. His explorations were continued by his pilot, Bartolomé Ferrello, who in 1543 reached the Oregon coast. (L. N. McA.)

CABRINI, SAINT FRANCES XAVIER (1850-1917), founder of the Missionary Sisters of the Sacred Heart and first United States citizen to be canonized, was born in Sant' Angelo, Lombardy, Italy, on July 15, 1850, the youngest of 13 children. From the time of her first communion and confirmation at the age of seven, Frances was fired with the desire to become a missionary, and her choice of Xavier as her name in religion was determined by this zeal.

Frustrated in her early attempts to become a religious, she agreed to take up residence in an orphanage sadly in need of reform. After three years the bishop encouraged her to take religious vows and appointed her superior of the orphanage. It was during the next three trying years that Frances Xavier became known as Mother Cabrini, the name to follow her through life. In 1880 she founded the Missionary Sisters of the Sacred Heart.

At the direction of Pope Leo XIII to "go west, not east," Mother Cabrini with a small group of sisters sailed for the United States in 1889. Their work in America was to be concentrated among the neglected Italian immigrants. This journey was the first in a series that was to take her through the Americas and into Europe. She became a naturalized citizen of the United States in 1909. Although plagued by ill-health most of the time, Mother Cabrini established 67 houses—one for each year of her life. She died Dec. 22, 1917, and was canonized July 7, 1946. Her feast is Dec. 22.

There is no satisfactory biography of St. Frances Xavier Cabrini. Two popular accounts are T. Maynard, *Too Small a World* (1945), and L. Borden, *Francesca Cabrini* (1945). (E. R. V.)

CABRIOLET: see CARRIAGE.

CABROL, FERNAND (1855-1937), French Benedictine monk and noted writer on the history of Christian worship and related subjects, was born at Marseilles, Dec. 11, 1855. He made his monastic profession in 1877 and was ordained priest in 1882. In 1896 he was sent to Farnborough, Hampshire, Eng., as prior of the monastery which had been founded there in the previous year; seven years later he was elected abbot, an office which he held until his death on June 4, 1937.

Of Cabrol's numerous works one of the most important, because of its wide circulation, was his *Livre de la prière antique* (1900; Eng. trans., *Liturgical Prayer*, 1922). *Monumenta ecclesiae liturgica* was the title of an ambitious series inaugurated by Cabrol, of which only three volumes were published. In 1907 was completed the first volume of another project, launched in 1903, the *Dictionnaire d'archéologie chrétienne et de liturgie*, of which the last volume appeared in 1953. D. Henri Leclercq and, after his death, H. Marrou were co-editors. Lesser works of Cabrol include the following: *Les Origines liturgiques* (1906); *L'Angleterre chrétienne avant les Normands* (1909); *La Prière des premiers chrétiens* (1929; Eng. trans., 1930); *Les Livres de la liturgie latine* (1930; Eng. trans., 1932); *St. Benoît* (1933; Eng. trans., 1934); and *The Year's Liturgy* (published posthumously, 1938-40).

See L. Gougaud in *Revue d'histoire ecclésiastique*, 33:919-922 (1937); A. des Mazis, *Dictionnaire d'histoire et de géographie ecclésiastiques*, vol. xi, pp. 45 ff. (AM. S.)

CACCIA (Ital. meaning "hunt." "chase"), a musical setting of a text realistically describing a hunt or similar event. The musical form originated in France about 1300 under the name *chace* and later was adopted in Italy. The French *chace* was a three-part vocal canon; the Italian *caccia* was a canon for two voices accompanied by an independent instrumental tenor. Polyphonic compositions with similar texts occur in Italy and France up to the late 16th century, but these lack the canonic and other formal features of the 14th-century *caccia*. The English word "catch" (*q.v.*), a type of round, may be derived from *caccia*.

See N. Pirrotta, "L'origine e la storia della caccia" in *Rivista musicale italiana*, vol. 48, no. 3 (1946).

CACCINI, GIULIO (sometimes called GIULIO ROMANO) (c. 1550-1618), Italian singer and composer, whose songs greatly helped to establish and disseminate the new monodic music introduced in Italy about 1600. Little is known of his early years. He was born in Rome, about 1550, but Florence, where he lived mainly from at least 1579, was the scene of his triumphs. During the last 20 years of the 16th century, while playing and singing in court masques (for some of which he composed music), he perfected, largely in the orbit of the Camerata of Count Giovanni Bardi (*q.v.*), the new conception of song that he revealed to the world in *Le Nuove Musiche* (1602). This consists mainly of solo madrigals and arias, preceded by an important explanatory preface (Eng. trans. in O. Strunk, *Source Readings in Music History*, 1952). The madrigals show his new manner most clearly: an elegant and pliable vocal line, scrupulously following the inflections of the words and heightened by affective embellishments, stands out against a subdued chordal accompaniment in diatonic harmony improvised from the newly invented *basso continuo*. During the next 30 years many other Italian composers took up the fashion for monodies, and Caccini himself produced two more collections. He also produced an opera in 1600 (performed Florence, 1602) on the same libretto as Jacopo Peri's *Eurzdice*, to which it is markedly inferior. Caccini's was essentially a lyrical, undramatic talent. He died in Florence in Dec. 1618 and was buried there on Dec. 10.

See F. Ghisi, *Alle fonti della monodia* (1940). (N. Fo.)

CÁCERES, capital of the Spanish province of the same name, lies 22 km. (14 mi.) S. of the Tagus river and 300 km. (186 mi.) by road W.S.W. of Madrid. Pop. (1960 est.) 52,020 (mun.).

CÁCERES, built on an eminence on a low east-west ridge, consists of two towns, an old and a new. The old, upper town, with its medieval palaces, turrets and massive walls, half Roman and half Arab, is dominated by the lofty tower of the Gothic church of San Mateo. The once-famous monastery and college of the Jesuits is now a hospital. Steep steps lead down through four gates to the lower, modern town containing the law courts, town hall, schools and the palace of the bishops of Coria. CÁCERES is situated on a branch railway.

CÁCERES produces cork and leather goods, pottery and cloth, and exports grain, oil, livestock, wool, sausages and phosphates from the neighbouring mines. The town is of Roman origin and probably occupies the site of Norba Caesarina.

CÁCERES PROVINCE, in the region of Extremadura, is the second largest province of Spain (1,995 sq.km. [7,701 sq.mi.]). In the

northeast it adjoins Portugal, and the Tagus river forms part of its boundaries. Pop. (1960 est.) 587,461. The mountainous areas are in the north and south, being formed by the Montes de Toledo and the Sistema Central. The remainder of the province is a plain with an average height of 1,300 ft. The climate is continental and extreme. The two mountain systems enclose an ample catchment area crossed from east to west by the Tagus, joined by its principal tributaries, the Alagón and Tiétar rivers, which flow from the Sierras de Gredos and de Gata. Among the dams recently constructed is that of Gabriel y Galán, on the Alagón, with a capacity of 924,000,000 cu.m. used for hydroelectric power and irrigation.

It is an agricultural and cattle-raising region. Soil and climate permit only the dry cultivation of cereals. Olive growing is important. Cultivation of cotton, tobacco and pepper has been increased and the new dams are transforming the economy of the province. Another source of wealth lies in the great flocks of sheep which come to the winter pastures of the Tagus from the hills of León. Pig keeping is also important. The province abounds with forests of evergreen oak and cork trees. Natural regions include La Vera, the richest, and Las Hurdes, one of the poorest and most backward in Spain where, however, conditions are being improved. The Plasencia valley is also fertile.

The region enjoyed great prominence during the Roman period. The roads leading to Mérida provided good communications with the rest of Spain and the bridge of Alcántara is one of the most notable Roman bridges. Xlfonso IX conquered Cáceres from the Moors in 1229, and it became part of León. Its defense and colonization by the military orders of Santiago and Alcántara gave rise to large *latifundios* (land grants). This explains the concentration of population in large, widely separated towns.

Melida, *Catálogo monumental de Cáceres* (1924); Antonio Floriano, *Historia de Cáceres* (1957). (M. B. F.)

CACHALOT: see SPERM WHALE.

CACHAR, a district of Assam, India, occupying the upper basin of the Surma river and bounded on three sides by hills. After the partition of India in 1947 the remnant of Sylhet district (most of which went to East Pakistan) was added to it, but in 1951 the North Cachar Hills was incorporated in the new district of Mikir and North Cachar Hills. Area 2,688 sq.mi. Pop. (1961) 1,381,566. The scenic hills generally rise steeply and are clothed with forests. The Surma is the chief river, and its principal tributaries from the north are the Jiri and Jatinga, and from the south the Sonai and Dhaleswari. Several extensive fens, notably that of Chatla, which become lakes in time of flood, are characteristic of the plain. This is alluvial and bears heavy crops of rice, next to which in importance is tea. The tea industry employs large numbers: about 90,000 self-supporting persons were engaged in the plantations in the 1960s and the annual output is about 42,000,000 lb. Manufacturing industries are otherwise slight.

The Eastern railway serves the district, including the headquarters town and trade centre of Silchar.

The district is the most thickly populated in Assam (415 per square mile). It takes its name from the former rulers of the Kachari tribe, who settled there early in the 18th century. Later the Burmese threatened to expel the Kachari raja and annex his territory; the British, however, intervened to prevent this and, on the death of the last raja without heir in 1830, obtained the territory under treaty. (S. GL.)

CACOMISTLE (CACOMIXL), or ring-tailed "cat," *Bassariscus*, two species of carnivores related to the raccoons (*q.v.*),

not cats. Their total length is about two feet, half of which is a black-and-white-ringed bushy tail. They have grayish-brown body fur, pointed snouts, long ears and white patches over the eyes. *B. astutus*, known as the ringtail, is found from the southwestern U.S. into Central America; *B. sumichrasti*, the true cacomistle, ranges in Central America to Peru. They are arboreal and nocturnal! and feed on fruits, mice, birds, lizards and grasshoppers. The voice is an explosive bark. The litter consists normally of four. (L. H. M.)

CACTUS. This word, applied by the ancient Greeks to a prickly plant, was adopted by Linnaeus for curious succulent or fleshy-stemmed plants, most of them spiny and leafless. As applied by Linnaeus, the name cactus included all the family Cactaceae.

Many species of small cacti are suitable for home cultivation. They may be planted in a mixture containing a third of each of the following: one-third garden loam, one-third leaf mold (well decomposed) and one-third sand (not from beaches). Sometimes poultry charcoal and crushed old mortar are added. It is important to have a porous and quickly drained soil, for few cacti can withstand retention of water around the roots. Contrary to common belief, most cacti need water, and outdoors in dry climates should be watered about twice a week in the growing season. Many species grow well in warm weather and full sun (provided the pots are large enough to maintain soil moisture), but others require some shade. Cacti grown indoors or in greenhouses may require less frequent watering and smaller pots which do not retain soil moisture, for under these conditions overwatering is a real danger. This is particularly true in areas of high humidity.

The stems have a woody skeleton overlain with thick masses of succulent tissue. They are various in character and form, being globose, cylindrical, columnar or of flattened joints. The surface may be ribbed, or developed into nipplelike protuberances, variously angular, or smooth. In nearly all species there are tufts of stiff, sharp spines, some of which may be horny and robust. These tufts are in special clearly defined areoles, each developed from a lateral bud. The areoles are special spine-bearing areas on the stems, being universal to the family (at least in juvenile states); they occur in no other plant family. The leaves, if present, are reduced, except in *Pereskia*. The flowers are frequently large and highly coloured.

In one group, *Cereus* and related genera, there is an elongated floral tube on the outer surface of which, toward the base where the tube covers the inferior ovary, are small, inconspicuous scales, which gradually increase in size upward, and at length become crowded, numerous and sepeloid. The sepeloid perianth parts shade into petaloid ones. The beauty of the flower is much enhanced by the multitude of conspicuous stamens and stigmas. In another group, represented by *Opuntia*, the flowers are more nearly rotate, the long tube being replaced by a short one. The ovary develops into a fleshy (often edible) fruit, that produced by the opuntias being known as the prickly pear or Indian fig.

The Cactaceae are characteristic of not only the arid and semi-arid areas but also of the wet tropical areas of North and South America. The only representative native to the old world is a species of *Rhipsalis* occurring in eastern Africa, Madagascar and Ceylon. However, species of *Opuntia* and other genera were introduced into the Mediterranean region shortly after the discovery of America, and some of them, especially species of *Opuntia*, soon became widely naturalized in India, the Malayan region, Hawaii and Australia.

The species of dry regions withstand aridity in consequence of the thickness of their cuticle and the small number of stomata. The thick fleshy stems and branches contain reserve water.

The succulent fruits of some cacti are edible, and for fevers are used as a cooling drink. In many parts of Latin America the opuntias and other cacti are planted around houses, to serve as almost impenetrable fences.

Numbers of genera and species are debatable. Probably 20 or more genera and 800 or more species are worthy of recognition. Some of the better-known genera are described below.

Cactus (Melocactus).—This is also called melon thistle or

WILLIS PETERSON

RINGTAIL (BASSARISCUS ASTUTUS)

Turk's-cap cactus. It is distributed in the West Indies, Mexico, Guatemala and Colombia. The typical species, *Cactus melocactus*, of Jamaica, is ovoid in form, one to two feet high, and with furrows and ribs. Each spine cluster includes about five larger spines, accompanied by smaller ones. The top of the plant is surmounted by a cylindrical crown (*cephalium*) three to five inches high, composed of reddish-brown, needlelike bristles, closely packed with cottony wool. At the summit of this crown the small rosy-pink flowers are produced, half protruding from the mass of wool, and these are succeeded by small red or pink elongated berries. The acid fruit is eaten in the West Indies.

Echinocactus.—Also called the barrel cactus, it is native to southwestern United States and to Mexico. The plants have extremely fleshy stems, these being either globose, oblong or cylindrical, ribbed as in *Melocactus*, and armed with stiff sharp spines. The flowers, produced near the top of the plant, are large and showy, yellow and rose being the prevailing colours. Each flower grows in a special area at the upper edge of the spine-bearing areole. The flowers are succeeded by scaly fruits, unlike those of *Melocactus*, which are smooth. *E. ingens* has 40 to 50 stem ribs, the aggregate number of the spines having been computed at 50,000 on one plant. Supposed genera have been segregated.

Echinocereus (Hedgehog Cactus).—The plants form clumps up to 10 or sometimes 20 in. high. The clear distinguishing feature from *Cereus* (see below) and all other cacti is bursting of the flower bud through the epidermis of the stem rib above a mature spine-bearing areole. The genus occurs from southern California to the Great Plains and Mexico.

Cereus.—*Cereus* (torch cactus) comprises numerous species, largely Mexican, South American and West Indian. Many supposed genera have been segregated. The stems are columnar or elongated. The saguaro (*Cereus giganteus*), largest of all cacti in the United States, is a native of desert regions of southeastern California, Arizona and Sonora.

The stems reach a height of 50 ft. and have a diameter of more than 2 ft. At first they are unbranched, but later branches grow out at right angles from the main stem, then curve upward and continue their growth parallel to it. The stems have from 12 to 20 ribs. The white flowers open at night but persist through the next day. The fruits, which are green oval bodies from 2 to 3 in. long, contain a crimson pulp from which the Indians prepare an excellent preserve, also using the ripe fruit as food. The night-blooming *Cerei* and others bear large flowers.

WILLIS PETERSON
FIG. 1.—TOP OF BRANCH OF A SAGUARO (*CEREUS GIGANTEUS*), LARGEST CACTUS IN THE U.S.

Mamillaria and **Coryphantha.**—Also called fishhook and pincushion cacti, these are low growing, clump forming or single stemmed. The stems have tubercles but no ribs. The flower of *Mamillaria* is produced between tubercles, that of *Coryphantha* on the upper side of the tubercle in a special area connected by an isthmus to the spine-bearing areole.

Epiphyllum (Leaf Cactus).—The genus occurs in the tropics and subtropics of Latin America. It differs from all the forms described above in being epiphytic and in having the branches compressed and dilated, resembling thick fleshy leaves, with a strong median axis and a woody base. The margins of these leaf-like branches are crenately lobed. The large flowers are produced from the sinuses. These are among the most ornamental plants of the family, being of easy culture, free blooming and showy. The colour of the flowers ranges from rose-pink to creamy white.

Opuntia (Prickly Pears and **Chollas**).—This is a large group occurring in North America, the West Indies and in South America as far south as Chile. Some have been introduced into

WILLIS PETERSON
FIG. 2.—CHOLLA (*OPUNTIA BIGELOVII*)

Australia with disastrous effects, since they overran large tracts of country. This situation was remedied by the introduction of certain insects and cactus diseases from America to destroy the plants. *Opuntias* are fleshy shrubs with flattened (in prickly pears) or cylindroidal (in chollas) succulent stems and branches, composed of separate joints. The leaves are fleshy and soon deciduous. In each leaf there is an areole bearing barbed or hooked bristles (glochids) usually accompanied by spines. The flowers are mostly yellow or reddish. The fruits are pear-shaped or egg-shaped and either dry or usually soft and fleshy. The sweet, juicy fruits of several species of prickly pears are edible. They are cultivated for their fruit from Mexico southward and in southern Europe, the Canaries and northern Africa.

The cochineal (*q.v.*) insect is nurtured on the allied *Nopalea coccinellifera* and sometimes also on species of *Opuntia*. Plantations, called nopaleries, are established for rearing this insect, *Coccus cacti*, and these often contain as many as 50,000 plants.

Pereskia.—This genus differs from *Opuntia* in having less succulent stems and in the broad, only slightly fleshy, leaves resembling those of other dicotyledons. One species, the Barbadoes gooseberry, climbs like the blackberry (*Rubus*) by recurved thorns; the others are spiny shrubs. The flowers are subpaniculate and white or yellowish. They are used frequently as a stock on which to graft other cacti. There are several species, mainly Mexican. See also references under "Cactus" in the Index volume.

BIBLIOGRAPHY.—For a conservative treatment of the genera see F. Vaupel, *Cactaceae*, in A. Engler and K. Prantl, *Die natürlichen Pflanzenfamilien*, ed. 2, 21:594-651, fig. 271-288 (1925); and for a more radical (but general) consideration of the entire family, N. L. Britton and J. N. Rose, *The Cactaceae*, 4 vol., Carnegie Institution Publication 248 (1919-23). For most of the species native in the United States, see L. Benson, *The Cacti of Arizona* (1940). (L. BN.)

CACUS AND CACA, brother and sister: were originally fire-deities of the early Roman settlement on the Palatine hill, where "Cacus' stairs" were later situated. Virgil describes Cacus as the son of the flame god Vulcan and as a monstrous fire-breathing brigand who terrorized the surrounding countryside. Cacus stole some of the giant Geryon's cattle from Hercules (*q.v.*), dragging them tailfirst to his lair on the Aventine hill. But a lowing cow betrayed him and Hercules, bursting in, overpowered and killed him. There are various later versions of this story, which is traditionally connected with the establishment of Hercules' oldest Roman place of worship, the Ara Maxima, in the "cattle market," whose name was believed to commemorate these events. (D. E. W. W.)

CADALSO Y VÁZQUEZ, JOSE DE (1741-1782), Spanish writer notable for his "Moroccan Letters." was born in Cádiz on Oct. 8, 1741, joined the army out of patriotism, although opposed to war on principle, and was killed on Feb. 27, 1782, at the siege of Gibraltar. He is studied mainly for his *Cartas marruecas* (pub. in *Correo de Madrid*, 1789; as a book, 1793), in which a Moorish traveler in Spain makes acute observations, still surprisingly relevant, about the country, its history and people. His satirical *Los Eruditos a la violeta* (1772), a digest of knowledge for the use of the pseudo-learned, was so successful that its title at once became an epithet.

Other works reflect the conflicting theories and tastes of the time: his rhymed tragedy, *Don Sancho Garcia, conde de Castilla* (1771), rigidly applies neo-classical precepts, while his autobiographical prose-work, *Noches lúgubres* (pub. in *Correo de Madrid*, 1789-90; as a book, 1798), foreshadows the subjective

attitude and disillusionment of the romantics. His poetry, *Ocios de mi juventud* ("Divisions of my youth"; 1773), combines the national poetic tradition of the 16th with the new foreign sensibility of the mid-18th century.

See J. A. Tamayo, *Cartas marruecas* (1935); Edith F. Helman, *Noches lúgubres* (1951). (E. F. H.)

CA DA MOSTO (CADAMOSTO), **ALVISE** (1432-1488), Venetian explorer and trader, who wrote one of the earliest accounts of western Africa. In 1454 he obtained permission from Prince Henry the Navigator to make a voyage to the south on a profit-sharing basis. Setting sail on March 22, 1455, he visited the Madeira group and the Canary Islands, and coasting the west Sahara arrived at the Senegal, whose lower course had already been explored by the Portuguese 60 mi. up.

The Negro lands and tribes south of the Senegal, and especially the country and people of Budomel, a friendly chief reigning about 50 mi. beyond the river, are next dealt with in his narrative. Da Mosto thence proceeded toward the Gambia which he ascended some distance, but finding the natives extremely hostile he returned direct to Portugal. His account includes an interesting description of the commerce between Morocco and the western Sudan, and particularly the "silent trade" in gold. He claims to have drawn a chart of his voyage and to have observed the Southern Cross at the mouth of the Gambia. In 1456 he went out again. Doubling Cape Blanco he was driven out to sea by contrary winds and thus discovered the Cape Verde Islands. Having explored Boa Vista and São Tiago and found them uninhabited, he returned to the African mainland and pushed on to the Gambia, Rio Grande and Geba. Da Mosto returned to Venice in 1463, where he subsequently held important official appointments.

His narrative, first printed in the *Paesi nuovamente ritrovati* (1507), has frequently been reprinted. It is translated in "The Voyages of Cadamosto," *Hakluyt Soc.*, 2nd ser., vol. 80 (1937).

BIBLIOGRAPHY.—R. H. Major, *The Life of Prince Henry of Portugal* (1868), where da Mosto's discovery of the Cape Verde Islands is rejected; C. R. Beazley, *Prince Henry the Navigator* (1895); A. da Mosto, "Il navigatore Alvise da Mosto," *Archivio Veneto*, 2 (1927). (G. R. C.)

CADBURY, GEORGE (1839-1922), British businessman and social reformer, who, with his elder brother Richard, was a founder of the modern Cadbury cocoa and chocolate manufacturing business, is chiefly remembered for his innovations in promoting the welfare of working men and in particular for improving the conditions in which they were employed and housed. He was born at Birmingham on Sept. 19, 1839, of long Quaker ancestry. The brothers took over their father's decaying business in April 1861 and, gaining a reputation for quality, built up a huge concern with interests in Great Britain and overseas. In 1879 their factory was moved from the heart of industrial Birmingham to a rural site outside the city which they called Bournville. On Richard's death in 1899 the business became a private company with George Cadbury as chairman. Working conditions and social security measures were introduced which were much in advance of their times.

Cadbury taught in a Birmingham adult school for many years and his experience there convinced him that bad housing lay at the root of much social evil. In his private capacity he acquired land adjoining the factory and in 1895 he began to build working-class dwellings which were unusual for their amenities, in particular their ample gardens. He sold, leased or rented these houses without reserving them for his own employees, intending from the first to put his experiment on an economic basis and to build up a multi-class community. Bournville, as an example of controlled suburban development, set the pattern for subsequent state and private housing and town-planning schemes. In 1900 Cadbury renounced his financial interest in the estate and founded the Bournville Village trust which, by 1960, owned 1,000 ac. at Bournville, as well as agricultural land, and engaged in research and other activities in furtherance of its founder's aims.

George Cadbury also did a great deal for the evangelical side of the work of the Society of Friends (Quakers); he was especially interested in bringing about the unity of the Christian churches and was one of the founders of the National Free Church council. In order that Liberal views should be expressed in the

press, he became chief proprietor of the London *Daily News* (afterward the *News Chronicle*) in 1901, and his family later acquired other newspapers, including the *Star* (1909), later incorporated in other newspapers. Cadbury died at Birmingham on Oct. 24, 1922.

CADDIS FLY, the common name for an order of aquatic insects, the Trichoptera. Adult caddis flies, some of which superficially resemble moths, range from 1.5 to 40 mm. in length, and have a pair of long to very long antennae. Mouthparts are reduced except for long palps or feelers. In repose the two pairs of membranous wings are held rooflike over the body and have a moderate number of longitudinal veins but few crossveins. Males of a few species have scales on the head and wings; in all other caddis flies the body and appendages are hairy but not scaled.

The young larvae, or caddis worms, with the exception of a few species found in ocean water or in damp moss, live in fresh water. They have distinct hard heads, three pairs of thoracic legs and a pair of hooks at the end of the abdomen. The mature larvae transform to pupae, which are very much like mummified adults.

The adults feed only on water and nectar. Generally the mated female crawls into the water and lays her eggs on or under a submerged object.

The larvae are omnivorous, feeding chiefly on microorganisms; in a few genera they are predators on other insects. Larvae of one group construct a fixed retreat and a net of some sort, eating the food strained from the water or caught on the net. Larvae of the family Rhyacophilidae are free-living, predaceous on other insects in the water. All others construct a portable case of mucous secretion, sand grains, bits of leaves or sticks, etc., with only the larval head and thoracic legs protruding from the case. Mature case-making larvae attach the case to a solid object, then pupate within it. Other larvae construct a cocoon for pupation.

When fully mature the pupa cuts its way out of the case or cocoon by using its strong, sawlike mandibles. It wriggles out of its house, then swims to the surface of the water and transforms to the adult stage. Many northern species have only a single generation per year; others may have more.

Caddis flies had already evolved about 200,000,000 years ago, as shown by fossil representatives in Triassic strata. About 5,000 living species have been described and classified in about 25 families; they are found on all the continents. Caddis flies are extremely abundant in practically all non-polluted fresh water and constitute an important segment of such aquatic communities. The primitive forms of all major groups live in cold streams (in which the order originally evolved), but over the aeons various lines have colonized warmer water and evolved into specialized genera and families, many of which now abound in tropical fresh-water habitats.

CADDO, a North American Indian linguistic stock, applied also to specific tribes and to archaeological remains. Caddoan-speaking peoples occupying most of the eastern Great Plains area were the Arikara and Pawnee (*qq.v.*) of the Dakotas and Ne-

FROM H. H. ROSS, "THE CADDIS FLIES, OR TRICHOPTERA, OF ILLINOIS" (STATE NATURAL HISTORY SURVEY OF ILLINOIS) ADULT CADDIS FLY (RHYACOPHILA FENES-TRA) (ABOUT FIVE TIMES NATURAL SIZE)

braska; the Wichita and Kitsai of Kansas, Oklahoma and Texas; and the Caddo proper consisting of three loose confederacies: Kadohadacho (Petit Caddo, Upper Nasoni and Nanatsoho), Hasinai (Nacogdoche, Anadarko, Lower Nasoni and others), and Natchitoches (Doustioni and Ouachita). Scattered farmsteads and hamlets of domed grass lodges and clay-walled huts with associated ceremonial centres of temple mounds were distributed along the Neches and Angelina rivers in Texas and the main course of the Red river from west central Louisiana into eastern Oklahoma and southwestern Arkansas. This is the area also of the Caddoan archaeological complex which has produced so many striking examples of American Indian workmanship. Throughout the whole area archaeological research shows the Caddoan tenancy to be ancient.

The Caddo proper may first have been seen by De Soto's party in 1542. The first adequate descriptions come from the survivors of La Salle's last voyage. The Caddo played an important role in early French and Spanish colonial ventures, and observers were impressed with the complexity of their culture. Advanced horticulture by the women was supplemented by the hunting of the men. There was a stable social stratification. A hereditary upper group marked by head deformation and other status symbols was concerned with directing political and religious activities. The religion involved regulation of daily life and prognostication through astronomical observations. There are scattered reports of ceremonial human sacrifice and cannibalism. These and other traits relate the peoples to the centres of high culture in Mexico and Yucatan. The total cultural fabric is reminiscent of the settled tribes of the lower Mississippi river and adjacent southeastern regions. There were influences from the plains but these were late and of minor importance. Early epidemics and continuing population decline reduced their numbers from many thousands to about 1,000 settled on a reservation in east central Oklahoma. See also PLAINS INDIANS; INDIAN, NORTH AMERICAN.

CADE, JACK (d. 1450), was leader of the English rebellion which began in Kent at the end of May 1450, and was provoked by fear of reprisals for the capture and subsequent murder of Dover (May 2) of William de la Pole, duke of Suffolk. The rebellion was also a protest against the tyranny and corruption of Henry VI's ministers, particularly the lord treasurer James Fiennes, Lord Saye and Sele. The rebels, led by Cade, calling himself "John Mortimer, captain of Kent," marched from Ashford to Blackheath (June 10), but retreated a week later when the king advanced with his troops. Overtaken at Sevenoaks, they defeated part of the royal army (June 18), returned and entered London (July 3) after Henry VI had retired to Kenilworth castle. Lord Saye and his son-in-law, William Crowmer, sheriff of Kent, were executed, but the Londoners were soon alienated by Cade's lawlessness and his supporters were driven from the city into Southwark (July 5-6). The rebels dispersed when the government offered a pardon, but Cade continued resistance and was killed by Alexander Iden, the new sheriff of Kent, on July 12, 1450.

Cade's real identity remains a mystery. The proclamation ordering his arrest describes him as an Irishman, resident in Sussex until he fled to France after murdering a woman. There is a legend that he was John Aylemere, a physician. Possibly the rising did not have the same captain throughout; according to *Gregory's Chronicle*, although Cade led the rebels back to London after the battle of Sevenoaks, he was not the original leader. Cade did not, as Tudor chroniclers maintained, claim kinship with Richard, duke of York, although he called himself Mortimer, the family name of the earls of March, from whom the duke was descended.

BIBLIOGRAPHY.—C. L. Kingsford, *English Historical Literature in the Fifteenth Century* (1913) discusses the sources; *Gregory's Chronicle* is printed in J. Gairdner (ed.), *Historical Collections of a Citizen of London in the Fifteenth Century* (1876). See also the same editor's introduction in his edition of *The Paston Letters* (1904); G. Kriehn, *The English Rising of 1450* (1892). (T. B. P.)

CADENCE in music is the name given to the approach to a phrase ending, sometimes now also called a close. Passing cadences

have about the same value as commas or semicolons in prose; half closes as colons or full stops; full closes as paragraph endings. The word cadence means "fall" (Latin, *cadere*) and its use in this connection derives from the fall of a tone in the tenor part that defined a formal cadence in medieval music. In later music a cadence is defined mainly by the harmony, of which the momentum is more or less momentarily checked. Important cadences generally need to be acknowledged by a corresponding slackening of the tempo. See also CADENZA. (R. Do.)

CADENZA, the Italian word for cadence, is the name given to an unaccompanied bravura passage introduced at or near the close of a movement as a brilliant climax, particularly in solo concertos of a virtuoso character where the element of display is prominent. Until well into the 19th century these interpolated passages were often improvised by the performer, at suitable openings left for the purpose by the composer. They were displays not only of executive powers but also of more or less spontaneous imagination and invention. Modern performers use written-out cadenzas even for classical concertos, and modern concertos, if they include cadenzas, have them ready-made by the composer. See also IMPROVISATION. (R. Do.)

CADER IDRIS (CADAIR IDRIS), "the chair of Idris," one of the highest mountains in north Wales, ranking next to Snowdon in popular favour. It stands south of Dolgellau and the Mawddach estuary in Merioneth, in an area which contains a superb collection of glacial features and shows very clearly the interaction of structure and process in landscape building. The main core of the mountain is formed by a beveled ridge about 8 mi. long, culminating in a small monadnock known as Pen-y-Gadair (2,927 ft.) and sharply defined by steep rock walls, nearly 1,000 ft. in height, to the north. The grassy slopes descending southward to the Dysynni valley are abrupt, while there is the sheer drop from the ridge to the dark tarn of Llyn-y-Cau, one of the most remarkable cirques (cwms) in Britain. Beyond the narrow wall, 1,000-1,200 ft. in height, is the opposing cwm, equally impressive, in which lies Llyn-y-Gadair. The views from the summit are impressive and varied on the north side; to the southwest the wide sweep of Cardigan bay is embraced. Mention of Cader Idris and its legends is frequent in Welsh literature, old and modern. (E. G. Bow.)

CADET, a younger son, or head of a junior branch of a family. As a military term, cadet commonly denotes a young man undergoing training to become an armed forces officer. The latter use arose in France, where it was applied to younger sons of the nobility who gained commissioned rank after being attached for a time without pay to active army units. The term "cadet," or "gentleman cadet," is applied in most nations to candidates for commission who are students in national military schools. In the United States, for example, cadet is the official title of students at the Military academy at West Point, N.Y., and at the Air Force academy in Colorado; students at the Naval academy at Annapolis, Md., however, are known as midshipmen, their official navy rank, though they were known as cadets in the 19th century. The word "caddie," a messenger boy or one who carries clubs at golf, is derived from "cadet" through the Scots form "cadee," as is the slang word "cad," a vulgar, ill-bred person. (T. N. D.)

CÁDIZ, a city of southern Spain, capital and principal seaport of the province of the same name, is situated on Cádiz bay, an inlet of the Atlantic ocean, 153 km. (95 mi.) S.S.W. of Seville by road. The population, commonly referred to as Gaditanos, was estimated to be 113,749 in 1960.

Cádiz is built on the low, rocky extremity of a narrow sandy spit projecting about 5 mi. into the sea in a northwesterly direction from the Isla de León, which is separated from the mainland by a broad channel known as the Rio Santi Petri. The isthmus and headlands on the mainland to the north nearly enclose the splendid bay, to which Cádiz owes its commercial importance. The outer bay, affording extensive anchorage in from six to ten fathoms of water, stretches from the promontory of Rota to the mouth of the Rio de San Pedro, formerly a distributary of the Guadalete, which enters the bay opposite Cádiz. The inner bay, guarded at its narrow entrance by the forts of Puntales and Cortadura on the isthmus and Trocadero on the opposite side, no

longer provides good anchorage. On its south shore is the important naval arsenal of San Fernando. The entrance to the bays is somewhat obstructed by the low shelving rocks of Los Cochinos and Las Puercas and by shifting mudbanks deposited by the rivers, but the channel is well marked by illuminated buoys. Because of its almost insular position Cádiz enjoys a mild climate, with temperatures never falling below 32° F. in winter or rising above 85° in summer.

The city, 6 to 7 mi. in circumference, is hemmed in by the sea and surrounded by a wall, now mainly demolished, and has only one land exit. The houses, three-storied or more high, have flat roofs and watchtowers in the Moorish style. The Alameda is the finest of the marine promenades which fringe the city. The general air of cleanliness is due partly to the houses being whitewashed every year. In 1947 the city suffered great damage from the explosion of a naval arms store. The old cathedral was originally erected by Alfonso X of Castile (1252–84) and rebuilt after 1596. The new cathedral, begun in 1722 and completed in 1838, is a notable example of Andalusian baroque architecture. Its famous covered crypt, built on a bold, vaulted plan, contains the remains of the Gaditanian contemporary composer, Manuel de Falla. The cathedral possesses a magnificent collection of art treasures, including the silver coach for the Corpus Christi festival. Among important works of art, the church of the Hospital de Mujeres (women's hospital) has the "Ecstasy of St. Francis" by El Greco and the Santa Cueva chapel three outstanding paintings by Goya. The church of the Capuchin friars, now secularized, contains an unfinished picture of the "Marriage of St. Catherine," by Murillo, who died after falling off the scaffold on which he was painting it (April 3, 1682). In the centre of the city there is a signal tower, the Torre de Vigía (100 ft.), a well-known landmark. Cádiz possesses three theatres and a bull ring accommodating 14,000 spectators, and several charitable institutions, schools and museums. An old fort as well as a lighthouse stands on the rock of San Sebastián to the west of the city. By the 1960s an entirely new quarter had grown up along the isthmus.

The loss of the Spanish colonies in the Americas dealt a blow to the trade of Cádiz from which it never recovered. Its decline was later accelerated by the disasters of the Spanish-American War of 1898, by the decreasing demand for sherry and above all by its antiquated harbour works. After 1900 considerable improvements were made, until the harbour had more than two miles of quayside and recovery proceeded steadily. A free depot established in 1823, but lapsing after 1832, was successfully revived on modern lines. Industrial development is rather small, but important naval and mercantile shipbuilding yards and various factories exist on the mainland and there are tunny fisheries off the coast. The city is primarily a commercial port, exporting much wine, principally sherry from Jerez, salt, olives, figs, corks and salted fish, and importing coal, iron and machinery, timber, cereals, coffee and other foodstuffs. Several shipping lines call there and passenger traffic is important. The development of Cádiz, however, must always be limited by the restrictions of its site. The railway connects the town with Jerez and Seville. There is a military airfield at Jerez, 50 km. (31 mi.) N.E., and a Spanish-U.S. naval and air base at Rota.

History.—Cádiz, founded as Gadir, according to tradition, by Phoenician merchants from Tyre as early as 1100 B.C., was occupied by the Carthaginians about 501 B.C. At the close of the Second Punic War the city willingly surrendered to Rome and from this time as Gades its prosperity steadily increased. The wealth and importance of Gades became so great that under Augustus it was the residence of no fewer than 500 equites (*q.v.*), and was made a municipium with the name of Augusta Urbs Julia Gaditana, with citizenship ranking next to that of Rome. Throughout the Roman world its cuisine and its dancing girls were famous. In the 5th century it was destroyed by the Visigoths. A few fragments of masonry, submerged under the sea, are almost all that remains of the original city. Moorish rule over the port, which was renamed Jezirat-Kadis, lasted from 711 until 1262, when Cádiz was captured, rebuilt and repopled by Alfonso X of Castile. Its renewed prosperity dated from the discovery of America in

1492. As the headquarters of the Spanish treasure fleets, it soon became the wealthiest port of western Europe. During the 16th century it repelled a series of raids by the Barbary corsairs; in 1587 all the shipping in its harbour was burned by an English squadron under Sir Francis Drake; in 1596 the fleet of the earl of Essex and Lord Charles Howard sacked the city and destroyed 40 merchant galleons and 13 men-of-war. But Cádiz quickly recovered, and its new fortifications enabled it to repel successfully attacks by British fleets under the duke of Buckingham in 1626, Admiral Blake in 1656 and Sir George Rooke and the duke of Ormonde in 1702. During the 18th century the wealth of Cádiz became greater than ever; indeed at this time it is said to have been wealthier than London. With the closing years of the century, however, it entered upon a period of misfortune. From Feb. 1797 to April 1798 it was blockaded by the British fleet, and in 1800 Nelson bombarded it. In 1808 the citizens captured a French squadron imprisoned by the British fleet in the inner bay. From Feb. 1810 to Aug. 1812 it was besieged by French forces, during which time it served as the capital of all Spain not under the control of Napoleon. There, too, the *Cortes* met and promulgated the famous liberal constitution of March 1812 which led to the 1820 revolution. Ferdinand VII was imprisoned there until released in 1823 by a French army. In the Spanish civil war of 1936–39 Cádiz fell to the Nationalists almost at once, and served as an important port of entry for reinforcements from Spanish Morocco.

CÁDIZ PROVINCE. In the historic region of Andalusia (*q.v.*) the province was formed in 1833 of districts taken from Seville. It is bounded on the north by Seville, east by Málaga, southeast by the Mediterranean sea, south by the Strait of Gibraltar and west by the Atlantic ocean. Pop. (1960 est.) 810,724; area 2,851 sq.mi.; exclusive, in each case, of Ceuta (*q.v.*), on the Moroccan coast, which, for administrative purposes belongs to Cadiz. The main features of the Atlantic coast line of Cádiz are the broad Guadalquivir estuary, which marks the frontier with Seville, the double bay of Cádiz, outlet for the Guadalete, chief river of the north districts, and Cape Trafalgar. Farther south, the Barbate river, draining the broad, marshy Laguna de la Janda, flows into the Strait of Gibraltar; and Punta Tarifa (Point Marroqui), on the strait, is the southernmost promontory of the European mainland. On the east coast the rock and fortress of Gibraltar overlook Algeciras bay; and the Guadiaro river, which drains the eastern highlands, enters the Mediterranean close to the frontier of Málaga. In the interior there is a striking contrast between the comparatively level western half of the province and the picturesque well-wooded mountain ranges of the east with splendid extensive views over the Strait of Gibraltar and the African coast. These mountains, which form the west end of the Boetic Cordillera, attain their greatest altitudes within the province in the Sierra del Pinar (5,426 ft.).

The climate is mild and equable, and with naturally fertile soil makes fruit, vine and olive growing one of the chief sources of wealth in the province, though severe droughts often cause great distress. Jerez de la Frontera (*q.v.*) is famous for the manufacture and export of sherry. Much cork is obtained from the mountain forests, and quantities of fish are caught off the coast and are salted for export. A considerable amount of salt is obtained by evaporation of sea water in pans near Cádiz bay. Railway communication is limited in the west to a line from Seville to Cádiz, with branch lines to Sanlúcar from Jerez and El Puerto de Santa Maria, and from Sanlúcar a few miles north to Bonanza; and in the east to a line from Seville to Algeciras. Apart from the provincial capital, the main centres of population (1950 census) are: La Linea (54,720), Sanlúcar de Barrameda (35,517), the naval station of San Fernando (38,174), Algeciras (52,392), El Puerto de Santa Maria (28,368) (*qq.v.*), Tarifa (17,765) and Puerto Real (13,283) on the coast; Jerez de la Frontera (105,467), Vejer de la Frontera (12,763), Medina-Sidonia (15,069) and Chiclana de la Frontera (18,386) inland; San Roque (14,973), Ubrique (9,172), Jimena de la Frontera and Grazalema are lesser towns trading in farm produce, wine and leather; Rota (15,482) is located on the northern shore of the Bay of Cádiz.

CADMAN, CHARLES WAKEFIELD (1881–1946), one of the first U.S. musical composers to become interested in the music and folklore of the U.S. Indian, was born at Johnstown, Pa., on Dec. 24, 1881. His songs "At Dawning" (1906) and "The Land of the Sky Blue Water" (1908) became American classics. Among his operas are *Shanewis (The Robin Woman)*, produced at the Metropolitan Opera house on March 23, 1918, and repeated in 1919, the first American opera to be carried over into a second season; *The Garden of Mystery*, produced in New York, March 18, 1925; *17ze Sunset Trail*, Denver, 1925; *A Witch of Salem*, Chicago Civic Opera company, Dec. 8, 1926. Other compositions include a cantata, *The Vision of Sir Launfal*; *American Suite* for strings; *Thunderbird Suite* for piano; *Huckleberry Finn Overture*; and *The Willow Tree* (1931), the first U.S. opera written for radio. Cadman was one of the founders of the Hollywood Bowl. He died in Los Angeles on Dec. 30, 1946.

CADMIUM, a metallic element, showing a close relationship to zinc, with which it is frequently associated. It was discovered in 1817 by Friedrich Strohmeyer in a sample of zinc carbonate yielding a yellow zinc oxide, although quite free from iron. Simultaneously K. S. L. Hermann discovered the new metal in a specimen of zinc oxide thought to contain arsenic, since it gave a yellow sulfide in acid solution on the addition of hydrogen sulfide.

Cadmium (Cd) does not occur naturally in the uncombined condition, and only one mineral is known which contains it in any appreciable quantity, namely, greenockite or cadmium sulfide: found at Greenock and at Bishopton in Scotland; and in Bohemia and Pennsylvania. It is, however, nearly always found associated with zinc blende (sphalerite) and with calamine (smithsonite and hemimorphite), although only in small quantities, rarely exceeding 3%.

The metal was first obtained from the blue powder (impure zinc dust,) collected in the condensers, or prolongs, of a zinc retort furnace during the first three or four hours of the distillation cycle. Repeated redistillations of this blue powder enriched the cadmium in the final blue powder. The latter was dissolved in sulfuric or hydrochloric acid, and a high-grade cadmium sponge was precipitated by the addition of metallic zinc dust. Metallic cadmium was then produced by retort distillation of the sponge at a temperature of about 800° C.

Most cadmium is recovered from the fumes eliminated during the sintering of zinc concentrates, from the dust collected from the gases leaving lead blast furnaces and from various purification cakes produced during the electrolytic recovery of zinc. Smaller quantities are recovered during the refining of zinc and the production and refining of lithopone and zinc oxide.

The raw fume or cake usually contains from 5% to 20% Cd, and it is commonly dissolved in sulfuric acid. The resulting solution or slurry is clarified and purified to remove many of the impurities. A cadmium sponge containing from 75% to 95% Cd can then be precipitated by the addition of metallic zinc dust. This sponge can be melted under molten caustic soda or it can be charged to retorts. It can also be dissolved in the acidic spent electrolyte from an electrolytic cadmium plant. The latter produces sheets of relatively pure cadmium, which are remelted and cast into shapes for the market.

The United States is the world's largest producer of cadmium, with an annual output of about 5,000 short tons. Mexico is an important producer of cadmium-bearing dusts and fumes, but most of these are smelted in the United States. The Republic of South Africa, Belgium and Canada each produce from 500 to 900 tons per year. Australia, Poland, Italy, the United Kingdom, Japan, Norway, France and the Federal Republic of Germany are also important producers. The output is linked to the production of zinc and cannot be changed substantially by short-term varia-

tions in price; occurrences of commercial significance are those of commercially exploited zinc ores (see ZINC).

USES

Electroplating.—About two-thirds of all cadmium produced is used in the plating of steel, iron, copper, brass and other alloys to protect them from corrosion. The metal is deosited electrolytically from an alkaline cyanide bath, a typical solution having the composition: 25 g. per litre of cadmium oxide and 100 g. per litre of sodium cyanide. The cadmium oxide is dissolved in the cyanide solution with the formation of $\text{Cd}(\text{CN})_4^{2-}$ and the liberation of two hydroxides, which render the solution alkaline. Cadmium anodes are used to replenish the metal as it is deposited on the cathode, and the process is carried out at room temperature! with a voltage of from 1 to 14 v., depending on the degree of stirring. Certain organic compounds are sometimes added during the electrodeposition, as their presence increases the brightness of the surface. Cadmium plating provides excellent resistance to outdoor corrosion and in this respect is at least the equal of zinc and superior to tin; it is especially resistant to attack by alkali. It is used on electrical parts because of the ease of soldering to it and because of its relatively low electrical conductivity.

Other Uses.—About one-fifth of the cadmium metal or purified metallic sponge is redissolved and converted to pigments; the sulfides and sulfoselenides provide the best yellow and red colorations in many finishes, including enamels and lacquers for automobiles.

Storage batteries using cadmium as one element have much longer lives than those using lead elements, and they have other advantages with respect to weight and ability to be stored in a discharged condition. They are particularly attractive for use in aircraft and special applications where first cost is not a dominant factor. (See also *Compounds*, below.)

One of the most interesting uses of cadmium results from its high neutron-absorption qualities (called cross section). It is therefore used in the control rods of some nuclear reactors.

PHYSICAL AND CHEMICAL PROPERTIES

Cadmium is a silver-white metal and is capable of taking a high polish; on breaking, it shows a distinct fibrous fracture. By sublimation in a current of hydrogen it can be crystallized in the form of regular octahedra; it is slightly harder than tin but is softer than zinc and, like tin, emits a crackling sound when bent. It is malleable and can be rolled out into sheets. The important atomic and physical properties of cadmium are shown in the accompanying table.

Atomic and Physical Properties of Cadmium

Atomic weight	112.41
Isotopes:	48
mass	106, 108, 110, 111, 112, 113, 114, 116
per cent abundance	1.4, 1.0, 12.8, 13.0, 24.2, 12.3, 28.0, 7.3
Density, 20° C.	8.65 g./ml.
Melting point	320.9° C.
Boiling point	767° C.
Specific heat, 25° C.	0.0551 cal./g./° C.
Electrical resistance, 20° C.	29.8×10^{-6} ohm cm.
Coefficient of linear expansion, 20° C.	18, 28, 29, 38, 39, 3d, 48, 49, 4d, 58
Ionization potentials:	2, 2, 6, 2, 6, 10, 2, 6, 10, 2
1st electron	8.96 v.
2nd electron	16.84 v.
3rd electron	38.0 v.
Electrode potential	$\text{Cd} = \text{Cd}^{2+} + 2e^- E^\circ = 0.4020 \text{ v.}$

The metal unites with the majority of the heavy metals to form alloys; some of these, the so-called fusible alloys, find a useful application from the fact that they possess a low melting point. The metal on boiling forms a deep yellow vapour which has been shown to be monatomic. The metal is quite permanent in dry air, but in moist air it becomes coated with a superficial layer of the oxide; it burns on heating to redness, forming a brown-coloured oxide; it is readily soluble in mineral acids with formation of the corresponding salts.

Cadmium is chemically related to zinc and mercury and in gen-

eral has properties intermediate between these elements. It is readily oxidized to the +2 oxidation state, giving the colourless ion Cd^{2+} . Alkali precipitates the hydroxide $\text{Cd}(\text{OH})_2$, which is insoluble in excess base. The cadmium ion, like the mercuric ion, forms many complexes in aqueous solution: such as $\text{Cd}(\text{NH}_3)_4^{2+}$, $\text{Cd}(\text{CN})_4^{2-}$, CdCl_3^- , CdCl_4^{2-} , etc. In addition to compounds of the +2 oxidation state, the solids Cd_2O and Cd_2Cl_2 , corresponding to the +1 state, have been reported.

Compounds.—Cadmium oxide, CdO , is a brown powder of specific gravity 6.5, which can be prepared by heating the metal in air or in oxygen or by ignition of the nitrate or carbonate, or by heating the metal to a white heat in a current of oxygen, when it is obtained as a dark-red crystalline sublimate. It does not melt at a white heat, and is easily reduced to the metal by heating in a current of hydrogen or with carbon. It is a basic oxide, dissolving readily in acids, with the formation of salts somewhat analogous to those of zinc.

Cadmium hydroxide, $\text{Cd}(\text{OH})_2$, is obtained as a white precipitate by adding potassium hydroxide to a solution of any soluble cadmium salt. It is decomposed by heat into the oxide and water, and is soluble in ammonia but not in excess of dilute potassium hydroxide; the latter property serves to distinguish it from zinc hydroxide.

The chloride, CdCl_2 , bromide, CdBr_2 , and iodide, CdI_2 , are soluble salts; and cadmium iodide, which is one of the few iodides which are soluble in alcohol, is sometimes used in photography. The cadmium ion is highly complexed by all of the halide ions in aqueous solutions, thus giving rise to anomalous chemical behaviour. In solutions of increasing halide concentration, the complexes containing one, two, three and four halide ions are successively formed.

Cadmium sulfate, CdSO_4 , is known in several hydrated forms. It is largely used for making standard electric cells, which give a practically constant voltage under normal conditions (see BATTERY: *The Nickel-Cadmium Battery*; INSTRUMENTS, ELECTRICAL MEASURING: *Primary Electrical Standards: Standard Cell*).

Cadmium sulfide, CdS , occurs naturally as greenockite, and can be artificially prepared by passing hydrogen sulfide through acid solutions of soluble cadmium salts, when it is precipitated as a pale-yellow amorphous solid. It is used as a pigment (cadmium yellow), since it retains its colour in an atmosphere containing hydrogen sulfide; it melts at a white heat, and on cooling solidifies to a lemon-yellow micaceous mass. An enamel pigment known as fine red or cadmium red is prepared from a mixture of 80%–90% of cadmium sulfide and 10%–20% of selenium. The product corresponds in composition to Cd_9SeS_2 .

Normal cadmium carbonate is unknown; a basic carbonate of variable composition is obtained on the addition of solutions of alkali carbonates to soluble cadmium salts.

Analysis.—Cadmium salts can be identified by the yellow precipitate formed when hydrogen sulfide is passed through their acidified solutions. This precipitate is insoluble in cold dilute acids, a behaviour which distinguishes it from the yellow sulfides of arsenic and tin. Cadmium may be determined quantitatively by precipitation as the sulfide, followed by the conversion of the latter to the sulfate. A better method involves the precipitation of the cadmium with trimethylphenylammonium iodide. This reagent is also an excellent qualitative indicator for cadmium under operating conditions at most cadmium plants.

TOXICITY

Certain cadmium compounds are very poisonous; others seem to have little effect when present in far larger quantities. The metal vapour itself and the very fine oxide which results from its combustion in air appear to cause the most violent reactions when taken into the lungs. Severe lung damage is noted in fatal cases, but exposed workers are usually warned by such symptoms as severe nausea and diarrhea before permanent damage is sustained. These disorders are not only warnings of an unsafe condition but also tend to force the affected workman to leave his job. In most cases of mild poisoning, the symptoms will have been relieved in 24 hours, and no permanent ill effects will be noted.

Soluble cadmium compounds are about as poisonous as those of lead and arsenic, and a few deaths have been ascribed to them in cases unrelated to cadmium recovery and production. Conditions causing mists or aerosols of cadmium solutions should be avoided if possible.

Cadmium sulfide is so insoluble that it can be tolerated in relatively large amounts. Coarse particles of cadmium oxide are also tolerated by most workmen, although in somewhat smaller quantities.

For areas continuously occupied by workmen sufficient ventilation should be provided to keep the concentration of fine metal fume or fine cadmium oxide below 0.1 mg. per cubic metre.

CADMUS, in Greek mythology, son of Phoenix or Agenor, king of Phoenicia, and brother of Europa. After his sister had been carried off by Zeus, Cadmus was sent out to find her. Unsuccessful in his search, he came to Delphi, where he consulted the oracle. He was ordered to give up his quest and follow a cow that would meet him, and to build a town on the spot where she lay down. The cow met him in Phocis and guided him to Boeotia, "cow land," where he founded the city of Thebes. Intending to sacrifice the cow, he sent some of his companions to a neighbouring spring for water. They were slain by a dragon, which in turn was destroyed by Cadmus, and by the instructions of Athena he sowed its teeth in the ground. From these sprang a race of fierce armed men, called Sparti (sown). By throwing a stone among them Cadmus caused them to fall upon each other till only five survived, who assisted him to build the Cadmea or citadel of Thebes and became the founders of the noblest families of that city (Ovid, *Metamorphoses*, iii, 1, ff.; Apollodorus III, i; iv). Cadmus, however, because of this bloodshed, had to do penance for eight years.

At the expiration of this period the gods gave him to wife Harmonia, daughter of Ares and Aphrodite, by whom he had a son, Polydorus, and four daughters, Ino, Autonoe, Agave and Semele, all ill-fated. At Cadmus' marriage all the gods were present; Harmonia received as bridal gifts a robe worked by Athena and a necklace made by Hephaestus, which caused much sorrow later (see HARMONIA). Cadmus is said to have finally retired with Harmonia to Illyria, where he and his wife were changed into snakes.

According to tradition, Cadmus brought the alphabet to Greece, and the Greek alphabet is in fact derived from a Phoenician script.

See H. J. Rose, *A Handbook of Greek Mythology* (1928); Edith Hamilton, *Mythology* (1942). (G. E. DK.; X.)

CADMUS of MILETUS, son of Pandion (date unknown), was, according to some ancient authorities, the inventor of history, or of prose, or simply the author of certain letters of the Greek alphabet. Despite this reputation for great antiquity there is no sign that any early Greek writer ever knew of Cadmus; in this he differs from Hecataeus and others. Dionysius of Halicarnassus was probably right in stating in his *De Thucydidis historiae iudicium* that the work current in his time under the name of Cadmus was a forgery. He was said to have written a book on the origins of Ionia.

See F. Jacoby, *Die Fragmente der griechischen Historiker*, vol. iii, no. 489 (1923 et seq.); Pauly-Wissoua-Kroll, *Real-Encyclopaedie der klassischen Altertumswissenschaft*, vol. x, 2., pp. 1473–76 (1919). (G. T. GH.)

CADOGAN, WILLIAM CADOGAN, 1ST EARL (1672–1726), British soldier, was an outstanding staff officer who gained political influence as the friend and trusted colleague of the duke of Marlborough. He was born at Liscarton, County Meath, Ire., in 1672, the son of Henry Cadogan, a Dublin barrister. Cadogan

began his military career as a boy cornet with William III at the battle of the Boyne (1690) and was later commissioned in the Inniskilling dragoons and served in Flanders. There he attracted the notice of Marlborough and was quartermaster to the Irish troops sent to Holland in 1701. When Marlborough became generalissimo of the allied armies in 1702, Cadogan became his quartermaster general and most trusted subordinate. Cadogan was present at Blenheim, rose rapidly in rank and distinguished himself not only in staff work, but in battle as colonel of the 6th (Cadogan's) Horse. In 1706 he served at Ramillies and received the surrender of Antwerp. In the later years of the war Cadogan took part in all the major actions, adding many diplomatic missions to his staff work. On Jan. 1, 1709, he was promoted to lieutenant general, and in 1710 served at Malplaquet and was wounded at Mons. Though the Tory party denigrated Marlborough by attributing the success of the campaign to Cadogan, he was in fact a first-class subordinate.

Cadogan figured largely in Marlborough's political following, and in 1705 entered parliament for Marlborough's pocket borough of Woodstock, which he retained until he entered the house of lords. He became lieutenant of the Tower of London in 1706. But from 1710 Cadogan suffered by his loyalty to the duke after Marlborough's political eclipse, and when the duke of Ormonde succeeded to the command of the army (1711), Cadogan retired to the Netherlands, losing his rank and offices. He was closely involved in plans to secure the Hanoverian succession, by force if necessary, and so on George I's accession his military promotion was resumed, and he was employed on various diplomatic missions abroad. In 1716, with the support of Marlborough, he displaced the duke of Argyll from the command of the campaign against the Jacobite earl of Mar, whose forces Cadogan crushed relentlessly. For these services he was made a baron. His diplomatic work as ambassador in the Netherlands, where he signed the Barrier treaty of 1715 and the triple alliance of 1717, earned him an earldom (1718). The divisions in the Whig party, however, exposed Cadogan (who, with Earl Stanhope and the earl of Sunderland formed the core of the ministry) to continuous attacks from Robert Walpole and his allies: while even his friends disliked his aspirations after political authority. Cadogan, like Marlborough before him, had become a thorough court politician and was more closely in league with the king and his Hanoverian advisers than any of the other ministers. His influence therefore suffered in the ministerial revolt against German influence and he had to accept a diplomatic mission to Vienna in 1720. After the death of Marlborough in 1722, Cadogan obtained his place of master general of the ordnance, and other offices, but without his patron's support he lost political significance. He died at Kensington on July 17, 1726. (W. R. Wd.)

CADORNA, LUIGI, CONTE (1850–1928), Italian soldier, chief of the general staff for the first three years of World War I, was born on Sept. 4, 1850, at Pallanza in Piedmont. The son of Raffaele Cadorna, who had distinguished himself in the wars of the Risorgimento and the Crimea, he entered the Italian army in 1866. In 1914, on the death of Gen. Alberto Pollio, chief of the general staff, Cadorna was appointed to succeed him (July 10). The army was in a deplorable condition, and Cadorna worked unceasingly to restore it.

When Italy entered World War I by declaring war on Austria-Hungary in May 1915, Cadorna was given command on the Austro-Italian frontier. He directed operations on the basis of maintaining a defensive attitude in the Trentino and taking the offensive on the Isonzo, but the Italians had no real success in either sphere until the capture of Gorizia (Aug. 1916), which cost them very heavy casualties. In the same month Italy declared war on Germany.

After the overwhelming defeat of the Italians on the Isonzo front in the battle of Caporetto (Oct.–Nov. 1917), Cadorna was removed to the Allied military council at Versailles. Then the official inquiry into the defeat at Caporetto led to his being recalled from Versailles and placed on half pay. He retired from the army on Sept. 2, 1918.

In his retirement, Cadorna published *La Guerra alla fronte*

italiana, two volumes (1921), which effectively answered much of the criticism that had been directed against his leadership. This was followed by *Altre pagine sulla Grande Guerra* (1925). He also wrote *Il generale Raffaele Cadorna nel Risorgimento italiano* (1922). He died at Bordighera on Dec. 21, 1928.

CADRE, a framework or skeleton, particularly the permanent establishment of a military corps, regiment, etc., which can be expanded on emergency. The modern tendency is for the cadre to be largely composed of commissioned and noncommissioned officers capable of filling higher grades on mobilization, and trained as instructors so that they may train the new recruits.

CADUCEUS (CADUCEUM), in classical times, was a badge showing that the bearer was a sacred person not to be molested. Originally it may well have been of magical potency, supposed to protect its bearer, as various other sticks or staves (e.g., a king's sceptre) are reasonably thought to have been. "Caduceus" is a Latin loanword, Gr. *karykeion* from *karyx* ("herald!"), hence "herald's badge of office." The change of "r" to "d" may originate in an idea that the word had something to do with *cadere*, *caducus* ("to fall." "fallen").

Its original form was in all probability a straight branch from the top of which two twigs grew, something like a dowser's rod. These twigs were then pulled back and twined around the branch, one of several ways of disposing of them attested by art monuments. Later, and quite possibly under the influence of oriental objects of like general shape though somewhat different origin, the twigs were interpreted as snakes, and thus the caduceus is often shown snake-entwined, somewhat like the staff carried by Asclepius, where the snakes are his familiars, creatures of the underworld to which he primarily belongs.

(For the staff of Asclepius, the symbol of the physician, see ASCLEPIUS.)

The most characteristic bearer of the caduceus is Hermes, who, as described by Homer and later writers, runs errands for the greater gods, especially Zeus, and so is easily thought of as a herald; in cult he is the patron of heralds as of other wayfarers. His *karykeion* is not to be confused with the magic wand which he, and on occasion other gods, sometimes carry.

See F. J. M. de Waele, *The Magic Staff or Rod in Gvaeco-Roman Antiquity* (1927). (H. J. R.)

CAECILIAN, the best vernacular name for a group of tropical limbless, wormlike amphibians first described by Linnaeus as a group of snakes but later recognized as an order of Amphibia to which the names Apoda and Gymnophiona have been given. Apoda is the name generally used by systematists. (See AMPHIBIA.)

LLOYD G. INGLES
PANAMAN CAECILIA (CAECILIA
OCHROCEPHALA)

The caecilians are all limbless, long-bodied Amphibia with a very short tail, the vent being nearly terminal. Most are 12 in. or less in length, although one variety reaches 4 ft. Their bodies are usually more or less ringed by dermal folds, which gives them the appearance of large earthworms. Within these folds in several genera are series of minute scales, a structure otherwise unknown in living Amphibia. All genera are characterized by a peculiar protrusible tentacle on the side of the face near the nostril or

eye that is said to function as a tactile organ but is radically different from such sense organs in other Amphibia.

Caecilians are primitive forms apparently directly derived from the extinct Lepospondylia. They show no close affinity to other living groups and are more primitive than the other living Amphibia, the frogs and salamanders, in having certain bones of the skull (a postfrontal in *Ichthyophis*, etc.; an ectopterygoid in *Hypogeophis*, etc.), a transitory spiracle cleft, a sixth gill sac, four pairs of functional thymus glands and two additional pairs of rudiments during development. The skull of caecilians is much more consolidated than those of the other living Amphibia. The

consolidation gives the skull rigidity and adapts it to the mechanical requirements of a burrowing existence. Reduction in the size of the eye, which in some species is hidden under the bones of the skull, is also an adaptation to burrowing. In spite of their primitive characters the caecilians are a highly aberrant and specialized group.

F. Nieden (1913) recognized 19 genera and 55 species, all referable as a whole to a single family, the Caecilidae. The primitive genera *Ichthyophis*, *Rhinatrema*, etc., have scales, exhibit the fewest fusions or skull elements and are the least modified for burrowing. The most specialized are either degenerate burrowers or aquatic (*Typhlonectes*). The structure of integument, skeleton or lungs may be modified as an adaptation to the habitat. The caecilians are seldom seen except after heavy rains or when uncovered by the plow.

The life histories of several genera of caecilians are known. *Ichthyophis* lays its eggs on land in damp situations, the larvae escaping to take up an aquatic existence. The more specialized *Hypogeophis* skips over the larval stage. Other genera, including the aquatic *Typhlonectes*, give birth to living young.

CAECILIUS (fl. early 1st century A.D.). Greek rhetorician. was next to Dionysius of Halicarnassus, the most important critic and rhetorician of the Augustan age. He was born at Calacte in Sicily. Only fragments of his works are extant, among which may be mentioned: *On the Style of the Ten Orators*; *On the Sublime*, attacked by Longinus (?) in an essay on the same subject; *History of the Servile Wars*, or slave risings in Sicily; *On Rhetoric and Rhetorical Figures*; an *Alphabetical Selection of Phrases*, an Attic lexicon, mentioned in the later Suda lexicon as one of its authorities; and *Against the Phrygians*, probably an attack on the florid style of the Asiatic school of rhetoric.

See E. Ofenloch (ed.), *Caecilii Calactini fragmenta* (1907).

(G. B. Kd.)

CAECILIUS STATIUS (STATIUS CACCILIUS) (d 168 B.C.) was a Roman comic poet of the generation preceding that of Terence. Aulus Gellius says that he was a slave and "therefore" called Statius (a name given to slaves). Jerome says that he was an Insubrian Gaul; that some said his birthplace was Milan, that at first he lived with the poet Ennius; and that he died a year later than Ennius (*i.e.*, in 168 B.C.) and was buried near the Janiculum hill in Rome. Suetonius' *Life of Terence* states that the aediles (magistrates in charge of theatres, etc.) ordered Terence to read his *Andria* (produced 166 B.C.) to Caecilius, this looks like a mere anecdote. Caecilius had some difficulty in winning popularity; he owed his final success to the loyal support of the actor Xmbivius Turpio. Of his comedies 42 titles and 280 lines or parts of lines are extant. Cicero speaks of him as a translator of the Greek comic poet Menander and quotes him in court in his speech *Pro Caelio*; Horace, in the *Epistles*, says that he was celebrated for moral force (*gravitas*); Varro praises his plots and emotional power; and the historian Velleius finds in him a vein of Latin wit. Volcacius Sedigitus, the literary critic, ranked him at the head of all Roman writers of comedy. Although Cicero criticized his Latinity, the fact that in his speech *De Fimibus* he could name Caecilius' *Hymnis* without any indication of the author is perhaps proof of its popularity. The fragments are free from topical allusions to Roman life. Gellius quotes considerable passages from his *Plocium* ("Necklace") side by side with the original by Menander to show how the Latin, though tolerable in itself, is inferior to the Greek in truth and delicacy. Caecilius has indeed translated with freedom; he has inserted crude jokes; his metres are varied, there is rhythmical effect and aordplay.

Information is too meagre to justify any very dogmatic statement. Perhaps it would be near the truth to say that Caecilius was a writer of considerable moral force, and that he was fond of Menander. He was probably less lively than Plautus and less polished than Terence.

orum poesis Fragmenta (1898). See also Pauly-Wissowa, *Realencyclopädie der classischen Altertumswissenschaft* (1897); G. E. Duckworth, *The Nature of Roman Comedy*, pp. 46-49 (1952); W. Beare, *The Roman Stage*, 2nd ed., pp. 76-80 (1955); E. Paratore, *Storia del teatro latino* (1957). (Wm. Be.)

CAECINA, the name of a distinguished Etruscan family of Volaterrae (Volterra), and later used by Romans of other districts as a *gentilicium* or family name.

AULUS CAECINA of Volaterrae (1st century B.C.) was defended by Cicero in 69 B.C. on a charge concerning a will. Either he or his son wrote an important work on Etruscan divination and was a close friend of Cicero during Julius Caesar's dictatorship, when he was banished for writing a tirade against Caesar.

AULUS CAECINA ALIENUS (d. A.D. 79), Vitellius' general in A.D. 69, was born at Vicetia (Vicenza) in northern Italy, and as quaestor in Baetica (southern Spain) aided Galba's rebellion in A.D. 68. Legate of a legion in upper Germany, he was censured by Galba for embezzlement and took his revenge by supporting Vitellius (*q.v.*). He led an army from Germany over the Great St. Bernard pass in 69, attacked Placentia (Piacenza) without success, and was defeated by Otho's troops at Forum Gallorum (Castel Franco). But he held the front until his colleague Fabius Valens arrived and the two then overcame Otho's army east of Cremona. Caecina was made consul and was given charge of the first operations against the forces of Vespasian in Sept. 69. But he then betrayed Vitellius, whose leaderless legions were defeated at Cremona. Caecina was honoured (though apparently not employed) by Vespasian, but in 79 Titus, shortly before his accession, had him executed for an alleged conspiracy.

Other bearers of the name were AULUS CAECINA SEVERUS, consul in 1 B.C., and governor of lower Germany in A.D. 14; AULUS CAECINA PAETUS, who had to commit suicide in A.D. 42 after an abortive revolt against the emperor Claudius; GAIVS CAECINA LARGUS, who was a close friend of Claudius; and AULUS CAECINA TUSCUS, who was foster brother of Nero and prefect of Egypt, banished in A.D. 66. (G. E. F. C.)

CAEDMON, the earliest English Christian poet. His story is known only from Bede's *Ecclesiastical History*. He was (see BEDE) a herdsman who received a divine call to poetry in a dream. One night, having quitted a company because, from want of skill, he could not comply with the demand made of each guest to sing, he dreamed that there appeared to him a stranger, who commanded him to sing of "the beginning of created things." He pleaded inability, but the stranger insisted, and he was compelled to obey. He found himself uttering "verses which he had never heard." Of Caedmon's song Bede gives a prose paraphrase, which, he says, represents the sense only, not the arrangement of the words. When Caedmon awoke he remembered the verses and added others. He related his dream to the farm bailiff under whom he worked, and was conducted by him to the monastery at Streaneshalch (now called Whitby). The abbess Hild recognized that the illiterate herdsman had received a gift from heaven, and, to test his powers, proposed that he should render into verse a portion of sacred history which the monks explained. By the following morning he had fulfilled his task. At the request of the abbess he became an inmate of the monastery. Throughout the remainder of his life his more learned brethren expounded to him Scripture history, and all he heard he reproduced in poetry. All his poetry was on sacred themes, and its unvarying aim was to turn men from sin to righteousness. Although many Englishmen after him essayed to compose religious poetry, none of them, in Bede's opinion, approached Caedmon.

Bede's account of Caedmon's deathbed has often been quoted, and is of singular beauty. It is often stated that he died in the same year as Hild, but for this there is no authority. Later evidence seems to point to his having died before her. All that is known certainly is that his dream took place during the period (658-679) in which Hild was abbess of Streaneshalch.

The hymn said to have been composed in his dream is extant in 1; manuscripts. The oldest version is added in a blank space in the Moore manuscript of Bede's *History*, in an 8th-century hand: it is in the Northumbrian dialect and three other Latin manuscripts, including the 8th-century Leningrad manuscript, have it

in this dialect, in the margin or text of Bede's account of the dream. Eight Latin manuscripts have the hymn transliterated into West Saxon. In the Old English translation of Bede's *History*, which survives in five manuscripts, a West Saxon text of the hymn replaces Bede's Latin paraphrase. Probably the Latin manuscript used by the translator contained this addition.

Several analogues have been brought forward to the story of a poet who composed in a dream; e.g., Hesiod, Aeschylus, the anonymous author of the Old Saxon *Heliand* (though in his case influence from Bede's work is probable), the Icelandic skald Hallbjorn Hali, etc., but these need not discredit Bede's account. Nor is the lack of poetic merit a strong argument against the authenticity of the poem, which was Caedmon's first essay in verse.

The hymn is best edited by E. van K. Dobbie, *The Manuscripts of Caedmon's Hymn and Bede's Death Song* (1937). See also C. Plummer, *Venerabilis Baedae opera historica* II, pp. 251-258 (1896); A. H. Smith (ed.), *Three Northumbrian Poems* (1933); L. Pound, "Caedmon's Dream Song," *Studies in English Philology; a Miscellany in Honour of Frederick Klaeber* (1929); G. Shepherd, "The Prophetic Caedmon," *Review of English Studies*, new series, v (1954).

The "Caedmon Poems."—Although this poor fragment is all that can be confidently affirmed to remain of the voluminous works of the man whom Bede so highly admired, a considerable body of verse was known by his name and for convenience the use of the name has been retained. The so-called Caedmon poems are contained in a manuscript written about A.D. 1000, which was given in 1651 by Archbishop Ussher to the famous scholar Franciscus Junius, and is now in the Bodleian library, Oxford. They consist of paraphrases of parts of Genesis, Exodus and Daniel, and three separate poems, the first on the lamentations of the fallen angels, the second on the "harrowing of hell" and the third (a fragment) on the temptation. The subjects correspond so well with those of Caedmon's poetry as described by Bede that Junius unhesitatingly attributed the poems to him. The ascription was rejected in 1684 by G. Hickes, whose chief argument, based on the dialect, is known to be fallacious, as much "West Saxon" poetry is certainly of Northumbrian origin. Since, however, Bede says that Caedmon had many imitators, it is unsafe to assume that a collection of poems in a late 10th-century manuscript contains any of his work. Research has shown that the "Caedmon manuscript" cannot be all by one author; some portions of it are plainly the work of a Latin scholar. Some of the rest may be genuine; but the internal evidence can afford no certainty, although the unlikeness of any particular passage to the nine lines of the *Hymn* is no reason for denying Caedmon's authorship.

Genesis contains a long passage (ll. 235-851), which differs markedly in style and metre from the rest. This passage is one of the finest in all Old English poetry. In 1877 E. Sievers argued, on linguistic grounds, that it was mainly a translation from a lost poem in Old Saxon, probably by the author of the *Heliand*, a conclusion brilliantly confirmed in 1894 by the discovery in the Vatican library of a manuscript containing 62 lines of the *Heliand* and the original of 28 lines of the interpolated passage of the Old English *Genesis*. The Old Saxon biblical poetry belongs to the mid-9th century; the translation is consequently later. Similarities between passages in *Paradise Lost* and parts of the translation from Old Saxon have caused it to be suggested that some scholar may have talked to Milton about the poetry published by Junius, and that the poet may thus have gained some hints. The parallels, however, though interesting, are not conclusive.

As *Genesis* begins with a line identical in meaning with the opening of Caedmon's *Hymn*, it may perhaps be inferred that the writer knew Caedmon's genuine poems; but when, after treating of the revolt of Lucifer, the paraprast comes to the biblical part of the story, he follows the sacred text with servile fidelity. The ages of the antediluvian patriarchs, for instance, are accurately rendered into verse. In all probability *Genesis* is of Northumbrian origin. The names assigned to the wives of Noah and his three sons (Phercoba, Olla, Olliu, Olliuani) have been traced to an Irish source, and this seems to point to the influence of the Irish missionaries in Northumbria.

Exodus is a fine epic poem, full of martial spirit, on how Moses

led his people out of Egypt. It differs from other extant poetry in its condensation of style and its bold use of imagery, and it has much unique vocabulary. It cannot be by the same poet as any of the other poems in the manuscript.

Daniel is not a great poem, but the narration is lucid and interesting. The author has borrowed some 70 lines from a poetical rendering of the Prayer of Azarias and the Song of the Three Children, of which there is a copy in the *Exeter Book*. The borrowed portion ends with verse three of the canticle, the remainder of which follows in a version for the most part independent. Elsewhere the paraprast draws only from the canonical book of Daniel. The poem is obviously the work of a scholar.

The three other poems, designated "Book II" in the Junius manuscript, are characterized by considerable imaginative power and vigour of expression, but show an absence of culture and are somewhat rambling. They abound in passages of fervid religious exhortation.

Of poems not included in the Junius manuscript, the *Dream of the Rood* (see *CYNEWULF*) is the only one that has with any plausibility been ascribed to Caedmon. It was affirmed by G. Stephens that the Ruthwell cross, on which a portion of the poem is inscribed in runes, bore on its top-stone the name "Caedmon"; but the traces of runes that are still visible exclude all possibility of this reading. The poem is certainly Northumbrian and earlier than Cynewulf. It would be impossible to prove that Caedmon was not the author, though his authorship of such a work would rank among the miracles of genius.

The name Caedmon (in the manuscripts of the Old English version of Bede written *Cedmon*, *Ceadmann*) has no simple philological explanation. The statement that it means "boatman" is founded on the corrupt gloss *liburnam*, *ced*, where *ced* is an error for *ceol*. It is most probably the British *Cadman*, intermediate between the Old Celtic *Catumanus* and the modern Welsh *Cadfan*. Possibly the poet was of British descent.

The oldest edition of the Caedmon poems is that of F. Junius (1655). There is a facsimile edited by Sir I. Gollancz (1927), and this work and the edition by G. P. Krapp, *The Junius Manuscript* (1931) contain bibliographies and full discussion of the various problems. The poems are translated by C. W. Kennedy, *The Caedmon Poems* (1916). See also C. W. Kennedy, *The Earliest English Poetry*, pp. 158-197 (1943); C. L. Wrenn, "The Poetry of Caedmon," *Proceedings of the British Academy*, xxxii (1946); J. W. Lever, "Paradise Lost and the Anglo-Saxon Tradition," *Review of English Studies*, xxiii (1947); E. B. Irving (ed.), *The Old English "Exodus"* (1953). (H. BR.; D. Wκ.)

CAELIUS, in full MARCUS CAELIUS RUFUS (82-48 B.C.), Roman politician and protégé of Cicero (*q.v.*), was the son of a Roman knight. Educated under the guidance of M. Licinius Crassus and Cicero, he was constantly with Cicero during Cicero's praetorship (66) and subsequently. In 63 he became friendly with Catiline, but according to Cicero was not involved in the conspiracy. In 61 he went to Africa as *comes* (attendant) to the proconsul Q. Pompeius Rufus, and on his return in 59 successfully prosecuted Gaius Antonius, who had been consul with Cicero, in a brilliantly savage speech.

Caelius is probably the Rufus whom the poet Catullus accused of stealing his mistress Clodia from him. In 56 he was prosecuted for violence (*vis*) at the instance of Clodia, whom he had deserted. Caelius spoke in his own defense and Crassus and Cicero, whose speech survives, also spoke for him. He was acquitted. In 52 he was tribune and opposed Pompey's measures for bringing T. Annius Milo to trial for the murder of P. Clodius. He was induced by Pompey, against his own judgment, not to veto the law of the ten tribunes, allowing Julius Caesar to stand for the consulship in absence.

In 51 Cicero went to Cilicia as proconsul, and Caelius by arrangement kept him supplied with news from Rome. His letters are preserved in the collection of Cicero's correspondence. In 50 he was aedile (*q.v.*), and his letters to Cicero contain many requests for panthers for his games. In Aug. 50 he foresaw civil war and seemed uncertain which side he should support. In 49 he decided, and later fought for Caesar in northwestern Italy and Spain. In 48 he was praetor *peregrinus* (see *PRAETOR*), but he quarreled violently with the urban praetor Gaius Trebonius, and

introduced measures amounting to a general cancellation of debts. The senate deprived him of his office, and he left Rome to join Milo and to start an insurrection, but he was soon killed at Thurii in Lucania. Brilliant and cynical, he was capable of impetuous acts of kindness or savagery. He lives more vividly than most of the men of his age, in his letters to Cicero.

See Cicero, *Pro M. Caelio oratio*, ed. by R. G. Austin, 3rd ed. (1960), *Epistolae*, ed. by R. Y. Tyrrell and L. C. Purser (1904-18).

(H. H. Sd.)

CAELIUS AURELIANUS, a physician of Sicca in Numidia, who probably flourished in the 5th century AD., although some place him two or even three centuries earlier. A translation by Aurelianus of two works of Soranus of Ephesus (2nd century), the chief of the "methodist" school of medicine, on chronic and acute maladies—*Tardae*, or *Chronicæ Passiones*, in five, and *Celeres*, or *Acutæ Passiones*, in three books—is extant, as are also considerable fragments of his *Medicinales Responsiones*, also adapted from Soranus, a general treatise dealing with rules of health (*salutaria praecepta*) and the pathology of internal diseases (ed. Rose, *Anecdota Graeca et Latina*, ii, 1870).

CAEN, a city of northwestern France, capital of the *département* of Calvados (*q.v.*), $7\frac{1}{2}$ mi. from the English channel and 149 mi. W.N.W. of Paris on the main railway to Cherbourg. Pop. (1954) 62,887; (1959 est.) 85,000. The city covers an area of approximately 6 000 ac., mostly on the left bank of the Orne river. The surrounding countryside is undulating, well-watered and fertile. To the southeast the extensive Plaine de Caen produces cereals; elsewhere, dairy farming and stock breeding are the chief agricultural activities.

Town Plan and Buildings.—Caen suffered great destruction following the Allied armies' invasion of Normandy in 1944; two-thirds of the buildings, including many ancient monuments, were destroyed or damaged. Rebuilding of the devastated area was completed by 1959. The central area of Caen is now an excellent example of modern town planning, with wide boulevards and spaced-out apartment buildings constructed of local freestone (as were many of the ancient buildings). The Avenue du Six Juin, the principal new thoroughfare, runs northward from the Orne to join the old Rue St. Pierre at its eastern end. The west side of the rebuilt area faces the open "Prairie," a green plain on which a race course is laid out.

The church of St. Étienne, or L'Abbaye-aux-Hommes, and the church of La Trinité, or L'Abbaye-aux-Dames, escaped damage in 1944; both date from the 1060s and both are fine specimens of Norman Romanesque. St. Btienne, in the west of the city, is characterized by its simplicity and purity of line. The west front, nave and two frontal towers rising to a height of 295 ft. are Romanesque; the spires were added in the early 13th century. The choir, one of the earliest examples of Norman Gothic, dates from the same period. The fine carved choir stalls date from the 17th century. A marble slab in front of the high altar marks the site of William the Conqueror's tomb. La Trinité, in the east, has a plain Romanesque front flanked by two square towers; the spires were destroyed during the Hundred Tears' War. The tomb of Queen Matilda, wife of William, stands in the 12th-century choir; beneath it is a fine 11th-century crypt.

Halfway between the two abbey churches stands the highly decorated, beautiful church of St. Pierre; restoration of the wartime damage is complete. Its architecture is mainly Gothic, but the choir and the apsidal chapels are magnificent examples of French Renaissance. The Hôtel d'Escoville, on the Place St. Pierre, is a Renaissance mansion (1538) that has been faithfully restored. The castle, of which there are considerable remains, was built by William the Conqueror and was one of the largest of medieval times. Near St. Étienne is the secularized church of St. Nicholas, a fine unaltered example of Benedictine Romanesque (c. 1090). The house where François de Malherbe was born (1555) stands in the Rue St. Pierre.

Caen is the seat of an academy for the whole of Normandy. Its university, founded in 1432 by Henry VI of England, was completely destroyed in 1944. A fine, spacious university, erected on the northern slopes of the city and having faculties of law,

letters and science, was opened in 1957. There are two teachers' training colleges, a school of art and music and a preparatory school of medicine and pharmacy. Public buildings include the prefecture of the *département* of Calvados, which also contains the archives; a law court; a chamber of commerce; theatre; and branches of most leading French banks.

Economy.—Caen is a centre of road and rail communications. From the main railway station, on the right bank of the Orne, express trains connect with Paris, Cherbourg, Rouen, Le Mans and Tours. Coach services link Caen with the chief towns of Calvados and neighbouring *départements* and with the Le Havre-Southampton-London cross-channel route. Carpiquet airport, 4 mi. W. of Caen, has a customs and is open permanently to private aircraft. Weekly passenger and freight service is operated to the Channel Islands (Jersey), and air taxis can be hired.

The industrial development of Caen owes much to the iron-ore mines in the Orne valley to the south, which are the second in importance in France. The chief industries are iron and steel, heavy trucks and machinery. Manufactures include cement, tiles and ceramics, furniture and chemicals. The port of Caen, in the east of the city, through which more than 2,000,000 tons pass annually, is connected with the sea by a canal 9 mi. long, which enters the Channel at Ouistreham. Principal imports are coal, timber, phosphates; exports are chiefly iron ore, cement, machinery, wheat and dairy products. Caen serves as the main distributive centre for all lower Normandy.

History.—Caen first became an important place in the 10th and 11th centuries, under the dukes of Normandy, and was the capital of lower Normandy in the time of William the Conqueror. In 1346 Caen was besieged and taken by Edward III of England. It was again taken by the English in 1417 and held by them until 1450. During the Wars of Religion, Caen embraced the reform; in the succeeding century its prosperity was shattered by the revocation of the Edict of Nantes (1685). In 1793 the city was the focus of the Girondist movement against the Convention. In June 1944 the German army made Caen the hinge of resistance to the British advance, and it was finally liberated by the Canadians in July 1944. (L. E. O.)

CAENEUS, in Greek mythology, son of Elatus, a Lapith. At the marriage of Pirithous, king of the Lapithae, the centaurs, who were guests, became drunk and attacked the bride and other women. Caeneus joined in the battle that resulted and, because he was endowed with an invulnerable body, killed five centaurs without trouble. In desperation, the other centaurs combined against him, piling huge pine trees upon him until the accumulated weight forced him, still standing, underground, never to appear again (Ovid, *Metamorphoses*, xii, 459 ff.). The centaurs' attack on Caeneus provided a favourite theme for Greek art, as in the friezes of the Theseum and the temple of Apollo at Bassae. A later story explained that Caeneus was originally a girl, Caenis, who yielded to Poseidon and received as reward the male sex and invulnerability (*Metam.* xii, 189 ff.). Ovid invents the metamorphosis of the buried Caeneus into a golden bird, perhaps a curlew. (Wm. S. A.)

CAENOLESTID, a small shrewlike, pouched mammal (marsupial) of the family Caenolestidae, known also as the selva or opossum-rat. Three genera occur in the Andes of Colombia, Ecuador and Peru, and on Chiloé Island, off southern Chile. They are of special interest since they have characteristics intermediate between two groups of marsupials, having the lower first incisor teeth greatly enlarged, and all toes of the hind feet separate; they possess only small, rudimentary pouches.

Caenolestids inhabit the ground beneath thick underbrush, are nocturnal in habit, and feed on insects, on small birds and their eggs and on other small animals. Their fossil history dates back to the Eocene (about 40,000,000 years ago) of South America. (R. H. MA.)

CAEN STONE, a soft cream-coloured Jurassic limestone found near Caen, France. It is closely identified with the Bath oolite stone found in England.

The quarries are of great antiquity, and partly because they are easily accessible to sea transportation, considerable quantities of

the stone were imported into England at an early date, probably from soon after the Norman conquest down to the middle of the 15th century. It was used extensively in building churches and cathedrals, in such well-known structures as Westminster abbey, Canterbury cathedral, Buckingham palace and the old Cathedral of St. Paul's in London. More than 400 tons were imported in 1443 to be used in building Eton college.

CAERE, an ancient city of Etruria (mod. CERVETERI; *i.e.*, *Caere vetus*), about 5 mi. from the coast and about 20 mi. N.W. of Rome. According to ancient writers its original Pelasgian name was Agylla; the Etruscans took it and called it Caere but the former name lasted on into later times. It was one of the 12 cities of Etruria and had much trade through its port Pyrgi (*q.v.*). After the invasion of the Gauls in 390 B.C., the vestal virgins and the sacred objects in their custody were conveyed to Caere for safety. A treaty was made between Rome and Caere in the same year. In 353, however, Caere took up arms against Rome out of friendship for Tarquinius (mod. Tarquinia), but was defeated and partially incorporated in the Roman state without voting rights for its members. The status is known as the *ius Caeritum*, and Caere was the first of a class of such municipalities. Under the Roman emperors Augustus and Tiberius its prosperity was to a certain extent restored, and inscriptions speak of its municipal officials (the chief of them called dictator) and its town council, which had the title of *senatus*. In the middle ages, however, it sank in importance, and early in the 13th century a part of the inhabitants founded Caere Novum (mod. Ceri) 3 mi. to the east.

The town lay on a hill of tufa, extending from northeast to southwest, isolated except on the northeast, and about 300 ft. above sea level. The modern town, at the western extremity, probably occupies the site of the acropolis. There seem to have been eight gates in the circuit of the city walls which was about 4 mi. in length. In the theatre many inscriptions and statues of Roman emperors were found. The necropolis on the hill to the northwest, known as the Banditaccia, is far more imposing. It has the aspect of a city of the dead, the tombs being in rows divided by paved streets. Other tombs are on the hills called Vignali and Monte Xbetone in the place called the Sorbo. The larger tomb chambers are hewn in the rock and covered by mounds. Several of them are interesting from their architectural and decorative details. The most important tomb of all, the Regolini-Galassi tomb (taking its name from its discoverers in 1836), which lies southwest of the ancient city, is a narrow rock-hewn chamber about 60 ft. long, lined with masonry, the sides converging to form the roof. The objects found in it (a chariot, a bed, silver goblets with reliefs, rich gold ornaments, etc.) are in the Etruscan museum in the Vatican; they are attributed to the 7th century B.C. and are important evidence for the orientalizing style.

Nogara*, pp. 147 ff. (1937).

CAERLEON, a village in the Monmouth parliamentary division of Monmouthshire, Eng., on the Gsk, 3 mi. N.E. of Newport. Pop. (1961) 4,184. It is important as the site of the Roman legionary fortress of Isca (not Isca Silurum), founded and garrisoned by the 2nd legion (Legio II Augusta) after the campaign against the Silures (*q.v.*). This legion had formed the right wing of the expeditionary force of 50,000 men landed in Britain by the emperor Claudius in A.D. 43. According to Tacitus (*Annals* xii, 32) it first entered south Wales in A.D. 50, and from then on was engaged in the reduction of the Silures from its base at Ringsholm, Gloucester. Under Sextus Julius Frontinus, governor in Britain A.D. 74 to 77–78, this task was successfully concluded and the legion moved to new quarters at Caerleon c. A.D. 75. The site, close to the tidal Usk, was chosen for its accessibility and for its strategic command of the approaches to the south Wales coastal plain. Together with Chester (Deva) it was the seat of the main Roman military power in western Britain for 200 years. The modern name is said to be a corruption of Castra Legionis (the legion's fort; Welsh Caer = fort).

Excavations.—The systematic exploration of the site was begun by the National Museum of Wales in association with the Caerleon Excavation committee in 1926. Finds are exhibited in the Legionary museum at Caerleon, consisting of a notable series of inscribed and sculptured stones, small bronzes, much pottery and many coins. The best of the structural remains thus disclosed, the amphitheatre and the Prysg field barracks, are conserved by the ministry of works.

The Defenses.—The defenses of the fortress consisted originally of a V-shaped ditch 25 ft. wide and 8 ft. deep and a rampart of clay more than 20 ft. wide revetted with timber, enclosing a rectangle of about 50 ac. About A.D. 100 the timber stockade was replaced by a stone wall 5 ft. thick and still standing in places to a height of 12 ft. The wall was built on a cobble foundation, offset on a sandstone plinth, and consisted of a rubble core faced externally with squared sandstone blocks set in yellow or pinkish mortar: the internal face was left rough as it abutted on the clay bank. The wall was probably 20 ft. high with a crenelated parapet protecting the wall walk, access to which was by small internal turrets at intervals of 50 yd. It was pierced by four symmetrically placed gateways, imposing structures with double-arched doorways with guardrooms in the flanking towers. The space behind the rampart, the *intervallum*, was used for cookhouses, a latrine and other buildings after the completion of the fortress; debris from the cookhouses was deposited in the turrets which were disused in the mid-2nd century.

The Interior.—1. The street system. The planning of the interior of the fortress conformed to the normal military type. The main road, the *via principalis*, crossed between the two lateral gateways and its line can be followed approximately in the Broadway and Backhall street. It was joined midway at right angles by the *via praetoria* leading in from the river crossing, a bridge over the Usk. Parts of two other lateral streets are indicated on the plan, lost beneath the medieval and modern streets. Excavation uncovered much of the rampart roadway, the *via sagularis*, that made a circuit of the defenses.

2. The principal buildings. In a legionary fortress these consisted of the headquarters building (*principia*), the commander's house (*praetorium*), the hospital (*valetudinarium*), the training schools (*scholae*), the workshops (*fabricae*), the granaries (*horrea*), the armoury and stores. Not all of these have been identified at Caerleon.

The headquarters building was known to occupy its customary position facing the central road junction, so the greater part was covered by St. Cadoc's church and churchyard. Immediately behind it, a large building covering more than an acre was tentatively identified as the *quaestorium*, used for the disposal of hostages and booty. To the northeast of this, in Jenkins' field, was the *fabrica* where the remains of smithies and workshops were found, and to the southeast beneath the primary school was a large residential building, probably the commander's house.

3. The barracks. The soldiers lived in barracks placed on the perimeter of the fortress, of which at least 24 were located by excavation. These buildings, which were of uniform construction, lay in pairs (*strigae*) facing inward into a narrow court. Each barrack was a single-storied building holding a company of 100 men (a century) and measuring 250 ft. long by 40 ft. wide. Two-thirds of it was fronted by a paved veranda and divided into 12 cubicles, in each of which 9 men slept and kept their accoutrements; the other third was wider and contained a more spacious set of rooms for the centurion, the officer in charge, and his assistants (*principales*). The buildings were substantially constructed of stone throughout, with roofs of red tile; windows were glazed and the floors paved or cemented.

The Environs.—The parade ground was identified outside the south gate, the *porta principalis sinistra*. There also was the amphitheatre for the staging of beast fights, gladiatorial shows or other entertainment. It was an oval structure 267 ft. long by 222 ft. broad, with an area entered by two imposing main gates on the long axis. There was seating for about 6,000 persons on wooden seats raised in tiers in the auditorium, an earthen bank buttressed and faced externally and internally by walls which gave

the building the appearance of a stone structure. Access to the seats was by stairs entered through six vaulted passages. The amphitheatre was built in the late 1st century, reconstructed after partial collapse c. A.D. 125 and again rebuilt in the early 3rd century; it fell into final disuse at the end of that century.

The buildings that made up the civil settlement (Cannabae), which were being systematically explored at mid-20th century, lay nearer the river, separated by a precinct wall from the military installations. A street, shops and houses were uncovered. The sites of three or four bath buildings are also known to the south and east of the fortress. Inscriptions to Jupiter Dolichenus, Diana and Mithras are evidence of temples dedicated to these deities in the environs.

History.—The foundation of the fortress can be dated archaeologically to c. A.D. 75. At first buildings and defenses were constructed in timber, but in the last years of the 1st century they were rebuilt in stone. An inscription found in 1928 records the construction of the *principia* under the emperor Trajan in the year A.D. 100, but the whole task was not completed for a decade. The full occupation of the new stone buildings was of short duration for c. A.D. 120 the garrison was radically reduced to release men for the northern frontier, including work on Hadrian's wall. The first quarter of the 3rd century saw a renewal of military activity, following 50 years' neglect, at Caerleon, as in Wales generally, due to the initiative of the Severan dynasty. An inscription records the repair of the headquarters building (?) by Septimius Severus and his sons (198–211), and some barracks and the amphitheatre were found to have been also reconditioned during the period A.D. 212–222. A later rebuilding of barracks alone is recorded in the joint reign of Valerian and Gallienus.

In the later empire Caerleon declined rapidly in importance in consequence of the military reorganization of the province. Some troops were probably moved to Cardiff to garrison the new type of coastal fort erected there against the Irish pirate menace, but the *Notitia Dignitatum*, a document recording the 4th–5th-century disposition of troops and officials, shows that the 2nd legion was stationed at Richborough (Rutupiae), Kent, a fort for the defense of the Saxon shore. Excavation, however, has shown that certain barracks and buildings were occupied or reoccupied at Caerleon until c. A.D. 350 or 375–380, but that such occupation was partial and sporadic.

Post-Roman.—No remains have been found to show that Caerleon was occupied in the dark ages, between the end of Roman rule and the Norman conquest of Gwent (c. A.D. 1070); but the *Urbs legionis* recorded by Gildas (*De Excidio Brit.*, ch. 10) as the place of martyrdom of two Romano-British saints, Aaron and Julius, is almost certainly Caerleon, and land presumably belonging to a church dedicated to these martyrs was the subject of dispute in the 9th century.

That King Arthur held court at Caerleon on Usk or was crowned there is highly improbable, though the green circle of the amphitheatre was long known locally as his "Round Table" and Lord Tennyson stayed at the Hanbury Arms, Caerleon, while writing the *Idylls of the King*. There is a tradition of a bishopric said to have been transferred to St. David's by St. David himself. To Giraldus Cambrensis (c. 1146–1220) Caerleon was recognizable as an ancient Roman city with many vestiges of its ancient splendour (*Itinerarium*, i. 5). The remains of a motte castle of the early medieval period stand outside the northeast angle of the Roman fortress; it was mostly in Welsh ownership and was burned down in 1235.

CAERNARVON (CAERNARFON), municipal borough and the county town of Caernarvonshire, north Wales: 9 mi. S.W. of Bangor by road near the west end of the Menai strait and

roughly midway along the Arton sea plain which stretches to the foothills of Snowdonia. Pop. (1961) 8,998. The castle and town walls, built by Edward I following the final conquest of Wales in 1282–83, occupy a rocky peninsula between the estuary of the Saint (Seiont) river and the Cadnant stream (the latter now covered over) where they flow into the strait. The castle (c. 1283–1322), finely preserved, stands in the southern part of this peninsula and is the dominating feature of the town. Of the medieval borough (charter granted 1284), the walls and wall towers (built 1283–85; largely repaired, 1295, after Welsh attack in 1294), the original street plan and the Chapel of St. Mary remain. Within the walls, which are nearly $\frac{1}{2}$ mi. in circumference, are the county hall (1863) and county offices, the main building of which was formerly the county jail. The guildhall (1874) is on the site of the east gate, the town's former principal gateway. The present main thoroughfare and shopping streets, Bangor and Pool streets, are outside the walls to the east and debouch into Castle square, an open space east of the castle. Statues of David Lloyd George, M.P. for Caernarvon borough (erected 1921) and Sir Hugh Owen, an education pioneer (1888) stand in the square. Residential areas have spread at different periods over the immediate hinterland of the town. Caernarvon is served by a branch line (1852) of the main London-Holyhead railway, which runs from Bangor to Afon Wen, where it joins the London-Pwllheli line. There is also a branch line from Caernarvon to Llanberis (1869). The road from Bangor to Pwllheli and Portmadoc passes through the town and those from Llanberis and Beddgelert also converge upon it. There is a small harbour which flourished in the 19th century with the export of slate, but the decline of the slate industry and other changes have greatly reduced its use. The port serves mainly as a distribution centre for petroleum and oil. Caernarvon is the county and assize town and is chiefly an administrative and shopping centre. In summer it is a tourist centre.

The Roman fort of Segontium, to which the name Caernarvon refers, (Welsh, Caernarfon, Caer yn Arfon, *i.e.*, the fort in the land over against Mona) was established c. A.D. 75 on a low hill, south-east of the present town. After Roman withdrawal (c. 380–390) the fort was occupied by local chieftains. Llanbeblig (after Peblig or Publicus), founded nearby probably in the 5th century, the church of the parish within which the later borough was established. The area around the Roman fort eventually became one of the "manors" of the princes of Gwynedd. Edward I by contrast built his castle on the strait, for easy access to the sea, on the site of a motte originally built by Earl Hugh of Avranches about 1090 during a brief period of Norman occupation. Edward fixed the capital of the principality of north Wales at Caernarvon. His fourth son, later Edward II, created prince of Wales in 1301, was born within the castle precincts in 1284. (W. O. W.)

CAERNARVONSHIRE (CAERNARFON), a county of north Wales. Pop. (1961) 121,194. Area 569 sq. mi. The county, long in shape, is bounded chiefly by the sea, and stretches from the tip of the Llŷn (or Llyn = lake) peninsula in the southwest Penrhyn bay near Llandudno in the northeast, a distance of approximately 55 mi.; its greatest width is approximately 23 mi. and the coast line is about 127 mi. long. The Llŷn peninsula, long and narrow, projects into the Irish sea between Caernarvon and Cardigan bays.

On the northwest, the Menai strait (*q.v.*) divides the county from Anglesey. East and southeast, the landward boundary is also largely formed by natural features, the county being separated from Denbighshire (east) by the Conway river for most of its course and from Merioneth (southeast) by high land and the lower course of the Glaslyn. Included within the county, though east of the Conway, are the Creuddyn peninsula (northeast of the Conway estuary) and the parish of Maenan.

Physiography.—The county is dominated by the great mass of the Snowdon mountains, rising on the east from the Conway valley and on the south from the Vale of Ffestiniog. This mass, called Snowdonia (Welsh, Eryri) is divided by valleys and passes into five tracts. The northernmost and largest is bounded by the Conway valley on the east and Nant Ffrancon and the Llugwy valley on the southwest. In the second tract are the Penrhyn and

CAMERA PRESS LTD.

LLYN PADARN, WITH SNOWDON PEAKS IN THE BACKGROUND, LLANBERIS PASS, CAERNARVONSHIRE

Dinorwic slate quarries, among the greatest of their kind in the world. The third tract, divided from the second by the pass of Llanberis, contains Snowdon (Welsh, *Y Wyddfa*), the highest peak in England and Wales (3,561 ft.). The fourth, southwesternmost, tract is detached from that of Snowdon by the valleys of the Gwyrfai and Colwyn. The deeply eroded valleys between these four tracts trend from southeast to northwest, but the fifth tract, lying to the south and southeast, is separated by a gentler line of valleys stretching from Betws-y-Coed in the east to Traeth Mawr in the southwest. To the southwest of the main Snowdon mass is a line of conical hills stretching down to the tip of the Llŷn peninsula. Despite the dominance of the Snowdon mass, the highland region (above 1,400 ft.) occupies only 99 sq.mi. of the county. Lowland areas (below 600 ft.) occupy 308 sq.mi. and uplands (600–1,400 ft.) 162 sq.mi. The lowlands stretch mainly along the northern coastal plain, opening out into the Arfon sea plain where most of the main urban areas are situated. Beyond the line of the Llŷn hills there are also large stretches of comparatively flat country reaching down to the southern coast of the peninsula.

There are more than 60 lakes in the county, varying in elevation from less than 176 ft. (Llyn Dinas) to more than 2,094 ft. (Melynllyn), with maximum depth from 10 ft. (Llyn Ognen) to 222 ft. (Llyn Cowlyd), and in size from small pools to lakes such as Llyn Padarn (more than 2 mi. in length). Some supply water to towns and villages; others are potential sources of hydroelectric power. Rivers radiate from the central mountain mass and are mostly short and swift. The longest is the Conway, navigable by small craft for about 12 mi from its mouth.

The Snowdon range originated in the mountain-building periods of the Pre-Cambrian Age. Volcanic activity and successive movements during the Paleozoic era were followed chiefly by long-continued denudation until the general shaping of the present mountains, with their northeast to southwest alignment, emerged in the later Cenozoic era. Quaternary glaciation gave to the county its chief surface features, its steep-sided valleys, narrow ridges, cwms (dingles) and glacial lakes. More than half the county is floored by rocks of Ordovician Age, consisting of a highly folded complex of grits, shales and slates with interbedded volcanic rocks in the form of lavas, tuffs and ashes. Igneous intrusions occur on a large scale, especially in the Llŷn peninsula and in the northeast around Penmaenmawr. Pre-Cambrian, Cambrian and Silurian rocks underlie some areas; an outcrop of Cambrian strata extends southwestward from near Aber toward Clynnog. Carboniferous limestone appears in the Great Orme's head and also in a narrow coastal strip fringing the Menai strait. Fault fissures in the Ordovician and Cambrian strata contain certain metalliferous minerals; mainly lead, zinc and copper, but

these appear to have been worked out, excepting some lodes in the Conway valley.

Prevailing winds are from the southwest across the sea and with the mountain barrier also hindering the passage of warm air, the county has mainly the mild, moist climate characteristic of the western coastal regions of Britain. Rainfall is relatively heavy in Snowdonia but considerably less in the coastal areas and in the Llŷn peninsula. The soils of the upland region are chiefly podsollic; those of the lowlands vary in texture and character but mainly between light and fairly heavy loam. Almost half the land area of the county consists of grasslands. Remains of natural woodlands (oak and alder) exist on some of the lower slopes of valleys but afforestation with conifers has taken place and is being extended over an ever wider area. The lowlands are largely enclosed and cultivated but are of relatively low fertility. The variation in contours and gradations between the Snowdonian summits and the coastlands produces a considerable variety in plant life, ranging from the rare mountain spiderwort of the alpine zone to the limestone flora of the Great Orme. In Snowdonia foxes are numerous, and there are occasional herds of wild goats and mountain ponies. The pine marten and polecat are also to be found. Otters are fairly common in the larger rivers and badgers relatively so in woodlands. The chough, peregrine falcon and ring ouzel are among the many birds to be seen in the mountains, while large colonies of sea birds nest on the Great Orme and along the coasts of Llŷn. About 44% of the county lies within the Snowdonia National park. (See also SNOWDON.)

History.—Evidence (chambered tombs, pottery and axes on Penmaenmawr) indicates that the earliest human settlements in Caernarvonshire, chiefly in the Llŷn peninsula and on the hill slopes of the immediate hinterland, were Neolithic (c. 2000 B.C.). The region was penetrated by the Beaker folk about 1500 B.C. and finds suggest that in the Bronze Age it was crossed by important trade routes linking the Mediterranean, Ireland and northern Europe. Climatic changes, causing undergrowth to choke the valleys, and other disturbances in the later Bronze Age may have driven the inhabitants back to the higher reaches of the hills, and stone hut circles found at 800–1,000 ft. may belong to this period. Penetration by Celtic traders and settlers appears to have taken place about 500–300 B.C., a Celtic tribe, the Ordovices, occupying the region at the time of the Roman invasion (c. A.D. 61). Complete Roman conquest of the area was achieved in A.D. 71–78, forts subsidiary to Deva (Chester) being established at Kanovium (Caerhun) near Conway and Segontium (Caernarvon), the latter not being finally abandoned till c. 380–390. Christian tombstones from the 6th century were found at Penmachno and many ecclesiastical sites bearing the names of their saint-founders date from this period.

In the early middle ages the region was divided into three cantreds or districts containing 100 townships (Arllechwedd, Arfon and Llŷn) and subdivided into *cymwds* or commots. These areas were at one time ruled by chieftains descended from the dynasty of Cunedda, who, coming from north Britain, appears to have taken possession of the region in the dark ages. The *cymwds* of Eifionydd and Creuddyn (joined in 1284 to the three cantreds to form Caernarvonshire) lay in cantreds Dunoding and Rhos respectively. The cantreds eventually became part of the principality of Gwynedd, ruled by the prince of Aberffraw and lord of Snowdon whose domain was protected from the west by the natural barrier of the Snowdon range.

Following his conquest of Wales in 1282–83, Edward I annexed to the English crown the principality of Llewelyn the Last (whose territories by 1282 had been much reduced by conflicts with England) and divided it into three counties, of which Caernarvon was one, by the Statute of Rhuddlan (1284). He built castles, founded English boroughs at Caernarvon and Conway and conferred borough status on the native settlement near the old Welsh castle of Criccieth. Charters were granted to two other Welsh settlements, Pwllheli and Nefyn (Kevin), in 1355. The revolt of Owen Glendower (1400–15) seriously affected the area. Fundamental changes in the county's economy culminated toward the close of the 15th century in the rise of landowning families, mostly

Welsh, who were to dominate the life of Caernarvonshire until mid-19th century. Tudor legislation (1536 and 1542) changed the administration introducing quarter sessions as the main organ of local government in the place of the offices of the Edwardian principality.

The late 18th and 19th centuries were the period of religious revival and of the Industrial Revolution. Slate and granite quarries were developed by their owners, quarrying villages (centres of Radicalism and Nonconformity) sprang up and ports flourished. At the same time, and especially after the railway to Bangor from Chester was built in 1848, the county became a popular tourist area. Seaside resorts developed on the northern coasts, notably at Llandudno (*q.v.*), and inland resorts at Betws-y-Coed, Beddgelert and Llanberis (*qq.v.*). Throughout the centuries the county has remained mainly Welsh in speech and character, especially in areas away from the main lines of communication and the holiday resorts. At mid-20th century the bulk of the population was bilingual but English influences, already dominant in the Llandudno area, were affecting the inhabitants more strongly than ever before.

Administration.— There are 4 municipal boroughs (Caernarvon, the county town, Conway, Pwllheli and Bangor [*qq.v.*]), 7 urban and 4 rural districts, 52 civil parishes and 2 parliamentary constituencies (Caernarvon division comprising the southern half and Conway division the northern half). The county is the diocese of Bangor except for a few northern parishes which are in that of St. Asaph.

The Economy.— The basic industries are agriculture (products, chiefly milk and meat), slate and stone quarrying and the tourist trade. Other industries included chemicals, metal manufacturing, engineering, shipbuilding, building and contracting, transport, the distributive trades and forestry. There are small hydroelectric power stations at Cwmdyli and Dolgarrog, where there is an aluminum works.

The main London-Holyhead railway runs along the coast between Llandudno junction and Bangor, crossing the Conway river and the Menai strait by tubular bridges. From Llandudno junction there is a branch to Llandudno and another up the Denbighshire side of the Conway. A branch connects Bethesda with Bangor (closed to passengers). A line runs from Menai Bridge station through Caernarvon and Penygroes to Afon Wen, linking north and south. The coast railway from Barmouth enters the county at Portmadoc and runs through Xfon Wen to its terminus at Pwllheli. Trunk roads into the county are: the one following the coastal route from Chester; the road entering at Betws-y-Coed, passing through Nant Ffrancon to Bangor and crossing the Menai suspension bridge into Anglesey; the road from Merioneth, entering across the Portmadoc embankment. Main roads within the county run chiefly along the coastal plains and through the mountain passes. The ports of Bangor, Caernarvon, Conway, Port Dinorwic, Portmadoc and Pwllheli are little used.

CAERPHILLY (CAERFFILI), a market town and urban district in the Caerphilly parliamentary division of Glamorgan, Wales, 7 mi. N. of Cardiff, 11 mi. W. of Newport by road, and near the Monmouthshire border. Pop. (1961) 36,008. It was formerly in the ancient parish of Eglwysilan, which joined with Bedwas, Monmouthshire to form an ecclesiastical parish in 1850. The parishes of Eglwysilan and Llanfabon were in 1893 constituted into an urban district. The ancient commot (early Welsh territorial and administrative unit) of Senghenydd, corresponding to the modern hundred of Caerphilly, comprised the mountainous district from the Cefn On ridge on the south to Brecknockshire on the north, being bounded by the Taff and Rhymney rivers on the west and east. Its inhabitants, though nominally subject to the lords of Glamorgan since Robert Fitzhamon's conquest, often raided the lowlands. To check this Gilbert de Clare, during the closing years of the reign of Henry III, built a castle on the southern edge of this dis-

trict, in a wide plain between the two rivers. Prince Llewelyn ap Gruffydd laid siege to and destroyed it in 1270. The present castle, begun in 1271, became the earliest and most complete example in Britain of a concentric plan known as "Edwardian" and is the largest castle in England and Wales, excepting Windsor. The great hall is a fine example of Decorated architecture. This and other additions are attributed to Hugh le Despenser (1318-26). It was taken by Owen Glendower in 1403. Before the middle of the 15th century it had ceased to be a fortified residence and was used as a prison. It eventually passed to the Bute family (via the earls of Pembroke) and underwent restoration in the 1930s after which the 4th marquess of Bute gave it to the crown.

The town grew up around the castle but never received a charter. Its markets during the 19th century were chiefly noted for Caerphilly cheese which is still widely sold in England. The district was one of the chief centres of the Methodist revival of the 18th century, the first synod of the Calvinistic Methodists being held in 1743 at Watford farm. With the development of the south Wales coal field the prosperity of Caerphilly increased. This industrial progress was helped by the opening in 1858 of a railway from Rhymney to Caerphilly, which was subsequently extended. Trade depression in the 1930s had especially marked effects in this locality and unemployment was widespread. Coal remained the main industry in the early 1960s.

CAESAR, GAIUS JULIUS (100-44 B.C.), Roman general and statesman; whose dictatorship and whose eventual assassination precipitated the civil wars that ended republican government in Rome, and whose history of his Gallic conquests is a primary source of our knowledge of Gaul. The origin of the word *Caesar*, the third name (cognomen) of a branch of the patrician family of the Julii prominent in public life from the time of the Punic Wars, was debated in antiquity, and was most commonly believed to have originated from a birth by caesarean section. This is stated as a fact by Pliny the elder, and is plausible on the analogy of *Vopiscus* and *Proculus*, words describing circumstances of birth, both of which are found as names in the Julian family. The Julii (by c. 100 B.C.) claimed descent through Julius, son of Aeneas, from Venus. "We Julii are descended from Venus," Julius Caesar is reported to have said in a speech at his aunt's funeral in 69 B.C. There were two branches of the Julii Caesares in the late republic, both deriving from Sextus Julius Caesar, praetor in 208. The branch to which Caesar the later dictator belonged was the less distinguished, his uncle Sextus Julius Caesar being its first consul (in 91 B.C.).

Early Career Until 60.—Caesar was born on July 12, 100 B.C. (not, as Afommsen held, in 102). His father, Gaius Julius Caesar, praetor probably in 92 and pro-consul of Asia a year later, died in 85. His mother, Aurelia, who was long remembered for the care which she took over her son's education, lived until 54. His father's sister Julia was wife of Gaius Marius (*q.v.*); and at the age of 16 Caesar himself married Cornelia, the daughter of L. Cornelius Cinna. From the start he was a *popularis*, brought up in the political entourage of Marius, who had used popular support as a weapon against the exclusiveness of the senatorial class or *optimates*.

Sulla having spared his life—with the warning that "Caesar had many Mariuses in him"—Caesar went east in 81 or 80, to join the staff of M. Minucius Thermus, governor of Asia, by whom he was sent on an embassy to King Nicomedes of Bithynia.

BY COURTESY OF MUSEO NAZIONALE, NAPLES
MARBLE BUST OF JULIUS CAESAR,
OF THE 1ST CENTURY, A.D. IN THE
MUSEO NAZIONALE, NAPLES, ITALY

When Sulla died in 78 B.C., he returned to Rome, decided not to support the foolhardy venture of Lepidus (*q.v.*) and in 77 won praise from his prosecution, unsuccessful though it was, of Gnaeus Cornelius Dolabella, lately governor of Asia. Leaving Rome again to study rhetoric in Rhodes, he was captured by pirates in winter 75–74 and, as he had promised them while awaiting the arrival of his ransom, he secured their subsequent crucifixion. Back in Rome in 73, he spoke in 70 for the *lex Plautia*, by which Roman citizenship was restored to the surviving followers of Lepidus.

Of his career in the 60s certain bare facts are beyond dispute. Elected quaestor for 69, he officiated in 69–68 in Further Spain; he was aedile in 65 and praetor in 62, both times with the optimate M. Bibulus, son-in-law of M. Porcius Cato, as a colleague; being already a pontifex (*q.v.*), he was elected pontifex maximus in 63; early in 61 he divorced his wife Pompeia, whom he had married in 67 after Cornelia's death, once it was clear that she was implicated, however innocently, in the trial of P. Clodius (*q.v.*) for violating the mysteries of the Bona Dea; he governed Further Spain as proconsul in 61 and, on his return in 60, when he was refused permission to stand in absence for the consulship of 59, he entered the city and offered himself as a candidate, thereby forfeiting the right to a triumph for which he had hoped in recognition of his conquests in Spain. He was elected, again with Bibulus for colleague. For the rest, much that the ancient historians recorded of him in the way of policy in these years was mistakenly backdated from his later career, and much that was discreditable (implication, for instance, in Catiline's alleged schemes of 65 and his great conspiracy of 63) was falsely imputed to him later, by Bibulus in 59 and by antagonistic historians.

Certain features of his personal outlook in the 60s are clear. To restore the discredited reputation of his uncle Marius, he replaced the trophies of Marius on the Capitol during his aedileship in 65. He opposed Q. Lutatius Catulus, the most distinguished of Sulla's surviving supporters, by speaking in favour of Pompey's extraordinary commands in 67 and 66 (see POMPEY). His election to be pontifex maximus against the far stronger claims of Catulus and of P. Servilius Isauricus was achieved by heavy bribery. As praetor in 62 he sought to discredit Catulus in connection with his rebuilding of the temple of Jupiter on the Capitol. He was behaving as an orthodox *popularis* when he opposed the legality of summary punishment after the passing of the *senatus consultum ultimum* (the last decree), supporting T. Labienus in 63 in his prosecution of Gaius Rabirius in connection with the events of 100 B.C. which culminated in the death of Saturninus (*q.v.*); and on Dec. 5 he opposed M. Porcius Cato (*q.v.*) in the senate, making a wise and humanitarian speech against the execution of the Catilinarian prisoners, and in favour of holding them in life imprisonment in cities outside Rome.

M. Licinius Crassus (*q.v.*) who lent him considerable sums of money was quick to appreciate his promise; but Caesar certainly acted independently of Crassus when he supported the grant of extraordinary powers to Pompey and, as praetor in 62, when he joined the tribune Q. Metellus Nepos in urging that Pompey should be recalled from the east to restore order; on which occasion he was temporarily suspended from office.

Association With Pompey and Crassus and Consulship of 59.—He achieved a triumph of political diplomacy in 60 when he reconciled Pompey and Crassus. With the limited objects of promoting measures in which both had been frustrated by optimate opposition (proceeding in the main from Cato) and securing a large military command for Caesar, the three agreed to combine political forces in the so-called "first triumvirate." Cicero was even sounded to see if he would like to make a fourth. Pompey wanted belated ratification of his eastern settlement and land allotments for his veterans; Crassus wanted concessions for the company of *publicani* which farmed the taxes of Asia.

There were two land bills, the first passed in all probability in late Jan. 59, the second, sanctioning distribution of the public land in Campania, at the beginning of May. When Bibulus tried to impede the passing of the first law, he was thrown from the platform and his fasces were broken. He retired to his house and, by announcing that until further notice he was engaged in *spectio*

(watching the heavens to discover whether the signs were auspicious for the transaction of public business), he endeavoured to bring the business of the state to a standstill. Disregarding Bibulus, Caesar continued to legislate. The measures in which Pompey and Crassus had an interest were passed. In return for 6,000 talents payment Ptolemy XII (Auletes) was recognized as king of Egypt and, probably in May, by a law of the tribune P. Vatinius, Caesar was appointed proconsul of Cisalpine Gaul and Illyricum for five years. The senate added a third province, Transalpine Gaul. In this year Pompey married Caesar's daughter Julia (who died in 54), and Caesar married Calpurnia, daughter of L. Piso, who became consul for 58.

Caesar in Gaul and Britain 58–51.—Each summer from March 58 to 51 B.C. (inclusive) Caesar campaigned north of the Alps, returning for the winter to deal with civil administration in Cisalpine Gaul and Illyricum. He kept in touch with Roman politics through visiting politicians and through agents in Rome, particularly the Spaniard Cornelius Balbus. P. Clodius, tribune in 58, was engaged from 58 to 56 to ensure that Caesar was not recalled prematurely and that Pompey, who had been frightened by Caesar's use of force in 59, did not desert his political alliance with Caesar in favour of the *optimates*. However great the personal sympathy that Caesar felt for Cicero, he knew that Cicero's banishment by Clodius (by a bill passed while Caesar was still in the vicinity of Rome in March 58) suited his own interest.

There was a good case for the creation of a strong military command in the north, where danger comparable with that which had followed the emigration of the Cimbri and Teutoni in 113 could reasonably be apprehended. To the northeast the first consolidation of Dacia as a kingdom under King Burebista was under way, with repercussions which were felt on the borders of Illyricum. Farther westward a series of migrations on the part of people living east of the Rhine had started or was imminent. The Boii had moved into Noricum and besieged Noreia. The Suebic chief Ariovistus (*q.v.*) had crossed the Rhine, helped the Sequani to inflict a crushing defeat at Admagetobriga (or Magetobriga) in 61 on Rome's old allies, the Aedui, and had since remained, an embarrassing guest, in the territory of the Sequani, attracting a constant stream of German immigrants from across the Rhine. Already in 61 the Roman senate had sent special instructions to the governor of Transalpine Gaul to protect the Aedui and after Admagetobriga had even anticipated an invasion of Roman territory early in 60; the recognition of Ariovistus as "a friend of the Roman people" in Caesar's consulship was, presumably, an act of deliberate deception. The Celtic Helvetii were on the point of starting an emigration, planned in 61 B.C., to the country of the Santones on the coast of Gaul, and it was the news that this emigration was imminent that took Caesar at once to Transalpine Gaul, where he campaigned for the following eight years.

The four legions which he took over in his provinces (three in Cisalpine, one in Transalpine Gaul) were numbered 7th to 10th. He raised two new legions (11th and 12th) in 58, and two more (13th and 14th) in 57. After making good losses suffered in winter 54, raising fresh legions and borrowing one from Pompey, his army at the end of 53 consisted of ten legions (between 40,000 and 45,000 troops), together with cavalry (about 400 to a legion) and auxiliaries (about one-tenth the strength of the legionaries). He sent 2 legions to Italy at the senate's request in 50, but by the end of 50, through further recruiting, had an army of 11 legions, including the famous Alaudae legion.

The Helvetii—368,000 of them, if Caesar is to be trusted—were on the move, across the Jura mountains and three-quarters of them across the Arar (Saône) river when Caesar (by his own account) or T. Labienus, his second-in-command (by Plutarch's), caught and defeated their rear guard, the Tigurini, at the crossing. The remainder of the tribe were defeated near Bibracte (*q.v.*). Then in the plain of Alsace Caesar attacked and defeated the indignant Ariovistus, who escaped after the battle, but did not long survive his escape. Caesar now planned to subjugate the whole of Gaul. With his victory over the Nervii, the most powerful of the Belgic tribes, in a battle on a site near the Sambre river in 57, the capitulation of the Atuatici and the submission to his lieutenant P. Cras-

sus of the western coastal tribes, Caesar was optimistic enough to think that the back of the conquest was broken, and a *supplicatio* or period of thanksgiving, of unexampled length, 15 days, was voted at Rome. He now looked further afield, over the English channel ("Oceanus") and across the Rhine and, to ensure that he was not recalled—for L. Domitius Ahenobarbus, candidate for the consulship of 55, had announced his intention of securing Caesar's recall—he met Crassus and Pompey at Luca (mod. Lucca) in April 56 and agreed that they should both become consuls for 55, displacing Domitius, receive each a five-year military command and secure the extension of his own command for a further five years.

The revolt of the Veneti and other coastal tribes in 56 was a surprise to him. Decimus Brutus, admiral of a makeshift Roman fleet, defeated them by cutting the rigging of their great barges. In 55 the Cispetes and Tencteri, who had crossed from the east bank of the Rhine, were destroyed in circumstances which Caesar himself described in disingenuous terms (*De bello Gallico*, iv, 4–15), and which prompted Cato to suggest in the senate that Caesar should be handed over as a prisoner to the Germans. Then, after building the famous bridge, Caesar crossed for 18 days to the east bank of the Rhine and later made a short reconnaissance of Britain, landing near Walmer in Kent. At Rome a second *supplicatio*, of 20 days, was voted. He made a second and longer expedition to Britain in 54 with five legions and an invasion fleet of 800 vessels; he crossed the Thames and received the submission of Cassivellaunus (*q.v.*). Attacks on his winter quarters in Gaul that winter were the first indication of coming trouble and one and one-half legions were destroyed. The Treveri rose in 53 and were defeated by Labienus, and Caesar made his second crossing of the Rhine. In 52 the storm broke. The whole of Gaul, even including in the end the Aedui, revolted. The Gauls had at last found, in the Arvernian chief Vercingetorix, a leader of genius, capable of uniting the tribes and intelligent enough to plan a scorched-earth policy which, if it had been followed wholeheartedly, might have driven the Romans from Gaul. Caesar won an early success when he succeeded in crossing the mountain range of the Cévennes in thick snow to join his legions. He was forced to lift his siege of Gergovia, the capital of the Arverni (about 4 mi. S. of Clermont-Ferrand) but later defeated Vercingetorix near Dijon and besieged him in Alesia (*q.v.*). After enduring terrible hardships and after the defeat of the relieving army under Vercassivellaunus and others, Vercingetorix capitulated. The year 51 was spent in mopping-up operations, including the capture of Uxellodunum (mod. Issoudun). Gaul was now organized as a Roman province; its annual tribute was 40,000,000 sesterces and, after its conquest, Caesar was an immensely wealthy man.

Negotiations in Rome for a Second Consulship.—Caesar had planned to hold a second consulship, after the necessary legal interval of ten years, in 48 B.C.; but he anticipated that his political enemies would try to prevent this by indicting him—whether for his conduct in 59, for misgovernment of his provinces or for bribery—after his entry to Rome for the election (in July 49) or in the interval between his election and his assumption of office on Jan. 1, 48. Therefore, in order not to enter Rome before the end of 49, he secured leave, through a law proposed by the whole college of ten tribunes in 52, to stand in absence at the elections in 49; and he expected to retain his Gallic command to the end of 49 since, by a clause in the *lex Pompeia Licinia*, the law by which his command had been extended for a further five years in 55, no consul of a year earlier than 49 could be appointed his successor, and any other measure to succeed him could be vetoed at Rome by a friendly tribune. Pompey's *lex de provinciis*, passed in 52, since it increased the scope of tribunitian veto on provincial appointments, caused him no anxiety; but the consul M. Marcellus made it clear by the summer of 51 that the optimate bloc in the senate did not propose to honour the law of the ten tribunes. Caesar retorted by bringing all provincial appointments to a deadlock, through the veto of Gaius Curio, tribune in 50, who sold his allegiance to Caesar for a large sum of money. M. Antonius (Mark Antony), who had been Caesar's quaestor in Gaul, and who succeeded Curio as tribune for 49, was to discharge the same function. Between Caesar and the optimate bloc there was a conflict of in-

attention which only skilful negotiation could have resolved; but when from the optimate side it was suggested that Caesar might be allowed to stand in absence if he first surrendered command of his army, Caesar stood firm in his insistence that in that case Pompey, on whose military support the opposition to Caesar depended, and who remained in Italy after receiving leave to administer his Spanish provinces through deputies, should resign his military command as well. That a compromise was desired by a majority of senators was shown when Curio's proposal that both should resign their military commands was carried by 370 votes to 22 on Dec. 1. But on the following day the hysterical consul Gaius Marcellus placed a sword in Pompey's hands, bidding him defend the state. Antony succeeded Curio on Dec. 10. On Jan. 7, 49, he and his fellow-tribune Q. Cassius were warned that to sustain their veto might prove dangerous to them. The "last decree" was passed, and they fled to Caesar. A day or two later the senate appointed Domitius Ahenobarbus to succeed Caesar in Gaul.

Civil War.—Caesar crossed the Rubicon (*q.v.*) and invaded Italy with one legion on Jan. 11. He claimed that his *dignitas* had been insulted, and that the insult was one which in honour he could not overlook. He still hoped for peace by negotiation, but Pompey refused to meet him, and the core of unyielding opposition to Caesar hardened. His opponents were oversanguine, largely through the mistaken belief of Labienus, who had left Caesar and joined them, that Caesar would be faced by serious mutiny among his troops. They were disappointed by the speed of Caesar's movements and by the warmth of the reception which he received from the country towns of Italy through which he passed.

When Domitius Ahenobarbus' army capitulated at Corfinium (Corfinio in the modern province of Aquila), Caesar set Domitius free, and even restored to him the 6,000,000 sesterces found in his war chest. Moving down the east coast, he was too late to cut Pompey off from Brindisi, from which Pompey embarked his army (the two legions given up by Caesar at the senate's request for service in the east in 50, and such soldiers as had since been levied in Italy) and crossed the Adriatic on March 17. The consuls and a large proportion of the senate had crossed earlier. Unable, without a fleet, to follow Pompey, Caesar moved rapidly through Rome to Massilia (Marseilles), which withstood him, and to Spain where, after brilliant maneuvering near Ilerda (*q.v.*), he defeated Pompey's two lieutenants L. Afranius and M. Petreius. Massilia capitulated. After a few days in Rome, when after being made dictator to preside over the elections, he was elected consul for 48 with P. Servilius Isauricus the younger, he crossed to Epirus, and Antony followed with the greater part of his army. Caesar's attempt to blockade Pompey in Dyrrhachium (mod. Durres in western Albania) was unsuccessful and, if Pompey had shown greater initiative, Caesar might have suffered a serious defeat. He moved eastward, and so did Pompey. Both received reinforcements, and Pompey's army was the larger. But Caesar won a decisive victory at Pharsalus (*q.v.*) in Thessaly on Aug. 9, 48. He pursued Pompey to Egypt, but arrived after his murder. The winter in Alexandria was spent in hard fighting against Ptolemy XIII and the Alexandrians, at the end of which he confirmed Cleopatra as queen, with her young brother Ptolemy XIV Philopator as consort (see CLEOPATRA). After a short inspection of Egypt from the Nile he moved northward into Asia Minor and defeated Pharnaces II, son of Mithradates, who had invaded Pontus, at Zela in June. (The famous *Veni, vidi, vici*—"I came, I saw, I conquered"—recording this lightning victory was not the text of Caesar's dispatch to Rome, but a caption recording his victory at his triumph in 46.) He was back in Rome in October, but left at the end of November for Africa, where the republican army, 14 legions strong, was reorganized under Juba, king of Mauretania and Q. Metellus Scipio (consul in 52). When Caesar's legions, led by his favourite, the 10th, mutinied in Campania, he addressed them as civilians—*Quirites*—and discipline was restored by the insult of this single word. The republicans were defeated at Thapsus (*q.v.*) on April 6, 46 (really Feb. 6, for by this time the disordered Roman calendar, later corrected by Caesar, was about two months wrong) and at Utica in north Africa Cato committed suicide rather than sue for pardon. Those who escaped made for

Spain, where the two sons of Pompey were trying to build up another army. Caesar was in Rome from the end of July until November, and in August on four successive days, he celebrated four tremendous triumphs, over Gaul (Vercingetorix, kept six years for the ceremony, was now executed), Egypt, Pharnaces and Juba. He left for Spain in late November and defeated the last of the republicans at Munda (*q.v.*) on March 17, 45. Gnaeus Pompeius was killed soon after, but Sextus Pompeius remained at large. Caesar entered Rome again in the autumn of 45 and celebrated a triumph which gave offense as being, unlike those of 46, a triumph over Romans. The following five months, the longest continuous period which Caesar spent in Rome since 59, were largely devoted by him to planning a vast military campaign in the east. An army was assembling in Illyricum with which, taking his great-nephew Octavius (later the emperor Augustus), he intended to march, first to the Danube, then to the east, to engage the Parthians and avenge the defeat of Crassus and his troops at Carrhae in 53. He planned to leave Rome on March 17. Two days earlier, on the ides, he was murdered at the foot of Pompey's statue at a meeting of the senate held in Pompey's theatre.

Constitutional Position of Caesar.—From 49 to 44 the republican constitution was virtually suspended. Caesar's first dictatorship, in early Dec. 49 (to which, in an unconstitutional way, he was nominated by M. Aemilius Lepidus, a praetor), lasted only 11 days; its sole purpose was to enable him to preside over the election of consuls for 48, a function which Lepidus himself, being praetor, was not entitled to discharge. As a result of this election Caesar was consul in 48. Later in that year, when the news of Pharsalus reached Rome, he was nominated dictator (probably by his fellow-consul Servilius) for no specific period, with Antony as master of the horse. He was consul for the third time in 46, with Lepidus for his colleague, and on the news of Thapsus he was nominated dictator for ten years, and Lepidus now became his master of the horse. He was consul for the fourth time, for the first nine months of the year without a colleague, in 45, and for the fifth time, with Antony as colleague, in 44. Early in 44 he was created perpetual dictator, Lepidus continuing to be his master of the horse. He was granted tribunitian power for life in 48, and in 46 received extensive censorial powers for three years, under the title *praefectus moribus*. In the prolonged period of his absence from Rome great power was exercised by his representatives, in particular by Antony and by Lepidus successively as masters of the horse, and by such men as Aulus Hirtius, Cornelius Balbus and the knight Gaius Oppius, whose influence as agents of Caesar in Rome was greatly resented in optimate circles.

Beyond passing measures which were known to have Caesar's backing, the senate, whose number was increased by Caesar to 900, did little but vote sycophantic honours to him, as victory succeeded victory in the civil war, introducing to Rome titles and honours, many of which conflicted offensively with deep-rooted Roman tradition. A statue was voted to him in 46 with the inscription, "He is a demi-god," which Caesar ordered to be erased. In May 45 his statue was erected in the temple of Quirinus in Rome and in winter 45-44 he was voted a priest (though Antony, allegedly designated for the position, was never inaugurated). The name of the seventh month of the year was changed from Quintilis to Julius. A new panel of Luperci, the Luperci Julii, was created, and at the Lupercalia (*q.v.*) in Feb. 44 an unsuccessful attempt was made—by Antony and two of the later assassins, Cassius and Casca—apparently without Caesar's foreknowledge or approval, to crown him. Already in Jan. 44, when Caesar returned from the Latin games, there had been cries of "Rex," to which he retorted, "*Non rex sum, sed Caesar.*"

Reasons for the Conspiracy.—The conspiracy to kill him owed its success to the respect in which M. Junius Brutus (*q.v.*) was evidently held. Of the 60 conspirators (of whom Cicero was not one) we know the names of 20. Plans were first formed, probably, when Brutus divorced his wife and married Cato's daughter Porcia, widow of Bibulus, in summer 45. The murder was the easier for the fact that only a month before his death Caesar had discharged his Spanish guard, and dispensed with any kind of military protection in Rome.

It is quite certain that Caesar scorned the punctilio of conventional politics, and that there were occasions in the last months of his life when he was brusque, difficult of access, discourteous to the senate and culpably lacking in tact (as when, unconstitutionally, he made Caninius Rebilus consul for a single day, the last day of 45, and when he expelled two tribunes from the senate a month later). For the rest, the evidence is capable of conflicting interpretations. To some historians it seems clear that Caesar was corrupted by success, that he welcomed even the most extravagant of the honours voted to him, and that he planned to remain an autocrat, replacing constitutional republicanism by monarchy of the Hellenistic type. If so, the conspiracy is easy to understand. But it is understandable, too, if Caesar's offense in the conspirators' eyes simply lay in the fact that after Munda he did not restore republican government at once. In that case it may be held—and the ancient evidence warrants the view—that Caesar neither considered himself to be, nor wished to be thought, a king or a god; that he did not interrupt the authoritarian type of government in winter 45-44 because it had worked efficiently during the civil wars and he wished it to continue during what might be a protracted absence in the east. If this view is correct, it is impossible to say what type of constitutional settlement he might have made on his return.

Administrative Achievements of Caesar.—Apart from the startling brilliance of his military career and the fact that, when he conquered Gaul and established the Rhine as the boundary of the Roman empire he shaped the future of Europe, his administrative achievements were outstanding in range, imagination and importance. The *lex Julia repetundarum* of 59 gave great protection to provincials against rapacious administration; and though the publication of the senate's proceedings (*acta senatus*), instituted in that year, was discontinued by Augustus, the publication of the *acta diurna*, an official daily gazette, which he inaugurated in 59, continued usefully long into the empire. In his dictatorship he increased not only the number but also the representative character of the senate—stories of trousered Gauls and of senators who could not speak Latin were evident exaggerations—and he made extensive grants of citizenship, completing the unification of Italy by authorizing the bestowal of full citizenship on the inhabitants of Cisalpine Gaul north of the Po in 49. He created a large number of colonies in the provinces—including Corduba, Hispalis and Tarraco in Spain, Narbo in Gaul and Carthage (colonia Julia Carthago) in Africa; his colony Genetiva Julia at Urso (mod. Osuna) in Spain was established after his death. His intention of producing a uniform system of municipal government in Italy, on which work had started in early 45, was a good one, although it was never completed. If free elections were effectively curbed, the corruption and bribery of elections, which no legislation of the republic had managed to restrain, were curbed too. The immediate debt crisis of 49 was not unjustly solved by the stipulation that, while interest was in effect excused, debts must be repaid in full. The number of recipients of the free monthly corn ration at Rome was reduced from 320,000 to 150,000. The greater part of the modern world is indebted to him for the act of reorganization by which in 46 he gave it what is, with very small adjustment in the middle ages, its present calendar.

Relations With Cicero and Others.—Though he failed in his last years to appreciate the psychology of politicians in the mass, he had a penetrating understanding of individual character, as is nicely instanced by the adroit flattery of his political approach to Cicero in 60 (which can be studied in Cicero's correspondence, *Ad Atticum* ii, 3, 3) and by his judgments on Brutus, *Quicquid vult, valde vult* ("Whatever he wants, he sets his heart on it") and on Cicero (*Ad Atticum* xiv, 1). And, although Curio assured Cicero in early 49 that Caesar's *clementia* was not genuine, but merely politic, nothing in Caesar's career is more remarkable than the generosity with which, if given the chance, he pardoned his defeated opponents in the civil war. It was the expression of such generosity, already experienced in his own case, in the case of M. Marcellus, consul of 51, which induced Cicero to "break silence" with his rapturous speech *Pro Marcello* in 46. There is a sharp contrast here with the blood bath which followed the victories of

Marius and Sulla before Caesar and that which followed the formation of the triumvirate in 43.

Caesar's Heir.—Julia, his daughter by Cornelia, was Caesar's only certain child. Though Servilia was his mistress, probably between 61 and 59, the story that Brutus, born long before this, was his son was no more than a canard. Cleopatra, who was certainly his mistress in Alexandria in the winter of 48–47, lived in Rome with her royal consort, Ptolemy XIV, from 46 until after Caesar's death. Cleopatra and Antony claimed later that her son Caesarion (Ptolemy XV Caesar), who was murdered on Octavian's instruction after Actium, was Caesar's son. The boy was almost certainly born not in 47 but after Caesar's death, and there is no convincing evidence at all that Caesar was his father. His heir, adopted by his will (made in autumn 45) was his great-nephew Gaius Octavius, son of Atia, who was daughter of Caesar's sister Julia. By his will Caesar left 300 sesterces to every member of the Roman populace. His body was burned in the forum, like that of Clodius earlier, after Antony had delivered a violent funeral speech, probably on March 20 (see ANTONIUS). The unpredicted appearance of a comet at the games in honour of Caesar's victory celebrated by Octavius (now, after acceptance of his adoption, Caesar Octavianus) between July 20 and 30, 44, was accepted by the credulous populace of Rome as visible evidence of Caesar's godhead, and after the formation of the triumvirate of Octavian, Antony and Lepidus, on Jan. 1, 42, by vote of the senate and people Caesar was made a god. Julius Caesar no longer, he was now Divus Julius, and Octavian was marked out from the rest of the contemporary world by having a god for his father; he was "Divi Juli filius."

Writings.—Caesar's two books *De analogia*, written during his proconsulship of Gaul, have perished; so has the *Anticato* which he published, probably in 45, in response to the hagiologies of Cato by Cicero, Brutus and others. His surviving works are the *Commentarii* on the Gallic war in seven books and on the civil war in three. The *De bello Gallico* describes, with one book devoted to each year's fighting, his campaigns in Gaul from 58 to 52. The campaigns were probably written up each winter and the whole work published in 51 as a naturally not unbiased record of his achievement in Gaul for the reading public at Rome, with an eye on his prospective candidature for the consulship of 48. The first two books of the *De bello civili* describe events of 49, and the third book those of 48, breaking off in Alexandria at the end of the campaigning season. Possibly the first two books were published in winter 49–48 and the third book a year later, to keep the Roman public informed of the course of the war from Caesar's standpoint. On the other hand it is not impossible that he wrote this for publication in the winter of 45–44 and that, had he not been killed, he would have carried his account of the war down to the battle of Munda. Book 8 of the *De bello Gallico* was written after Caesar's death by Hirtius, who had probably been Caesar's secretary during the latter part of his time in Gaul, to bridge the gap between the end of Caesar's *De bello Gallico* and the start of his *De bello civili*. The surviving *Bellum Alexandrinum* may be by Hirtius; the authorship of the *Bellum Africum* and the *Bellum Hispaniense* is uncertain.

Commentarii were intended as material for history books, not as finished works of history; but Cicero, writing in Caesar's lifetime in 46, reasonably stated of the *De bello Gallico* that it had the elegance and perfection of a finished work of history. After Caesar's death Xsinius Pollio was more critical, stating that sometimes deliberately, sometimes from forgetfulness, Caesar wrote much that was not true; that, in particular, he was sometimes too uncritical of the reports of his subordinate officers. He concluded that had Caesar lived he would have produced a revised edition, free from blemishes. It is a long—and a wrong—step from such intelligent criticism to the unrestrained denunciation of Caesar's veracity in which modern scholarship has occasionally indulged.

CAESAREAN SECTION, in obstetrics, is the operation for removal of a fetus from the uterus by an abdominal incision. (For the association of the name of Julius Caesar's family with the operation, see CAESAR, GAIUS JULIUS.) It has been practised on the dead mother since very early times; it was prescribed by Roman law that every woman dying in advanced pregnancy should be so treated; and in 1608 the senate of Venice enacted that any practitioner who failed to perform this operation on a pregnant woman supposed to be dead laid himself open to very heavy penalties.

The first recorded instance of its being performed on a living woman occurred about 1500, when a Swiss pig gelder operated on his own wife. It was tried in many ways and under many conditions, but almost invariably resulted in death of the mother from sepsis or hemorrhage. Even in the first half of the 19th century the recorded mortality was more than 50%. Fetal craniotomy—in which the life of the child is sacrificed to save that of the mother—was almost invariably preferred.

The introduction of asepsis and use of improved methods of suturing the incised uterine wall have so reduced the mortality that the operation is frequently performed. Where possible, however, it is better to avoid the operation except under favourable conditions and in skilled hands. It still carries a definite hazard. See OBSTETRICS.

CAESAREA PALESTINAE, an ancient seaport on the coast of Palestine, the site of the modern village of Qisarya, 22 mi. S. of Haifa, in northern Israel. The town was originally built (25–13 B.C.) by Herod the Great, king of Judaea, as port for his capital Sebaste on an ancient Phoenician fortified site known as Strato's Tower. Josephus describes the palaces, temple, theatre, amphitheatre, hippodrome, aqueducts and other monumental structures (*Antiquitates*, xv, 9, 6). The harbour was constructed by reinforcing two reefs with vast stone blocks so that the mouth faced north away from the rough seas whipped up by the prevailing southerly winds. Caesarea played a prominent role in the lives of the early Christians. Peter first preached to Gentiles there at the invitation of the Roman centurion Cornelius. Philip the Evangelist lived there (Acts xxi, 8) and entertained Paul and his friends. On the death of Herod Agrippa I (A.D. 44) Caesarea had become the seat of the Roman procurator of Judaea. Paul was tried by Felix and imprisoned in Caesarea for two years (A.D. 57–59); he appeared there before Festus, Felix' successor, and Herod Agrippa

II and sailed from there to Italy for his final appeal to the emperor. Caesarea saw the first incidents in the Jewish revolt against the Romans (A.D. 66), and Vespasian, who made the town his headquarters, was proclaimed emperor there in 69. In the reign of Alexander Severus (A.D. 222-235) it became the metropolis of Syria. Its bishop, therefore, became metropolitan of Syria, an office which the historian Eusebius held from c. 314 to 318. Caesarea was also the home of the historian Procopius and the abode of Origen, the theologian. By A.D. 640 when the Muslims occupied the town its sea power had faded and it rapidly shrank in size and importance. Under the crusaders the city revived, for they rebuilt and walled about one-tenth of the Roman city adjacent to the harbour to serve as a citadel. It was successively captured: in 1101 by Baldwin I, on which occasion the Holy Grail was discovered; by Saladin in 1187; and by Richard I in 1191. Louis IX strengthened its fortifications (1251), and it was finally demolished by the Mameluke sultan Baybars I in 1265. Stones from the ruin were transported to Acre and Jaffa (Joppa) for building purposes during the 19th century.

In modern Israel an agricultural settlement adjoins the ancient site. (J. S. I.)

CAESAREA PHILIPPI, an ancient city (modern BANIYAS, in the Damascus *mohafazet* of Syria), lying at the southern end of the Hermon range where the main source of the Jordan river flows from a cave. Baal worship may have been practised there in Old Testament times, and the site may be Baal-gad of Josh. xi. 17 ff., or Baal-hermon of I Chron. v. 23. Worship of Baal later gave way to that of the Greek god Pan, and the name Paneas was applied to the city and the district. It was the site of the battle (c. 198 B.C.) in which the Seleucid king Antiochus III wrested Palestine from the Egyptian Ptolemy V (Polybius xvi, 18). Caesar Augustus presented the region to Herod the Great (king of Judaea from 37 to 4 B.C.) and Herod erected a temple to the emperor and installed his image in it.

Philip the Tetrarch (d. A.D. 34), Herod's son, enlarged the town, naming it Caesarea after Augustus and adding "Philippi" to distinguish it from Caesarea Palaestinae (*q.v.*). Jesus visited the region and gave the famous charge to Peter there (Mark viii, 27 ff.). Vespasian rested his army there for three weeks before advancing into Galilee to crush the Jewish revolt in A.D. 67. The city was the scene of fighting during the second crusade. Some broken columns and carved stones, parts of the old wall and citadel, traces of an aqueduct and some niches in the rock beside the spring are now the only visible remains of the ancient city. (J. S. I.)

CAESARIUS, SAINT, OF ARLES (c. 470-542), a monk of Lérins, celebrated preacher and opponent of Semipelagianism, was born in the environs of Chalon-sur-Saône about the year 470. At the age of 20, against his family's wishes, he entered the monastery at Lérins, and later held there the post of cellarer. Either because of poor health, with which he was constantly plagued, or because of differences with his colleagues, he left Lérins and, having been ordained priest, became abbot of a monastic community on an islet in the Rhône near Arles. He succeeded his kinsman, Aeonius, as archbishop of Arles, the see of which Pope Symmachus made primatial for Gaul and Spain. In his capacity as primate, Caesarius held various regional synods of importance. Among these, the second Council of Orange (529) is a landmark in the history of dogma because it decisively rejects the grace theories of Cassian and Faustus of Riez (Semipelagianism) in favour of a moderate Augustinianism. The Orange decrees have become the Roman Catholic norm for doctrines on grace, predestination and free will. Caesarius was no great theologian, but he was a great preacher whose many sermons were preserved and frequently used after his death. He wrote a rule, *Regula ad virgines*, for the women's monastery of which his sister, St. Caesaria, was abbess, and also a directory for monks. He died in 542 and his liturgical feast is Aug. 27.

Caesarius' works were published in J. P. Migne, *Patrologia Latina*, vol. 67, pp. 997-1166. The complete critical edition is Germain Morin, *Opera omnia S. Caesarii*, 2 vol. (1937-42). The Morin edition of the sermons appears as vol. 103 and 104 in *Corpus Christianorum* (1953). An English translation of the sermons by

Sister Mary Magdeleine Mueller appears in vol. 31 of *The Fathers of the Church* (1956).

See Carl Franklin Arnold, *Caesarius von Arelate* (1894). (G. W. L.)

CAESARIUS OF HEISTERBACH (c. 1170-c. 1240), German preacher and writer of ecclesiastical histories and ascetical works, was born at Cologne. He joined the Cistercian order in 1199 and became prior of the Heisterbach house in 1228.

Caesarius was one of the most popular authors of 13th-century Germany and for that reason is of interest to cultural historians. His *Dialogue on Miracles* (c. 1223; Eng. trans., 2 vol., 1929), consisting of edifying narratives dealing with Cistercian life, was his most widely read work. He also composed eight books on miracles (edited by Meister, 1901), a life of St. Engelbert (edited by Gelenius, 1663; Ger. trans., 1955), a life of St. Elizabeth of Hungary (edited by Hyskens, 1908) and a biographical list of the archbishops of Cologne from 94 to 1238 (in *Monumenta Germaniae Historica*, vol. xxiv). Caesarius was noted for his practical sermons and opposition to the rationalistic tendency of scholastic philosophy. (Wm. J. B.)

CAETANI (GAETANI), the name of a Roman princely house, which according to family tradition is descended from the 10th-century dukes of Gaeta and which documentary record carries back at least to the 12th century, when Caetani appear in Naples, Rome, Xnagni and Pisa. Of these the Caetani of Anagni were raised to sudden prominence on the election of Benedetto Caetani as Pope Boniface VIII in 1294. It was at once the ambition and the policy of Boniface to increase the territorial power of his family and to diminish that of the Colonna (*q.v.*), the dominant feudal family of Rome. As a result the Caetani themselves became in the 14th century the dominant feudal family with lands and lordships throughout the Campagna, Marittima and Terra di Lavoro, which included Anagni itself, Sermoneta, Fondi and Piedimonte. The possession of domains in two different states, that of Naples and that of the church, induced the Caetani about 1420 to divide their patrimony. From this partition derive the two modern lines of the family, the Caetani of Rome, princes of Teano and dukes of Sermoneta, and the Caetani of Naples (dell' Aquila d'Aragona), princes of Piedimonte and dukes of Laurenzana. The Roman Caetani were created dukes of Sermoneta by Sixtus V in 1586 and received the principality of Teano in 1750 by exchange for Caserta, which they had acquired in 1659 as the result of a marriage. The Neapolitan Caetani were granted the surname d'Aragona by royal privilege from the Aragonese king of Naples in 1466. The duchy of Laurenzana came to them by marriage in 1606, and the lordship of Piedimonte was raised to a principality in 1715.

See F. Gregorovius, *History of the City of Rome in the Middle Ages*, Eng. trans. (1900-09); G. Caetani, *Domus Caietana* (1927).

(P. J. J.)

CAFFEINE, a vegetable-base stimulant present in coffee beans, tea leaves, cocoa beans and kola nuts, with the formula, $C_8H_{10}N_4O_2$. See PURINES; see also references under "Caffeine" in the Index volume.

CAFFIÉRI, the name of a large family of French sculptors and bronzeworkers, of Italian descent, founded by FILIPPO CAFFIÉRI (1634-1716). Filippo, after serving Pope Alexander VII, was taken to France in 1660 by Cardinal Mazarin and later appointed sculptor to Louis XIV; he worked in wood, stucco and bronze.

The most celebrated member of the family was JACQUES CAFFIÉRI, sixth son of Filippo. In 1715 Jacques designed a pall, his first recorded work, for a guild of which he had recently been elected a member. From 1736 until his death, payments appear regularly (though frequently in arrears) in the royal accounts for work he carried out at Versailles and other royal residences.

Little of this is now identifiable, but among his most important surviving works are the signed mounts for the chest of drawers delivered by R. A. Gaudreau for Louis XV's bedchamber at Versailles in 1739 (Wallace collection, London), and the mounts executed in 1747 for the chimney piece in the dauphin's bedchamber, which are still in position at Versailles. He was a master of the rococo style which he redeemed from triviality by his vigorous and spontaneous handling and which he was still using in the 1750s when

it was already becoming retardatory. The most important of these late works are the two monumental chandeliers in the Wallace collection (both signed and one dated 1751), probably presents from Louis XV to his daughter Louise Elisabeth, duchess of Parma, and the case of the astronomical clock designed by Claude Simon Passemant, completed in 1753 for the Cabinet Ovale at Versailles where it still stands. About the same period he probably made for Mme. de Pompadour the two rococo chandeliers later acquired by the Bibliothèque Mazarine. Jacques Caffiéri also executed portrait busts, notably of the baron de Bezeneval and his son (both signed and dated 1737 and 1735 respectively).

Jacques seems always to have used the signature "Caffiéri" even when (as on the Passemant clock case) he was collaborating with his elder son Philippe Caffiéri (1714-74). At Jacques's death the latter succeeded to his father's royal appointments. His most important works were the new altar furniture executed in 1759 for Notre Dame, Paris, which disappeared during the Revolution, and the surviving cross and candlesticks commissioned for Bayeux cathedral in 1771. He seems to have signed his own works "P. Caffiéri," sometimes adding *l'ainé*, to distinguish himself from his younger brother JEAN JACQUES CAFFIÉRI (1725-92). Jean Jacques became sculptor to Louis XV and also provided ornamental designs for metalwork, notably for the staircase at the Palais Royal.

See Lady Dilke, *French Furniture and Decoration of the 18th Century* (1901); F. J. B. Watson, *Catalogue of the Furniture in the Wallace Collection* (1954).
(F. J. B. W.)

CAFFRE CAT (KAFFIR CAT) (*Felis lybica cafra*), a variety of the wildcat of Africa, southern Europe and Asia. It is larger than the domestic cat, with which it occasionally hybridizes. It is nocturnal in habits and lives principally on mice, birds and lizards.
(R. T. O.)

CAGAYAN, the northeasternmost province on Luzon, Republic of the Philippines. Pop. (1960) 445,697. Land area 3,470 sq.mi. Physiographically it is composed of three regions. The eastern portion is the rugged, isolated Sierra Madre mountains, a forested area peopled in part by Negritos. The western section consists of foothills and associated valleys of the Cordillera Central, the main mountain mass of northern Luzon. The central portion and the heart of the province is the lower Cagayan valley, composed of sedimentary rocks and recent alluvial deposits. Climatically there are two seasons, wet from June until November, dry from December until May. It is an agricultural province with rice, corn, tobacco and coconuts the principal products. Slash-and-burn agriculture is practised in the Sierra Madres. Grazing is a secondary industry and Aparri (*q.v.*) is a fishing port. The Christian Filipinos are principally Ibanags and Ilocanos. Tuguegarao (pop. [1960] 43,044) is the capital and regional centre of the Cagayan valley.
(AN. C.)

CAGE, in mining, a frame with one or more platforms used for hoisting men, supplies, equipment and mine cars in a mine shaft. See ELEVATOR: *Mine Hoists*.

CAGE BIRD, any bird that, because of its cheery call or song, attractive colouring, bizarre appearance, curious habits or ability to mimic human speech, is kept caged by man as a pet. Although perhaps many different kinds of birds can be trained to endure a rather sedentary captivity, those most popular have been species chosen from three large groups of perching birds (Passeriformes): Psittacidae, the parrot (*q.v.*) family, including lorries, macaws, budgerigars and lovebirds; Sturnidae, the starling family, including mynas (see MYNAB); and Fringillidae, the finch family, including canaries (see CANARY).

On a more ambitious scale, especially in estates, parks and zoological gardens, many more kinds of birds are kept in enclosures called aviaries, essentially very large cages in which the birds are less restricted and live more naturally (see AVIARY AND AVICULTURE). See also BIRD.

CAGLIARI, the capital of Sardinia and the chief town of Cagliari province, is by sea 334 km. (270 mi.) W.S.W. of Naples and 604 km. (375 mi.) S. of Genoa. Pop. (1957 est.) 160,358. It lies at the northern extremity of the Gulf of Cagliari, in the centre of the south coast of the island, and is exposed to winds in winter,

while in summer the climate is hot and dry. The medieval town occupies a long narrow hill running north and south. On each side of the town are lagoons. That of Santa Gilla on the west, which produces fish in abundance, was originally an open bay. The upper town retains in part its fortifications, including the two great Pisan towers at the two extremities, called the Torre dell' Elefante (1307), and the Torre di San Pancrazio (1305); near the former is the university (founded 1806) and near the latter the archaeological museum. On the edge of the cliffs on the east is the cathedral of Sta. Cecilia, built 1257-1312 (rebuilt 1676), which retains two of the original transept doors. North of the town is the Roman amphitheatre, dug out of the rock. At the south extremity of the hill a large terrace, the Passeggiata Umberto Primo, was constructed. Below it are covered promenades, and steps descend to the lower town, the oldest part of which (the Marina! slopes toward the sea. The quarter of Stampace lies to the west, and beyond it again the suburb of Sant' Xvendrace. East of the Marina is the quarter of Villanova, which contains the 8th-century domed church of S. Saturnino. The harbour is good and was expanded in 1938. The chief exports are lead, zinc and other minerals and salt. Agriculture is the main occupation. A rail and road network connects with other parts of Sardinia.

The province of Cagliari (area 3,590 sq.mi.; pop. [1961] 750,410) is the most southerly of the three into which Sardinia is divided. It covers about one-third of the island and extends much farther northward on the west of the island than on the east. Other towns include Iglesias, Guspini, Oristano and Carloforte (*q.v.*).

The Ancient City.—Known to the Greeks as Caralis and to the Romans as Carales, the ancient city was the most important of Sardinia. It is attributed to the Phoenicians, and Punic tombs exist in considerable numbers near the present cemetery on the east, and still more on the rocky plateau to the northwest of the town. It first appears in Roman history in the Second Punic War, and probably obtained full Roman civic rights from Julius Caesar. In imperial times it was the most important town in the island, and in the 4th and 5th centuries it was probably the seat of the governor (*praeses Sardiniae*). It is mentioned as an important harbour in the Gothic and Gildonic wars. It was also the chief point of the road system of Sardinia. The site of the medieval town with its Pisan fortifications must have been the Carthaginian acropolis; such a site could not have been neglected. The Romans probably made use of it, though the lower quarters were mainly occupied in imperial times. The nucleus of the Roman *municipium* is probably represented by the present quarter of the Marina, in which the streets intersect at right angles and Roman remains are often found. The western quarter seems to have been far more important and a large Roman house (or group of houses) is still visible. Beyond this quarter begins an extensive Roman necropolis.

It is probable that the acropolis of Carales was occupied even in prehistoric times; but more abundant traces of prehistoric settlements have been found on the Capo Sant' Elia to the southeast of the modern town. The museum contains objects collected from many of the local sites.

CAGLIOSTRO, ALESSANDRO, CONTE DI (GIUSEPPE BALSAMO) (1743-1795), Sicilian charlatan and adventurer reputed to have magical powers, was born in Palermo. He later claimed to have spent some of his youth in Alexandria learning alchemy. In Rome he married the beautiful Lorenza Feliciani, called Serafina. In 1776 they appeared as Count and Countess Cagliostro in London, where Cagliostro was initiated into Freemasonry.

After traveling in eastern Europe practising hypnotism, Cagliostro appeared in Strasbourg, France, in 1780 and made the acquaintance of the disgraced cardinal Louis de Rohan, who invited him to Paris. There his séances became the rage of fashionable society. A contemporary witness thus describes one of them: "I only stole a look at him, and I still do not know what to make of him, that face, that headdress, the whole appearance of the man, impressed me in spite of myself. I waited for him to speak. He talked some

gibberish, a mixture of Italian and French, and gabbled quotations in something which passed for Arabic, but which he did not trouble to translate." Like the comte de Saint-Germain, he claimed to be 2,000 years old. The Affair of the Diamond Necklace (*q.v.*), in 1785, ruined Cagliostro's career in France. Although innocent in that swindle, he had previously promised the infatuated cardinal de Rohan to reconcile the queen, Marie Antoinette, to him. To the cardinal's delight he went through a performance of producing an apparition of her in a carafe of water—visible, however, not to the cardinal himself, but only to a child, who was supposed to have the "purity of an angel." This performance aroused great enthusiasm among Cagliostro's admirers, but the subsequent scandal over the necklace affair caused Louis XVI to banish him from France (1786).

In 1789 Cagliostro and his wife took refuge in Rome, but there she denounced him to the holy inquisition as a heretic, magician, conjuror of demons and Freemason. Condemned to life imprisonment, he died in the fortress of San Leo, in the Apennines, in 1795.

(AN. CA.)

CAGNIARD DE LA TOUR, CHARLES, BARON (1777–1859), French engineer and physicist, is best known for his invention in 1819 of a siren, known by his name, which he used to determine the number of vibrations corresponding to a sound of any particular pitch. He was born in Paris on March 31, 1777, and attended the École Polytechnique. He was made a baron in 1818, and died in Paris on July 5, 1859.

He was the author of numerous inventions, including the cagniardelle, a blowing machine, which consists essentially of an Archimedean screw set obliquely in a tank of water in such a way that its lower end is completely, and its upper end partially, immersed, and operated by being rotated in the opposite direction to that required for raising water.

In course of an investigation, in 1822–23, on the effects of heat and pressure on certain liquids, he found that for each there was a certain temperature above which it refused to remain liquid, but passed into the gaseous state, no matter what the amount of pressure to which it was subjected. In the case of water he determined this critical temperature to be 683.3° F., a remarkably accurate figure for his day.

Cagniard de la Tour also made experiments on the mechanism of voice production.

CAGOT (Span. AGOTES), people belonging to communities of outcasts in the Basque country, southwestern France and Brittany. A common phenomenon in the later middle ages and after, they were known as Capots, Gafets, Gahets, Gafos, Cacous, Caqueux and Caquins. The community which preserved its character until most recently was at Bozate de Arizcun in the valley of the Baztbn (Navarre). Regarded as unclean and credited with physical characteristics denoting degeneracy or leprosy, they were originally subject to severe restrictions such as inferior legal status, exclusion from political life, the professions and physical contact with others, and were even buried apart. They were forbidden to carry arms or to walk barefoot, and were obliged to wear a mark in the shape of a duck's foot or a piece of red cloth. In church they had a place reserved for them, sometimes with a separate door and a separate stoup, and the sacrament was administered to them on the end of a stick. They made their livelihood as woodcutters, carpenters, barrelmakers, masons, quarrymen, saddlers, fishermen and weavers, and in certain cases were noted as musicians, a role in which they were admitted to popular festivals.

Various explanations of their origin have been offered on ethnic, religious and physiological grounds, suggestions being that they were descendants of Romans or Goths or Moors, that they were descended from excommunicated Albigenses or that they were afflicted with cretinism or leprosy. Attempts were first made to liberate them in the 17th century and it has long been recognized that they are in no way abnormal. Pilar Hors, who studied them in 1952 in Bozate de Arizcun, found that their physical characteristics and blood groups resembled the population of southern France and were significantly different from the surrounding Spanish Basques, a circumstance exaggerated by the ban on mixed marriages which had continued into the 20th century. She sug-

gests that they were descendants of persons who took sanctuary in a leper colony, preferring the risk of disease to the dangers outside, and in support of her argument she refers to the use of the French word *cagot* to mean "hypocrite."

(J. A. P.-R.)

CAGUAS, an important industrial city situated on an extensive and fertile plain in the east central part of Puerto Rico. A four-lane divided highway, 25 mi. long, connects Caguas with San Juan, the capital and principal port of the island. Pop. (1960) mun., 65,098; town, 32,015. Sugar cane, tobacco, some fruits and vegetables are the main products of the Caguas rural district. Cigars, leather goods, glassware, foam rubber and electronic products are manufactured.

In the centre of the town is a beautiful plaza surrounded by attractive stores and public buildings. Founded in 1775, Caguas derived its name from the Indian chief Caguax, who lived in the surroundings and who was one of the first Indian chiefs to embrace the Christian faith.

(T. G. Ms.)

CAHIR (CATHAIR DHÚIN IASCAÍGH), a market town of County Tipperary, Republic of Ireland, lies in a good agricultural district at the foot of the eastern end of the Galty mountains, on the river Suir, midway between Clonmel and Tipperary. Pop. (1956) 1,731. An ancient fortress on an island in the river, called *Dhúin Iascaígh* ("abounding in fish"), was destroyed in the 3rd century. The present castle was built in 1142 (restored 1840) by Conor O'Brien, prince of Thomond, and is the largest of its type in Ireland. It was besieged by the earls of Essex (1599) and Inchiquin (1647) and by Cromwell in 1650. There is very good salmon and trout fishing in the Suir and the Aherlow; the latter river joins the Suir above the town.

CAHITA, a group of North American Indian tribes who inhabited the northwest coast of Mexico along the lower courses of the Sinaloa, Fuerte, Mayo and Yaqui rivers. They numbered about 100,000 when first encountered by the Spaniards in 1533 and were the most numerous of any single language group in northern Mexico. They spoke closely related dialects of the Taracahitian family of the Uto-Aztecan stock and were thus similar in language to the Nahuatl-speaking Aztecs in central Mexico and the Shoshonean-speaking Hopis of northern Arizona. They were agriculturalists and demonstrated a capacity for effective military organization.

Despite initial resistance to the Spanish conquest, they were rapidly gathered around missions by the Jesuit missionaries and during the 17th century were all converted to Christianity. They developed a complex fusion of native and Christian religion and became noted for their distinctive Easter ceremonies.

The chief surviving tribes are the Mayos and Yaquis. The latter played an important role in Mexican history, maintaining virtual autonomy of their church-centred communities until the 1890s when the Mexican government inaugurated a program of deportation. Thousands of Yaquis and Mayos were sent to Yucatán between 1905 and 1910. Others fled their homeland and scattered widely through northwestern Mexico and southwestern United States. The last Yaqui rebellion took place in 1927.

The Yaqui deer dancer occupies a central place in the official seal of the state of Sonora, and the vigorous music of the deer dance was utilized by the Mexican composer Carlos Chvez as a symphonic theme.

CAHOKIA MOUND, the largest prehistoric American earthwork north of Mexico, one of a group formerly numbering 45 considerable mounds (not including a great number of smaller ones), standing in Illinois. 6 mi. E. of St. Louis, Mo. The great mound is a quadrangular pyramid 998 ft. by 721 ft. by 99 ft. in height,

with a terrace, 30 ft. high, extending outward about 200 ft. from one side and with a width of 500 ft. The area of the base is more than 16 ac.

The mound is named for the Cahokia, a tribe of the Illinois confederacy, who occupied the neighbourhood in historic times and who were gathered into a mission settlement near the site of the present town of Cahokia, Ill., around 1698 by the Jesuit Pierre Pinet.

Various Indian artifacts and relics, including pipes, shells, etc., are preserved in a museum at Cahokia Mounds State park.

See also MOUND BUILDERS; NORTH AMERICA: *Prehistory and Archaeology*. (H. B. Cs.; X.)

CAHORS, a city of southern France, capital of Lot *département* and formerly capital of Quercy, is situated on a rocky peninsula surrounded by the Lot river, 111 km. (69 mi.) N. of Toulouse. Pop. (1954) 12,760. The city is divided by the Boulevard Gambetta, which runs north and south, and continues national route 20; to the east is the old town, dominated by the cathedral of St. Étienne. Built in 1119, and rebuilt in part between 1285 and 1500, it was the first cathedral in France to have cupolas; the two cupolas form the roof of the aisleless nave. Another remarkable feature is the finely sculptured north portal (c. 1190). Adjoining the cathedral are the remains of a cloister (1494–1509). The church of St. Ursicse is nearby on the river bank. It dates from the 12th and 13th centuries and preserves Romanesque capitals recarved in the 14th century. Of the palace of Pope John XXII, the great Avignon pope who was born at Cahors, only a square tower stands, the rest being in ruins or unfinished. The residence (mainly 14th-century) of the seneschals of Quercy, the Château du Roi, is near the river, upstream from the church of St. Ursicse. To the west of the Boulevard Gambetta is the newer quarter, with wide streets and spacious squares. There, too, is the Porte de Diane, probably the entrance to the Roman baths.

Four bridges span the Lot: the Pont Valentré (13th and 14th centuries), the finest medieval fortified bridge in France, with three towers, to the west; the railway bridge and Pont Louis Philippe, built in the reign of the king whose name it bears, which carries the main road to Toulouse and the south; and to the east the Pont Neuf, an iron bridge built in 1906, which replaced the humpbacked 13th-century stone bridge, by which Henry of Navarre took the town in 1580. A medieval rampart protected the city on the northern side. Just outside the loop of the river to the southeast is Mont St. Cyr, from which a fine view of the city can be obtained. Cahors is on the main railway from Paris and Orléans to Toulouse and Spain. Electrical equipment, door handles and sandals are manufactured and printing is carried on. An important market of geese and truffles is held between November and February.

The Divona of the Romans, Cahors was the capital of the Cadurci, the sacred Fons Divona (Divonne spring) now providing the city with water. It was famous for its linen cloth under the Romans and had a bishop from the 3rd century. It was later occupied by the Visigoths and the Saracens. Until after the Albigensian crusade it was a fief of the counts of Toulouse and in the 13th century became well known as a financial centre. From 1316 to the Revolution the administration was in the hands of royal officers, coseigneurs with the bishops. Pope John XXII founded a university at Cahors which survived until 1751 when it combined with that at Toulouse.

In addition to Pope John XXII, other famous natives of Cahors include the statesman Léon Gambetta and the poet Clément Marot. (E. D. DE G.)

CAILLAUX, JOSEPH MARIE AUGUSTE (1863–1944), French statesman, an outstanding finance minister and an able diplomat who is remembered also for the charges brought against his conduct in World War I, was born on March 30, 1863, at Le Mans. His father, Eugène Caillaux, was twice minister in conservative governments (1874–75 and 1877). In 1882, after a brilliant academic career, Joseph Caillaux entered the civil service as inspector of finance. In 1898 he was elected deputy for Mamers and soon joined the Radical-Socialist group in the chamber. Fi-

nance minister in René Waldeck-Rousseau's cabinet (1899–1902), he showed great ability. Georges Clemenceau gave him the same post in his cabinet of 1906–09. During this second term Caillaux was responsible for a bill introducing income tax, which brought upon him the enmity of the conservatives.

When Ernest Monis resigned in June 1911, Caillaux succeeded him as prime minister. He immediately had to deal with the Agadir crisis, which for a short time seemed likely to provoke war between France and Germany. A pacifist and a "European" at heart, Caillaux personally conducted the difficult negotiations over the head of his foreign minister, Justin de Selves. By ceding a small part of the French Congo, he successfully won Germany's acquiescence to the establishment of a French protectorate over Morocco. Nevertheless his many adversaries in France bitterly attacked him, and the hostility of the inquiry committee of the senate, led by Raymond Poincaré and Clemenceau, obliged him to resign.

Finance minister again in Dec. 1913, Caillaux secured the passing of the income tax bill. A virulent press campaign was started against him in *Le Figaro* and letters which had passed between himself and his wife before their marriage were published. Madame Caillaux, considering her honour assailed, shot the editor, Gaston Calmette. She was tried and was acquitted, but her husband had been forced to resign.

On the outbreak of World War I Caillaux was for a short time sent on an economic mission to South America. He came back to take his seat in the chamber but was systematically left out of the successive war governments. Thinking that the indefinite prolongation of hostilities was highly detrimental to Europe as a whole, he was indiscreet both in his talk and in the choice of his associates. When, in Nov. 1917, Clemenceau came to power fully determined to carry on the war till complete victory, Caillaux was accused of seeking a premature peace and of preparing a coup d'état. On Dec. 11, 1917, Clemenceau moved the suspension of Caillaux's parliamentary immunity. This was voted by the chamber and, on Jan. 4, 1918, Caillaux was imprisoned. It was not, however, until Feb. 1920, when Clemenceau was no longer head of the government, that Caillaux was brought before the senate, sitting as high court of justice, and indicted as having "plotted against the security of the state abroad." After a long debate it was felt that nothing definite could be proved against him. Nevertheless the court found him guilty of "communications with the enemy, but without premeditation." He was sentenced to three years' imprisonment and to five years' compulsory residence outside Paris. As he had already spent three years in prison, he was released next morning. Retiring to Mamers, he wrote two books: *Mes Prisons* (1921) and *Où va la France? Où va l'Europe?* (1922; Eng. trans. 1923).

The amnesty of 1924 restored to Caillaux his political rights. When Paul Painlevé formed a government in April 1925 he invited Caillaux to join it as the one man capable of putting the shaky French finances in order. Caillaux accepted and started by tackling the problem of inter-Allied debts. He began negotiations in Washington and in London, but in the French parliament the right was against him on general principles while the left disapproved of his financial orthodoxy. On Oct. 28, 1925, Painlevé formed a new ministry without him.

Meanwhile Caillaux had been elected senator for the Sarthe *département*. In June 1926 he was again finance minister in Aristide Briand's cabinet. The chamber, however, refused to grant him the almost dictatorial powers that he requested in order to restore the financial situation, and he had to resign after only three weeks in office.

Caillaux was finance minister for the last time in Fernand Bouisson's short-lived cabinet (June 1–4, 1935). As chairman of the finance committee of the senate he was instrumental in bringing about the fall of Léon Blum's ministry in June 1937. Caillaux died at Mamers on Nov. 21, 1944.

Although for some time he led the Radical Socialist party, Caillaux was always primarily a *grand bourgeois*. He was an excellent debater and a man of far-reaching vision, but in political circles his great qualities were somewhat impaired by his ostentatious self-

esteem and his rather supercilious manner.

See R. de Fleurieu, *Joseph Caillaux* (1951). (J. C. DE C.)

CAILLETET, LOUIS PAUL (1832–1913), French physicist and ironmaster, is noted for his work on the liquefaction of gases. Born at Châtillon-sur-Seine on Sept. 21, 1832, he worked in his father's ironworks and later was in charge of the works. He was also active in scientific research. On Dec. 2, 1877, Cailletet liquefied oxygen at a pressure of 300 atm. and at -27° C. The oxygen was obtained in the form of a cloud, but later he repeated his experiments at the École Normale at Paris, when he liquefied hydrogen, nitrogen and air. This work was carried on independently of the work of R. P. Pictet on liquefaction and there was considerable discussion as to which of the two had succeeded first.

Cailletet was the author of a number of papers in *Comptes Rendus* and other French scientific periodicals on the liquefaction of gases and the production of low temperatures, on the passage of gases through metals, on manometers for measuring high pressures, on critical points and on the state of matter at low temperatures. He was interested in aeronautics and devised an apparatus for measuring the altitude of an airplane. He was a member of the Paris Academy. He died in his native town on Jan. 5, 1913.

CAILLIE, RENÉ AUGUSTE (1799–1838), French explorer and the first European to visit Tombouctou (Timbuktu) and to return alive, was born at Mauzé, near La Rochelle, France, on Nov. 19, 1799. Before he was 20 he had made two voyages to Senegal and had traveled in the country. In 1824 he returned and prepared for an attempt to reach Tombouctou by learning Arabic and being educated as a convert to Islam. Pretending to be an Arab returning to Egypt he left the coast in April 1827, proceeded inland, crossed the upper Niger at Karoussa and after five months delay due to illness reached Tombouctou on April 20, 1828. He remained there a fortnight and then crossed the Sahara to reach Fès (Fez) in August. For his achievement he received a prize of 10,000 fr. from the Geographical Society of Paris. His *Journal d'un voyage à Tombouctou et à Jenné dans l'Afrique centrale* (ed. by E. F. Jomard) was published in three volumes in 1830; an English version was published in the same year entitled *Travels through Central Africa to Timbuctoo . . .* Caillié died at La Badère, Champagne, probably on April 17, 1838.

See A. Lamandé and J. Nanteuil, *La Vie de René Caillié* (1928); G. Welch, *The Unveiling of Timbuctoo: The Astounding Adventures of Caillié* (1938); A. Demongeot, *René Caille* (1948). (R. M. P.)

CAIN, according to Gen. iv, 1, the first-born son of Adam and Eve (*q.v.*). Gen. iv, 2–16, interrupting the genealogy, relates how Cain, a farmer, enraged because the Lord accepted the offering of his shepherd brother Abel in preference to his own, murdered Abel. For this crime he is cursed and banished from the settled country. Before he departs to the land of Nod (wandering), feeling that in his exile he will be the victim of any man who encounters him, he obtains from the Lord a sign of protection, and a promise that if he is slain despite it he shall be avenged sevenfold. The story is probably intended to explain how a certain tribe, bearing the name of Cain, came to have a certain tattoo mark, and to be noted for the plenteous vengeance it took upon any other tribe by whose hands one of its members was killed. It explains, too, from the point of view of the settled peoples, how this tribe came to live a nomad life. It has been argued that the tribe in question is the Kenites. In the parallel genealogy in Gen. v, the Kenan who appears fourth in the list is probably to be identified with Cain. The representation of Cain as a city-builder accords ill with the picture of Cain the nomad.

Irenaeus and other early writers mention a Gnostic sect of the 2nd century called the Cainites, who believed that Cain derived his existence from the superior, Abel from the inferior power, and that Cain was the first of a line which included Esau, Korah and the Sodomites. They are said to have had a Gospel of Judas. See also ABEL; GENESIS. (W. L. W.; X.)

CAINE, SIR (THOMAS HENRY) HALL (1853–1931), English writer whose novels achieved great popularity, was born at Runcorn, Cheshire, May 14, 1853. After working in a builder's office, and 3s a journalist and lecturer, he attracted D. G. Rossetti's

interest by sending him a copy of a lecture in his defense, and in 1881 became his secretary. When Rossetti died Caine earned a living by journalism, and in 1885 published *The Shadow of a Crime*, the first of many novels which combined strong characterization, sentiment, moral fervour and skill in conveying local atmosphere. Among the best known were *The Deemster* (1887), *The Manxman* (1894), *The Eternal City* (1901), *The Woman Thou Gavest Me* (1913) and *The Woman of Knockaloe* (1923). He settled in the Isle of Man, where he sat in the House of Keys, 1901–08, and died there, Aug. 31, 1931. In 1918 he received a knighthood of the British empire for his work as an Allied propagandist in the United States and in 1922 was made companion of honour.

ÇA IRA, a song of the French Revolution, with the refrain:

Ah! ça ira, ça ira, ça ira!
Les aristocrates à la lanterne.

The words, written by one Ladré, a street singer, were put to an older tune, called "Le Carillon National," and the song rivaled the "Carmagnole" (*q.v.*) during the Terror. It was forbidden by the Directory.

CAIRD, EDWARD (1835–1908), British philosopher, one of the leaders of the Neo-Hegelians, was born at Greenock, Scot., on March 23, 1835, a younger brother of the theologian John Caird. Educated at Glasgow university (1850–56), at St. Andrews (1856–57) and at Balliol college, Oxford (1860–63), Caird was tutor of Merton college, Oxford, from 1864 to 1866, professor of moral philosophy at Glasgow from 1866 to 1893 and master of Balliol from 1893 to 1907, when a paralysis obliged him to retire. He died at Oxford on Nov. 1, 1908.

Caird was one of the most influential British exponents of German idealism (see NEO-HEGELIANISM). While his friend Thomas Hill Green (*q.v.*) did more to develop the system positively, particularly in the field of ethics, Caird was chiefly distinguished for applying its principles to the interpretation of philosophy and theology both ancient and modern. His works include: *A Critical Account of the Philosophy of Kant* (1877); *Hegel* (1883); *The Social Philosophy and Religion of Comte* (1885); *The Critical Philosophy of Immanuel Kant*, two volumes (1889); *Essays on Literature and Philosophy*, two volumes (1892); *The Evolution of Religion*, two volumes (1893); the Gifford lectures for 1890–91 and 1891–92; and *The Evolution of Theology in the Greek Philosophers*, two volumes (1904; Gifford lectures, 1900–01 and 1901–02).

See Sir Henry Jones and J. H. Muirhead, *The Life and Philosophy of Edward Caird* (1921).

CAIRD, JOHN (1820–1898), British theologian and preacher, an exponent of theism in Hegelian terms, was born at Greenock, Scot., on Dec. 15, 1820, the son of an engineer. Ordained as a Presbyterian minister on graduating from Glasgow university (1845), he made a nation-wide reputation with his learned and eloquent sermons and was appointed professor of theology at Glasgow in 1862 and principal of the university in 1873. He died at Greenock on July 30, 1898.

In *An Introduction to the Philosophy of Religion* (1880) and in *The Fundamental Ideas of Christianity*, 2 vol. (1899; the Gifford lectures for 1892–93 and 1894–96), both of which follow Hegelian teaching closely, Caird argues that universal thought is the reality of all things and that the existence of this Infinite Thought, namely God, is demonstrated by the limitations of finite thought. His *Spinoza* (1888) is also Hegelian in its approach. His sermon "Religion in Common Life" (1855) was many times reprinted and translated into Gaelic, German, Czech and Hungarian. There are collected editions of his *Sermons* (1858), *University Sermons*, 1873–1898 (1898) and *University Addresses* (1898).

See Charles L. Warr, *Principal Caird* (1926).

CAIRN, a term used to denote a pile of stones. This can be of various shapes, depending upon the purpose for which it has been constructed. Cairns are used as boundary and track marks, and for burials, and are often erected on high ground. Burial cairns, also called barrows, show a great variety in shape and size, from the conical form covering a single grave to a more elaborate structure comprising several chambers.

In the British Isles there are a number of different types of cairns of the Neolithic and Early Bronze Ages. They may be horned, double horned, lobster claw (as in Donegal or Sligo, Ire., where the horns curve round the forecourt), long (often pear shaped, and higher at one end than the other), ring (as in Scotland), long cists or gallery graves, wedge shaped (also called Paris cists, found usually in the north of France and Cornwall), heel shaped and chambered.

In Britain the burial chamber is seldom excavated in the soil under the cairn, but is enclosed within the structure itself. In the Mediterranean region a subterranean vault is often to be found. Both long and round cairns were originally delimited by a curb built of dry stone masonry; these were probably covered like the main structure, by a blanket of earth and stones. As monuments they were carefully built to conform to certain ceremonial requirements, and appear to have been reused as family vaults for more than one generation.

Cairns are still used in various parts of the world as burial places, particularly where the soil is difficult to excavate or where wild animals might disturb the body. (M. V. S.-W.)

CAIRNES, JOHN ELLIOTT (1823-1875), Irish economist, often described as "the last of the classical economists." was born at Castle Bellingham, Ire., on Dec. 26, 1823. He was educated at Trinity college, Dublin, where he became professor of political economy (1856), subsequently holding chairs at Queen's college, Galway, and University college, London (1866-72). He died at Blackheath, London, on July 8, 1875.

His first book was *The Character and Logical Method of Political Economy* (1857; new ed., 1888), one of the main classical works on the methodology of the subject. He emphasized the abstract deductive nature of classical political economy and advocated its scientific neutrality as between different policies and political principles in particular in respect of the *laissez faire* maxim. His "Essays on the Gold Question" (published in *Essays in Political Economy*, 1873) dealt with the effects of the discoveries of gold in Australia and California, analyzing how different prices would be differently affected in time and degree, and are among the most important works of the 19th century on monetary theory. His book *The Slave Power* (1862 and 1863) expounded the inherent disadvantages of slave labour and considerably influenced British opinion in favour of the North in the U.S. Civil War.

Cairnes's last and largest work was *Some Leading Principles of Political Economy Newly Expounded* (1874). Most of the more characteristically "classical" doctrines are all restated here. For example, he expounds a cost-of-production theory of competitive values; he is about the last to defend a reformulated version of the wage-fund doctrine, he insists on what he calls "the great Malthusian difficulty" in bettering the condition of the mass of the people; and he repeatedly proclaims the identity of aggregate demand and aggregate supply. His analysis of "noncompeting" groups, in particular in the labour market, may be said to have foreshadowed the more systematic treatment of imperfectly competitive and monopolistic conditions. (T. W. H.)

CAIRNGORM, a yellow or broan variety of quartz, named from Cairngorm or Cairngorum, one of the peaks of the Grampian mountains in Banffshire, Scot., is a favourite ornamental stone in Scotland and is used in brooches worn with Highland costume.

Also known as smoky quartz, the mineral occurs in crystals lining cavities in highly inclined veins of a fine-grained granite running through the coarser granite of the main mass. Shallow pits were formerly dug in the decomposed granite for the sake of the cairngorm, and the mineral was also found as pebbles in the bed of the river Avon.

CAIRNS, HUGH McCALMONT CAIRNS, 1ST EARL (1819-1885), Irish statesman, lord chancellor of Great Britain, of great parliamentary influence in ecclesiastical and legal issues, was born at Cultra, County Down, Ire., on Dec. 27, 1819, and was educated at Belfast academy and Trinity college, Dublin, graduating in classics in 1838. In 1844 he was called to the bar by the Middle Temple, to which he had migrated from Lincoln's Inn. During his first years at the chancery bar, Cairns showed little promise of the eloquence which afterward distinguished him. In

1852 he entered parliament as member for Belfast, and his Inn, on his becoming a queen's counsel in 1856, made him a bencher.

In 1858 Cairns was appointed solicitor general and was knighted. In 1866, when Lord Derby returned to office, he was made attorney general and in the same year, after a breakdown in health, he became a lord justice of appeal. In 1867 he became Baron Cairns of Garmoyle.

As soon as Benjamin Disraeli took office in 1868 he offered the lord chancellorship to Cairns in place of Lord Chelmsford. Less than a year later his party lost office and Cairns became leader of the opposition in the house of lords. In the commons he had distinguished himself by his resistance to the Roman Catholics' Relief bill in 1865, and in the lords his efforts on behalf of the Irish church were equally strenuous. When privately offered concessions if he withdrew his opposition to W. E. Gladstone's Suspensory bill, he had no time to consult his party, and accepted. In consequence he resigned his leadership, but was soon induced to resume it, and in 1870 he took a strong part in opposing the Irish Land bill. In 1874 the Conservatives returned to power and Cairns was lord chancellor again until his party's defeat in 1880. He had become Viscount Garmoyle and Earl Cairns in 1878. He died at Bournemouth on April 2, 1885.

Cairns combined strength with clarity and cogency, despite that was usually a somewhat reserved manner. His judgments were in the main expositions of principle, with a few decisions cited at the end as illustrations. In the legislation of the day, particularly on questions involving the church or legal reform, his influence was great, and the harmony with which he could work with his great friend and opponent, Lord Selborne, led to this influence being felt while he was in opposition as well as when he was in office.

Among the statutes with which he was concerned were the Judicature acts, 1873-75, the Conveyancing acts, 1881-82, the Settled Land act, 1882, and the Married Women's Property act, 1882.

CAIRNS, a city and seaport of northeastern Queensland, Austr., lies on Trinity bay on the narrow lowland strip between the Atherton plateau and the sea, 860 mi. N.W. of Brisbane by rail. Pop. (1961) 23,358. Area 14.2 sq. mi. The climate is tropical (average maximum temperature 84.6° F.; average minimum 68.3° F.; average annual rainfall 87.6 in., falling mainly from December to April). Cairns is well laid out, with wide tree-lined streets and attractive parks. In Abbott street are the city council chambers (1930), built of reinforced concrete in bungalow style and surrounded by gardens, while other public buildings include a Roman Catholic cathedral and the School of Arts library. Railways connect Cairns with Brisbane and with the hinterland; there are air services to Brisbane, Sydney, Melbourne and New Guinea; and during the winter tourist coaches travel to and from the south. The port is well equipped with slipways, warehouses and concrete wharves.

Cairns is the outlet for an important agricultural and mining area. Dairying and the growing of sugar, maize, tobacco and peanuts are carried on, while timber is extracted from the forests on the seaward portions of the Atherton plateau. The plateau is highly mineralized; tin is dredged near Mount Garnet (96 mi. S.W.) and there are numerous deposits of wolfram, fluor spar and scheelite. In the district there are sugar mills, sawmills, a brewery, a fertilizer works; while other local industries include a meat freezing plant and butter, bacon and tobacco factories. Exports include sugar, timber, plywood, maize, meat, tobacco and metals. Fertilizers, petroleum products, galvanized iron and general cargo are imported. Thousands of tourists visit Cairns annually, attracted by the mild winter climate and by the scenery of the highlands and the gorge and falls of the Barron river.

Cairns was founded in 1876 and named after the then governor of Queensland, Sir William Wellington Cairns. Its prosperity was assured when sugar growing started in 1882. It became a municipality in 1885 and a city in 1923. (C. DE G. W.)

CAIRO (AL QAHIRAH), the capital city of Egypt, is also a governorate (*muhafaza*). It lies on the east bank of the Nile about 12 mi. S. of the apex of the delta, with extensive suburbs on the west bank. Immediately east of Cairo are the desert hills of Al Mokattam (Jabal al Muqattam) from which a splendid view stretches across the great city, the Nile and the fields beyond, to the Libyan desert and the pyramids at Giza. It is by far the largest city in Africa and the middle east.

The population of Cairo was 2,090,654 in the census of 1947; it increased rapidly and in 1960 was 3,346,000.

The climate is dry and reasonably stable throughout most of the year, average day temperatures ranging from 65° F. in January to 96° in July and August. Between December and March strong, cold winds from the desert may lower the temperature to the freezing point at night, and in April and May the sand-laden hot southerly wind, or khamsin, may raise it to 100° or more. The maximum summer temperature is around 108°. Agreeable sunny days are the rule and rain falls only three or four times a year, always in winter.

The City.—The road from the civil airport, to the northeast, leads through the big modern suburb of Heliopolis and branches into Sharia Rameses (formerly Nahdet Misr) and Sharia al Geish (formerly Faruk). Sharia Rameses opens into a large square facing the railway station, Rameses square (formerly Bab al Hadid), dominated by a colossal ancient statue of Rameses II moved in 1955 from the site of Memphis. From there Sharia al Gumhuria, one of several main streets, leads to Opera square. The Opera house was opened in 1869 as part of the celebrations for the inauguration of the Suez canal. In the centre of Opera square is a fine equestrian statue of Ibrahim (d. 1848), son of Mohammed Ali Pasha.

Opposite is the Continental-Savoy hotel and located nearby are restaurants and a public garden, Al Ezbekia. Through this garden runs a long street, Sharia July 26 (formerly Fuad al Awal), which leads over the river to Gezira Island, and to the north of which lies a poor quarter, Bulak, part of which has been cleared and rebuilt. From this street Sharia Suliman Pasha leads southward into Suliman Pasha square and from there runs, in an easterly direction, Sharia Kasr al Nil, in which stands the National Bank of Egypt (founded 1898). Off Sharia Suliman Pasha are some of the chief newspaper offices, from where magazines and newspapers circulate throughout the Arabic-speaking world. Close by is Mohammed Ali club, the leading club for men. In Suliman Pasha square stands a statue of the soldier of that name (d. 1860), and in Mustafa Kamil square (formerly Emad al Din), along Sharia Kasr al Nil, is a statue of Mustafa Kamil, an Egyptian nationalist (d. 1908). This square contains the Cairo women's club. Between Suliman Pasha square and the Nile is Liberation (Tahrir) square (formerly Ismailia), a large space, divided by grass plots and flower beds, where ten streets meet. On its southern side is a modern block of government offices and opposite stands the great Egyptian museum (built 1902) where the Tutankhamen treasures are housed with many other unique and priceless works of ancient Egyptian art. Nearby also is the Museum of Modern Art (founded in 1928) in a fine Arab-style house. On the western side of Liberation square stood the Ksar al Nil barracks, demolished in 1955–56. The site was taken by the Nile-Hilton hotel; south of the Kasr al Nil bridge, facing the river, are the Semiramis and the new Shepherd's hotels (the old Shepherd's hotel in Sharia al Gumhuria was burned down during the riots of Jan. 26, 1952).

Between modern Cairo and Al Mokattam hills lies much of the Arab city built between the 11th and 16th centuries. In this area is gathered a greater quantity of Arab architectural riches than is to be found in any other city of the world. The scheduled historical monuments alone number nearly 400. The scene is dominated by the Ottoman-style mosque built by Mohammed Ali, where he was buried in 1849. It stands in the citadel originally built by Saladin in the 12th century and refortified and occupied by invading or nationalist armies ever since. There the British army handed over authority to the Egyptian army in 1946. Below the citadel is the great Salah al Din (Saladin) square in which polo matches, parades and executions were held from the 12th to

the 19th century. Across this square from the main citadel entrance is the mosque of Sultan Hasan, built about 1361. Its magnificent proportions are considered by many experts to be unsurpassed in Islamic architecture. Opposite it is the modern mosque of Al Rifa'i, finished in 1912, where lie the remains of King Fuad and members of his family.

A vast network of streets surrounds this point and is, especially northward, a delight and interest to the tourist, the artist and the scholar alike, for its medieval aspect and its bazaars of local produce and handicraft, as well as for its historical and architectural treasures. Near the centre of this area is the famous university mosque of 41 Azhar founded by the north African Fatimite invaders in 970. Students of the Koran, Islamic law and jurisprudence, Arabic in all its branches, philosophy and history gather there from as far afield as China, Indonesia, Morocco and Somaliland. Students and professors wear the traditional robes and turban worn by Azharites for centuries. The influence that emanates from this edifice to the whole Islamic world is out of all proportion to the signs visible by the passing visitor. A wide street, Sharia al Azhar, cuts through the mesh of medieval lanes from Al Azhar to modern Cairo near Opera square.

The Muski and the Khan Khalil, well known to tourists, lie to the north of Sharia al Azhar and beyond these bazaars are several fine old buildings, including the 13th-century mausoleum of Sultan Kalaun. At the north of the old city is an imposing 11th-century gateway, the Bab al Futuh. This, with the Bab al Nasr close by and the Bab al Zuweila southwest of Al Azhar, form part of the defenses built by Badr al Gamali in the 11th century during the Fatimite regime. They contain features of military architecture which antedate similar developments in medieval European fortresses. Beyond the Bab al Nasr is a vast burial ground on the edge of the desert, sometimes misleadingly called the Tombs of the Caliphs. No caliph is entombed therein, but it is embellished with splendid mausoleums dating from the end of the 14th century to the beginning of the 16th and with all manner of subsequent tombs and funereal edifices including a dignified war memorial to Egyptian soldiers who lost their lives in the 1948 fighting in Pales-

A. F. KERSTING

ABLUTION FOUNTAIN IN COURTYARD OF THE MOSQUE OF SULTAN HASAN, CAIRO: c. 1361

tine. An insignificant tomb, not far from the Bab al Nasr, covers the bones of the great scholar and traveler J. L. Burckhardt. To the north are the army barracks of Abbassia beyond which is the residential suburb of Kuba where King Faruk had one of his palaces.

The most notable mosque in the southern part of the old city is that of Ahmad ibn Tulun, called after the sultan who built it in 876–879. It is designed on the oldest mosque plan, of an open courtyard flanked by arcades. The patterns cut in plaster in the soffits of the arches are remarkably beautiful, resembling early Islamic decoration in Samarra, near Baghdad, from where Ahmad ibn Tulun originally came. To the southeast of this mosque lies the great southern cemetery, sometimes called the Tombs of the Mamelukes or Al Karafa. There are tombs and mausoleums of many centuries including the 20th. In this vicinity is the fine domed mausoleum (built 1211) of the imam al Shafi'i (d. 820), a founder of one of the four great rites of orthodox Islam to which belong the large majority of Egyptian Muslims. On Al Mokattam heights above this cemetery stand a fort of the Turkish era and the beautiful small mosque-tomb of Al Giyushi (1085). These relics now keep company with a newly built casino (for tourists only) and with the beginnings of a housing estate. A fine road has been made to the top of the cliff where before but a rough track existed, and many trees have been planted in an erstwhile barren zone nearby. An interesting monastery of the Bektashi dervishes is there, on the side of the hill.

Some way southwest of the Tombs of the Mamelukes is the desolate area of Al Fustat where stood the earliest Arab settlement formed at the time of the Arab conquest in 641. Between Al Fustat and the Nile is the quarter known as Old Cairo (Misr al Atika) where, since the early days of Christianity, an Egyptian Christian (Coptic) community has lived. There are some old Coptic churches and a charming museum of Coptic art founded in 1910. Close to it is a Roman Byzantine gateway. From Old Cairo several roads lead to modern Cairo. One of these, Sharia Kasr al Aini, passes the Cairo university medical school and the antirabic hospital, which is one of the very few in the world. Between Sharia Kasr al Aini and the Nile are the residential quarters of Kasr al Dubara, where are some of the embassies, and Garden City, and to the other side of the road are several of the ministries and also the parliament houses (built 1923). Nearby are the tomb of Saad Zaghlul, the well-known nationalist (d. 1927), the Geological museum (1923) and the American university.

In the large Gumhuria square, to the east, is the Presidency, official residence of the republic's president, which was the Abdin palace of King Faruk and his immediate forebears. It is a fine building, with a spacious garden, standing in a comparatively poor district.

Behind the palace is Ahmed Maher square (formerly Bab al Khalk) where are the Museum of Islamic Art, an outstanding collection, and the Egyptian library, founded by the khedive Isma'il in 1869, which contains magnificent collections of middle eastern illuminated manuscripts and coins.

The Islands.—In the Nile opposite Cairo are two islands, Gezira (Jazirat al Zamalik) and Roda (Jazirat ar Rawdah), which almost form part of the town itself as they are linked to both banks by several large bridges. Gezira is $3\frac{3}{4}$ mi. long and just under 1 mi. at its widest. The northern end is mostly residential with large blocks of flats, villas and gardens. There are also various educational establishments. Sharia July 26, with its eastern end in Cairo, runs over a bridge, across Gezira and past the Egyptian army officers' club, and over another bridge to the western mainland. In the centre of the island is the Gezira Sporting club with racecourse, golf links, polo grounds, squash courts, swimming bath, etc., and tennis courts where zone matches for the Davis cup are played. A public garden, running along the east bank, is much frequented on holidays and at the southern end of the island are a large exhibition ground, a horticultural experimental garden of the ministry of agriculture, sports clubs, public gardens and a hospital.

Roda Island, a mile or so upstream, is rather smaller than Gezira. It contains the big government hospital of Kasr al Aini, the former

palace and gardens of Prince Mohammed Ali and many blocks of flats. On the southern tip of Roda is the Nilometer, first constructed in A.D. 716, where the annual rise of the Nile was measured and proclaimed to the country for more than 1,000 years.

Suburbs.—On the mainland west of Gezira and Roda are various villages and suburbs, among them, to the north, Embaba, where Napoleon defeated the Mamelukes in 1798 and which now contains one of several new housing estates for workmen. The upper Egypt railway bridge crosses the Nile north of Embaba while to the south is Dokki, a residential area with tree-lined roads and some nursery gardens, where stands the remarkable Museum of Agriculture. Giza, farther south, has a poor and populous old town but also contains villas, embassies and the fine zoological gardens. There too is Cairo university, an imposing domed building surrounded by gardens, founded in 1908, though it did not function as a full university till 1924. A new bridge was built in 1958 across the Nile opposite the university, and an ornamental fountain lit by coloured lights plays in the river nearby. The main road to the pyramids and sphinx runs from Giza to the base of the Great Pyramid and the Mena House hotel. This road was originally built for the empress Eugénie to visit the pyramids in comfort when she came to open the Suez canal in 1869. Three motor roads branch south from this road and all lead past the ancient Egyptian site of Seqqarah, about 11 mi. S. of the Great Pyramid.

A few miles south of Cairo, on the east bank, is the garden suburb of Al Ma'adi and south of that again, past the prisons and stone quarries of Tura, is Hulwan, on the edge of the desert, well known for its sulfur springs. This area is partly industrialized. About 15 mi. N.W. of Cairo is the delta barrage across the Nile, an irrigation work of great interest, standing as it does at the control point for the whole delta. There are beautiful surrounding gardens and an irrigation museum close by.

Cultural and Social Institutions.—Cairo has a great variety of cultural and social institutions, among which are a co-operative training centre, popular cultural institutes, the Academy of Arabic, the Academy of Arabic Music, a society of arts, a productivity and vocational training centre, an audio-visual aid centre (in Heliopolis). There are also numbers of voluntarily run centres, schools, homes, clinics, etc., for helping the underprivileged. These are in addition to government establishments administered by the ministry of social affairs. Besides the old Al Azhar, there are two other national universities—Cairo university at Giza, with more than 27,000 students, including 3,000–4,000 women students, and Ain Shams (founded 1950), with more than 18,000 students. The American university (founded 1919) has over 700 students. All the chief churches of the Christian faith have their places of worship in Cairo and there are several synagogues. The Anglican cathedral, which occupies a fine site on the Nile, was consecrated in 1938.

Communications.—Cairo is linked to the rest of Egypt by main-line trains (steam and diesel) and by a network of minor lines. The first railway in Africa was built in Egypt by George Stephenson's son Robert. It linked Alexandria with Cairo in 1855.

The main roads out of Cairo run to Alexandria through the delta; to Port Said via Ismailia and to Suez; up the Nile valley to the south; and via the desert to Alexandria. Along this desert road, 20 telephone and first-aid posts have been set up between Cairo and Alexandria. Another desert road links Cairo to Al Fayyum. There is also a road from Al Ma'adi through the desert to Sokhna on the Red sea. One of the most imposing features is the Corniche road which runs along the Nile front for the whole length of the city and continues southward for a further 12 mi.

Cairo airport is 16 mi. N.E. of Cairo, in the desert beyond Heliopolis. It is served by most international airlines and internal airways.

The Nile is a means of transport for merchandise. Sailing vessels carry produce such as onions, chopped straw, melons and upper Egypt pottery. Their wharves are south of Old Cairo. Steam launches and barges carry such freight as baled cotton northward, agricultural machinery and vehicles southward.

Cairo is intersected by a network of bus and trolley bus routes,

which also serve the suburbs. Outlying districts are connected to Cairo by buses of a rougher type, but Alexandria and Port Said are linked to the capital through desert or delta by fast, comfortable buses.

Industries and Occupations.—In the Hulwan area several heavy industries were started during the 1950s as part of Egypt's five-year industrialization plan. They include steel, iron, cement and rolling-stock plants. The people of Cairo and its vicinity are variously employed: in government administration, educational, medical, legal and other professions; in the processing of tobacco, leather, basic chemicals, cement, etc.; in food processing and petroleum products; in building construction; in business and trade of many sorts and in the film industry. The first Egyptian film was produced in 1926 and from the suburb of Al Jizah have come virtually all Arabic-language films.

History.—The ancient Egyptian capital of Memphis was on the west bank of the Nile south of Gezira. There is very little left of this once great city. The next forerunner of Cairo was the Roman-Byzantine town of Babylon where Old Cairo now stands.

The Arab conqueror of Egypt, Amr ibn-al As, entered its great bastioned gateway in A.D. 641 and built Al Fustat, on the site of his camp immediately east of Babylon. In the 9th century, when Egypt was controlled by Arab governors from Baghdad, one of them, Ahmad ibn Tulun (who subsequently made himself the first independent Muslim ruler of Egypt), founded Al Katai to the northeast, where his famous mosque still stands. When the Fatimites invaded Egypt in the 10th century their general, Jauhar (Gohar) al Rumi, built a new capital northward of Al Katai, calling it Al Kahira ("the victorious") from which the name Cairo is derived. Part of the encircling wall and three great gateways still survive. The Ayyubites next ruled Egypt (1169–1250), the most famous and first of the dynasty being Saladin, the great opponent of Richard Coeur de Lion. Saladin extended the walls round the citadel, which he built on a spur of the Mokattam hills. A small portion of his original wall can still be seen in the southeastern corner. From 1250 to 1517 Egypt was governed by two dynasties of Mameluke sovereigns who, though ruthless and unscrupulous, embellished Cairo with architectural and other works of art in great quantity and of high quality, many of which can be enjoyed today. A few outstanding buildings still preserved are the mosques and mausoleums of Sultan Hasan (1351), Al Mu'ayyad (1422), Barkuk (1386), Al Ghuri (1508), Al Mardani (1340) and Qa'itbay (1475). They are scattered over the whole present area of medieval Cairo. At its height the Mameluke empire incorporated Egypt and Syria, the present Lebanon, Israel and Jordan. Cairo and Damascus were joint capitals and were in frequent communication despite the 500 mi. between them. Baybars, a great Mameluke sultan, was proud of the fact that he could play polo in Cairo and in Damascus in the same week; and a carrier pigeon post was maintained between the two cities.

In 1517 Cairo fell to the invading forces of Ottoman Turks who hanged the body of the last Mameluke sultan from the gateway of Zuweila. The Turkish domination of Egypt had a deadening effect on the flowering of the arts in Cairo. Mosques built during the next 300 years were mostly to a stereotyped pattern often recognizable today by the "pencil point" minarets. Some of them have charm, notably the small mosque known as Sidi Sarai in the citadel, the first to be built after the Ottoman conquest. The tomb-mosque of Mohammed Dahab (1774) near Al Azhar is impressive. Mohammed Dahab was one of the Mamelukes who remained in Egypt after the Ottoman conquest and who often carried greater weight in governing Cairo than did the Turkish pasha sent from Constantinople for the purpose. A few fine houses of the Turkish era can still be seen and numerous small buildings called *sebil kutub*, endowed by pious men of the time. Their function was to provide free drinking water on the street level and a small free school on the floor above, for learning the Koran.

In 1798 Cairo was captured by the French who were driven out in 1801 by Turkish and British forces, and the city was handed over to the Turks. The people of Egypt chose Mohammed Ali as their governor in 1805. He finally made himself master of the country by massacring, in 1811, the remaining Mamelukes who were still

an obstacle to his ambition. The Mamelukes were killed as they were leaving the citadel by the Bab al Azab after attending a ceremony to which he had invited them. Cairo thus became once more the capital of a virtually independent kingdom, and from that time the city's western part expanded. In 1882 Cairo was occupied by the British and its history was merged in that of Egypt. It was the headquarters of the British middle east command in World War II; the British forces left the city in 1946.

Much modern development of Egypt is evident in Cairo from its functional and administrative buildings of all sorts and in all quarters, such as its hospitals, schools, embassies, ministries, flats, factories and telephone exchanges. Considerable development of telegraph and telephone networks has been made, including modern carrier systems linking Cairo and Damascus.

CAIRO, the southernmost city of Illinois, U.S., at the confluence of the Ohio and Mississippi rivers, 150 mi. S.E. of St. Louis, Mo.; the seat of Alexander county. Built upon a low-lying delta formed by a prehistoric Ohio river that emptied into the nearby gulf, Cairo was so named because its site was thought to resemble that of its Egyptian counterpart, and southern Illinois has become known as "Little Egypt." Cairo and the Bank of Cairo were chartered in 1818 when there was no settlement and there were no depositors. A second and successful try at establishing a town was made in 1836–37 by the Cairo City and Canal company; the company, which sold its bonds in England, came to a disastrous end in 1840. Finally in 1816, 10,000 ac. were purchased by the trustees of the Cairo City property, a group of eastern investors, who with one exception never resided in the town but were closely identified with the Illinois Central Railroad company and were interested in making the town the prosperous terminus of the projected railroad. City government was not established in Cairo until 1855. During the American Civil War Cairo was Ulysses S. Grant's headquarters during the western campaigns, and as a military camp frequently housed 30,000 soldiers. Nothing about the town, strategical or otherwise, impressed either of two English visitors, Charles Dickens in 1842 and Anthony Trollop in 1862, and they said as much in print.

The city is a shipping centre for the entire Ohio and Mississippi river valleys as well as for southern Illinois. Industries include lumber and woodworking and the manufacture of cottonseed and soybean products. Cairo is protected by levees; in 1937, when the Ohio river rose to 59.6 ft., it was the only city in the entire Ohio river valley that was not flooded.

For comparative population figures see table in ILLINOIS: *Population* (N. M. BE.)

CAIRO CONFERENCES: see WORLD WAR II CONFERENCES, ALLIED.

CAIROLI, BENEDETTO (1825–1889), Italian statesman whose policy of neutrality and peace was ill-suited to the nationalism and imperialism of his time, was born in Pavia on Jan. 28, 1825. From 1848 until the completion of Italian unity in 1870, his whole activity was devoted to the Risorgimento, as Garibaldian officer, political refugee, anti-Austrian conspirator and deputy to parliament. One of his brothers was killed and another wounded during Garibaldi's rebellion and attempt to march on Rome in 1867. When in 1876 the left came into power, Cairolì became important in politics and, after the fall of Agostino Depretis, formed his first cabinet in March 1878 with a Francophile and irredentist policy. Italian nationalists were affronted by his and Luigi Corti's policy of "clean hands" at the Berlin congress (1878), where Italy obtained nothing while Austria-Hungary secured a European mandate to occupy Bosnia and Herzegovina. The attempt of G. Passanante to assassinate King Humbert at Naples (Nov. 17, 1878) caused Cairolì's downfall on Dec. 19, in

spite of the fact that he himself was wounded. He returned to power, however, on July 14, 1879, and on Nov. 29 formed with Depretis his third coalition ministry, in which he retained the premiership and the foreign ministry. Confidence in French assurances and belief that Great Britain would never permit the extension of French influence in north Africa prevented him from foreseeing the French occupation of Tunis (May 11, 1881). In view of nationalist indignation he resigned three days later. He died at Capodimonte near Naples on Aug. 8, 1889.

See *M. Rosi, I Cairoli*, 2nd ed., 2 vol. (1929).

CAISSON has a variety of distinctly different meanings. When employed in military parlance, it denotes an ammunition wagon or chest; in architecture, a sunken panel; and in civil engineering, a boxlike structure that is used to install structures that extend below water level. In this latter sense there are three types—box caissons, open caissons and pneumatic caissons.

Box Caissons.—These are open at the top and closed at the bottom. They are usually constructed on land, then launched, floated to position and sunk onto a previously prepared foundation. The sides of the caisson, when it is sunk in position, emerge above the water level. This structure serves as a shell for a bridge pier, sea wall, breakwater, jetty or similar work. The box-caisson method of construction is suited for the installation of structures in open water where foundation conditions are such that the caisson need not be sunk below the bottom of the water bed.

Open Caissons.—These are open at the bottom as well as at the top. The open bottom, which is provided with a cutting edge, permits removal of soil beneath the caisson by dredging through shafts from the top of the caisson. As excavating proceeds, the caisson sinks and, as it sinks, additional sections are added to the top so that the caisson sides always extend above water. This process is continued until the caisson has been sunk to the required depth. The surface to which the caisson has been sunk is then carefully cleaned, usually by divers, and concrete is deposited under water to provide a bottom seal. The dredging wells can then be unwatered and filled to complete the structure. An open caisson may be of single- or multiple-dredging well type, circular or rectangular in plan and of double- or single-wall construction.

Pneumatic Caissons.—These are similar to open caissons except that they are provided with an airtight bulkhead installed about six to eight feet above the cutting edge. The space between the bulkhead and the cutting edge, which is called the working chamber, is pressurized to the extent necessary to control the inflow of soil and water; thus the excavating can be performed by workmen operating in the working chamber at the bottom of the caisson. Pressure in the working chamber is maintained by means of an air lock. Provision can be made to convert an open caisson to a pneumatic caisson when, during sinking operations, conditions develop that require it. This conversion is made by the addition of the necessary airtight bulkhead and air lock.

The word caisson is sometimes used to designate any cast-in-place type pier. Strictly speaking, however, it refers only to the shell that is used in the installation of the pier and that becomes an integral part of it. See also **CONCRETE: Applications: Harbour Facilities**.

BIBLIOGRAPHY.—Clarence W. Dunham, *Foundations of Structures* (1950); Ralph B. Peck, Walter E. Hanson and Thomas H. Thornburn, *Foundation Engineering* (1953); F. D. C. Henry and R. H. Evans, *The Design and Construction of Engineering Foundations* (1956).

(R. E. FM.)

CAISSON DISEASE, or decompression sickness, a group of symptoms brought on by sudden reduction of the atmospheric pressure, *i.e.*, too rapid for the body to accommodate to the change.

It occurs in men who work in deep caissons or tunnels where very high atmospheric pressure must be maintained in order to exclude water. Symptoms do not appear while the air pressure is being increased nor so long as it is maintained but appear only after it has been reduced too quickly. The condition may also occur in deep sea divers or men escaping from sunken submarines who come to the surface too rapidly. It may also occur in aviators inadequately protected against sudden decompression.

The symptoms include pains in the muscles and joints (the

bends), fainting, vomiting, deafness, paralysis (divers' palsy) and even sudden death. The symptoms are produced by effervescence of gas, principally nitrogen, that has been dissolved in the blood and other body fluids. When the atmospheric pressure is suddenly reduced, the dissolved gas comes out of solution as tiny bubbles that occlude capillaries and other small blood vessels. If the atmospheric pressure is diminished gradually, dissolved nitrogen comes out of solution slowly enough to be removed by the lungs without the formation of bubbles.

Caisson disease can, therefore, be prevented by slow decompression. A decompression rate of at least 20 minutes for each atmosphere (about 15 lb. per square inch) of pressure has been recommended. Younger men seem to be less susceptible to caisson disease than older men.

See **DIVING APPARATUS: Effects of Air Pressure on the Diver**.
(C. P. M.)

CAITHNESS, a county occupying the extreme northeast of Scotland, is bounded on the west by Sutherland, on the north by the Pentland firth and on the east and southeast by the North sea. Its land area is 686 sq.mi.

Physical Features.—Caithness is a plateau sloping mostly northward and northeastward and truncated on the north and east by an almost continuous line of sea cliffs. This plateau is mainly cut across Old Red Sandstone, with Highland schists in the high ground of the south and west, which, at 1,000 ft., is one of the largest flat surfaces at such an altitude in Britain. Above this southern plateau a series of massive hills rise abruptly. Morven (2,313 ft.) and Maiden Pap (1,587 ft.) are in Old Red Sandstone conglomerate, Scaraben (2,054 ft.) is in schist and the granites of Knockfin heights swell more gently in the west. The Old Red Sandstone conglomerates include the famous gray flagstones, rich in fossil fish, of many a field boundary in Caithness. In the southeast the Berriedale, Dunbeath and Latheronwheel burns (streams) cut through the plateau in deep, sheltered glens. To the north, the plateau sinks to where the Wick and Thurso rivers flow slowly over alluvial haughs (plains) just above sea level. There, small lochs are numerous, the largest being Loch Calder, the county's main source of water, and Loch Watten. Several of the lochs were left by the flow of glaciers from the northwest Highlands. These glaciers deposited great spreads of blue shelly boulder clay whose lime content is important for agriculture, but the western two-thirds of the county are still under peat.

The cliffs, which are varied by deep eroded inlets known as goes or geos and some spectacular offshore stacks, reach 400 ft. in height near the southern border but fall to frame long, sandy beaches at Sinclair's bay, Freswick, John o'Groat's house (*q.v.*), Dunnet Head, Thurso and Reay. Caithness is separated from the Orkney Islands by the Pentland firth, through which tides race at up to 10 knots. Sunken rocks called the Boars of Duncansby create breakers, and eddies from St. John's point break on the Men of Mey, while off Stroma island is the Swelkie whirlpool.

Despite its northern latitude Caithness has a fairly moderate climate, though it is subject to strong winds. Spring comes later and winter earlier than in the south of the British Isles, but mean summer and winter temperatures (54.5° F. in July and 37.8° F. in February) are similar to those in the Lothians. By the 19th century Caithness was practically treeless, except for a few stunted birches and hazels in the straths. Small private plantations succeeded and after 1944 the Forestry commission planted at Humster and Dunnet. Moor burning and deer threaten the alpine plants and in the east agricultural drainage has radically altered the flora, but the flowering plants near the coast are of great interest, including *Saussurea alpina* in its most northerly habitat. Foxes and an occasional wildcat are found and the pine marten has been trapped near the north coast, while the sea cliffs form natural sanctuaries for many rare birds, including the great skua.

History.—Caithness is rich in prehistoric remains dating from Neolithic times onward. Cairns, standing stones, hill forts, etc., abound and there are more brochs (ancient dry stone buildings) than in any other county. There are traces of early Christian chapels in every parish, a very early example being St. Mary's, Forse, Thurso. The ruins of old St. Peter's church, Thurso, and

the parish churches of Dunnet, Canisbay and Reay are all pre-Reformation. The coast castles of Dunbeath and ruined Auld Wick, Girnogie, etc., date from medieval times, while later in date are inland castles such as Mey, owned by Queen Elizabeth, consort of George VI, and Braal.

A Pictish province named Cait or Cat at the dawn of history, Caithness was early invaded by the Norsemen and place names testify to their domination. Caithness was for a time integrated firmly into the kingdom by William the Lion and divided into parishes by Bishop St. Gilbert. Till 1231 the earldom of Caithness was held by the Norse earls of Orkney. Then it passed to several Scottish noble families until in 1455 William Sinclair, third Sinclair earl of Orkney, was invested with the Caithness earldom by James II of Scotland (*see* SINCLAIR). At the Reformation the earls gained both land and power which they held until debts forced the sixth Sinclair earl to sell his title and estates to Sir John Campbell of Glenorchy, later earl of Breadalbane and Holland. As the Sinclairs rejected his claim, Glenorchy invaded Caithness and defeated the Sinclairs at the battle of Altimarlach (1680), the last clan battle in Scotland. Later a Sinclair regained the earldom, but Glenorchy sold the estates to various Caithness families. Thereafter interest centres mainly on the agricultural improvements encouraged by such of them as the Traills of Castle-town in the 18th century, the development of town life with the great herring fisheries of the 19th century and the then great export industry in Caithness flagstones.

Population and Administration.—In 1961 the population of Caithness was 27,345. Wick (*q.v.*), the county town (7,397), and Thurso (*q.v.*) are small burghs. The county joins with Sutherland to send a member to parliament and it forms a sheriffdom with Sutherland, Orkney and Shetland, a sheriff substitute sitting at Wick.

Industries and Communications.—Farming and fisheries are the two main industries, although after 1955 the construction and working of the Atomic Energy authority's breeder-reactor at Dounreay provided employment for many people. Formerly a stock-raising county, after 1938 Caithness began to change over to dairy cattle, which by 1954 had increased by 62%. The main breed is the Shorthorn. Sheep are also very important, the breeds being Border Leicester and especially North Country Cheviot, introduced in the 18th century by Sir John Sinclair of Ulbster and now bred chiefly in Caithness. In the early 1960s about two-thirds of the land was rough grazing and more than 70,000 ac. (16% of the total) was arable land, the chief crops being oats, turnips and swedes. Small holdings predominate, more than half being of 15 ac. or less.

White fishing and salmon fishing both flourish, but the herring fishery has almost come to an end. There is a shellfish processing factory at Thurso, while at Wick are a distillery and knitwear, ice and glass factories. In the early 1960s tourism became a significant industry.

There are bus services throughout the county, which has good roads; and railway services connect Wick and Thurso with Inverness. The mail steamer for the Orkneys calls at Scrabster and air services from Wick airport connect with Inverness, Aberdeen and the south, and the Orkneys.

Carruthers, *The Geology of Caithness* (1914); J. Mowat, *A New Bibliography of the County of Caithness* (1940); S. W. E. Vince, "Caithness," *The Land of Britain*, pt. 15 (1944). (F. W. RN.)

CAIUS (KEES, KEYS, KAY, KAYE, etc.), **JOHN** (1510–1573), English physician and second founder of the modern Gonville and Caius college, Cambridge, was born at Norwich, Oct. 6, 1510. He was admitted a student at what was then Gonville hall, Cambridge, where he seems to have studied divinity. In 1533 he visited Italy, studying under Montanus and Andreas Vesalius at Padua. After an extended tour in Europe he practised medicine in London, where he was for several years president of the College of Physicians. In 1557 he enlarged the foundation of his old college, named it Gonville and Caius college and endowed it generously. In Jan. 1559 he accepted the mastership of the college. His large

body of literary work, together with a Memoir by John Venn, was edited by E. S. Roberts (1912). His medical writings are of particular interest; his name is associated especially with the sweating sickness (*q.v.*), of which his account is classical. As a Catholic in a period of strong anti-Catholic feeling, Caius suffered numerous indignities, retaining always, however, the high regard of members of his own profession. He died in London on July 29, 1573.

CAJAMARCA, a northern sierra department of Peru (pop., 1958 est., 785,233; area 13,675 sq.mi.) bounded north by Ecuador, west by Piura and Lambayeque, east by Amazonas and south by La Libertad. The department is watered by the Marañón river, which forms nearly the whole of its eastern boundary, and by tributaries entering the river from the west. The cultivated valleys produce alfalfa, cereals, coffee, sugar, fruits and vegetables. The breeding of cattle and a hardy type of sheep is carried on where conditions are favourable. Mineral resources worked in the department include gold, silver, coal and copper. The population is chiefly Indian and mestizo. Cajamarca city, the historic capital, Cajabamba and Cutervo are its most important centres. (J. L. TR.)

CAJAMARCA (CAXAMARCA), a city of northern Peru (pop., 1958 est., 23,175), capital of the department and of the province of the same name. It lies at 9,440 ft. above sea level on the bank of the Camarca river, a tributary of the Marañón. The mean temperature is 52° F. It was an ancient Inca city and historically it is notable as the scene of the capture in 1533 of the Inca ruler Atahualpa by Francisco Pizarro. It is one of the principal commercial and industrial centres of the inter-Andean district, manufacturing textiles, hats, leather and metal goods. The city and neighbouring area are the focus of the northernmost clusters of predominantly Indian population in highland Peru. In the valleys of the surrounding region, alfalfa, cereals, coffee and sugar are cultivated and cattle and sheep raised. Mineral resources worked in the region include gold, silver, coal and copper. The city is notable for its Inca ruins, the thermal springs known as the Baths of the Incas being an important tourist attraction. Cajamarca preserves colonial character to a remarkable degree as exemplified by the cathedral, the church of San Francisco, the architecture, building materials and the city plan. The city stands on the old northern overland route to Iquitos via Chachapoyas and Yurimaguas. It is 188 mi. from Trujillo by road and lies 16 mi. by road from the Chilete station on the Pacasmayo railway. (J. L. TR.)

CAJETAN, SAINT, OF THIENE (GAETANO DA TIENE) (1480–1547), co-founder of the Theatines and an important figure of the Catholic Reformation, was born of a noble family at Vicenza in Oct. 1480. He won his doctorate in both civil and canon law at Padua on July 17, 1504, and by March 1508 was a prothonotary in the Roman curia. Associated with the local Oratory of Divine Love, established in Rome about 1513, he was ordained a priest on Sept. 30, 1516, and continued the charitable works characteristic of the association. Leaving Rome for Vicenza in 1518, he revitalized oratories there and at Verona (1519). At Venice, during Lent 1522, Cajetan founded a hospital for the incurably ill and a local branch of the oratory.

Subsequent to his return to Rome late in 1523, he met Archbishop Giovanni Pietro Caraffa, the future Pope Paul IV. Together they established and entered, Sept. 14, 1524, the Congregation of Clerics Regular (Theatines) to further among diocesan priests the ideals of the Oratory of Divine Love. After the sack of Rome, Caraffa and Cajetan succeeded in reaching Venice on June 17, 1527. Following his dispatch in Aug. 1533 as Theatine superior to Naples, Cajetan created at the church of St. Paul Major (May 1538) a centre of Catholic reform. There, except for 1540–43, when he was at Venice, he remained until his death on Aug. 7, 1547. Cajetan was canonized by Pope Clement X on April 12, 1671. His feast is celebrated on Aug. 7.

Gaetano da Thiene* (1954); H. Thurston and D. Attwater (eds.), *Butler's Lives of the Saints*, vol. iii, pp. 272–274 (1956). (H. G. J. B.)

CAJETAN (CAJETANUS or GAETANO; TOMMASO DE VIO) (1468?–1534), a major Catholic theologian of the Thomist school,

was born at Gaeta in the kingdom of Naples, probably on Feb. 20, 1468 (some say 1469). Entering the Dominican order in 1484. He studied at Bologna and then at Padua, where he became professor of metaphysics (1494) and came into contact with the theology of Duns Scotus and with the Averroism of Pietro Pomponazzi; of Scotism in particular Cajetan became, and remained, a relentless critic. In 1494, as a result of his brilliance in a public disputation with Pico della Mirandola at Ferrara, he was made a master in theology. From 1501 to 1508 he taught theology at Rome, during which time he began his great commentary on the *Summa theologiae* (more commonly, *theologica*) of St. Thomas Aquinas. In 1508 he was elected Dominican master general, remaining in this office until 1518. As general, Cajetan felt obliged to check certain manifestations of the cult of Savonarola which threatened to divide the order; but he was himself an ardent upholder of the Dominican ideal, especially with regard to poverty and the study of theology. Between 1511 and 1517 he was occupied with defending papal authority against the schismatical council of Pisa (1511) and with work in connection with the fifth council of the Lateran (1512-17), at which he urged the reform of the church. In 1517 Leo X made him a cardinal.

In 1518 Cajetan came into personal contact with Martin Luther. As the papal legate in Germany, he was authorized to examine Luther on points of doctrine, and they met at Augsburg in October a year after the reformer had published his theses at Wittenberg. On Luther's own admission, Cajetan dealt kindly with him, but the two men could not agree doctrinally. The meeting however helped to convince Cajetan of the need for meeting the reformers on their own ground, and he devoted the later years of his life to an attempt to provide a literal interpretation of the Bible, based on a fresh translation from the original tongues. His commentary on the Psalms (1527) was followed by others on the New Testament and on most of the books of the Old Testament. Meanwhile, recalled to Rome in 1519 and made bishop of Gaeta in the same year, he helped to draft the bull *Exsurge Domine*, condemning Luther (1520). In 1522 he was influential in the election of the reforming pope Adrian VI, to whom he dedicated his commentary on the third part of the *Summa*. In 1523-24 he was papal legate in Hungary, Poland and Bohemia. Recalled by Clement VII, he retired to Gaeta in 1527. He died in Rome probably on Aug. 10, 1534.

Cajetan's fame rests chiefly on his difficult but profound commentary on the *Summa*. Much of this work is, in form, a reply to the criticisms of Scotus and others; but in effect it is something far more valuable, a rigorously analytical examination of the basic principles of natural and Christian theology. Without some acquaintance, indeed, with Cajetan's commentary one can have no adequate idea of the resources of Thomism. It may be read in the critical *editio Leonina*, begun under Pope Leo XIII (1882 onward), of St. Thomas, vol. iii-xii. Cajetan also wrote commentaries on Aristotle and many opuscula.

BIBLIOGRAPHY.—*Dictionnaire de théologie catholique*, vol. ii, col. 1313-29 (1905); *Revue thomiste*, vol. xvii (1934-35); *Angelicum*, vol. xi (1934). (K. F. F.)

CAJORI, FLORIAN (1859-1930), U.S. educator and mathematician, who was noted as a historian of science, was born at St. Aignan, Switz., on Feb. 28, 1859, and emigrated to the U.S. in 1875. He was graduated from the University of Wisconsin, Madison, in 1883, and received a Ph.D. degree from Tulane university, New Orleans, La., in 1894. He was a member of the faculty of Tulane (1885-88) and of Colorado college, Colorado Springs (1889-1918), where he was dean of the department of engineering from 1903. In 1918 he became professor of the history of mathematics at the University of California, Berkeley.

His major works included *A History of Mathematics*, 2nd ed. (1919), and *A History of Mathematical Notations*, two volumes (1928-29); he also wrote *A History of Physics* (1899) and the biographies *William Oughtred, a Great Seventeenth-Century Teacher of Mathematics* (1916) and *The Chequered Career of Ferdinand Rudolph Hassler* (1929). His revised translation of Sir Isaac Newton's *Principia* was published posthumously in 1934 and his *A History of Elementary Mathematics*, 2nd ed. (1917), was re-

issued in 1950. Cajori died at Berkeley on Aug. 14, 1930.

CAKCHIQUEL, the language spoken by about 350,000 Indians of highland Guatemala. Most Cakchiquel speakers are in the departments of Sololá, Chimaltenango, Sacatepéquez and Escuintla. The language is part of the Quichean family of the Mayan stock and very similar to Quiche and Zutuhil. Language is not the basis of forming social units nor does it correlate with cultural distinctiveness in this region of Guatemala. Cakchiquel-speaking Indians, like other Mayan peoples of the highlands, are organized on the basis of a *municipio* with its own variations from the broad pattern of Indian culture in the area. A Cakchiquel-speaking community differs from other Cakchiquel communities to about the same degree and in the same ways as it varies from neighbouring Quiché or Zutuhil-speaking communities. (See QUICHE; ZUTUHIL). Each community has its own political and religious hierarchy, a distinct costume (at least for the women), a local patron saint and an economic specialty. The general culture of the area is a fusion of Spanish and Indian elements in the context of a peasantry stabilized in the region centuries ago.

Prior to the Spanish conquest (1524) the Cakchiquels were a principality which contested with other Indian principalities, especially the Quiché, for political domination. The archaeological site, Iximché, was the fortified capital city of the principality, covering about three miles. The ruins suggest class distinctions between nobles and commoners; as well as the warfare concerns of the people just prior to Spanish conquest. Their history is preserved in a manuscript written in Cakchiquel but using the Spanish alphabet. The Cakchiquel peoples received the Spanish peacefully and did not offer resistance until Spanish demands for tribute and forced labour occasioned a revolt a year after conquest.

The distribution of Cakchiquel-speaking Indians reflects their preconquest sites but is largely derived from the Spanish administrative policy of grouping Indians in manageable units for political control and religious conversion. See also CENTRAL AMERICA; *Ethnology*; MAYA INDIANS; for the early Cakchiquel calendar and chronology, see CALENDAR: *Middle American Calendars*, and CHRONOLOGY: *Pre-Columbian America*.

See F. W. McBride, *Cultural and Historical Geography of Southwest Guatemala* (1947). (M. NA.)

CAKES: see FOOD PREPARATION.

CAKEWALK, a dance of American Negro origin. The couples form a square with the men on the inside and, stepping high to a lively tune, walk in this square formation. There are several judges who consider the precision with which the corners are turned, the elegant bearing and carriage of the men and the grace and ease of their partners as they are swung about. The couples are eliminated one by one, the last being presented with a highly decorated cake as a reward. This is the original cakewalk, as it was danced in slavery days. From it many modifying steps have been evolved, all of which are called cakewalks.

CAKMAK, FEVZI (1876-1950), Turkish marshal and statesman who played a leading role in the creation of modern Turkey, was born at Istanbul on Jan. 12, 1876, the son of an artillery colonel. He was educated at the Kulili military college and the general staff academy at Harbiye, in Istanbul. A lieutenant in 1895, he was made lieutenant colonel and appointed chief of staff of an army corps in 1910. He fought in the Balkan Wars of 1912-13 as commander of a division and in World War I as commander of an army corps and (in 1917-18) of an army. War minister in 1920, he resigned the commission and office granted him by the sultan and joined Mustafa Kemal Atatürk's "rebellion" in Ankara. There he was made prime minister and minister of defense. Promoted to the rank of full general during the Greek invasion of Anatolia, he resigned his premiership in 1922 and became deputy to Ismet Inönü, then chief of staff. After the victorious conclusion of the War of Liberation, he was promoted as the new republic's first marshal and appointed chief of staff, holding that position for 20 years. In the 1946 elections he stood as an Independent and was elected to the grand national assembly with a great majority. In 1948 he accepted the honorary leadership of the conservative Millet (Nation's) party.

Čakmak died at Istanbul on April 10, 1950.

ČAKSTE, JANIS (1859–1927), promoter of Latvian independence and first president of the Republic of Latvia, was born at Lielsesava in Courland on Sept. 14, 1859. He was educated at the Jelgava (Mitau) gymnasium, studied law at the University of Moscow and was for some years in the public prosecutor's office of the Courland government. Leaving the public service in 1888, he practised law in Jelgava and edited a Latvian newspaper *Tevija* (Fatherland). He served on a committee appointed by the local administration to inquire into agricultural conditions in Courland (1902) and was frequently employed on Russian imperial government committees. In 1906 he was elected member of the first Russian duma. After the first duma was dissolved by the imperial government, Čakste was one of those who signed the Viborg protest. The German invasion of Courland (July 1915) obliged him to leave Jelgava. He moved to Petrograd (Leningrad), where he was one of the founders of a central relief committee for war refugees. In 1916 he went to Stockholm to promote the cause of Latvia's independence and there published his book *Die Letten und ihre Latvija*. Čakste was elected chairman of the Latvian people's council in 1918 and was later head of the delegation sent to Paris and London to secure the recognition of the Latvian republic. He was president of the Latvian national council and, in 1920, of the Latvian constituent assembly. He also became professor of international law at the University of Riga. Elected president of Latvia by the first Latvian *saeima* (parliament) on Nov. 14, 1922, he was re-elected on Nov. 6, 1925, for a further period of three years, but died on March 14, 1927. (A. ŠP.)

CALABAR BEAN, the seed of a leguminous plant, *Physostigma venenosum*, a native of tropical Africa. The plant is a climber and attains a height of about 50 ft. The seed pods, which contain two or three seeds or beans, are six or seven inches in length; and the beans are about the size of an ordinary horse bean but much thicker, with a deep chocolate-brown colour. Although highly poisonous, the bean has nothing in external aspect, taste or smell to distinguish it from any harmless leguminous seed, and disastrous effects have resulted from its being left in the way of children.

The bean usually contains less than 1% of alkaloids, of which several have been isolated, the most important being physostigmine or eserine. It occurs in small white crystals, turned red by exposure to light or air, slightly soluble in water, soluble in ether, chloroform and alcohol, and with a bitter taste. Medicinally, physostigmine is employed as the salicylate.

The pharmacological activity of physostigmine is due to its action in inhibiting the destruction of acetylcholine, permitting the latter to exert its characteristic effects in an intensified manner. According to the chemical theory of nerve transmission, acetylcholine is liberated at the nerve endings of all parasympathetic nerves and certain cholinergic sympathetic nerves, such as those supplying the sweat glands in human beings, at the ganglia of all autonomic nerves and also at the end plates of motor nerves to skeletal muscles. The effects of physostigmine at cholinergic nerve endings are antagonistic to those of atropine (see ATROPINE). Thus, the secretions of the salivary, mucous and sweat glands tend to be increased, the heart may be slowed and the blood pressure tends to fall; the pupil is constricted; the tone and motility of the gastrointestinal tract are increased and the bronchi are constricted. Because of its action at sympathetic ganglia, certain contradictory effects may be obtained such as increase in heart rate and blood pressure. The effect of physostigmine on skeletal muscle is observed with larger doses and is manifested by fibrillary twitchings.

In ophthalmology physostigmine is used in glaucoma to reduce the intraocular pressure and alternately with atropine to break up adhesions between the iris and the lens. It may be used to increase the motility of the gut or reduce abdominal distention. Physostigmine and, more especially, a synthetic substitute, neostigmine, have been used in the treatment of myasthenia gravis because they facilitate transmission of impulses at the myoneural junction by delaying the destruction of acetylcholine.

The calabar bean was formerly used by native tribes for "trial by ordeal." Gastrointestinal symptoms appear first and consist of violent peristalsis, nausea, vomiting, colic and diarrhea; there is restlessness and weakness with fibrillary twitchings of all voluntary muscles. The pupils are pinpoint, and salivation, sweating and lacrimation may be marked. There may be difficulty in breathing because of bronchiolar constriction. Death is due to respiratory paralysis. The administration of atropine will counteract all symptoms with the exception of the muscular twitchings.

(F. L. A.)

CALABASH, the shell of a gourd or pumpkin made into a vessel for holding liquids; also a vessel of similar shape made of other materials. It is also the name of a tree, *Crescentia cujete* (family Bignoniaceae) of tropical America, and its gourdlike fruit is so hard that vessels made of the rind can be used over a fire many times. Tobacco pipes are made from the necks. The bottle gourd, *Lagenaria vulgaris*, is also called the calabash. Pictographic records were kept on dried calabashes by the Indians of the Matto Grosso. According to Sir James Frazer in *The Golden Bough*, sorcerers in primitive cultures in Hawaii were thought to be able to imprison souls of living persons in calabashes. See also GOURD.

CALABOZO, founded in 1695, capital of Guárico state of Venezuela until 1934, is located in the llanos cattle region on the Guárico river, 120 mi. S.W. of Caracas. Pop. (1959 est.) 5,665. The town gained prominence in the 1950s as the headquarters for the Guárico river project south of the city, which cost about \$145,000,000 and is concerned with the cattle industry, irrigation and flood control. A nine-mile-long earth dam across the river forms a lake of 94 sq.mi, which irrigates 272,000 ac. of land including about 550 farms of approximately 494 ac. each. Calabozo is a town of considerable commercial importance, highways focusing on it from all directions. (L. WE.)

CALABRIA, a region of southern Italy comprising the provinces of Catanzaro, Cosenza and Reggio di Calabria (*qq.v.*). Pop. (1961) 2,045,215. Area 15,080 sq.km. (5,822 sq.mi.). Sometimes referred to as "the toe of the Italian boot," Calabria is a peninsula of irregular shape, jutting out in a northeast-southwest direction from the main body of Italy, and separating the Tyrrhenian and Ionian seas. Most of the region is mountainous or hilly, the only extensive lowlands being those of the lower Crati valley near Sibari (which derived its name from ancient Sybaris), of the Marchesato near Crotona, of Sant' Eufemia and of Gioia Tauro. In the north Calabria is linked to the Lucanian Apennines (Appennino Lucano) by the massif of Monte Pollino (2,248 m. or 7,375 ft.); the Pollino is continued southward along the west coast by the coast range, which in turn is separated by the Crati river from the extensive La Sila massif (highest point: Botte Donato, 1,928 m., or 6,325 ft.). A narrow isthmus between the Gulf of Sant' Eufemia in the west and the Gulf of Squillace in the east separates the northern from the southern part of the region; the uplands continue as the Calabrian Apennines (Appennino Calabrese) and culminate in the southernmost part as the massif of the Aspromonte (Mont-Alto 1,956 m., or 6,417 ft.).

The mainstay of Calabria's economy is farming, once characterized by large landed estates and tiny peasant holdings. Under the Italian land reform the majority of the former *latifundia* were broken up after 1951 and new, small peasant holdings created, with rural service centres, new houses and new roads. Formerly the agriculture of Calabria concentrated almost entirely on cereals and the raising of sheep and goats, with occasional work in the forests of the Sila uplands. New commercial crops, citrus fruit (mostly on the west coast), figs and chestnuts, were introduced. Hydroelectric power was developed during the 1920s and 1930s in La Sila and is an important feature of the Calabrian economy, supplying electric railways and the industrial centre of Crotona on the Ionian coast, which has chemical industries. There are two trunk railways: the Rome-Naples-Reggio di Calabria line on the west coast (the direct line between Rome and Sicily), and the Ionian or Taranto-Reggio di Calabria line on the east coast. The two lines are connected from Paola to Sibari (connection for Cosenza), and from Sant' Eufemia to Marina di Catanzaro; there

are also local lines. The highways are well developed, with extensive bus services. A railway and car ferry links the ports of Reggio di Calabria and Villa San Giovanni with Messina in Sicily.

Calabria is one of the few areas of south Italy with a non-Italian minority: the Albanians who settled in the region during the 15th and 16th centuries under Turkish pressure, and who have retained their speech, the Greek Catholic rite in their churches and, on festival occasions, their colourful national costumes.

In classical times the region was a centre of Greek colonization; Crotona, Sybaris (*qq.v.*), Reggio (now Reggio di Calabria) were Greek cities of wide fame. After the Roman conquest the splendour of the Greek cities slowly gave way to a remote provincial existence, and eventually *Ager Bruttius* as it was then called passed to the Byzantines who applied the name Calabria (which was also the Roman name for the southeast extremity of the Italian peninsula, see CALABRIA [ANCIENT]). The Lombards controlled the region from Benevento and, later, from Salerno. After another period of Byzantine rule Calabria shared with the rest of southern Italy its Hohenstaufen, Angevin and Aragonian rulers; it became a stronghold of Italian republicanism until the *Risorgimento* (the movement for political unity), and part of Italy after Garibaldi's expedition in 1860. In World War II Reggio di Calabria, chief supply centre for Sicily, was heavily bombed by the Allies.

(G. KH.)
CALABRIA (ANCIENT), the name applied from the 3rd century B.C. to a district of ancient Italy in the southeastern extremity of the peninsula between the Adriatic and the Gulf of Tarentum ending in the Iapygian promontory (Salentina); the village on this promontory was called Leuca (Gr. *leukos* "white") from its white cliffs (mod. Santa Maria di Leuca). Calabria occupied the southern part of modern Apulia (Ital. Puglia), consisting of the provinces of Lecce, Brindisi and Taranto, though the latter extends farther westward than the ancient district (modern Calabria comprises the ancient territory of the Bruttii, the southwestern extremity of Italy).

The land forms a low terrace of limestone, the highest parts of which seldom reach 1,500 ft.; the cliffs, though not high, are steep, and it has no important rivers, but despite lack of water it was remarkably fertile. Strabo mentioned its pastures and trees, and reference was frequently made to its olives, wines and fruit trees. The wool of the ports of Tarentum (Taranto) and Brundisium (Brindisi) was famous and the former had considerable dyeworks. Traces of a prehistoric population are to be found all over Calabria, especially near Lecce, Gallipoli and Muro Leccese.

Between 272 and 266 B.C. six triumphs were recorded in the Roman *fasti* (calendar) over the Tarentini, Sallentini and Messapii, while the name Calabria does not occur; but after the foundation of a colony at Brundisium about 246 and the final subjection of Tarentum in 209, Calabria became the general name for the peninsula. According to Strabo (1st century A.D.) earlier Calabria had been extremely prosperous and had had 13 cities, but all except Tarentum and Brundisium had dwindled to villages. The Appian way, extended to Brundisium probably by 244 B.C., passed through Tarentum; the shorter route by Canusium (Canosa di Puglia), Barium (Bari) and Egnatia (near Fasano) was only made a main route by the emperor Trajan. When the emperor Augustus divided Italy into *regiones* he joined Calabria to Apulia and the territory of the Hirpini to form the second region. From the end of the 2nd century Calabria was associated for juridical purposes either with Apulia or with Lucania and the district of the Bruttii, while the emperor Diocletian placed it under one *corrector* (governor) with Apulia. When the Lombards seized Calabria about A.D. 668 its name became transferred to the southwestern peninsula of Italy.

See J. Whatmough, *The Foundations of Roman Italy* (1937); G. Palumbo, *Rivista di Scienze Preistoriche*, vol. x (1955).

CALAHORRA, a town of northern Spain, province of Logroño, is situated on the left bank of the Cidacos river near its confluence with the Ebro, and is 49 km. (31 mi.) E.S.E. of Logroño by road. Pop. (1950) 13,183 (mun.).

The cathedral, dating probably from the 5th century, was re-

stored in 1485, with a facade dated 1680–1704 and much subsequent alteration. The Gothic church of San Xndres is also notable. The Casa Santa, visited by thousands of pilgrims on Aug. 31, supposedly contains the bodies of the martyrs Emeterius and Celedonius. Calahorra is on the main railway from Bilbao to Saragossa and Barcelona. The town was famous for its four years' resistance to Pompey, 76–72 B.C. Augustus gave it Roman citizenship, and it later was called Calagurris Nassica to distinguish it from Calagurris Fibularensis nearby. (M. B. F.)

CALAIS, a seaport on the Strait of Dover and industrial town of northern France in the *département* of Pas-de-Calais, is 274 km. (170 mi.) by road from Paris. Pop. (1954 census) 60,160. Area 2,937 sq.km. (11½ sq.mi.). The old town with the citadel of 1560 was virtually destroyed in World War II and is now a new quarter. It stands on an island bordered by the canal and harbour basins which separate it from the larger quarter of St.-Pierre to the south, which, also badly damaged, is still the industrial area. The principal thoroughfares are the Place d'Armes, Place Crèvecoeur, Place Albert I, the Rue Royale, and Jacquard, Pasteur, Gambetta and La Fayette boulevards. The 13th-century Tour du Guet (watchtower) still stands in the old town; and the modern hôtel de ville (town hall) in St.-Pierre was built (1910–22) in Flemish Renaissance style.

Calais is the second most important passenger port in France, and the first for passenger traffic with England. It is linked by railway with Boulogne, Paris, Lille and Dunkirk, and by sea with Dover (the shortest crossing from England 21 mi.) and Folkestone. For passengers and automobiles there are several daily cross-channel sea services, and air services from Calais-Marck airport. There is a river transport link with Saint-Omer. The principal industry is lacemaking, including point lace and pillow lace, and tulles and embroideries are exported all over the world. Other exports are pit coal and sand. Imports include timber, cellulose pulp, iron ore and pyrites. Other manufactures include papier-mâché, Calais yarns, chemical products, biscuits and submarine cable.

Originally a fishing village, Calais was improved by Baldwin IV, Count of Flanders, in 997, and fortified in 1224 by Philip Hurepel Count of Boulogne. After the battle of Crécy it was besieged (1346) for nearly a year by Edward III of England, and reduced by famine. The famous episode of the six burghers of Calais, who surrendered themselves to save their town, is related to this siege and is commemorated by Auguste Rodin's monument. Calais remained English until 1558, when it was taken by François de Lorraine, 2nd duke of Guise. From this time the Calaisis, or territory of Calais, was known as the Pays Reconquis. It was occupied by Spain from 1596 to 1598, but returned to France by the treaty of Vervins. In 1803, 6,000 men of Napoleon's "army of England" were encamped there. It was often a German objective in World War I and in World War II was one of the main objectives of the German drive to the sea in May 1940, from which time it remained in German hands until its recapture by the Allies in Sept. 1944. It had then been, for about three months, a base for the robot bombs directed against England.

CALAIS AND ZETES, in Greek mythology, the winged twin sons of Boreas and Oreithyia. On their arrival with the Argonauts at Salmydessus in Thrace, they liberated their sister Cleopatra, who had been thrown into prison with her two sons by her husband, Phineus, the king of the country. According to another story, they delivered Phineus from the Harpies. They were slain by Heracles near the island of Tenos, in consequence of a quarrel with Tiphys, the pilot of the Argonauts, or because they refused to wait during the search for Hylas. Legend attributed the foundation of Calais in Campania to Calais.

CALAMIAN ISLANDS, an island group lying between Mindoro and Palawan, Republic of the Philippines. Politically a part of Palawan province, this group consists of Busuanga (344 sq.mi.), Culion (150 sq.mi.), Coron (27 sq.mi.) and many lesser isles and islets. Manganese was mined on Busuanga prior to Japanese occupation of the Philippines and again in the immediate postwar years. Culion is best known as the site of a leper colony. All the larger islands have some agriculture, principally subsist-

ence cropping, and fishing is a significant activity. The principal settlement is Coron (pop. [1960] 10,222) on Busuanga opposite the island of Coron. See also PALAWAN; CULION ISLAND.

(AN. C.)

CALAMINE, the mineral name applied to hydrous zinc silicate (see HEMIMORPHITE), an important ore of zinc, by U.S. mineralogists and to zinc carbonate (see SMITHSONITE) by British mineralogists. The word calamine is a corruption of *cadmia*, the old name for zinc ores in general; even today many miners include both the hydrous silicate and the carbonate under this same term, probably because of their similar appearance. In 1532, however, F. S. Beudant restricted the name calamine to the hydrous silicate and proposed the name smithsonite for the carbonate. Although U.S. mineralogists adopted this usage, English mineralogists (following Henry Brooke and William Miller, 1852) reverse these designations.

(F. D. B.)

CALAMIS (fl. 470–450 B.C.), Athenian sculptor, made statues of Apollo the averter of ill, Hermes the rambearer, Aphrodite and other deities, as well as part of a chariot group for Hiero, king of Syracuse. His works were praised by ancient critics for delicacy, simplicity and orderliness. Copies of the Aphrodite or Sosandra have been identified, but evidence for his other works is inconclusive.

See Gisela M. A. Richter, *The Sculpture and Sculptors of the Greeks*, pp. 203–207 (1950).

(C. C. V.)

CALAMY, EDMUND (1600–1666), English Presbyterian minister, a leader among the Presbyterians in England in the mid-17th century, was born in London in Feb. 1600 and educated at Merchant Taylors' school, London, and Pembroke hall, Cambridge. After holding positions in the eastern counties, he became rector of St. Mary Aldermanbury, London, in 1639. In 1641 he was one of five writers who, over the nom de plume of Smectymnuus, made a noted attack on episcopacy and liturgy conceived as of divine right and inalterable; and in 1643 he was a member of the Westminster Assembly of Divines. When in 1646 parliament ordered Presbyterianism to be established in England, Calamy was one who served as moderator of the provincial assembly set up in London, and he contributed to various publications which it issued. He was prepared for discussion with Independents; and at the Restoration he accepted a chaplaincy to Charles II. He declined a bishopric, but was appointed to nominate those other than bishops to the Savoy conference of 1661. But a policy of comprehension proved impossible, and in Aug. 1662, under the Act of Uniformity, Calamy was ejected from his living, and in December became the first Nonconformist to suffer imprisonment for disobeying the act. He died on Oct. 29, 1666. His son, grandson and great grandson were all Nonconformist ministers of the same name and his grandson was the biographer of the ejected ministers.

(G. F. N.)

CĂLĂRAȘI, a town of Rumania, is situated 104 km. (65 mi.) E.S.E. of Bucharest on the left bank of the Borcea arm of the Danube, forming the Danube delta. It is the administrative centre of a district of the same name in the Bucharești region. Pop. (1956) 25,269. Călărăși is a river port and trading centre. Its chief industry is food manufacturing, particularly fish processing and flour milling. The first documentary mention of the town occurred in 1593, during the reign of Michael the Brave.

CALAS, JEAN (1698–1762), the Huguenot cloth merchant of Toulouse whose judicial murder in 1762 became a cause célèbre in the history of toleration and first aroused Voltaire's passion for the reform of the French criminal code, was born in the village of Lacabarède, near Castres in Languedoc, on March 19, 1698. On Oct. 13, 1761, Calas' eldest son, Marc Antoine, was found by his family hanged in his father's shop. Local prejudice against the Huguenots, led by a panic psychology, accused the Calas family of having murdered Marc Antoine to prevent or punish his rumoured conversion to Roman Catholicism. Calas first attributed the crime to an unknown intruder, but later insisted that his son had committed suicide. He was tried by the *capitouls* (local magistrates) and finally condemned to death by the *parlement* of Toulouse, sitting as an appellate court, on March 9, 1762. Throughout his trial and subsequent torture Calas maintained his

innocence. On March 10, 1762, he was publicly broken on the wheel, strangled and then burned to ashes. His son was buried as a martyr to the Roman Catholic faith. Influential friends of the family in Geneva interested Voltaire in the case, and it was largely through his efforts that European opinion was mobilized and that Calas' innocence was vindicated in 1765. The family was indemnified and the sentence of the *parlement* was stricken from the record. Though the local magistrates had scrupulously observed most of the established procedure, much of the evidence that they admitted had been mere hearsay. The Calas case powerfully strengthened the argument for criminal law reform in France, though this did not come about till 1788.

(A. GN.)

CALBAYOG, a city chartered in 1948 in the province and island of Samar, Republic of the Philippines, on the west coast at the mouth of the Calbayog river, about 30 mi. N.W. of Catbalogan, the provincial capital. Its area includes much rural farmland, comprising three municipalities with three administrative centres, and a total of 83 barrios (local districts). The 1948 population of 79,503 decreased to a 1960 population of 77,821. The coastal plain is narrow, and rice production is insufficient for local needs, but Calbayog is a regular port of call for interisland ships since it is less subject to storms than ports of the north coast. It is the leading exporter of Samar Island abacá (Manila hemp), an important exporter of copra, and the chief importer of rice and manufactures for northern Samar.

(J. E. SR.)

CALCAR (KALKAR, KALCKER), **JAN STEPHAN VON** (c. 1499–c. 1546), German painter, whose artistic personality is obscure, was from c. 1536/37 in Venice, where he studied under Titian, and in 1545 in Naples, where he died. Vasari praises his portraits; both these and his drawings, according to Karel Van Mander, are virtually indistinguishable from Titian's. A male portrait of 1540 (Louvre, Paris), attributed to him in a French royal inventory of 1683, forms the basis of all modern attributions of paintings to Calcar.

His only certain works are the designs for three anatomical plates published for Andreas Vesalius (*q.v.*; 1538); the superb illustrations of the latter's *De humani corporis fabrica* (1543) are also generally ascribed to him.

(D. KG.)

CALCEOLARIA, a genus of shrubs and herbs belonging to the figwort family (Scrophulariaceae; *q.v.*), containing about 500 species, chiefly natives of the South American Andes of Peru and Chile, and sometimes called slipperworts. The calceolaria of the florists has been developed into a decorative herbaceous plant with large numbers of mostly red and yellow spotted, pouchlike inflated flowers. It is generally raised annually from the seed, which is sown about the end of June in a mixture of loam, leaf mold and sand. The shrubby calceolarias, sometimes used for bedding, are propagated from cuttings planted in autumn in the cool greenhouse.

CALCHAQUI, a generic term for a subgroup of Diaguita-speaking peoples who occupied a large territory in northwestern Argentina in the region of the Santa Maria valley. Knowledge of these Indians comes from Spanish chronicles and archaeological surveys. Their language affiliation remains uncertain.

The Calchaqui were described as warlike, and their stone fortifications located at strategic places in their territory attest to this observation. Most Calchaqui lived in unfortified settlements, retreating to hilltop redoubts when under attack; but there were also some fortified villages. Settlements were autonomous except in wartime, when they united under the military alliance of influential chiefs. The Calchaqui adopted horses early in the colonial era and became effective cavalymen who carried the attack to Spanish towns and destroyed houses and fields.

Archaeological remains and chronicle reports indicate that the Calchaqui lived in small, sedentary agricultural villages where they farmed terraced fields, sometimes built irrigation canals, and also kept herds of llama. Their technological skill also extended to loom weaving llama-wool textiles, which were dyed; basket-making; and a rather elaborate ceramic industry, as evidenced by

pottery molded into anthropo- and zoomorphic shapes, and otherwise decorated and painted. Metallurgy was also known, work being done in silver, gold, copper and a copper-tin alloy called "Calchaqui bronze."

Religious beliefs involved shamanistic practices for the cure of illness felt to be caused by witchcraft. Shamans also appear to have held public fertility rites connected with agriculture, during which animal and sometimes human (enemy) sacrifice was made to the sun. Funeral ceremonies were elaborate and protracted, involving ceremonial wailing, flexed-burial of the deceased in a pit or special chamber and, in the case of infants, urn burial, apparently in special cemeteries.

See J. H. Steward (ed.), *Handbook of South American Indians*, Bureau of American Ethnology Bulletin 143, vol. ii, pp. 637-654, with bibliography (1947); also, J. H. Steward and L. C. Faron, *Native Peoples of South America* (1959). (L. C. FA.)

CALCHAS, son of Thestor, the most famous soothsayer among the Greeks at the time of the Trojan war. He foretold the duration of the siege, demanded the sacrifice of Iphigeneia and the return of Chryseis; he suggested that Neoptolemus and Philoctetes should be fetched to Troy, and advised the construction of the wooden horse. It had been predicted that he should die when he met his superior in divination; and the prophecy was fulfilled in the person of Mopsus, whom Calchas met after the war, at Clarus, or at Siris in Italy.

Beaten in a trial of soothsaying, Calchas died of chagrin or committed suicide.

CALCIMINE: see DISTEMPER, WHITEWASH AND CALCIMINE.

CALCINATION. Solids, when heated to a high temperature for the purpose of removing volatile substances, for the purpose of oxidizing a portion of the mass, or to render them friable, are said to be calcined. Calcination, therefore, is sometimes considered a process of purification. A typical example is the manufacture of lime from limestone. In this process the limestone, usually admixed with coke or other fuel to maintain the high temperature but sometimes treated in rotary kilns heated by gas or powdered fuel, is brought to a temperature high enough to expel the carbon dioxide, producing the lime of commerce in a highly friable or easily powdered condition. Calcination in special cases may be carried on in furnaces designed to exclude air, for which an inert gas may be substituted.

CALCITE, a widely distributed rhombohedral mineral consisting of calcium carbonate and noted for the beautiful development and great variety of its crystals.

The name calcite is of comparatively recent origin, being first used in its present sense by W. K. Haidinger in 1845. However, the mineral had long been known by the name calcareous spar, and the transparent variety called Iceland spar had been much studied. The strong double refraction and perfect cleavage of Iceland spar were described in detail by Erasmus Bartholin in 1669 in his book *Experimenta crystalli islandici disdiaclastici*; a study of the same mineral led Christiaan Huygens to discover in 1678 the laws of double refraction. From an investigation of the cleavage and crystal forms of calcite, R. J. Haüy in 1781-1801 developed a theory of crystal structure which played an important part in the development of modern structural crystallography. In 1808 E. L. Malus discovered the polarization of light by Iceland spar.

Modes of Occurrence.—The modes of occurrence of calcite, CaCO_3 , are exceedingly varied. It occurs as one of the most common sedimentary rocks, limestone, and as the metamorphic equivalent, marble. It is a common constituent of the shells of invertebrates. It frequently occurs as crystals in association with zeolites, lining the cavities of basaltic rocks, and is a common product of hydrothermal solutions, forming the gangue material in many ore deposits. CaCO_3 is appreciably soluble in ground water containing organic acids and dissolved carbon dioxide, obtained in passing through soils, and is redeposited when the CO_2 escapes. This solution mechanism is responsible for the frequency of limestone caverns and the wide distribution of stalactites and stalagmites in caves, massive banded deposits of travertine around springs, and spongy calcareous tufa in ordinary streams and springs. *Caliche* is a soil or porous rock zone in arid

 (F) combination of basal pinacoid (*c*) with prism (*m*) and rhombohedron (*e*)

the light to the side, leaving a single, completely polarized ray. Other methods of producing polarized light, either by reflection or absorption, do not give such complete polarization. Although the double refraction (see *Physical and Chemical Properties*, below) of some other minerals is much greater than that of Iceland spar (0.1723 while for cinnabar it is 0.347 and for calomel 0.683), the former materials cannot be obtained in large thick transparent pieces. (See also LIGHT: *Polarization and Electromagnetic Theory: Methods of Producing Polarization*; POLARIMETRY.)

Crystal Forms.—Crystals of calcite show a greater variety of forms than any other mineral. In his *Atlas der Kristallformen* (1912-23), V. Goldschmidt showed more than 2,500 drawings of calcite crystals. By the second half of the 20th century, 328 forms had been definitely established, with an additional 296 regarded as uncertain. In spite of this variety, there are four most frequently encountered types, namely: (1) prismatic, with various terminations; (2) scalenohedral, many times very complex, and when occurring in acute forms called dogtooth spar; (3) rhombohedral, varying from flat to very acute; and (4) tabular, with the basal face prominent, and sometimes occurring in almost paper-thin crystals. Clusters of parallel crystals are common. These may be nearly identical, or rhombohedral crystals may be perched on a scalenohedron (nailhead spar). Sometimes an earlier formed crystal will be completely enclosed by a later growth, giving a phantom crystal. Subparallel growths of platy crystals form an undulatory lamellar variety with a pearly lustre, called argentine. Calcite is also remarkable for the variety and perfection of its twinned crystals. (See CRYSTALLOGRAPHY.)

In addition to its perfect rhombohedral cleavage, calcite is characterized by a specific gravity of 2.71 and a hardness of 3 on Mohs' scale. It effervesces briskly with cold dilute acids, and is transparent and colourless when pure. Various colours may be imparted by other elements replacing the calcium, such as pink by manganese. Colour may also be due to admixed impurities such as red or brown from disseminated hematite or cuprite, and green from malachite or chlorite. Clear transparent crystals of calcite containing bright metallic flakes of copper are found in northern Michigan. A remarkable case of enclosed impurities is that of sand-calcite crystals. These consist of calcite with up to

regions which has been enriched in CaCO_3 by the evaporation of ground water. Oolites are formed in the Sea of Azov and in the shallow waters of the Bahaman platform at places where upwelling waters lose CO_2 through warming, agitation and photosynthetic uptake by algae. Although often precipitated as aragonite, oolites subsequently invert to calcite.

Commercial Importance and Uses.—Calcite is the most important mineral constituent of limestones and marbles, which are of great commercial importance in the building, steel, chemical, glass and other industries (see LIMESTONE; MARBLE). Iceland spar, which was first produced as early as the 17th century from masses and enormous crystals in a large cavity in basalt on the east coast of Iceland, is used in polarizing prisms such as the Nicol and Ahrens prisms. These are used in polarizing microscopes to study the behaviour of crystalized substances, in polariscopes such as the saccharimeter used in the sugar industry, and in other optical instruments. These prisms reflect one component of

64% of quartz sand, and are found at Fontainebleau near Paris and in the Bad Lands of South Dakota.

Physical and Chemical Properties.—Calcite is made up of calcium ions and carbonate ions in alternate planes perpendicular to the crystallographic *c*-axis to yield a structure which is a distorted equivalent of that of NaCl. This arrangement results in a marked anisotropism of chemical and physical properties including dielectric constant, thermal expansion, hardness, rate of solubility in acid, linear compressibility and refractive index. Thus, calcite is less resistant to scratching on a basal face than on a prism, and on the rhombohedral cleavage it is distinctly softer when scratched toward the apex than away from it. Optically, calcite is uniaxial negative, the index of refraction for the ordinary ray being 1.6585 and for the extraordinary ray 1.4862 (sodium light). The difference, 0.1723, between these two indexes is a measure of the strong birefringence or double refraction, which is sufficient so that an object viewed through a cleavage rhombohedron is seen double. W. L. Bragg was able in 1924 to calculate the refractive indexes of calcite from the atomic arrangement, one of the first such calculations to be made.

Calcite is polymorphous with aragonite, which is orthorhombic, with vaterite, which is hexagonal, and with several forms which apparently exist only under rather extreme experimental conditions. Calcite is the stable form at all temperatures and pressures encountered at or near the earth's surface.

The radius of the Ca^{2+} ion is markedly greater than those of Mn^{2+} , Fe^{2+} and Mg^{2+} , the cations in the three most common of the carbonates having the same crystal structure as calcite; *i.e.*,

FIG. 2.—FOUR SPECIMENS OF TWINNED CRYSTALS OF CALCITE

rhodochrosite, siderite and magnesite. Solid solutions between calcite and these minerals are therefore incomplete. Small amounts of zinc, lead, barium and strontium have also been found in calcite. Calcites from marbles contain up to $7\frac{1}{2}$ mole per cent MgCO_3 ; when these materials exist in equilibrium with dolomite in the rock: the amount of MgCO_3 in solid solution may be used as a geologic thermometer. Manganese-rich ore bodies such as those of Franklin, N.J., and Långban, Swed., contain calcites with up to 40 mole per cent MnCO_3 in solid solution. The calcites making up the hard parts of some invertebrates contain as much as 18% MgCO_3 . The content of both magnesium and strontium in such skeletal calcite varies with the kind of organism and with water temperature.

The relative amounts of the O^{18} and O^{16} isotopes in shells consisting of calcium carbonate may be used to calculate the temperature of the water in which the organisms lived. The C^{14} isotope content of CaCO_3 less than about 40,000 years old may often be used to measure the age of the material, if the source of CO_2 incorporated in the carbonate can be inferred.

See also references under "Calcite" in the Index volume.

(D. L. G.)

CALCIUM, a metallic element, symbol Ca, was so named by Sir Humphry Davy because of its occurrence in chalk (*q.v.*).

Calcium does not occur in the free state, but compounds of the element are widely distributed. In the earth's crust calcium is the fifth most abundant element; it constitutes 3.63% of the igneous rocks and 3.22% of the entire crust of the earth. It is found as the sulfate in gypsum and related minerals.

The fluoride of calcium occurs as fluorite and (with calcium

phosphate) as apatite. Many minerals, notably feldspars and zeolites, contain calcium silicates. Asbestos is composed of calcium magnesium silicate, $\text{CaMg}_3(\text{SiO}_3)_4$. Calcium phosphate is the principal inorganic constituent of bones; it also occurs as the mineral phosphorite, $\text{Ca}_3(\text{PO}_4)_2$. Calcium carbonate (calcite) occurs in limestone, chalk, marble, dolomite, eggshells, pearls, coral, stalactites, stalagmites and the shells of many marine creatures.

Production.—In 1808 Davy showed that lime was an oxide of the metal which he named calcium. Robert Bunsen electrolyzed calcium chloride, and A. Matthiessen obtained the metal by the electrolysis of a mixture of fused calcium and sodium chlorides. While calcium was formerly produced by electrolysis of anhydrous calcium chloride, practically all commercial production is by the reduction of lime by aluminum in heated retorts under low pressures. Calcium distills out of the reaction mass and is collected in a cool section of the retort or in a condenser.

Uses.—Calcium is employed as an alloying agent for aluminum, copper, lead, magnesium and other base metals (see also ALLOYS; BEARING METALS). It is an important deoxidizer for chromium-nickel, chromium-nickel-iron and related resistance high-temperature alloys, and for nickel, steel and tin bronzes. It is a getter or evacuating agent for high vacuums as in thermionic tubes, radio and television components. It has been employed as a reducing agent in the preparation of chromium, thorium, uranium, zirconium and other metals from their oxides; as a dehydrating agent for organic liquids; a desulfurizer for petroleum fractions; and a decomposing agent for thiophenes and mercaptans. Calcium as a 0.04% calcium lead is employed on telephone cables and in storage batteries (see BATTERY: Stationary Batteries).

Various compounds of calcium have numerous important uses (see Compounds, below). (See also separate articles on calcium-bearing minerals, as CALCITE; FLUORITE; ZEOLITE; etc.)

Physical and Chemical Properties.—Calcium is one of the alkaline-earth metals of Group II of the periodic table. It is a silvery-white metal when freshly prepared, but it reacts readily with oxygen and nitrogen and tarnishes when exposed to the air to produce a gray and slightly yellow surface. There are six stable isotopes of the element; these, arranged in the order of abundance, have mass numbers of 40, 44, 42, 48, 43 and 46. Several artificial radioactive isotopes have also been prepared. The properties of calcium are given in the accompanying table.

The arrangement of electrons in the levels and sublevels of the atom of calcium is: $1s^2, 2s^2, 2p^6, 3s^2, 3p^6, 4s^2$.

The chemical properties of calcium are similar to those of strontium and barium. In their compounds, these three elements have a valence number of +2. They are also active reducing agents and their compounds have structures and properties commonly possessed by compounds of active metallic elements. Calcium is somewhat less readily oxidized to form ions than strontium and barium and is, therefore, a slightly less active metal.

Under ordinary conditions of temperature calcium reacts slowly with the oxygen and nitrogen of the air to form a yellow layer composed of the oxide, hydroxide and nitride. This layer protects the metal from rapid oxidation. The element burns brilliantly when in air or in pure oxygen to form the monoxide, CaO . It reacts rapidly with warm water and more slowly with cold water to produce a stream of bubbles of hydrogen.

Calcium reacts directly with most nonmetallic elements. At high temperatures, it reacts with nitrogen to form the nitride, Ca_3N_2 , and with carbon to form the acetylide CaC_2 , often but incorrectly called calcium carbide. Upon reaction with water CaC_2 gives acetylene C_2H_2 . The true carbide Ca_2C , which upon reaction with water would give hydrocarbonic acid H_4C (Methane CH_4), is not stable at high temperatures and does not form. It reacts with the nitrogen of air in the electric furnace to form calcium cyanamide (see CYANAMIDE, CALCIUM). At somewhat lower temperatures, it reacts with sulfur to form the sulfide, CaS , and with phosphorus to form the phosphide, Ca_3P_2 .

Compounds.—In general, the compounds of calcium resemble those of strontium and barium but are, with a few exceptions, somewhat more soluble in water.

Calcium hydride, CaH_2 , sometimes called hydrolith, is obtained

by heating the metal in a current of hydrogen. This compound is easily transported and on treatment with water yields hydrogen, which can be used in filling dirigibles. Calcium forms the monoxide, CaO, the peroxide, CaO₂, and possibly a tetroxide, CaO₄. The monoxide is commonly called lime (*q.v.*) or quicklime and the corresponding hydroxide, Ca(OH)₂, is sometimes called slaked lime.

The hydroxide is an inexpensive alkaline substance. It is not very soluble in water, and is generally used in the form of a suspension of the solid in water called milk of lime. Among its most important uses is the production of mortar or plaster which contains, in addition to calcium hydroxide, sand and water.

These materials set as they dry and as the hydroxide is slowly converted into calcium carbonate by the action of carbon dioxide in the atmosphere.

The peroxide is obtained by the addition of hydrogen peroxide to limewater; the resulting hydrate, CaO₂·8H₂O, loses water on being heated to 130° C. and forms the peroxide as a pale buff-coloured powder. It is used sometimes for bleaching and antiseptic purposes.

sodium fluoride. The chloride, CaCl₂, occurs in many natural waters and is produced as a by-product in several manufacturing processes. The crystals may contain two, four or six molecules of water for each gram molecular weight of the chloride. The pure anhydrous chloride is obtained by heating the crystals above 200° C. in a current of hydrogen chloride. It melts at 772° C. It is used as a drying agent. The hexahydrate is used to produce freezing mixtures. Concentrated solutions find some use in laying dust on roads and elsewhere. Bleaching powder (*q.v.*) is now regarded as a mixture of the basic chloride, CaCl₂·Ca(OH)₂(H₂O), and the basic hypochlorite, Ca(OCl)₂·2Ca(OH)₂. It is made by exposing thin layers of slaked lime to chlorine at 30°-40° C. (See ALKALI MANUFACTURE; BLEACHING.)

Calcium carbonate, or calcite, CaCO₃, occurs in all limestones and in other minerals (see above) and as bicarbonate, Ca(HCO₃)₂, in some naturally hard waters. The loss of carbon dioxide by the evaporating or heating of such waters results in the deposition of CaCO₃ and, hence, the hardness of water resulting from the presence in solution of calcium bicarbonate is called temporary. Precipitated chalk is prepared by mixing solutions of calcium chloride and a soluble carbonate.

Calcium nitride, Ca₃N₂, is produced by heating calcium in nitrogen; it is a grayish-yellow powder, which is readily decomposed by water with formation of ammonia.

Calcium nitrate, Ca(NO₃)₂, is a highly deliquescent salt; it is sometimes called lime saltpetre. The hydrate, Ca(NO₃)₂·4H₂O, has been produced in the flaming arc process for fixing atmospheric nitrogen. It is used as an artificial manure either directly or after conversion into ammonium nitrate.

Calcium phosphide, Ca₃P₂, is obtained by passing phosphorus vapour over strongly heated lime. It produces spontaneously inflammable hydrogen phosphide on reacting with water, and, therefore, is used in marine signal lights.

Normal calcium phosphate, Ca₃(PO₄)₂, is the principal inorganic constituent of bones and of bone ash (see PHOSPHORUS); it occurs as phosphorite, Ca₃(PO₄)₂, in Florida, Tennessee and certain western states of the U.S. and in northern Africa. It also occurs as apatite, Ca₅F(PO₄)₃, or Ca₅Cl(PO₄)₃, in Canada and elsewhere. The acid salt, CaH₄(PO₄)₂, is obtained by evaporating a solution of the normal salt in hydrochloric or nitric acid; it is very soluble and, with calcium sulfate, is a standard superphosphate fertilizer which is produced by treating mineral phosphates with sulfuric acid (see also FERTILIZERS AND MANURES).

Calcium phosphate is used in medicine; as a source of phosphorus; as polishing powder in tooth pastes (as calcium metaphosphate); in ceramics and porcelain manufacture; and in enameling.

Calcium sulfide, CaS, is produced by heating the sulfate with charcoal or by heating lime in a current of hydrogen sulfide. The hydrosulfide, Ca(SH)₂·6H₂O, is produced by saturating a cold suspension of lime with hydrogen sulfide. The di- and pentasulfides, CaS₂ and CaS₅, are formed when milk of lime is boiled with flowers of sulfur. The sulfides of calcium are used as a depilatory in the manufacture of leather; in medicine; and in luminous paints.

Calcium sulfate, CaSO₄, occurs as gypsum, alabaster, anhydrite, satin spar and selenite, and in water, in which it is one of the salts causing permanent hardness; *i.e.*, hardness not removed by boiling. The dihydrate, CaSO₄·2H₂O, is converted into a semi-hydrate, CaSO₄·½H₂O, on being heated to 120°-180° C.; this hydrate is called plaster of paris (*q.v.*).

Analysis.—Most calcium compounds impart an orange-red colour to the flame of the Bunsen burner, more especially if they are moistened with hydrochloric acid. Spectroscopically, calcium exhibits two characteristic lines—Ca α , orange; λ 6,163; and Ca β , green, λ 4,229. Calcium ion is not precipitated by hydrogen sulfide either in acid or in ammoniacal solution, but is precipitated by ammonium carbonate in the presence of ammonium ion. It is quantitatively precipitated as calcium oxalate, a white solid, insoluble in acetic acid, either by ammonium oxalate or sodium oxalate. Calcium is usually separated in this form and subsequently dried and converted either to the oxide by heat or to the sulfate by sulfuric acid and weighed as such.

Calcium salts are not toxic; deficiency of calcium in the diet

Physical Properties of Calcium

Atomic number	20
Atomic volume (c.c./gram atom)	25.9
Atomic weight	40.08
Boiling point	1,450° C. (2,632° F.)
Colour	White, approximating silver
Compressibility:	
30° C. (86° F.)	
0 atm. pressure	5.885 X 10 ⁻⁸
11,600 atm. pressure	5.300 X 10 ⁻⁸
20° C. (68° F.)	
99-493 atm. pressure	5.8 X 10 ⁻⁸
100-500 megabars/sq.cm.	5.7 X 10 ⁻⁸
Compressibility = $\frac{1}{\text{vol. (cu.cm.)}} \times \Delta \text{ pressure (atm.)}$	A vol. (cu.cm.)
Crystal structure	Face centred cubic. a = 5.56kX
Density (g./c.c.)	
20° C. (68° F.)	1.55 (0.056 lb./cu.in.)
450° C. (842° F.) α phase in extruded wire	1.48
480° C. (896° F.) β phase	1.52
Elastic limit (p.s.i.)	1,470

cubic, 0°-21° C. (32°-70° F.)	0.000717
Transformation temperature (cooling)	450° C. (840° F.)
Valence	2
Volume conductivity referred to standard copper (%)	48.7

Whereas calcium chloride, bromide and iodide are deliquescent, soluble substances, the fluoride is only slightly soluble in water. Calcium fluoride, CaF₂, occurs as fluorite and can be prepared as a white precipitate by mixing solutions of calcium chloride and

leads to diseases of the body resulting from the lack of material for bone formation.

CALCULATING MACHINES: see COMPUTING MACHINES, ELECTRONIC; OFFICE MACHINES AND APPLIANCES: *Computing and Accounting Machines*.

CALCULUS (IN MEDICINE) is an abnormal concretion, composed ordinarily of mineral salts, occurring in any hollow organ of the body in which there is stagnation of the fluid contents together with an excess of some particular substance in solution. Calculi may also occur from the same cause in the ducts leading from glands.

The chief places where calculi (or stones) occur are the urinary system and the gall bladder.

Urinary Calculus Disease.—Urinary calculi have been known since ancient times. Descriptions have been found in ancient Sumerian literature and in the early writings of Egypt, while dissections of mummies more than 5,000 years old have revealed objects that doubtless were kidney calculi. Later, in the age of the Greeks, Hippocrates described the symptoms of kidney stones with remarkable accuracy. By A.D. 900 the Arabians had already devised an operation for the surgical removal of bladder stones, an operation similar to one sometimes still used.

In modern times, urinary calculus disease can be found in all lands, although its prevalence varies widely in the different regions. The disease is especially common in certain sections of India and China. Areas of high incidence in the western hemisphere are found in southern United States and the western coast of South America. In Europe several stone areas may be delimited, among them the Scandinavian countries and the region along the Dalmatian coast, where stones in children are particularly common. The cause for this striking variation in geographic incidence is obscure, though differences in diet and climate are frequently mentioned as possible factors.

Essentially, urinary stones are aggregates of crystals laid down layer upon layer in an organic matrix or framework. The crystalline component ordinarily comprises calcium and magnesium salts of phosphate or oxalate. More rarely the stone is composed of uric acid or the amino acid cystine. All these relatively insoluble materials are excreted in the urine. Under certain circumstances they tend to crystallize out of solution and produce stones.

However, a calculus is not simply a mere jumble of crystals, for the crystals are laid down in a highly organized pattern in conjunction with a matrix framework of noncrystalline organic material. Because the matrix provides a skeleton, stones often have a highly complex internal and external structure. The source of the matrix material is uncertain; it may be a product of irritation and inflammation of the membranes that line the urinary passages.

Urinary calculi may develop in any part of the urinary tract, but the commonest sites are the kidney and bladder. Kidney stones tend to mold themselves into the shape of the kidney cavity within which they develop. Occasionally a stone forms a complete cast of the interior of the kidney, being then called staghorn calculus, since the central body of the stone has extensions up into all the branches of the kidney cavity, somewhat resembling the branches of the horns of a stag. Smaller stones (or fragments of larger ones) tend to pass down from the kidney into the ureter, the tube that leads to the bladder. They often become lodged in the ureter and block the flow of urine, causing dilatation and swelling of the ureter above the block. A sudden complete obstruction of this type provokes extremely severe pain, called kidney colic, in the flank.

An incomplete block is very often asymptomatic, though gradual destruction of kidney substance may be in progress. Blood in the urine occurs in all instances where a stone is present, since the stone continually produces minute abrasions of the urinary membranes.

Bladder calculi are much commoner in males than in females because the female urethra, or bladder outlet, allows easy passage of incipient stones before they have time to reach significant size. The structure of the male urethra is such that a rudimentary stone, once formed, has a greater chance of remaining in the bladder, where it continues to grow until there is no possibility for spontaneous passage during urination. Partly for this reason stones in the bladder are particularly common as a complication of prostate enlargement. Bladder stones often assume enormous size, sometimes ten centimetres or more in diameter. They are usually round or ovoid, but many bizarre forms occur. A bladder stone may act like a ball valve at the outlet of the bladder, so that urination is difficult. The urinary stream becomes small in calibre and subject to frequent interruptions as the stone repeatedly falls against the bladder neck, obstructing the outlet of urine. Severe spasms of pain usually accompany such episodes of obstruction.

Despite much investigation, the cause of stone disease defies complete understanding. In a few instances it is associated with a chemical disturbance of the body such as gout (which explains the occurrence of some uric acid stones) or overactivity of the parathyroid glands (explaining some calcium-type stones). In such conditions an increased amount of the stone-forming minerals appears in the urine, producing a state of excessive urinary saturation. However, the majority of stone sufferers manifest no such general metabolic disease. Many other contributing factors have been advanced as partial explanations for the formation of stones, among which may be mentioned vitamin deficiency, dietary imbalance and reduced water intake.

Often the fundamental cause of stone disease seems to be in an antecedent abnormality of the structure of the urinary tract itself—abnormalities leading to imperfect drainage, stagnation and infection.

Many stones ultimately pass from the urinary tract spontaneously. Stones lodged in the ureter may sometimes be extracted by instruments introduced through the lower urinary passages, while even large stones in the bladder may be crushed with special instruments and the fragments extracted. Other stones, wherever found, may be removed surgically by open operation. So-called stone solvents and stone-preventing medications have been ineffective, though a host of such treatments has been advocated over the centuries.

Biliary Calculi or Gallstones.—These, like urinary stones, are composed of crystalline substances imbedded in a small amount of protein material, the stone matrix. The chief crystalline components are cholesterol, bile pigments and insoluble calcium salts, all substances that may be present in high concentration in the bile. Inflammation, stasis and stagnation predispose to precipitation of these stone-forming materials, thus initiating the stone process.

The commonest site of gallstone formation is usually the gall bladder itself, though occasionally they may form in the bile ducts within the liver or in the common bile duct, which delivers the bile into the intestines. A large number of stones may be present simultaneously, but more frequently a single large stone develops in the gall bladder.

The stones are hard bodies, with a smooth surface of varying colour, white, yellow, green or even black, dependent upon the chemical composition. Gallstone formation is much commoner in women than in men.

Many gallstones give rise to no clinical symptoms, especially when located within the gall bladder. Sometimes they set up an inflammatory process in the gall bladder, producing acute cholecystitis with severe toxic symptoms and pain in the gall bladder region.

When a stone becomes lodged in the bile ducts, obstruction leads to increased pressures above the site of blockage, resulting in the severe pain known as biliary colic. When the outflow of bile has been impeded for several days, jaundice supervenes because of the inability of the body to rid itself of the bile pigments.

Gallstones sometimes pass into the intestines spontaneously, and

the acute attack of pain is thereby relieved. More rarely, a large stone may ulcerate through the wall of the bile passages, provoking bile peritonitis, which may be fatal if untreated. In most instances, however, a blocking stone must be removed by surgical operation. Usually the gall bladder is removed at the same time in order to prevent further stone production. There is no known method for dissolving gallstones by means of oral medications.

Calculi in Other Organs.— Apart from the urinary and biliary systems, significant stone disease occasionally develops in the pancreatic, salivary and prostate glands. All these stones are composed principally of calcium phosphate. They occur within the gland ducts and may result in blockage of outflow of the normal gland secretions. Infection of the gland tissue then follows, often necessitating surgical intervention.

Stonelike bodies, called fecaliths, sometimes form in the intestinal canal. They are usually of minor importance since they are too small to produce obstruction, but an exception is the development of fecaliths in the vermiform appendix. Since the calibre of the appendix is relatively small, an appendicial fecalith may obstruct the appendix and precipitate an attack of acute appendicitis.

On X-ray examination the majority of older people are found to have rounded opaque bodies in the pelvic region. These stony objects, called phleboliths, are located in veins that have previously become obstructed for one reason or another. They are of negligible clinical significance. (C. W. V.)

CALCULUS. ABSOLUTE DIFFERENTIAL: see VECTOR AND TENSOR ANALYSIS.

CALCULUS, BARYCENTRIC: see BARYCENTRIC CALCULUS.

CALCULUS, DIFFERENTIAL AND INTEGRAL.

Calculus is generally defined as that branch of mathematics which is based on the concept of the limit (*q.v.*). This concept is used in other branches of mathematics. For example, it occurs in plane geometry in the calculation of the area of a circle when the area is considered to be the limit of the areas of regular inscribed polygons of $4n$ sides, as n increases without bound. In elementary algebra the concept is used when repeating decimals are introduced. The limit concept, however, plays a central role in the subject called calculus, while its use in plane geometry and elementary algebra is only incidental.

Two particular limits, the derivative and the *definite* integral, are the most fundamental ones in elementary calculus (to which this article is restricted). The area of study based on the former is called differential calculus while the latter forms the basis of the topic called integral calculus. These two subjects are very closely related, as will be shown subsequently.

DIFFERENTIAL CALCULUS

The Derivative.— If $f(x)$ is a real-valued function of a real variable and x_0 a real number, consider the difference quotient

$$\frac{f(x_0 + h) - f(x_0)}{h} \tag{1}$$

where h is any real number except zero. If this difference quotient approaches a number as h approaches zero, this number is called the *derivative of the function $f(x)$ at the point x_0* . For example, if $f(x) = x^2$ and $x_0 = 1$, the difference quotient is

$$\frac{f(1 + h) - f(1)}{h} = \frac{(1 + h)^2 - 1^2}{h} = \frac{2h + h^2}{h} = 2 + h$$

It is clear that as h approaches zero the difference quotient approaches the number 2. Thus, the function has derivative 2 at the point 1.

On the other hand, there exist "well-behaved" functions that fail to have a derivative at some given point. A simple example is the following: Let $f(x) = x$ if x is positive or zero and $f(x) = -x$ if x is negative (that is, $f(x) = |x|$, the absolute value of x), and choose x_0 to be 0. Then, if h is positive, the difference quotient is

$$\frac{f(0 + h) - f(0)}{h} = \frac{h - 0}{h} = 1,$$

while if h is negative, the quotient is

$$\frac{f(0 + h) - f(0)}{h} = \frac{-h - 0}{h} = -1$$

Thus $f(x)$ cannot have a derivative at $x_0 = 0$ because, arbitrarily close to 0, the difference quotient assumes the values 1 and -1 , and this fact clearly excludes the possibility that this difference quotient approaches a single number as h approaches zero.

The derivative of $f(x)$ at x_0 (if it exists) is usually denoted by

$$f'(x_0) \text{ or by } \frac{df}{dx}(x_0)$$

Geometrical interpretation.— Perhaps the quickest way to obtain some insight into the concept of the derivative is to learn its geometrical interpretation. As an example, suppose that $f(x) = x^2/2$ and $x_0 = 1$, and examine the graph of this function near the point $P = [x_0, f(x_0)] = (1, \frac{1}{2})$. It is then easy to check that the

difference quotient $\frac{f(x_0 + h) - f(x_0)}{h}$ is merely the ratio $\overline{QM}/\overline{PM}$

(see fig. 1). But, as is well known from analytic geometry, this

ratio is the slope of the line passing through the two points P and Q ; that is, it is the trigonometric tangent of the angle θ_h made by this line and the x -axis. Now, let L be the line tangent to the graph of $f(x)$ at the point P . It is intuitively clear that as h approaches zero, the point Q moves along the

FIG. 1.—GEOMETRICAL INTERPRETATION OF DERIVATIVE CONCEPT

graph of $f(x)$ toward the point P and the angle θ_h approaches the angle θ made by the line

L and the x -axis. Consequently, the trigonometric tangent of θ_h approaches the trigonometric tangent of θ . The latter is the slope of the line L . On the other hand, by the definition of the derivative, this slope must also be the derivative of $f(x)$ at x_0 .

We see, therefore, that the derivative of $f(x)$ at x_0 is the slope of that line tangent to the graph of $f(x)$ which passes through the point $[x_0, f(x_0)]$.

This geometrical interpretation and the argument justifying it extend equally well to other functions, provided that their graphs are sufficiently smooth, *i.e.*, smooth enough to guarantee the existence of a unique tangent line passing through the point in question.

Conversely, if the graph of $f(x)$ fails to satisfy this condition at a point, then the derivative fails to exist. For example, it has already been shown that the function $f(x) = |x|$ fails to have a derivative at $x_0 = 0$. This is reflected geometrically by the fact that the graph of $f(x)$ has a "corner" at the point $[x_0, f(x_0)] = (0, 0)$ (see fig. 2).

Instantaneous Velocity.— An important physical interpretation

FIG. 2.—GRAPH OF $F(x) = |x|$ SHOWING THAT $F(x)$ HAS NO DERIVATIVE AT $x_0 = 0$

of the derivative arises from the concept of instantaneous velocity. In fact, to arrive at a precise definition of the velocity of a moving particle at a given time, t , leads to exactly the same limiting process that occurred in the definition of the derivative, as will now be shown.

Suppose, for simplicity, that a particle is moving along a straight line and in a fixed direction. Its position as a function of time can then be represented in the following way. Choose a point on the line of motion of the particle. Then the particle's position at time t is completely determined by the distance, $f(t)$, between the particle and the chosen point, and no other dimension is needed to locate the particle.

Using this notation, the average velocity of the particle during

an interval of time of length h , beginning at time t_0 , is defined to be the ratio

$$\frac{f(t_0 + h) - f(t_0)}{h} \quad (2)$$

that is, the distance traveled during this interval of time divided by the length of this interval of time.

On the other hand, a little reflection will show that, whatever meaning is attached to the concept of the instantaneous velocity of the particle at time t_0 , it should, first of all, be a number, and, second, the average velocities of the particle during small intervals of time starting at time t_0 should approximate this number. Comparison of the ratio (2) with the difference quotient (1) shows that these considerations make it obligatory to define this instantaneous velocity to be the derivative $f'(t_0)$.

An important example of this situation is given by a freely falling body. It is an experimentally established law that if a body is allowed to fall from rest it will traverse, in time t , a distance that is proportional to t^2 (provided the air does not offer resistance). This law can also be expressed by asserting that the distance traveled by the body is a function of time having the form $f(t) = ct^2$ (where the constant c depends on the units used in measuring distance and time). Thus the average velocity of the body during an interval of time of length h , beginning at time t_0 , is

$$\frac{f(t_0 + h) - f(t_0)}{h} = \frac{c(t_0 + h)^2 - ct_0^2}{h} = \frac{2ct_0h + ch^2}{h} = c(2t_0 + h)$$

It is clear that the limiting value of this ratio, as h approaches zero, is $2ct_0$. Thus, it has been shown that the instantaneous velocity of the freely falling body at time t_0 is $2ct_0$, and also that $f'(t_0) = 2ct_0$.

Maxima and Minima. — It is now possible to discuss one of the more important applications of elementary differential calculus: the location of the maxima and minima of a function. Given a function $f(x)$, a real number \bar{x} is said to be a relative maximum of the function if $f(\bar{x})$ is at least as large as all the values $f(x)$, where x ranges throughout an interval about \bar{x} . If, on the other hand, $f(\bar{x})$ does not exceed the values $f(x)$ when x ranges throughout an interval about \bar{x} , the number \bar{x} is called a relative minimum of the function. In fig. 3 x_1 and x_3 represent minima while x_2 and x_4 represent maxima.

Suppose, now, that $f(x)$ has a derivative $f'(x)$ for all values of x satisfying $a < x < b$. Then, it is intuitively clear that when the tangent to the graph of $f(x)$ passes through a point $[\bar{x}, f(\bar{x})]$ corresponding to either a maximum or a minimum, and \bar{x} is interior to the interval (a, b) , this tangent must be horizontal; that is, the slope of the tangent must be zero (see fig. 3). The rigorous proof of this fact is not difficult. For, assuming x_0 is a maximum, it is seen that if h is positive and sufficiently small, the difference quotient (1) cannot be positive [because $f(x_0) \geq f(x_0 + h)$ if $x_0 + h$ is near enough to x_0]; similarly, for h negative, but of small absolute value, the difference quotient (1) cannot be negative (because in this case neither the numerator nor the denominator are positive). Thus, the number $f'(x_0)$ must be arbitrarily close to numbers that cannot be negative and to numbers that cannot be positive. The only number having this property, however, is zero. Thus, $f'(x_0) = 0$. Obvious changes in this argument will show that the result is equally valid for the case where x_0 is a minimum.

It has just been shown that, if x is either a maximum or a minimum of $f(x)$, then $f'(x) = 0$. Simple examples show that the converse of this statement is not always true. The value of the positive result just obtained, however, lies in the fact that if it is desired to locate a maximum or a minimum it is only necessary to look at those numbers x for which $f'(x) = 0$. In general, this greatly simplifies the task.

FIG. 3.—MAXIMA AND MINIMA OF A FUNCTION

Consider a simple, but illuminating, example. Suppose that 100 ft. of fence is available in order to enclose a rectangular pasture. What dimensions should the pasture have in order to contain the maximum possible area? If x denotes one length of the rectangle, then $50 - x$ must be the other length. Thus, the area of the pasture is $(50 - x)x = 50x - x^2$. The problem, then, reduces to finding the largest value (hence, a maximum) of the function $f(x) = 50x - x^2$, $0 \leq x \leq 50$. Now

$$\frac{f(x + h) - f(x)}{h} = \frac{50h - 2xh - h^2}{h} = 50 - 2x - h$$

therefore $f'(x) = 50 - 2x$. Thus, a maximum must satisfy the equation $f'(x) = 50 - 2x = 0$; therefore, $x = 25$. Hence, assuming the intuitively obvious fact that a maximal area is attained, the area is largest when $x = 25$; that is, when the rectangle is a square of side 25 ft.

Differentiation Formulas; Computation of Derivatives. — It has already been shown that if $f(x) = x^2$ then $f'(x) = 2x$. This is just a special case of one of several formulas for differentiation that are obtained in elementary calculus. That is, it follows readily from the definition of the derivative that if $n = 1, 2, 3, \dots$ is any positive integer and $f(x) = x^n$, then $f'(x) = nx^{n-1}$; or, written more compactly,

$$(x^n)' = nx^{n-1} \quad (3)$$

In fact, by means of an appropriate limiting process, it can be shown that, for each real number n , the expression x^n , for positive x , has a natural definition as a real number (for example, $n = \frac{1}{2}$ gives the familiar square root function: $x^{\frac{1}{2}} = \sqrt{x}$). Formula (3) extends to include all functions of the form $f(x) = x^n$.

Many other well-known functions have simple expressions for their derivatives. For example, the trigonometric functions have derivatives that are expressible in terms of other trigonometric functions. The most basic of these formulas are

$$(\sin x)' = \cos x \quad (4)$$

$$(\cos x)' = -\sin x \quad (5)$$

$$(\tan x)' = \sec^2 x \quad (6)$$

$$(\cot x)' = -\csc^2 x \quad (7)$$

In addition to such specific formulas, several general rules for differentiation are easily derived from the definition of the derivative. The four most basic of these rules will now be stated.

Suppose that $f(x)$ and $g(x)$ are two functions and a and b two constants. Then, whenever $f'(x)$ and $g'(x)$ exist,

$$[af(x) + bg(x)]' = af'(x) + bg'(x) \quad (8)$$

$$[f(x)g(x)]' = f(x)g'(x) + f'(x)g(x) \text{ (Leibniz's rule)} \quad (9)$$

$$\left[\frac{f(x)}{g(x)}\right]' = \frac{f'(x)g(x) - f(x)g'(x)}{[g(x)]^2} \quad (10)$$

provided $g(x) \neq 0$.

The fourth basic rule, the chain rule, may be stated in the following way. Suppose that, for each real number x for which $g(x)$ is defined, the number $g(x)$ is such that $f[g(x)]$ is defined. The composite function $h(x) = f[g(x)]$ can then be formed. The chain rule asserts that, if both $g(x)$ and $f'[g(x)]$ exist, then $h'(x)$ exists and satisfies the equation

$$h'(x) = f'[g(x)] \cdot g'(x) \quad (11)$$

These four rules, together with formulas (3) through (7), permit the computation of the derivatives of a large class of functions. For example, the reader can check that (3) and (8) can be used to obtain the derivative of the most general polynomial, $p(x) = a_0 + a_1x + \dots + a_kx^k$. In fact, $p'(x) = a_1 + 2a_2x + \dots + ka_kx^{k-1}$.

If, in addition, rule (10) is used, a formula for the derivative

of the most general rational function (*i.e.*, the quotient of two polynomials) can be obtained.

Use of all four of the above rules reveals that functions having fairly complicated expressions have explicit formulas for their derivatives. The reader can check, for example, that if

$$f(x) = \frac{\sin(x^2 + 3x + 2)}{1 + x}, \text{ then}$$

$$f'(x) = \frac{(1 + x)(2x + 3)\cos(x^2 + 3x + 2) - \sin(x^2 + 3x + 2)}{(1 + x)^2}$$

It was the development of formulas and rules such as (4) through (11), enabling mathematicians to calculate derivatives in this manner: that motivated the use of the name calculus for this mathematical discipline.

INTEGRAL CALCULUS

The Definite Integral. — It was mentioned at the beginning of this article that another limit, the integral, plays a key role in the area of study called integral calculus. As in the case of the derivative, one of the best ways to begin the study of this concept is to consider its geometrical aspect.

Let *a* and *b* be two real numbers and suppose that there is a function *f*(*x*) defined for all *x* satisfying $a \leq x \leq b$. For the sake of simplicity suppose, for the moment, that the values *f*(*x*) are never negative. The basic problem of integral calculus can then be stated in the following way: What is the meaning (and numerical value) of the area of the region below the graph of *f*(*x*) and above the interval (*a*, *b*) on the *x*-axis?

FIG. 4. — REPRESENTATION OF AREA UNDER CURVE AS EXPRESSED BY INEQUALITY 13 (See TEXT)

Assume that it is known what is meant by "area" in case the region is a rectangle. Assume also that, if a region can be subdivided into a finite number of nonoverlapping rectangles, then its area is the sum of the areas of these rectangles. Having made these assumptions it is not hard to give an answer to the above question.

First, subdivide the interval (*a*, *b*) into *n* subintervals by choosing consecutive points $a = x_0, x_1, x_2, \dots, x_n = b$. In each of the subintervals $I_i = (x_{i-1}, x_i)$ choose a point ζ_i ($i = 1, 2, \dots, n$) such that the value *f*(ζ_i) is smallest among the values assumed by the function in I_i (if such a point ζ_i exists). Then, the rectangle with base I_i and height *f*(ζ_i) (see fig. 4, where $n = 4$ and $\zeta_i = x_{i-1}$) lies below the graph of *f*(*x*). Thus, it is reasonable to assert that the area in question should be a number exceeding the sum of the areas of the rectangles that have been constructed (that is, the area of the shaded region in fig. 4). In other words, the inequality

$$A \geq f(\zeta_1)(x_1 - x_0) + f(\zeta_2)(x_2 - x_1) + \dots + f(\zeta_n)(x_n - x_{n-1}), \quad (12)$$

where *A* denotes the area below the graph of *f*(*x*) and above the interval (*a*, *b*), should be satisfied.

Next, make a similar construction, except that, instead of choosing the point ζ_i in the subinterval I_i , choose a point μ_i (if it exists) such that the value *f*(μ_i) is the largest among the values assumed by the function in I_i (see fig. 5, where $\mu_i = x_i$ and, again $n = 4$). Then, clearly, there should be, in analogy to inequality (12), the inequality

$$A \leq f(\mu_1)(x_1 - x_0) + f(\mu_2)(x_2 - x_1) + \dots + f(\mu_n)(x_n - x_{n-1}) \quad (13)$$

(the sum on the right being the area of the shaded region in fig. 5).

A sum of the type occurring in inequality (12), in which the smallest value of *f*(*x*) in each subinterval I_i is used, is called a lower sum (with respect to the given subdivision); while a sum of the type occurring in inequality (13) is called an upper sum. Thus, with this terminology, it can be stated that the area in question should be a number, *A*, less than or equal to any upper

sum and greater than or equal to any lower sum. If the notion of area as used here is to have an unique meaning, however, there should exist only one number with this property. Thus, the following definition is forced upon us:

Suppose that *f*(*x*), defined for *x* satisfying the condition $a \leq x \leq b$, has the property that there exists exactly one number less than or equal to any upper sum and greater than or equal to any lower sum. Then this number is the area of the region below the graph of *f*(*x*) and above the interval (*a*, *b*).

First of all, note that the restriction $f(x) \geq 0$, which was made only in order to obtain a better grasp of the geometrical aspects of the construction, can be dropped without having to make any change in the above definition. Note, however, that this implies that regions below the *x*-axis and above the graph of a negative-valued function will have negative areas.

FIG. 5. — REPRESENTATION OF AREA UNDER CURVE AS EXPRESSED BY INEQUALITY 12 (See TEXT)

The area that has just been defined is usually called the Riemann integral (or the definite integral, for reasons that will be shown) of the function *f*(*x*) over the interval (*a*, *b*). It is denoted symbolically by $\int_a^b f(x)dx$.

Integrable and Nonintegrable Functions. — It is natural, at this point, to attempt to determine what classes of functions have a Riemann integral. It is not hard to show that if *f*(*x*) is continuous (roughly speaking, this means that whenever x_1 and x_2 are "close" then $f(x_1)$ and $f(x_2)$ are "close"), then it has an integral or, more briefly, is (Riemann) integrable. In fact, this restriction is not only sufficient but comes close to being a necessary condition for this type of integrability.

Two simple examples of functions that are not integrable are the following:

1. Suppose $a = 0, b = 1$. Let $f(x) = \frac{1}{x}$ for $0 < x \leq 1$, and put $f(0) = 0$. Then, it can be seen that the upper sums of this function are not defined (for, in the first interval, I_1 , of any subdivision, there is no number μ_1 such that the value $f(\mu_1)$ is the largest among the values assumed by the function in I_1).

2. Again, let $a = 0, b = 1$, and suppose $f(x) = 0$ if *x* is rational, while $f(x) = 1$ if *x* is irrational. Then, it is easy to check that each upper sum is 1, while each lower sum is 0. Thus, in this case there does not exist a unique number less than or equal to any upper sum but greater than or equal to any lower sum.

It is important to realize that the above definition of integrability is equivalent to the following one, which does not involve the concept of upper or lower sum. Subdivide the interval (*a*, *b*) as before and, again, form a sum of the type

$$f(\zeta_1)(x_1 - x_0) + f(\zeta_2)(x_2 - x_1) + \dots + f(\zeta_n)(x_n - x_{n-1}) \quad (14)$$

except that the only restriction on ζ_i ($i = 1, 2, \dots, n$), is that it must belong to the interval I_i . If, as the subdivision is made finer (*i.e.*, when the length of each subinterval approaches zero), the sum (14) tends to a limit, then the function is integrable. This limit, of course, is $\int_a^b f(x)dx$.

FUNDAMENTAL THEOREM OF CALCULUS

The connection between the two basic concepts, the derivative and the integral, is perhaps the most important feature of calculus. This connection can be summarized roughly by saying that integration and differentiation are inverse operations; that is, if first one of these operations and then the other is applied to a function, the original function is obtained (this is analogous to the operation of addition, and then subtraction, with a given number).

In order to describe this situation more precisely, the concept of the indefinite integral must be introduced. Suppose that *f*(*x*) is continuous (hence, integrable) in some interval I , and let *a* and *y* be two points of this interval. If the number *a* is fixed, then a function of *y*, *F*(*y*), can be formed by letting

$$F(y) = \int_a^y f(x)dx$$

(if $y < a$, $F(y)$ is equal to $-\int_y^a f(x) dx$). The function $F(y)$ is called an indefinite integral of the function $f(x)$.

The connection between differentiation and integration can then be stated in the following way:

The function $F(y)$ (as defined above) is differentiable and $F'(y) = f(y)$; furthermore, if $G(y)$ is any other differentiable function satisfying $G'(y) = f(y)$ for all y in I , the difference $F(y) - G(y)$ is constant.

This statement is known as the *fundamental theorem of calculus*.

A function such as $G(y)$, satisfying $G'(y) = f(y)$, is called an *antiderivative* of $f(y)$. Clearly, if a constant function is added to an antiderivative of $f(y)$, another antiderivative is obtained (because it is obvious that the derivative of a constant function is zero). The fundamental theorem of calculus can then be paraphrased by saying that the most general antiderivative of $f(y)$ can be obtained by adding a constant function to an indefinite integral of $f(y)$.

One of the immediate, and most important, consequences of the fundamental theorem of calculus is that the integrals of a large class of functions can be obtained merely by inverting the already developed formulas for differentiation. For example, in formula (4), $\sin x$ is an antiderivative of $\cos x$. Thus, $F(y) = \int_0^y \cos x dx$ must differ from $\sin y$ by a constant; that is, $F(y) = \sin y + C$. The constant C is easily determined because it follows readily from the definition of the integral that $F(0) = 0$. Hence, $0 = F(0) = \sin 0 + C = C$. Therefore, it has been shown that

$$\sin y = \int_0^y \cos x dx \quad (15)$$

for all y .

The power of the fundamental theorem can be appreciated once it is realized that explicit formulas for integration, such as (15), are by no means easy to obtain by working directly from the definition of the integral. However, it should be noted that, unlike the case of differentiation, there are many functions that can be expressed by simple formulas but have no simple expression for their antiderivatives.

HISTORICAL DEVELOPMENT

The methods used by the Greeks for determining the area of a circle and the volumes of the cylinder, cone and sphere were similar to the modern methods of integration. It was not until the 17th century, however, that calculus began to develop. A number of special cases of integration were discovered by J. Kepler, B. Cavalieri, C. Huygens, G. Roberval, R. Descartes, P. De Fermat and others. A systematic account of the methods then in use was given, along with much that was original on his part, by B. Pascal in his *Lettres de Amos Dettonville sur quelques-unes de ses inventions en géométrie* (1659). The problem of finding the tangent lines to given curves was also solved in several special cases; however, mathematicians of the first half of the 17th century were not as proficient in finding derivatives as they were in performing integrations.

The reciprocal relation between differentiation and integration was first explicitly stated in I. Barrow's book *Lectiones opticae et geometricae* (1663-64), although this relation was noticed only in certain special cases and was not applied to obtain formulas for areas. The power and generality of this relation were discovered independently by Sir Isaac Newton (who was Barrow's pupil) and by G. Leibniz. The definite abandonment of the old tentative methods of integration in favour of the method in which this operation is regarded as the inverse of differentiation was primarily due to Newton. Both the precise formulation of simple rules for the process of differentiation in each special case and the introduction of the notation which was ultimately adopted were primarily the work of Leibniz (the notations $\frac{d}{dx}$ and $\int_a^b \dots dx$ originated with him).

The 18th century saw a great development of the subject. L. Euler in 1734 and A. C. Clairaut in 1739 introduced the notion of partial differentiation of functions of more than one variable; this led to the extension of many of the ideas of calculus to such

functions. The beginning of the theory of differential equations can also be traced to the same century.

The rigorous foundations of calculus, however, were not well understood by the mathematicians of the 17th and 18th centuries. Consequently, serious attacks were leveled against mathematicians of this period. Perhaps the most famous is the criticism by Bishop Berkeley contained in a tract entitled *The Analyst*; or a Discourse Addressed to an Infidel Mathematician (1734).

It was not until 1823, when A. L. Cauchy published his treatise *Résumé des leçons sur le calcul infinitesimal*, that we encounter the first presentation of the subject that meets modern standards of rigour. In addition to this establishment of the logical foundations of calculus and the introduction of the modern concept of function, the 19th century saw the development of most of the various topics constituting that branch of mathematics called analysis, of which calculus is the elementary foundation. The theory of functions of a complex variable, trigonometric series and real variables are just a few of the topics that had their beginning in that century.

This development carried into the 20th century with H. L. Lebesgue's discovery of a very natural and useful extension of the integral described in this article. This new method of integration gave rise to several new applications of analysis in other branches of mathematics and was instrumental in the initiation of several new abstract topics in modern mathematics.

BIBLIOGRAPHY.—An excellent introduction to the subject can be found in R. Courant and H. Robbins, *What is Mathematics?* (1941). A comprehensive text is R. Courant's *Differential and Integral Calculus*, vol. i and ii (1936). A very readable account of the history of calculus can be found in O. Toeplitz's *The Development of the Infinitesimal Calculus* (1936). (Gu. W.)

CALCULUS OF DIFFERENCES. Let $f(x)$ be a given function of the variable x . The differential calculus is concerned with the properties of

$$f'(x) = \frac{df(x)}{dx} = \lim_{\omega \rightarrow 0} \frac{f(x + \omega) - f(x)}{\omega}$$

which is a function of the single variable x (see CALCULUS, DIFFERENTIAL AND INTEGRAL). The calculus of differences, or finite calculus, on the other hand, is concerned with the properties of

$$\Delta f(x) = \frac{f(x + \omega) - f(x)}{\omega} = \frac{\Delta f(x)}{\omega}$$

which is a function of the two variables x and ω .

More generally, in contrast with the infinitesimal calculus, the finite calculus is concerned with the values of a function at a set of isolated points and with such properties as may be derivable therefrom.

Suppose that the numbers $f(x_1), f(x_2), f(x_3), \dots$, and an argument x different from x_1, x_2, x_3, \dots , are given. Among the subjects of inquiry which present themselves are the following:

1. The determination of $f(x)$ from the given functional values. This is the interpolation problem (see INTERPOLATION).
2. The determination of

$$f'(x) \text{ and } \int_a^b f(x) dx$$

These are the problems of numerical differentiation and integration.

3. The determination of the properties of the functions $f(x)$ defined by the equation

$$\frac{f(x + \omega) - f(x)}{\omega} = g(x)$$

where $g(x)$ is a given function. This constitutes the summation problem, which is analogous to the problem of integration in the integral calculus.

4. Consideration of more general relations between $f(x), f(x + \omega), \dots, f(x + n\omega)$ leads to the study of difference equations analogous to the differential equations of the infinitesimal calculus.

These several points will now be exemplified by means of some simple illustrations.

Divided Differences. — Consider a function $f(x)$ of the variable x whose values are given for $n + 1$ different arguments (or values of the variable) $x_0, x_1, x_2, \dots, x_n$. The divided difference of $f(x)$ for the arguments x_0, x_1 is written $[x_0x_1]$ and is defined by

$$[x_0x_1] = \{f(x_0) - f(x_1)\} / (x_0 - x_1) = \{f(x_1) - f(x_0)\} / (x_1 - x_0) = [x_1x_0] \quad (1)$$

so that the divided difference $[x_0x_1]$ is symmetric in the arguments; that is, its value does not change with interchange of the arguments. In the same way $[x_1x_2] = \{f(x_1) - f(x_2)\} / (x_1 - x_2)$ is defined, and so on for any pair of arguments.

Similarly, the divided differences of three, four and five arguments are defined by

$$[x_0x_1x_2] = \{[x_0x_1] - [x_1x_2]\} / (x_0 - x_2) \quad (2)$$

$$[x_0x_1x_2x_3] = \{[x_0x_1x_2] - [x_1x_2x_3]\} / (x_0 - x_3) \quad (3)$$

$$[x_0x_1x_2x_3x_4] = \{[x_0x_1x_2x_3] - [x_1x_2x_3x_4]\} / (x_0 - x_4) \quad (4)$$

The process can be continued to define divided differences of any positive integral order.

Table I shows the divided differences of $f(x) = x^3$ for certain

TABLE I.—Divided Differences of $f(x) = x^3$

Argument	x	x^3	first order	second order	third order	fourth order
x_0	0	0				
x_1	1	1	1			
x_2	3	27	13	4		
x_3	7	343	79	11	1	0
x_4	5	125	109	15		

arguments. The table illustrates that the third order divided differences of x^3 are constant and that the fourth order divided differences are zero. More generally, for any positive integral power x^n the divided differences of order n are constant and those of order $n + 1$ are zero. The same result must therefore hold for a polynomial of degree n , e.g., $3x^5 - 7x^2 + 2$.

If in (1), (2), (3) and (4) x is substituted for x_0 and then, starting with (4), $[xx_1x_2x_3]$, $[xx_1x_2]$ and $[xx_1]$ are successively eliminated, the following identity results:

$$f(x) = f(x_1) + (x - x_1)[x_1x_2] + (x - x_1)(x - x_2)[x_1x_2x_3] + (x - x_1)(x - x_2)(x - x_3)[x_1x_2x_3x_4] + R_4(x) \quad (5)$$

$$\text{where } R_4(x) = (x - x_1)(x - x_2)(x - x_3)(x - x_4)[xx_1x_2x_3x_4]. \quad (6)$$

This is Sir Isaac Newton's interpolation formula with divided differences, with the remainder term $R_4(x)$ in the case of four arguments.

Because $R_4(x)$ vanishes when $x = x_1, x_2, x_3$, omission of the remainder term from (5) gives the interpolation polynomial of degree 3,

$$f(x_1) + (x - x_1)[x_1x_2] + (x - x_1)(x - x_2)[x_1x_2x_3] + (x - x_1)(x - x_2)(x - x_3)[x_1x_2x_3x_4] \quad (7)$$

whose value, as is easily verified, coincides with the value of $f(x)$ when $x = x_1, x_2, x_3$.

In the case of the function $f(x) = x^3$, because $[xx_1x_2x_3x_4] = 0$, the remainder term vanishes and

$$x^3 = 1 + (x - 1)13 + (x - 1)(x - 3)11 + (x - 1)(x - 3)(x - 7)$$

Thus, for example,

$$4^3 = 1 + 3 \times 13 + 3 \times 11 - 9 = 64$$

Similarly, for n arguments x_1, x_2, \dots, x_n it is found that

$$f(x) = f(x_1) + \sum_{s=1}^{n-1} (x - x_1)(x - x_2) \dots (x - x_s)[x_1x_2 \dots x_{s+1}] + R_n(x) \quad (8)$$

$$R_n(x) = (x - x_1)(x - x_2) \dots (x - x_n)[xx_1x_2 \dots x_n] \quad (9)$$

By means of this general interpolation formula the evaluation of

the function $f(x)$ whose value is known for the arguments x_1, x_2, \dots, x_n is reduced to the problem of evaluating the remainder term $R_n(x)$. Should this term be known or negligible, the value of $f(x)$ can be calculated from (8).

Starting from (1), it is easy to show by induction that

$$[x_0x_1 \dots x_n] = \frac{f(x_0)}{(x_0 - x_1)(x_0 - x_2) \dots (x_0 - x_n)} + \frac{f(x_1)}{(x_1 - x_0)(x_1 - x_2) \dots (x_1 - x_n)} + \dots + \frac{f(x_n)}{(x_n - x_0)(x_n - x_1) \dots (x_n - x_{n-1})} \quad (10)$$

which proves that divided differences are symmetric functions of their arguments, i.e., the value does not depend on the order, just as in (1) it was proved that $[x_0x_1] = [x_1x_0]$.

If in (10) x is substituted for x_0 , it can be inferred that

$$f(x) = \sum_{s=1}^n \frac{f(x_s)}{x - x_s} \frac{\phi(x)}{\phi'(x_s)} + R_n(x) \quad (11)$$

$$\text{where } \phi(x) = (x - x_1)(x - x_2) \dots (x - x_n)$$

and where $R_n(x)$ is still given by (9). This is Lagrange's interpolation formula, which has the same remainder term as Newton's formula (8) and therefore has the same range of application and yields the same results. The distinction is that Newton's formula is used with a divided-difference table such as Table I, whereas Lagrange's formula employs the tabulated values directly.

Difference Operators. — It is usual to tabulate numerical values of a function, e.g., $\sin x, \log x, e^x$, for arguments such as $a, a + \omega, a + 2\omega, a + 3\omega, \dots$, in arithmetical progression. Here it is useful to introduce the difference operator Δ defined by

$$\Delta f(x) = f(x + \omega) - f(x) \quad (12)$$

The operation can be repeated as often as desired to form second, third, fourth, . . . , order differences:

$$\Delta^2 f(x) = \Delta \{ \Delta f(x) \}, \Delta^3 f(x) = \Delta \{ \Delta^2 f(x) \} \quad (13)$$

The successive differences of a tabulated function are easily formed from the definition (12) by simple subtraction. For example, see Table II, where again the fact is illustrated, that; like divided differences, the n th order differences of a positive integral power (and, thus, also those of a polynomial) of degree n are constant.

TABLE II.—Successive Differences of $f(x) = x^3$

x	x^3	Δ	Δ^2	Δ^3	Δ^4
0	0				
1	1	1			
2	8	7	6		
3	27	19	12	6	
4	64	37	18	6	0

Along with the operator Δ it is useful to consider the incremental or shift operator E defined by

$$E^\omega f(x) = f(x + \omega) = f(x) + \Delta f(x) \quad (14)$$

Thus there is the symbolical equivalence of operators

$$E^\omega = 1 + \Delta \quad (15)$$

leading to Gregory's theorem

$$f(x + n\omega) = E^{n\omega} f(x) = (1 + \Delta)^n f(x) = f(x) + \binom{n}{1} \Delta f(x) + \binom{n}{2} \Delta^2 f(x) + \dots + \binom{n}{n} \Delta^n f(x) \quad (16)$$

which expresses $f(x + n\omega)$ in terms of differences of $f(x)$ and the binomial coefficients $\binom{n}{r}$.

Similarly,

$$\Delta^n f(x) = (E^\omega - 1)^n f(x) = f(x + n\omega) - \binom{n}{1} f(x + (n-1)\omega) + \binom{n}{2} f(x + (n-2)\omega) + \dots + (-1)^n \binom{n}{n} f(x) \quad (17)$$

If in (10) $x_0 + s\omega$ ($s = 1, 2, \dots, n$) is substituted for x , formula (17) shows at once that

$$[x_0 x_1 \dots x_n] = \frac{1}{n! \omega^n} \Delta^n f(x_0) \quad (18)$$

when the arguments x_0, x_1, \dots, x_n are in arithmetical progression.

Gregory's theorem can be applied to find the sum of a series, as can be seen by considering the differences shown in Table III.

u_n	Δu_{n-1}		

Definition (12) gives

$$\Delta u_0 + \Delta u_1 + \dots + \Delta u_{n-1} = (u_1 - u_0) + (u_2 - u_1) + \dots + (u_n - u_{n-1}) = u_n - u_0 = \binom{n}{1} \Delta u_0 + \binom{n}{2} \Delta^2 u_0 + \dots$$

from Gregory's theorem, and therefore a simple change of notation in which u_0 replaces Δu_0 , and so on, gives

$$u_0 + u_1 + \dots + u_{n-1} = \binom{n}{1} u_0 + \binom{n}{2} \Delta u_0 + \binom{n}{3} \Delta^2 u_0 + \dots \quad (19)$$

Thus, for example, use of Table II gives for the sum of the cubes of the first n integers

$$1^3 + 2^3 + 3^3 + \dots + n^3 = \binom{n}{1} + 7 \binom{n}{2} + 12 \binom{n}{3} + 6 \binom{n}{4} = \left[\frac{1}{2} n(n+1) \right]^2$$

which is the square of the sum of these integers.

Newton's Interpolation Formula.—In Newton's general interpolation formula with divided differences, (8), write

$$x_s = a + s\omega, (s = 1, 2, \dots, n)$$

This gives Newton's interpolation formula

$$f(x) = f(a) + \frac{x-a}{\omega} \Delta f(a) + \frac{(x-a)(x-a-\omega)}{\omega^2 2!} \Delta^2 f(a) + \dots + \frac{(x-a)(x-a-\omega) \dots (x-a-n-1)\omega}{\omega^n n!} \Delta^n f(a) + R_n(x) \quad (20)$$

where it can be shown that for a differentiable function,

$$R_n(x) = \frac{(x-a)(x-a-\omega) \dots (x-a-n-1)\omega}{n!} f^{(n)}(\xi) \quad (21)$$

where ξ lies somewhere in the interval bounded by the greatest and least values of $x, a, a + n - 1\omega$.

As a simple example, write $a = 1, x = 1.5, \omega = 1$. Then, using the values of A, Δ^2 and A^3 from Table II,

$$(1.5)^3 = 1 + .5 \times 7 + \frac{(.5)(-.5)}{2} \times 12 + \frac{(.5)(-.5)(-1.5)}{6} \times 6 = 3.375$$

for here, because the fourth difference vanishes, so does the remainder term.

From Newton's interpolation formula (8) a variety of special formulas can be obtained by similar steps, the best known being associated with the names of Gauss, Bessel and Stirling.

Reciprocal Differences.—Interpolation by means of divided differences is equivalent in the end to approximating the function to be interpolated by a polynomial. This works when, in the range of interpolation, the effect of the differences of some order becomes negligible. It would not work for a function like $1/x$ in a range which includes $x = 0$, where the function has a pole. Interpolation in the neighbourhood of a pole can be effectively performed by using, instead of a polynomial, a rational function, *i.e.*, a function of the form $P(x)/Q(x)$, where $P(x)$ and $Q(x)$ are polynomials.

To construct such a function *reciprocal differences*, defined as follows, are used. Let the values of the function $f(x)$ be given for arguments x_0, x_1, \dots, x_n . Then reciprocal differences ρ_1, ρ_2, ρ_3 of the first, second and third orders are defined by

$$\rho_1(x_0 x_1) = \frac{x_0 - x_1}{f(x_0) - f(x_1)} = \frac{x_1 - x_0}{f(x_1) - f(x_0)} = \rho_1(x_1 x_0) \quad (22)$$

$$\rho_2(x_0 x_1 x_2) = \frac{x_0 - x_2}{\rho_1(x_0 x_1) - \rho_1(x_1 x_2)} + f(x_1) \quad (23)$$

$$\rho_3(x_0 x_1 x_2 x_3) = \frac{x_0 - x_3}{\rho_2(x_0 x_1 x_2) - \rho_2(x_1 x_2 x_3)} + \rho_1(x_1 x_2) \quad (24)$$

and generally for the n th order,

$$\rho_n(x_0 x_1 \dots x_n) = \frac{x_0 - x_n}{\rho_{n-1}(x_0 x_1 \dots x_{n-1}) - \rho_{n-1}(x_1 x_2 \dots x_n)} + \rho_{n-2}(x_1 \dots x_{n-1}) \quad (25)$$

It should be pointed out that the operation denoted by ρ_2 is not a simple repetition of that denoted by ρ_1 . The operator does not obey the index law and is not distributive.

It can be proved that reciprocal differences of any order are symmetric functions of their arguments, as in (22), where it is shown that $\rho_1(x_0 x_1) = \rho_1(x_1 x_0)$.

Reciprocal differences of the function $(1 + x^2)/(1 + x)$ are shown in Table IV. The table illustrates that the reciprocal differences of some order (in this case the third) of a rational function are constant.

TABLE IV.—Reciprocal Differences of $f(x) = (1 + x^2)/(1 + x)$

x	$(1+x^2)/(1+x)$	ρ_1	ρ_2	ρ_3
0	1	∞		
1	1		1	
2	5/3	3/2	-5	1
3	5/2	6/5	-20	1
4	17/15	10/9		

In (22), (23) and (24) write x for x_0 and successively eliminate $\rho_1(x x_1), \rho_2(x x_1 x_2)$. This gives the continued fraction

$$f(x) = f(x_1) + \frac{x - x_1}{\rho_1(x_1 x_2)} + \frac{x - x_2}{\rho_2(x_1 x_2 x_3) - f(x_1)} + \frac{x - x_3}{\rho_3(x_1 x_2 x_3) - \rho_1(x_1 x_2)}$$

Thus in the case of $(1 + x^2)/(1 + x)$, the data from Table IV give

$$\frac{1 + x^2}{1 + x} = 1 + \frac{x - 1}{\frac{3}{2} + \frac{x - 2}{-6 + \frac{x - 3}{-\frac{1}{2}}}}$$

The above continued fraction method can be generalized to include reciprocal differences of any order. If the continued fraction is stopped at the n th order, the result is

$$f(x) = \frac{p_n(x)}{q_n(x)} + R_n(x)$$

where $p_n(x)$ and $q_n(x)$ are polynomials and $R_n(x)$ is the remainder term whose somewhat complicated structure can be expressed to involve an n th derivative. When the remainder term is negligible, a rational function approximation to $f(x)$ results from the computation.

Numerical Differentiation.—Here again a symbolic operator method will be used. If D denotes the differentiation operator d/dx , Taylor's theorem gives

$$f(x + \omega) = f(x) + \omega Df(x) + \frac{\omega^2}{2!} D^2 f(x) + \dots = e^{\omega D} f(x)$$

But $f(x + \omega) = E\omega f(x) = (1 + \Delta)f(x)$ from (15). This gives the operational equivalence $e^{\omega D} = 1 + \Delta$. Taking logarithms (to

base e) gives

$$\omega D = \ln(1+A) = A - \frac{1}{2}A^2 + \frac{1}{3}A^3 - \dots$$

using the logarithmic series expansion. Therefore

$$\omega f'(x) = \Delta f(x) - \frac{1}{2}\Delta^2 f(x) + \frac{1}{3}\Delta^3 f(x) - \dots \quad (26)$$

and if this series is stopped with the term

$$(-1)^{n-2}\Delta^n f(x)/(n-1),$$

there will be a remainder term which can be proved to be proportional to $f^{(n)}(\xi)$, where ξ lies in the interval $(x, x + w)$. For example, when $f(x) = x^3, f'(2)$, using the data of Table II, is

$$f'(2) = 19 - \frac{1}{2} \times 18 + \frac{1}{3} \times 6 = 12$$

and this is exact, because fourth order differences vanish.

Numerical Integration.— To illustrate the principle of numerical integration, start with the Lagrangian interpolation formula (11). Integration of $f(x)$ from a to b gives

$$\int_a^b f(x)dx = \sum_{s=1}^n h_s^{(n)} f(x_s) + R_n, \quad R_n = \int_a^b \phi(x)[xx_1 \dots x_n]dx \quad (27)$$

where

$$h_s^{(n)} = \int_a^b \frac{\phi(x)}{\phi'(x_s)} \frac{dx}{x - x_s}$$

which depends only on the arguments x_1, x_2, \dots, x_n and not on $f(x)$. From this basic result many integration formulas follow. For example, taking arguments $x_s = a + sw, s = 1, 2, \dots, n$, where $w = (b - a)/(n - 1)$ leads to Cotes' formula:

$$\int_a^b f(x)dx = (b - a) \sum_{s=1}^n H_s^{(n)} f[a + s - 1w] + R_n \quad (28)$$

$$H_s^{(n)} = (-1)^{n-s} \frac{n}{n-1} \binom{n-1}{s-1} \int_1^n \frac{1}{t-s} \binom{t-1}{n} dt \quad (29)$$

The trapezoidal rule results when $n = 2$:

$$\int_a^b f(x)dx = \frac{b-a}{2} \{f(a) + f(b)\} - \frac{(b-a)^3}{12} f''(\xi) \quad a < \xi < b$$

For $n = 3$, there is the well-known Simpson's rule:

$$\int_a^b f(x)dx = \frac{b-a}{6} \{f(a) + 4f\left(\frac{a+b}{2}\right) + f(b)\} - \frac{(b-a)^5}{2880} f^{(4)}(\xi)$$

Space does not permit a discussion of the many types of integration formulas, but the above shows their general dependence on interpolation formulas. Such formulas have an important application to the integration of differential equations.

The Summation Problem.— Consider the function

$$F(x|1) = \int_c^\infty g(t)dt - \sum_{s=0}^\infty g(x+s) \quad (30)$$

Then

$$F(x+1|1) = \int_c^\infty g(t)dt - \sum_{s=0}^\infty g(x+1+s)$$

Therefore $\Delta F(x|1) = g(x)$. The function $F(x|1)$ is therefore a solution of the difference equation

$$f(x+1) - f(x) = g(x) \quad (31)$$

and (following N. E. Nörlund) is called the *principal solution* of this equation, or alternatively the *sum* of $g(x)$ from c to x . When the integral and series do not converge, a definition along the same lines as (30) is available by a limiting process.

An important application is to the psi function $\Psi(x)$, defined as the sum of $1/x$ from 1 to x , so that

$$\Delta \Psi(x) = \frac{1}{x} \quad (32)$$

The psi function is therefore the analogue of $\ln x$, defined by

$$\ln x = \int_1^x \frac{dx}{x}$$

representation of the result by $c + \ln \Gamma(x)$, where c is so chosen that $\ln \Gamma(1) = 0$, introduces the gamma function $\Gamma(x)$ which, from its definition, satisfies the equation

$$\ln \Gamma(x+1) - \ln \Gamma(x) = \ln x$$

so that

$$\Gamma(x+1) = x\Gamma(x) \quad (33)$$

Because $d \ln x / dx = 1/x$, the psi and gamma functions are related by

$$\Psi(x) = \frac{d}{dx} \ln \Gamma(x) = \frac{\Gamma'(x)}{\Gamma(x)} \quad (34)$$

Difference Equations.— Let u_x denote a function of x . A relation between $x, u_x, u_{x+1}, \dots, u_{x+n}$ constitutes a difference equation of order n . By use of Gregory's theorem (16) any such relation can be replaced by one between $x, u, \Delta u_x, \dots, \Delta^n u_x$. Thus, for example, the first order equations

$$(u_{x+1})^2 - 3u_x u_{x+1} + 2(u_x)^2 = 0, \quad (\Delta u_x)^2 - u_x (\Delta u_x) = 0$$

are the same, and each has the solutions $u_x = c, u_x = c_x 2^x$, where c_x is an arbitrary periodic function such that $c_{x+1} = c_x$.

While some difference equations may have compact solutions like the above in terms of elementary functions, in general a difference equation must be regarded as defining a class of functions whose properties are to be inferred from the equation itself. When, however, the variable proceeds by equal steps from a given initial value of the function, difference equations lend themselves to machine computation. For this reason numerical problems are often approached via an approximating difference equation. This is the basis of so-called "relaxation" methods.

The following is a specific example which leads to a difference equation with constant coefficients.

A coin is spun n times. The probability of its showing head at the first spin is p' , while at any subsequent spin the probability that the coin shows the same face as at the previous spin is p . What is the probability that the coin shows head at the n th spin?

Let u_n be the required probability. At the $(n - 1)$ th spin the coin has probability u_{n-1} of showing head, or probability $1 - u_{n-1}$ of not showing head. Therefore

$$u_n = pu_{n-1} + (1-p)(1-u_{n-1}) = (2p-1)u_{n-1} + 1-p \quad (35)$$

First, solve the equation $u_n = (2p - 1)u_{n-1}$ by writing $u_n = A\rho^n$ so that $p = (2p - 1)$. Next, find a particular solution of (35) by putting (in this case) $u_n = c$, a constant, which gives $c = \frac{1}{2}$. The complete solution is therefore $u_n = \frac{1}{2} + A(2p - 1)^n$. But $u_1 = p'$, therefore $A = (p' - \frac{1}{2})/(2p - 1)$, so the required probability is

$$u_n = \frac{1}{2} + (p' - \frac{1}{2})(2p - 1)^{n-1}$$

If $p' = \frac{1}{2}$, this is equal to $\frac{1}{2}$ for all values of n and p .

See L. M. Milne-Thomson, *The Calculus of Finite Differences* (1960). (L. M. M.-T.)

CALCULUS OF VARIATIONS.

When two points, A and B, are given in a plane, as shown in the accompanying figure, there is an infinity of arcs joining them. A simple problem of the calculus of variations is that of finding in this group of arcs (such as E and E') one which has the shortest length, the solution of the problem being, of course, a straight line segment. But it may also be desired to find in the group of arcs joining A with B one down which a particle, started with a given initial velocity, will fall from A to B in the shortest time; or which one of these arcs, when rotated about the x-axis, will generate a surface of revolution of minimal area. These are typical problems of the calculus of variations of the so-called simplest type.

These problems illustrate the usual situation in the calculus of variations, in which mathematicians seek to find that arc from some given class for which some quantity, the value of which depends on the entire arc (its length, etc.), is a minimum or a maximum. The calculus of variations also deals with problems involving surfaces or functions of several variables. For example, if a circular wire is bent in any way, dipped in a soap solution, and then withdrawn, the soap film spanning the wire will assume

the shape of the surface of least area bounded by the wire. The calculus of variations has been useful as a unifying principle in mechanics and as a guide for the determination of new laws of physics.

Albert Einstein's theory of general relativity, for example, utilizes the calculus of variations extensively. One of the most widely applicable variational statements of classical mechanics is known as Hamilton's principle; it states that the trajectories of many dynamical systems are the solutions of some variational problem involving an "energy integral."

Some of the problems of the calculus of variations were considered and partially solved by the ancient Greeks. The introduction of the calculus gave great impetus to the study and to the solution of variational problems. After a number of special problems had been solved, L. Euler in 1744 deduced the first general rule, now known as Euler's differential equation, for the characterization of the maximizing or minimizing arcs. Much of the terminology of the calculus of variations was introduced shortly thereafter by J. L. Lagrange.

Mathematical Formulation of Variational Problems.—All of the problems mentioned in the first paragraph reduce to the determination of that differentiable arc

$$y = y(x) \quad (1)$$

joining the two points (x_1, y_1) and (x_2, y_2) which minimizes an integral of the form

$$\int_{x_1}^{x_2} f[x, y(x), y'(x)] dx \quad \left(y' = \frac{dy}{dx} \right) \quad (2)$$

among all such arcs. The length of the arc (1) and the area of the surface of revolution obtained by revolving it around the x axis are found from elementary calculus to be given respectively by the integrals

$$\int_{x_1}^{x_2} \sqrt{1 + \left(\frac{dy}{dx} \right)^2} dx \quad \text{and} \quad \int_{x_1}^{x_2} 2\pi y(x) \sqrt{1 + \left(\frac{dy}{dx} \right)^2} dx \quad (3)$$

In the case of the curve of steepest descent, the time required for a bead to descend along a wire in the shape of the arc (1) from the point (x_1, y_1) to the point (x_2, y_2) under the action of gravity is given by the integral

$$\int_{x_1}^{x_2} (\alpha - y)^{-1/2} \sqrt{1 + \left(\frac{dy}{dx} \right)^2} dx \quad (4)$$

if friction is neglected; here

$$\alpha = y_1 + v_1^2/2g$$

where v_1 is the initial velocity of the bead and g is the acceleration of gravity. The function $f(x, y, p)$ occurring in (2) has the respective forms

$$\sqrt{1 + p^2}, \quad 2\pi y \sqrt{1 + p^2}, \quad \sqrt{1 + p^2} / \sqrt{\alpha - y} \quad (5)$$

in these examples, p being the third variable in f . The integrals arising from Hamilton's principle are of the type in (2), where x is replaced by the time t (this usually does not appear in the function f in such applications) and the single variables y and p are replaced by several variables y_1, \dots , and p_1, \dots, p_n , the p_i standing for the derivatives dy_i/dt .

Euler's Equation.—Euler's differential equation for the determination of a minimizing arc is derived as follows: Suppose that $y = y(x)$ is a minimizing arc which passes through the two points, and assume that the second derivative y'' and the second partial derivatives of f are all continuous. If $\eta(x)$ is any differentiable function such that

$$\eta(x_1) = \eta(x_2) = 0 \quad (6)$$

then for any λ the arc

$$y = y(x) + \lambda \eta(x) \quad (7)$$

is another arc joining the two given points. Forming the integral (2) for this new arc gives a function

$$I(\lambda) = \int_{x_1}^{x_2} f[x, y(x) + \lambda \eta(x), y'(x) + \lambda \eta'(x)] dx \quad (8)$$

of λ which is differentiable and must have a minimum for $\lambda = 0$.

From elementary calculus, it follows that

$$I'(0) = \int_{x_1}^{x_2} \left\{ \eta(x) f_y[x, y(x), y'(x)] + \eta'(x) f_p[x, y(x), y'(x)] \right\} dx = 0 \quad (9)$$

The integral on the right in (9) is called the first *variation* of the integral (2); this corresponds roughly to the total differential of a function of several variables, the function $\eta(x)$ corresponding to the set of differentials of the variables. Now, using the differentiability assumptions, the term involving $\eta'(x)$ in (9) may be eliminated by integrating by parts to obtain

$$\int_{x_1}^{x_2} \eta(x) \left\{ f_y - \frac{d}{dx} f_p \right\} dx = 0 \quad (10)$$

Because (10) holds for every function $\eta(x)$ allowed above, it follows from a well-known theorem in analysis that

$$\frac{d}{dx} f_p = f_y \quad (11)$$

which is Euler's differential equation; it is understood that the values $x, y(x)$ and $y'(x)$ are to be inserted in the expressions for f_p and f_y in (10) and (11).

If (11) is written out in more detail, the rules of differentiation yield

$$f_{pp} \frac{d^2 y}{dx^2} + f_{py} \frac{dy}{dx} + f_{pz} = f_y \quad (12)$$

which shows that Euler's equation is of the second order. Euler's equation becomes singular iff., $f_{pp} = 0$. Hence *regular* variational problems are those for which f_{pp} never vanishes; in that case it is assumed that $f_{pp} > 0$, which makes minimum problems more natural than maximum problems.

Some Questions Involving Arcs.—The analysis leading to Euler's equation applies just as well to a maximizing arc as to a minimizing one. The first attempt to find a condition which would single out a minimizing arc was to consider the second *variation*, which is obtained, for any given $\eta(x)$, by finding $I''(0)$, $I(\lambda)$ being defined by (8).

Clearly $I''(0) > 0$ for every $\eta(x)$ if $y(x)$ is a minimizing arc, but the condition that $I''(0) > 0$ for every $\eta(x)$ is not sufficient to ensure that $y(x)$ is minimizing. The attempt to find conditions which would ensure that a given arc is a relative minimum led to many interesting discoveries and raised many new questions.

After Karl Weierstrass's famous example of a continuous function which does not possess a derivative at any point (thereby showing that a function having a continuous first derivative

need not have a continuous second derivative), the question was raised as to why a minimizing arc, or more generally any arc for which the first variation is zero

for every η , should possess a continuous second derivative, as required in the derivation of Euler's equation. By the end of the 19th century, the problem of the existence of a minimizing arc had

been raised and the existence proved by D. Hilbert under certain hypotheses. L. Tonelli developed the so-called "direct methods" of the calculus of variations in order to simplify and amplify the results of Hilbert concerning the existence of minimizing arcs.

These results were applied to very general situations by the "metric geometry" methods of K. Menger and H. Busemann. Most of the remaining important problems involving arcs were solved between 1910 and 1940 by such mathematicians as O. Bolza, G. A. Bliss, E. J. McShane and others.

The fact that not every minimum problem has a solution is seen by studying the following example:

$$Z = \int_0^1 \left\{ 1 + [y'(x)]^2 \right\}^{-1/2} dx, \quad y(0) = 0, y(1) = 1$$

Clearly $0 < Z < 1$ for every $y(x)$. Setting $y(x) = x^n$, $n = 1, 2, \dots$, shows that Z may be made arbitrarily close to 1. By taking

$$y(x) = x + n \sin nax, \quad n = 1, 2,$$

SIMPLE PROBLEM OF ARC LENGTH (See TEXT)

it is seen that \mathbf{I} may be made arbitrarily close to zero. However, there is no $y(x)$ for which $\mathbf{I} = 0$ or 1.

Multiple-Integral Problems.—Meanwhile interest had developed in problems involving functions of two or more variables, and the derivation of Euler's equation had been extended to integrals of the form

$$I = \iint_G f[x, y, z(x, y), z_x(x, y), z_y(x, y)] dx dy \quad (z_x = \partial z / \partial x, z_y = \partial z / \partial y) \quad (14)$$

Replacing z by $z + \lambda \zeta$, where $\zeta = 0$ on the boundary of the region G , and proceeding as in (8), (9) and (10); results in the equation

$$\frac{\partial}{\partial x}(f_p) + \frac{\partial}{\partial y}(f_q) = f_z \quad (p = z_x, q = z_y) \quad (15)$$

which is Euler's equation for the integral (14).

Early in the 19th century C. F. Gauss and W. Thompson had observed that Laplace's equation (which had already been recognized as having important applications) was the Euler equation for the integral

$$\frac{1}{2} \iint_G (z_x^2 + z_y^2) dx dy \quad (16)$$

as is easily seen by setting $f(x, y, z, p, q) = (p^2 + q^2)/2$ in (14) and (15).

This fact is the formal basis for what is now known as *Dirichlet's principle* (after P. G. Lejeune Dirichlet), which states that (subject to certain hypotheses) there is a unique function z which minimizes the integral (16) among all differentiable functions having given boundary values and that that unique function is the solution of Laplace's equation with those boundary values.

This principle has proved to be of great importance not only in potential theory and in the theory of partial differential equations, but also in the theory of functions of a complex variable and in conformal mapping. The applications to these fields was begun by B. Riemann around 1850 and important advances have been made in them since 1935 by such mathematicians as R. Courant, L. Ahlfors, D. C. Spencer, M. M. Schiffer, P. R. Garabedian and others. Riemann simply assumed the principle but, of course, the objections which were raised concerning problems involving arcs applied to the Dirichlet principle with even greater force; the first proof of the principle was given by D. Hilbert in 1900.

The almost simultaneous solutions by J. Douglas and T. Radó in 1930 of the problem of J. Plateau, *i.e.*, the proof of the existence of a minimal surface (surface of least area) bounded by a simple closed curve in space, aroused a renewed interest in variational problems for surfaces. The Plateau problem was solved for surfaces bounded by several curves and for more complicated surfaces by Douglas, R. Courant and others. More general variational problems for surfaces were solved by Tonelli, McShane, C. B. Morrey, Jr., L. Cesari, A. G. Sigalov, and others between 1930 and 1957 by extending the direct methods of Tonelli; these involve considering the surfaces as "points" in a "space" in which limits are defined and using the general theorem in functional analysis that "a function which is lower-semicontinuous on a compact set attains its minimum on that set." In order to apply this theorem it was found expedient to enlarge the classes of arcs or surfaces, etc., within which the minimum is sought. Unfortunately the enlarged classes usually contain surfaces which do not possess the properties of differentiability required in the derivation of Euler's equation.

In the case of the Plateau problem, the differentiability of the solutions follows from the Dirichlet principle. The differentiability of the generalized solutions of certain other problems for surfaces was proved by C. B. Morrey, and some of his results were extended in 1957 to problems in higher-dimensional spaces by E. De Giorgi and J. Nash.

An interesting attack on problems for surfaces has been made by L. C. Young, W. H. Fleming and others through their introduction of "generalized surfaces."

Morse's Theory of Critical Points.—If a function $f(P)$ is defined on an n -dimensional manifold (*see* MANIFOLDS), its behaviour near a particular point may be studied by introducing co-ordinates, in which case f becomes just a function of n co-ordinates x_1, \dots, x_n . A point (*i.e.*, set of numbers x_1, \dots, x_n) is a critical

point ($q.v.$) of f if all its partial derivatives are zero there. If x_1, \dots, x_n is such a point, then

$$f(x_1 + \eta_1, \dots, x_n + \eta_n) - f(x_1, \dots, x_n) = \frac{1}{2} \sum_{i,j=1}^n a_{ij} \eta_i \eta_j + R \quad (17)$$

where R consists of the higher order terms; here

$$a_{ij} = \partial^2 f / \partial x_i \partial x_j$$

evaluated at the point. It is known that linear combinations ξ_1, \dots, ξ_n of the η_i can be chosen so that the double sum becomes

$$-\xi^2 - \dots - \xi_r^2 + \xi_{r+1}^2 + \dots + \xi_s^2 \quad (18)$$

(where $r = 0$ if there are no negative terms, etc.). Moreover, the numbers r and s are independent of the coordinate system and the way the ξ_i are chosen as long as the form (18) is obtained. If $s = n$, the critical point is said to be nondegenerate, in which case r is called the index.

M. Morse first proved certain inequalities between the number of critical points of a given index of a (nondegenerate) function on a manifold and the so-called "Betti numbers" of the manifold. His greatest contribution was to generalize the notion of a nondegenerate critical point and his inequality results to situations where the functions and spaces were too general for differentiability to be defined. Morse applied his theory to spaces whose elements were arcs or closed curves on a manifold or surfaces in space. He was able to prove the existence of "unstable" minimal surfaces (*i.e.*, surfaces furnishing some critical value other than a minimum to the area) and to prove such theorems as that there exist at least three closed geodesics on a surface homeomorphic to a sphere. His theory has been applied to variational problems for arcs with great success; the theory of multiple-integral problems in the calculus of variations is not sufficiently far advanced to consider solutions other than the one furnishing a minimum. *See also* ANALYSIS, COMPLEX; TOPOLOGY, GENERAL.

BIBLIOGRAPHY.—For a lucid introduction to the theory of the calculus of variations for problems involving arcs only, *see* G. A. Bliss, *Calculus of Variations* (1925); for a more extended treatment of this subject *see* G. A. Bliss, *Lectures on the Calculus of Variations* (1946). For an introduction to certain double-integral problems, *see* R. Courant, *Dirichlet's Principle, Conformal Mapping, and Minimal Surfaces* (1950) and Courant and D. Hilbert, *Methods of Mathematical Physics* (rev., 1953). For expositions of Morse's theory of critical points, *see* M. Morse, *Calculus of Variations in the Large* (1934) and H. Seifert and W. Threlfall, *Variationsrechnung im grossen (Theorie von Marston Morse)* (1938). (C. B. M.)

CALCUTTA, the premier city of India, capital of West Bengal and one of the largest commercial and cultural centres of the east, is situated on the east bank of the Hooghly distributary of the Ganges, about 80 mi. from the head of the Bay of Bengal, and extends over a surface of 39 sq.mi. of which 34 sq.mi. is occupied by the city proper.

Topography.—The city owes much of its size and importance to its commanding position on the easternmost distributary of the Ganges. The river there is wide and deep and navigable for seagoing vessels as far as the city. Hence Calcutta, like London, developed on a point of transshipment from water to land and from river to sea. With the Chitpur creek on the north, a vast salt marsh on the east and the Adi-Ganga river on the south it was by far the most easily defensible site on the banks of the Hooghly. The wider setting of Calcutta perhaps contributed more than its local setting toward its rapid growth as the leading commercial hub of India. Not only the rich Ganges delta, but the entire Gangetic plains and the Assam valley on the north and the mineralized zones of Bihar, Orissa and Madhya Pradesh on the west constituted its great hinterland.

The mean height of Calcutta is about 20 ft. above sea level and the ground slopes gently from the riverbank toward the salt lake in the east. The surface is studded with broad and shallow depressions, which cause flooding during monsoonal months.

The weather remains hot from March to September when the mean monthly temperature ranges from 81° to 87° F. and the daily temperature may rise to 117°. With the high humidity the weather becomes very oppressive. The only relief in hot weather is the southerly breeze which at the close of the day

MARIE J. MATTSON FROM BLACK STAR

JAIN TEMPLE OF BADRI DAS. CALCUTTA

blows regularly from the Hooghly estuary. Occasional thunder-squalls or nor'westers in the evening also bring rain and lower the temperature. In the latter part of June the monsoon sets in and bursts of rain alternating with sporadic showers and rainless breaks continue for another three months. The normal monthly rainfall in monsoonal months ranges from 13 in. (July) to 10 in. (September). There is very little post-monsoonal rain except when occasional depressions come from the west. The weather remains pleasantly cool in the daytime from October to February and the evenings of December and January are sufficiently cold to make a fire agreeable.

Places of Interest. — Calcutta's chief glory is the maidan (plain or park), 1,283 ac. in area. Ft. William stands west of the maidan, facing the Hooghly. It is the shape of an irregular octagon and can accommodate about 10,000 men. The Victoria memorial, considered the finest building in Calcutta, stands southeast of the maidan adjoining the racecourse. It contains a picture gallery and a museum. To the east is St. Paul's cathedral, built in 1839-41 in "Indo-Gothic" style. In the northeast of the maidan stands the Ochterlony monument, the most conspicuous landmark in Calcutta. It is a beautiful column of Saracenic type, 165 ft. high. Curzon park, farther north, has lost much of its former beauty. Another beauty spot, Eden gardens, the extreme northwest of the maidan, contains the massive All India Radio building and the Ranji stadium. Government house, known as Raj Bhavan, close to Eden gardens, is the official residence of the governor of West Bengal. Farther west lie three imposing buildings, the legislative assembly, high court and town hall. The first has a beautiful copper-plated dome. The high court building, built in 1872 on the model of the Cloth hall at Ypres, Belg., has a massive 180-ft. tower. The town hall (1813) contains a fine collection of historical portraits. Facing the maidan for a length of about 2 mi. is Chowringhee, once a row of palatial residences but later given up almost entirely to hotels, shops, offices and museums. There stands the Indian museum with its fine archaeological, ethnographic and zoological collections.

Commercial and administrative Calcutta lies north of the Raj Bhavan around Dalhousie square. On the north stand Writers'

buildings, which house the West Bengal secretariat. The 14-story secretariat in Hastings street is the tallest building of Calcutta. Almost all the big commercial houses are situated farther north alongside the former Clive street, renamed Netaji Subhas road. In central Calcutta Nakhuda Masjid, the largest mosque in the city, Mahajati Sadan and Marble palace with its art collection deserve special mention. North Calcutta has most of the educational institutions, including the University of Calcutta and Presidency college. Cossipore and Chitpur, the two northern suburbs, are the principal centres of jute pressing and cotton ginning. Cossipore also has ordnance factories. Another suburb on the east, Manick-tala, has in its neighbourhood the famous Jain temple, named after Badri Das, enclosing one of the prettiest gardens of Calcutta. The eastern parts of these two and adjoining suburbs have most of the factories and mills. South of the maidan extend Kidderpore, Alipore, Bhawanipur, Kalighat, Ballygunge and Tollygunge, formerly suburbs but now within the city limits. The docks are at Kidderpore. Alipore, with its open spaces and many historic buildings, includes the zoological and botanical gardens and meteorological observatory. Also in Alipore are Belvedere house and Hastings house, the former housing the National library, the latter educational institutions for women. Bhawanipur is the most congested residential area in the south. Kalighat is noted for its Kali temple, which stands on the Adi-Ganga, a silted-up channel of the Ganges.

Greater Calcutta includes areas outside the city limits. It is almost a continuous built-up area astride the Hooghly with an area of about 78 sq.mi. and an estimated population of about 5,000,000 (1960).

Population. — In 1901 the population of Calcutta reached about 1,000,000 and by 1951 there was a further increase of 1,500,000. Pop. (1961) 2,926,498. The area of the city during this period increased by only 50%, resulting in considerable overcrowding. Cosmopolitan in character, Calcutta has within its confines persons speaking different languages. About two-thirds of the citizens are Bengalis, the remainder being Hindi-speaking people from north India. The British are by far the largest European element. More than one-third of Calcutta's citizens are engaged in professions and other services and another third in commercial pursuits. Industry absorbs one-fifth of the total population.

Education and Research. — Calcutta has two universities, the University of Calcutta and Jadavpur university. The University of Calcutta was founded in 1857 on the model of the University of London; it has its own postgraduate departments and also exercises control over about 145 affiliated colleges. The University of Jadavpur came into being in 1955 with the upgrading of the former college of engineering and technology at Jadavpur, a southern suburb of Calcutta.

Of the research institutes functioning in the city, the Royal Asiatic Society of Bengal founded in 1784 by Sir William Jones, the Indian Association for the Cultivation of Science founded in 1876 by Mahendra Lal Sircar and the Bose institute founded in 1917 by Sir Jagadis Chandra Bose deserve special mention.

Municipal Administration. — The municipal government of Calcutta is guided by the Calcutta Municipal act, 1951, amended in 1953. The corporation consists of 80 elected councilors and one ex officio councilor who is the chairman of the Calcutta improvement trust. The intake for the supply of filtered water for domestic use is from the Hooghly at Palta, about 14 mi. above Calcutta. To supplement the main water supply about 1,500 tube wells have been sunk all over the city. The sewage from the city is carried from the three main pumping stations to the Kulti river about 22 mi. E. Both gas and electricity are used for street lighting. There are eight municipal markets, the largest of which, named after Sir Stuart Hogg, offers an immense variety of merchandise.

Commerce and Industry. — Commerce and industry are well organized in Calcutta. There are as many as eight chambers of commerce in the city representing all sections of trade, commerce and industry, of which the Bengal chamber of commerce is the largest. There are also more than 30 other Indian trade associations and at least 12 trade commissions organized by foreign governments. The commercial prosperity of Calcutta results

mainly from its fine port on which rail, river and air traffic converge. The chief exports by sea are gunnies (jute sacking), hemp, tea, linseed, coal, pig iron, iron and manganese ores, mica, carpets, hides and skins. The principal items of import are salt, food grains, petroleum, iron and steel, machinery, cement, hardware and other consumer goods. The port of Calcutta, one of the busiest in the world, is under the control of the Calcutta port commissioners, whose jurisdiction extends to the mouth of the Hooghly. Vessels of 16,000 tons, drawing 28 ft. and more, go up the river to Calcutta. The passage is dangerous because of strong tides and bores and consequent changes in bed level, but it is kept safe for navigation by the vigilance of the port commissioners and the skill of the pilots. The main accommodation for ships in the port is provided in Kidderpore docks, King George's dock, Calcutta jetties, Garden Reach jetties and petroleum wharves at Budge Budge. On the completion of the second Indian five-year plan in 1961, the handling capacity of the port rose to 12,000,000 tons a year.

The port has its own railway system which provides the terminal for the Eastern and Southeastern railways for goods traffic to and from the port and deals with local goods traffic within the port area. Railway passengers to Calcutta have to terminate their journey on the outskirts of the city in Howrah (*q.v.*) and Sealdah stations. Calcutta has air links with practically all the important cities of the world. The Calcutta international airport is at Dum Dum.

Next to commerce, industry plays the most important part in the economy of the city. Within the city proper there is a very large concentration of printing and bookbinding establishments and on the outskirts are jute mills, jute presses, ordnance factories, chemical and glass works, match factories and rice mills. Not only these industrial concerns, but the tea gardens, coal mines and industrial concerns of West Bengal and the neighbouring states are managed, controlled and financed from Calcutta.

(S. P. C.)

History.—The history of Calcutta for all practical purposes dates from Aug. 24, 1690, when it was founded by Job Charnock (*q.v.*) of the English East India company. In 1596 Calcutta had obtained a brief entry as a rent-paying village in the survey of Bengal executed by command of the emperor Akbar. In 1686 the English merchants at Hooghly retreated about 26 mi. down the river to Sutanati, a village now within the boundaries of Calcutta. They occupied Sutanati temporarily in Dec. 1686 and permanently on Aug. 24, 1690. The new settlement soon extended itself along the riverbank to the then village of Kalikata, and by degrees the cluster of hamlets grew into the present town.

In 1696 the English built the original Ft. William by permission of the nawab, and in 1698 they formally purchased the three villages of Sutanati, Kalikata and Govindpur from Prince Azim, son of the emperor Aurangzeb. The town grew up without any fixed plan and with little regard to sanitary arrangements. Some parts of it lay below high-water mark on the Hooghly, and its low level throughout made drainage difficult.

The chief event in the history of Calcutta is the sack of the town and the capture of Ft. William in 1756 by Siraj-ud-Daula, nawab of Bengal. The majority of the English officials took ship and fled to the mouth of the Hooghly. The Europeans who remained were compelled, after a short resistance, to surrender. The prisoners, numbering 146 persons, were forced into the guardroom, a chamber measuring 18 ft. by 14 ft. 10 in. with only two small windows, where they were left for the night. It was June 20, the heat was intense, and next morning only 23 were taken out alive, among them J. Z. Holwell, who left an account of the awful sufferings endured in the "Black Hole." In Jan. 1757 an expedition dispatched from Madras, under Adm. Charles Watson and Col. Robert Clive, regained possession of the city.

After the battle of Plassey (June 23, 1757), Mir Jafar, the nominee of the English, was created nawab of Bengal, and by the treaty which raised him to this position he agreed to make restitution to the Calcutta merchants for their losses. By another clause in this treaty the East India company was permitted to establish a mint, the visible sign in India of territorial sovereignty,

and the first coin, still bearing the name of the Delhi emperor, was issued on Aug. 19, 1757.

Modern Calcutta dates from 1757. The old fort was abandoned and its site devoted to the customhouse and other government offices. The new Ft. William was begun by Clive a short distance lower down the river. At this time also the maidan was formed.

Up to 1707, when Calcutta was first declared a presidency, it had been dependent upon the older English settlement at Madras. From 1707 to 1773 the presidencies were maintained on a footing of equality, but in the latter year an act of parliament was passed which provided that the presidency of Bengal should exercise a control over the other possessions of the company; that the chief of that presidency should be styled governor general; and that a supreme court of judicature should be established at Calcutta. In 1772 Warren Hastings had taken, under the immediate management of the company's servants, the general administration of Bengal.

The treasury was removed from Murshidabad to Calcutta which thus became the capital. In 1834 the governor general of Bengal was created governor general of India. It was not until 1854 that a separate head was appointed for Bengal. In 1912 the 1905 partition of Bengal was reversed and Calcutta was no longer the capital of India, the seat of government being transferred to Delhi (*q.v.*).

In 1926 Calcutta was the scene of communal rioting in which more than 200 shops were looted and 12 sacred buildings either desecrated or destroyed. Serious riots took place also in 1930 as a result of Gandhi's manifesto authorizing mass disobedience to the salt laws, and in 1946, 1947 and 1950; the riots from Aug. 16 to Aug. 20, 1946, were the worst in Calcutta's history. Japanese air raids in Dec. 1942 and in Jan. and Dec. 1943 inflicted heavy casualties among the dock workers.

CALDARA, POLIDORO: see CARAVAGGIO, POLIDORO DA.

CALDAS, a department of Colombia, situated to the northwest of Bogotá. Area 5,005 sq.mi.; pop. (1951) 1,068,180, (1961 est.) 1,365,980. The terrain is varied, including sections of the Andes cordilleras as well as the Cauca and Magdalena river valleys. Coffee constitutes four-fifths of its agricultural production and 37% of all Colombian coffee. Its capital is Manizales, with a 1958 estimated population of 151,670 (mun.). The department was created in 1905 and was named for the scientist-martyr of the independence period, Francisco José de Caldas. Penetrated by conquistadores early in the 16th century, it was a part of the colonial province of Antioquia, Spain's leading gold production area. Gold production is now negligible. Besides coffee, plantains and other agricultural products, Caldas has some manufacturing which is centred in Manizales, Armenia and Pereira. The department is served by several railroads, highways, airlines and an aerial cable between Manizales and Mariquita (department of Tolima).

(T. E. N.)

CALDECOTT, RANDOLPH (1846–1886), English illustrator, painter and sculptor whose gently satirical drawings and book illustrations earned great popularity, was born at Chester on March 22, 1846. While a bank clerk at Whitchurch, Shropshire, and at Manchester, Caldecott began drawing for local magazines. Through George du Maurier he began contributing to the periodical *London Society* in 1871; the next year he settled in the capital and turned professional, ultimately drawing for *Punch* and *Graphic*, among other periodicals. He increased his skill by painting under Sir E. Poynter, by sketching and modeling in the studio of J. Dalou and by dissecting birds and animals. In 1872 he went with his lifelong friend Henry Blackburn to Germany. His drawings for Blackburn's book, *The Harz Mountains*, fix Caldecott's style in

the tradition of Richard Doyle—moderate in distortion, affably satirical. He illustrated Washington Irving's *Sketch Book* (1875) and *Bracebridge Hall* (1876). These more sophisticated drawings were close to those of Du Maurier and W. P. Frith, though with an original sense of caricature, and they established Caldecott's reputation. His coloured picture books for children included W. Cowper's *John Gilpin* (1878), Oliver Goldsmith's *Elegy on a Mad Dog* (1879) and *The Great Panjandrum Himself* (1885). He also exhibited paintings at the Royal Academy, and made metal reliefs and terra cottas. He died at St. Augustine, Fla., on Feb. 12, 1886.

CALDER, ALEXANDER (1898–) U.S. sculptor, the originator of the mobile, was born in Philadelphia, Pa., on July 22, 1898, into an American family of artists. He was trained primarily as an engineer. In the 1920's, Calder created witty and playful sculptures such as his toylike circus, "The Hostess" (1926), and several portraits in which the sculpture consists of suggestively drawn shapes in wire. The familiar bulk and weight of the body is replaced with space. The viewer's imagination completes the sculpture. During long stays in Paris, Calder was inspired by Hans Arp, Picasso and Piet Mondrian, and by 1930, was working in more abstract forms. Calder's gift to sculpture was his development in 1932 of the mobile, sculpture that moved with the aid of air currents and its own delicate balance. While often lacking in specific reference, his mobiles and stationary metal sculpture recall movements, shapes and structures in nature. Calder's inventiveness produced a mercury fountain, stage sets, a water ballet and many fine architectural commissions.

See J. J. Sweeney, *Alexander Calder* (1951). (A. E. EL.)

CALDER, SIR ROBERT, 1ST BARONET (1745–1818), British admiral, who was court-martialed for failing to do his utmost to destroy a French fleet in 1805, although he fought in unfavourable conditions, was born at Elgin in Scotland on July 2, 1745. He entered the navy in 1756 and as a lieutenant participated in 1762 in the capture of the Spanish ship "Hermione," homeward bound from Lima with a cargo of cash and bullion valued at more than £540,000 and probably the richest prize ever taken. He was captain of the fleet under Sir John Jervis at the battle of Cape St. Vincent in Feb. 1797, for which he was knighted (1798). In 1801 as a rear admiral he unsuccessfully chased Admiral Ganteaume's force which escaped from Brest for Egypt. In 1804 he joined the fleet blockading Brest under Admiral Cornwallis. In Feb. 1805 he was detached to watch El Ferrol in Spain in order to intercept Admiral Villeneuve on his return from the West Indies. This he failed to do on July 22, though he captured two Spanish ships when the combined fleet pressed past him in thick weather to reach Vigo. Aware of his inferiority in numbers, Calder sailed north to rejoin Cornwallis, but was sent south again on Aug. 16, an action which Napoleon described as "remarkably stupid" because Cornwallis thus divided his force, but it was approved by the admiralty and by that date Villeneuve had already turned south to Cadiz. On Aug. 30 Calder joined Vice-Admiral Collingwood off that port. Since much indignation was expressed at home over his action in July, Calder demanded a court-martial which was held in December. At this he was severely reprimanded for failing to renew action, but was acquitted on all other charges. This ended his career at sea. He died at Holt, Hampshire, on Aug. 31, 1818.

See J. Corbett, *Campaign of Trafalgar* (1910); "Biographical Memoir of Sir Robert Calder, Bart.," *Naval Chronicle*, vol. xviii. (1807). (C. C. L.)

CALDER, an ancient district of Midlothian, Scot. It comprises West Calder parish (pop. [1961] 6,873), the district centre, and East Calder district (pop. [1961] 6,727), consisting of Kirknewton parish and Mid Calder parish. Calder stretches from 10 to 25 mi. S.W. from Edinburgh and, with the exception of Pumpherstons, lies along the south banks of the Almond and Breich rivers, rising from them into barren moorlands. Oil is the principal industry, established in the mid-19th century to produce paraffin. From oil shale mined around West Calder crude oil is extracted at Addiewell; refining, the extraction of by-products and brickmaking from spent shale take place at Pumpherstons. Coal is mined in West Calder. At Mid Calder is a small paper mill.

Sandstone, limestone and fire clay are quarried near West Calder.

Mid Calder has an ancient church where John Spottiswoode, the Scottish reformer, was minister. At Calder house John Knox first administered Holy Communion according to the Protestant rite; Frédéric Chopin stayed there in 1848. There are several tumuli, ruined castles and a Roman camp in the district. (J. McB.)

CALDERÓN, RODRIGO (1570?–1621), conde de Oliva and marqués de Siete Iglesias, Spanish royal favourite, who enjoyed considerable authority during the ascendancy of the duque de Lerma in the reign of Philip III, was born at Antwerp, the son of an army officer. On the accession (1598) of Philip III, Calderón attached himself to the king's favourite and chief minister, Lerma, by whom he was employed as a secretary. Intelligent and capable, he soon distinguished himself and was repeatedly honoured by the king. There seems little doubt that Calderón exploited his influence for private gain and he became the main target for the anti-Lerma opposition, headed by the queen, Margarita, for whose death in 1611 he was unjustifiably alleged by his enemies to have been responsible. But the position of Calderón, who was awarded his marquessate on returning from a special mission (1612–14) to Flanders, remained strong until Lerma's fall in Oct. 1618. He was then arrested, tortured and implicated in the murder of a certain Francisco Xuara. After spending more than two years in prison, he was about to be released when Philip III died. This proved fatal for Calderón, for the conde de Olivares, the chief minister of the new king, Philip IV, wishing to disassociate his government from the previous regime, determined upon Calderón's execution, which took place in Madrid on Oct. 21, 1621. The Spanish saying *Tener más orgullo que don Rodrigo en la horca* ("To be haughtier than Don Rodrigo on the scaffold") derived from his behaviour on this occasion. (J. RE.)

CALDERÓN DE LA BARCA, PEDRO (1600–1681), Spanish dramatist and poet, who succeeded Lope de Vega as the greatest Spanish dramatist of his age, was born at Madrid on Jan. 17, 1600. His father, a fairly well-to-do government official who died in 1615, was a man of harsh and dictatorial temper, and strained family relations must have had a profound effect on the youthful Calderón, for several of his plays show a preoccupation with the psychological and moral effects of unnatural family life in that they present anarchical behaviour directly traced to the abuse of paternal authority through unloving severity, injustice or tyranny.

Destined for the church, Calderón matriculated at the University of Alcalá in 1614, transferring a year later to Salamanca where he continued his studies in arts, law and probably theology until 1619 or 1620. Abandoning an ecclesiastical career, he entered the service of the constable of Castile and in 1623 began to write plays for the royal palace, rapidly becoming the leading member of the small group of dramatic poets whom Philip IV gathered around him. In 1636 the king made him a Knight of the Military Order of St James. Calderón's popularity was not confined to the court, for these early plays were also acclaimed in the public theatres, and on the death of Lope de Vega (1635) Calderón became the master of the Spanish stage. On the outbreak of the Catalan rebellion he enlisted in 1640 in a cavalry company of knights of the military orders and served with distinction until 1642 when he was invalided from the army. In 1645 he entered, probably as secretary, the service of the duke of Alba. A few years later an illegitimate son was born to him; nothing is known about the mother and the idea that sorrow at her death led him to revert to his intention of joining the priesthood is pure surmise. He was ordained in 1651 and announced his intention of writing no more for the stage. This he kept as regards the public theatres, but at the king's command he continued to write regularly for the court theatre. He also wrote each year the two Corpus Christi plays for Madrid. Appointed a prebendary of Toledo cathedral he took up residence in 1653. The fine meditative religious poem *Psalle et sile* is a product of this period. Receiving permission to hold his prebend without residence he returned to Madrid in 1657 and was appointed honorary chaplain to the king in 1666. He died in Madrid on May 25, 1681.

The court patronage which Calderón enjoyed uninterruptedly

constitutes the most important single influence in the development of his art. The court drama grew out of the popular drama and at first there was no distinction in themes and style between the two, but the construction of a special theatre in the new palace of the Buen Retiro, completed in 1633, made possible spectacular productions beyond the resources of the public stage. The court plays became a distinctive baroque genre combining drama with dancing, music and the visual arts, and departing from contemporary life into the world of classical mythology and ancient history. Calderón, as court dramatist, is thus associated with the rise of opera in Spain. In 1648 he wrote *El jardín de Falerina*, the first of his *zarzuelas*, plays in two acts with alternating spoken and sung dialogue. In 1660 he wrote his first opera, the one-act *La púrpura de la rosa*, with the whole dialogue set to music. This was followed by *Celos aun del aire matan* (1662), an opera in three acts with music by Juan Hidalgo. Following Italian tradition the music was subordinate to the poetry; all Calderón's musical plays are poetic dramas in their own right.

Calderón's drama must be placed within the context of the court theatre, with its conscious development of an unrealistic and stylized art-form. Though for two centuries after his death his pre-eminence remained unchallenged, the realistic canons of criticism prevailing at the end of the 19th century produced a reaction in favour of the more lifelike drama of Lope de Vega. Calderón appeared mannered and conventional: the structure of his plots artificially contrived, his characters stiff and unconvincing, his verse often affected and rhetorical. Although he used technical devices and stylistic mannerisms that by constant repetition became conventional, Calderón remained sufficiently detached to make his characters, on occasion, poke fun at his own conventions. This detachment indicates a conception of art as a formal medium whose artifice is so contrived as to compress the externals of human life the better to express its essentials, and the justification for his formalism lies in the extent to which its self-consistency succeeds in lifting the surface of experience to disclose the permanent and universal.

In this direction Calderón developed the dramatic traditions he inherited. From the start he manifested his technical skill by subordinating the characters and incidents of his plots to the development of a dominant idea. As his art matured his plots became more complex, and the action more constricted and compact. The creation of complex dramatic patterns in which the artistic effect resides in the totality of the design through the inseparability of the parts is Calderón's greatest achievement as a craftsman. *El pintor de su deshonra* and *La cisma de Ingalaterra* are masterly examples of this technique, in which poetic imagery, characters and action are subtly interconnected by dominant symbols that elucidate the significance of the theme. While rhetorical devices, typical of the Spanish baroque style, remained a feature of his diction, his verse developed away from excessive ornamentation toward a taut style compressed and controlled by a penetrating mind.

The difficulties that Calderón's art presents to the modern reader have tended to obscure the originality of his themes. Accepting the conventions of the comedy of intrigue, of which *La dama duende* (1629) is a neat and lively example, he used them for a fundamentally serious purpose. In *Casa con dos puertas, mala es de guardar* (1629) the intrigues of secret courtship and disguises are so presented that the convention of seclusion of women on which they are based is shown to create social disorder by breeding enmity and endangering love and friendship. *No siempre lo peor es cierto* and *No hay cosa como callar* (1639) mark the peak of this development; although the conventions of comedy remain, the overtones are tragic: both plays are implicit criticisms of the accepted code of honour, the former being a plea for frankness and trust between men and women, the latter upholding silence and forgiveness as more dignified and noble than scandal and revenge. Calderón's critical attitude to the rigid assumptions of the code of honour is evident also in his tragedies. In the famous *El alcalde de Zalamea* the secrecy and vengeance demanded by the code are rejected, the dishonoured father makes his dishonour public because justice is a social act and punishment lies

with the law, not the individual. This play also presents a powerful contrast between the aristocracy and the people: the degeneration of the aristocratic ideal is exposed, wealth is associated with manual labour and honour is shown to be the prerogative of moral integrity irrespective of class. Yet this profound humanity of Calderón has been denied in connection with *El médico de su honra* (1635). The critics who allege that Calderón approves of the murder of an innocent wife, because honour demands it, overlook the fact that the horror we feel at this deed is precisely what Calderón has made us feel. This moving play presents objectively the grimness of a world ruled by the code of honour.

Calderón's tragic view of life is, however, wider than his preoccupation with the social code of honour. A keynote is his deep-seated realization that a man can be responsible, through his own wrongdoing, for the wrongdoing of another. This can be connected with Calderón's own family experience. In *La devoción de la cruz* and *Las tres justicias en una* the heart of the tragedy lies in the fact that the greatest sinner is also the most sinned against, in that others, before he was born, had begun to dig his grave. To this group should be added *El pintor de su deshonra*, the plot of which is so contrived that each of the major characters, through actions in themselves reprehensible, forges a link in the chain that leads to the tragic conclusion. The human predicament, as seen by Calderón, lies in the fact that each man is separated from all other men, yet is in intimate solidarity with them, caught in circumstances that are the collective responsibility of all, whose ramifications he cannot see because he is the prisoner of his own limited vision. Connected with this is another keynote of Calderón's drama, that of "confusion," the difficulty of seeing clearly and choosing correctly in the maze of possibilities that life offers. *La vida es sueño* (1635) exemplifies this in the splendidly presented symbol of life as a dream. The material and social advantages that life can bestow are like a dream because they are transient. By seeing nothing beyond them man can blunder into disaster; the only guiding thread is renunciation of personal advantage for the good of others.

The fully developed court plays are best represented by *La hija del aire* (1653). This play in two parts, which dramatizes the legend of Queen Semiramis, has many claims to be considered Calderón's masterpiece. Highly stylized, it succeeds in conveying a strong impression of violence. It presents, with considerable complexity, the contrast between passion and reason. Passion, self-seeking, grasping power and devouring everything in the urge to domination, breeds disorder and leads to destruction; reason, sacrificing self-interest to justice and loyalty, produces order. This basic contrast underlies the themes of the plays of Calderón's last period, its various aspects being expanded in a number of interesting variations, many directly concerned with the positive values of civilization. Though none has the intensity of *La hija del aire*, most exemplify a thoughtful, dignified and restrained art. Mythological themes, treated more or less allegorically, predominate, as in *Eco y Narciso* (1661), *La estatua de Prometeo* (1669) and *Fieras afemina amor* (1669).

Calderón's vision of the human world in his secular plays is one of confusion and discord due to the inevitable clash of values in the natural order—honour in conflict with love, ambition with loyalty, peace with justice, and so on. The values underlying his thought in these plays are based on natural reason: prudence and social co-operation through unselfishness, trust and love. His religious plays round off his view of life by confronting natural values with supernatural ones. The most characteristic group, following the tradition established outside Spain by the Jesuit drama, are stories of conversion and martyrdom taken usually from the saints of the early church. One of the most beautiful is *El príncipe constante* (1629), which dramatizes the martyrdom of Prince Ferdinand of Portugal; by worldly standards this is a story of defeat and disaster, but worldly failure is changed into spiritual triumph by the saint's self-sacrificing loyalty to his faith: by contrast the human values of the other characters are shown to be morally inadequate. *El mágico prodigioso* (1637; later revised and expanded) is a more complex religious play; *Los dos amantes del cielo* and *El Josef de las mujeres* are the most subtle

and difficult. The basic human experience upon which, in this type of drama, Calderón relies for rational support of religious faith is decay and death and the consequent incapacity of the world to fulfil its promise of happiness. This promise is centred in such natural values as beauty, love, wealth and power which, though true values if pursued with prudence, cannot satisfy the mind's aspiration for truth or the heart's longing for happiness. Only the apprehension of an infinite Good can assuage the restlessness of men. This religious philosophy is given its most moving expression, in terms of Christian dogma, in the autos sacramentales. Seventy-six of these allegorical plays, written for open-air performance on the feast of Corpus Christi, are extant. In them Calderón brought the tradition of the medieval moralities to a high degree of artistic perfection. The range of his scriptural, patristic and scholastic learning, together with the assurance of his technique and poetic diction enable him to endow the abstract concepts of dogmatic and moral theology with convincing dramatic life. At their weakest the autos tend to depend for their effect upon the ingenuity of their allegories, but at their best they are imbued with profound moral and spiritual insight, and with a poetic feeling varying from tenderness to forcefulness. *La cena de Baltasar* and *El gran teatro del mundo* are fine examples of the early style; the greater complexity of his middle period is represented by *No hay más fortuna que Dios* and *Lo que va del hombre a Dios*. But his highest achievement in this type of drama is to be found among those autos of his old age that dramatize the dogmas of the Fall and the Redemption, notably *La vida del Señor* (1674), *La nave del mercader* (1674), *El nuevo hospicio de Pobres* (1675), *El día mayor de los días* (1678) and *El pastor fido* (1678). Here is found the most moving expression of that compassionate understanding of human waywardness that characterizes all Calderón's work, presented through Christ's compassion for human suffering and sorrow and through the timeless re-enactment of Calvary in the regeneration of the individual sinner.

To have found a dramatic form that conveys the doctrines of the Christian faith gives Calderón a special place in literature. But his greatness is not confined to this; the depth and consistency of his thought, his supremely intelligent craftsmanship and artistic integrity, his psychological insight and the rationality and humanity of his moral standards make him one of the major figures of European drama.

CALDERWOOD, DAVID (1575–1650), Scottish Presbyterian minister and historian of the Church of Scotland. About 1604 he became minister of Crailing, near Jedburgh, Roxburghshire. In 1617, while James was in Scotland, a remonstrance, which had been drawn up by the Presbyterian clergy, was placed in Calderwood's hands. He was summoned to St. Andrews and examined before the king, but neither threats nor promises could make him deliver up the roll of signatures to the remonstrance. The privy council ordered him to be banished from the kingdom for refusing to acknowledge the sentence of the high commission. On Aug. 27, 1619, he sailed for Holland. During his residence in Holland he published his *Altare Damascenum* (1623) attacking episcopacy. Calderwood appears to have returned to Scotland in 1624, and he was soon afterward appointed minister of Pencaitland, East Lothian. He spent his last years writing his *History of the Kirk of Scotland*, the only published edition of which was

made in digest form by the Wodrow society (1842–49). He died at Jedburgh on Oct. 29, 1650.

CALDWELL, ERSKINE (1903–), U.S. author whose novel *Tobacco Road* added the southern poor-white to world literature and made its title a name for poverty, degeneracy and sex comedy. He was born in Coweta county, Ga., on Dec. 17, 1903. Because of his father's frequent moves as a home missionary of the Associate Reformed Presbyterian Church, Caldwell's schooling was irregular. He attended Erskine college, Due West, S.C., and the University of Virginia, Charlottesville, but did not graduate. From his numerous and fantastic jobs as listed in *Call It Experience* (1951) and other autobiographical statements, he not only gained an extraordinarily broad experience of life in the U.S. but also developed an active social conscience. His text for *You Have Seen Their Faces*, in collaboration with Margaret Bourke-White (1937), and such stories as "Candy-Man Beecham" still arouse indignation against injustice.

Caldwell was a prolific writer whose fiction had very large sales, but his reputation rests on three novels—*Tobacco Road* (1932), *God's Little Acre* (1933) and *Tronble in July* (1940). After 1940 Caldwell produced nothing that equaled these three novels, but there was no question as to his great narrative gift or his perfect ear for southern country speech. Both these gifts were first exhibited fully in his collected stories, *Jackpot* (1940), but his mastery of the story has not been properly appreciated. (S. McI.)

CALDY (YNYS BŶR), an island in Carmarthen bay, Pembrokeshire, Wales, lies 2¼ mi. S. of Tenby. It is 1½ mi. long from east to west and at its widest nearly 1 mi. across, with about 9 mi. of coast line. Excavations have produced Neolithic remains and Roman pottery of the 1st century A.D. It is known that Ynys Bŷr was inhabited in the 6th century by monks and the hermit Pyro who was succeeded as abbot by Samson, later archbishop of Dol and now Caldy's patron saint. In the 12th century Caldy became a cell of the Benedictine monastery of St. Dogmael's, Pembrokeshire, and the remains of those buildings are part of the old Priory church (St. Illtyd's) which contains a stone doubly inscribed with Ogham characters (see OGHAM SCRIPT) and Latin. After the dissolution of the monasteries Caldy changed hands many times until in 1906 it was bought by the Reformed Order of Anglican Benedictines who built the present monastery and original abbey church. In 1928, 15 years after becoming Roman Catholics, they moved to Prinknash near Gloucester, having sold the island to Reformed Cistercians (Trappists) from Chimay in Belgium. These monks cultivate the island and grow herbs from which they make perfumes. Caldy has a small village, and a lighthouse (1828) at its southernmost point.

CALEB, in the Old Testament, one of the spies sent by Moses from Kadesh in south Palestine to spy out the land of Canaan. Only Caleb and Joshua advised the Hebrews to proceed immediately to take the land; for his courage he was rewarded with the promise that he and his descendants should possess it (Num. xiii–xiv). Subsequently Caleb settled in Hebron (Kiriath-arba) after driving out the three sons of Anak; he gave his daughter Achsah to Othniel, his brother, who took nearby Debir (Josh. xv, 13–19; cf. Josh. xiv, 6–15; Judg. i, 10–20). In the time of David, a Calebite named Nabal, the husband of Abigail, lived at Maon, south of Hebron (I Sam. xxv).

The stories of Caleb probably represent the movements of a clan that invaded Palestine from the south, settled in the region of Hebron and southward, and eventually became absorbed in the tribe of Judah. He is called "the son of Jephunneh the Kenizzite" in Num. xxxii, 12; Josh. xiv, 14, and his brother Othniel is called a "son of Kenaz" (Josh. xv, 17; Judg. iii, 9), the latter being counted as a descendant of Esau (Edom) in Gen. xxxvi, 11. This may mean that the clan was loosely related to the large group known as Edomites living south and southeast of Palestine, but it was not antagonistic to the Hebrews. That this clan was eventually absorbed into the tribe of Judah is indicated by the fact that Caleb is described as being from the tribe of Judah in Num. xiii, 6; xxxiv, 19, and that Judah in the later tradition was considered to have given Hebron to Caleb (Judg. i, 10, 20). In the genealogies of I Chron. ii, Caleb is apparently a descendant of Judah. Since

the word "Caleb" means dog, some scholars believe the dog was originally the totem of the clan. See also JUDAH; JERAHMEEL.

CALEDONIA, the Roman name of north Britain. There were (1) a district Caledonia, of which the southern border as understood by Tacitus lay beyond (*i.e.*, to the north of) the isthmus between the Clyde and Forth rivers, (2) a Caledonian forest (possibly in Perthshire) and (3) a tribe of Caledones or Calidones, assigned by the 2nd-century geographer Ptolemy to Glenmore in Inverness-shire. The Romans first occupied Caledonia in the first sense under Agricola in A.D. 82, penetrating deeply and fighting the decisive battle of the war, according to Tacitus on the slopes of the Mons Graupius. Agricola's temporary camps of an army on the move have now been identified as far north as the Pass of Grange (Banffshire), where the Mons Graupius may well have been. Permanent occupation centred upon the legionary fortress of Inchtuthil (near the village of Dunkeld in Perthshire near the union of the Tay and Isla rivers), and is represented by large forts for auxiliary troops in Perth at Callander, Dealginross near Comrie, Fendoch in Glenalmond, Cardean near Meigle, and in Angus, at Stracathro near Edzell, all blocking the highland passes; also at Ardoch, Strageath on the Earn river and Bertha on the Tay river (all in Perthshire). Inchtuthil, however, was evacuated about A.D. 90 and with it all sites north of the Earn, all Scotland being abandoned during the first half of Trajan's principate. Finally Hadrian fixed the frontier to the south of the Cheviot hills. About A.D. 142, when the district up to the Firth of Forth was again annexed, a rampart with forts along it, the wall of Antoninus Pius, was drawn from sea to sea (*see* BRITAIN: Roman Britain; ANTONINUS PIUS). At the same time the north road as far as the Tay at Bertha and Carpow was reoccupied in an attempt to gain political control of Strathmore (the large valley in central Scotland extending through the counties of Perth, Angus and Kincardineshire). But the conquest was stubbornly resisted, and after at least two risings the land north of the Cheviot hills was lost not earlier than A.D. 180–185. In A.D. 209 the emperor Septimius Severus carried out an extensive punitive expedition against the northern tribes who had overrun Hadrian's wall in A.D. 197, and a similar incursion in A.D. 296 evoked a comparable campaign by Constantius I. The occupation was military and produced little civilizing effect. Details of native conditions are beginning to be revealed by excavation. The "crannogs," or lake dwellings, and the underground stone houses, locally called "weems," in which Roman objects of trade have been found, belong to this age. Ptolemy gives a list of tribes and place names, but no certainty has been reached about ethnological problems, though the non-Indo-European character of the Pictish language is now generally agreed.

CALEDONIAN CANAL, a waterway connecting the east and west coasts of Scotland. In 1773 James Watt was employed by the government to make a survey for such a canal, which was constructed by Thomas Telford and opened in 1822. From the northern entrance on Beaulie firth to the southern, near Ft. William, the total length is about 60 mi., that of the artificial portion being about 22 mi. The number of locks is 28, and their lift is in general about 8 ft., but some of them are for regulating purposes only. The canal is now little used because of its small size and the increased power and range of steam fishing vessels. *See* WATERWAYS, INLAND.

CALENDAR, a word derived from the Latin *kalendne* (calends), literally, the day on which the accounts are due. It now refers to an accounting, usually for civil purposes, of days and other divisions of time. The calendar now used for civil purposes throughout the world is called the Gregorian calendar, after Pope Gregory XIII, who introduced it in the 16th century. Chronology

(*q.v.*), the science of reckoning time by regular divisions or periods, is closely related to calendar development. The present article discusses the important calendar systems in use from prehistoric to modern times in different regions of the world, and is outlined as follows:

- I. Primitive Calendar Systems
 1. Days, Hours, Weeks and Months
 2. Seasons
 3. The Year
 - Solar Year
 - Lunar Year
 4. Time Determination by Stars and Moon
 5. Solstices and Equinoxes
 6. Intercalation and Extracalation
 7. Early Methods of Time Reckoning
- II. Western Calendar
 1. Roman Republican Calendar
 2. Julian Calendar
 - Easter and the Ecclesiastical Calendar
 - Dionysian or Great Paschal Period
 - Cycle of Indiction
 - Julian Period
 3. Gregorian Calendar
 - Epacts
 - Adoption and Adjustments
 - Calendar Reform
 4. Perpetual Calendars
- III. Chinese Calendar
- IV. Egyptian Calendar
- V. Hindu Calendar
 1. Nakshatra System and Other Early Systems
 2. Classical Calendar Forms
- VI. Babylonian and Assyrian Calendars
 1. Babylonian Calendar
 2. Assyrian Calendar
- VII. Jewish Calendar
 1. Months and Important Days
 2. Origin
- VIII. Greek Calendar
 1. Days and "Thirds"
 2. Months
 3. The Year
 4. The Athenian Prytany Calendar
- IX. Muslim Calendar
- X. Middle American Calendars
 1. Maya Calendar
 2. Mexican Calendar

I. PRIMITIVE CALENDAR SYSTEMS

Early man required a calendar primarily for religious observance although, of course, when he settled in agricultural communities he came to need a civil calendar as well. Unlike modern man, who uses artificial time intervals, often of a very sophisticated kind, primitive man utilized the cycle of recurring natural phenomena familiar to him in his everyday life. The most obvious and most precise of these were the alternation of night and day and the phases of the moon. The phases of the moon were considered important because their full cycle coincides with the menstrual period of women, which was deemed of great significance by many primitive tribes and was usually accompanied by various taboos; the phases of the moon are also significant for the hunter. Other less precise but naturally recurring phenomena were also made use of for calendar purposes; *e.g.*, the sprouting of leaves, the habits of animals (especially the birth of their young'), the coming of the rains or of the dry season, or the periodic flooding of rivers. In general, however, these less precise phenomena can best be described as a "discontinuous" form of time reckoning, because their cyclic return is markedly irregular. Longer periods of time for which lunations were considered inconveniently short were often marked off in the form of the number of harvests, the number of snows or the total of some other easily noted occurrence; thus, a child who has lived through ten harvests or ten snows is ten years old. Methods such as these formed the foundation of the more elaborate calendars of later civilizations.

As might be expected, primitive man was both intrigued by and in awe of the various celestial phenomena that were displayed before him in the clear night skies. He recognized the stars, long before he invented written records, by grouping them into patterns which could be identified either with familiar animals or with the gods, goddesses, heroes, heroines and creatures of mythology

(see CONSTELLATION). Thus the pattern of the stars was recognizable in a way which allowed, in due course, of a synthesis between the predominant constellations and the natural phenomena such as the sprouting of leaves and the advent of dry and wet seasons. This grouping of stars into constellations not only allowed patterns to be recognized but also enabled particular stars to be referred to without difficulty. It was then possible to trace the path of the moon and, more particularly, that of the sun, through the sky. Because primitive man rose with the dawn and, generally speaking, went to bed at sundown, he naturally watched those constellations visible just before sunrise or just after sunset. More particularly he noted those which were on the eastern horizon at sunrise and on the western horizon at sunset and which were therefore about to rise or set at these times. By observing that a given group would rise each day about four minutes earlier than the day before, he could work out the constellation in which the sun was situated by watching the risings of those stars that appeared just before sunrise. Those stars about to set just after sunset gave, as it were, the other side of the field of stars in which the sun lies. These heliacal risings and settings of stars (*i.e.*, risings and settings that coincide with the rising and setting of the sun) thus allowed the position of the sun among the stars to be derived. This evidence of the sun's position is not, of course, direct because the very appearance of the sun in the sky renders the stars invisible; but by using the phenomenon of heliacal risings and settings and by so tracing the sun's apparent circling of the heavens it is possible to obtain a calendrical year. Seasonal activities in nature—the ripening of plants, the birth of certain young animals, the coming of the rains—were correlated with the changing position of the sun among the stars. Moreover, natural phenomena were also associated with the height to which the sun rose above the horizon at midday; thus those times at which the sun reached its greatest altitudes, and in consequence would be above the horizon for the longest period, would be at midsummer. Primitive civilizations used the shadows cast by trees or by a stick placed vertically in the ground (a gnomon) to measure the maximum altitudes reached by the sun. In such a way they could discern the seasons by means of what are, in fact, astronomical measurements.

The moon's phases follow the cycle new moon to new moon (see MOON). Technically, new moon occurs when the moon lies directly between the earth and the sun and, in consequence, cannot be seen. While it is clear that the full cycle of the moon's phases was used by primitive man in his lunar reckoning it is equally clear that his lunar cycle must have had an easily observable commencement. It is likely, therefore, to have begun when the moon first appeared in the evening sky as a thin crescent—indeed, this crescent is still often referred to as "new moon." The cycle of the moon's phases gives a first approximation to the month (it takes $29\frac{1}{2}$ days) so that it was a natural interval for primitive man to use for this reason as well as for those mentioned above. (Modern months are, of course, arbitrary periods of numbers of whole days.) The use of a true seasonal year based on the sun's position among the stars as distinct from a year based purely on seasonal changes in nature, which are subject to fluctuation, was obviously a later development. Thus it is seen that primitive man began his calendar by utilizing the more obvious natural phenomena. As he progressed, so his calendar was increasingly based on astronomical observations.

1. Days, Hours, Weeks and Months.—The day is to some extent a natural division of time. However, its subdivision into a number of equal intervals of, for instance, 24 hours, is a late development and although of great convenience is purely artificial. In the most primitive societies the day was recognized merely as an alternation between light and darkness and in many languages there is no word meaning day—which is perhaps not surprising since the concept of a day as a period of 24 hours involves a marrying together of the periods of light and darkness into one unit. The expressions "light and darkness" were sometimes used but, in general, primitive man counted days as so many dawns, suns, nights or sleeps. The ancient Teutons used terms derived from counting in nights, *viz.*, sennight (a week) and fortnight (two

weeks). Divisions of the light period were at first based upon the daytime effects of sunlight, namely, daybreak, sunrise, noon, afternoon, twilight, sunset and so on; upon the compass position of the sun, sometimes in relation to natural and local surface features (the peoples of the far north particularly noted where the sun lay in relation to mountain peaks at various times of day); and also upon the occurrence of daily events such as the crowing of cocks, the yoking or unyoking of oxen and the siesta. There were many variations in reckoning the commencement of the day. Dawn was used by some and in Israel the day began at evening. The present method of reckoning from midnight is a late innovation and it is of interest to note that astronomers, for convenience in observing, use a day beginning at noon which allows them to keep the same date throughout night observations.

The artificial division of the day into hours became necessary for commercial reasons as trade became more than just a simple system of barter. When the concept of hours was first used these intervals were unequal in duration; this was because people had the idea of an equal number of hours per natural division of the day; *i.e.*, the time between dawn and dusk consisted of just so many hours. Therefore, as this period would be longer in summer than in winter, the summer daylight hours would be of longer duration than their winter counterparts. As far as night was concerned, time indication was best obtained by observing the passage of the stars across the sky. However, with the advent of mechanical clocks, hours of equal duration became more convenient and have since been adopted in all civilized countries.

The week is an entirely artificial division of time and cannot really be correlated with any astronomical or natural phenomena except insofar as it is a closed cycle of days. Again it is in trade that an explanation of the beginning of this concept is to be found. It occurred among those primitive peoples advanced enough to undertake regular trading and appeared first as the interval between market days. This market week varied in length according to the area in which trading occurred. For example, among some west African tribes the interval was four days; in central America it was five days; the ancient Assyrians used a six-day interval; while the ancient Romans had a *nundinae* or eight-day period and the Incas a ten-day interval. It has been suggested that the seven-day week of the Israelites may have been derived from the market week, but it must be remembered that their seventh day differed from that of other peoples in that it was not only set aside for religious observance but was also accompanied by taboos against trading and certain other activities. If, then, this suggested derivation is correct, it would seem clear that some change in outlook occurred when Israel took over this concept. It was, however, a habit of certain other ancient peoples, especially in Africa, to set apart one day each week for religious observance.

The seven-day week which is now universally used may have been derived from the mystical significance attached to the number seven. Support for this view may perhaps be derived from the use of the names of gods and goddesses for each of the seven days. The Romans and the Saxons used such a nomenclature, which has been carried on to modern times as Table I shows.

The month is, as has been said, a calendrical period derived from the lunation. As the earliest adopted of the longer calendar periods, it had a significance in religious observance. The Jewish calendar was a lunar one and a lunar calendar is still used in the Christian church and by Islam, while monthly (lunar) reckoning is, of course, the method universally used for calculating pregnancy. A total of 12 lunations amounts to 354 days and is, roughly, a year. A period of 12 lunations was therefore used by some primitive peoples to make their year, while others used one

TABLE I.—Days of the Week

Latin name	French name	Saxon name	English name
Dies Solis	Dimanche	Sun's day	Sunday
Dies Lunae	Lundi	Moon's day	Monday
Dies Martis	Mardi	Tiw's day	Tuesday
Dies Mercurii	Mercredi	Woden's day	Wednesday
Dies Jovis	Jeudi	Thor's day	Thursday
Dies Veneris	Vendredi	Frigg's day	Friday
Dies Saturni	Samedi	Seterne's day	Saturday

of 13 months; the former period was too short by $11\frac{1}{4}$ days and the latter too long by $18\frac{1}{4}$ days, and thus the solar year and calendar could not be correlated exactly with a lunar-based calendar. Various arrangements were adopted by early civilizations, but only gradually did a solution along the lines of the present system become accepted. The fact that the month is still used is merely a recognition of its utility as a conveniently brief calendar division.

2. Seasons.—In all except tropical countries the seasons are fairly well-defined, but even in tropical lands there are alternating rainy or dry periods. It was the seasons of the more temperate countries which led to the use of a solar calendar as distinct from a lunar one, the reason for this change being the need to have a calendar which was closely tied to the agricultural year of sowing and reaping. Such an agricultural calendar might not, of course, be one of an actual year's duration because it depended upon the natural phenomena chosen to represent seasons and on their frequency. For example, in the tropics the dry and rainy seasons were chosen, and because there are two dry and two rainy periods per solar year the primitive "year" of peoples in tropical lands, which comprised one dry and one rainy period, was of only six months' duration. In temperate climates the seasons can be correlated with agricultural changes, but again this does not necessarily mean that a solar year is chosen; the Teutonic peoples recognized only winter, spring and summer—three seasons—and their choice did not, therefore, result in a true year. Moreover, the seasons are not of equal duration and they undergo minor variations from year to year. In consequence they are not, per se, particularly suitable for calendar periods; those chosen depended entirely upon local climate. However, as more elaborate civilizations developed and trade between peoples increased, the need for an agricultural calendar in which the seasons of one people could be correlated firmly with the seasons of another became vitally necessary. Gradually, then, because seasonal changes are directly dependent upon the position of the earth in its annual orbit around the sun, a solar calendar was adopted over those comparatively large areas of the world where nations traded with one another.

In primitive times seasonal changes were often correlated with regular changes in the habits of animals. Thus in Greece the cry of migrating cranes was an indication that it was time to sow or to reap, and the climbing of plants by snails signified that plowing in the vineyards should cease. Changes in plant life were also observed for this purpose, suitable conditions for sea navigation being indicated by the sprouting of fig trees. Indications of this kind have been used from the earliest times and have not been limited to settled agricultural communities only. Farmers still make use of such indications, and rightly, for calendar dates are artificial and a late spring or late autumn, without particular significance for the townsman or for the factory worker, has a great importance for the farmer. Nowadays the seasons are only general indications of the time of year.

3. The Year.—The year, as now understood, is a concept of comparatively late development in mankind's history. In primitive times it grew from the need to have a calendar period longer than the month. Such a period became essential to early peoples when they wished to compare the age of one man with that of other men. The lunation is too short to be convenient for such a measurement and is wholly inadequate for reckoning the life span of groups of people. The method of counting by generations was evolved comparatively early, as was also the habit of calculating years not by numbers but by reference to some notable event. Thus a plague, a famine, a war, a migration, an unusually large harvest, etc., would form significant points from which counting could commence or recommence. This method was widely used, for example, in early Arabia, in Babylonia and as far away as North America among the Indian tribes. Later, the beginning of the reign of a new monarch or chief was used as the starting point for counting while, where the ruler was changed annually, the years were named for him—in Rome for the consul and in Greece for the archon.

The requirement of a long calendar period meant that some

cycle of repeated phenomena had to be chosen, and the most primitive long calendar periods appear to have been those based on a cycle of seasons or, more precisely, on an association of natural phenomena of such a kind that phenomena within it would recur in the same order. Such a grouping need not necessarily coincide with a true year. A calendar period which contained one monsoon and one dry period and which had a "year" of six months has already been mentioned. That the true year is a later conception is shown clearly in this instance, because the two monsoon periods are in fact different, one monsoon blowing from the southwest and one from the northeast, and to compound a calendar period containing both the southwestern and the northeastern monsoon required a degree of sophistication which would not be expected to occur early. Another example of an early grouping of phenomena to give a calendar period longer than the month may be seen in the vegetation year, which lasted for ten months, the gap between one such period and the next being passed over. Again, a true year required a more sophisticated approach and meant that the use of concrete phenomena was supplanted in favour of an astronomical computation. Thus it is plain that the concept of a year needs to be based upon astronomical observation.

Solar Year.—It is now known that the true year is that period of time in which the earth performs one revolution in its orbit around the sun. This period is found by noting the apparent passage of the sun through the constellations; *i.e.*, one journey of the sun along its apparent path—the ecliptic (see **TIME MEASUREMENT**). The year thus computed, called the "tropical year," contains 365 days 5 hr. 48 min. 46 sec. of mean solar time, *i.e.*, 1 min. 14 sec. less than $365\frac{1}{4}$ days. While mean solar time is an artificial subdivision of the day, the fact that the orbital period of the earth is not a whole number of days is real enough; thus for a calendar period to be formulated for the year, it is necessary to have a 365-day period and then to make some arrangement to take account of the fractional quarter day. The most convenient method of doing this is to wait for it to accumulate to a whole day. If the fraction is left out of consideration, the 365-day year will, over the centuries, come to begin at different seasons and the year as a calendar period will thus be made useless. It is, however, necessary to use some period, even though it be other than the true astronomical year. Such a period is the civil year, which has three basic requirements to fulfill. It must contain the full series of the seasons; it must always begin at the same season; and the lunar calendar should, as far as possible, be incorporated in it. Therefore such months as are used for it must be of equal length, or as nearly so as can be arranged.

Once the concept of a year had been achieved, various attempts were made to meet these three requirements. Observations of the heliacal risings and settings of certain stars made it possible to select a time, geared to the sun's position on the ecliptic, for the beginning of the year. In this way the beginning of the year could, apparently, be kept at a fixed time from both equinox and solstice (see **SOLSTICES AND EQUINOXES**, below). However, this fixture could not be exact, because the seasons are determined both by the earth's position in its orbit and by the inclination of its axis to the plane of this orbit. The seasons therefore gradually get "out of step," because although the angle of inclination of the earth's axis remains static, its direction in space is continually altering (see **PRECESSION OF THE EQUINOXES**). This precession of the axis is observable, over many years, as an apparent motion of the ecliptic against the background of the stars; in consequence, if the commencement of the year is taken from observed heliacal risings and settings of particular stars, the year will get out of alignment with the sun's true position in the sky and thus with the seasons. For the year to keep in correspondence with the seasons it must correspond with the equinoxes, for precession alters the time at which these occur and an additional correction to the number of days in the year is required—in other words, use of the fractional quarter mentioned above is not sufficiently accurate. The early civilizations which adopted the year did not, of course, realize this. The very small correction necessary was for a long time unobservable, and the phenomenon of precession remained undiscovered until *c.* 130 B.C. As a result, the Egyptians, who com-

menced their year with the heliacal rising of the star Sirius, found, after centuries, that instead of continuing to coincide with the flooding of the Nile, this rising occurred at an increasingly later time. With the discovery of precession a new precision in the calendar reckoning of the year was possible. Just as the quarter day was accounted for by the addition (intercalation) of a whole day every four years, so the effect of precession could be taken into account by postponing the intercalation of a day by one year whenever the precessional factor amounted to, *e.g.*, a quarter day.

Because the lunar cycle cannot be exactly reconciled with the year, if it is decided to make the month at least as long as a lunation, then either the months must contain unequal numbers of days—as in all modern calendars—or days left over after equal-number months must be unallotted and intercalated each year. The latter approach has, after due experience, given way to the former in which the months, although not equal in length, are very nearly so.

Lunar Year.—A period of 12 lunar months constitutes a lunar year. If a lunar month is counted as $29\frac{1}{2}$ days, the lunar year contains 354 days. It is thus $11\frac{1}{4}$ days shorter than the solar year and a cycle of lunar years will, therefore, become progressively more and more out of step with the seasons. After 34 lunar years the difference between the lunar calendar and the solar calendar reaches a minimum, but it is still significant. For these reasons a lunar year is of no real use for calendar purposes; its use as a collection of lunations only may be of help to primitive peoples whose time reckoning is based on the lunar month.

The incompatibility of the lunar and solar years was one of the problems which had to be faced by early civilizations. The lunar calendar had great religious significance while the solar calendar had a prime importance from the seasonal or agricultural point of view, and it was early desired to marry together the two systems. This could be accomplished only by extending the lunar year of 12 lunar months, either by adding a number of monthless days at the end of the year or by taking an artificial value for each month and by so doing destroy the nature of the month as a truly lunar period. In either event the dates of those religious festivals determined by lunations must change from year to year.

4. Time Determination by Stars and Moon.—The problem of indication of time within the year cannot easily be solved by reference to seasonal changes for the simple reason that the length of particular seasons is not constant from year to year. Some other means of time measurement must be found, and the stars, particularly their heliacal risings and settings, provide a ready and accurate one. Such a system requires familiarity with the constellations and with the brighter stars, and most primitive peoples had some form of star recognition. The Indians of South America, the Polynesians and Melanesians, for example, as well as other primitive civilizations, knew the stars well. Homer and Hesiod refer to the various constellations and bright stars and, as do other classical authors, indicate time by referring to the rising and setting of certain stars. For example, they state that vines should be pruned before Arcturus is seen to rise in the evening, and that autumn storms are to be expected, and autumn sowing should be undertaken, when the Pleiades are seen to set before dawn. Even now, certain primitive peoples count the time of year by the Pleiades. Some South American Indians use the Pleiades to indicate the passage of a solar year and, indeed, have the same word for both Pleiades and year. The Egyptians used the heliacal risings and settings of Sirius for the same purpose. Intervals of time during the night may also be determined by the stars; this was done before the advent of accurate clocks and it is still considered necessary to teach military recruits to tell the time in this way.

The course of the moon in the sky and the cycle of its phases provide a natural division of periods of time intermediate between the year and the day. These periods are short enough to be remembered easily and the phases can be noted at a glance; therefore, the month constitutes a natural, definite and limited unit of time. Moreover, the phases follow one another with a gap of only a few days (new moon) when no moon is visible, so that they present an almost continuous sequence from waxing to waning;

this doubtless suggested to early man the idea of continuous time reckoning. The lunation was often divided into two periods, corresponding to the waxing and the waning of the moon, while some peoples even divided it into four, the extra divisions being made at the first and last quarters. The moon's phases were of great importance for religious observance, and at both new moon (*i.e.*, the first thin crescent) and full moon, festivals were often held.

5. Solstices and Equinoxes.—The solstices and equinoxes are, of course, dependent upon the apparent position of the sun. At solstice the sun reaches that position on the ecliptic where it is at its furthest north or south from the celestial equator and "stands still" before moving again toward it. At equinox the sun is at one of the two points where the ecliptic intersects the celestial equator, so that day and night are then of equal length. The sun's positions are important because they indicate the seasons. At summer solstice the sun appears at noon at its maximum highest altitude above the horizon, while at winter solstice it reaches only its minimum highest altitude. The solstices may be observed either by noting the length of the shadow cast by a gnomon or by using a fixed observing point and noting the sun's position in relation to local landmarks. The latter course was practised by, for example, the Indians of Arizona and the Eskimos, while the gnomon was used in middle eastern countries and in Greece. The observation of the equinoxes is more difficult and requires at least some means of measuring the relative duration of daylight and darkness. Certain of the more advanced primitive peoples, such as the Eskimos, the northern Scandinavians and the Polynesians, made such observations.

6. Intercalation and Extracalation.—Intercalation is the insertion of an additional day or days in a calendar in order to bring it into line with the solar year. For a lunar year of 12 lunations, the total number of days that must be added is $365\frac{1}{4} - (12 \times 29\frac{1}{2})$, or $11\frac{1}{4}$ days. Extracalation is the marrying together of a lunar year of 13 lunations with the solar year by subtracting days; in this case the number of days subtracted from the lunar year is $(13 \times 29\frac{1}{2}) - 365\frac{1}{4}$, or $18\frac{1}{4}$. In the 12-lunation year the lunations will precede the seasons earlier and earlier if the process of intercalation is not used, while in the 13-lunation year the months will arrive later and later than the appropriate seasons unless extracalation is carried out. The question facing those who compile a calendar is to decide when intercalation or extracalation is to be done. If the series of months is named for and is intended to fit into a seasonal pattern, then the purpose of the procedure is to keep these months in their proper positions.

The earliest method of carrying it out involved the repetition or removal of an entire lunation, so that the change occurred at most only every three years. Very often in the 12-lunation year that lunation which coincided with the harvest was repeated, its first appearance in that year being referred to as "lost" or "forgotten." In the 13-lunation year that lunation was omitted which had become so out of step that it usurped the position originally held by the lunation which followed.

From the practice of intercalation there arose the lunisolar year, which had alternately 12 and 13 months, but this soon became out of step with the seasons because of the seven-day error ($-11\frac{1}{4} + 18\frac{1}{4}$ days) every two years. A more exact method of synchronization was to name some or all of the months (lunations) after appearances of stars or constellations coinciding with the true solar year. Such, for example, was the practice of the Indians of northwest America and the peoples of Polynesia. In Babylonia, before the middle of the 3rd millennium B.C., a series of 12 months was used and one particular month was singled out as that to be intercalated.

The intercalation was, in primitive civilizations, an empirical procedure and occurred when the seasons and their appropriate months became noticeably and sufficiently out of step. The decision to intercalate or not was taken by the priests, for they were concerned with the religious observances tied to the calendar. Empirical intercalation continued into Greek times, but in the 7th century B.C. the Greeks introduced a cycle of intercalation known as the octaeteris and in this way began the scientific regulation of the calendar. The solar year is a naturally recurring cyclic

phenomenon and, in a sense, has no natural beginning. The commencement of a lunisolar year was, however, often tied to the agricultural year, but even this could lead to wide variations.

7. Early Methods of Time Reckoning.— Any calendar system involves the recording of the days, lunations or years which have passed. Early peoples did this by means of some kind of tally. But as the calendar system became more sophisticated (for example, in the computation of a lunisolar year), the methods of reckoning became more elaborate, and it seems likely that the abacus was used. The reckoning was in the hands of the priests, and they saw to it that the religious festivals which, in the most primitive societies, had been regulated purely by lunar phenomena or by the beginning and ending of seasonal activities like sowing and reaping, were celebrated regularly. Thus the priesthood, through the accumulated knowledge and experience of many generations, acquired considerable information on calendar matters. Usually this information was jealously guarded. There has been much research on the methods of calculation used in Babylonian times, and it is clear that by the 2nd millennium B.C. a considerably developed system of arithmetical calculation existed. Recording was carried out in cuneiform script on clay tablets which were later baked for permanence. It is the work of those early peoples who first tackled the questions relating to the correlation of lunar phenomena, the seasons and the cyclic appearances of stars and constellations, which furnished the basic material and methods of attack for the development of the modern system of time reckoning and the more sophisticated type of calendar.

II. WESTERN CALENDAR

1. Roman Republican Calendar.— The calendar of the Roman republic was similar in style to the Greek calendar. It was, however, more primitive than the latter and appears to have been derived from an earlier Roman calendar which was lunar. This earlier calendar contained ten lunations which ran from March to December and had a two-lunation gap in the winter. The information available about the Roman republican calendar is derived from the fragmentary pre-Julian calendar of the city of Antium, extant about 70 B.C., as well as from various later literary references. The republican calendar contained 12 months—seven equal in length to a lunation, four with two additional days each and one with one day less. Thus the total length of the calendar year was 355 days, or $10\frac{1}{4}$ days less than the solar year. The months were named as follows, the figures in parentheses giving the number of days in each: Martius (31), Aprilis (29), Maius (31), Iunius (29), Quintilis (31), Sextilis (29), September (29), October (31), November (29), December (29), Ianuarius (20) and Februarius (28).

The earlier calendar was traditionally attributed to Numa Pompilius, the second king of Rome (c. 716–673 B.C.), and it was also believed that Ianuarius and Februarius were the months which were added in order to bring the calendar up to its full quota of 12 months. Certainly the leaving of a gap of 60 days, as such a ten-month year would entail, is not unknown in many early civilizations. It has also been suggested that the 12-month form of the calendar was due to the Etruscans of Tuscany, and in support of this theory it is claimed that the name of the fourth month, Iunius, is a derivation from *Iunonius*, which is connected with the Etruscan form of the name of the goddess *Uno* (Juno).

March remained the first month of the year for a long period, but the name *Ianuarius* has been taken by some scholars to indicate that the Etruscans, whose dynasty was expelled early in the fourth century B.C., had commenced the year in January, since this title referred to the festival of the god of gates or god of "first beginnings." The commencement of the year on Jan. 1 instead of March 1 became officially recognized in 153 B.C. However, in the popular mind the year was thought to end on Feb. 23 (the *Terminalia*), for it was after this date that intercalation was made. An intercalary month, the *mensis intercalaris*, which occurred once or twice every four years, was followed by the remaining five days of February.

The operation of the calendar was under the jurisdiction of the pontifices or priests. Every month they watched for the new moon and proclaimed its appearance; after the dedication of the

Capitol in 509 B.C. the proclamation of the new moon was made from there, as was the announcement of the appropriate *nonae* or "nones," i.e., the ninth day of the month before the *idus* or ides, the backward reckoning from the ides being inclusive. The ides fell in mid-month, this being the time of the full moon. They occurred on the 15th day in Martius, Maius, Quintilis and October and on the 13th day of the other months. In consequence there were either seven or five days from the beginning of the month to the nones—seven in the months Martius, Maius, Quintilis and October and five in the remainder. The first day of the month, the day of proclamation of the new moon and of the nones, was known as the *kalendae* or callings. The second day was known as the *postridie kalendas*, and this day, the *nonae* and the *idus* were believed to be unlucky, the *postridie kalendas* especially so. The *nonae* were sometimes festival days, while on the *kalendae* sacrifices were offered to Juno, the spouse of Jupiter, and to Janus, the god of beginnings; the *idus* was held sacred to Jupiter.

The Roman republican calendar made use of *nundinae*; i.e., ninth days or market days, which resulted in the use of an eight-day interval or "week" between *nundinae*. These weeks were independent of the months. They had no individual names and were unconnected with any religious festivals; they were, indeed, merely intervals between one market day and the next. Some days of astrological significance are to be found in some later calendars of the republic; such days were known as "Egyptian" (*dies Aegyptiaci*), but they had nothing to do with any Roman religious cult. On the other hand, some of the months had religious associations with the god Mars, and the festival of purification (*februa*) occurred in Februarius. Festivals were most often held on odd-numbered days and, if a festival lasted for more than one day, there were gaps of either one or three days in between: for example, the festival *Lucretia*, which lasted two days, was held on Quintilis 19 and 21 and the *Carmentalia*, honouring the prophetess Carmentis, on Ianuarius 11 and 15.

Inscriptions given on the calendar (many of which have survived) showed for each day a sign to indicate its civil standing. Some of these were: F for *fas* (lawful), indicating those days available for legal business; N for *nefas*, indicating days not so available; C for *comitialis* (relating to the *comitia* or assembly), indicating days on which a meeting of the assembly could occur; and NP (perhaps *nefas feriae publicae*), denoting public feast days on which sacrifice was offered. Such permissions were sometimes divided during a day; thus a day could be *nefas* in the morning and evening and *fas* in the afternoon.

Elaborate and ingenious though the republican calendar was, it became hopelessly confused by the end of the republic both because of failures on the part of the priests and because of political maneuvers. The calendar was interfered with so as, for example, to reduce or extend the term of office of a particular magistrate. It therefore needed revision, and this was undertaken by Julius Caesar in the first century B.C.

2. Julian Calendar.— The Julian calendar, the basis of the civil calendar now used throughout the world, was derived from the Roman republican calendar as reformed by Julius Caesar. By 46 B.C. the republican calendar had become so seriously out of step with the seasons that the calendar equinox had become separated from the astronomical equinox by three months. As a result, the seasons were no longer in proper relationship with the calendar months: winter was carried back into the autumn months and autumn into summer. Caesar, as *pontifex maximus* and dictator, and advised by the Alexandrian astronomer Sosigenes, began his reformation in 36 B.C. by intercalating 67 days between the months November and December, thus making that year 445 days in length. By this action the civil and astronomical years were brought into line and the stage was set for a new calendar which would avoid the errors of the old.

For his new calendar to have any degree of permanency, Caesar realized that so gross a discrepancy between the astronomical and civil calendars must be prevented from occurring again. Dictatorial action was necessary and, upon the advice of Sosigenes, the lunar calendar was abolished and it was decreed that regulation should be on the basis of a solar calendar. Sosigenes also sug-

gested, from astronomical evidence, that the length of the year should be $365\frac{1}{4}$ days. But such a length was not practical inasmuch as an odd quarter day could not be fitted into a civil reckoning. It was therefore decided that there should be a four-year cycle in which the first three years each had 365 days and the fourth year 366 days. The new calendar was first adopted in 45 B.C., over 700 years after the date on which Rome is believed to have been founded, and the year was taken to begin on Jan. 1.

There has been a tradition that in his reformation of the calendar Julius Caesar so ordered matters that the odd-numbered months, *i.e.*, January, March, May, July, September and November, each had 31 days; April, June, August, October and December 30 days; and February 29, or 30 days every fourth year. However, there seems to be no evidence, either ancient or modern, to support this view, and indeed the grammarian Ambrosius Theodosius Macrobius (4th–5th century A.D.) in his *Saturnalia* flatly contradicts it. In 44 B.C. the month Quintilis was renamed July as a memorial to Julius Caesar's reform.

The emperor Augustus is reputed to have made in 7 B.C. adjustments to the Julian calendar rendered necessary by a mishandling of the intercalations in the 38 years since its adoption; it is said that he lengthened the month Sextilis and had it renamed Augustus in his own honour. However, research during the 19th century led most scholars to the conclusion that much was attributed to Augustus without warrant, and that certainly the lengthening of the month Sextilis and its renaming as August should not be credited to him. Macrobius gives evidence which indicates that Sextilis was renamed by the consuls Asinius Gallus and Marcus Censorinus. The idea of renaming months after emperors appears to have continued, for Macrobius and others say that Caligula changed the name of September to Germanicus in memory of his father and that Domitian decreed that October should be called after himself. These last two decrees seem to have been abolished after the deaths of these emperors, however, for the surviving names of the months are those of the original Roman republican calendar with, of course, the changes of Quintilis and Sextilis to July and August respectively.

The additional day which Julius Caesar had decreed should be inserted every fourth year was intercalated in February, the shortest month, between the 23rd and 24th days, and thus occurred after the sixth day preceding the calends (first day) of March. This intercalation resulted in any fixed festival which occurred after February falling on the next weekday but one to the day on which it fell in those three years when intercalation was not made. Thus the intercalation caused Feb. 23 to occur twice in the intercalary year; the intercalated day was therefore known as the *bissexto* kalendas and the year in which the intercalation occurred as a bissextile year. (The modern term "leap year" appears to have been derived from the Old Norse *hlaupar*, although the term "bissextile" is still used occasionally).

The Julian calendar assumed the length of the year to be equal to 365.25 days, whereas the tropical year (the apparent passage of the sun from one solstice to the same solstice again, or from equinox to equinox) is nearly 365.2422 days. The calendar year was therefore 0.0078 days, or a little over 11 min. 15 sec. too long. This small fractional error does not, of course, become significant until a long time has passed and amounts only to a little over a day after 130 years. Thus it is clear that the Julian calendar was a satisfactory means of so arranging the civil dating that the seasons occurred at the same time each year; and only after centuries did it become so markedly out of step with the seasons that an attempt to provide a still more refined method of calendar reckoning had to be considered, with intercalation more exactly regulated over a period longer than the Julian four-year cycle.

Easter and *the Ecclesiastical Calendar*.—The Julian calendar brought order into the computation of dates and, being in principle a solar calendar, was successful in correlating the civil and astronomical years over a long period, thus keeping the seasons and the months in step. However, it could act only as a guide for the regulation of the dates of religious festivals in the Christian Church because the chief of these were founded on events dated by the Jewish lunar calendar. The Christian Church had therefore

to find a method of reckoning these festivals and of synchronizing the observance of each by Christians throughout the world: this necessitated the construction of a combined lunisolar calendar. Those festivals based on Jewish reckoning were movable, *i.e.*, they were held on a different date each year in consequence of their dependence on the phases of the moon; while those established by later ecclesiastical decree, *e.g.*, commemorations of saints, could be immovable, *i.e.*, on the same date each year, through being reckoned by the solar calendar and not by the lunar.

The earliest question to be decided was the date of Easter, which is the most important of the church's festivals and from which the dates of all other "movable" feasts are determined. There arose, by the 2nd century A.D., disputes among Christians concerning the date on which it was proper to celebrate Easter. Because the crucifixion occurred before the Jewish Passover, Easter was computed according to the Jews' mode of determining this festival. The Passover was ordained to be celebrated on the 14th day of the first month of the new year; *i.e.*, of the lunar month whose 14th day falls on or next follows the vernal equinox. However, because the civil calendar was of solar origin and because Sunday was the main day for Christian congregational worship, it became generally agreed that the Sunday next following the date of the old Jewish Passover should be the date set aside for Easter. There were, however, those who wished to take a more literal view and to observe the exact Jewish date and so celebrate Easter on the 14th day of the lunar month; *i.e.*, on the day usually conceded to be the time of full moon. These literalists, or Quartodecimans, as they were called, were a minority and were regarded as heretics. In A.D. 325 the ecumenical Council of Nicaea ordained that Easter day should thenceforth be celebrated on the Sunday immediately following either that full moon which occurs on the day of the vernal equinox or, if there is no full moon on that day, then on the Sunday following that full moon which occurs next after the day of the vernal equinox. In order to prevent the festival from coinciding either with the Jewish Passover or with the celebrations of the Quartodecimans, special provision was made, should the full moon actually occur on a Sunday, to defer the celebration of Easter until the next Sunday.

It was now necessary to make sure that every congregation held the festival on the same date in the solar calendar. Because the time of Easter depended upon the occurrence of astronomical phenomena—*i.e.*, full moon and vernal equinox—tied to the tropical year, the problem to be solved was that of marrying together the civil week, the lunation and the astronomical (solar) calendar. Because of the nature of the case the rules for doing this could not be simple, and the determination of Easter is complicated. The rules constitute what is known as the ecclesiastical calendar.

The first thing to do is to correlate the civil and the astronomical calendars. The problem is, therefore, to devise a means whereby the day of the week corresponding to a given day in any year can be found. The total number of days in the week is 7; the total number of whole days in the year is 365. Because 365 is not exactly divisible by 7, two successive years cannot begin on the same day of the week. Thus, if one year begins on a Sunday, the next year will begin on a Monday or, if it is a leap year, on a Tuesday. Now if some system is arranged so that the day of the week with which any particular year commences can be ascertained, then the dates on which the days of the week will fall throughout that year can be determined. For the ecclesiastical calendar, therefore, it was decided to allot to each day of the week a letter, beginning at the commencement of the year with the letter A, so that Jan. 1 is A, Jan. 2 is B, and so on, Jan. 7 being denoted by G; after which the cycle commences again with Jan. 8 as A. One of the letters A to G, depending on which weekday Jan. 1 comes, will then fall on Sunday. Every Sunday during that particular year will be represented by this same letter. If, for example, Jan. 3 happens to be a Sunday, then the letter C will represent it and every other Sunday throughout the year. This Sunday code letter, known as the dominical letter, is then given to the year, thus indicating how all the weekdays are placed with respect to the dates throughout the year.

In the Julian calendar the dominical letters recur in the same

order every 28 years; this forms a comparatively short cycle which is computed by multiplying the number of years in a complete Julian cycle (*i.e.*, four, because every fourth year is a leap year and can be considered to complete a cycle) by the number of days of the week, because these cover the complete series of the dominical letters. The date of this invention is unknown but it would appear not to have been earlier than the Council of Nicaea. The 28-year cycle was known as the cycle of the sun or the solar cycle, and after a complete round the same dominical letters referred to the same civil calendar dates as at the commencement of the cycle. Thus a table of dominical letters could be drawn up and, provided that the tabulation covered a period of 28 years, the dominical letter for any year could readily be found. The cycle was taken to have commenced nine years before the Christian era, making the year A.D. 1 the tenth year of the first solar cycle, and the following rule to determine the position of any year in the cycle was formulated: Add 9 to the date and divide the sum by 28; the quotient is the number of cycles elapsed and the remainder is the year of the cycle. Should there be no remainder then, of course, the year concerned is the final year of a cycle.

Once the position of a year in the solar cycle has been determined, its dominical letter can be ascertained provided that the dominical letter of the first year of the Christian era is known. This began on a Saturday and, as the tenth year of the first solar cycle, had the dominical letter B. The year A.D. 2 is then denoted by C, A.D. 3 by D, A.D. 4 by both E and F (because it was a leap year and thus put the dominical reckoning out by one day; *i.e.*, by one letter) and A.D. 5 by the letter G. A.D. 6 started the dominical letter group over again with A. The dominical letter which begins a solar cycle can be found by working out this sequence.

Next, for determining Easter, the lunar nature of the festival had to be taken into account. The framers of the ecclesiastical calendar took lunations to consist alternately of 29 and 30 days (making up a lunar year of 354 days) and adopted a lunar cycle on this basis. This cycle was equal to 19 Julian years; *i.e.*, it amounted to $19 \times 365\frac{1}{4}$ or $6,939\frac{3}{4}$ days. Now 6×19 lunations of 29 days each amounts to $6 \times 19 \times 29$ or 3,306 days, and 6×19 lunations of 30 days each amounts to 3,420 days; together these total 6,726 days. In 19 Julian years there are five leap years (unless the fourth year of the 19-year cycle is itself a leap year, in which case there are only four); in consequence, the total number of days in the lunar cycle would be either $6,726 + 5 = 6,731$ days or $6,726 + 4 = 6,730$ days. Six intercalary months of 30 days each (a total of 180 days) as well as one intercalary month of 29 days were added during the cycle to make it coincide as closely as possible in length with 19 tropical years. Thus the total number of days in a lunar cycle amounts either to $180 + 29 + 6,731 = 6,940$ or to $180 + 29 + 6,730 = 6,939$. The average length of the lunar cycle is, therefore, $\frac{1}{2}(3 \times 6,940 + 6,939) = 6,939\frac{3}{4}$ days, and thus it exactly equals 19 Julian years.

By means of this lunar cycle the dates of new moon could be indicated in the civil calendar, for the cycle virtually places these phenomena on the same days of the month, and thus the phase of the moon on any given day in one year of the cycle will be the same in the equivalent year of the next cycle. In consequence a table showing the phases of the moon for 19 years will serve for any year provided that the number in the cycle of that year is known. This cycle is sometimes known as the Metonic cycle (see Greek Calendar, below). A year's number in the cycle is called its golden number, perhaps because of the colour with which it was marked in ancient calendars, or perhaps because of its importance for the determination of Easter.

The golden numbers were introduced about the year 530, but were arranged as they would have been if they had been adopted at the time of the Council of Nicaea. The cycle was taken to begin in a year when new moon fell on Jan. 25. This date for new moon occurred in the year preceding the commencement of the Christian era, and so to find the golden number for any year the rule is: Add 1 to the date and divide the sum by 19; the quotient is the number of lunar cycles elapsed and the remainder is the golden number. When the remainder is zero, that year is the last of a

cycle. However, the true motions of the sun and the moon are not completely regular and, in consequence, while a complete lunar cycle is very nearly correct, there are errors in it which often become significant during its progress, and the actual new moon may be as much as two calendar days from its theoretical position as calculated by the cycle.

Dionysian or Great Paschal Period.—The solar cycle brings back the days of the month to the same day of the week, and the lunar cycle restores the new moons to the same day of the month; therefore the cycle $28 \times 19 = 532$ years includes all the variations involving the new moons and the dominical letters, and is consequently a period after which the new moons again occur on the same day of the month and the same day of the week. This "grand cycle" was first employed by the astronomer Victorius of Aquitaine, who had been appointed by Pope Hilarius about 465 to revise and correct the church calendar, and the cycle was therefore known as the Victorian period. However, its use for determining Easter by the 6th century Scythian monk Dionysius Exiguus (Denis the Little) led to the more usual appellation Dionysian period or Great Paschal period.

Cycle of Indiction.—The Roman emperor Diocletian (reigned A.D. 284–305) instituted a census for taxation purposes and ordered that it be taken every 15 years. This 15-year period later became known as the cycle of indiction. It had no astronomical significance, and as it was primarily a fiscal period, its date of commencement could be varied if necessary. Gradually its use became more widespread and it was sometimes utilized for other than financial purposes. During the middle ages the cycle was taken as commencing on Jan. 1. It was used in the 11th century and later as a form of dating for charters and public deeds, the year of indiction being given as well as the year of the Christian era. Taking Jan. 1 as the commencement of each year in the cycle and reckoning backward from the year 313, it is found that the first year of the Christian era would have been the fourth year of a cycle of indiction; in consequence, the rule for finding the position in this cycle of any year may be expressed as follows: Add 3 to the date, divide the sum by 15, and the remainder is the year of indiction. When the remainder is zero, that year is the 15th or last of a cycle.

Julian Period.—Obviously a calendar showing months and days is convenient from the civil point of view, but it is not a suitable means for counting back long periods of time in order to find out how many days have elapsed since the occurrence of some astronomical phenomenon or civil event. This problem was tackled in 1582 by the Italian Protestant scholar Joseph Scaliger (1540–1609). He realized that during a period made up of the product of the solar cycle, lunar cycle and cycle of indiction, *i.e.*, $28 \times 19 \times 15$ or 7,980 years, no two years can be expressed by the same number in all three cycles. He therefore proposed the use of this very long period for chronological purposes, and it became known as the Julian period. Scaliger fixed its commencement arbitrarily at Jan. 1, 4713 B.C., thinking that this would be early enough to include all historical events and all precisely observed and recorded astronomical phenomena. The great value of the Julian period is that each day is consecutively numbered from Jan. 1, 4713 B.C., so that the interval between any previous event and the present time can be precisely ascertained. So numbered, the days are known as Julian days. By international agreement among astronomers, who are now the primary users of the system, each Julian day is taken as commencing at noon so that observations made during the night can be referred to by one calendar date.

3. Gregorian Calendar.—Although the Julian method of intercalation was not only convenient but also provided a calendar whose length closely approximated the tropical year, its deficiency showed up in due course, so that further reform became imperative. Its basic defect was that, in taking a period of $365\frac{1}{4}$ days as the length of the tropical year, it overestimated this length by a little more than 11 min. 15 sec. or, more exactly, by 0.0078 days. Thus, although the error amounted only to one whole day in 128 years, it was constantly increasing and over a long time became troublesome. By A.D. 730 it resulted in the vernal equinox having advanced by three days from its position in the calendar at the time of the Council of Nicaea, and this was noted by the English

historian Bede of the monastery of Jarrow. By the 13th century the discrepancy had increased to just over seven days; attention was drawn to this fact by the Paris professor Johannes de Sacrobosco (John of Holywood, *fl.* 1230) in his *De Anni Ratione*, as well as by Roger Bacon, who wrote a treatise, *De Reformatione Calendarii*, suggesting that a change should be made. This treatise was not published but was transmitted to the pope. No action was taken and it was not until the 15th century that there was a revival of criticism of the calendar; the discrepancy between the true vernal equinox and its calendar date of March 21 by then amounted to nine days. In 1472 Pope Sixtus IV invited the astronomer Johann Miiller (Regiomontanus) to come to Rome to superintend the necessary changes in the Julian calendar, but Regiomontanus was assassinated in 1476 and no reformation took place. In the 16th century, after further criticisms the Vatican again made an effort to reform matters, and this time it was successful. Pope Gregory XIII approached the governments of the principal states of the Holy Roman empire, and all agreed to accept his alterations. He then promulgated a new calendar known as the Gregorian or new style calendar in a brief issued in March 1582.

Gregory was advised in his reformation by the Neapolitan astronomer and physician Aloysius Lilius or Luigi Lilio Ghiraldi. But Lilius died in 1576, before the reformation was fully completed, and Gregory then sought the assistance of the German Jesuit and mathematician Christopher Clavius (1537–1612), who verified all the calculations and developed the rules. Clavius published his *Romanii Calendarii a Gregorio XIII P.M. restituti Explicatio* in 1603.

The first thing to do in preparing a new calendar was to take account of the fact that the tropical year amounts to 365.2422 and not 365.25 days. This difference amounts to three days in 128×3 or 384 years, *i.e.*, to approximately 3 days in 400 years; and it was this approximation which Gregory adopted. To take account of this difference Gregory ordered that no century year should be counted as a leap year unless it was exactly divisible by 400. By the time this reformation took place the displacement of the beginning of the year had increased to ten days, so Gregory directed that the day following the feast of St. Francis, *i.e.*, Oct. 5, should be reckoned as Oct. 15. In consequence the next vernal equinox fell correctly on March 21 instead of on March 11. The difference between the Gregorian calendar (new style) and the Julian calendar (usually referred to after this reformation as old style) remained ten days until the year 1700, after which it amounted to $10 + 1$, or 11 days, because the year 1700 was a leap year in the old style but not in the new. These procedures of changing the intercalation of leap years and dropping 10 days were simple enough, but problems arose concerning the change required in the lunar cycle.

Epacts.—It was Lilius who tackled this problem of changing the lunar cycle. It amounted to 6,939.75 days, whereas the true period, for 235 lunations, should have been 235×29.530588 or 6,939.68818 days. Because a lunar cycle covers 19 Julian years, the difference of 0.06182 days amounts to one whole day in a little over 307 years and so, after this period, the new moons occur one day earlier than indicated by the golden numbers. For the reform it was decided, therefore, to reject the golden numbers and adopt the "epact." (This term was derived from the Greek *epakte* and meant, originally, an intercalation, but was later used to signify the age of the moon at the beginning of the year.) Now the difference between the calendar year and the lunar year is $365 - 354$, or 11 days; and therefore if a new moon falls, for example, on Jan. 1 in one year, it will be 11 days old on Jan. 1 of the next year and 22 days old on Jan. 1 of the year after that. The epact of the second year is then said to be 11 and that of the third year, 22. However, Lilius gave every third year of the lunar cycle an intercalary month of 30 days; therefore in the fourth year the age of the moon on Jan. 1 would be not 33 days but only 3. It might, therefore, appear that to find the epact of any particular year, 11 should be added to the epact of the previous year and, when the sum exceeds 30, deduct 30. However, the problem of leap years and the above-mentioned inaccuracy of the lunar cycle have to be taken into account.

The omission of a leap year every century except when the date was exactly divisible by 400 meant that the omission of the intercalary day would result in the astronomical new moon occurring one day later in every month following such an omission. Thus the age of the moon would be one day less at the end of every such month. Therefore it was necessary that the epact should be diminished by unity, and so the epacts 11, 22, 3, 14, etc., would become 10, 21, 2, 13, etc. On the other hand, the lunar cycle was not exact; as mentioned above, the error amounted to one day in a little over 307 years, the astronomical new moon arriving one calendar day earlier. This required an increase of the epact by unity so that epacts 11, 22, 3, 14, etc., became 12, 23, 4, 15, etc. What was subtracted in order to bring matters into line through more accurate intercalation had largely to be added on again to allow for errors in the lunar cycle, and it was therefore decided that any change in the epact which might be required should be held in abeyance until the commencement of the appropriate century. Corrections of the epact for errors in the lunar cycle were to be made only at the end of 300 years, and in the Gregorian calendar this correction was assumed, for convenience, to amount to one day in $312\frac{1}{2}$ years or eight days in 2,500 years. Thus changes of epact were made at the end of seven successive 300-year periods and once at the end of a 400-year period. From the way in which the epacts were disposed at the time of the reformation of the calendar, it was found that the most correct result was to be obtained by assuming one of the 2,500-year periods to terminate with the year 1800. Reckoning from the time of the Gregorian reform, the correction to the epact for intercalation occurs in the years 1700, 1800, 1900, 2100, 2200, 2300, 2500, etc., and that for the lunar cycle in 1800, 2100, 2400, 2700, 3000, 3300, 3600, etc. In the former instances the epact is diminished by unity; in the latter it is augmented by unity. When the changes coincide, as they do in the years 1800 and 2100, for example, no change in epact is made.

In the light of the above, epact numbers can be so calculated as to minimize calendar errors. Because the purpose of the epact is to indicate the age of the moon at the beginning of a year, it is clear that, in the course of time, the epact will have values ranging from 1 to 30 inclusive to correspond with the days in a full lunar month. To compute the epact the last date of the last lunation of the previous year is taken; this shows the date of the last new moon in the year and thus the age of the moon on the last day of that year is found. The moon's age in days is the epact of the next year. For example, if the last lunation ends on Dec. 2, then the last new moon falls on Dec. 3, and so the age of the moon on Dec. 31 is $31 - 2$, or 29 days. The epact of the year following is therefore 29. Similarly, if the last lunation of the year had occurred on Dec. 3, the epact of the year following would have been 28. This computation will only be altered if the new year to which the epact applies is 1700, 1800, 1900, 2100, etc. If it is 1700 the epact is $29 - 1$ or 28 because of intercalation; if it is 1800 the epact is $29 - 1 + 1 = 29$ owing to intercalation and the correction for the lunar cycle. In 1900 intercalation makes the epact 28 again; in 2100 the double correction will leave 29 once again unaltered.

The principal use of the epact is in determining Easter, the date of which is regulated by the moon's age as given by it, with the vernal equinox taken as occurring on March 21. Even the Gregorian calendar is not exact and the vernal equinox can be as much as two days early, so that a full moon may occur after the true equinox but still before the calendar equinox (March 21); however, it is the calendar equinox which is the regulating factor. Thus the ingenious but complicated system invented by Lilius meant that the date of Easter could be determined without reference to astronomical observation solely by the correct use of tabulated values. Moreover, the epacts were so arranged that there was no chance for the paschal full moon to coincide with the Jewish Passover.

Introduction of the Gregorian calendar also involved a change in the dominical letters because of the omission of an intercalary day every 100 years; this change makes it possible to use the dominical cycle throughout a century. However, since the cycle

contains 7 days and since in the Gregorian calendar the full intercalary period is 400 years, the dominical letters will repeat after 7 X 400 or 2,800 years. Tables can be made to cover this period completely.

Adoption and Adjustments.—The Gregorian calendar was adopted in various Italian states, in Portugal, in Spain and in France in the same year (1582) as in Rome. The Roman Catholic states of Germany followed suit in 1583. Protestant countries did not immediately adopt the Gregorian calendar, but clung tenaciously to the Julian for over 100 years longer. In 1700, however, the imperial diet of Regensburg decreed the Gregorian calendar for the Protestant states of Germany. Nevertheless the golden numbers and epacts for determining Easter and the movable feasts were not adopted; instead, the paschal moon was determined by astronomical calculation from Johannes Kepler's "Rudolphine" tables, which he had dedicated to the emperor Rudolph II in 1627. In 1774, however, the Prussian king Frederick II ordered this method to be abandoned. The Protestant countries of Denmark and Sweden adopted the Gregorian calendar at about the same time as the German Protestants. Russia did not alter until the advent of the Soviet government (1917).

Great Britain, too, took a long time to make the change. In 1751, however, a Calendar (New Style) act was passed and the Gregorian calendar was thenceforth ordered to be used for all legal and public business. By that time the difference between the Julian and Gregorian calendars amounted to 11 days and it was, therefore, further enacted that the day following Sept. 2, 1752, should be termed Sept. 14. Many people did not understand the nature of the change and were under the misapprehension that they were being cheated in some way: riots ensued with the slogan "give us back our eleven days." At the same time that the calendar was adjusted, the date of the commencement of the new year was also changed. Hitherto the year had begun on March 25, but by the act of 1751 this was changed to Jan. 1—an enactment which had been carried out in Scotland as early as 1600. (It is important to remember this when dealing with legal deeds executed in Scotland between 1600 and 1751.) For the determination of Easter the rule laid down by the Council of Nicaea was adopted, but the epacts and golden numbers were fixed by the full moon instead of by the new moon. In the Church of England calendar, in those years when the course of the epacts is changed in the Gregorian calendar, the golden numbers are moved to refer to different days. A new arrangement of the table is, of course, made at the years 1800, 1900, 2100, etc. By means of this scheme, Easter is celebrated on the same date as that computed by the Gregorian calendar but, because the Church of England calendar changes from century to century, it is essentially of the same general form as the old Roman calendar.

The Orthodox church in Greece has adopted the Gregorian calendar with a 900-year cycle, but computes the date of Easter by means of the moon's actual movements rather than the simplified assumptions of the ecclesiastical calendar, basing its calculations on the meridian of Jerusalem.

Later, a slight change was made in the Gregorian calendar to bring it still more closely into line with the tropical year. The Gregorian calendar is still in error by one day in 3,323 years and, in consequence, a further rule of intercalation has been adopted that makes the years 4000, 8000, etc., common years, *i.e.*, years without an intercalated day. The calendar is now, therefore, correct to within one day in 20,000 years.

Calendar Reform.—A number of proposals designed to give greater regularity to the Gregorian calendar have been suggested. One proposed calendar, called the International Fixed calendar, would divide the year into 13 months of exactly four weeks each: The present month names would be retained (although some have suggested the use of Roman numerals instead), and the extra month, called Sol, would fall between June and July. The day following Dec. 28, *i.e.*, the 365th day (366th day in leap year), would bear no designation of month or weekday. In leap years, the intercalary day would be the day following June 28, and it also would bear no designation of month or weekday. Every month would begin on Sunday and end on Saturday. A serious disadvantage of

the 13-month year from a business standpoint is that it is not readily divisible into quarters.

Another proposal involves the so-called World calendar, which would divide the year into four 91-day quarters of three months each. In each quarter the first month would have 31 days and the last two months would have 30 days each. The day following Dec. 30 would bear no designation of month or weekday, nor would the intercalary day following June 30 in leap years. The twelve month names would be the same as at present, and January 1 would fall on Sunday, as would April 1, July 1 and October 1. In the International Fixed calendar, the dates of holidays would be fixed and annual production of new calendars would no longer be necessary. Critics of the World calendar have pointed out that each month would extend over parts of five weeks, and that each month in a given quarter would begin on a different day of the week.

4. Perpetual Calendars.—So-called "perpetual calendars" give the date and the day of the week either throughout the future or for hundreds of years. Such calendars may be of the chart or of the mechanical type.

The chart calendar covers long periods. In the late 18th century some chart calendars were published, an example being the Secular Diary of D. Barstow, which covered all dates from 1601 to 1900 inclusive. More elaborate kinds were produced in the 19th century, such as that published in Edinburgh in 1868 by John Gardiner. Called *A Perpetual Almanack and Calendar for the Investigation of Dates*, it was printed on stiff paper and had a kind of slide-rule calculator as an integral part. By its use the days of the week in both old, and new styles could be found for all past and future dates.

Mechanical types of perpetual calendar vary in complexity. Probably the simplest kind is the desk calendar, where the date, the month and sometimes also the day of the week are changed by hand. A certain amount of automatic control is found in the calendar wrist watch, in which a date wheel rotates once every 24 hours; but manual correction has to be made from time to time because of the variable number of days in a month. In some wrist and pocket watches a month wheel, performing one-twelfth of a rotation during each revolution of the date wheel and displaying the name of the month in abbreviated form, is incorporated as well; a few models have a wheel rotating once every 29 days so that the phases of the moon may be displayed. This feature is also to be found in certain old clocks having long cases.

Perpetual calendars of considerable complexity have been fitted to clocks. A French mechanism consisted of an automatic device to take account of the unequal lengths of the months and also of the February leap-year day. Similar mechanisms have on rare occasions been incorporated into pocket watches. (CN. A. R.)

III. CHINESE CALENDAR

It is well known that the ancient Chinese reckoned their days, months and years by a sexagenary cycle formed from the combination of 10 celestial stems and 12 terrestrial branches. Each double name in the cycle consists of a stem name (in roman) and a branch name (in italics). In order to complete the cycle of 60 the 10 stem names are repeated five times alongside the 12 branch names, which are repeated four times. (See Table II.)

Some of these cyclical names were supposed to have originated as far back as the 27th century B.C.; however, books recording these dates were mostly written between the 6th and 4th centuries B.C. and were based on sources of the 11th century B.C. and later. It is thus difficult to say exactly at what time the sexagenary cycle was invented. The inscribed oracle bones excavated in Honan

TABLE II.—Stem Names and Branch Names in Chinese Calendar

1. Chia-tzu	11. Chia-hsü	...
2. I-ch'ou	12. I-hai	...
3. Ping-yin	13. Ping-tzu	...
4. Ting-mao	14. Ting-ch'ou	...
5. Wu-ch'en	15. Wu-yin	...
6. Chi-szu	16. Chi-mao	56. Chi-wei
7. Keng-wu	17. Keng-ch'en	57. Keng-shen
8. Hsin-wei	...	58. Hsin-yu
9. Jen-shen	...	59. Jen-hsü
10. Kuei-yu	...	60. Kuei-hai

from the mausoleums of the Shang dynasty (c. 1766–c. 1122 B.C.) have revealed that the ancestors of the founder of this dynasty, during the preceding two centuries, were designated with characters taken from the stem and branch names, and that in the Shang calendar the 60 names in the cycle were borne by each 60 consecutive days. This 60-day period was divided into six *hsün*, each of ten days. Because the first day of each *hsün* contains in its double name the stem name "Chia," the six *hsün* were referred to as the "six Chia." Throughout all ages the 60-day cycle has been an essential part of the lunar calendar used in China and in those neighbouring countries, such as Japan, Korea and Vietnam, which have inherited Chinese culture.

Application of the cyclical names to months and years does not occur on the inscribed Shang bones or on the inscribed bronze vessels of the Chou dynasty (c. 1122–256 B.C.), but books of the later Chou period occasionally give the cyclical names with the number of lunar months or with years of a king's reign. Books on history and astronomy written from the 5th to the 3rd centuries B.C. (e.g., *Tso Chuan*, *Shih's Classic of Astronomy*) indicate that a cycle of 12 years, known as *Chi*, was used since the 7th century B.C. In this cycle each year was designated by a special name, which was related to the constellation through whose zodiacal sign the pear star (*Sui-hsing*, or Jupiter) passed. The names of the 12 years were arranged according to the order of the 12 terrestrial branches, beginning with the third branch (*Yin*) and ending with the first two branches (*Tzu* and *Ch'ou*), as shown in Table III.

TABLE III.—*Twelve-Year Cycle Based on Jupiter's Positions*

Designation of year	Branch order	Position of year star
1. She-t'i-ke	3. Yin	
2. Chih-hsü	5. Yin	Ch'ü-tzusiao (Capricornus)
3. Chih-hsü	5. Ch'e	
4. Ta-huang-lo	6. Su	Chiang-lü (Aries)
5. Tun-tsang	7. Wu	Ta-liang (Taurus)
6. Hsieh-hsia	8. Wei	Shih-ch'eng (Gemini)
7. T'un-t'an	9. Shen	Chun-shou (Cancer)
8. Tso-o	10. Yu	Chun-huo (Leo)
9. Yen-mao	11. Hsü	Chun-wei (Virgo)
10. Ta-yüan-hsien	12. Hai	Shou-hsing (Libra)
11. K'un-tun	1. Tzu	Ta-huo (Scorpio)
12. Ch'ih-fen-jo	2. Ch'ou	Hsi-mo (Sagittarius)

But since Jupiter takes approximately 11.86 years to complete its course in the zodiacal belt, there were certain solar years when Jupiter's positions did not coincide with the predicted zodiacal signs into which it was expected to enter. When after a number of years Jupiter was observed to have advanced to a position corresponding to its next year's zodiacal sign, it was described as having "leaped over one constellation" (*ch'ao-ch'en*).

The Chinese civil year normally consists of 12 lunations of alternate! 30 days for a "big month" and 29 days for a "small month." But, unlike the Muslim lunar year, it has always been adjusted to the length of the solar year. This is best illustrated by (1) its insertion of one intercalary month in a period of three civil years, or of two intercalary months in a period of five years or of seven in a period of 19; and (2) its division of the solar year into 24 equal portions, using the equinoxes and solstices as four fixed points. Each portion is called a *chieh* (node) and has 15.218 days. The 24 *chieh* have between them two generic names: the first, third, fifth, etc., are called *chieh-ch'i* (node-portions); the second, fourth, sixth, etc., are called *chung-ch'i* (centre-portions). Because the celestial sphere is divided into 360°, the first *chieh* of the year, *li-ch'un* (advent of spring), is a *chieh-ch'i* on which the sun reaches 315° (i.e., Feb. 5); the fourth *chieh* of the year, *ch'un-fen* (vernal equinox), is a *chung-ch'i* on which the sun reaches 0° (i.e., March 22); the winter solstice is the day on which the sun reaches 270°; etc. In this way the four seasons of the solar year are neatly divided, each covering six *chieh* of which three are *chieh-ch'i* and the alternative ones are *chung-ch'i*. Since the interval between two *chung-ch'i* lasts for 30.436 days, i.e., longer than the synodic period of the moon, it must happen that in some lunar months the sun does not enter a new sign, or that a *chung-ch'i* does not occur in a certain lunation. Such a lunar month is designated "intercalary" (*jun*), and it is called by the ordinal number of its predecessor with *jun* added as

a prefix. The 24 *chieh* have been regarded by the Chinese peasants as a strict timetable for their farm work.

The Chinese day is divided equally into 12 periods (*shih*, or double hour) named after the 12 branches (*Tzu*, *Ch'ou*, *Yin*, *Mao*, etc.). The first period, *Tzu*, begins at midnight and lasts for two hours. The last period, *Hai*, ends at midnight. In ancient times, when the water clock was used, the whole day was divided into 100 *ke*. On the summer solstice the day consisted of 60 *ke*, the night of 40; on the winter solstice these numbers were reversed. With the advent of the western clock in the 18th century the *ke* came to mean "a quarter of an hour." The night was divided into five matches, each lasting for two hours. The first watch, at 8 P.M. clock time, coincided with the ancient curfew.

(WU S.-C.)

IV. EGYPTIAN CALENDAR

The Egyptians appear to have begun with a lunar calendar. There is no definite proof of this, but the writing of the word "month" with the moon symbol, the importance of the monthly and half-monthly festivals in later times and the adoption of the month as a unit in the later calendar place it beyond doubt.

At a very early date, the Egyptians had begun to observe the heliacal rising of the star Sirius or Sothis, a conspicuous object in the Egyptian sky. The Egyptians noted that this rising corresponded very closely with the rise of the Nile, on which the agricultural welfare of the country depended. Small wonder then that they chose this for the first day of the year, and took the period between two such observed risings to form a unit of time which was convenient not only as being much longer than the old month, but as including a complete cycle of the seasons.

made the basis of the year was not subdivided into the changing seasons. Twelve nominal months of 30 days each gave 360 days, and the missing 5 days were added on at the end under the name of "days additional to the year." The months were grouped into three sets of four, the first four forming the inundation season, the second four the winter or sowing time and the third four the summer or harvest.

The constructors of this calendar either overlooked or ignored the fact that every four years, as observation must have shown, Sothis rose a day later, i.e., after a lapse of 366 and not 365 days, the reason being, as is now known: that the star year, which is virtually identical with the solar year, measures about 365¼ days. This error meant that their calendar got out of gear with the solar year, and consequently with the seasons, to the extent of one day every four years. The error became greater and greater until eventually, after 1,460 (365 × 4) solar years, known as a Sothic period, the calendrical New Year's day had worked right around the seasons and come back to its correct place again. The Egyptians were not unaware of this error, but it was not until quite late times that they sought to correct it by the insertion of an extra day every four years (leap year), and even then the attempt failed.

The Latin writer Censorinus (fl. 3rd century A.D.) states in his *De Die Natali* that the first day of the Egyptian calendar year coincided with the rising of Sothis in A.D. 139, and it must therefore have done the same thing 1,460 solar years earlier and before; i.e., in 1321 B.C., 2781 B.C., 4241 B.C., 5701 B.C., etc. Quite possibly it was at one of these times that the calendar was introduced. The religious texts inscribed in the pyramids of the 5th and 6th dynasties show that the calendar with its five extra days was then already in existence. Egyptologists consequently date the introduction of the calendar to 4241 B.C. or to 2751 B.C., according to whether they believe the pyramids to be earlier or later than the latter date. A still higher date, e.g., 5701 B.C., is hardly likely.

The Egyptians used no unit of time longer than a year. Consequently they had no dating by eras in the modern sense. In very early times each year was named after some important event in it, e.g., "The year of the first smiting of the east," and was at the same time connected with the reigning king. Later, under the 5th and 6th dynasties, the biennial cattle census was used for time reckoning, and the years of a king's reign were numbered alternately as "The year of the first (second, third, etc.) census" and

"The year after the first (second, third, etc.) census." Still later the years of the reign were numbered straightforwardly (1, 2, 3, etc.).

In early Egyptian documents the months bear no special names, being written merely as the first, second, third or fourth month of such and such a season. In the Persian period, however (6th century B.C.), there began to appear month names drawn from festivals which took place during the month; these names may of course have been used in speech earlier, even though they were apparently never written. Considerable uncertainty surrounds the origin of some of them, and the question is complicated by the fact that at some date in or before the Ramesside age all of the names seem to have been shifted one month back in the year.

The week of seven days was totally unknown to the early Egyptians, and the evidence brought forward for its existence in very late times is far from convincing.

The day and the night were each divided into 12 hours, but since the day was measured sometimes from sunrise to sunset and sometimes from the appearance of daylight to its disappearance, the length of day and of night varied through the year. Consequently the Egyptians cannot claim to have established the hour as a fixed unit of time. (T. E. P.)

V. HINDU CALENDAR

1. **Nakshatra System and Other Early Systems.**—In the most ancient Indian texts, the four Vedas, some elements of the calendar in use at that time are alluded to, although not fully described. At the time of the Rigveda (about 1500 B.C.) the duration of a civil year seems to have been estimated at 360 days, or 12 months of 30 days plus one intercalary month added to every cycle of five years. This is more clearly attested in subsequent texts, with some variations evidencing the diversity of the attempts to establish a convenient calendar. This calendar was lunisolar, simultaneously taking into account the revolutions of both the moon and the sun. The daily positions of the moon and the monthly positions of the sun were referred to 27 or 28 constellations on the ecliptic—the nakshatras. The list of these, beginning with *Krittika*, the Pleiades, is already given by the Yajurveda and by the Atharvaveda (between 1500 and 1000 B.C.). Thus, the *nakshatra* system was already in use at that time.

Although the method is not indicated, it must have been very simple, as it was in later times. The numbers 27 (Yajurveda) and 28 (Atharvaveda) both corresponded to a rough estimate of the duration of the lunar month. The positions of the moon and the sun each night among the nakshatras could be found—the positions of the moon were directly observable except at new moon, and those of the sun were deduced, at full moon, from the sun's opposition to the moon. At every midnight, the nakshatra culminating on the meridian indicated the sun's actual position, because the sun was, at that time, in the *nakshatra* 180° removed from that observed at the meridian. Any error in such a determination of the sun's daily position could be corrected at the next full moon.

The days of the new moon (*amavasya*) and full moon (*punyamasi*) divided the lunar month into two parts: the "bright one" (*sukla*), i.e., fortnight of increasing light from the new moon onward; and the "black one" (*krishna*), i.e., fortnight of decreasing brightness after full moon.

For some sacrificial and cosmographical purposes the civil (*savana*) month (*masa*) of 30 days (*ahoratra*) was used; it was intermediate between the lunar month and the solar month, each day being divided into 30 "moments" (*muhurta*). The number of these moments in an ordinary civil year (*samvatsara*) of 360 days was thus 10,800 (*Satapathabrahmana*). The adjustment of the civil year to both the lunar and the solar year was done not only by adding one civil intercalary month (*amhasapati*, *malimluca* or *samsarpa*) every five years but also by the addition of days. The average length of a year at the end of a period of five years (*yuga*) covering 61 civil months (1,820 days) plus 10 days, was 366 days (1,830 days in 5 years). According to the same computation, 62 lunar months of 29.5 days would elapse during the same period.

The year was generally divided for religious purposes into three

periods of four months each. Each period was itself divided into two seasons (*rtu*). Thus the seasons were six in number: *vasanta*, spring (months called Madhu, Madhava); *grisma*, hot season (months Sukra, Suci); *varsah*, rains (months Nabhas, Nabhasya); *sarad*, autumn (months Isa, Urja); *hemanta*, winter (months Sahas, Sahasya); *sisira*, dewy season (months Tapas, Tapasya).

The year was also divided into two other periods according to the apparent motion of the sun alternatively toward north and south. The first was the northward course, *uttarayana*, during which the point of sunrise is gradually moving northward from the winter solstice. The second was the southward course, *daksinayana*, during which the point moves southward from the summer solstice.

A brief treatise, the *Jyotisavedanga* ("The article of knowledge dealing with the heavenly lights"), which exists in two versions as a technical appendix to the Vedas and which probably dates from the last centuries B.C., uses the same calendar elements with some additions. It gives essentially the "knowledge of the times" (*kalajnana*) for the cycle of five years (*yuga*) beginning with the bright fortnight of the month of Magha (January–February) and ending with the black fortnight of the month of Pausa (December–January). That is, it begins at new moon, the sun and the moon being in conjunction in the constellation Delphinus, this time being taken also as the beginning of the northward course. Already, classical denominations of months appear side by side with the Vedic names. The times of junction between two consecutive fortnights (*paksa*) are called *parvan*.

Two kinds of seasons of 60 months were in use: the civil one (*savana*), consisting of 60 days, and the solar one of 61 days. A lunar season is one-sixth of the lunar month, and the lunar month is also divided into 30 lunar days (*tithi*).

The calendar of the Brahmanical books of rules (*sutra*) generally agrees with the Vedangajyotisa calendar; in it, the dates of rituals are adjusted to those of the latter. The ancient religious communities of Buddhists and Jains used a quite similar calendar. The most important Jain work on the subject is the *Suriyapannatti*.

2. **Classical Calendar Forms.**—With the introduction into India of much scientific material from Mesopotamian and Greek sources during antiquity and especially during the first centuries A.D., Indian astronomy no longer confined itself to adjusting ritual operations to the cosmic order. Methods of astrology and forecasting came into vogue, using largely Greek astronomical and astrological data side by side with the Brahmanical data. The main feature of the new calendar was the adoption of the zodiacal system without abandoning the *nakshatra* system.

The Sanskrit names of the zodiacal signs (*rasi*) are: Mesha (Aries), Vrishabha (Taurus), Mithuna (Gemini), Karkata (Cancer), Simha (Leo), Kanya (Virgo), Tula (Libra), Vrischika (Scorpio), Dhanus (Sagittarius), Makara (Capricornus), Kumbha (Aquarius), Mina (Pisces).

The *nakshatras* are mathematically defined as covering 13° 20' each, while the zodiacal signs cover 30° each. A *nakshatra* being divided into four parts (3° 20' each), every zodiacal sign corresponds to two *nakshatras* and a quarter. The entering of the sun into a given sign or constellation (these no longer coincide because of the precession of the equinoxes) is called *samkranti*. The most noticeable *samkrantis* are *Mesasamkranti* and *Makarasamkranti*, theoretically corresponding to the vernal equinox and to the winter solstice respectively. Two systems of notation are in use. The first (*sayana*) takes into account the precession and makes the distinction between the sun's entering into the constellation (Aries) and the true vernal equinox now in Pisces, but it gives to the entrance corresponding to the winter solstice the designation *Mesasamkranti*, *mesa* referring in this case to the so-called sign and not to the constellation. In the second system (*nirayana*) the precession is not taken into account and a theoretical vernal equinox is considered as occurring when the sun enters the constellation Aries.

In the Malayalam country (Kerala state, southwest coast), the names of the months are borrowed from the names of the zodiacal constellations in which the sun is situated. Elsewhere, the months are named according to the *nakshatras* in which the full moon

appears; *e.g.*, the month during which the full moon appears in the asterism *Citra* (the star Spica or α Virginis) is Chaitra. At that time, the sun is diametrically opposite, in the sign of Aries (now the constellation of Pisces). The month begins either with the new moon (*amanta* or *sukladi* system) or with the full moon (*ṣurnimanta* or *krishanadi* system).

The Sanskrit names of months generally in use are: Chaitra (March–April), Vaisakha (April–May), Jyaishta (May–June), Ashadha (June–July), Sravana (July–Aug.), Bhadrpada (Aug.–Sept.), Asvina (Sept.–Oct.), Karttika (Oct.–Nov.), Margasirsha (Nov.–Dec.), Pausha (Dec.–Jan.), Magha (Jan.–Feb.), Phalguna (Feb.–March). The year generally begins with Chaitra. These months, beginning with Chaitra, regularly correspond with the vedic months from Madhu onward.

Because of the differences in duration between lunar and solar months and the inequality of length of the solar months themselves, two lunar months may begin during the same solar month. In such a case, both these lunar months are called by the same name, the first being denoted as intercalary or additional (*adhika*) and the second as natural (*nija*). It is in the latter that the beginning of a new solar month occurs, and therefore it is the latter which is the starting point of a new period of adjustment between lunar and solar months. Less frequently, two solar *samkrantis* may occur in the same lunar month. Then there is a lack of one lunar month corresponding to the second *samkranti*; *i.e.*, one month suppressed (*ksayamasa*). Similarly, when two sunrises occur on the same lunar day (*tithi*), a second day is added with the same date number. When no sunrise occurs during another lunar day, one is omitted. In this way the solar and lunar elements of the calendar are made to agree by periodic adjustments.

The Hindu week, of seven days, is identical with the western week. The names of the days are: Ravivara (Sunday), Somavara (Monday), Mangalavara (Tuesday), Budhavara (Wednesday), Guruvara (Thursday), Sukravara (Friday), Sanivara (Saturday).

The classical Hindu almanac is called *panchang*, "having five members," because it chiefly indicates: (1) *tithis*, or lunar days; (2) *varas*, or weekdays; (3) *nakshatras*, or constellations through which the moon is successively passing; (4) *yogas*, or times during which the joint motions of the sun and moon cover the space of a *nakshatra*; (5) *karanas* or half *tithis*.

The most popular *panchangas* are based on the classical astronomical treatise *Suryasiddhanta*, which dates, in its present state, from about the 9th century AD. They are used for both ordinary and astrological purposes, and vary slightly in different parts of the country. Because one lunar month generally ends and the next begins during the course of a solar month, the solar month, taken as the current civil month, receives, for example, in the Tamil country the name of the first of these lunar months and in Bengal the name of the second. Therefore, the successive Tamil months Cittirai and Yaikaci correspond to the Bengali months Chaitra and Boisakho, etc. The Tamil names of the months are: Citterai (April–Xlay), Vaikaci (May–June), ANi (June–July), Adi (July–Aug.), Avani (Aug.–Sept.), Purattaci (Sept.–Oct.), Aippaci (Oct.–Nov.), Karttikai (Nov.–Dec.), Markali (Dec.–Jan.), Tai (Jan.–Feb.), Maci (Feb.–March), Pankuni (March–April).

The main divisions of the civil day (*divasa*) are the vedic *muhurta* (48 min.), or more usually the *ghatika* (24 min), containing 30 *kala* (48 sec.), 60 *pala* (24 sec.), 360 *prana* (4 sec.), 3,600 *vipala* (0.4 sec.) or 216,000 *prativipala* (0.00666 sec.).

With a view to unification of the Hindu calendar for official purposes, the government of India introduced throughout India a new calendar from 1 Chaitra, 1879 Suka era (see CHRONOLOGY: *Hindu*), which corresponds to March 22, 1957. (J. L. A. F.)

VI. BABYLONIAN AND ASSYRIAN CALENDARS

Two methods of time reckoning were available to the early inhabitants of Babylonia and Assyria in the preliterate period: one was based on the periodic motion of the sun, the moon and the stars, the other on the equally periodic growth of plants such as cereal grains and fruit trees. The former method originated among populations worshipping the heavenly bodies, whereas the latter was used by farmers whose gods embodied the forces of

nature that influence plant life. With the development of writing and the ensuing recording of observations, calendars based on the statistical evaluation of such observations came into use.

1. Babylonian Calendar. — The daily rising and setting of the sun provided the basic time unit of the Babylonian calendar, the day (Akkadian *umu*, Sumerian *ud*). The day began at sunset and was, for astronomical purposes, divided into six watches or vigils, three from sundown to sunrise and three from sunrise to sundown. Only on the days of the equinoxes were the six matches of equal length. In everyday life, the day comprised 12 double hours (*beru*) of equal length. Sundials and water clocks served to count the hours.

The moon provided the next time unit, the month (Akkadian *warkhu*, Sumerian *itu* or *iti*), *i.e.*, the period of 29 or 30 days from one appearance of the lunar crescent to the next. The next larger unit, used in the earliest lunar calendar of southern Babylonia, was based upon the observation that a lunar eclipse occurs approximately once every six months. Because lunar eclipses were interpreted as the moon god's descent to the nether world, they were marked by the celebration of a festival, the *akitu*, in which the moon's absence from his heavenly abode was symbolized by the transfer of the deity's statue to a suburban sanctuary. The god's resurrection from the realm of the dead, which manifested itself in the appearance of the next crescent, marked the beginning of a new "year" that comprised the approximately six months until the next eclipse. The early use of the "years" of six months, which was not limited to the moon worshipers of Babylonia, explains not only certain features of the later Babylonian calendar described below but also may explain the superhuman length attributed by the Bible to the lives of certain personages.

In the early historic period, the calendars in use in the various city-states of Babylonia comprised 12 lunar months of 354 days; these were brought into agreement with the seasons by the occasional insertion of an intercalary month, without which they would have rotated throughout the agricultural year. Since several of the early Sumerian month names allude to the agricultural activity taking place during the month so named, and since, in particular, the 12th month was called *iti She-gur-ku*, "month of the grain harvest," it is reasonable to assume that it was decided by the authorities whether or not an extra month should be inserted according to the state of ripeness of the standing grain. If the grain was not ripe at the beginning of the 12th month, an intercalary month (Sumerian *iti Dirig*) was added, so that the grain harvest always occurred during the month named for it.

In the Sumerian period, each of the city-states had its own series of month names. With the unification of these states in the Old Babylonian period (about 1900 to 1600 B.C.), the names in use at Babylon replaced the older series. These names, with their Sumerian equivalents, are listed in Table IV.

Intercalary months were the second Ululu and the second Xdaru. A letter addressed by the famous lawgiver King Hammurabi to a provincial governor states that the following month would be a second Ululu and that taxes normally due in Tashritu were to be paid in this intercalary month. The habit of doubling either the sixth or the twelfth month for intercalation and the designation of the seventh month as Tashritu, "beginning," bear witness to the relationship of this calendar to the archaic lunar calendar that had "years" comprising approximately six months.

Because planting and harvesting time vary considerably within a large area, the old method of intercalation based on the ripeness of the grain eventually proved unsatisfactory. About the 9th century B.C., after centuries of statistical recording, the Babylonians discovered that 235 lunar months contain almost exactly the same number of days as do 19 solar years, and that, therefore

TABLE IV.—*Babylonian and Sumerian Month Names*

Babylonian	Sumerian	Babylonian	Sumerian
Nisanu	Bar-zag-ga	Tashritu	Du
Ayaru	Gu-si-sa	Arakh-samna	Apin-du-a
Simanu	Sig-ga	Kislimu	Gan-gan
Du'uzu	Shu-numun	Shabatu	Ziz
Abu	he-ne-gar	Tebet	Ah-ba-e
Ululu	Kin-Ninni	Adaru	She-gvr-ku

lunar and solar years can be adjusted to each other if seven months are intercalated over a period of 19 years. Within this cycle, later called the Metonic cycle, the intercalary months were arranged so as to limit the variations of the first day of Nisanu to a period of 27 days around the vernal equinox.

In the Sumerian and Old Babylonian periods, years were named for the most important event that had taken place in the preceding year, numerous year names alluding to military achievements or to pious deeds. From the Kassite period on until the end of Babylonian independence, the years were designated as "year 1, 2, 3, etc., of king so-and-so," year 1 being the first full year following a king's accession to the throne. The Babylonian year began with an *akitu* festival for Marduk, the god of Babylon, which lasted 11 days. The months were divided into halves, the middle of each month being characterized by a festival called *isinnu* (Sumerian *ezen*). Certain days, in particular the 7th, 14th, 21st and 28th of each month, were considered ominous days, whereas the 20th was a lucky day. The belief in these ominous days with numbers divisible by seven, on which people were to refrain from certain activities, seems to have led to the institution of the seven-day week as a time unit.

2. Assyrian Calendar. — The oldest Assyrian calendar is known from the so-called Kiiltepe texts, which consist of letters and documents found at this site (the ancient city of Kanesh) that were written by Assyrian merchants doing business in the eastern part of Asia Minor. The following month names are used in these documents:

1. Ab-sharrani
2. Khubur
3. Sippum
4. Qarratum
5. Tanmarta
6. Ti'inatum or Sin
7. Kuzallu
8. Allanatam
9. Belti-ekallim
10. Narmak Ashshur-sha-saratim
11. Narmak Ashshur-sha-kinatim
12. Makhur-ili

At least two of these names were chosen for astronomical phenomena which occurred every year during the months so named: Tanmarta, "heliacal rising," was the month of the rising of the constellation Canis Major, the principal star of which, Sirius, played an important part in the Assyrian pantheon; and Makhur-ili, "meeting of the gods," alludes to the conjunction between the moon and the Pleiades prior to the heliacal setting of the latter—an event to which Assyrian mythology attributed great significance. In agreement with these names, which point to a stellar rather than to a lunar year, the year attested in the Kiiltepe texts of the 19th century B.C. had 360 days which were supplemented every three years by the insertion of 15 epagomenal (additional) days called *shapattum*. Thus the year was divided into 12 months of equal length. Throughout the years and the epagomenal days, the Assyrians counted ten-day periods called *khamshatum* (sing. *khamushtum*). For three years, these *khamshatum* ran congruently with the months and with the years. Then, after the insertion of a 15-day *shapattum* period, they overlapped from one month into the next, returning to congruency with the months after the next *shapattum*. Each year bore the name of an official, the *limmu*, who functioned in the capital city, Ashur. The *khamshatum* were also named for officials. Because the days were rarely numbered, a date in an Old Assyrian document had the following form: *khamushtum* of A (name of an official); month M; *limmu* C (name of an official). Lists of the *limmu* as well as of the *khamushtum* officials were used to identify the dates.

This calendar disappeared with the advent of a usurper, Ring Shamshi-Adad I, who introduced the following series of month names:

1. Mana
2. Aiarum
3. Makranum
4. Dumuzi
5. Abum
6. Tirum

7. Niqumum
8. Kinunum
9. Tamkhirum
10. Nabrum or Dagan
11. Mamitum
12. Adarum

In this calendar, an intercalary month was called warakh Dirigum ("supplementary month"). Since the beginning of the grain harvest (which, in Assyria, falls around May 10 in the Gregorian calendar) fell in the last days of Aiarum, the year began, like that of the Babylonians, about half a month before the vernal equinox which, in the 18th century B.C., fell around April 5. Two of the month names of this series, viz., Kinurium and Tamkhirum, recur occasionally in the later Assyrian sources; the former, which was named for the brazier used for heating purposes (*kanunu* or *kinunu*), survived as the name of a month in the calendars of the Aramaeans and the Arabs.

In a later period, the Assyrians resumed the use of the older calendar. In the region of Nuzi and Arrapkha (modern Kirkuk), which had long been an Assyrian dependency before it became part of an independent Hurrian state, the year of 365 days was in use about 1400 B.C. In documents from Ashur, and from provincial Assyrian towns, the old month names occur in date formulas as late as the time of King Tiglath-Pileser I. However, neither the *khamushtum* period of ten days nor the *shapattum* period of 15 epagomenal days is traceable in these documents. Moreover, the beginning of the year had been shifted to the month of Sippum.

During the reign of Tiglath-Pileser I who, by conquering Babylon, brought Assyrians into closer touch with Babylonia, Babylonian dates begin to appear occasionally in Assyrian inscriptions. In the centuries that followed, the use of Babylonian dates became increasingly frequent until, in the neo-Assyrian period, the Old Assyrian calendar had completely disappeared and only the Babylonian lunisolar calendar and the Babylonian month names were used.

The Assyrian sources include vestiges of a time unit larger than the year. Especially in records dealing with the reconstruction of sacred buildings, mention is made of a unit of 350 years, the rule being to postpone such restorations until 350, 700 or 1,050 years had elapsed since the previous reconstruction or the original erection of a temple. A further peculiarity, traceable particularly in neo-Assyrian royal inscriptions, is the designation of the days of the month not only by their number but also by the name of the deity to whose service the day was dedicated. This habit passed from the Assyrians to the Persians and from the Persians to the Romans, and explains the present-day practice of designating the days of the week by names referring to the planetary deities of old under the names by which they were known to the Romans or the Germanic peoples, or to both. (HI. LE.)

VII. JEWISH CALENDAR

The Jewish calendar in use today is lunisolar, the years being solar and the months lunar. Because the solar year exceeds 12 lunar months in length by about 11 days, a 13th month of 30 days is intercalated in the 3rd, 6th, 8th, 11th, 14th, 17th and 19th years of a 19-year cycle. For practical purposes, e.g., for reckoning the commencement of Sabbaths, the day begins at sunset; but the calendar day of 24 hours always begins at 6 P.M. The hour is divided into 1,080 parts (*halagim*), each part (*heleq*) equaling 35 sec. The *heleq* is further divided into 76 *rega'im*. X synodic month is the interval between two mean conjunctions (conjunction = *molad*), which is reckoned at 29 days 12 hr. 44 min. 35 sec. In the calendar month, however, only complete days are reckoned, the full (*male*) month containing 30 days and the defective (*haser*) month 29 days. The months Nisan, Sivan, Ab, Tishri, Shebat and (in a leap year) I Adar are always full; Iyyar, Tammuz, Elul, Tebet and Xdar (reckoned as II Adar in a leap year) are always defective; while Heshvan and Kislev vary.

The number of days in a year varies. The number of days in a synodic month multiplied by 12 in a common year and by 13 in a leap year would yield fractional figures. Hence, again reckoning complete days only, the common year has 353, 354 or 355 days and the leap year 583, 384 or 385 days. A year in which both

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

(LEFT) ORBITAL SPHERES OF MOON, SUN AND FIXED STARS WITH HEBREW NAMES OF SIGNS OF THE ZODIAC; (RIGHT) CELESTIAL VAULT WITH SUN, MOON AND STARS WITHIN. FROM AN ILLUMINATED 13TH-CENTURY MANUSCRIPT OF A JEWISH CALENDAR TREATISE

Heshvan and Kislev are full, called complete (*shelema*), has 355 or (if a leap year) 385 days; a normal (*sedura*) year, in which Heshvan is defective and Kislev full, has 354 or 384 days; while a defective (*hasera*) year, in which both these months are defective, has 353 or 383 days. The character of a year (*qevi'a*, literally "fixing") is described by three Hebrew letters, the first and third giving the respective days of the weeks on which New Year occurs and Passover begins, while the second is the initial of the Hebrew word for defective, normal or complete. There are 14 types of *qevi'oth*, 7 in common and 7 in leap years. The new year begins on Tishri 1, which may be the day of the molad of Tishri but which is often delayed by one or two days for various reasons. Thus, in order to prevent the Day of Atonement (Tishri 10) from falling on a Friday or Sunday, and the seventh day of Tabernacles (Tishri 21) from falling on a Saturday, the new year must avoid commencing on Sundays, Wednesdays or Fridays. Again, if the *molad* of Tishri occurs at noon or later, New Year is delayed by one or, if this would cause it to fall as above, two days. These delays (*dehiyyoth*) necessitate, by reason of the above-mentioned limits on the number of days in the year two other delays.

The mean beginning of the four seasons is called *tequfa* (literally "orbit" or "course"); the *tequfa* of Nisan denoting the mean sun at the vernal equinoctial point, that of Tammuz the mean sun at the summer solstitial point, that of Tishri the mean sun at the autumnal equinoctial point and that of Tebet the mean sun at the winter solstitial point. The mean length of the seasons was reckoned by Mar Samuel (c. 165–254, head of the academy at Nehardea in Babylon) at 91 days and $7\frac{1}{2}$ hr. Hence, with his solar year of $365\frac{1}{4}$ days (52 weeks and $1\frac{1}{4}$ days), the *tequfoth* moved forward in the week, year after year, by $1\frac{1}{4}$ days. Accordingly, after 28 years the *tequfa* of Nisan reverted to the same hour on the same day of the week (Tuesday 6 P.M.) as at the beginning. This cycle is called the great or solar cycle (*mahzor gadol* or *hamma*). Retaining the above length of the solar year for observance of a few minor rituals only, the present Jewish calendar is mainly based on the value 365 days 5 hr. 55 min. $25\frac{5}{7}$ sec.—more accurate, yet still in excess of the true tropical year by about $6\frac{1}{2}$ min. It is often ascribed, on no sound grounds, to Rabbi 'Adda (perhaps Rabbi 'Xdda bar Ahava, a Babylonian Talmudic teacher of the 3rd century).

To a far greater extent than the solar cycle of 28 years, the Jewish calendar employs, as mentioned above, a small or lunar cycle (*mahzor qatan*) of 19 years, adjusting the lunar months to the solar years by means of intercalations. Passover on Nisan 15 is not to begin before the spring *tequfa*; therefore the intercalary month is added after Adar. The *mahzor qatan* is akin to the Metonic cycle, and is based on the nearly correct notion that 235 lunar months = 19 solar years; hence there are 7 intercalations ($19 \times 12 = 228$; $228 + 7 = 235$), at the intervals set forth above, in a 19-year cycle.

The era in use today is that of the creation (*Anno Mundi, lizira*, with its epoch in 3761 B.C., see CHRONOLOGY: *Jewish*). The

Jewish year 5719 A.M., which was the 19th in the 301st lunar cycle and the 7th in the 205th solar cycle, was a leap year of 13 months, or 383 days. The *qevi'a* was BHH, which indicates that new year began on the 2nd (B = 2) and Passover on the 5th (H = 5) day of the week and that the year was defective (H = *hasera*); i.e., Heshvan and Kislev had 29 days each. This year (1958–59 of the Christian era) began on Sept. 15, 1958, and ended on Oct. 2, 1959. Neglecting the thousands, current Jewish years A.M. are converted into years of the current Christian era by adding 239 or 240;—239 from the Jewish new year (about September) to Dec. 31, and 240 from Jan. 1 to the eve of the Jewish new year. The adjustment differs slightly for the conversion of dates of now antiquated varieties of the Jewish era of the creation and/or of the Christian era. For exact conversion of dates the best tables are in E. Mahler's *Handbuch der jüdischen Chronologie* (1916).

1. Months and Important Days.—The months of the Jewish year and the notable days are as follows:

Tishri: 1–2, Rosh Hashana (New Year); 3, Fast of Gedaliah (II Kings xxv, 22–25; Zech. viii, 19); 10, Yom Kippur (Day of Atonement); 15–21, Sukkoth (Tabernacles); 22, Shemini Azereth (Eighth Day of Solemn Assembly); 23, Simhath Torah (Rejoicing of the Law).

Heshvan.

Kislev: 25, Hanukkah (Feast of Dedication) begins.

Tebet: 2 or 3, Hanukkah ends; 10, Fast (II Kings xxv, 1; Zech. viii, 19).

Shebat: 15, New Year for Trees (Mishnah, *Rosh hash-Shanah* i, 1).

Adar: 13, Fast of Esther (*She'ilthoth* 66); 14–15, Purim (Feast of Lots).

II Adar or Veadar (intercalated month): Adar holidays fall in Veadar during leap years.

Nisan: 15–22, Pesach (Passover).

Iyyar: 5, Israel Independence Day.

Sivan: 6–7, Shabuoth (Feast of Weeks [Pentecost]).

Tammuz: 17, Fast (II Kings xxv, 3; Zech. viii, 19; Mishnah, *Ta'anith* iv, 6).

Ab: 9, Fast (II Kings xxv, 8; Zech. viii, 19; Mishnah, *Ta'anith* iv, 6).

Elul.

See also JEWISH HOLIDAYS.

2. Origin.—The Jewish calendar is the result of long development: its present form is not of great antiquity. Before the Babylonian exile the months were commonly designated by numbers, the Bible recording only four ancient Hebrew names of the months i.e., Abib (1), Ziv (2), Ethanim (7) and Bul (8). During the exile the Jews adopted the Babylonian names. From the Diaspora, where they are attested in the Murashu documents and the Aswan papyri (5th century B.C.), they spread to Palestine, where Nisan, Sivan, Elul, Kislev, Tebet, Shebat and Adar are used in the Bible. By the 1st Christian century all 12 names are used in the Scroll of Fasting (*Megillath Ta'anith*).

Intercalation, already evident from Ezek. i, 1, iii, 15, iv, 4–6 and viii, 1, was at first empirical, an intercalary month being added for various reasons at irregular intervals. The length of each of the months was determined from the observation of witnesses who reported having seen the new crescent moon and who were carefully questioned by the authorities (at first perhaps the priests and eventually the Sanhedrin), while the length of the year varied from 352 to 356 days or (if a leap year) from 382 to 386 days. Gradually observation gave place to calculation, with the right to adjust the calendar reserved to the patriarchate. The establishment of the present continuous calendar, with some of its principal elements traceable in Talmudic records, is traditionally ascribed to the Palestinian patriarch Hillel II in the 4th century A.D., though modern scholars believe it may have originated in Babylon some centuries later. The rights of the patriarchs (presidents of the Sanhedrin) were at first successfully defended against the Babylonian claims. However, a great calendric controversy arose in A.D. 921. Ben Meir, claiming the old Palestinian prerogative as a descendant of the patriarchs (whose office had been abolished by the Romans in the 5th century A.D.), maintained that new year

was not to be deferred unless the *molad* occurred $\frac{642}{1080}$ of an hour after noon. The controversy ended, mainly through the championship of Saadia (892-942), with complete Babylonian victory. Since then the Jewish calendar has remained unchanged. The sole difference between Babylon on the one hand and Palestine (with Italy and France) on the other, as to whether the year should begin with Tishri or Nisan, was settled about 1250 in favour of Babylon; *i.e.*, commencement with Tishri.

The Book of Jubilees (usually dated in the 2nd century B.C.) advocates a peculiar calendar whose details are supplemented in certain calendric fragments found among the Dead sea scrolls. This sectarian calendar was based on a solar year of 364 days or exactly 52 weeks, with 8 months of 30 days and 4 months of 31 days. All years commenced on Wednesday and all festivals fell on fixed days of the week—the first days of Passover and of Tabernacles and New Year's day on Wednesday, Pentecost on Sunday and the Day of Atonement on Friday. Scholars disagree as to the date or identity of the sect using this calendar.

The Karaites vehemently opposed the views of the Rabbanites on the calendar; they regarded calculation as impious and sought to reintroduce observation. This easily disproved the theory of their great Rabbanite opponent Saadia that calculation preceded observation, a theory which was also rejected by notable Rabbanites; *e.g.*, Maimonides (1135-1204). Yet by about A.D. 1500 the Karaites were constrained to adopt calculation. (ER. W1.)

VIII. GREEK CALENDAR

The sturdy independence of the Greek city-states, so marked a characteristic of their political history, is evidenced also by the striking diversity of their calendars. However, although one city might name its months differently from another, and begin its year at a different season, the underlying basis of all the calendars was the same; *viz.*, an attempt to combine in a single system the lunar year of 12 lunar months totaling 354 days and the solar year of 365.25 days. The fundamental incompatibility of these two "years" led to an attempt to reconcile them by means of an eight-year span or octaeteris; G. Thomson (Journ. Hell. Stud., lxiii, 52-65, 1943) believes that this may go back to the Mycenaean period. The difference between eight lunar years (2,832 days) and eight solar years (2,922 days) is 90 days, or some three lunar months. Intercalation of three months in each octaeteris thus kept the calendar roughly in step with natural phenomena, and seems to have been practised as early as the time of Hesiod (*c.* 8th century B.C.). To begin the month with the new moon remained a constant requirement, and for ordinary use this intercalation was found adequate. Farmers and seafarers used their own reckoning based on observation of the heliacal rising and setting of the constellations (such and such work to be done when the Pleiades rose; navigation dangerous after the setting of Xrcturus; etc.) and on seasonal phenomena such as migration of birds. Many people had calendars (*parapegmata*) on which, by moving a peg from one hole to another, it was possible to check the relative

positions of the lunar month and such seasonal indications.

Theories advanced in the interests of greater accuracy had little general effect; the Greeks did not have clocks and apparently did not demand calendric exactitude. The Athenian astronomer Meton, however, proposed a 19-year cycle or "great year," in the course of which seven months were intercalated. This gave on an average a month of 29 days 12 hr. 45 min. 57 sec.—less than two minutes too long. It has been contended that the Metonic cycle, begun on Hecatombaeon 1 (*c.* mid-July), 432 B.C., was adopted by the Athenians as the basis of their official calendar, but this view cannot be reconciled with the evidence. Meton's system was later improved upon by Callippus of Cyzicus (*c.* 370-300 B.C.), whose cycle contained four of those of Meton, and finally Hipparchus of Nicaea (2nd century B.C.) combined four of Callippus' cycles into one great cycle of 304 years to obtain a substantial degree of accuracy.

1. Days and "Thirds."—The first day of the month (*noumenia*) officially began at sunset, but was ordinarily reckoned from the following dawn, so that its predecessor, the last day of the previous month, was called the "old-and-new" day (*hene kai nea*). The day had no regular division into hours; the Greeks ordinarily used terms such as "cockcrow," "when the market place is full," etc., but reckoning by shadow lengths of a man or of a gnomon was also used. There were no weeks, but there was a division into "thirds"; the *men histamenos* or "beginning month" and the *men phthinon*, "waning month," described the first and last ten-day periods. For the middle section there was no regular description. Thus at Athens Hekatombaionos hekte *histamenou* = Hecatombaeon 6 and *Hekatombaionos hekte epi deka* = Hecatombaeon 16. But *Hekatombaionos hekte phthinontos* (or, after *c.* 330 B.C., hekte *met eikadas*, "after the twenties") = Hecatombaeon 24 or 25, since in the last period the days were counted backward from the end of the month, as explained below.

Days, like months, could be intercalated, but this was not always done for the sake of calendric accuracy; the double dating "by the archon" and "by the god" found in some Athenian inscriptions testifies to arbitrary tampering for political or religious purposes.

2. Months.—The Athenian calendar which is the one best known and most studied, customarily began its year with the first new moon after the summer solstice. The months were called Hecatombaeon, Metageitnion, Boedromion, Pyanepсион, Maemacterion, Poseideon, Gamelion, Anthesterion, Elaphebolion, Munychion, Thargelion and Scirophorion. When intercalation was necessary a second Poseideon followed the first. Each month consisted of 29 or 30 days, being designated either "hollow" (*koilos*) or "full" (*pleres*). There was no rigid alteration of full and hollow months, although in practice the principle of alternation was probably followed, with an occasional doubling of the 30-day month if the first of the month strayed too far from the observable new moon. *Hekatombaionos hekte phthinontos* meant either the 25th or the 24th day (counting back from the last day), depending on whether the month was full or hollow.

The Macedonian calendar became of importance in the Hellenistic period; its year (like that of Sparta) began at the autumnal equinox, and its months were Dios, Xpellaivos, Audynaivos, Peritios, Dystros, Xanthikos, Artemisios, Daisios, Panemos, Loivos, Gorpiaivos and Hyperberetaivos. The Egyptian calendar achieved wide popularity among Greeks during the Ptolemaic period. In this calendar the year consisted of 365 days (12 × 30 plus 5 extra days named *epagomenai*); its discrepancy with the solar year resulted in a cycle of 1,460 years, at the end of which the calendar became correct again (see Egyptian Calendar, above). The Egyptian months were Thoth, Phaophi, Hathyr, Choiak, Tybi, Mechir, Phamenoth, Pharmouthi, F'achon, Pauni, Epiphi and Messori.

The Greek months generally derived their names from festivals occurring in the season at which they fell; calendars adopted later (*e.g.*, in Achaea) used numbers rather than names. There was a general similarity of month names among cities with the same ethnic background, such as the Ionian or Dorian cities, because their festivals had a common derivation; however, similar names might not refer to the same lunar month in each case.

3. The Year.—Years were not numbered in the classical period,

EHEM STAATL. MUSEEN BERLIN

FRAGMENT OF LATE 2ND CENTURY B.C. GREEK CALENDAR (PARAPEGMA)
FOUND AT MILETUS, ASIA MINOR

but were designated by the name of an eponymous magistrate or priest—*epi archontos* x or *epi stephanephorou* y . This practice, although adequate for ordinary purposes, made difficulties for writers of history and in international relations, especially when Greek horizons widened after Alexander the Great's conquests 334–323 B.C. Historians found a reckoning by the four-year periods of the Olympiads to be useful, although this was not adopted as an official system by the city administrations. The Hellenistic kings used the numbered years of their own reigns as a generally acceptable dating system, and most cities began to use an era numbered from their foundation or refoundation (cf. the Roman "ab urbe condita") or from some significant event such as their incorporation into a Roman province. Macedon during the Roman period used eras numbered from the years of the final Roman conquest (148–147 B.C.) and the battle of Actium (32–31 B.C.). Under the Roman empire both the Macedonian and the Egyptian calendars were reformed along Julian lines.

4. The Athenian Prytany Calendar. — Side by side with their civil (lunar) calendar, the Athenians used for administrative purposes a calendar based on the subdivisions of their council of 500, whereby the councilors from each tribe acted in turn as a standing committee or *prytany* during the year. Until 307–306 B.C. there were ten tribes, thereafter 12, except between 224–223 and 201–200, when there were 13 (as was also the case after A.D. 124). Thus Athenian public documents were dated both by the day of the *prytany* of such and such a tribe (with the ordinal numeral of its sequence in the year, which was decided by lot) and by the day of the lunar month. These equations have contributed much of great value, and much also of controversy, to the study of calendric problems. In the period of Aristotle (4th century B.C.), when there were ten tribes, the normal succession of *prytames* was described as 4×36 days followed by 6×35 days, however, variations in the length of the *prytames* are known to exist and the sequence could even have been 6×35 followed by 4×36 .

(GE. W.)

IX. MUSLIM CALENDAR

On Thursday, July 16, in the year A.D. 622, Mohammed, the prophet of Islam, fled from Mecca to Medina. His second caliph, Omar I (reigned A.D. 634–644), introduced the era of the emigration (Hegira [see HEJIRA]), taking the preceding month as its beginning. This era is also known as the Mohammedan era. The years are lunar and always consist of 12 lunar months alternately 30 and 29 days long, beginning with the approximate new moon. The year has 354 days, but the last month (Dulheggia) sometimes has an intercalated day, bringing it up to 30 days and making a total of 355 days for that year. The months do not keep to the same season in relation to the sun, because there are no intercalations of months. The months retrogress through all the seasons every $32\frac{1}{2}$ years.

The names of the months and the number of days in each are as follows:

Muharram	30	Rajab	30
Saphar	29	Shaahan	29
Rabia 1	30	Ramadan	30
Rabia 2	29	Shawwal	29
Jomada 1	30	Dulkaada	30
Jomada 2	29	Dulheggia	29

Ramadan, the ninth month, is observed throughout the Muslim world as a fast month. According to the injunctions of the Koran, Muslims must see the new moon with the naked eye before they can begin their fast. The practice has arisen that two witnesses should testify to this under oath before a qadi (judge), who, if satisfied, communicates the news to the mufti, who then orders the beginning of the fast. Although the time of seeing the moon in one Muslim country is not binding on other countries, it has become usual for middle eastern Arab countries to accept, with reservations, the verdict of Cairo. Should the new moon prove to be invisible for any reason, then the month Shaaban, immediately preceding Ramadan, will be reckoned as 30 days in length and the fast will begin on the day following the last day of this month. The end of the fast follows the same procedure.

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

MUSLIM TABLE SHOWING SEASONS OF THE YEAR WITH THE POSITIONS OF THE SUN IN THE ZODIAC AND THE SYRIAN MONTHS. A.D. 1787

The era of the Hegira is the official era in Saudi Arabia, Yemen and the principalities of the Persian (Arab) Gulf. The United Arab Republic, Syria, Jordan and Morocco use both the Mohammedan and the Christian eras. In all Muslim countries people use the Mohammedan era in private, although the Christian era may be in official use.

Some Muslim countries have made a compromise on this matter. Turkey, as early as 1088 AH. (A.D. 1677), took over the solar (Julian) year with its month names but kept the Mohammedan era. March 1 was taken as the beginning of the year (commonly called *marti* year after the Turkish word *mart* for March). Late in the 19th century the Gregorian calendar was adopted. In the 20th century, President Mustafa Kemal Atatürk ordered a complete change to the Christian era. Iran, under Riza Shah Pahlavi (reigned 1925–1941), also adopted the solar year, but with Persian names for the months and keeping the Mohammedan era. March 21 is the beginning of the Iranian year. Thus the Iranian year 1339 began on March 21, 1960. This era is still in use officially.

(N. A. Z.)

X. MIDDLE AMERICAN CALENDARS

1. Maya Calendar. — The various calendars of Middle America do not differ structurally. The description of the Maya calendar which follows therefore applies to all Middle American calendars insofar as it deals with pattern; it is not relevant to nomenclature nor, entirely, to function.

All Middle American calendars were based on a period of 260 days. This consisted of 20 day names attached to the numbers 1 to 13, both re-entering cycles which ran concurrently. Because 20 and 13 have no common measure, 260 days (20×13) must pass before a given day name and number again coincide. A section of this period, using the Maya names current in Yucatan in the 16th

TABLE V.—*Maya Day Names*

1 Imix	11 Chuen	8 Imix	5 Chuen	2 Imix
2 Ik	12 Eb	9 Ik	6 Eb	3 Ik
3 Akbal	13 Ben	10 Akbal	7 Ben	4 Akbal
4 Kan	1 Ix	11 Kan	8 Ix	5 Kan
5 Chicchan	2 Men	12 Chicchan	9 Men	6 Chicchan
6 Cimi	3 Cib	13 Cimi	10 Cib	7 Cimi
7 Manik	4 Caban	1 Manik	11 Caban	8 Manik
8 Lamat	5 Etz'nab	2 Lamat	12 Etz'nab	9 Lamat
9 Muluc	6 Cauac	3 Muluc	13 Cauac	10 Muluc
10 oc	7 Ahau	4 oc	1 Ahau	11 oc

century, is given in Table V. Each column in turn should be read downward, starting with the one on the left.

Since there are 20 names but only 13 numbers, the number attached to any name increases by 7 at each recurrence, while 13 is deducted if the total exceeds that number. Thus the numbers attached, for example, to Imix will be 1, 8, 2, 9, 3, 10, 4, 11, 5, 12, 6, 13, 7 and then 1 again. hforeover, a person could not say, for example, that today is Ik; he had to give the number, for the two complemented each other like the exchange name and number on the telephone.

This 260-day cycle had a ritualistic function, as noted below. For keeping count of the seasons there was a year of 365 days composed of 18 months of 20 days each with an extra 5 days at the end of the year. These days formed a period of extreme misfortune called "Uayeb" and other names descriptive of their dire nature.

The month and day names used in Yucatan at the time of the Spanish conquest are employed by modern students in dealing with the Maya calendar. but it must be remembered that in other parts of the Maya area other names were current. The Yucatecan month names are: Pop, Uo, Zip, Zotz, Tzec, Xul, Yaxkin, Mol, Ch'en, Yax, Zac, Ceh, Mac, Kankin, Muan, Pax, Kayab, Cumku. Then follow Uayeb or *u lobil kin*, "the evil days."

The days of each month are numbered from 1 to 19, but between the end of one month and the beginning of the next in sequence (for example, 19 Yaxkin and 1 Mol) came a day which may be called either "end of Yaxkin" or "seating of hlol." Glyphically this was expressed either by a sign for termination affixed to the glyph for Yaxkin or a sign for seating affixed to the glyph for Mol. Before this arrangement was understood by modern scholars, the seating glyph was translated as zero, and thus written 0 Mol. This use of the zero sign for the day preceding the first of a month is retained for convenience, but nith the understanding that it does not mean zero. The days of the Uayeb period are similarly designated "seating" and 1 to 4.

The year, as used in the Classic period c. 100 B.C.—A.D. 900 and seemingly throughout the Maya lowlands until the Spanish conquest, started with 1 Pop. The 260-day almanac and the 365-day year were so interlocked that only the days Akbal, Lamat, Ben and Etz'nab could fall on 1 Pop. This mas so because 365 divided by the number of day names leaves a remainder of 5, which is the interval between these various days. Furthermore, 365 divided by 13 leaves a remainder of 1. It follows therefore that if 1 Akbal 1 Pop is the new year day now, 2 Lamat 1 Pop, 3 Ben 1 Pop, 4 Etz'nab 1 Pop, and 5 Akbal 1 Pop will be the next four new year days. The sequence will continue until at the end of 52 years 1 Akbal again falls on 1 Pop. The day on which the year commenced was called the year-bearer. and late in Maya history, but probably not during the Classic period, a year took the name of its bearer, so that an event was said to have occurred in the year 13 Lamat or whatever the year-bearer happened to be.

This period of 52 years (18,980 days) is called by Maya students the Calendar Round (its Maya name is unknown). Every one of its 18,980 days has a different combination of day name, day number, month name and month position. Every such date (12 Caban 15 Ceh, for instance) is called a Calendar Round date. This fourfold calendar, particularly in combination with the Long Count (see CHRONOLOGY: *Maya and Mexican*), forms a remarkably perfect system for reckoning time, because the sundry rules check one another, as in bookkeeping, by double entry. This enables students to decipher partly obliterated inscriptions; for example, an Initial Series, which shows the position of a date in the Long Count, can be deciphered in many instances even if more than half

its component elements are illegible. Similarly, modern students have even found mistakes in calculation or misreadings by the artist of the drawings he was supposed to copy. The Maya calendar was, however, well-constructed; it was not, as is constantly asserted, an accurate measurer of the length of the solar year. There is evidence, not accepted by all students, that the Maya calculated the error between their year of 365 days and the true solar year of 365.242199 days which had accumulated in nearly 4,000 years since the starting point of their count. Such corrections were recorded in separate entries; they were not an integral part of the calendar.

Because there was no intercalation of leap days, the Maya new year receded in the solar year at the approximate rate of 24.2 days per century. In Yucatan, 1 Pop coincided with July 25 (new style) in A.D. 1556; *i.e.*, at just about the time that the Maya system was ceasing to function correctly under pressure of the European calendar. The Chol Maya calendar, the only other lo land calendar about which there is information, was synchronous with this. The various calendars of the highland Maya were not in agreement with these: the Quiche new year of 1556 fell on June 13, and that of the Jacalteca, projected backward from the present time, would have coincided with June 14. The reason for the difference of two Maya months is not known; the further differences of 1 and 2 days were caused by local variations in the sets of days which could serve as year-bearers.

In the Maya lowlands, except for Campeche and adjacent parts of Yucatan, the year-bearers were, as already noted, Akbal, Lamat, Ben and Etz'nab, but in Campeche and some parts of western Yucatan they were Kan, Muluc, Ix and Cauac, those days coinciding with 1 Pop. It was formerly thought that this was a late innovation, but it is now known that this local variation was in force during the Classic period, because it is recorded on stelae, dating from the middle of that period, found at Etzna, Campeche. Whereas Campeche and western Yucatan used the set of days one position later than the standard Akbal group, the Quiche and Cakchiquel tribes used the set Ik, Manik, Eb and Caban, which were one position earlier than the Akbal group. Despite these shifts and local variations in the names of the days, the 260-day almanacs were completely synchronized throughout Middle America. If the day is 10 Imox (local form of Imix) in one village, it is 10 Imox throughout this whole wide area of isolated settlements, except among the Mam, who have dropped the number attached to their day names. For them the day is merely Imox. This unity over a wide area (it extends to the Mixe in remote mountain villages of Oaxaca, Mexico) bears witness to the great ritualistic importance of the 260-day count and to the care with which the local priests and shamans have kept the count inviolate without loss or gain of a day in the face of four centuries of effort by the Spaniards to suppress it.

This sacred almanac was of supreme importance as a guide to daily conduct and as an instrument of divination. Both the day names and the day numbers represented gods, and on their combined influences depended the fortune of each day. For example, the day Kan was the maize god, Chicchan was the day of the serpent god of rain and Cimi the day of the death god; and the numbers 1, 4, 5 and 8 represented respectively the moon goddess, the sun god, the old god of the interior of the earth and the maize god. Thus 8 Cimi, for example, combined the influences of the maize god and the death god; the priest, in making his divination, could weigh the benevolence of the former against the malevolence of the latter.

The calendar priest was consulted as to lucky days on which to undertake any venture, whether for the nation or for the individual. He indicated good days for starting a war or a communal hunt or for building a new house, and decided whether a youth horn on such and such a day might wisely marry a girl born on day so-and-so. In some parts of the Maya area and among the Mixtec and some other Mexican groups, men and women were named for the day on which they were born. Everywhere in Middle America a man's lot in life was largely decided by the luck of the day on which he was born. Two of the three surviving Maya hieroglyphic books consist largely of 260-day sacred almanacs giving divinatory

information on a variety of subjects, among them weather, crops, hunting, beekeeping, idol making and diseases. The Maya name for the 260-day cycle is not known; students sometimes call it *tzolkin*, but this usage is to be deprecated since that term is known to have had a different meaning.

2. Mexican Calendar.—The Aztec 260-day almanac was called *tonalpoahualli*, and in function and structure resembled the Maya almanac, but the day names and their glyphs were different. These names are translatable and the glyphs represent them pictorially. In English they are: Crocodile monster, Wind god, House, Lizard, Snake, Death, Deer, Rabbit, Water, Dog, Monkey, Dead grass, Reed, Jaguar, Vulture, Eagle, Earthquake, Stone knife, Rain and Flower. The same glyphs were used by other peoples of central Mexico, such as the Mixtec, Cuicatec, Tlapanec and Otomi, but each group named the days in its own language. There are a few regional variations in the glyphs (e.g., in one area a picture of a grinding stone replaces the eagle).

The Zapotecs, authors of the great civilization centred at Monte Alban, had day signs distinctive from both the Maya and the Mixtec-Aztec groups. Not all of their signs have been finally identified, but in essentials they clearly fall into the general Middle American pattern. The 260-day cycle survives among the Mixe of Oaxaca. The Aztec count of the early 16th century and that of the present-day Mixe and the various Maya almanacs are synchronous; throughout this area these almanacs through their divine associations still govern, as they have always done, the daily life of community and individual.

The Aztecs and related peoples also used a year composed of 18 months of 20 days plus the final 5 unlucky days, but this 365-day year was of far less importance to the Aztecs than it was to the Maya. In general, dates were reckoned not in terms of the Calendar Round but by recording the year-bearer (House, Rabbit, Reed and Stone Knife, corresponding to the Maya Akbal group) and the day itself; for instance, in the year 6 Reed on the day 12 Flower so-and-so happened. Often, the year-bearer alone was given. For example: on 9 Calli (House) Ahuitzotzin died; on 10 Tochtli (Rabbit) Moctezuma became the ruler. Because a year denominated 9 Calli will recur after 52 years, confusion easily arises as to the position of an event in a longer chronological sequence.

Religious festivals were related in some cases to the 260-day almanac, in others to the 20-day months. Glyphs of the months are rare and the codices in which they occur are of post-Spanish conquest date or contemporaneous with it. (J. E. S. T.)

CALENDER, a machine that has wide application in the finishing of textile fabrics, the production of vinyl plastic sheeting, rubber sheeting, coated fabrics and the manufacture of paper. The mechanized plain calender was in common use in the mid-18th century after having been introduced into England from Flanders in the 17th century. A special type called the friction calender was patented in 1805 by William Smith, and the schreiner calender was developed about 1895. Calenders for embossing and moiré are other types in use.

Calenders are made in many different forms and employ from 2 to 12 heavy rollers, usually mounted vertically in a series on a strong frame. The essentials of the machine are the pressure and temperature applied when the material being processed passes under or between the rollers. The number, arrangement and type of rollers are the chief factors that determine how the calender functions. In the finishing of broad-woven fabrics, calendering produces results similar to ironing clothes at home. The pressure applied closes the threads, removes creases from the cloth, flattens it to the required thickness and imparts a smoothness and lustre, or other special effects, to the cloth. In the plastics industry calendering is the leading method for producing vinyl film or sheeting. Resin and other ingredients are blended and formed into a hot plastic mass and passed through the hot rollers of the calender. The plastic emerges as a flat film or sheet whose thickness is determined and made uniform by the gap set on the gauging rollers of the calender. Similar applications are employed in the production of coated fabrics or rubber sheeting. See PAPER: Calenders; RUBBER: PRODUCTION AND MANUFACTURE: Calendering. (J. E. Ho.)

CALEPINO, AMBROGIO (c. 1440-1510), one of the earliest Italian lexicographers, was born at Bergamo of the family of the counts of Caleppio. He became an Augustinian monk and compiled a dictionary of Latin languages, published at Reggio (1502), which, though imperfect, long served as a model. In later editions other languages were added until, in an edition published at Basel (1590), 11 languages were represented, including Polish and Hungarian. Calepino died at Bergamo in 1510.

CALES (mod. CALVI), an ancient city of Campania in Italy, belonging originally to the Aurunci, on the Via Latina, about 13 km. (8 mi.) N.N.W. of modern Capua. It was taken by the Romans in 335 B.C. and became a Latin colony in 334. It was long the centre of Roman control in Campania. It was an important base in the war against Hannibal (218-202), but refused Rome further help in 209. It was reinforced in 184 and became a municipium (q.v.) after 90 B.C. The fertility of its territory and its manufacture of black glazed pottery made it prosperous. Since the 5th century A.D. it has been an episcopal see, though now a mere village. The cathedral, of the 12th century, has a carved portal, three apses, a fine pulpit and episcopal throne. Near it are two

grottoes which have been used for Christian worship and contain frescoes of the 10th and 11th centuries. Inscriptions name six gates of the town, and the ancient remains include parts of an amphitheatre, theatre and a supposed temple.

See R. Pagenstecher, *Die calenische Reliefkeramik* (1909); C. L. Woolley, *Journal of Roman Studies*, vol. i (1911). (H. H. Sd.)

CALGARY, a city of southern Alberta, Can., on the western edge of the Great Plains (elev. 3,438 ft.) at the junction of the Bow and Elbow rivers, about 40 mi. from the foothills of the Rocky mountains. The population of the city in 1961 was 242,589, that of the metropolitan area 271,764.

As the centre of the highly diversified agricultural region of southern Alberta. Calgary ranks with the provincial capital, Edmonton. 182 mi. to the north, as a leading city in the province. Wheat farming is important and the region is Canada's outstanding ranching area. The city is Alberta's most important wholesaling centre, its distributing area including all of southern Alberta and southeastern British Columbia. Coal is available from the mining districts of the Rocky mountains; electric power is developed on the Bow river; and natural gas and oil are piped in from Turner valley, 38 mi. S.W. Industry is based primarily on the processing of raw materials from the surrounding area. Calgary has large flour mills, meat-packing plants, a distillery, a malting plant, oil refineries and plants for manufacturing nitrogen fertilizers and sulfur from natural gas. Metal products are fabricated, especially for the oil industry, and the city has large railway shops. It is an important centre for the western Canadian construction industry, manufacturing asphalt roofing, gypsum and lime products.

Founded as Fort Calgary by the North-West Mounted police in 1875, Calgary's importance was assured when Canada's first transcontinental railway reached there in 1883 on the route to Kicking Horse pass, at the head of the Bow river, 135 mi. to the west. Calgary was incorporated as a town in 1884 and quickly became the regional centre of southern Alberta, being chartered as a city in 1893. In 1904 large-scale irrigation projects were undertaken in the Western Irrigation district near Calgary, and thereafter such special crops as alfalfa, sugar beets and canning vegetables were grown on the irrigated land. With the discovery of natural gas at Turner valley in 1914 and oil in the same area in 1925. Calgary's function began to change. After the discovery of oil at Leduc, Alta., in 1947, Calgary became the administrative, operations and financial centre of the rapidly expanding petroleum industry in western Canada. After 1952 the municipal government of Calgary was operated on the commission-with-council plan. Three commissioners form the executive body. The city owns and operates the urban electric light, heat and power systems, the waterworks system and the transit system. It is the seat of Mount Royal (junior) college (1910), the University of Alberta at Calgary (1945) and the Provincial Institute of Technology and Art (1916) which offers nonuniversity technical courses. All are affiliates of the University of Alberta. The Calgary "Stampede," an annual rodeo and exhibition, attracts visitors from all over Canada and the United States. The name Calgary is a Gaelic word meaning "clear running water." (J. N. H. W.)

CALHOUN, JOHN CALDWELL (1782-1850), L.S. statesman and controversial political philosopher, was born in Abbeville district, S.C., March 18, 1782. He was of Scotch-Irish stock, the son of a hill-country farmer who owned a few slaves. An immigrant from County Donegal, Ire., his father, "Pat" Calhoun, was a political leader in the upcountry of South Carolina who disliked even the restrictions of the federal constitution. John C. Calhoun, largely self-educated until he was 18, had two years at the famed "log college" taught by his brother-in-law, the Rev. Moses Waddell (1770-1840), a Presbyterian minister who later became president of the University of Georgia. Calhoun then entered the junior class at Tale and graduated with distinction in 1804.

He studied at the law school in Litchfield, Conn., conducted by Tapping Reeve and heard Reeve expound the right of secession. He took up the practice of law in South Carolina and served as a member of the South Carolina legislature during the sessions of

1808 and 1809. It was during these years that South Carolina hammered out the constitutional compromise that recognized the upcountry farmers and the low-country planters as two separate interests, and established a government of concurrent powers rather than of the mere numerical majority. Although Calhoun was always avowedly an upcountryman, his marriage in 1811 to his young cousin, Floride Bonneau Calhoun of Charleston, did more than give him entry to South Carolina plantation society. It gave him an understanding of the aristocratic ideal, which he was later to transmute into a philosophy of government. In the same year he took his seat in the L.S. house of representatives. When Calhoun entered congress, Henry Clay was speaker of the house and one of the leaders of the group that was eager for war with England. Clay named Calhoun to a place on the important committee on foreign affairs. This committee, of which Calhoun soon became the dominating member, recommended the adoption of resolutions urging war with England. These resolutions were adopted by the house of representatives, and it is estimated that no other two members of congress were more influential in precipitating the War of 1812 than were Clay and Calhoun.

After the war he became secretary of war in President Monroe's cabinet and in 1824 was elected vice-president under John Quincy Adams and re-elected in 1828 under Andrew Jackson. Three events shaped Calhoun's thinking during his years in this office. He became an active farmer; the cotton economy began to decline; and he came under the influence of the brilliant, if unstable, John Randolph of Roanoke. During the Missouri Compromise debates in 1820 Randolph had perceived a fundamental idea: if the south conceded to the northern congressional majority the power to prohibit slavery in the territories, it was thereby conceding the power of simple majority rule.

The immediate issue in the late 1820s, however, was the so-called "tariff of abominations." Years earlier, under the stress of war emergency, Calhoun had urged that the vast American nation be linked together by highways and that its young industries receive tariff protection. In thus promoting the general welfare Calhoun had seen no threat to the south that he loved. But time and John Randolph were to change his opinions. He became convinced that a permanent tariff program was, in effect, a subsidy paid by the agriculturists of the south for the benefit of the industrialists of the north.

When congress offered no relief, Calhoun wrote his famed *Exposition and Protest*, and in 1831, the *Fort Hill Letter*. Both pointed out that the states had made the union! and were thus the ultimate judges of the powers they had delegated. It was their duty to interpose or to nullify acts of the federal government that they deemed unconstitutional, rendering them void within their own state boundaries. Jefferson and Madison had taken this same stand at the turn of the century in the Kentucky and Virginia resolutions that had brought about the end of the Alien and Sedition laws.

Nullification by South Carolina of the Tariff act of 1832 had no such effect on the tariff. Pres. Andrew Jackson saw the question more as one of anarchy than of constitutional theory, and threatened to arrest Calhoun. Calhoun promptly resigned the vice-presidency, but returned to Washington in 1833 as a senator from South Carolina to debate the issues with Daniel Webster. For the next 15 years he served in the senate, taking his stands courageously, without regard to party alignments, with a brief interlude (1844-45) as secretary of state under President Tyler.

When Jackson was authorized by the "Force Bill" in 1833 to halt resistance in South Carolina, Henry Clay brought in a compromise settlement of the tariff question. The duties were reduced, but the tariff principle was retained. South Carolina repealed its act of nullification, but the great questions remained unanswered.

Jackson, in his subsequent war with the Bank of the United States, thought big government was necessary to counter big business; Calhoun, in his battle against the tariff, had seen big government as no less of a threat than big business. Both men, however, had recognized unrestrained finance capitalism as the common enemy of the labouring masses, the southern planters and the small farmers everywhere. Calhoun, therefore, strove to unite

these dissident groups within the Democratic party, and laboured to dedicate the party to states' rights and agricultural interests, as a barrier against both financial and federal centralization. Constitutions, he said, were created to protect minorities against the inherent selfishness of majorities; the majority could look after itself. Liberty and equality he saw as incompatible, for to force men down into an artificial equality would deny them the very right of self-expression which was essential to liberty.

During the 1840s Calhoun expanded his ideas in two books—*A Disquisition on Government* and *A Discourse on the Constitution and Government of the United States*—works remarkable for their insight into the nature of the American political system. He saw, for instance, that political parties were vital mechanisms in the American form of government. He saw that the citizenry had a natural tendency to divide itself into blocs, and that the genius of the American system was to utilize these blocs, not against, but for the vital interests of each other. In a country of such diversity as the United States, he believed, justice could be secured only by obtaining the concurrent agreement of each interest group, not by a simple numerical majority.

Calhoun recognized that by 1850 the north and south were virtually two countries and that only force, military or legal, could compel the north to recognize southern rights. His final thinking, however, was not specifically in terms either of nullification or states' rights. He believed that the great economic interests of his time could only be safeguarded regionally, and sought legislation that would artificially restore the lost equilibrium between the two sections.

The tragedy was that the freedom of the white south had to be defended in terms of the slavery of the Negro. When enough free states had entered the union they could simply vote to end slavery, and with it the southern economy and the federal nature of the union. Hence, during the impassioned debates of the 1840s, Calhoun had taken an unyielding stand. He led the opposition to the Wilmot Proviso, which would have denied the south's "right" to slavery in the territories. He set his face indomitably against the compromise of 1850. No compromise of the immediate issues, he foresaw, could long settle the fundamental questions.

Worn out by illness and anxiety, he dragged himself to the senate to hear his last warning read, and Daniel Webster's rejoinder a few days later. He died on March 31, 1850. "The dissolution of the Union," he had said, "is the heaviest blow that can be struck at civilization and representative government." He did not deny the south's right to secede: secession would come within ten years, he predicted; but secession would mean that the great American experiment in diversity had failed.

John C. Calhoun is remembered not so much for what he did as for what he thought and felt and believed. His life has been described as a Greek tragedy. He wore out his great powers in a futile attempt to avert the conquest of the south that he foresaw but could not tell how to avoid.

CALL, one of the leading cities of Colombia, capital of the department of Valle del Cauca. It stands 3,327 ft. above sea level on the western side of the Cauca valley, one of the richest agricultural areas of Colombia. The Río Cali, a left-bank tributary of the Cauca, bisects the city. Its population (1961 est. 639,900) is mainly Negro and mulatto.

In the 1950s Cali was one of the most rapidly growing cities in the country and distinctly modern. The Cauca valley development project, a 20-year scheme to promote the agricultural and industrial development of the surrounding region and modeled after the Tennessee Valley authority, has its headquarters there (see CAUCA RIVER). The nearby coal fields at Yumbo are the most important in Colombia. Both railroad and highway connect Cali with the port of Buenaventura, 100 mi. W on the Pacific coast. All the traffic between Buenaventura and the interior of the republic, including three out of every four sacks of Colombian coffee exported, is channeled through Cali. The international air-

port is a regular stop on flights between Panamá and Quito, Ecuador

Cali was founded in 1536 by Sebastián de Belalcázar, who had come north from Quito, but its landlocked position long retarded its economic development. Cali rivals Bogotá, Barranquilla and Medellín as an industrial centre, with branches of numerous foreign manufacturing concerns located in its environs. The agriculture of the 120-mi. long Cauca valley, an old inter-Andean lake bed that was once in great cattle and sugar estates, is rapidly being intensified and diversified. (Js. J. P.)

CALIBRATION: see GRADUATION AND CALIBRATION.

CALIBRE, the interior or bore diameter of a gun, the diameter of a projectile fired from a gun or the length of a gun expressed in relation to its interior diameter. In rifled weapons the calibre is normally obtained by measuring between opposite lands (not grooves). With small arms, British and American practice has been to express calibre as a fraction of an inch, as calibre .30 or calibre .50, the bore diameter of a calibre .30 rifle being $\frac{30}{100}$ in., that of a calibre .50 weapon, $\frac{1}{2}$ in. In former years British usage carried the figure to another decimal point, as in the calibre .303 rifle of World War II. In both Great Britain and the United States the trend after 1950 was to follow the metric system, with calibre 7.62 mm. corresponding to calibre .30. The bore diameter of artillery weapons may be expressed either in inches or millimetres, a 75-mm. gun corresponding roughly to a 3-in. gun (or 15-pounder in British terminology). The bore of a shotgun is indicated by the term gauge.

The word calibres (always in the plural) is also used to indicate the length of big guns in relation to their bore diameters. The number of calibres is determined by dividing the length of the bore (from muzzle to breech face) by the bore diameter. Thus a gun with a bore diameter of 5 in. and length of 200 in. is said to be 40 calibres long. (H. C. T.)

CALICO, a trade term that designates an inexpensive variety of all-cotton fabric woven in plain or "tabby" weave and printed with simple designs in one or more colours.

Calico is one of the oldest staples known. The name is derived from Calicut, India, where the fabric originated. Calicut was an important seaport in southwestern Madras and, after Goa, was the chief centre for Indian trade in the 16th century. The term calico at that time was a general one for many varieties of cotton cloth imported from western India, whether figured or plain. These cloths were known to the trade by such names as Calecut, Calicute, Kalyko, Calyco, etc.

The most important early calicoes were those with printed and painted designs, the outline being printed and the coloured pattern filled in with a brush. These were imported into Europe from India by foreign merchants, particularly the Portuguese and Spanish, who held a monopoly on the trade and caused the price to remain so high that only royalty and wealthy nobility could afford them. At that time, calico was the favoured material for handkerchiefs, inner sleeves and doublets and, with linens, rivaled silk in popularity. The monopoly of Indian trade was broken in 1599 when the British East India company was founded. After that date, calico was imported into Europe in larger quantities and became more commonly used.

About 1772, England began to manufacture calico which rapidly became one of the staple products of that country. Calico was also made in France and gained great popularity because of its fine quality and beautiful colours. Some of the early European calicoes were made of linen and cotton but most were all-cotton fabrics.

Calico was well-known and popular in colonial America, and many small establishments in the early days printed imported plain material. The manufacture of calico in the United States began after the Industrial Revolution and grew to importance with the rising cotton industry.

The technique of calico weaving is a simple one: one set of warp threads are woven one-over and one-under with one set of weft threads. Calico fabrics are almost invariably woven in the "gray" state; i.e., in the natural colour of the raw cotton staple. A considerable quantity of calico is used in the gray state for

domestic purposes and is also shipped in large quantities all over the world. In the Manchester district and in Great Britain generally the term calico designates a plain gray or white shirting or sheeting free from any ornamentation.

A considerable amount of calico is bleached, dyed and printed for every conceivable household use and for articles of clothing. Generally, calicoes are in two colours, one for the ground and the other for the figure or design. The ground colour is usually piece-dyed in some solid colour and the design printed on the cloth later by means of a revolving cylinder on which the design has been stamped or cut out. Such machines are capable of printing several colours in one design. Calico fabrics include an infinite variety of textures and qualities according to the different uses for which they are intended, ranging from the finest muslin and cambric to those of coarser and stronger textures.

See also COTTON MANUFACTURE.

(M. DA.)

CALICUT: see KOZHICODE.

CALIFORNIA, most southwestern of the Pacific coast group of the United States, was nicknamed the "Golden state" because of its early and sustained gold production. California was admitted to the union in 1850, as the 31st state; it officially adopted the golden poppy, the California valley quail and the California redwood as its state flower, bird and tree respectively. The grizzly bear is the official state animal, and the state fish is the South Fork golden trout. In size California ranks third in the union, Alaska and Texas being larger. Geographically bounded on the north by Oregon, east by Nevada and Arizona, south by Mexico's Baja California territory and west by the Pacific ocean, the state extends from 32° 30' to 42° N. Extreme longitudinal limits are approximately 114° and 124° 29' W. Length of its north-south medial line is 770 mi. and its breadth varies from 150 to a maximum of 589 mi. in an east-west direction. Total area is 158,693 sq.mi., including 1,953 sq.mi. of water. The general coast line, which does not recognize all of the details, is 840 mi. in length. When all details of indentations—bays, sounds and other bodies of water to the head of tidewater—are included, the shore line measures 3,427 mi.

PHYSICAL GEOGRAPHY

Physical Features.—California's physiography is simple; its main features are few and bold; a mountain fringe along the ocean, another mountain system along the east border, between them—closed in at both ends by their junction—a splendid valley, and outside all this a great area of barren, arid lands, belonging partly to the great basin and partly to the open basin region. Along the Pacific, and about 20–40 mi. in width, runs the Coast range, composed of numerous indistinct chains that are broken into innumerable ridges and spurs, and small valleys drained by short streams of rapid fall. The range is cut by numerous fault lines, some of which betray evidence of recent seismic activity: it is probable that movements along these faults cause the earthquake tremors to which the region is subject, all of which seem to be tectonic. Coast range altitudes vary from about 2,000 to 8,000 ft.; near San Francisco bay the culminating peaks are about 4,000 ft. in height (Mt. Diablo 3,849 ft.; Mt. St. Helena, 4,344 ft.), and both north and south the elevation of the range increases. In the eastern part of the state is the magnificent Sierra Nevada, a great block of the earth's crust, faulted along its eastern side and tilted up so as to have a gentle back slope to the west and a steep fault escarpment facing east. The Sierra proper, from Lassen peak to Tehachapi pass in Kern county, is about 400 mi. long (from Mt. Shasta in Siskiyou county to Mt. San Jacinto in Riverside county, more than 600 mi.). Far higher and grander than the Coast range, the Sierra is much less complicated, being indeed essentially one chain of great simplicity of structure. Precipitous gorges, often from 2,000 to 5,000 ft. in depth, become a more and more marked feature of the range as one proceeds northward; over great portions of it they average not more than 20 mi. apart. The eastern slope is very steep, because of a great fault which threw the rocks of the great basin region abruptly downward several thousand feet. Fen passes cross the chain. Between 36° 20' and 38° N., east of Fresno, the lowest gap of any kind is more

than 9,000 ft. The Tioga, most used of all, is 9,941 ft. high. About 40 peaks are catalogued between 5,000 and 5,000 ft., and there are 11 above 14,000. The highest portion of the system is between 36° 30' and 37° 30' N.; there the peaks range upward to Mt. Whitney, 14,495 ft., being the highest summit of the United States! outside Alaska.

Of the mountain scenery the granite pinnacles and domes of the highest sierra opposite Owens lake, where there is a drop eastward into the valley of about 10,000 ft. in ten miles; the snowy volcanic cone of Mt. Shasta, rising 11,000 ft., above the adjacent plains; and the lovely valleys of the Coast range, and the south fork of the Kings river—all these have their charms; most beautiful of all is the unique scenery of the Yosemite valley (see YOSEMITE NATIONAL PARK). Much of the ruggedness and beauty of the mountains was caused by the erosive action of many alpine glaciers that once existed on the higher summits and left behind their evidences in valleys and amphitheatres with towering walls, polished rock expanses, glacial lakes and meadows and tumbling waterfalls. Remnants of these glaciers are still to be seen—notably on Mt. Shasta—though shrunk to small dimensions. The canyons are largely the work of rivers. The finest of the lakes is Tahoe, 6,229 ft. above sea level, lying between the true Sierras and the basin ranges, with peaks on several sides rising 4,000–5,000 ft. above it.

Lava covers most of the northern half of the range, and there are many craters and ash cones, some recent and of perfect form. Of these the most remarkable is Mt. Shasta. In Owens valley, east of the Sierra Nevada, is a fine group of extinct or dormant volcanoes.

Earthquakes.—Among other indications of great geological disturbances on the Pacific coast may be mentioned the earthquakes to which California like the rest of the coast is subject. They occur in all seasons, scores of tremors being recorded every year: they are of slight importance, and even of these the number affecting any particular locality is small. In 1812 great destruction was wrought by an earthquake that affected all the southern part of California; in 1868 the region about San Francisco was violently disturbed; in 1872 the whole Sierra and the state of Nevada were shaken; in 1906 San Francisco was largely destroyed by a shock (and ensuing fire) that caused great damage elsewhere in the state (see EARTHQUAKE); and in 1925 Santa Barbara was severely shaken.

The Central Valley.—North of 40° N. lat. the Coast range and Sierra system unite, forming an extremely rough country. The eastern half of this area is very dry and barren, lying between precipitous, although not very lofty, ranges; the western half is magnificently timbered and, toward the coast, excessively wet. Between 35° and 36° N. lat. the Sierra, at its southern end, near Bakersfield, turns westward toward the coast as the Tehachapi range. The Central valley is thus closed to the north and south, and surrounded by a mountain wall broken at a single place, the gap behind the Golden Gate at San Francisco. Through this passes the entire drainage of the interior. The length of the valley is about 450 mi., while its breadth averages about 40 mi. if the lower foothills be included, the entire area being about 18,000 sq.mi. From the mouth of the Sacramento river to Redding, at the northern head of the valley, the rise is 552 ft. in 192 mi., and from the mouth of the San Joaquin southward to Kern dry lake bed it is 282 ft. in 260 mi.

The two rivers for which the valleys forming the Central valley are named—the Sacramento and the San Joaquin—drain this interior basin. The San Joaquin valley comprises more than three-fifths of the entire basin, while the Sacramento comprises the remainder. The eastward flanks of the Coast range are scantily forested, and they furnish not a single stream permanent enough to reach either the Sacramento or San Joaquin throughout the dry season. On the eastern side of both major rivers are various important tributaries, fed by the more abundant rains and melting snows of the Sierra's western flank. Feather river is the most important tributary emptying into the Sacramento. A striking feature of the Sacramento system is that for 200 mi. N. of the Feather it does not receive a single important tributary.

Another peculiar and very general feature of the state's drainage system is the presence of numerous so-called river sinks, where the waters disappear, either directly by evaporation or (as in Death valley) after flowing for a time beneath the surface. These sinks are therefore not the true sinks of limestone regions. Some of the mountain lakes indicate by terraces about them that water stood during the glacial period much higher than it does now. Tulare lake, which has practically disappeared, was formerly a shallow body of water, about 25 mi. broad, that received the drainage of the southern Sierra, a flow that is believed to have shrunk greatly after 1850.

Southern California.— Finally along the sea below Point Conception are fertile coastal plains of considerable extent, separated from the interior deserts by various mountain ranges from 5,000 to 7,000 ft. high, and with peaks much higher (San Bernardino, 10,691; San Jacinto, 10,831; and San Antonio, 10,064). Unlike the northern Sierra, the ranges of southern California are broken in a number of places. It is over these passes—Soledad, 3,210 ft.; Cajon, 3,820 ft.; and San Geronimo, 2,590 ft.—that railways cross to the coast. That part of California which lies south and east of the Coast range and the Sierra comprises an area of fully 50,000 sq.mi. and belongs to the basin range region. Generally it is excessively hot and barren. The Mojave desert (*q.v.*)—embracing parts of Kern, Los Angeles and San Bernardino, as also a large part of San Diego, Imperial and Riverside counties—belongs to the great basin, while a narrow strip along the Colorado river, which divides California from Arizona, belongs to the open basin region. They have no drainage to the sea, save fitfully for slight areas through the Colorado river. In San Diego, Imperial and Riverside counties a number of creeks or so-called rivers, with beds that are normally dry, flow centrally toward the desert of Salton sink or sea; this is the lowest part of a large area that is depressed below sea level, being 273 ft. below at Salton. In 1900 the Colorado river (*q.v.*) was tapped south of the Mexican boundary for water for irrigation in Imperial valley along the Southern Pacific railway, south of Salton sea. The river enlarged the canal, and finding a steeper gradient than that to its mouth, was diverted into the Colorado desert, flooding Salton sea; when the break in this river was closed in 1907, a lake of 300 sq.mi. in area was left. The region east of the Sierra, between the crest of that range and the Nevada boundary, is very mountainous.

Near Owens lake the scenery is extremely grand, for the valley there is very narrow, and on either side the mountains rise from 7,000 to 10,000 ft. above the lake and river. Still farther east, about 40 mi. from the lake, is Death valley (*q.v.*)—named for the fate of a party of "forty-niners," 13 of whose members perished there by thirst or by starvation and exposure. Death valley, approximately 50 mi. long and on the average 20–25 mi. broad from the crests of the enclosing mountain ranges (or 5–10 mi. at their base), constitutes an independent drainage basin. It is 282 ft. below sea level at its lowest point (the lowest point on the continent), and is one of the most remarkable physical features of California. The mountains about it are high and bare and brilliant with varied colours.

The Amargosa river, entering the valley from Nevada, disappears in the salty basin. Enormous quantities of borax and of nitrate of soda, have been extracted from the surrounding country, the borax an almost pure borate of lime (colemanite) in Tertiary lake sediments.

Climate.— The climate is very different from that of the Atlantic coast, and indeed very different from that of any part of the country save that bordering California. The climate of the entire Pacific coast is milder and more uniform in temperature than that of the states in corresponding latitudes east of the mountains. A mean annual temperature as low as that of Halifax, Nova Scotia (44° 39' N. lat.), is not found at any Pacific coast point south of Sitka, Alaska (57° N. lat.), while the mean at San Diego is 6° to 7° less than that at Vicksburg, Miss., and Charleston, S.C., in roughly the same latitude. Moreover, the means of winter and summer are much nearer the yearly mean in California than in the east. This condition is not so marked as one goes inward from the coast; yet everywhere, save in the high mountains, the winters are

comparatively mild. Division of the year into two seasons—a wet one and a dry one—marks this portion of the Pacific coast in the most decided manner, being truly characteristic neither of Baja California (Lower California) nor of the greater part of Oregon, though more so of Nevada and Arizona. And finally, except on the coast (where temperatures rarely exceed 90° F.) the dryness of the air and the consequent rapidity of evaporation greatly lessen the disagreeableness of summer heat.

Precipitation.— Along both the Coast range and the Sierra considerable rainfall is certain, although, because of slight snow accumulations the streams of the former are decidedly variable. A heavy rain belt, with normal fall of more than 40 in., covers all the northern half of the Sierra and the northwest counties; shading off from this is the region of 10–20 in. fall, which covers all the rest of the state except Inyo, Kern, San Bernardino and Imperial counties and the eastern portion of Riverside county, all in the southeastern section of the state; the precipitation of this belt is from 0 to 10 in. In the mountains precipitation increases with altitude; above 6,000 or 7,000 ft. it is almost wholly in the form of snow, which melting in summer: is of immense importance to the state, supplying water at one time for placer mining and later for irrigation. The northwest counties are extremely wet; many localities there have normal annual rainfalls of 60–70 in. and even higher. Along the entire Pacific coast, but particularly north of San Francisco, there is a night fog from May to September. Below San Francisco precipitation decreases along the coast, until at San Diego it is only about 10 in. The extreme heat of the southeast is tempered by the extremely low humidity characteristic of the great basin. Many places in northern, southern, central, mountain and southern coastal California normally have more than 200 clear days a year, and many in the mountains and the south, even on the coast, have more than 250.

Water Resources.—Water for irrigation and for industrial and urban use has become one of the state's primary problems. The state's water resources are unequally distributed both geographically and seasonally; more than 80% of annual precipitation occurs during the five months of winter and spring, and there is wide variation from year to year, often deviating 25% to 50% from normal in the driest and wettest years. Irrigation was introduced in southern California before 1780, but its use was desultory and its spread slow until after 1850. By 1890, however, about 1,000,000 ac. were irrigated (see *Agriculture*, below).

In the south artesian wells and canals, and in the Central valley, the rivers of the Sierra slope are the main sources of water supply. In the 1930s federal agencies entered the field of water resources development. The construction of great dams such as Hoover dam and others on the Colorado river and the Friant and Shasta dams in the Central valley project helped relieve some of the shortage. But the domestic, sanitation and industrial needs continued to increase especially in the Los Angeles and San Diego areas. In spite of sectional political controversies over allocations of funds, the voters in 1960 approved a bond issue including the huge Feather river project for carrying northern California water hundreds of miles to the south.

Temperature.— The Colorado desert (together with the lower Gila valley of Arizona) is the hottest part of the United States. Along the line of the Southern Pacific railroad the yearly extreme is frequently from 124° to 129° F. (*i.e.*, in the shade, which approaches the greatest heat recorded in any part of the world). At the other extreme, temperatures of –20° to –36° are recorded yearly near Lake Tahoe. Normal annual means of the coldest localities of the state are from 37° to 44° F., monthly means from 20° to 65° F.

The normal annual means of Indio, Mammoth Tanks, Salton and Volcano springs are from 73.9° to 78.4° F.; the monthly means from 52.8° to 101.3° (frequently 95° to 98°). Another weather factor is the winds, which are extremely regular in their movements. There are brisk diurnal sea breezes, and seasonal trades and countertrades. Along the coast an onshore breeze blows every summer day; in the evening it is replaced by a night fog, and the cooler air is drawn down the mountain sides in opposition to its movement during the day.

There is variety of local climates. At some points in southern California one may actually look from sea to desert and from snow to orange groves. Distance from the ocean, situation with reference to mountain ranges and altitude are all important determinants of these climatic differences; of these the last seems most important. Death valley surpasses for combined heat and aridity any meteorological stations on earth where regular observations are taken, although for extremes of heat it is exceeded by places in the Colorado desert.

Soil.—Sand and loams in great variety, grading from mere sand to adobe, make up the soils of the state. The plains of the north-east counties are volcanic, and those of the southeast sandy. It is impossible to say with accuracy what part of the state may properly be classed as tillable.

Much land seems too rough, too elevated or too arid to be made agriculturally available, but irrigation, and the work of state and national agricultural bureaus in introducing new plants and promoting scientific farming, have accomplished much that once seemed impossible.

Plant and Animal Life.—California's plant and animal life is as diverse as the six natural geographical divisions (climate and temperature zones) which comprise the state. These zones depend more on altitude than latitude for their characteristics—Lower Sonoran (less than 500 ft.), Upper Sonoran (up to 3,000–5,000 ft.). Transition (a narrow elevational range, 2,000–5,000 ft.), Canadian, Hudsonian and Arctic-Alpine (above 5,000 ft.).

The range of plant life extends from the creosote bush, greasewood, mesquite, yucca and giant cacti of the Sonoran zones, through the pines and cedars, and the enormous sequoia and redwood of the Transition zone, the fir, pine and aspen of the Canadian zone and the hemlock and heather of the Hudsonian zone, to the dwarf willow and stunted mountain plants of the Arctic-Alpine zone.

About 400 species of mammals have been identified in the state. The best-known desert mammals of the Lower Sonoran zone are the Fresno pocket gopher, the California ground squirrel, the black-tailed jack rabbit, the California badger, several mice and the coyote. Among larger animals are the Yuma cougar, the desert wildcat and rarely the desert bighorn or mountain sheep. The Upper Sonoran zone, which once boasted herds of antelope and California elk (wapiti), is the habitat of the raccoon, fox and coyote. In higher zones bear, deer and occasional mountain lions are found. Among the 600 species of birds identified within the state are the valley quail, mourning dove, burrowing owl and the curious road runner (a species of cuckoo) of the Lower Sonoran zone; the tiny Anna's hummingbird, towhee and phainopeplas of the Upper Sonoran; the sage hen, band-tailed pigeon and robin of the Transition; and the grouse, hawks and eagles of the upper zones. California birds are generally grayer and paler, and of slighter build, than eastern ones.

There are fewer species of snakes but more of lizards than in other states, and few native fresh-water fish. Porpoises are encountered in coastal waters, and the harbour or hair seal and the sea lion frequent the rocky coast isles. Gulls, terns, cormorants, pelicans and sea ducks abound.

Parks and Monuments.—Many of California's scenic attractions are featured in Lassen Volcanic, Yosemite, Kings Canyon and Sequoia national parks (*q.v.*) which draw thousands of visitors annually.

There are eight national monuments in the state, Lava Beds (established 1925), Muir Woods (1908), Cabrillo (1913), Pinnacles (1908), Joshua Tree (1936), Channel Islands (1938), Devils Postpile (1911), and Death Valley (1933) (*q.v.*). California also has more than 150 state parks and monuments and contains 18 national forests and several small state forest reserves.

HISTORY

"Gold made California!" The most important feature of modern Californian history is the way in which the territory came to be a part of the United States, with gold as the underlying dramatic element. In the 18th century fear lest England or Russia might obtain California, and thus threaten Mexico, caused

Spain at length to occupy it. The Spanish occupation merely kept others out, to the ultimate advantage of the American union, which would not have been strong enough to take over California much prior to the time when it actually did so. If the Spanish settlers had discovered California's gold, the destiny of the province would have been different from what it proved to be; in that event it might have become a Spanish-American republic, or England might have acquired it. Gold was not discovered there, however, until the Americans were already pouring into the province. Thereafter the rush of American settlers put the stamp of certainty on the connection with the United States.

Exploration and Early Settlement.—The name California was taken from Garci Ordóñez de Montalvo's story, *Las Sergas de Esplandián* (1510), of black Amazons ruling an island of this name "at the right hand of the Indies . . . very close to that part of the Terrestrial Paradise." The name was given to the southern part of Lower California probably in 1533–34, but at any rate before 1542. By extension it was applied in the plural to the entire Pacific coast north from Cape San Lucas. Necessarily the name had for a long time no definite geographic meaning. The lower Colorado river was discovered in 1540 by a Spanish expedition under Hernando de Alarcón, which saw but did not penetrate California; in 1542–43 Juan Rodriguez Cabrillo and his successor, Bartolomé Ferrello, explored probably the entire coast to a point just north of the state boundary; in 1579 Sir Francis Drake (*q.v.*) repaired his ships in Trinidad or Bodega bay (north of San Francisco) and named the land Nuevo Albion; Spanish galleons en route from the Philippines to Acapulco usually sighted the coast, and certainly did so in the voyages of 1584 and 1595; and in the famous voyage of 1602–03 Sebastián Vizcaíno carefully explored the coast, and discovered the bay of Monterey. There was apparently no increase of knowledge thereafter for 150 years. Most of this time California was generally supposed to be an island or a group of islands.

Jesuit missionaries entered Lower California as early as 1697, and maintained themselves there until expelled in 1767 by order of Charles III of Spain; not until Russian explorations in Alaska from 1745 to 1765 did the Spanish government take definite action to occupy Upper California. Because of the fear of foreign danger, and the longfelt need of a refitting point on the California coast for the galleons from Manila, San Diego was occupied in 1769 and Monterey in 1770. San Francisco bay was discovered in 1769. Meanwhile the Jesuit property in the peninsula had been turned over to Franciscan monks, but in 1772 the Dominicans took over the missions, and the Franciscans not unwillingly withdrew to join their brethren who had gone with the expeditions of 1769 to Upper California. There they were to thrive remarkably for about 50 years. (See CALIFORNIA. LOWER.)

The Mission Period.—In all, 21 missions were established in California between 1769 and 1823, extending from San Diego in the south to Sonoma in the north. Economically the missions were the blood and life of the province.

The hides and tallow yielded by the great herds of cattle at the missions were the support of foreign trade, and did much toward paying the expenses of the government. As for the intellectual development of the Indians the mission system accomplished nothing; save the care of their souls they received little instruction, they were virtually slaves, and were trained into a fatal dependence, so that once coercion was removed they relapsed at once into native customs (see *Missions*, below). The missions, however, were only one phase of Spanish institutions in California. The government of the province was in the hands of a military officer stationed at Monterey. There were also several other military establishments and civilian towns in the province, as well as a few private ranches.

The political upheavals in Spain and Mexico following 1808 made little stir in this far-off province. When revolution broke out in blexico (1810), California remained loyal to Spain. In 1820 when the liberal Spanish constitution of 1812 was again proclaimed it was duly snorn to in California. In 1822 allegiance was given to newly independent blexico.

The Mexican Period.—Under the Mexican federal constitu-

tion of 1824 Upper California! first alone (it was made a distinct province in 1804) and then with Lower California, received representation in the Mexican congress. The following years before American occupation may be divided into two periods. From about 1840 to 1848 foreign relations are the centre of interest. From 1824 to 1840 there is a complicated and not uninteresting movement of local politics and a preparation for the future—the missions fall, republicanism grows, the sentiment of local patriotism becomes a political force, there is a succession of sectional controversies and personal struggles among provincial chiefs, and an increase of foreign commerce, of foreign immigration and of foreign influence.

The Franciscans were mostly Spaniards in blood and in sympathies. They viewed with displeasure and foreboding the fall of Agustín de Iturbide's empire and the creation of the republic. After 1821 secularization of the missions was the burning political question. Active and thorough secularization of the missions did not begin until 1834; by 1835 it was consummated at 16 missions out of 21, and by 1840 at all. In 1831 the mission question led to a rising against the reactionary clerical rule of Gov. Manuel Victoria. He was driven out of the province. This was the first of the *opéra bouffe* wars. The causes underlying them were serious enough. In the first place, there was a growing dissatisfaction with Mexican rule, which accomplished nothing tangible, although its plans were as excellent as could be asked had there been peace and means to realize them. In the second place, there was growing jealousy between northern towns and southern towns, northern families and southern families. In 1831 Governor Victoria was deposed; in 1836 Gov. Mariano Chico was frightened out of the province; in 1836 Gov. Nicolás Gutiérrez and in 1844–45 Gov. Manuel Micheltona were driven out of office. The leading native Californians headed this last rising. There was talk of independence, but sectional and personal jealousies could not be overcome. Pastoral California had few schools, no newspapers, hospitals or cities worthy of the name; yet from this colourful feudalistic era derive place names, land titles, trails which became highways and the traditions of Mexican law which became the heritage of the later state.

Foreign Influence. — Foreign commerce, which was contrary to all Spanish laws, was active by the beginning of the 19th century. It was greatly stimulated during the Spanish-American revolutions in South America, for, as the Californian authorities practically ignored the law, smuggling was unnecessary. In the early 1840s about three-fourths of the imports, even at Monterey itself, are said to have paid no duties, being landed by agreement with the officials. Trade with the United States was by far the most important. The trade supplied almost all the clothing, merchandise and manufactures used in the province; hides and furs were given in exchange. If foreign trade was not to be received, still less were foreign travelers, under the Spanish laws. However, Russians came in 1805 and founded in 1812 at Fort Ross a post they held until 1841, whence they traded and hunted (even in San Francisco bay) for furs. In 1826 U.S. hunters first crossed to the coast; in 1830 the Hudson's Bay company began operations in northern California. The true overland immigration from the United States began only about 1840. As a class, foreigners were respected, and they were influential beyond proportion to their numbers. Many were naturalized, held generous grants of land and had married into California families, not excluding the most select and influential. The most prominent foreigner in the interior was John A. Sutter (1803–80), who held a grant of about 50,000 ac. encompassing the present site of Sacramento, whereon he built a fort. Though Sutter himself was Swiss, his establishment became a centre of U.S. influence. His position as a Mexican official, and the location of his fortified post on the border, made him of great importance in the years preceding and immediately following U.S. occupation.

U.S. Interests. — Americans were hospitably received and very well treated by the government and the people. There was, however, some jealousy of the ease with which they secured land grants, and an entirely just dislike of "bad" Americans. Many of the later comers wanted to make California an independent

republic. As early as 1805 (at the time of James Monroe's negotiations for Florida), there are traces of Spain's fear of U.S. ambitions, even in this faraway province. Spain's fears passed on to Mexico, the Russians being feared only less than the Americans. An offer made by Pres. Andrew Jackson in 1835 to buy the northern part of California, including San Francisco bay, was refused. From 1836 on, foreign interference was much talked about. Americans supposed that Great Britain wished to exchange Mexican bonds for California; France also was thought to be watching for an opening for gratifying supposed ambitions; and all parties saw that, even without overt act by the United States, the progress of U.S. settlement seemed likely to gain the province.

In 1842 Commodore T. A. C. Jones (1790–1858) of the U.S. navy, believing that war had broken out between his country and Mexico, and that a British force was about to seize California, raised the American flag over Monterey (Oct. 19), but finding that he had acted on misinformation, he lowered the flag the next day with due ceremony and warm apology. By 1845 there was certainly an agreement in opinion among all American residents (then not 700 in number) regarding the future of the country.

The U.S. consul at Monterey, Thomas O. Larkin (1802–58), was instructed in 1845 to work for the secession of California from Mexico, without overt aid from the United States, but with their good will and sympathy. He very soon gained from leading officers assurances of such a movement before 1848. At the same time U.S. naval officers were instructed to occupy the ports in case of war with Mexico, but first and last to work for the good will of the local population.

Capt J. C. Frémont (*q.v.*), while engaged in a government surveying expedition, aroused the apprehensions of the Californian authorities by suspicious and, very possibly, intentionally provocative movements, and there was a show of military force by both parties. In violation of international amities, and practically in disobedience of orders, he broke the peace, caused a band of Mexican cavalry mounts to be seized and prompted some American settlers to occupy Sonoma, near San Francisco. (June 14, 1846). This episode is known as the Bear Flag war, inasmuch as there was short-lived talk of making California an independent state, and a flag with a bear as an emblem flew for a few days at Sonoma. Fortunately for the dignity of history, and for Frémont, it was quickly merged in a larger question, when Commodore John Drake Sloat (1781–1867) on July 7 raised the flag of the United States over Monterey, proclaiming California a part of the United States.

The opening hostilities of the Mexican War had occurred on the Rio Grande. The aftermath of Frémont's filibustering acts, followed as they were by wholly needless hostilities and by some injustice then and later in the attitude of Americans toward the inhabitants, was a growing misunderstanding and estrangement, regrettable in California history.

Admission to the Union. — By the treaty of Guadalupe Hidalgo, in 1848, Mexico ceded California to the United States. Gold was discovered at Sutter's mill on the American river in 1848 (for details see *Mineral Products*, below), and the new territory took on great national importance. Discussion as to what should be done with California began in congress in 1846, immediately involving the question of slavery. A furious conflict developed, so that nothing was accomplished in two successive sessions; even at the end of a third, in March 1849, the only progress made toward creating a government for the territory was that the national revenue laws had been extended over it; and San Francisco had been made a port of entry. Meanwhile conditions grew intolerable for the inhabitants. Never was a population more in need of clear laws than the motley Californian people of 1848–49; yet they had none when, with peace, military rule and Mexican law technically ended.

Early in 1849 temporary local governments were set up in various towns, and in September a convention framed a free state constitution and applied for admission to the union. On Sept. 9, 1850, a bill finally passed congress admitting California as a free state. This was one of the bargains in the Compromise Measures of 1850 (*q.a.*)

The Gold Rush.—Meanwhile the gold discoveries culminated and surpassed "three centuries of wild talk about gold in California." Settlements throughout the state were completely deserted; homes, farms and stores were abandoned. Ships deserted by their sailors crowded the bay at San Francisco—there were 500 of them in July 1850; soldiers deserted wholesale, churches were emptied, town councils ceased to sit, merchants, clerks, lawyers and judges and criminals, everybody in fact, flocked to the foothills. Gold fever spread to the rest of the nation. It is estimated that 80,000 men reached the coast in 1849, about one-half of them coming overland; three-fourths were Americans. Rapid settlement, excessive prices, reckless waste of money and wild commercial ventures that glutted San Francisco with all objects usable and unusable, made the following years astounding from an economic point of view; but not less bizarre was the social development, nor less extraordinary the problems of state-building in a society "morally and socially tried as no other American community ever has been tried" (Josiah Royce; *q.v.*). There was, of course, no home life in early California. In 1850 women numbered only 8% of the population, and in the mining counties only 2%. Mining times brought out some of the most ignoble and some of the best traits of American character. Through varied instruments—lynch law, popular courts, vigilance committees—order was, however, enforced as time went on, until stability was achieved.

The gold rush changed California as much culturally as it had economically and politically. Rapid influx of a cosmopolitan population, combined with sudden increases in wealth, provided consumers and purchasing power for the amenities of civilized life. Virtually overnight new towns and cities were founded and old ones expanded. San Francisco, the new western metropolis, boasted magazines, newspapers, theatres, libraries and even able historians. Artists, such as C. C. Nahl, depicted the drama of the scene, while Bret Harte, Mark Twain and others created a gold rush literature.

The slavery question was not settled for California in the Compromise of 1850. Until the American Civil War the division between the Whig and Democratic parties, whose organization in California preceded statehood, was based essentially on slavery. The followers of Sen. William M. Gwin, one of the first two U. S. senators to represent the state, hoped to divide California into two states and hand the southern over to slavery; on the eve of the Civil War they considered the scheme of a Pacific coast republic. The state remained loyal to the North, however, when war came. The later 1850s are characterized by H. H. Bancroft as a period of "moral, political and financial night." National politics were put first, to the complete neglect of needed reform of excessive taxation, financial extravagance, ignorant legislation and corruption.

Land Grants.—During the Mexican period, California's social, economic and political life had centred about large cattle ranches. The great majority of grants date from Mexican rule; less than 30 applications for land grants had been received during the entire Spanish era and not all of these were confirmed. By 1846, 8,000,000 ac. were in the possession of 800 grantees, whose holdings in several outstanding instances resembled kingdoms in the wealth and power they brought to their owners. But the complicated formalities theoretically essential to the validity of the grants were very often, if not usually, only in part attended to. Instead of confirming all claims existing when the country passed to the United States, and so ensuring an immediate settlement of the matter, the U. S. government undertook, through a land commission and courts, to sift the valid from the fraudulent. Claims of enormous aggregate value were thus considered, and a large part of those dating from the last years of Mexican dominion, many probably antedated after the commission was at work, was finally rejected.

1865–1910.—In state gubernatorial elections after the Civil War the Democrats won in 1867, 1875, 1882, 1886, 1894; the Republicans were successful in all the other contests. Features of political life and of legislation after 1876 were a strong labour agitation, the struggle for the exclusion of the Chinese, for the control of hydraulic mining, irrigation and the advancement by

state aid of the fruit interests. Labour conditions were peculiar in the decade following 1870. Mining, war times and the building of the Central Pacific had up to then inflated prices and prosperity. Then there came a slump. The dismissal by the Central Pacific lines (principally in 1869–70) of about 15,000 Chinese, who flocked to San Francisco, augmented discontent and the reaction from flush times. Labour unions became strong and demonstrative. This is called the "sand-lots agitation" from the favourite meeting place (in San Francisco) of the agitators. The outcome of these years was the constitution of 1879, and the exclusion of Chinese by national law. Congress re-enacted exclusion legislation in 1902. All authorities agree that the Chinese in early years were often abused in the mining country and their rights most unjustly neglected by the law and its officers. The exclusion had much to do with making the huge single-crop ranches unprofitable and in leading to their replacement by small farms and varied crops.

In 1906–07 there was throughout the state a remarkable anti-Japanese agitation, centring in San Francisco and affecting international relations and national politics. The Japanese question was brought to an acute situation in 1913 by the Webb Alien Land law, which prevented Japanese from holding real estate. The question was then taken up diplomatically between the United States and Japan, and Japan agreed to the exclusion of further immigration of its citizens.

The 20th Century.—The period 1910–25 was one of reform, designed largely to secure greater popular control of government. The state's subsequent history broadly paralleled that of the nation as a whole.

The economic depression of the 1930s, although generally less pronounced than in most other states, created great social unrest, accentuated by the influx of migrant labourers, chiefly from the dust bowl area of the southwest. A result was the rise of various radical socioeconomic nostrums (such as the "end poverty in California" [EPIC] plan, a comprehensive social welfare scheme presented by Upton Sinclair [*q.v.*], and various old-age pension plans) and the rapid growth of the Democratic party, long of minor importance in the state. Except for a brief interregnum of four years (1939–43), California was led by Republican governors during the first half of the 20th century, including among others Earl Warren who resigned the governorship in 1953 to become chief justice of the United States, the first Californian to hold this office. In 1958, however, a sweeping Democratic victory installed Edmund Brown as governor. The Republican defeat in the 1958 election, although reflecting a national trend, was epoch-making for California—Democrats not only won gubernatorial and U. S. senatorial races, but for the first time in the 20th century they received a majority of seats in both houses of the state legislature. Capping their victory, the Democrats in 1959 ended the system of cross-filing, peculiar to California, whereby a candidate could offer himself to voters of both parties in primary elections—a system which had most often been of profit to the Republicans.

The state's large population growth after World War II gave it an increasingly influential position in national politics. Congressional reapportionment after the 1950 census raised the number of California's representatives from 23 to 30 and after the 1960 census the number rose to 38, second only to New York (41) and, for the first time, exceeding Pennsylvania (27).

Missions.—Perhaps the unique cultural heritage of California is the extensive chain of Franciscan missions, from San Diego in the south to Sonoma in the north, which were established during the Spanish occupation. Constructed between 1769 and 1823 these institutions of hispanic control were more effective than the accompanying institutions—the presidio and the pueblo. The mission was not merely a religious institution but had political and economic significance as well. Its role was not only to spread the faith but also to act as civilizing agent for the Spanish monarchy.

The coastal chain founded by the Franciscans in Upper California comprised the following missions (date of founding in parentheses): San Diego (1769), San Carlos (1770), San Antonio (1771), San Gabriel (1771), San Luis Obispo (1772), San Francisco (1776, better known as Mission Dolores), San Juan Capis-

trano (1776), Santa Clara (1777), San Buenaventura (1782), Santa Bárbara (1786). La Purísima Concepción (1787), Santa Cruz (1791), La Soledad (1791), San José de Guadalupe (1797), San Juan Bautista (1797), San Miguel (1797), San Fernando (1797), San Luis Rey (1798), Santa Inés (1804), San Rafael (1817), and San Francisco Solano (1823). Mission sites were chosen with regard to contiguity of Indian rancherías (villages). Intervening distances between establishments required about one day's travel. Proximity to the coast was a general characteristic of California missions, but near the end of the mission period a parallel chain of inland establishments was proposed but left un-built. Two attempts at inland foundations in the Colorado river area during the early period—Purísima Concepción and San Pedro y San Pablo—met with disaster at the hands of hostile Yuma Indians who massacred four priests and many of the soldiers of the accompanying garrison.

Daily life at the missions was a routine of work and instruction punctuated by worship services. The chapel—spiritual centre of the mission—was well appointed and decorated with fixtures acquired at considerable expense and trouble by the missionaries. The remainder of the establishment was relatively rude. The priest was forced by circumstances into numerous vocations; he was businessman, farmer, cattleman, trader, explorer, preacher, teacher, manufacturer, doctor, builder and jack-of-all-trades. The difficult task of teaching the culturally backward California Indians was a challenge to the fathers. Indians whose chief technical excellence was the art of basketmaking were taught to become agriculturalists, builders and craftsmen. Natives were taught to make blankets, tan hides, manufacture shoes, make soap and pottery, mill flour and perform a myriad of other tasks.

Noteworthy was the singleness of purpose and devotion to duty of the padres. Outstanding among the leaders was the first father president, Junipero Serra (*q.v.*), under whose leadership (1769–84) the initial struggles for stability were successful. A holy, devout man, Serra founded the first nine missions. Another important leader was Father Fermín Francisco de Lasuén, founder of nine other establishments. Education consisted of instruction in the Spanish language, Christian dogma and hymn singing. Customarily two priests were assigned to each mission, and a mission guard of four or five soldiers was provided by the nearest presidio.

Economically the missions were large-scale production units embracing orchards, gardens, fields, pastures, workshops, looms, granaries. When secularization occurred and the missions' land monopoly was broken in 1834 there were 31,000 Indians in the 21 missions. More than 750,000 head of livestock (the majority cattle) were owned by the Franciscans. There can be little doubt concerning the economic prosperity of the missions. Results of the system as regards the natives were not entirely satisfactory. Many were converted, but many also died from disease in the process of assimilating the white man's civilization. However, secularization was far harder on the California Indians than was the mission system. With the secularization of the missions, the Indians were to obtain rights of citizenship and one half of all mission lands, livestock and agricultural implements. But shorn of protection, they were despoiled and exploited as never before.

The distinctive architecture of the missions gave rise at a later date to a typical California style of building. The missions had solid, massive, stucco-covered adobe walls with broad undecorated wall faces, and were customarily built around a patio with a fountain or garden. Arcaded corridors and low-pitched red-tile roofs with wide projecting eaves characterized most of these buildings. Style was determined mostly by materials of construction rather than by choice. The ravages of time destroyed much of the original structures, but preservation and reconstruction tend to maintain the old Franciscan atmosphere. All of the existing former missions are open to the public; some are state historical monuments but most are under church administration.

GOVERNMENT

California's first constitution was framed by a convention at Monterey, ratified by the people and proclaimed by U.S. military

governor Bennett Riley all in the same year, 1849. The second constitution, still in effect in the second half of the 20th century, was framed by a convention in 1878–79; it came into full effect in 1879, and was subsequently amended. It was the work of the Workingmen's party, passed at a time of high discontent, and went at great length into the details of government, as was demanded by the state of public opinion. The qualifications required for suffrage are in no way different from those common throughout the union, except that by a constitutional amendment of 1894 it is necessary for a voter to be able to read the state constitution and write his name. As compared with the earlier constitution it showed many radical advances toward popular control, legislative power being everywhere curtailed. Power was taken from the legislature by specific inhibition in 31 subjects previously within its power. Lobbying was made a felony; provisions were inserted to tax and control common carriers and great corporations, and to regulate telegraph, telephone, storage and wharfage charges. The constitution may be amended by a two-thirds vote of all elected members of each house of the legislature, followed by ratification by a majority of the qualified electors voting on the proposition. Since 1911 amendments may be submitted directly to the people by means of the initiative. A constitutional convention may be called if approved by a two-thirds vote of the entire membership of the legislature and by a majority vote at the following general election. Work of the convention itself must be submitted to the people for approval or rejection.

State executive officers include the governor, lieutenant governor, secretary of state, treasurer, controller, attorney general and superintendent of public instruction. Election to office is for a four-year term. In addition there are more than 50 administrative and other boards, commissions and officers appointed by the governor, in some cases subject to confirmation by the senate. The legislature is bicameral—a senate of 40 members, not more than one to a county, and an assembly of 80 members, apportioned according to population, elected for four-year and two-year terms respectively. The legislature meets biennially, and its sessions are divided into two parts, with a recess of at least 30 days intervening. In the latter part no new bills may be introduced without consent of three-fourths of the membership.

The state's judicial powers are vested in a supreme court, four district courts of appeal, superior courts, municipal courts and justice courts. The supreme court, consisting of a chief justice and six associate justices, holds regular sessions at Sacramento, San Francisco and Los Angeles. District courts of appeal have six judges each for the first and second districts, and three each for the third and fourth; but in every case three judges constitute a separate court.

Supreme and district court judges serve 12-year terms. Under a constitutional amendment of 1934 they are appointed by the governor, with the approval of a special judicial council comprising the chief justice, the attorney general and the ranking appellate court justice. At the following general election, however, and again at the expiration of his term, the new appointee is subject to removal by a majority vote of the electorate. Any county so desiring may elect to adopt a similar system. Each county has a superior court, with one or more judges, serving six-year terms. Justices of the peace (at least one for each township) are elected for four years.

The California constitution provides that agreement by three-fourths of a jury shall be sufficient in civil cases and that jury trial may be waived in minor criminal cases, the latter procedure based on experience under Mexican law.

City government is diverse in type—the mayor-council, commission and city-manager systems are all in common usage. Notable among measures granting a greater popular control of government are the primary law of 1909 and the constitutional amendments of 1911 establishing the initiative and referendum, the recall (including recall of judges) and the adoption of the short ballot.

Finance.—The chief source of local revenue is the property tax. Until 1911 the state, too, drew most of its general revenue from levies on property, but thereafter no state levy was made, although a 1933 constitutional amendment permitted a property

tax up to 25% of the amount of state appropriations.

After mid-20th century, the state's receipts from all sources amounted to almost \$2,000,000,000 annually. The chief sources of state revenue are retail sales tax (adopted 1933), gasoline tax, bank and corporation franchise, personal income tax, motor vehicle registration and motor vehicle licence fees. State expenditures went chiefly for education (about 40%, and the largest single item), highway construction and maintenance, social welfare and public health, and mental hygiene and corrections. The state's bonded debt remained about \$1,000,000,000. The state's income after mid-20th century was about six times as large as it had been just before World War II. Per capita annual income had tripled in the same period and was among the highest in the union, about \$2,500.

POPULATION

The population of California in 1850, the year the state entered the union, was 92,597, of which 92.6% was rural. California's population ranked 30th among the 37 states and territories that then composed the union. Thirty years later the state's population was 864,694, of which 57.1% was rural, and ranked 24th among the 48 states and territories. By 1910 the population totaled 2,377,549, of which 61.8% was urban, and ranked 12th among the states. In the next three decades, California's population almost tripled, to 6,907,387 (1940), of which 71% was urban, and ranked 5th in the union. In the next two decades California's population more than doubled, to 15,717,204 (1960).

California's rapid and enormous growth, as well as its high

percentage of urban dwellers (86.4% in 1960), was reflected in the state's emergence as one of the most influential elements in national politics.

The ten standard metropolitan statistical areas existing in 1960 (Bakersfield, Fresno, Los Angeles-Long Beach, Sacramento, San Bernardino-Riverside-Ontario, San Diego, San Francisco-Oakland, San Jose, Santa Barbara and Stockton) contained 86.5% of the total state population, compared with 82.7% in 1950.

The population per square mile in 1960 was 99.0, as compared with 49.7 for the United States as a whole. The population of the state was distributed by colour in 1960 as follows: 92% white; and 8.0% nonwhite, including 5.6% Negro, 0.6% Chinese, 1.0% Japanese and 0.4% Filipino. The American Indian population of the state was 39,014 (0.2%).

EDUCATION

The educational system of California provides a complete system of free instruction from kindergarten through the state university, and in the elementary and secondary schools even textbooks and supplies are furnished without cost to individual pupils. At the head of the public school system are the state superintendent of public instruction and the state board of education, a body consisting of seven members appointed by the governor. All schools are governed by local boards of education. Outside the cities the school districts are governed by boards of trustees of three members, and, in the case of union districts, of five members. There was a compulsory attendance law passed in 1874 which later was amended to require all children between the ages of 8 and 16 to attend for the entire school year unless graduated from a four-year high school or exempted by the proper school authorities. Secondary schools are closely affiliated with, and inspected by, the state university. School personnel pension funds in all cities are authorized by state law. Minimum salaries of \$4,500 per year in public schools became effective July 1, 1960. Local units are responsible for supplementing the state support of \$125 per student in average daily attendance at all education levels. In addition, equalization funds, which vary from district to district, are provided by the state.

Notwithstanding the enormous growth in California's school population after mid-20th century, the state spent considerably more money per public school student than the United States spent as a whole.

Schools for the physically handicapped include a school for the blind, a school for the deaf and two schools for cerebral palsied children.

By the early 1960s there were 136 institutions of higher education in the state. California was the first state to make legal provision for junior colleges (1907), and opened the first public junior college at Fresno (1910). The state also pioneered in the junior high school movement; the first such institution was opened at Berkeley in 1909.

Of the institutions of higher education, the University of California (1858), with campuses at Berkeley, Davis, La Jolla, Los Angeles, Mount Hamilton, Riverside, San Francisco and Santa Barbara, is the largest in the state. The university began instruction in 1869 in Oakland. In 1873 removal was made to the present site of the Berkeley campus, where instruction is given in the colleges of letters and science, agriculture, architecture, chemistry, engineering and pharmacy and the schools of business administration, criminology, education, forestry, law, librarianship, medicine, nursing, optometry, public health and social welfare. Davis is the site of colleges of agriculture and letters and science, a school of veterinary medicine and the university farm. At San Francisco are the schools of medicine, nursing and public health, the colleges of dentistry and pharmacy, the university hospital and various medical clinics and research organizations. The California School of Fine Arts and the Hastings College of Law are also there. The Los Angeles campus, second in size to Berkeley in enrollment, offers instruction in colleges of letters and science, engineering, applied arts, agriculture and pharmacy and schools of business administration, education, law, medicine, nursing, public health and social welfare. The Riverside campus is the location of the citrus

experiment station and a college of letters and science. At Mount Hamilton is the Lick astronomical observatory, at La Jolla the Scripps Institution of Oceanography and at Santa Barbara a four-year liberal arts college. The Los Alamos Scientific laboratory, New Mexico, is operated under contract with the Atomic Energy commission. California also maintains several state colleges: at San Jose, San Diego, San Francisco, Fresno, Chico, Sacramento, Arcata (Humboldt), Los Angeles, Long Beach, California State Polytechnic college at San Luis Obispo, California State Polytechnic at Pomona and San Fernando Valley state at Northridge. The California Maritime academy (Vallejo) is a special technical institute. Stanford university (Palo Alto) and the University of Southern California (Los Angeles) are the largest private universities in the state. Smaller schools include the College of the Pacific (Stockton), Mills college (Oakland), Occidental college (Los Angeles), the University of Redlands (Redlands), Whittier college (Whittier) and the associated schools, Claremont Men's college, Claremont Graduate school, Mudd college, Pomona college and Scripps college (all at Claremont). The University of San Francisco, the University of Santa Clara and Loyola university at Los Angeles are Roman Catholic institutions. The California Institute of Technology at Pasadena and the nearby astronomical observatories (Mount Wilson and Mount Palomar) are centres of scientific research.

ECONOMY

Agriculture.— Rapid development of irrigation and of intensive cultivation and increase of small farms made California an important agricultural region and a great fruit-producing area. By the middle of the 20th century less than 5% of California's population lived on farms, and less than 9% of its area was under cultivation. The state accounted for only 2% of the nation's total utilized crop lands. Yet California led the nation in cash income from agriculture, surpassing Iowa, Texas and other farm states.

By 1890, about 1,000,000 ac. were under irrigation, and by 1920 almost 4,000,000 ac. By 1960 California led all other states with about 8,000,000 ac. irrigated. Staple products changed with increasing knowledge of climatic conditions, of life zones and of fitness of crops. The completion of two key dams, Friant (1942) and Shasta (1945), in the Central Valley project added to the water resources of the state (*see also Precipitation: Water Resources, above*).

Horticultural products are the principal products of the soil. The modern orange industry practically began with the introduction into southern California in 1873 of two seedless orange trees from Brazil; from their stock were developed, by budding, millions of trees bearing a seedless fruit which acquired a high rank in the U.S. market. Shipments continued all the year round. Southern California by no means monopolizes the warm-zone fruits. Oranges, lemons and walnuts come chiefly from that section, but citrus fruits grow also in the Sierra foothills of the great interior valley. Almonds and peaches, pears, plums, cherries and apricots come mainly from the north. More than one-half of the prune crop comes from Santa Clara county, and the bulk of the raisin output from Fresno county. Olives thrive as far north as the head of the great valley. Vines were first introduced by the Franciscans in 1771 from Spain, and until 1860 "Mission" grapes were practically the only stock in California. Afterward many hundreds of European varieties were introduced with great success. By the 1950s California accounted for about seven-eighths of U.S. wine production.

Highly intensive cultivation accounts for much of California's agricultural wealth. Every major crop, with the exception of tobacco, produced anywhere in the nation is grown commercially. The state leads in the production of such specialties as lemons, grapes, almonds, apricots, plums, prunes, walnuts, olives, dates and figs. It is among the U.S. leaders in oranges, hops, sugar beets, lettuce, asparagus, beans, carrots, spinach and melons. By mid-20th century California accounted for more than one-third of the fruit and almost one-third of the truck crops grown in the nation.

Cash farm income reached almost \$3,000,000,000 annually in the 1950s. The average size of farms in 1850, when the large

Mexican grants were practically the only farms, was 4,466 ac.; in 1910 it was 316.7 ac. and in 1935 only 202.4 ac., from which it rose again to over 300 ac. by mid-20th century. There were about 40,-000,000 ac. in farms in the state.

Increasing urbanization after World War II reduced the state's cultivatable or cultivated land at the rate of about $\frac{1}{8}$ ac. for each new resident and 26 ac. for each mile of new highway. In Los Angeles county alone, fruit-nut acreage diminished by 40,000 ac. during 1949-56. On the other hand, more acreage was being devoted to truck farming because of the large local market for vegetables in California's growing cities.

Perhaps the most interesting development in California agriculture after World War II was the increasing area dedicated to cotton production, principally in the southern San Joaquin valley. In the decade 1940-50 the value of cotton produced increased 1,048.3%, and by the end of the succeeding decade cotton had become the most important cash crop in the state.

The livestock industry was started by Spanish Franciscan fathers and flourished in both the Spanish and Mexican periods; it was once California's chief economic asset. By mid-20th century California's one important livestock specialty was turkey growing, and the state produced about one-sixth of the U.S. output.

To assist California agriculture, its farm labour supply is supplemented by the employment of numerous migrant labourers and Mexican nationals hired under contract.

Fisheries.— Although in value fishing represents a small fraction of California's total production, the output is greater than that of any other state. The total commercial fish catch landed in 1949, a peak year, was more than 1,000,000,000 lb. Of this amount about 300,000,000 lb. were taken from waters south of the international boundary. The most important fish taken were sardines, tuna and mackerel. But less than 10 years later the total of fresh fish landed was only about 600,000,000 lb., resulting from the disappearance, at least temporarily, of the sardine. Other important commercial fish caught by the California fishing fleet include anchovies, barracuda, rockfish, salmon, sole and yellowtail. California exceeds all other states in the canning of both tuna and imported sardines. Chief port areas for the fishing fleets are Eureka, San Francisco, Monterey, Santa Barbara, Los Angeles and San Diego.

Manufacturers and Employment.— Prior to 1860 almost everything used in the state was imported from the east or from Europe. For many years manufacturing was handicapped by lack of coal, but the opening of petroleum fields and the development of electric power obviated the difficulty. By 1919 manufacturing had replaced agriculture as the state's leading industry, increasing in relative importance thereafter.

Before World War II California's civilian labour forces totaled 2,997,000. Ten years later it had almost doubled to 4,639,000 (1950), an increase of 55% over 1940. Of the employed about 20% worked in trades, about 12% in services, 5% in construction, 4% in finance, 15% in government, 8% in transportation, communication and utilities and 25% in manufacturing.

Despite the decline of the war-fostered shipbuilding industry, California industry, as a whole, grew continuously after World War II. By the 1950s the value added by manufacturing far exceeded the combined total value of products of raw-material producing enterprises—agriculture, mining, forestry and fishing. In 1900 California was responsible for only 2% of the nation's manufacturing output, but by the second half of the 20th century, it accounted for approximately 8% of the total. After mid-20th century manufacturing expanded more rapidly than did population. The development of new sources of supply of steel, wood, aluminum, rubber, paper and chemicals in the west and the expansion of electric power, natural gas, fuel, oil and water supplies were important incentives to the growth of manufacturing in the state after mid-20th century.

Transportation equipment (aircraft and parts, automotive manufactures and shipbuilding) was first in importance among California industries, and the largest manufacturing employer in the state, employing more than 300,000 persons. California's second largest manufacturing enterprise was food and beverage manufac-

turing. The state produces about 55% of the national output of dried and dehydrated fruits and vegetables and is a leader in the frozen food industry, which increased its production by more than 500% in the decade following the end of World War II. The production of motion-pictures and television films has its centre in Hollywood (*q.v.*). The manufactures of machinery and electrical equipment were also important.

In lumber production California ranks second in the United States. The state has the largest per capita use of lumber in the nation—approximately 5,000,000,000 bd.ft. being used yearly within the state. Estimated timber cut on private and national forest land is 4,000,000,000 bd.ft. per year, while the growth rate of forests is about 1,300,000,000 bd.ft. annually. The disparity between growth and cutting rates threatens to exhaust the state's forest reserves. Chief varieties of commercial timber are ponderosa pine, Jeffrey pine, redwood and sugar pine.

Transportation.—The transportation facilities increased rapidly after the completion of the first continental line in 1869 by the connection of the Central Pacific and Union Pacific lines. Total railway mileage by mid-20th century exceeded 15,000 mi. This was supplemented by almost 2,000 mi. of electric railroads.

After 1919 there was rapid improvement of highways. The state highway system has almost 15,000 mi. of roads, supplemented by many miles of surfaced and unsurfaced county roads. In 1947 the state inaugurated a ten-year highway development plan for modernization of highways and establishment of freeways. Subsequent federal legislation provided for further aid.

Epochal events in the development of highway communication were the opening in 1936 of the 8½-mi. San Francisco-Oakland bay bridge, and in the following year the opening of the Golden Gate bridge linking San Francisco with Marin county. The San Francisco bay bridge between San Rafael and Richmond was opened in 1956. Highway transportation by truck, motor coach and automobile was more highly developed in California than in any other state. Metropolitan areas were dependent on trucking to supply agricultural freight. Vehicle registration more than doubled in the decade after World War II, and by 1960 there was an average of one vehicle registered for every two persons (considerably higher than the average for the nation as a whole). Consequently multi-lane highway construction increased, and there appeared continuous highway systems, such as the Golden State freeway between Los Angeles and Sacramento and the coast highway between San Diego and San Francisco.

Normally there is frequent freight and passenger service from San Francisco and the port of Los Angeles to Hawaii, Australia and Asia, as well as to American ports on both the Atlantic and Pacific. World War II materially affected the volume and nature of shipping handled by California ports. Normally the chief exports are petroleum, grains, fruit, vegetables, fish and manufactured products. Developments in man-made harbours include the dredging and subsequent growth of San Pedro—the port of Los Angeles—and the growing importance of the interior deep-water port of Stockton on the San Joaquin river. San Diego has an excellent harbour, but it is principally used by the navy. San Francisco, formerly the most important port, was surpassed by Los Angeles. By the second half of the 20th century more than \$1,000,000,000 annually in exports and imports moved through Los Angeles, San Francisco and San Diego customs districts.

Mineral Products.—The existence of gold had been suspected in California long before 1848, and there had been desultory washings in parts where there was very little to reward prospectors. The first authenticated discovery was made near Los Angeles in 1842. The discovery of real historical importance was made on Jan. 24, 1848, at John A. Sutter's mill, on the south fork of the American river near Coloma, by a workman, James W. Marshall (1810–85). At the time of their greatest productiveness from 1850 to 1853, the highest yield of washings was probably not less than \$65,000,000 a year. From the record of actual exports and a comparison of the most authoritative estimates of total production, it may be said that from 1848 to 1856 the yield was almost certainly not less than \$450,000,000, and that about 1870 the \$1,000,000,000 mark had been passed. Placer-mining was of chief importance in

the early years, followed by an important but devastating era of hydraulic mining; after the richer deposits had been exploited the machine-worked quartz mines came into prominence. By 1933 more than half the gold output was from such mines. Quartz veins are often as rich at a depth of 3,000 ft. as at the surface. A remarkable feature of mining after 1900 was gold dredging. (For detail on dredging see **GOLD: Gold Mining and Refining: Placer Prospecting and Mining.**) Thousands of acres of land were thus treated.

In 1933 the stimulus of higher prices for the metal resulted in a marked expansion of gold mining. The number of mines increased and production of gold likewise rose. Until 1941 California was the national leader in gold production. The total value of gold produced in California in the century following the Sutter's mill discovery was more than \$2,000,000,000. Pre-eminence was regained in 1948 with production valued at \$14,751,555, but again declined in the succeeding decade. Many of the important lode mines, closed by government orders in World War II, were not reopened. Gold production continued to decline after mid-century as several underground mines ended operations.

Petroleum and the products associated with it have an annual value far in excess of the historically important gold. The production of crude petroleum grew rapidly after 1895, its output soaring from 4,325,000 bbl. in 1900 to 262,876,000 bbl. in 1923. In 1929 it ascended to 292,534,000 bbl. The depression of the 1930s drove production downward, but by 1939 production figures reached 224,354,000 bbl. By the end of the succeeding decade annual production exceeded 300,000,000 bbl., and continued at that level into the second half of the 20th century. The value of petroleum production is greater than the combined total of the value of all other mineral resources within the state. About 77% of the state's total mineral production value is from petroleum. Leading petroleum producing areas are situated in Wilmington, Long Beach, Huntington Beach, Midway-Sunset, Kettleman hills and Coalinga. Other less famous wells and areas rival these in activity. California is second only to Texas in crude oil productive capacity and provides about 15% of U.S. oil. The existence of oil pools offshore had been known since 1896, but not until 1954 was the first offshore well drilled from a man-made island; within a year seven additional wells had been drilled from the island. The federal Tidelands act of 1953 and California's Shell bill of 1955 were designed to promote exploration and development in this activity to meet state needs for more fuel. (See **PETROLEUM: Methods of Production: Offshore Drilling.**)

California has a greater variety of valuable minerals in workable form than any other area of its size on earth. It has the largest known reserves of boron minerals, and after World War II produced more than 90% of the world's requirements. The first shipment of uranium ore was made from San Bernardino county in 1954 and by 1960 radioactive minerals had been discovered in about 300 places, mostly in desert areas of southern California.

Other leading mineral products were cement, sand, stone and gravel, salt, clay, lead, lime, magnesium and magnesium compounds and gypsum. California was also the chief source of quicksilver, chromite, iodine and pumice.

and control by an office staff, and are of very unequal value; they are a vast storehouse of detailed material, and are of substantial historical accuracy and adequacy. Written by himself, and more uniform in treatment, is Hittell's *History of California*, 4 vol. (1885-97).

The earliest historian of California was Francisco Palóu, a Franciscan, the friend and biographer of Serra; his most important work was "Noticias de la Nueva California" in *Documentos para la historia de México*, series iv, vol. vi-vii (1857) and also *San Francisco*, 4 vol. (1874). See in this connection Palou, *Historical Memoirs of New California*, ed. by H. E. Bolton, 4 vol. (1926). The best contemporary material on the Mexican period is afforded by A. Forbes, *History of Upper and Lower California From Their First Discovery to the Present Time* (1839); R. H. Dana, *Two Years Before the Mast* (1840); also A. Robinson, *Life in California* (1846); see also F. W. Blackmar, *Spanish Institutions of the Southwest* (1891). Helen Hunt Jackson's novel, *Ramona* (1884), gives a beautiful and vivid picture of the old society. For the mission period the standard Franciscan work is Z. Engelhardt, *The Missions and Missionaries in California*, 4 vol. (1908-15). Palou, *Relación Histórica de la Vida . . . de . . . Serra* (1787) is an important contemporary source. On the flush mining years the best books of the time are E. Bryant, *What I Saw in California* (1848); J. Q. Thornton, *Oregon and California*, 2 vol. (1849); Bayard Taylor, *Eldorado*, 2 vol. (1850); W. Colton, *Three Years in California* (1850). See also C. H. Shinn, *Mining Camps: a Study in American Frontier Government* (1885); J. Royce, *California—A Study of American Character, 1846-1856* (1886); Owen C. Coy, *Gold Days* (1929) and *The Great Trek* (1931); and for a pictorial and factual account *The Mother Lode Country*, State Division of Mines Bulletin 141 (1948). See also the works of Bret Harte.

A good general geography is P. F. Griffin and R. N. Young, *California, the New Empire State* (1957). See also C. M. Zierer (ed.), *California and the Southwest* (1956).

For government, see D. E. McHenry and W. W. Crouch, *California Government* (1949); the *California Blue Book*; and reports of various officers and departments of the state government, and of the State Chamber of Commerce. An excellent geographical dictionary is Erwin G. Gudde, *California Place Names*, 2nd rev. ed. (1959). There are various guides, including C. F. Saunders, *Finding the Worth While in California* (1930); A. Drury, *California: an Intimate Guide* (1947).

Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments; the principal figures, together with the current history, are summarized annually in the *Britannica Book of the Year*, American edition.

(C. E. CH.; R. H. SH.; D. C. CR.; J. E. BA.)

CALIFORNIA, LOWER (Sp. BAJA CALIFORNIA), the peninsular extension of California (U.S.) which bounds it on the north, belonging to Mexico. Pop. (1960) 604,346, divided between a northern state with 520,913 and a federal territory occupying the area south of the 28th parallel, 83,433. Area 55,634 sq.mi. Lower California is 776 mi. long, with a breadth varying from 30 to 150 mi. Its western and southern coasts are bounded by the Pacific ocean. Between its eastern shores and continental Mexico lies the Gulf of California, also called the Sea of Cortés. Its land connection with the rest of Mexico is a narrow strip at the head of the gulf and south of the international boundary from Yuma, Ariz., to the Pacific.

Off the nearly 2,000 mi. of irregular coast line lie numerous islands in the Pacific and gulf, most of them barren and hazardous to navigation, although Guadalupe is of some interest for its wild goat population.

The cordillera which traverses Lower California from north to south is an extension of the San Jacinto range of California and under various local names follows the gulf from which it rises steeply, in the San Pedro Mártir range is found a high peak, La Encantada (10,069 ft.), and midway stands the extinct volcano Las Tres Virgenes.

The rich delta of the Colorado river, which flows southward for about 90 mi. before emptying into the Gulf of California, called the Imperial valley on the U.S. side, becomes the Mexicali valley in northeastern Lower California. The basic geologic material of the mountain backbone and the rest of the peninsula is a grayish biotite granite. Much eroded and overlaid with alluvial and volcanic strata, it is veined with various minerals. In general the north of the peninsula is the chief gold-bearing area, the central sections are noted for copper and iron, while silver has predominated in the south. Mica, tin, tungsten, manganese and various minor substances are found.

The prime fact of Lower California's climate is its excessive aridity and generally high temperatures. Nonhere is rainfall abundant: the northwest corner, with less than 10 in. annually, is

perhaps the best watered section, though isolated mountain valleys and high peaks of the Gulf range receive as much or more moisture. Agriculture must depend on irrigation, and permanent water supplies are few; they consist of the Colorado river and groups of small stagnant pools found mainly north of Ensenada, around Mulegé and La Purísima, and south of the 24th parallel. There is no permanent river system.

Flora and fauna correspond to the climatic conditions. Lower California has one of the world's richest and most remarkable ranges of desert vegetation. It includes vast forests of giant cactus or cardon, cirio, neird-looking elephant wood (*Veatchia discolor*), heavy growths of barrel cactus, as well as various species of *Opuntia*, yucca, ocotillo and nearly every other desert plant. On some high mountain slopes are pine forests. After water was diverted from the Colorado river at the turn of the 20th century, the Mexicali section began to bloom; the combined agricultural and industrial growth of northern Lower California led it to outstrip the southern half in population and wealth. Separated by the central barrens, each tended to live its own life.

Inadequate communications, internally and externally, contributed to the isolation of Lower California from the rest of Mexico. About 75 mi. south of Ensenada, goods and people move in cumbersome carts or on muleback over stony trails, a peril to automobiles. Flash floods or rains make the dirt trails impassable. In the north, a local net of highways began to evolve in the 1940s. Rail communications are found only in the north near the international boundary. Railways link Tijuana and Algodones to Mexicali and the latter to the United States. The joining of the Inter-California del Sur line from Mexicali to trunk lines of the National Railways of Mexico in 1950 tied Lower California to continental Mexico. Feeder routes from the northern centres connect with principal national and international air lines. The southern territory is more firmly knit to Mexican Pacific and gulf ports by communications than to its northern neighbour. Transgulf steamship and air lines from Santa Rosalia and La Paz terminate at Topolobampo, Guaymas, and Mazatlán. Between Mazatlán and La Paz are telephone and wireless telegraph lines. Despite its long coast line, Lower California has few good natural harbours.

The people of the peninsula are Mexican, with less than 500 Indians remaining at mid-20th century from an estimated population of 25,000 in 1700. Illiteracy is lower than in much of Mexico. Principal towns with their 1960 populations are: Mexicali (171,648), political and economic capital of the north, which also includes Tijuana (137,644) and Ensenada (18,140 in 1950); in the south, La Paz (23,252) is the capital and an economic centre; Santa Rosalia (6,950 in 1950), hub of a mining district.

In 1931 Lower California was subdivided politically into two federal territories, with the boundary giving each approximately half the area. Each was provided with an appointed governor and appropriate governing apparatus. Their respective populations then were northern territory, 48,327; southern territory, 47,089. By 1950 the northern territory registered a total of 226,965; it had become the fastest growing entity in Mexico and surpassed the minimum of 80,000 persons which the Mexican constitution set for statehood. The legislatures of the other Mexican states and the Mexican congress acted favourably on a presidential request that Lower California north be admitted as a free and sovereign state into the Mexican union. In Jan. 1952 it became the 29th Mexican state. Lower California south, with a 1950 population of 60,864, retained its territorial status. However, by 1960 Lower California south, with a population of 83,433, exceeded the minimum population requirements for statehood.

Lower California north is a progressive agricultural and industrial area, closely tied to U.S. markets and sources of power. The Mexicali area is a noted cotton producer. In the ten years 1940-50 its acreage increased from 115,000 to 400,000 and the harvests from 60,000 *pacas* or bales to 265,000. In addition this area grows wheat, alfalfa, grapes, tomatoes, melons, linseed and maize. The United States furnishes a ready market for its winter vegetables. Connected with mounting commercial agriculture has been industrial activity, especially food processing and cotton-seed manufacturing. Public revenues grew from 5,300,000 pesos in 1930 to

more than 36,000,000 in 1950, with corresponding growth of education, communication and public services. Earlier in its history the northern area was a notable mining area, as gold was mined after its discovery near Real del Castillo (1872).

The southern territory remained a mining, grazing and subsistence agricultural region. Near Mulegé is a mountain of iron, and gold was found nearby in 1884. The French company founded in that year to mine and process copper from the Boleo mines continued to extract that metal and silver for shipment to the United States in their own vessels; this operation came to dominate. Santa Rosalía and since mid-20th century was the largest mining enterprise on the peninsula, though tungsten comes from the Fenómeno mine near Ensenada. La Paz is a leatherworking and dairy centre for nearby grazing activities; its modern shoe factories obtain only a third of the needed hides from local sources; cheese and wine making are also significant. In earlier days La Paz was a pearl-fishing centre. The main agricultural zone of the south is the cape section at the tip of the peninsula.

History.—The Spanish discovered and explored Lower California. It was first sighted by one of Cortés' pilots in Dec. 1533, and the conquistador wasted much substance trying to settle the place in face of hostile Indians. After these and other expeditions, terminating with that of Juan Rodriguez Cabrillo (1542-43), proved futile, the peninsula was neglected for many years. After initial failures Jesuit missionaries, under the leadership of Juan Maria Salvatierra, successfully landed and established the first permanent settlement at Loreto in 1697. The first Jesuits found the aborigines of Lower California animallike, without knowledge of agriculture, houses or clothing. In the string of missions, finally amounting to 20 stretching into upper California, the Jesuits congregated these charges and instructed them under a feudal arrangement. When in 1767 the Jesuits were expelled from the Spanish realms, their native charges passed into the hands of the Franciscan order, but the latter shortly evacuated the peninsula (1772) and left it to ministrations of the Dominicans. They founded some new missions, but their influence was lessened because of widespread deaths among the Indians, and by secularization of the church establishments in 1833. During the war between Mexico and the United States (1847-48), Lower California was occupied by U.S. troops. Numerous filibustering campaigns, as well as offers by the United States to purchase all or part of the area, kept Lower California in international affairs. From 1903 to 1910 the U.S. fleet used Magdalena bay for drills and target practice and from 1866 to 1925 maintained a coaling station near La Paz. Ensenada and La Paz were military headquarters for the important defense zone that included Lower California during World War II and the Mexican navy used Magdalena bay as a base.

In the second half of the 20th century Lower California's popularity as a tourist centre increased. Several airlines linked the chief towns with the United States and Mexico. Paved highways were extended in the northern Tijuana-Mexicali section, and in the extreme south around La Paz. In addition to the mild winter climate, the peninsula offers hunting, deep-sea fishing and swimming. La Paz, Ensenada and several other towns have good hotels. Tijuana is a favourite place for sailors out of San Diego. Its bullfights and horse races draw large crowds from the U.S.

Around La Paz nearly 300,000 ac. were under irrigation in the early 1960s, planted in banana and other fruit trees, citrus, sugar cane, melons, grapes and winter vegetables. There are also numerous coconut and date palms, papaya, mango, avocado and walnut trees. In 1958 Lower California had the highest number of automobiles per capita of any Mexican state, and its total output per capita was surpassed only by that of the Mexico City area.

mitted at the graduate level) in Pasadena, Calif. See PASADENA.

CALIFORNIA LILAC (*Ceanothus thyrsiflorus*), a name given to a handsome North American evergreen shrub or tree of the buckthorn family (Rhamnaceae; *q.v.*), also called blue blossom and blue myrtle. It grows on canyon sides from Monterey northward to Oregon and is especially abundant in the redwood belt. Usually a shrub 3 ft. to 8 ft. high, it sometimes becomes a small tree 25 ft. in height with straight ascending branches. The showy blue or occasionally white flowers, borne in dense clusters about three inches long, make this plant prized as an ornamental. See CEANOTHUS; NEW JERSEY TEA; OREGON TEA TREE.

CALIFORNIA PITCHER PLANT: see DARLINGTONIA.

CALIFORNIA POPPY

(*Eschscholtzia californica*), a popular annual herb of the poppy family (Papaveraceae), abundant in the valleys and foothills of the Pacific coast of the United States. It has erect or diffusely spreading stems one foot to two feet high, finely dissected leaves and large, pale-yellow to deep golden-orange or red flowers, four inches or more across, the petals glowing with a brilliant sheen.

It is one of the most handsome and best-known representatives of the California flora, is widely

HORACE MCFARLAND CO.
 (ESCHSCHOLTZIA CALIFORNICA)

cultivated as an ornamental and has become extensively naturalized in India, Australia and elsewhere. A red-flowered variety is known as geisha. See also POPPY.

CALIFORNIUM. The synthetic element californium has the chemical symbol Cf and the atomic number 98. It occupies a position in the periodic system of the elements as the ninth member of a rare-earth-like transition series, the actinide series, which includes the heaviest known elements in which an inner electronic shell (the 5f shell) is being filled. For a discussion of its discovery, see TRANSURANIUM ELEMENTS.

As in the case of a number of the other actinide elements, there is no unambiguous designation of an atomic weight. In those instances where there is a formal requirement for this quantity, the use of the mass number of the longest-lived isotope might be considered. The long-lived isotopes are produced from Bk²⁴⁹ (see BERKELIUM) as follows. The isotope Cf²⁴⁹ results from the beta decay of Bk²⁴⁹ while the heavier isotopes are produced by intense neutron irradiation of either Bk²⁴⁹ or Cf²⁴⁹. In the case of Bk²⁴⁹ the capture of a neutron results in the production of Bk²⁵⁰ which decays with negative beta particle emission to yield Cf²⁵⁰. The bombardment of Cf²⁴⁹ with neutrons produces successively Cf²⁵⁰, Cf²⁵¹ and finally Cf²⁵².

Californium (as a mixture of these four isotopes) was first isolated in weighable amounts by S. G. Thompson and B. B.

Isotopes of Californium

Isotope	Half-Life	Type* and energy of radiation (MeV)
Cf ²⁴⁴	25 min.	α 7.17
Cf ²⁴⁵	44 min.	EC (70%) α (30%) 6.11
Cf ²⁴⁶	35.7 hr.	α 6.753 (78%) 6.711 (22%)
Cf ²⁴⁷	2.5 hr.	EC
Cf ²⁴⁸	350 days	α 6.26
Cf ²⁴⁹	400 yr.	α 6.190 (3%) 5.91 (6%) 5.82 (90%)
Cf ²⁵⁰	9.3 yr.	α 6.024 (83%) 5.980 (17%)
Cf ²⁵¹	800 yr.	α pred.
Cf ²⁵²	2.2 yr.	α (97%) 6.112 (82%) 6.069 (15%)
Cf ²⁵³	19 days	β ⁻
Cf ²⁵⁴	56 days	SF

*EC = electron capture; α = alpha particle; β⁻ = negative beta particle; SF = spontaneous fission.

Cunningham in 1958. The material was obtained from the same irradiation that resulted in the first isolation of berkelium in weighable amounts.

Tracer chemical studies indicated that the III oxidation state is the most stable in aqueous solution, as might be expected from its position as the homologue of dysprosium. Much of the investigation of the chemical properties of californium was concerned with its ion exchange properties in elution experiments with columns packed with ion exchange resins, and these methods are used to separate it from the other tripositive actinide elements. It can be separated from the rare-earth elements by the use of eluting agents such as concentrated hydrochloric acid, which forms complex ions with the actinide elements that are much more stable than the corresponding ones with the rare-earth elements.

Solubility properties of californium III appear to be just those expected and seem to be entirely analogous to those of all the tripositive actinide and lanthanide elements. Thus such compounds as the fluoride and oxalate appear to be insoluble in acid solution while the nitrate, halide, sulfate, perchlorate and sulfide all appear to be soluble.

CALIGULA (GAIUS CAESAR) (A.D. 12–41), Roman emperor from A.D. 37 to 41 in succession to Tiberius. He was handsome, intelligent and well-educated, and when, with no administrative experience, he became emperor, he was immensely popular. In under four years he squandered Tiberius' accumulated savings and lost all his popularity. The accounts of his reign by ancient historians are so biased that the truth is almost impossible to disentangle.

Named Gaius Caesar, his nickname "Caligula" (little boot) was given him in childhood by the soldiers of the Rhine army which his father Germanicus (q.v.) commanded from A.D. 12 to 16. The death of his father in A.D. 19, of his mother Agrippina in 33 and his two elder brothers, Nero Caesar in 31 and Drusus Caesar in 33, were popularly ascribed to the malevolence of Tiberius. Gaius and his three sisters Agrippina, Drusilla and Livilla survived. Adopting his father's distinguished name, he became Gaius Caesar Germanicus.

He was severely ill seven months after his accession; after this he restored treason trials, showed great cruelty and indulged in wild despotic caprice, e.g., he bridged the Bay of Naples with boats from Baiae to Puteoli in summer 39. In 38 he executed Naevius Sertorius Macro, prefect of the praetorian guard, to whose support he owed his accession, and Tiberius Gemellus, grandson of Tiberius, whom he had supplanted in the succession. He made pretensions to divinity, and showed extravagant affection for his sisters, especially Drusilla who, on her death in 38, was consecrated as Diva Drusilla, the first woman in Rome to be so honoured. This relationship has prompted the suggestion that he aimed at establishing a Hellenistic type of monarchy, on the example of the brother-sister marriages of the Ptolemies. Others have thought that after his illness he was mad; but much so-called evidence of his madness—e.g., that he made his horse consul—is untrue.

Appearing unexpectedly on the upper Rhine in Oct. 39, he suppressed an incipient revolt, executing Drusilla's widower M. Aemilius Lepidus and Gnaeus Lentulus Gaetulicus, the commander of the upper Rhine armies, and restored discipline by stiff maneuvers, travestied in the accounts of ancient historians. In 40 he was in Gaul, and probably raised two new legions and planned to invade Britain in spring 40. Possibly the troops refused to go on board: on this occasion, instead of ordering them to embark, Gaius allegedly commanded them to pick up shells. A pogrom in Alexandria in Aug. 38 and trouble in Palestine in winter 39 led Gaius to order the governor of Syria to erect his statue in the temple at Jerusalem in summer 40. Under the suave persuasion of Herod Agrippa at Rome Gaius countermanded the order. A conspiracy was formed (A.D. 40–41) and Gaius was murdered by Cassius Chaerea, a tribune of the guard, at the Palatine games on Jan. 24, A.D. 41.

CALINESCU, ARMAND (1893–1939), Rumanian statesman, a representative of peasant interests who was prime minister for a few months in 1939, was born at Pitești on May 22, 1893, the son of an army officer and landholder. After graduating in law at the University of Bucharest and obtaining a doctorate in political science at Paris, he established a legal practice in Pitești, later entering politics as a prefect of his county and as an organizer for the National Peasant party, formed in 1926. An expert in agricultural economics, he was appointed secretary-general of the ministry of agriculture and later was undersecretary for the interior in the National Peasant administration which lasted from 1928 to 1931. In Dec. 1937 he became minister of the interior in the National Christian cabinet of Octavian Goga, and he retained this portfolio in the two cabinets headed by the patriarch Miron Cristea after the establishment of King Carol II's dictatorship in Feb. 1938.

When Cristea's health failed, Calinescu was appointed vice-premier, and on Cristea's death he became premier (March 7, 1939). A bitter enemy of the "All for Fatherland" party (Iron Guard), he was assassinated on Sept. 21, 1939, by Iron Guardists while driving to his house at Cotroceni, near Bucharest.

(B. BR.)

CALIPH, a title of the head of the Muslim community (see CALIPHATE; ISLAM). When Mohammed died on June 8, 632, Abu Bakr (q.v.) succeeded to his political functions by the choice of the Muslims of Medina, with the title of khalifnt *rasul-Allah* ("deputy or-successor of the Messenger of God"). *i.e.*, caliph. The office has been in abeyance since the Caliphate congress held in Cairo in 1926.

CALIPHATE, a term restricted, in general historical usage, to the history and rule of the successors of the prophet Mohammed in the government of the Muslim community and of the territories occupied or subjugated by the Arabs. These comprise: (1) the first four caliphs, the immediate successors of Mohammed at Medina; (2) the Omayyad caliphs of Damascus; (3) the Abbasid caliphs of Baghdad. To these three groups the present article is confined. For the western caliphs see ABD-AL-RAHMAN; ALMOHADS; and SPAIN: History. For the Egyptian caliphs see EGYPT: History; and FATIMIDS. The history of Arabia proper will be found under ARABIA.

THE FIRST FOUR CALIPHS

Mohammed died at Medina on June 8, 632, without leaving any instructions for the future government of the Muslim community. In the confusion that followed several parties began to form, notably among the Medinian tribes, and a meeting of the Khazraj tribe was convened to choose a leader. Several of the Meccan companions, including Abu Bakr and Omar, joined in the meeting. After lengthy argument, it was agreed to recognize Abu Bakr as leader of the community, and the choice was ratified on the following day by the people as a whole, except for Mohammed's son-in-law Ali, who made submission only some months later. Abu Bakr adopted the title of khalifat *rasul-Allah* ("successor of the Messenger of God"), whence the term "caliph."

Abu Bakr (632–634).—Abu Bakr was confronted immediately by the revolt of several tribes in Hejaz and Nejd against the government of Medina. In face of his uncompromising attitude the Hejaz tribes submitted without fighting, but the Nejd tribes, excited by the appearance of "false prophets," had to be subjugated by military forces under the command of Khalid ibn al-Walid. After a desperate struggle against Musailima in Al Yamamah (Al Kharj, eastern Nejd) in May 633, minor expeditions secured the submission of the rest of the Arabian peninsula. Meanwhile Khalid, with support from the tribe of Bakr, raided the borderlands of Iraq and captured Hira (q.v.). In the same year, the tribesmen were summoned by Abu Bakr to join in expeditions into Palestine and Transjordan, under Amr ibn al-As (q.v.) and other leaders. In face of the Byzantine counteroffensive,

Khalid made a hazardous march across the Syrian desert, re-joined the combined Arab forces in southern Palestine and defeated the Greeks at Ajnadain (July 30, 634).

Omar (634-644).—The first steps toward a regular conquest of Syria had thus been taken before the death of Abu Bakr (Aug. 23, 634) and the immediate and uncontested succession of Omar, under whom the conquests were extended to Iraq, Mesopotamia and Egypt. On his accession Omar took the title of *amir al-mu'minin* ("commander of the faithful"; *i.e.*, of the believers), which became the formal title of all later caliphs.

For the history of the Arab conquests scarcely any contemporary annals have survived, and their progress has to be largely reconstructed from the traditions preserved by the Arabic chroniclers about two centuries later. Though confused in part by the growth of tribal sagas and heroic legends, the core of these traditions proves to be remarkably accurate and consistent in its presentation of the main events. Many details still remain obscure, particularly in regard to the conquest of Egypt and to the strategy and tactics of the opposing forces. The Greek chronicles which describe the campaigns are, unfortunately, no earlier than the Arabic and contain only curt mentions of battles and sieges.

The armies of the Arabs were formed entirely of tribesmen mounted on camels and horses, whose traditional method of fighting was to charge in a long line, cast a shower of javelins on the opposing force, wheel back to a prearranged base line, repeat the tactics until the enemy line showed signs of breaking and then engage in hand-to-hand combat. In arms (lance, bow and sword) they were little inferior to their enemies, whose tactics were familiar to the frontier tribes from centuries of warfare as allies or as opponents of Roman and Persian armies. But, having no siege equipment, they were unable to besiege cities and fortresses, which they could capture only by storm, treachery or blockade. Their greatest advantage (besides their mobility) was that, as the aggressors, they were able to choose their ground and to fight their chief battles on the edge of the desert, where they were safe from attack in the rear and their communications were fully protected. The forces engaged on both sides are often greatly exaggerated, but it is probable that in numbers of fighting men the Arabs were seldom inferior to their opponents in pitched battles.

Khalid, following up the retreating Greek army, defeated it again at Fihl (Pella), near Beisan (Jan. 23, 635), surrounded Damascus, which surrendered on Sept. 4, and pushed northward. Early in 636 he withdrew south of the Yarmuk river before a powerful Greek force which advanced simultaneously from the north and from the coast of Palestine. But the Greek armies were composed mainly of Arab, Armenian and other auxiliaries, who felt little loyalty to the empire; the treasury and the provinces were exhausted by the long Persian wars and the Persian invasions; and the populations were apathetic, if not actively hostile. When a rebellion broke out in the Greek camp, Khalid, reinforced from Medina and possibly from the Syrian Arab tribes, attacked and destroyed the Greek forces in the precipices of the Yarmuk valley (Aug. 20, 636). Damascus was regained in the same year; and three Arab armies occupied, against little resistance, the northern cities, Palestine and the coastal region. Jerusalem held out until the caliph Omar received its surrender in person in 638; and Caesarea and Gaza fell in 640. The last Greek strongholds, Ascalon and Tripoli, capitulated only in 644 and 645. The Arab troops were established in military cantonments (called *jund*) in Damascus, Jabiya, Homs (ancient Emesa) and Kinnasrin; and in 640 the Omayyad Mu'awiya ibn Abi Sufyan was appointed governor of all Syria.

After Khalid's withdrawal, the tribesmen of Bakr, defeated by the Persians, withdrew to Hira, but on the arrival of Yemenite reinforcements drove back a Persian counterattack at Buwaib (Oct. 635). Only after the victory of the Yarmuk did Omar feel free to organize a full-scale invasion, under the command of Sa'd ibn Abi Wakkas; the main Persian army, commanded by Rustum, was broken at Kadisiya (June 637), the Sasanian capital Ctesiphon (al Mada'in) fell in the following month, and the remaining Persian forces were again defeated at Jalula (near Hulwan) in December. Two new garrison cities (*misr*) were founded for the

Arab troops at Kufa and Basra, from which annual expeditions were organized, each tribe being allotted its own quarter in the city.

Syrian troops had already begun to occupy Mesopotamia from the west in 638-639; in 640 Iraqi troops conquered Mosul and Kurdistan and pushed into Azerbaijan, while the Syrians raided Armenia for several years in succession.

The conquests made by the Arabs hitherto had been in the relatively flat and familiar area of the fertile crescent. But their possession of Iraq remained insecure so long as the Persians were at liberty to reorganize their forces in the Iranian plateau. Undeterred by the difficulties of the terrain and of adapting their methods of fighting to mountain warfare, the Arab generals in Iraq set out to effect the systematic conquest of Persia. While the troops of Basra were engaged in the task of reducing Khuzistan (638-644) and Fars (644-650), those of Kufa began to penetrate the highlands through the Hulwan gap. After a fresh Persian army had been defeated in a hard-fought battle at Nehavand (641), the western edges of the Persian plateau were conquered piecemeal, but the Arabs continued to encounter obstinate resistance both in Rayy and in the province of Fars. It was only on the final subjugation of Fars in 650 that the troops of Basra were able to sweep across the plateau to occupy Kerman and Khurasan.

The last Sasanian king, Yazdegerd III, fleeing before them, perished miserably near Merv in 651; and in the following year the campaigns were rounded off with the occupation of Merv, Balkh and Herat.

In 639, Amr ibn al-As, on his own initiative, led his 4,000 Yemenite troops down into Egypt on an extensive raid. Reinforced from Medina in 640, he concentrated his forces on the edge of the delta at 'Ayn Shams (Heliopolis). The Greek forces advancing from the fortress of Babylon to engage him were severely defeated in July, and during the following siege of the fortress Amr negotiated the submission of the Coptic population. On the surrender of Babylon (April 641), he advanced on Alexandria, which surrendered after a truce of 11 months. In 642 a new garrison city was founded at Al Fustat (modern Misr al Qadimah); in the same year expeditions were sent into Nubia and westward into Cyrenaica; and Tripoli was captured after a siege in 643. A last attempt at reconquest was made by the Greeks in 645 with a sudden naval attack on Alexandria, but Amr regained the city by assault. (See also EGYPT: History: *Medieval Period*.)

The part played by the caliph in these conquests was a far from passive one. Though the details of strategy were necessarily left to the discretion of the commanders, Omar maintained a remarkable measure of general control over their objectives and policy. Their government of the provinces was closely supervised and any delinquency sharply reprimanded or punished. The most difficult problem that confronted the Arab rulers was the administration of the newly conquered territories. The method generally adopted was to leave the land in the possession of its existing owners and taxation in the hands of existing officials, in return for fixed annual payments in money and kind. The conquests constituted a perpetual endowment for the upkeep of the Arab garrison troops, who received four-fifths of the provincial revenues and of war booty; the other fifth, together with crown lands and sequestered estates, was at the caliph's disposal for distribution at Mecca and Medina.

Othman (644-656).—On the death of Omar, who was stabbed by a Kufan workman in the mosque at Medina (Nov. 3, 644), a conclave of Meccan nobles at Medina elected the already aged Othman as caliph. For six years or more the conquests proceeded steadily and Syrian armies began to probe Asia Minor. A notable new development was the organization of Syrian and Egyptian fleets, which occupied Cyprus and in 655 defeated the Greek fleet near Phoenix in Lycia. But with the removal of external dangers the tribesmen began to resent the control exercised by the caliph and his governors, the economic exploitation of the conquests by the commercial aristocracy of Mecca and the favours shown to his kinsmen of the Omayyad family by Othman. Encouraged by the caliph's weakness and by preachers who denounced his errors and innovations (notably his issue of an official text of the Koran and order to destroy all others), the troops in Kufa and Al Fustat rebelled. A party from Egypt, headed by the son of Abu

Bakr, marched to Medina, besieged Othman in his house and killed him (June 17, 656).

Ali (656–661).—The mutineers and Medinians then recognized Ali (*q. v.*), Mohammed's son-in-law, as caliph. Two Meccan nobles, Talha and Al-Zubayr, joined by Alohammed's widow Aisha, escaped to Iraq and gained the support of the garrison at Basra. The rival garrison at Kufa now joined Ali, who defeated his opponents in the "battle of the camel" (ridden by Aisha), and established himself in Kufa.

When Mu'awiya, governor of Syria, calling for vengeance for the blood of his kinsman Othman, refused to recognize Ali, the Kufans invaded Syria; the armies met at Siffin and, after long and indecisive negotiations and skirmishes, agreed to submit the case to arbitration (Aug 657). In the surviving accounts of the meeting of the arbitrators there is more legend than history, but it seems to have turned out unfavourably for Ali.

A group of fanatical dissidents at Kufa moved out to Nahravan (hence their name *khawarij*, sing. *khariji*, "outgoers," whence Kharijites) and openly rebelled; although Ali severely defeated them (July 658), similar, if smaller, risings broke out in various quarters, while Khurasan was lost through a Persian revolt, and Egypt regained for Mu'awiya by Amr ibn al-As. The Syrian raids on Xli's territories in Iraq and Arabia grew bolder and more effective; Mu'awiya could count on the obedience of loyal and disciplined troops, while Ali, having risen to power on a wave of revolution, was rendered powerless by the insubordination, on the one hand of the zealots who held him guilty for agreeing to arbitration, on the other of the ordinary tribesmen of Iraq who refused to engage the Syrians again, while he had lost the sympathies of Medina by transferring the capital to Kufa.

The zealots attempted to assassinate both Mu'awiya and Ali, but succeeded only in killing Ali (Jan. 661). His son Hasan, in face of an invasion by Mu'awiya and discord among his troops, abdicated a few months later and retired to Medina, where he died in 669.

THE OMAYYAD CALIPHS

Mu'awiya (660–680).—On his entry into Kufa, Mu'awiya, who had been proclaimed caliph in Jerusalem in July 660, received the submission of all Iraq, contested only by the *khawarij*, whose local revolts continued to disturb the peace for many years. His first care was to re-establish Arab rule in Khurasan, and several years later new garrison cities were founded at Merv and in Seistan, from which expeditions were directed into central Asia and north-western India.

The Egyptian armies under Okba ibn Nafi' began the invasion of northwest Africa and founded another garrison city at Kairouan. His expeditions culminated in a triumphal march to the shores of the Atlantic (681), followed by a Byzantine and Berber rising which drove the Arabs back to Cyrenaica. But the main Arab offensive was directed against the Byzantine empire. With the support of the fleet, Constantinople was attacked in 669, but in the following winter the Arab army was destroyed at Amorium. A fresh campaign was mounted in 673, and for four years Constantinople suffered an annual siege of several months. The invaders were repeatedly driven off by Greek fire, and their heavy losses compelled them to withdraw in 678.

Mu'awiya was a typical Arab *sayyid* ("gentleman"). He governed not by force but by superior intelligence, self-control, mildness and magnanimity. But behind him stood the disciplined army of Syria, with the most powerful tribe in which, the Kalb, he had allied himself by marriage. Well aware that the allegiance of this army was now the sole guarantee of the unity of the Arab empire and that the old Arab method of election to the caliphate was no longer practicable, he secured during his lifetime a general oath of allegiance to his son Yazid as his successor. The introduction of the hereditary principle was, however, an offense to Muslim ideas and especially disliked in Iraq, already restive over the transference of the capital to Damascus and the predominance of the Syrian army. Mu'awiya had had the good fortune to find an excellent governor for Iraq in Ziyad, a former partisan of Ali, said to be a bastard of Mu'awiya's father and publicly acknowledged

by the caliph as his brother. During his firm but just government Iraq remained quiet, but after his death in 673 the old tensions began to revive in the garrison cities and were further complicated by the gradual combination of groups of tribes into tribal and political factions.

Yazid I (680–683).—The opposition in Kufa flared into action on Mu'amiya's death, when the faction favourable to the house of Ali (the *Shi'a* or Shi'ites) invited Ali's second son Husain from Mecca to Kufa, to claim the caliphate. Yazid, informed of the threatening behaviour of the Shi'ites at Kufa, sent Obaidallah, the son of Ziyad, and governor of Basra, to restore order. Using the same tactics as his father before him, Obaidallah summoned the chiefs of the tribes and made them responsible for the conduct of their men.

Meanwhile Husain had set out with all his family, expecting to be received with enthusiasm at Kufa. Though warned on reaching Iraq of the change that had taken place, he persisted in his journey and at Karbala was confronted with a Kufan force commanded by Omar, a son of Sa'd ibn Ahi Wakkas. He gave battle and fell, with most of his family and followers, on Oct. 10, 680.

No other issue of this rash expedition could have been expected. But the tragic death of the prophet's grandson, with so many of his house, caused a strong revulsion of feeling, not only among the Shi'ite partisans at Kufa, who were the principal authors of the disaster, but among devout Muslims everywhere; and the facts soon acquired a wholly romantic colouring. This event, rather than the misfortunes of Ali, became the emotional root of Shi'ism; Omar ibn Sa'd and his officers, Obaidallah and Yazid himself, came to be regarded as murderers and their names to be held accursed by all Shi'ites, who have ever since observed the tenth day of Muharram, the day of *'Ashura*, as a day of public mourning (see *HASAN AND HUSAIN*). Among the Sunnis also it cast a cloud over the Omayyads and gave a handle to all their enemies.

Another of these enemies saw his own claim to the caliphate facilitated by the removal of Husain. Abdullah ibn al-Zubayr, the son of Ali's rival al-Zubayr, obtained the allegiance of Nedina and Mecca. After prolonged negotiations Yazid sent a Syrian army against Medina; the forces of the citizens were easily overcome and, according to tradition, the city was given up to plunder for three days. The Syrians then marched on Mecca in Sept. 683 and found Abdullah ibn al-Zubayr ready to defend it. The siege had lasted 64 days (during which the Ka'ba was damaged by bombardment) when the news came of the death of Yazid (Nov. 10, 683), whereupon the army returned to Syria.

Mu'awiya II (683).—Yazid's young and sickly son succeeded him, but died within two or three months. Abdullah ibn Zubayr was recognized throughout Arabia, Iraq and Egypt; but Marwan ibn Hakam of another branch of the Omayyads, proclaimed caliph at Damascus by the Kalb or Yemen faction in June 684, defeated the Kais (Qays) or northern Arab (Mudar) faction, who had declared for Abdullah, at Marj Rahit in the vicinity.

Marwan I (684–685).—Marwan immediately reconquered Egypt (Dec. 684) and installed as governor his second son Abdul-Aziz. Shortly after his return to Damascus he died (April 685) and was succeeded by his eldest son Abd-al-Malik.

Abd-al-Malik (685–705).—Meanwhile, in the provinces nominally subject to Abdullah ibn al-Zubayr also, the tribal factions were in open or latent hostility to one another, especially in the east, where the recently conquered populations revolted and drove the Arabs back upon Khurasan. In eastern Arabia, the province of Basra and Khuzistan, the Kharijites maintained a reign of terror and isolated Abdullah in the Hejaz. In Kufa the Shi'ites, defeated in their first engagement with Obaidallah, found a leader in Mukhtar, who organized the *marwali* ("clients"; *i. e.*, freed slaves and non-Arab freemen) and with the aid of the Yemenite Shi'ites crushed the Arab opposition and defeated and killed Obaidallah in Mesopotamia (Aug. 686).

Abdullah's brother Mus'ab Zubayr, governor of Basra, sent the troops of Basra under the Yemenite general Muhallab to regain control of Kufa, and the Shi'ites, after a desperate resistance, were put down with great slaughter.

For several years Abd-al-Malik was wholly occupied in Syria,

first against the Mardaite tribes in Lebanon, who had received Byzantine support, and then against the Kais tribes in the north. His major task was to reunite the factions in a reformed Syrian army; when this was accomplished in 692 he had little difficulty in defeating Mus'ab's forces and reoccupying Iraq, wearied by the Kharijite ravages.

In the same year a force of 2,000 Syrians, commanded by al-Hajjaj ibn Yusuf, after investing Mecca for six months, killed Abdullah ibn al-Zubayr, sword in hand, in the final assault. The Kharijite bands still held out; those in Arabia were broken up in 694 by Muhallab, but the troops of Basra and Kufa showed little enthusiasm for a further campaign in Khuzistan. At length, in 696, Abd-al-Malik committed the government of Iraq to al-Hajjaj. Within three days of his arrival the tribesmen of Kufa, overawed by his personality and biting eloquence, were on the march, and those of Basra soon followed.

After dispersing the Kharijites Muhallab was appointed in 697 to the government of Khurasan, under al-Hajjaj. He restored Arab control over the Oxus frontier, but the large contingent of his Yemenite fellow tribesmen who accompanied him introduced into the factional tensions of the province a new and powerful force, which was subsequently to play an important role in its history. The governor of Seistan likewise attempted to reimpose Arab control over Afghanistan (then called Zabulistan), but was caught at a disadvantage in the difficult passes by the king of Kabul and held to ransom. Al-Hajjaj dispatched the troops of Kufa and Basra in 699 to exact retribution, under a Yemenite chief, Ibn al-Ash'ath, but after their arrival in Seistan, resenting the peremptory commands of al-Hajjaj, they revolted and marched back on Iraq. The governor's weak forces were brushed aside and the rebels occupied first Basra and then Kufa. Al-Hajjaj, reinforced by Syrian troops, held his ground at Dair al Jamajim, outside Kufa, until the Kufan army broke, when he re-entered the city, but the rebellion was put down only after a violent battle at Maskin, on the Dujail (701). The defeated Iraqians fled to Seistan, pursued by the Syrians, and eventually surrendered to Muhallab's son at Herat. Ibn al-Ash'ath took refuge with the king of Kabul and on the demand of al-Hajjaj for his surrender either was killed or committed suicide.

Ibn al-Ash'ath's rebellion was primarily a bid by the tribesmen of Iraq to throw off the government of Syria. The proud tribal chiefs smarted under the iron control of the plebeian al-Hajjaj and his demand for instant obedience; the troops resented the higher rates of pay enjoyed by the Syrian troops and the transfer to Syria of the surplus revenue from the province; the cultivators, who had streamed into the cities during the disturbed years of the civil war and had become Muslims, were embittered by their forcible resettlement on the land and by al-Hajjaj's insistence on their payment of the full land tax; and the growing body of religious leaders, called "Koran reciters" (*kurra*), took offense both at the administrative measures of the governor and at his imposition of Othman's official recension of the Koran to the exclusion of their own provincial text. The failure of the rebellion marked an epoch in the evolution of the Arab empire. The Syrian hegemony was reimposed and maintained by the foundation in 702 of a new city on the Tigris for the Syrian troops, then permanently garrisoned in Iraq; lying halfway between Kufa and Basra, it was called Wasit (middle).

The Iraqi forces were never again called out on campaign en masse, and Kufa and Basra gradually became rival centres of sedentary pursuits.

After the reoccupation of Iraq Abd-al-Malik resumed the war with the Byzantine empire on the northern frontiers and in Africa. In Asia Minor annual raids gave the Syrian army continual military exercise, but no conquests were made; in Africa, on the other hand, the Egyptian troops, with the support of a fleet, recaptured Kairouan and, after defeating the Greek fleet, expelled the Greeks from Carthage. A new naval base was established in Tunis, Pantelleria was captured, and naval raiding was extended to Sicily and Sardinia.

Abd-al-Malik also reorganized the administration of the empire in several directions. More effective centralization was attained

by a regular post service from Damascus to the provincial capitals for government dispatches and the appointment of postmasters to keep the caliph informed of events and economic conditions in their areas. The financial administration, which had hitherto remained in the hands of the former cadres of Greek and Persian officials, was partially reformed and ordered to be conducted in Arabic.

A new Islamic coinage, with gold dinars and silver dirhems, was instituted in 693 to replace the former Greek and Sasanian type coinage.

Al-Walid I (705-715).—Thanks to the organization and order established by Abd-al-Malik, the reign of his son al-Walid was, next only to that of Omar I, the most brilliant in the history of the caliphate. The Syrian army, commanded by the caliph's brother Maslama, captured Tyana in 708 and ranged with impunity over Asia Minor and Armenia, while the Byzantine empire was distracted by military revolutions. From its new headquarters at Kairouan the African army under Musa ibn Nusair (himself under the orders of the caliph's uncle Abdul-Aziz, still viceroy of Egypt) swept to the far west in 708, and his freedman Tarik was set up as governor in Tangier.

Three years later, after a trial raid on the Spanish coast, Tarik, in command of an army of 7,000 Berbers, and freedmen, crossed the strait to the mountain which still bears his name (Gibraltar-Jabal Tarik) and, reinforced by 5,000 Arabs, defeated the Gothic king Roderic on the Rio Barbate and overran the greater part of Spain. In 712 Musa himself took command and subdued the remaining fortresses, until from the coast of Galicia he was recalled to Damascus.

In the east also the Arab armies, under the general control of al-Hajjaj, gained spectacular successes. The Khurasanian garrisons, commanded by Qutaiba ibn Muslim, conquered Bukhara, Samarkand. Khwarizm (modern Khiva) and Fergana and Tashkent beyond the Jaxartes (Syr-darya) from their Sogdian and Turkish princes. Meanwhile an army from Basra under Mohammed ibn al-Kasim, a cousin of al-Hajjaj, invaded Makran and Sind, took the port of Daibul, defeated the Indian king Dahar and after a prolonged siege captured Multan, with immense booty.

But it was not only in warfare that al-Walid's reign stands out. It was a time of intensive agricultural development, especially in Iraq under the direction of al-Hajjaj; new canals were constructed, marshes drained, uncultivated lands brought under the plough. Roads were cared for, wells dug for the convenience of travelers and pilgrims.

The Omayyad mosque in Damascus, converted by the caliph from the Church of St. John Baptist, and the Dome of the Rock in Jerusalem (begun by Abd-al-Malik and completed by al-Walid) are among the architectural glories of Islam; and al-Walid also enlarged and beautified the Aksa mosque in Jerusalem and the Prophet's mosque in Medina.

Suleiman (715-717).—Al-Walid was succeeded by his self-indulgent brother Suleiman, under whom the rhythm of conquest slackened in the east, except for the capture of Jurjan. Suleiman was an implacable enemy of al-Hajjaj (who had died in 714) and of his adherents. Qutaiba had attempted to revolt but was killed by the hostile Arab factions; Mohammed ibn al-Kasim was recalled and put to death. Abdul-Aziz, the son and successor of Musa in Spain, was murdered, and the Christians of the Asturias rose in revolt against the Arabs.

Meanwhile the Byzantine war was energetically pressed. The Syrian reserves were called up, a fleet of 2,000 vessels manned and Constantinople was blockaded by land and sea (717). Leo III, the Isaurian, who had in fact been proclaimed emperor by Maslama, conducted a brilliant defense of the city; and the besiegers, after suffering from a severe winter, were compelled to make a disastrous retreat through Anatolia, while the fleet was destroyed by storm.

This shattering disaster was the climax and turning point of the Arab conquests. Apart from the loss of prestige, the destruction of the Syrian army removed the main prop and stay of the Omayyad dynasty. At this critical moment, however, a precious respite was gained by Suleiman's fortunate and unexpected nomination

as his successor of a cousin, Omar, the son of Abdul-Aziz, whose simple and universally respected piety brought a brief relaxation of tensions.

Omar II (717-720).—The main object of Omar's administration was to reform the system of taxation and finance. In addition to the grievances of the troops of Iraq at the privileges enjoyed by the Syrians, the Muslim converts in every province resented the continuance of Omar I's regulation by which the Arab troops alone (with few exceptions) received stipends from the public revenue, besides paying preferential rates of taxation on their estates. Omar II's principle was that all Muslims should be placed on the same footing, without respect of nationality. Although the existence of established rights and the necessity of maintaining cultivation prevented the thoroughgoing application of this principle, he reversed the policies enforced by al-Hajjaj, allowed the immigration into the cities of converted *mawali* (who thereby became in principle eligible for stipends) and strictly forbade the imposition of poll tax upon converts, and other illegal imposts. These and other measures made serious inroads on the public revenue; but Omar went on uncompromisingly to dismiss non-Muslim employees from the public services and to issue severe regulations (known as the "ordinance of Omar") for the conduct and dress of Christians and Jews.

The effect was to throw the financial administration into disorder in several provinces, especially in Egypt, but also to encourage mass conversions to Islam; to the remonstrances of his governors the caliph replied, "God sent Mohammed to call men to the Faith, not to collect taxes."

Although in principle, again, Omar discouraged frontier raiding for the sake of booty, warfare was still carried on at both extremities of the empire. He had at one time thought of ordering the Arab armies to evacuate Spain, but sent a new governor, Samh, with instructions to distribute certain reserved lands among the troops, in 719; and both Samh and his predecessor Hurr made expeditions across the Pyrenees into southern Gaul.

Omar died in Feb. 720, leaving a reputation for piety and sanctity such as no other caliph of the Omayyad or Abbasid houses attained or even approached.

Yazid II (720-724).—His successor, by the nomination of Suleiman, was a son of Abd-al-Malik and a daughter of Yazid I, who thus united temporarily the two branches of the Omayyad family. He was at once faced with serious difficulties. The state of the public finances called for urgent stopgap measures which, as they inevitably reversed some of Omar's relaxations, caused discontent and some outbreaks of violence. But the most dangerous rising had no connection with this. The caliph was a partisan of al-Hajjaj, whose niece he had married; his namesake, Yazid ibn Muhallab, who had been prominent in the hunt against al-Hajjaj's associates, fled to Basra and stirred up a general revolt of the Yemenite faction in Iraq and southern Persia. Defeated by Maslama with a reformed Syrian army near Babylon, the leaders of the rebellion fell in battle or were pursued into India and there killed.

This violent outburst of the Yemenite faction set in train among the Arabs a sequence of factional struggles which grew in intensity and finally pulled down the Omayyad dynasty. For the moment Yazid had no alternative but to confide the government of Iraq to Kaisite officers, who revenged themselves upon the Yemenites; in Syria, on the other hand, he showed equal favour to both the Kais and the Kalb (Yemenite) tribes, and the latter even took a prominent part in suppressing the Iraqi rising. In the chronicles he is represented, perhaps unjustly, as a frivolous and pleasure-seeking prince.

Hisham (724-743).—Yazid II nominated as his successor his brother Hisham, the fourth of Abd-al-Malik's sons to mount the throne, with his own son Walid as second heir. Whatever Yazid may have been, Hisham was severe in morals and manners, earnest though with little imagination, just but heavy-handed. The Arab empire had now for a century been organized for expansion; Hisham was confronted with the problems of stabilization that arise when such an organism reaches or overreaches the limits of expansion. The military problem was met in part by the organi-

zation of frontier defenses; the internal problems were beyond his powers to solve. But his most remarkable achievement was to lay the foundations of the bureaucratic system which (after the turmoil of the civil war and destruction of his house) was taken over and developed under the Abbasid caliphs.

During the early years of his reign the Syrians resumed, with some success, the attack on Asia Minor, and the Spanish Arab forces penetrated into central France. But on the central Asian front the Arabs were already on the defensive against the attacks of Turkish forces from the steppes, aided by discontent among the subject population of Sogdiana. In 730 or 731 they were disastrously defeated near Samarkand; and simultaneously the Khazar Turks from the southern steppes of Russia destroyed the Arab armies in Azerbaijan.

In northern India also a revolt drove the Arabs back on Sind, where they founded the two strong garrison cities of al Mahfuza and al Mansurah. In 732 Charles Martel put an end to the advance into France at the battle of Poitiers (Tours), and in 740 Leo III destroyed the main Arab forces in Asia Minor at Akroinos (Afion Karahisar). The two latter defeats were decisive, but the more serious Turkish threats in the east and north were energetically countered. The Khazars were driven back beyond Derbent and forced to pay tribute; the central Asian Turks, defeated near Balkh in 737, evacuated Sogdiana, which was reoccupied by the Arabs under Kasr ibn Sayyar and pacified by a just redistribution of taxation. But both victories were gained by the Syrian troops, and the frontiers were guarded by Syrian garrisons at Derbent and Balkh.

Shortly afterward, when the African army was destroyed by a Berber revolt in Morocco (741), a large force of Syrians was sent to restore order; these too were cut to pieces on the river Sebou (742), and Kairouan was saved only by the dispatch of a fresh army from Egypt and Syria. The Arab empire had thus ended by becoming a Syrian empire, maintained by Syrian troops dispersed in garrisons from central Asia to Kairouan; and the strain which this involved was too great to be borne indefinitely, even after cutting the losses in Asia Minor.

For 14 years Hisham maintained the Yemenites in power in Iraq. The Kais chafed under the rule of his governor Khalid al-Kasri, but had their revenge when the Kaisite Yusuf replaced him in 738. For the moment, however, the factional spirit was kept within bounds; when Zaid, a grandson of Husain ibn Ali, headed a Shi'ite revolt at Kufa in 740 he found little support; Yusuf's Syrian troops easily suppressed the movement; and Zaid's son Yahya fled to Balkh, where he was killed several years later. For about two centuries, nevertheless, the Zaidis remained the most active of the Shi'ite parties, and the sect still predominates in the highlands of Yemen.

Al-Walid II (743-744).—Hisham had intended to nominate his son Mu'awiya to succeed him, setting aside the nomination of his nephew al-Walid, but Mu'awiya was killed in a hunting accident. Al-Walid's dominating passion became a hatred for Hisham and all that Hisham stood for; and after his accession he withdrew to his desert castle in Transjordan, neglecting the duties of his office. In order to pay for his new castle of Mshatta he sold Khalid al-Kasri to Yusuf, the governor of Iraq, whose cruel murder of his opponent roused Yemenite anger to fever pitch in every province. When the caliph proclaimed his two young slave-born sons as his heirs, the sons of al-Walid I revolted in Syria with Yemenite support, and one of them, Yazid, was proclaimed caliph in Damascus. A Yemenite force was sent to deal with al-Walid and killed him with little opposition.

Yazid III (744).—By this action, the moral authority of the Omayyad caliphate, already undermined by the frivolous character of al-Walid II, was all but destroyed. Dying less than six months after his proclamation, Yazid nominated his brother Suleiman to succeed. But Hisham's cousin, Marwan ibn Mohammed, who had, as governor of Azerbaijan, built up a powerful army of Mesopotamian Kaisites, marched into Syria in the name of Walid's sons, defeated the Yemenites and, since the young princes had in the meantime been put to death, was proclaimed caliph.

Marwan II (744-750).—Marwan's first task was to pacify

Syria, but when he transferred his capital to Harran in Mesopotamia the Syrians rebelled (745). Scarcely had he put down this revolt and assembled an army to march into Iraq when a fresh revolt broke out, led by Suleiman ibn Hisham. This time Marwan took decisive measures, demolished the walls of Homs, Damascus and other towns, and left Syria utterly crushed and defenseless (746), thus destroying the bulwark of Omayyad power.

While this struggle was in progress the other provinces of the empire were left to themselves. A Shi'ite rising in Kufa, led by a distant relative of Ali named Ibn Mu'awiya, had after a brief success been put down by the Omayyad governor, a son of Omar II (744). Ibn Mu'awiya retired to Isfahan and within a short time had become master of all southern Persia. Immediately afterward the Kharijites rose near Mosul; Ibn Omar and the rival governor appointed by Marwan, making common cause against them, were defeated, and the whole of Iraq joined in the revolt. Only in 747 mas Marwan able to break their hold on the province. The remains of their army joined Ibn Mu'awiya in Fars, but in 748 both were dispersed by the new governor of Iraq, Yazid ibn Hubaira. In the same year another Kharijite band, which had occupied the holy cities in Arabia, was destroyed, and Marwan might well have felt satisfied that his authority was securely established in the central and most important provinces of the empire.

But the decisive challenge to Omayyad rule was to come from another quarter. In Khurasan, during the struggle in Syria, the governor Nasr ibn Sayyar had persuaded the Arab chiefs to accept him as amir until a caliph should be universally acknowledged. It was not long, however, before the Yemenites, naturally opposed to a Kaisite governor and inflamed by the murder of Khalid and by the general hostility of their faction toward Marwan, rose against Nasr. The Kais faction, split by internal divisions, gave him inadequate support; and, abandoning Merv to the Yemenites, he retired to Nishapur (746). In the next year, the Kais split having been healed, he marched again on Merv, after sending vain appeals to Marwan for reinforcements, but the struggle between the factions ended in a stalemate, which opened the way to the intervention of a third party.

About 40 years earlier a great-grandson of Mohammed's uncle Abbas had acquired control of a secret missionary organization, operated by and among the non-Arab *marwali* of Kufa, on behalf of a Shi'ite party known as the Hashimiya. This had grown out of the revolutionary party led by Mukhtar in the time of Abd-al-Malik, which recognized as its imam a son of Ali known by the name of Mohammed ibn al-Hanafiya. Under this Mohammed's son Abu Hashim the propaganda organization was strengthened, and on his death the majority of the Hashimiya acknowledged the Abbasid Mohammed ibn Ali as their imam. The tenets of its adherents varied from an ultra-Shi'ite gnosticism to a simple non-doctrinal hatred of the Omayyads, and the task of the missionaries was to preach the infidelity and injustice of the Omayyads and the coming of a saviour from the house of the Prophet, the mahdi (*q.v.*) who would "fill the earth with justice, as it is now filled with violence and iniquity."

Mohammed ibn Ali, realizing that no revolutionary hopes could be placed on Kufa, sent out missionaries to Khurasan, still populated thinly by Arabs but with a virile and warlike Iranian population. Though directed mainly to the non-Arabs, the propaganda gained over also the Arab Shi'ite in Khurasan, who came mostly from among the Yemenite tribes.

Ibrahim, who succeeded his father Mohammed as imam in 743, sent as his personal representative to Khurasan a freedman from Kufa named Abu Muslim. In the general confusion of the times Abu Muslim gained a wide success, especially among the Iranian landowners, converting, among others, Khalid ibn Barmak, the son of the hereditary high priest of an influential Buddhist sanctuary near Balkh (see *BARMECIDES*).

There were some difficulties with the leaders of the Arab Shi'ite, but they were eventually overcome, and by general agreement Abu Muslim unfurled in 747 the black banner which, in popular belief, was the symbol of the precursor of the mahdi. His Iranian partisans gathered round him at Sikadanj, near Merv, and Shi'ite risings broke out at Herat and other cities. For several months

little more happened on either side, but when Nasr appeared to be on the point of reconciliation with the Yemenites Abu Muslim appealed to the Yemenite Shi'ite, who broke the truce and gave Abu Muslim the opportunity to enter Merv (748).

The union of the Abbasid partisans with the Yemenites of Merv compelled Nasr to flee again to Nishapur. This was a crucial error, for it split the anti-Abbasid forces in Khurasan, and left the burden of opposition to the Syrian garrison at Balkh, to overcome which the Abbasid party had to wage a severe campaign. On the orders of the imam Ibrahim, the command of the Abbasid army was entrusted to the Yemenite general Kahtaba; the struggle against Nasr and the belated reinforcements from Iraq thus took on the character of a conflict between Yemen and Kais, and Kahtaba's success roused an empire-wide revolt of the Yemenites. The Yemenite governor of Kufa revolted and, with the support moreover of the Syrian garrison, opened its gates to the Abbasid forces in Sept. 149. There, after some hesitations—probably resulting from the fact that, since the Abbasid leadership of the revolt had been kept secret, the Kufans saw in it a Shi'ite revolt on behalf of the house of Ali—the Khurasanian leaders, instructed by Abu Muslim, forced the issue. Ibrahim had recently died in prison at Harran, but his brother Abu'l-Abbas, with other members of the family, had arrived in Kufa; and on Nov. 28, 749, Abu'l-Abbas, declaring himself to be al-Saffah, the precursor of the mahdi, was proclaimed caliph.

Marwan had still to be reckoned with, but at this point a wave of enthusiasm, nourished by popular predictions and aspirations for the reign of the mahdi, turned the scale. The Khurasanian army had at last furnished the instrument of power which could match the hitherto invincible Marwanid army; the moment of destiny was come, and from all sides volunteers flocked to join the Khurasanians. The final defeat of Marwan's depleted forces on the Great Zab (Jan. 750) was due largely to the conviction that the Shi'ite movement (as it was still believed to be) owed its success to divine agency and that there was no longer any hope of stemming the tide.

Marwan retreated to Harran, thence to Syria, pursued by the Khurasanian forces. When the citizens of Damascus opened their gates he fled to Egypt and was killed at Busir in Aug. 750. The members of the Omayyad house were hunted down and put to death; only a few escaped, among them a grandson of Hisham, Abd-al-Rahman, who fled to Africa and thence to Spain, where he founded a few years later the Omayyad dynasty of Cordoba (see *SPAIN: History*).

THE ABBASID CALIPHS

The transfer of the caliphate from the Omayyad to the Abbasid house meant at first no more than the transference of the capital to Iraq and the substitution of a standing army based on Khurasan for one based on Mesopotamia. The Syrian hegemony had already been broken by Marwan, and the general lines of administration laid down by Hisham. The Khurasanian army was still predominantly Arab in composition; the armies of Egypt and Africa were still composed of tribal units, and those of Syria and Mesopotamia were soon reconstituted for frontier warfare against the Byzantines. In the latter provinces the tribal feuds which had destroyed the Omayyad caliphate still flared up from time to time; in the more professional Khurasanian forces, on the other hand, they were rapidly extinguished.

The fact, however, that the power of the dynasty rested upon the two provinces, Iraq and Khurasan, in which the mingling of Arab and Persian had gone furthest and continued with increasing momentum, favoured the development of a common Muslim civilization in which the Arab no longer predominated. While the Arab religion and Arab language maintained themselves and spread over the whole empire (the revival of Persian as a cultural language began only in the 10th century), in the court and the administration, on the other hand, the traditions of the Persian Sassanian empire set the tone. In keeping with this tendency, the Abbasid caliphs devoted much attention to strengthening and emphasizing the religious basis of their rule, insisting, particularly against the Shi'ite opposition, upon the claim of the house of Abbas to be the

legitimate heirs of Mohammed. Their patronage of religion, while marked by a demand for conformism and persecution of heresy, created also favourable conditions for the expansion of religious learning, out of which the new Muslim Arabic literary culture developed.

At the same time, the growth of luxury and the cessation of wars of conquest gave an impulse to industry and commerce, both within the empire and overseas.

In these conditions the Abbasid capital at Baghdad rapidly became the centre of a brilliant intellectual and material civilization which spread over the entire Muslim world and reached its height in the 10th century, when the Abbasid caliphate itself was already far in decline.

Abu'l-Abbas (750-754).—Since the Abbasids had seized the caliphate in a wave of revolutionary enthusiasm that temporarily united all the enemies of the Omayyads, their first task was to convert a local and precarious act of usurpation into a valid, because universally recognized, claim. The revolutionary unrest continued for many years and found expression in risings and rebellions on behalf of rival parties and groups, not only in Syria and Mesopotamia, Libya and Oman, but also among the Arabs in Khurasan. The reign of Abu'l-Abbas was filled largely with campaigns against a succession of rebels; and the governorships of the provinces were given almost exclusively to the caliph's uncles and brothers, except for Khurasan, which remained under Abu Muslim.

Al-Mansur (754-775).—On the death of Abu'l-Abbas the succession of his brother Abu Jafar—who took the "mahdist" title of al-Mansur ("the divinely aided")—was challenged by his uncle Abdullah, the governor of Syria. In order to defeat Abdullah's largely Syro-Mesopotamian army, al-Mansur was forced to call in the assistance of Abu Muslim. The continued influence of Abu Muslim over the Khurasanian troops (combined, perhaps, with the discontent of the Arabs in Khurasan with Abu Muslim's government and Abu Muslim's own sense of importance) held such dangerous possibilities that al-Mansur summoned him to the court before he returned to Khurasan and had him murdered. The result was a violent reaction of the original Iranian converts of Abu Muslim in Khurasan against the Abbasids; under the name of Muslimiyya, venerating Abu Muslim as the true imam, they broke out in a succession of revolts.

Though these were put down without great difficulty by the local troops, the existence of this discontent among the Iranians was too much for the loyalty even of some of the Arab governors, and Khurasan was only restored to order when al-Mansur's eldest son, significantly entitled al-Mahdi, was appointed to its government in 759. In 761, a considerable body of Arab Khurasanian levies was transferred to Kairouan, in order to restore Abbasid authority in Africa, shaken by Berber and Kharijite revolts; but in Spain all al-Mansur's efforts to dislodge the Omayyads by supporting local rivals came to nothing.

In contrast to the Muslimiyya, the ultra-Shi'ite Hashimiyya of Kufa still remained loyal to the Abbasids, but their importunities and payment to him of divine honours became so embarrassing that al-Mansur took the opportunity of a demonstration in 758 to root them out and thus give public proof of the orthodoxy of the Abbasid house. This was the more urgently necessary since the true Shi'ites, hitherto quiescent for lack of an active leader, had now found one in Mohammed, a grandson of Hasan. Al-Mansur, well aware of the danger of a widespread Shi'ite rising, took stringent measures against the Hasanids in the holy cities, but Mohammed eluded him and in 762 seized Medina and Mecca. A Khurasanian force, commanded by the heir presumptive Isa ibn Musa, easily defeated and killed Mohammed, but in the meantime his brother Ibrahim had occupied Basra, Khuzistan and Fars. Al-Mansur himself, with a small force, held his ground at Kufa until the Khurasanians returned from Arabia and in a severe engagement at Bakhmra, 48 mi. from Kufa, killed Ibrahim.

Thanks to the disunity of its opponents and the fighting qualities of the Khurasanians, the Abbasid dynasty was now established. Al-Mansur signaled the event by founding a new capital, completed in 766, on the Tigris at the old market town of Baghdad

(*q.v.*; officially renamed *Medinat al Salam*, "City of Peace"), close to the former Persian capital at Ctesiphon, which served as a quarry. Built in the first place as a fortified garrison city, it rapidly grew into the great metropolis which, in spite of riot, flood and siege, remained the centre of Islam until the end of the Abbasid caliphate. At the same time he took in hand the reorganization of the administration.

Under the general control of the *wazir* (vizier), an office introduced by him, a number of *diwans* (divans) or ministries were set up for the chancery, finance, army, posts, etc., staffed largely by Khurasanians, Persians and other *marwali* (although this term was now beginning to fall out of use). The most notable of his ministers was Khalid ibn Barmak, for a time minister of finance.

Al-Mahdi (775-785).—Isa ibn Musa had been nominated by Abu'l-Abbas as successor of al-Mansur and had taken the leading part in suppressing the Alid revolt. But al-Mansur, determined to secure the succession for his own son Mohammed al-Mahdi, gained the army's interest on his behalf and persuaded Isa to renounce his immediate right of succession; and on al-Mansur's death a dispute was averted by the prompt action of the vizier in installing and obtaining the oath of allegiance to al-Mahdi.

The year after his accession was marked by a revolt of the Muslimiyya in Transoxiana under al-Mukanna' (the veiled prophet). From his stronghold at Sanam, near Kish, he attacked the Arab governments at Bukhara and Samarkand; and during the eight years which elapsed before the rebellion was crushed there were several risings of the Iranians in other parts of Khurasan. The caliph devoted his interest largely to the war with Byzantium which, after some inconclusive raiding during the reign of al-Mansur, had taken an unfavourable turn when the Greek general Michael captured Mar'ash. In 779 al-Mahdi led a powerful army of Khurasanians, Syrians and Mesopotamians into Cilicia; and an expedition commanded nominally by his second son Harun, under the guardianship of his tutor, the Barmecide Yahya ibn Khalid, captured the fortress of Semalouos in the interior (780). In the following year the Arabs fell back before a fresh Greek offensive. Harun was again dispatched with orders to march on Constantinople and, after defeating the Greek commander at Nicomedia, forced the empress Irene to conclude a truce for three years, on payment of an annual tribute of 70,000 or 90,000 dinars (782). This success gained for Harun the nomination as second heir after his elder brother Musa al-Hadi and the title of al-Rashid. Three years later al-Mahdi set out for Khurasan, on Musa's refusal to obey his order to return to Baghdad, but died suddenly on the way at the age of 43.

During his reign the zeal of the Abbasids for religious orthodoxy was signalized by a vigorous persecution of freethinkers and crypto-Manichaeans (*zindik*s). The administrative services were expanded and improved, and the taxation in Iraq was reformed. With increasing prosperity there was a marked development of intellectual and cultural pursuits, which laid the foundations of the brilliant Islamic civilization of the next century.

Al-Hadi (785-786).—Shortly after al-Hadi's succession a fresh Alid revolt broke out in Medina. Though it was put down with little difficulty, two Alids, brothers of the earlier rebel Mohammed, escaped; one, Yahya, made his way to Dailam, in the Elburz range in northern Persia, the other, Idris, to Morocco, and both founded independent kingdoms in due course. Al-Hadi also intensified the persecution of *zindik*s. By his efforts to set aside Harun's nomination as his successor he alienated his mother Khaizuran and the Barmecide Yahya, but before he could take definite action he fell sick and died, in circumstances which created some suspicion.

Al-Rashid (786-809).—Harun succeeded his brother without opposition and appointed his former tutor Yahya ibn Khalid as vizier with full powers. Under the prudent government of Yahya and his son Fadl, the Abbasid empire reached its highest degree of power and prosperity; the armies and frontiers were well manned and controlled, the public treasury, in spite of the magnificence of the court, carefully safeguarded. Yet even at its height there was seldom peace throughout the empire. An Omayyad revolt and tribal indiscipline in Egypt, a protracted outbreak of the Arab factions in Syria, a succession of Kharijite insurrections in Meso-

potamia, and the Dailamite following of the Alid Yahya, all gave evidence of the strains and stresses which accompanied the readjustment of populations and gradual regrouping of social and economic forces among the widely diverse peoples and diversified terrains of the vast empire, and which no administration, however skilful, could do much to alleviate.

A further cause of weakness was the growth of rivalries and jealousies at court. The power of the Barmecide Yahya and of his sons Fadl and Ja'far, the caliph's boon companion, raised up a host of enemies, among whom the chamberlain Fadl ibn Rabi' was the most active. Through his influence the important government of Khurasan was given in 796 to a certain Ali ibn Isa ibn Mahan, whose violence and extortions created general discontent and a widespread revolt of the Iranian schismatics in the northern provinces. Externally, however, the power of the dynasty was vindicated against the Greeks in a series of campaigns.

Harun, who had transferred his residence to Rakka, on the Euphrates, led an army in person to Ephesus and Ancyra in 767 and reimposed terms of truce on Irene; and when her successor Nicephorus broke the treaty in 803 he again marched to Heraclea. On a later campaign in 805 he occupied Heraclea and Tyana and increased the tribute by a personal impost on the imperial house. Cyprus was overrun in 807. An interchange of embassies with Charlemagne, motivated probably by common enmity to the Omayyads of Spain and the Greeks, resulted in increased facilities for Christian pilgrims to Jerusalem. In 799, on the other hand, the Khazars from the Volga broke through into Armenia, causing severe losses; and at the end of Harun's reign the tide of war had begun to turn in Anatolia.

In 803 the rivals of the Barmecides succeeded in winning the caliph's favour. Without warning Ja'far was seized and beheaded, Yahya and Fadl imprisoned and their property confiscated. Whatever the reasons for their overthrow may have been, the suddenness of this action could only intensify the internal strains; and when, two years later, the caliph confirmed Ali ibn Isa in his government of Khurasan, a serious revolt broke out in Transoxiana under Rafi' ibn Laith, a grandson of Nasr ibn Sayyar (806). In spite of the efforts of the Khurasanian guard the rebels held out, and in 808 Harun himself marched from Baghdad with the remainder of the Abbasid troops, but died on the way at Tus, in March 809.

In 802, during a pilgrimage to Mecca, Harun had formally divided the territories of the empire between his heirs and assigned the government of Khurasan outright to his second heir, Abdullah, surnamed al-Ma'mun. On his last journey to the east, moreover, he willed that the whole of the Khurasanian guard should fall to the lot of al-Ma'mun and took an oath from the troops to that effect.

Al-Amin (809-813).—On Harun's death, however, the troops returned to Baghdad, either of their own accord or at the instigation of Fadl ibn Rabi'. Relations between the new caliph al-Amin and his brother al-Ma'mun were thus strained from the beginning and causes of dispute rapidly multiplied. When al-Ma'mun gained a strong following in Khurasan and enrolled a new Khurasanian army under the Iranian general Tahir, open war followed (811). Al-Amin's old Khurasanian guard was repeatedly worsted, and he was finally besieged in Baghdad. For nearly two years the city put up a desperate resistance, but at length the caliph's troops gave way, and he himself was captured and killed while attempting to escape, leaving a reputation of frivolity and incompetence as a ruler.

Al-Ma'mun (813-833)—For several years al-Ma'mun continued to reside at Merv, under the influence of his Persian vizier Fadl ibn Sahl, whose brother Hasan was appointed governor of Iraq, while the western provinces of the empire were assigned to Tahir. But the civil war had weakened the authority of the caliphate, and most of Syria and Egypt remained for more than a decade beyond its control. In Iraq a Shi'ite movement, beginning in Kufa, gained the support of the Bedouins and for a year (814-815) held all southern Iraq and the holy cities in Arabia. Scarcely had the Khurasanian garrison of Baghdad put down this rising than it in turn rebelled against the Persian government of Hasan.

To add to these dissatisfactions there came in 817 orders from the caliph designating as his successor the Alid imam Ali al-Rida. Al-Ma'mun's reasons for this step are not clear: the common assumption that it was intended to give satisfaction to the supposed Shi'ite sympathies of the Persians has no substantial foundation; and it is indeed more probable that it was the Shi'ites of Iraq whom he had in view. But the population of Baghdad, always hostile to Shi'ism, rose almost to a man under the leadership of the Abbasid family and, joined by the Khurasanian garrison, proclaimed Ibrahim, a son of al-Mahdi, caliph. Ibrahim, however, proved incapable of maintaining order either in the city or in the provinces, and his supporters rapidly dwindled. On receiving news of the revolt al-Ma'mun at last realized the facts of the situation and set out himself for Baghdad. The journey occupied a year and a half; during its course Fadl ibn Sahl was murdered and Ali al-Rida died where his shrine now stands at Meshed. His Khurasanians reoccupied Baghdad against little opposition in 819, and a few months later al-Ma'mun proclaimed a general amnesty and made his ceremonial entry into the city.

During the remainder of his reign al-Ma'mun showed himself to be possessed of a strong practical sense and independence of judgment. He gave his patronage to science and literature, founding at Baghdad a kind of academy where Greek works on mathematics, astronomy, medicine and philosophy were translated; and he extended official patronage to the rationalizing Mu'tazilite school of theology. At the same time the restoration of order and imperial control in the outer provinces was vigorously pursued. Syria was easily regained; but the suppression of the disorders in Egypt required several expeditions, the last (832) led by the caliph in person after a particularly dangerous rising of both Arabs and Copts. In Media a local Arab dynasty came to terms with the caliph only in 829. The most serious military problem was the revolt of the Persian schismatics (*khurramis*) under Babak in Azerbaijan, which was not put down until after al-Ma'mun's death. The repercussions of this revolt on Khurasan compelled the caliph unwillingly to confide the government of Khurasan in 821 to his general Tahir, combining his governorship with the office of military commander at Baghdad. In the following year Tahir dropped al-Ma'mun's name from the public prayers and died immediately after. But al-Ma'mun, aware that the power of the Abbasid caliphate now rested on a close alliance with Khurasan, could not afford to risk a breach with the Tahirids. Tahir's son Talha was appointed to his father's posts both in Baghdad and Khurasan and was succeeded on his death in 828 by another son, Abdullah. The Tahirids thus became to all intents independent, though tributary, in Khurasan, and their alliance with the caliphate continued until the extinction of the dynasty toward the end of the century.

In the last years of his reign al-Ma'mun reopened hostilities with Byzantium. Expeditions in 830, 831 and 832 under his own command achieved such successes that the emperor Theophilus sued for peace, which the caliph haughtily refused to grant. In June 833, a further expedition commanded by his son al-Abbas occupied Tyana, but shortly afterward al-Ma'mun caught a fever, of which he died in August. He was buried in Tarsus.

Al-Mu'tasim (833-842).—Although al-Abbas was proclaimed caliph by the troops, he quickly yielded to the claim of al-Ma'mun's brother Abu Ishak, surnamed al-Mu'tasim. The first task was to deal with the rebel Babak, who was now co-operating with the Greeks. A formidable force, commanded by the Sogdian general Afshin, took the field in 835 and finally broke the revolt in 837. In the same year Theophilus attacked the Muslim frontier and laid waste the town of Zibatra, with a ferocity which roused a wave of indignation. Assembling the most powerful army ever conducted by a caliph, al-Mu'tasim penetrated into Asia Minor, defeated Theophilus and captured and destroyed the two strong fortresses of Ancyra and Amorium (Aug. 838).

To al-Mu'tasim, who had a passion for the army, was due the introduction of a new element in the Muslim forces. Al-Ma'mun's Khurasanian guard already differed from its predecessor in composition by the enrollment of troops from the inner districts of Transoxiana and the Turkish frontier regions. To these al-Mu'tasim added large numbers of Turkish slaves, acquired by

capture or purchase, from central Asia, who were formed in regiments of light horse, equipped with sword, lance and bow. The officers of the new Turkish guard rapidly distinguished themselves in war and rose to influential positions. Since the excesses of these troops created a dangerous state of tension in Baghdad, al-Mu'tasim in 835 moved his residence to a new garrison city at Samarra, about 70 mi. N. of Baghdad. This policy, however, by putting the caliph almost wholly at the mercy of his guards, was to have serious consequences for his successors.

Al-Wathik (842-847).—Under his son Harun, entitled al-Wathik, the increasing power of the Turks was shown by the appointment of two generals, Ashinas and Itakh respectively, to the titular but lucrative government of the eastern and western provinces. He intensified state support of the Mu'tazilite doctrine to the point of persecution of the orthodox, thereby arousing violent discontent in Baghdad. But the only event of importance in his reign was a combined rising of Arab tribes in Nejd and Hejaz, which was put down by the imperial guard under the Turkish general Bogha only with much difficulty, after a campaign lasting three years (844-847).

This revolt marks the definitive alienation of the Arab tribes from the caliphate and paved the way for the Shi'ite and Bedouin risings in the next generation.

Al-Mutawakkil (847-861).—Harun was succeeded by his brother Ja'far, entitled al-Mutawakkil, whose whole reign was occupied by the effort to regain control over the Turks. In order to conciliate the orthodox Muslims, he abjured the Mu'tazilite doctrine, persecuted not only the Mu'tazilites but also the Shi'ites and imposed severe restrictions on Jews and Christians, compelling them to wear distinctive dress. In 858 he attempted to remove the capital to Damascus, but immediately returned to Samarra and there built a new residence farther to the north. The financial stability of the Abbasid state, already burdened by the upkeep of the vast military establishments of Samarra and threatened by revolts in Azerbaijan, in Armenia (Bogha had to penetrate to Tiflis before the rebels were subdued), in Syria and in the east, was undermined by this new extravagance. The fact that the imperial treasury was in difficulties probably contributed largely to the disorders of the next two decades.

The Byzantine war, which had ceased for a time under al-Wathik, was renewed in 851 by the frontier troops. A Greek fleet burned Damietta in 853, but in 856 the Muslim armies were reinforced by the immigration of the heterodox Paulicians, following on a violent persecution of the sect by the orthodox authorities. The annual raids by both sides were attended with alternate successes, the chief events being the restoration of Ancyra by the Greeks in 859 and the surrender of Lu'lu'a to the Muslims in 860, followed by a truce and exchange of prisoners.

Early in his reign al-Mutawakkil had divided the empire between his three sons, nominating them as his successors in order of seniority. The eldest, Mohammed, called al-Muntasir, gradually became estranged from his father and finally conspired with the commanders of the Turkish guard to murder him in Dec. 861.

Al-Muntasir, al-Musta'in, al-Mu'tazz and al-Muhtadi.—The murder of the caliph played straight into the hands of the Turkish generals, who became the real rulers and already began to form dynasties, handing on their power to their sons and sons-in-law. The disorder in the central government was extreme. When al-Muntasir died six months after his father's assassination, the generals selected as his successor a cousin, who took the title of al-Musta'in (862-866). His attempt to check the Turks with the aid of the citizens and Tahirid forces in Baghdad led to a siege of the city (865) and his forced abdication and murder. Al-Mu'tazz (866-869), the brother of al-Muntasir, unable to find the money to pay for the troops, was seized and starved to death. Al-Muhtadi (869-870), a son of al-Wathik, and a man of firm and upright character, was chosen to succeed, but became entangled in the rivalries which had broken out between the Turkish generals and their troops, and was similarly put to death.

Such conditions of anarchy in the capital made it impossible to maintain ordered government in the provinces. Although the caliphs continued to be recognized from Tunisia to Turkistan, local

chiefs and Turkish generals had gained the substance of independence over most of their nominal dominions. In the east a popular movement in Seistan led by the Saffar brothers broke the power of the Tahirids in Khurasan (*see SAFFARIDS*) coupled with a similar movement in the northern provinces of Persia under an Alid leader, Hasan ibn Zaid. In Transoxiana the Samanids (*q.v.*), the lieutenants of the Tahirids, assumed the responsibility of government and concentrated all political authority in their own hands. In Mesopotamia a powerful revolt of the Khawarij broke out, and in Arabia the tribesmen were ready to support any Shi'ite rising. In Egypt, the deputy governor Ahmad ibn Tulun, appointed in 868, set his hand to the task of restoring the prosperity of the ruined countryside and of creating a powerful Egyptian principality (*see EGYPT: History: Medieval Period*). On the Greek frontier, after a bold raid on Amisus (Samsun) in 863, the Muslim garrisons were severely defeated and forced on the defensive. Finally, in 870, a rising of the Negro slaves in southern Iraq, under an Alid leader, had begun to assume serious dimensions.

Al-Mu'tamid (870-892).—This desperate situation was slowly retrieved during the reign of al-Mutawakkil's son Ahmad, entitled al-Mu'tamid. The real ruler was, however, his brother Abu Ahmad, known as al-Muwaffak, who had already distinguished himself as a soldier and who, aided by the exhaustion of the rival Turkish families, regained control over the guard. With immense effort he restored order and discipline in Iraq, defeated a Saffarid attempt to march on Baghdad (876) and finally, after many reverses, overcame the Negro rebels in the marshes above Basra (883). The dangerous isolation of the caliphs at Samarra was ended in 883, by removing the seat of government back to Baghdad.

In the outer provinces, al-Muwaffak had to rely on diplomacy. Against Ibn Tulun he was practically powerless; Ibn Tulun's son and successor Khumaruya not only added Syria and Mesopotamia to his dominions, but forced a formal investiture from the caliph. In Persia, the system of private wars and seizure of provinces had to be tolerated, and in Arabia the Shi'ites firmly established themselves in Yemen.

Al-Mu'tadid (892-902).—The fruits of al-Muwaffak's labours were, however, reaped by his son Ahmad, entitled al-Mu'tadid, who began by forcing al-Mu'tamid to disinherit his son. By a wise choice of officers he secured unexampled harmony in the administration, which was reorganized and the financial system reformed. The Tulunids were conciliated by the caliph's marriage with Khumaruya's daughter; the Saffarids were left in peace until they challenged the Samanids and were utterly defeated (900); the Mesopotamian Arabs and Kurds were subdued. But the last years of his reign were darkened by a sinister shadow. During the long period of disorders, the missionaries of the extreme Shi'ites or Ismailis had gained a ready following among the oppressed cultivators of lower Iraq and the Bedouin tribes of the Euphrates and northeastern Arabia.

In 899 the long-prepared revolt broke out. The leader of the Karmatians (*q.v.*) or Karmatis, as they were called, Abu Sa'id al-Jannabi, defeated the imperial troops, and withdrew to al-Hasa, where he founded a Karmatian state.

Al-Muktafi (902-908).—Shortly after the accession of al-Mu'tadid's son Ali, entitled al-Muktafi, the Bedouin tribes on the Syrian border rose under Karmatian leaders and, though defeated in their assault on Damascus, swept over all northern Syria. An imperial army defeated them in 904 and, taking advantage of the weakening of the Tulunid house, reoccupied Egypt in 905. The Bedouins of Mesopotamia were kept in order by the chiefs of the Hamdanid family who, though Shi'ite in sympathies, now laid the foundations of their future fortunes by alliance with the caliphate. A second Karmatian rising on the Syrian border, followed by the massacre of a pilgrim caravan in lower Iraq, led to fresh military operations against them, but the headquarters of the sect in northeastern Arabia remained inviolate.

In the last year of al-Muktafi's reign the Arab princes of Tunisia were driven out by Berber forces organized by Ismaili missionaries in the name of the rival caliphate of the Fatimids (*q.v.*).

Al-Muktadir (908-932).—The restoration of imperial con-

trol over the western provinces under the three previous caliphs was a tour de force, which had imposed an immense strain on the resources of the caliphate. The forces of disruption had only been temporarily checked by a succession of resolute and vigorous rulers. The accession of al-Muktafi's younger brother Ja'far, a boy of 13, who was saluted with the ironical title of al-Muktadir (the powerful through God), allowed the resumption of the internal rivalries and seizures of authority which preluded the rapid and fatal decline of the Abbasid house. Al-Muktadir himself was twice deposed and reinstated, and met his death, sword in hand, in combat outside Baghdad.

The mainstay of the caliphate for most of his reign was the general Mu'nis, who defeated the first Fatimid attempts to seize Egypt (915 and 921) and rectified the deteriorating situation on the Byzantine frontier. But against the Karmatians of Arabia the imperial arms were unavailing. After sacking Basra in 923 they created turmoil and dismay in Iraq for many years: Kufa suffered the same fate in 925 and Baghdad was itself threatened. In 929 a band of Karmatians raided Mecca and carried off the sacred Black Stone to their capital, where it remained for about 20 years.

Al-Kahir, al-Radi, al-Muttaki and al-Mustakfi.—The short reign of al-Muktadir's depraved brother Mohammed al-Kahir (932–934) was notable only for the execution of the loyal Mu'nis. On his deposition the troops elected al-Muktadir's son Ahmad al-Radi (934–940), and al-Kahir was blinded. A pious and well-meaning man, al-Radi lacked the force of character needed for the times. He was succeeded on his death by his brother Ibrahim al-Muttaki (940–944), whose attempt to use the Hamdanid princes of Mosul against the Turks led to his deposition and blinding in turn, with the complicity of his cousin Abdullah, son of al-Muktafi, who succeeded him with the title of al-Mustakfi (944–946).

During this troubled period the authority of the caliphate scarcely extended outside Baghdad, and its external history consists of little more than the successive attempts of powerful generals to take possession of the city. In 936 al-Radi conferred on the victor of the moment, Ibn Ra'ik, the title of amir al-umara or generalissimo (see AMIR), and henceforth the administration was in his hands and those of his successors. Egypt and Damascus were held by an independent Turkish governor, the Ikhshid; northern Syria and Mesopotamia by the Arab Hamdanids; Armenia and Azerbaijan by the Transoxanian Sajids. Meanwhile the mountaineers of Dailam, unified under the banner of Shi'ism, had begun from about 920 to expand over western Persia. Led by three brothers of the house of Buya or Buwayh, they constituted between 933 and 937 a powerful group of allied principalities from the Caspian sea to the Persian gulf (see PERSIA: History). It could only be a matter of time before they crushed the petty rival amirates of Iraq; and after some preliminary probing the Buyid Ahmad marched on Baghdad and entered it without a blow in Jan. 946. The caliph al-Mustakfi conferred on him the title of Mu'izz al-Dawla, but was immediately seized and blinded. For a moment the Shi'ite conqueror thought of abolishing the Abbasid caliphate altogether, but for reasons of state reversed his decision and appointed another of al-Muktadir's sons, al-Fadl, to the vacant office, with the title of al-Muti'.

Al-Muti', al-Ta'i' and al-Kadir.—During the century of Buyid rule Baghdad was a provincial capital; and after an attempt by Ahmad's son Bakhtiyar to make himself independent there (977) it was generally held by the ruling prince of Fars. The administration which the Buyids inherited was already politically and financially bankrupt and few of them showed any administrative ability; rivalries between the younger princes and feuds between their Dailamite infantry and Turkish cavalry troops aggravated the general disorder. In all this the caliphs had little part or say, and their long and generally uneventful tenures tell their own tale. They no longer had viziers, but merely secretaries, and received a modest pension for their household needs. Al-Muti' (946–974) was compelled to abdicate by reason of paralysis in favour of his son Abd-al-Karim al-Ta'i' (974–991), who was in turn deposed by a Buyid amir wishing to loot his palace and replaced by his cousin Ahmad al-Kadir (991–1031). But they still exerted a certain influence upon the Sunnis bureaucracy, and

as the Buyid power weakened through internal disputes and the general disorganization, the growing revulsion of feeling against Shi'ism invested them with a symbolic significance. Al-Kadir was able to utilize this in order to reassert in some degree the prerogatives of the caliphate, the more so that his reign coincided with the career of the great Turkish conqueror Mahmud of Ghazni (*q.v.*) in Afghanistan, who acknowledged his authority and threatened the Buyid dominions from the east.

Al-Ka'im (1031–75).—In the reign of his son Abdullah, entitled al-Ka'im, the Sunnis revival came to a head and the caliphate was liberated from Shi'ite control. The agents of this revolution were the Seljuk Turks (see SELJUKS), whose chief, Togrul Beg, defeated Mahmud's successor in 1040 and established himself in Khurasan. With the aid of the Sunnis Persian bureaucracy Togrul Beg built up a powerful administration which enabled him to control the nomadic forces under his command and make an orderly advance to the west. Summoned by the caliph to put an end to the anarchy of the later Buyid regime, Togrul Beg marched on Iraq, entered Baghdad in Dec. 1055 and was formally invested with the title of sultan. In 1058, however, during a revolt of the Seljuk tribes, a Dailamite officer occupied Baghdad in the name of the Fatimid caliph of Egypt and forced al-Ka'im to swear allegiance to his rival, who was quickly driven out again by Togrul Beg, under whose son Alp Arslan (1063–73) and the vizier Nizam-al-Mulk the administration was reformed and order restored. As a symbol of the restoration of his authority the caliph now had his own vizier again, but his sphere of activity remained confined to religious matters.

Al-Muktadi (1075–94).—The reign of al-Ka'im's grandson Abdullah, entitled al-Muktadi, coincided with that of Alp Arslan's son Malik Shah (1072–92), under whom the Seljuk empire reached its zenith. The Abbasid caliphate was now again acknowledged throughout Muslim Asia, although the caliph had in reality little more power than his predecessors. In spite of al-Muktadi's marriage with a daughter of the sultan, the first rifts began to disturb the harmony of their relations, but Malik Shah died before an open breach ensued. His last years were shadowed by the menace of a new Ismaili organization, the Assassins (*q.v.*), who had established themselves in Dailam and had begun to create a reign of terror in northern Persia.

Al-Mustazhir (1094–1118).—Al-Muktadi's son Ahmad, entitled al-Mustazhir, succeeded during a conflict between Malik Shah's sons, in which he was a passive onlooker. When order was restored under the strong hand of Sultan Mohammed (1105–18) and appeals for help against the crusaders came from the Muslims of Syria, the caliph showed little concern. He left, however, a great reputation for uprightness and fair-dealing.

Al-Mustarshid (1118–35) and al-Rashid (1135–36).—After Sultan Mohammed's death the Seljuk power in Iraq began to be challenged with increasing boldness by provincial governors and the Arabs of lower Iraq. Since the task of defending Baghdad against their attacks often fell to the caliph, he was enabled to form again an army of his own, to intervene in the conflicts between local rivals and even, on occasion, to take the offensive. Al-Mustazhir's son al-Fadl, who succeeded his father as al-hustarshid, after several military exploits of this kind, ended by organizing a coalition against Sultan Mas'ud (1133–52) and marched out against him, only to be deserted by his troops, captured and subsequently killed by assassins. His allies recognized his son Mansur as his successor, with the title of al-Rashid, but deserted him on the sultan's approach to Baghdad. After a brief resistance, al-Rashid fled to Azerbaijan and was formally deposed.

Al-Muktafi (1136–60).—Al-Mustarshid's brother Mohammed was installed in his place, with the title of al-Muktafi. It was this caliph who, after the death of Sultan Mas'ud, succeeded at last in regaining the independence of the caliphate. The Seljuk army was defeated by the caliph's forces in 1155, and the sultan's attempt to capture Baghdad two years later failed ignominiously. By the end of his reign, the temporal power of the caliph extended over most of Iraq to the borders of Mosul.

Al-Mustanjid (1160–70) and al-Mustadi (1170–80).—Al-Muktafi's son Yusuf al-Mustanjid and grandson al-Hasan al-

Mustadi successfully maintained their control of Iraq against the Seljuks and the Arabs, but their government suffered from internal rivalries, in the course of which the former was assassinated. Although the suppression of the Fatimid caliphate in Egypt by Saladin (*q.v.*) in 1171 and the substitution of the Abbasid allegiance seemed to restore the position of the Abbasid caliphs as the only recognized caliphs in Islam outside northwest Africa and Spain, their reassertion of temporal power in Iraq had rather the contrary effect of depressing them to the status of rulers of one among many petty kingdoms.

Al-Nasir (1180–1225).—Al-Mustadi's son Ahmad, who on succeeding his father took the title of al-Nasir, made it his constant aim and ambition to emerge from this equivocal position and to revive the universal empire of the early caliphs. Through an alliance with the shahs of Khwarizm (then the rulers of eastern Persia) the Seljuk sultanate was finally destroyed, and the caliph was able to add part of its Persian territories to his dominions (1190). But the result was only to bring him into conflict with his former allies, and these local interests distracted him from giving effective support to Saladin (of whom he was, in any case, jealous) in the desperate struggle of the third crusade. The breach went so far that in 1215 the shah of Khwarizm had al-Nasir declared deposed, and in 1217 sent a force against Baghdad, which was turned back, however, by snowstorms and Kurdish attacks in the mountains. The caliph, on his part, incited the shah's eastern neighbours and rivals against him; but there is little evidence for the story that he invoked the help of Genghis Khan (see JENGHIZ KHAN), whose Mongol armies invaded Transoxiana and Khurasan in 1220, leaving a trail of burned cities and depopulated countryside.

Al-Zahir (1225–26), al-Mustansir (1226–42) and al-Musta'sim (1242–58).—Under al-Nasir's son Mohammed and grandson al-Mansur the presence of the Mongols in Persia prevented further attempts at expansion, except within the boundaries of Iraq. Al-Mustansir's son Abdullah, entitled al-Musta'sim, by refusing to ally himself with the Mongols against the Assassins, provided a pretext for the final attack. Hulagu, a grandson of Genghis Khan, had crossed the Oxus at the head of fresh Mongol forces and, after destroying the Assassin strongholds, summoned the caliph to appear before him and to dismantle Baghdad. On his refusal the city in 1258 was invested, surrendered and sacked, and al-Musta'sim put to death.

Later Abbasids.—The Abbasid caliphate had played, for all its pretensions, so small a part in the real political life of the Muslim world for so many centuries that the fall of Baghdad, sensational as it was, made no change in the general structure of its political institutions. The defense of Islam against the menace of the Mongols passed to the Mameluke sultans of Egypt (see EGYPT: History). After the defeat of the first Mongol invasion of Syria, Sultan Baybars, with the aim of securing for Egypt both the political and the religious leadership of Islam, proclaimed the refugee Ahmad, a brother of al-Mustansir, caliph, with the same title, in 1261. His pretensions proved irritating, and Baybars, having accompanied him as far as Damascus on an expedition to recover Baghdad, allowed him to proceed by himself with what forces he could collect; and he was defeated and killed at Hit (1262). In the next year a new Abbasid caliph from a cadet branch was installed, but with diminished and purely formal powers; and this shadow caliphate continued in his line until the Ottoman conquest of Egypt in 1517. Except for a brief moment, in 1412, when a caliph occupied the sultanate, they had little influence and less power and only exceptionally enjoyed the recognition of a foreign prince. The last of the line, al-Mutawakkil III, was taken to Constantinople by Sultan Selim I, but returned to Cairo, where he died in 1538. The supposed transfer of his prerogatives to the Ottoman sultan is not confirmed by any contemporary Arabic or Turkish sources.

OTTOMAN CLAIMS

The old Sunnis orthodox, or classical, theory of the caliphate which, based upon the history of its first two centuries, assumed that all Muslims would always live under the government of one

Muslim ruler, who should be descended from the prophet's tribe of Quraish (Koreish) had, in fact, long been discarded, though independent princes, moved by antique piety or uneasy consciences, might still from time to time apply to the caliphs for a diploma of investiture or title of honour. Later jurists, particularly after the Mongol conquests, held that the true caliphate had come to an end with the four original caliphs of Medina and that subsequent holders of temporal power, by whatever name they might be called, derived their authority directly from God. In the diplomatic styles of most princes, from the 13th century onward, the terms "sultanate," "imamate" and "caliphate" became interchangeable in their local application. This, or a parallel theory, underlay the usage of the early Ottoman sultans also and was continued by them after the conquest of Egypt; in the public prayers, the title applied to them was always sultan, not khalifa.

But in course of time the vast dominions and long rule of the Ottoman sultans endowed their line with something of the prestige which had formerly been associated with the Abbasid caliphs of Baghdad; and in the 19th century Turkish diplomatists found it convenient in their relations with Christian powers to make use of the false analogy current in Europe between the caliph and the pope and to claim for the sultan spiritual authority over all Muslims, even if these were not actually his subjects.

Abdul-Hamid II (1876–1909) especially emphasized this claim, and from the outset of his reign endeavoured to obtain recognition of himself as caliph by sending emissaries to Egypt, Tunis, India, Afghanistan, Indonesia and China. This was the basis of the "pan-Islamic" policy, which was continued even after his deposition in favour of his successors. The attempt to implement this policy when Turkey entered World War I in 1914 by the proclamation of a jihad, or "holy war," summoning all Muslims to fight in defense of the caliphate, showed up the unreality of the Ottoman claim, although many Muslims, especially in India, were distressed at the fact of hostilities between Turkey and the governments to which they gave their loyalty. The abolition of the caliphate by the Turkish grand national assembly in March 1924 caused even greater perturbation among Muslims. An attempt by King Husain of the Hejaz (see HUSAIN IBN ALI) to fill the vacuum met with little support outside Arabia and Syria, and an international Caliphate congress held at Cairo in 1926 decided in effect that until all the Islamic peoples could join in establishing a new caliphate the office remained in abeyance. See also references under "Caliphate" in the Index volume. (H. A. R. G.; X.)

CALISTHENICS, bodily exercises done without the use of apparatus or with light hand apparatus, used to develop grace and co-ordination or to "loosen up" muscles before participating in other strenuous activities, particularly body contact sports such as football or boxing. For competitive calisthenics see GYMNASTICS.

CALIXTUS (CALLISTUS), the name of three popes and one antipope.

CALIXTUS I (d. 222), pope from 217 or 218 to 222, was little known before the discovery of the book of the *Philosophumena*. From this work which is in part a pamphlet directed against him, we learn that Calixtus was originally a slave. Falling on evil times, he was brought into collision with the Jews, who denounced him as a Christian and procured his exile to Sardinia. On his re-

turn from exile he was pensioned by Pope Victor. Later he was associated with Pope Zephyrinus in the government of the Roman Church. After the death of Zephyrinus (217) he was elected in his place and occupied the papal chair for about five years. His theological adversary Hippolytus (*q.v.*), the author of the *Philosophumena*, accused him of having favoured the modalist or Patripassian doctrines (*see* MONARCHIANISM) both before and after his election. Calixtus, however: condemned Sabellius, the most prominent champion of modalism. Hippolytus accused him also of certain relaxations of discipline. It appears that Calixtus reduced the penitential severities applied against fornication and adultery, which the church had previously regarded as irremissible except by God Himself. Under Calixtus and his two immediate successors, Hippolytus was the leader of a schismatic group, organized by way of protest against the election of Calixtus. In the time of Constantine the Roman Church reckoned him officially among the martyr popes. (L. D.: X.)

CALIXTUS II (Guy of Burgundy) (d. 1124), pope from 1119 to 1124, was a son of William I, count of Burgundy. Appointed the archbishop of Vienne in 1088, he rose to fame as the fearless spokesman of the reform party and critic of imperial policy. When Gelasius II died at Cluny, the cardinals there elected Guy to succeed him, on Feb. 2, 1119. He made his way to Reims, where he held a synod in which lay investiture was again condemned and the emperor Henry V and the antipope Gregory VIII were again excommunicated. In 1120 Calixtus was able to enter Rome in triumph. The German princes now forced the emperor to come to terms with the pope, and the concordat of Worms was negotiated (1122) to terminate the contest over the investiture. For the conclusion of peace, Calixtus called a general council (the 9th). This, the first Lateran council, met on March 18, 1123, ratified the concordat and published important reforming canons. On Dec. 13 or 14, 1124, Calixtus "died in the peace of the Church which he, by God's help, had established." His bull *Etsi Judaeis* (1120) afforded a considerable measure of protection to the Jewish community in Rome.

CALIXTUS III (John of Struma), antipope from 1168 to 1178, was elected as Paschal III's successor in opposition to Alexander III. He was the protégé of the emperor Frederick I Barbarossa until the treaty of Anagni (1176). This ended the schism in Alexander's favour, with the proviso that Calixtus should have an abbacy to compensate him for his deposition. Calixtus nevertheless ignored the treaty and remained obstinate even after the conclusion of the peace of Venice (1177) between Frederick and the Lombards. In Aug. 1178, however, he submitted to Alexander, who treated him generously.

CALIXTUS III (Alfonso de Borja, or Borgia) (1378–1458), pope from 1457 to 1458, was born near Xativa, in Valencia, Spain, on Dec. 31, 1378. As professor of law at Lérida, he won a great reputation for juristic learning and austerity of life. He attached himself to Alphonso V, king of Aragon and Sicily, and his services in reconciling his master with the pope gained him the bishopric of Valencia in 1429 and the cardinalate in 1444. After a struggle in the conclave between the Colonna and Orsini, he was chosen pope on April 8, 1455, as a compromise candidate who was unlikely to last long in view of his advanced age. The master idea of his pontificate was the organization of a crusade to recover Constantinople from the Turks. In this he failed, despite heroic efforts, but he raised a pontifical fleet which did good work in relieving many of the Aegean islands. The repulse of the Turks from Belgrade on Aug. 6, 1456, marked the turn of the tide, and Calixtus commemorated it by instituting the feast of the Transfiguration (1457) and ordering that it be observed on that day. His personal life was blameless, but he followed the fashion of his time in showering favours on his nephew, Rodrigo Borgia, whom he made cardinal and generalissimo of the papal forces. He died on Aug. 6, 1458. (C. H. LE.)

CALIXTUS (CALIXT), **GEORG** (1586–1656). German Protestant theologian who tried to develop a theological system

that would permit reunion of Lutherans, Calvinists and Roman Catholics. was born at Medelbye, Schleswig, on Dec. 14, 1586. After studying philology, philosophy and theology at Helmstedt, Jena, Giessen, Tübingen and Heidelberg he traveled through Holland, France and England, where he became acquainted with the leading reformers. In 1614 he was appointed professor of theology at Helmstedt, and he held this post for 40 years, making Helmstedt a centre of reasonableness in an age of bitter theological controversy.

Calixtus constantly pressed for a milder treatment of confessional differences, and thought that a basis for the reunion of all the churches could be found in the study of the Christian fathers. His ideas were those later advocated (also fruitlessly) by Leibniz. In 1613 he published a book, *Disputationes de praecipuis religionis christianae capitibus*, which provoked the hostile criticism of orthodox scholars; in 1619 he published his *Epitome theologiae*, and several years later his *Theologia Moralis* (1634) and *De Arte Nova Nihusii*. Statius Buscher charged the author with a secret leaning to Romanism. Calixtus refuted the accusation of Buscher, but after the conference of Thorn (1645) a charge of a secret attachment to Calvinism was preferred against him, principally at the instance of Abraham Calovius. The disputes on the possibilities of the reconciliation desired by Calixtus—known in the church as the syncretistic controversy—lasted during the whole lifetime of Calixtus, and distracted the Lutheran Church, until a new controversy arose with P. J. Spener and the Pietists of Halle.

Calixtus died on March 16, 1656.

See E. L. T. Henke, *Georg Calixtus und seine Zeit*, 2 vol. (1853–60).

CALLA, a genus of plants of the arum family (Araceae, *q.v.*), comprising only one species (*C. palustris*), known as arum lily, water arum or wild calla, found widely in wet places in cool north temperate and subarctic regions. It is a handsome plant, with heart-shaped leaves, showy white flowering spathes and a fruit cluster of brilliant red berries. The juice of *C. palustris* is violently poisonous.

The well-known calla, or calla lily, of the gardeners comprises several species of *Zantedeschia*, the chief of which is *Z. aethiopica* of South Africa, a stout herb with a brilliantly white corolla and arrowhead-shaped leaves, widely grown for the florist trade. The golden or yellow calla lily is *Z. elliotiana*, also of South Africa, as is the pink or red calla lily, *Z. rehmannii*. *Z. aethiopica* is grown outdoors in mild climates, but all calla lilies are best grown in the greenhouse where they need a rich soil, plenty of water and a temperature of about 60°. Dormant fleshy roots or tubers are planted in 7-in. pots filled with 2 parts cow manure, 1 part sand, 2 parts loam and 2 parts leaf mold. When through flowering the pots should be plunged outdoors for the summer.

HORTICULTURAL VARIETIES OF
CALLA LILY (ZANTEDESCHIA)

CALLANDER, a small burgh of Perthshire, Scot., 16 mi. N.W. of Stirling by road. Pop. (1961) 1,654. It is mainly on the north side of the Teith, there crossed by a three-arched bridge. It owes much of its prosperity to its position on the road from Edinburgh to Oban and Fort William and to its proximity to the Trossachs, Loch Katrine (*qq.v.*), and Lochs Xchray and Venachar. This romantic and scenic region was described in Sir Walter Scott's *The Lady of the Lake*. Ben Ledi (2,873 ft.) is 4 mi. W.N.W., and 1 mi. N.E. are the Bracklinn falls.

Northwestward road and railway enter the Pass of Leny, 4 mi. beyond which is Loch Lubnaig ("the crooked lake"), 4½ mi. long and divided into two reaches by a picturesque rock. Little Leny, ancestral burial ground of the Buchanans, is nearby.

CALLAO, the principal seaport and warehouse centre of Peru, lies on the central coast of the republic at 12° 05' S., and 77° 08' W. Although it is the seaport for the capital city of Lima, about 8 mi. inland. Callao is a constitutional province (*Provincia Constitucional del Callao*). Pop. (1958 est.) of the province 175,332; of the city 129,365. Occupying an area of 28 sq.mi., with an inner harbour of 655 ac., the province includes the port of Callao: its suburbs. La Punta, Bellavista and Chucuito; and several islands, notably San Lorenzo, Frontón and Las Palominas. In addition to its maritime role, Callao, in conjunction with Lima! is part of Peru's chief industrial and commercial district. It is connected with the capital city by three major highways, a railroad and an electric interurban line.

The average annual temperature is about 66° F., and there is little seasonal variation. The annual rainfall seldom exceeds 2 in., but overcast, misty days are common. The north-flowing current of cold water, called the Humboldt current, helps to produce sea and air temperatures many degrees colder than is usual for this latitude.

In selecting the Lima-Callao site for his capital in 1535 (actually founded in 1537) Francisco Pizarro recognized that the area afforded two advantages: it was suitable for irrigation with an abundant supply of water from the Rio Rimac; and it had a fine anchorage protected by a large offshore island and a long promontory of land pointing toward the island from the mainland. The harbour was given further protection from the sea, in modern times, by breakwaters; its entrance and channels have a depth of 37 ft. A modern maritime terminal was opened in 1935 and the shipping facilities were improved by the construction of a 570-ft. drydock in 1933: a naval arsenal was completed the same year.

As the leading shipping point for the gold and silver taken by the Spanish conquerors from the Inca empire, the port was frequently assaulted by pirates and the European rivals of Spain. It was pillaged by Sir Francis Drake in 1578. A tidal wave, following an earthquake, inundated Callao in 1746, and the city was rebuilt about three-quarters of a mile from the original site. The extensive fortification called Castillo del Real Felipe was built after the disaster. It withstood a number of sieges by Spanish forces during the wars of independence. Simón Bolívar landed at Callao in Sept. 1523 and three years later it was the scene of the final surrender of Spain. The city was bombarded by a Spanish fleet in 1866 in a vain effort by that country to regain its lost colonies. In 1881, during the War of the Pacific (*q.v.*) it was occupied by Chilean forces. Chile restored the port to Peru in 1883 by the treaty of Ancón. Further rebuilding of the city and port was necessary after a severe earthquake in 1940.

In 1958 the International Bank for Reconstruction and Development made a loan of \$6,575,000 for the improvement and expansion of the port of Callao. It was expected that Peru's competitive position in world markets would be improved and that the nation's foreign trade earnings would be increased with the completion of the development program. The loan was made to the Port of Callao Authority, an autonomous agency which operates the port. The authority was established in 1952 after the bank had made a loan of \$2,500,000 to the Peruvian government for the purchase of cargo-handling equipment.

The planned expansion consisted of the construction of a new two-berth pier for the handling of petroleum products, a new berth with mechanical equipment for the loading of minerals, two new general cargo berths, three new storage sheds, improved accommodations for passengers, the purchase of two diesel tugs and a cutter section dredge, new maintenance shops and a gear store. A new petroleum pier was designed to permit tankers discharging inflammable loads to berth away from other ships and thus greatly reduce the risks of explosion and fire involved when general cargo ships use the same pier as the tankers. The new installations for handling bulk minerals were to have a capacity up to 14,000 tons daily compared with the former loading rate of between 500 and 800 tons. The addition of two new general cargo berths, together with those released when the petroleum and mineral berths are commissioned, were to give Callao a total of 12 general cargo berths and enable it to cope with the long-term growth of general

cargo and refined metals traffic. As the port of Callao serves the mining and agricultural areas of the Central Sierra and Lima, about 60% of the country's exports and imports pass through the port; it handles a significant volume of coastal traffic as well. In terms of tonnage, the leading exports are minerals, refined metals and general cargo such as wool, cotton, hides and fish meal; the chief imports include such items as wheat, machinery, lumber, newsprint and automobiles. The industrial establishment of the city of Callao comprises metallurgical industries, lumber mills, flour mills, soap and candle factories, sugar refineries, breweries and meat-packing plants. Agricultural products grown in the province, chiefly for the local market: include vegetables, fruits, maize and sugar cane.

The suburb of La Punta, site of the naval academy, is a popular seaside resort. (J. L. TR.)

CALENDAR, HUGH LONGBOURNE (1863-1930), British physicist best known for his work in heat and thermodynamics, was born at Hatherop in Gloucestershire. Educated at Marlborough and at Cambridge, he was professor of physics at McGill university, Montreal (1893-98); at University college, London (1898-1902) and at the Imperial College of Science.

Callendar was successful in devising and carrying out accurate methods of heat measurement and in designing new apparatus. The electrical resistance thermometer, with the Callendar-Griffiths bridge and various recording devices used with it, was the subject of papers published in 1886-87. This was followed by his work on the electrical continuous flow calorimeter, giving a new method of measuring specific heats of liquids, which eliminated the water equivalent of the apparatus and simplified the radiation correction; the full description was given in 1902. In addition, Callendar was responsible for a compensated air thermometer (1891) and a radio-balance (1910).

His researches on steam (*q.v.*) led to the formulation of the Callendar steam equation and the publication of *Callendar Steam Tables* (1911); *Properties of Steam and Thermodynamic Theory* (1921); *Abridged Callendar Steam Tables C. and F. Units* (1922 and 1927), and *Callendar Steam Diagram C. and F. Units* (1922).

In 1925 he presented a report to the Electrical Research association on the continuous flow method of measuring the total heat of steam at high pressures. Callendar was the author of a number of papers on various subjects such as internal combustion engines, thermometric scales, radiation, vapour pressure, osmotic pressure of solutions, absolute expansion of mercury and the boiling point of sulfur. He was also responsible for Air Ministry reports and memoranda on work carried out by himself and colleagues on *Dopes and Detonation* (1926) and on the effect of anti-knock compounds on engine knock (1927). He died in London on Jan. 21, 1930.

Callendar was a member and officer of many societies; he was awarded the Rumford Medal of the Royal Society in 1906 and the first Duddell Memorial Medal of the Physical Society in 1924; he received the C.B.E. in 1920. (D. HY.)

CALLES, PLUTARCO ELÍAS (1877-1945), president of Mexico, was born at Guaymas, Sonora, Sept. 25, 1877. Of humble origin, he was a schoolteacher before entering politics as a member of the revolutionary movement. He served the cause of constitutionalism in the successive struggles against Victoriano Huerta and Pancho Villa. In 1917 he became governor of Sonora and sponsored notable labour and agrarian legislation. In 1919 Calles was appointed secretary of commerce, labour and industry under Pres. Venustiano Carranza, but resigned to support Álvaro Obregón's candidacy.

A member of the Sonora triumvirate that overthrew Carranza in 1920, Calles served in the provisional government of De la Huerta and as secretary of interior under Obregón. His own term as president, 1924-28, was marked by a continuation, if somewhat modified, of the agrarian, labour and educational program of the Mexican revolution. Programs of irrigation, agricultural credit and road building were initiated.

The stability of the regime was threatened by controversy with the United States over the passage of alien land and petroleum laws, and by a Catholic rebellion precipitated by application of

the religious and educational provisions of the constitution.

The assassination of President-elect Obregón in 1928 created a political vacuum that only Calles could fill. For the next six years he remained the power behind the president. Cynicism prevailed as the agrarian program was slowed and labour's power curbed. In 1936 Lázaro Cárdenas, although elected with the support of Calles, successfully asserted his independence. Forced into exile, Calles lived in California until 1941, when he returned to Mexico City. He died there on Oct. 19, 1945. See also MEXICO.

(S. R. R.)

CALLIAS AND HIPPONICUS, names borne alternately by the heads of a noble and wealthy Athenian family in the 5th and 4th centuries B.C. The office of *daduchus* (torchbearer) at the Eleusinian mysteries, which was hereditary in the clan Ceryces, was held by all those listed below.

CALLIAS (5th century B.C.), second of the name, an influential figure who won three victories at Olympia and married Elpinice, sister of Cimon. He distinguished himself at Marathon (490), but his best-known activities came at the end of his life, his embassy to Susa and the negotiation of peace between Athens and Persia in 449 (this last has been doubted, but on insufficient grounds), and his part in the Thirty Years' peace between Athens and Sparta in 446.

BIBLIOGRAPHY.—Herodotus, vii, 151; Diodorus, xii, 4, 7; Plutarch, *Cimon*, 13; Demosthenes, *On the Embassy*, 273; H. T. Wade-Gery, *Essays in Greek History*, pp. 201–232 (1958); E. M. Walker, *Cambridge Ancient History*, v, pp. 469–471 (1927).

HIPPONICUS (5th century B.C.), son of the above, with Nicias and Eurymedon commanded the Athenian forces which won a minor victory near Tanagra in 426, and was killed at the battle of Delium in 424 (see PELOPONNESIAN WAR). He was the first husband of the wife of Pericles.

BIBLIOGRAPHY.—Thucydides, iii, 91; speech wrongly attributed to Andocides, *Against Alcibiades*, 13; Plutarch, *Pericles*, 24; Isocrates, *On the Team of Horses*, 31.

CALLIAS (5th–4th century B.C.), son of the above-mentioned Hipponicus, was ridiculed by the comic poets for his extravagance in youth; he also quarreled with Andocides who attacked him violently in his speech *On the Mysteries*. But he was friendly with the philosophers, and his house is the scene of Xenophon's *Symposium* and Plato's *Protagoras*. In 390 during the Corinthian War he commanded the Athenian hoplite force at Corinth, on the occasion when Iphicrates' lighter-armed troops destroyed a Spartan regiment. In 371 he headed the embassy which made peace with Sparta shortly before the Spartans were defeated by the Thebans at Leuctra; in the speech which Xenophon attributes to him on this occasion, caricaturing his vanity, he asserts that he had led two such embassies successfully before.

BIBLIOGRAPHY.—Aristophanes, *Frogs*, 429, *Birds*, 283; Andocides, *On the Mysteries*, 110–131; Xenophon, *Symposium*, 1; Plato, *Protagoras*, 311a; Xenophon, *Hellenica*, iv, 5, 13–15; vi, 3, 2–6. (A. As.)

CALLIÈRES, FRANÇOIS DE (1645–1717), French diplomat, famous for his exposition of the principles of diplomacy, was born at Torgny in Normandy. Having been sent on diplomatic missions to Poland (three times), to Savoy (twice), to Holland and to Bavaria in the period 1670–93, he went as French plenipotentiary to Holland in 1695 and 1696 for the preliminaries of the peace of Ryswick (1697). His success there was rewarded by Louis XIV with the post of cabinet secretary (1698). After a mission to Lorraine (1700), he spent the rest of his life at Versailles or in Paris, where he died on March 5, 1717.

Callières had been elected to the Académie Française in 1689 for a panegyric of Louis XIV (1688). This and most of his other writings (guides to courtly behaviour and polite conversation) are now rarely remembered; but his treatise *De la manière de négocier avec les souverains* (1716; modern Eng. trans., *The Practice of Diplomacy*, London, 1919) remains a model introduction to its subject, covering the qualifications, duties, conduct and methods of the ideal negotiator and showing sound psychological insight in its assessment of the proper use of flattery and bribery and in its condemnation of trickery as prejudicial to the confidence that an envoy must inspire.

(J. G. R.-S.)

CALLIGRAPHY is the art of fine writing. Writing is a means of communication by agreed signs; if these signs or symbols are painted or engraved on wood or stone the result is an extension and application of writing known as lettering, *i.e.*, a large script generally formed with mechanical aids such as the rule, compass and square. But it is the essence of handwriting that it be free from such, though not from all, government; and of beautiful handwriting that it possess style. When the agreed forms passing through a mind sensitive to symmetry are expressed upon vellum, paper or other suitable material by an instructed hand with an appropriate tool, the result may be a handwriting possessing style. Calligraphy may be defined as freehand in which the freedom is so nicely reconciled with order that the understanding eye is pleased in contemplating it. Hence the reader immediately recognizes the beauty resulting from proper proportion of the components to the whole of a letter, and between the parts to the whole of a word. Many scripts of the remote or recent past, such as the Rustic Capitals, Uncial, Half-Uncial, the Caroline Minuscule and the later Gothics, demonstrate that handwriting, though an elementary craft, is capable of infinite variations. Changes of fashion so affect the form, the cutting of the tool and the manner of holding it that a collection of the hands employed in pre-Renaissance Europe exhibits a series of almost bewildering variations. The necessity for speed is the first great cause of variation; a second equally potent occasion lies in the use of special hands for certain purposes. In the medieval period, outside the monastic scriptoria where the most formal upright and deliberate text hands were written, there were several recognized classes occupied with writing, such as clerks, public scribes and public notaries, as well as certain others who were precursors of the later professional writing masters. Finally, there were writers of the special hands used in documents issued from the papal and other chanceries. Most of these classes, in the hope of preventing forgery, wrote hands of deliberate complexity.

Renaissance Developments.—The Renaissance, by its reaction from the complicated late Gothic and reversion to the simpler Caroline hands, changed the writing tradition of all Europe, but not all the cisalpine countries adopted the new hands simultaneously—the tenacity, in fact, of Gothic is still not completely broken in its chief stronghold, Germany. Though the humanists deliberately reverted to the Caroline hand, theirs was not a barren facsimile of the 9th-century letter for, since they laboured for a return to classical traditions, many scribes broke completely with the Caroline exemplars in the matter of majuscules, so that adaptations of the old geometrically formed Roman inscription letters appear upon the vellum pages of humanistic codices equally with majuscules based upon the fine Tours forms.

The Renaissance did more than merely revert to the art styles of antiquity. In its early phase it was a movement in which a limitless curiosity of the mind—the mark of the true humanist—predominated and had not yet aroused the jealousy of the church. Indeed, in the early 15th century, ecclesiastics vied with secular scholars in the task of renewing art and science. Acknowledgment is due the secular humanistic scribes for the fine round book letter that is the foundation of roman printing, and to the scribes of the papal chancery for the running hand. In an age in which science, religion and art were the chief interests, with commerce subordinate, these novel scripts were introduced and propagated by artists and ecclesiastics, while merchants, bankers and lawyers kept accounts and indited conveyances in a tortuous Gothic. The development of handwriting owes nothing to commerce until the following century.

In medieval society the development of handwriting depended upon the officials of church and state. Hands were invented and books written in accordance with liturgical, administrative and judicial requirements. Like other courts, the Roman *Curia* maintained (and maintains) a group of canon lawyers and scribes known as the Apostolic Chancery from which were issued papal bulls, and later a more modest class of document. A small, easily formed hand was reserved by order of Pope Eugenius IV (1431–47) for the engrossing of these minor documents that were written swiftly (*brevi manu*) and known as "briefs." The script itself

became famous as *cancelleresca corsiva*, chancery cursive, and in the 16th century printed and engraved models of it abounded.

The first works on letter formation deal with capital letters and were compiled by enthusiastic admirers of the old Latin inscriptions, such as Ciriaco of Ancona, who transcribed, collated and copied all the memorials, gravestones and tablets they could discover. Andrea Mantegna introduced into his famous frescoes at the Eremitani in Padua careful renderings of certain inscriptions (since destroyed). Feliciano of Verona compiled a collection of inscriptions and dedicated it to Mantegna; and from the same scholar's hand flowed a codex (Cod. Vaticanus 538) that represents the earliest extant treatise on the shapes of inscription letters. The manuscript is dated 1463 and is the first to give diagrams and instructions for the geometrical formation of Roman capitals. The earliest printed work of the kind (probably about 1480–83) is a modest anonymous work with an undated colophon: "*impressum Parme per Damianum Moyllum, Parmensem.*" Since there are extant several manuscripts signed by Damiano Moille it may be assumed that he had a share in the authorship as well as in the printing of the alphabet.

At about the same time the friar and mathematician Luca Pacioli was busy on his *De Divina Proportione*, a treatise that included an appendix on the geometry of letter making. Pacioli's book was not printed until 1509 but existed in a finely illuminated manuscript copy much earlier, having been presented to Ludovico Sforza (il Moro) of Milan.

Fanti of Ferrara in 1514 first extended the geometrical method to the rounded Gothic letter then greatly used for large choir books: *Theorica et practica Perspicassimi Sigismundi de Fantis . . . De Modo Scribendi Fabricandique omnes Litterarum species* (Venice, Rubeus, 1514). The title is fuller than the contents. For Fanti gives no more than the Roman capitals in the method of Feliciano. Moille and Pacioli, plus a set of round semi-Gothic letters similarly made and roughly cut on wood by da Carpi. Whereas the models of capitals already published had been useful to architects and antiquarians and a few scribes. Fanti's small Gothic letters (lower case) of the kind then known as "modern letter" (*lettera moderna*) were serviceable to the numerous clerks in monasteries and elsewhere. Arrighi, a calligrapher from Vicenza and subsequently an assistant in the Apostolic Chancery, published in 1522 a book of models of a current correspondence hand based upon the *lettere de brevi*. This, the first of all copybooks, was entitled *La Operina di Ludovico Vicentino, da imparare di scrivere littera cancellarescha*. The script in this first publication of Arrighi is a singularly effective and beautiful combination of the neo-Caroline minuscule, slightly inclined by speed, with perpendicular majuscules reminiscent of the inscriptions, their austerity relieved with additional characters of a decorative form, **BCDEPRN**. There are also to be found flourishes,

ligatures, and initial and terminal letters of grace and freedom. Arrighi's fine professional hand is ornamental in comparison with the somewhat angular and pinched version of the same hand as it was officially used 50 years earlier.

The popularity gained by the chancery script during the half-century 1470–1520 exposed it to great risks. Writers of diplomatic documents practised it with a discretion foreign to the temper of Mantegna, Cellini, da Vinci and scores of other artists, nobles and scholars who adopted it. The habit of writing "private" letters with a view to their being handed about as specimens of true Latinity developed interest in calligraphy, and with this powerful support the cursive rapidly became the favourite correspondence script of the fashionable classes, absorbing a multitude of mannerisms that corrupted it until its original simplicity was scarcely recognizable. Although, in Vicentino's specimens, flourished forms were offered as an occasional pleasant alternative to the rigid capital and both were modestly proportioned to the height of the ascending letters (*d, h* and *l*), later models exhibit an irritating superfluity of display. Much of the character of the early italic hands derived from the "broad pen" with which they were written; this was a quill cut with a broad, fairly stiff nib, which, depending upon the direction of stroke and angle of cut, produced

either a thick or a thin line. The burin of the copper engraver produced an excessively brilliant line that tempted pupils to employ a correspondingly fine pen, so that the later writing of the century was dominated rather by the technique of the engraver's burin than that of the scribe's pen.

The first Italian writing book in copperplate is the handsome, ornate, though practical *Essempiare utile* of Hercolani, a Bolognese notary (1571). His book is valuable as a good specimen of the late chancery hand distinguished by its decorative treatment of the ascending and descending letters. In the pure Vatican style these forms terminated in an angular serif, which existed side by side with a variety that terminated in a short blunt curve from right to left. The angular serif went out of use before 1520 and thereafter no models of the chancery hand for secular or official Vatican use recommended it.

Gradually, by means of a fine pen and a supple wrist, the originally unassuming serif was turned into the most conspicuous feature in the word—and in the page—so that a late Italian 16th-century letter is almost a network of deliberately formed blots. This development may be conveniently watched in the books of Cresci (1560) and of Palatino (1540), a first-rate scribe who gained great renown in Spain, where he was copied by Yciar. Pens then became finer and enabled Periccioli (Siena, 1610) to execute not only very delicate calligraphical *entrelac* borders but exceedingly subtle script that gained a seductive sparkle when reproduced from intaglio plates. All the Italian scripts found their way abroad; the fine early hands and their bulbous successors may be met in various parts of Europe. The Italian artists transplanted to Fontainebleau by Francis I included a humbler rank of decorators, craftsmen and calligraphers. These found Gothic, formal and cursive, generally practised. Geoffroy Tory, who wrote an Italian hand, made his *Champ Fleury* (1529) a plea for beautiful lettering and an elaboration of the geometrical method of making Roman capitals he had learned from Pacioli and A. Dürer (*Underweysung der Messung*, 1525). Gothic book hands are also given, but a French pattern book of correspondence hands did not appear until a generation later. In the books of Hamon (1561) and de la Rue (1565) there appear good chancery models and a number of *Lettres de Fantaisie* (alphabets of wavy, crooked, clubfooted and other similarly treated letters). *Cursive françoise*, as current Gothic was called, always appears in the early French books. From it the *Civiltik* type was made; in the next generation it was to be amalgamated with the Italian hand, producing the elegant compromise known as *ronde*. Early fine rondes are to be found in the books of Louis Barbedor (c. 1640).

In mid-17th century, Colbert, when he was the financial secretary of Louis XIV. took in hand the revision of French official scripts, and, in consequence, the clerks in the offices of state were instructed to abandon the old Gothic cursives and to confine themselves to the upright *ronde* known as *financière*, inclined *bâtardé* and a running form known as *coulée*.

Rise of Non-Gothic.—Such changes gained effect gradually: generations of masters recommended almost any non-Gothic as the "Italian hand," so great was the prestige of that name. The rise of the fine French school of portrait engraving influenced the use of Roman scripts, and the opposition of Colbert left Gothic scarcely a vestigial existence by the end of the century.

To Colbert, the eminent master Senault dedicated his fine book—*Livre d'écriture representant la beauté de tous les caractères financiers . . .* (1600). Other French models of calligraphy circulated also in England and in Holland; French influence in England was more direct than the Italian, though there were Italians such as Petruccio Ubaldini who taught calligraphy to the English Court (c. 1580). *A Booke containing divers sortes of hands* by Jean de Beauchesne and John Baildon (1570) is the first English manual of calligraphy. It contained admirable models having handsome forms of prevailing Gothic and secretary hands as well as fine italics. The italic hand had been written in England for a number of years before this, particularly in university and court circles. Elizabeth I learned it as a child from her tutor Roger Ascham (1516–68), a pupil at Cambridge of Sir John Cheke (1514–57), whose highly individual variety of humanistic cursive

was widely imitated at the university. By 1600 most educated Englishmen wrote two scripts: humanistic cursive and a late Gothic "secretary hand," the latter for legal and business use.

Martin Billingsley's *The Pens Excellencie* (1618) still has many more secretary, court and other Gothic hands than Roman. Billingsley's is one of the few English books independent of the designs of Materot (1608) and Barbedor that powerfully affected London masters of the 17th century. But though England learned much from France, specimens of the work of Van de Velde, Boisens, Perlingh and other conspicuous Dutch exponents of the art were highly esteemed when the London writing masters found their services demanded by youths training for clerkships in the growing English commercial houses. The Dutch possessed at that time most of the carrying trade and were for that reason directly imitated in England. The Dutch naturally copied the French since French literature was not only read but, owing to the repressive legislation against Paris printers, also printed in the Low Countries.

The difference between the Italian late 16th-century and French and Dutch early 17th-century hands was not considerable—mainly a matter of width of letter. The Italians had a habit of angularizing the letter, the Dutch of widening it and giving it greater inclination. What French, Dutch and English writers called the "Italian" hand is a free, flowing and inclined hand in which the ascenders are looped and the majuscules cursive—wholly different from Arrighi's Chancery. This was the result of the demand for speed, the concomitant of commercial development.

Rise of the English Hand.—English writing gained in importance as commerce expanded. When, in 1658, Oliver Cromwell broke the Dutch commercial power and by his Mercantile act made certain that every cargo shipped to England was carried in English vessels, there resulted a vast increase in the nation's shipping. Commercial clerkships became desirable positions, bringing a fine opportunity for such professors as Snell (1693), Seddon (1695) and others who had learned from the Dutch masters but whose hands drew away from their models and finally expressed those characteristics that, in another generation, came to be regarded by the rest of the world, if not by Englishmen, as thoroughly English and admirable for the purposes of salesmanship. Thus the commercial success of England drew hearty foreign respect for the script in which English bills of lading and notes of exchange were made out; named *anglaise* in France, *letra inglesa* in Spain, it dominated in Italy itself at the end of the 19th century as "*lettere inglese*." Gothic now persists only with the greatest difficulty—where once it had been used for the text of deeds it fights for existence as a script for their titles, and today **Whereas** and **This Indenture** remain its sole traces outside the German-speaking world, where, despite the showing of italic hands by Neudörffer, Fugger and other masters during the 16th century, the Gothic national hands were never completely replaced.

In France the national hands are still taught (the *ronde* is part of the public school curriculum) but the emphasis is on the *anglaise*.

The situation is not very different in present-day Spain. The magnificent 16th-century specimens of Yciar (1550) and Brun (1583) were adaptations of the hands of Palatino and Vicentino, but these writers succeeded neither in acclimatizing these nor inventing any new, living, national hands. This was achieved by Lucas (1571), who created a characteristic Spanish upright round hand together with a companion inclined *bâtarde*, which with astonishingly trifling variations remained in use for two centuries, giving way only before *anglaise*. The hands of many English writing masters were familiar to the leading Spanish calligraphers of the 18th century.

It would be an exaggeration to claim that the script that is customarily termed "copperplate" possesses an attractive personality. It is colourless, thoroughly unromantic and dull. These, however, were precisely the qualities that commended it to those who wrote out invoices. Above all it was expeditious, and the writing masters of London knew better than to teach that ascenders in solid blacks or capitals with meandering loops would endear their own calligraphy to present and future. The simple and practical nature of the English business hand did not exactly serve

the material interests of the English writing master. Plain round hand is not so difficult to acquire as to need either perpetual practice at home or continual resort to a master.

The American Hand.—The early American colonists followed the calligraphical styles of the home country, and Benjamin Franklin practised a fine *aizglaise* from which a printing type was subsequently engraved. *The American Instructor* (1748), the popular school book that Franklin's firm plagiarized from an equally popular London work of the period, stressed the English round hand; so did the first U.S. writing manual of any consequence, John Jenkins' *The Art of Writing* (1791). Joseph Carstairs of London championed a theory of handwriting in which the forearm and not the fingers controlled the script. His book was translated into French and Spanish and was introduced into the United States by Foster in 1830. It was employed there with such success that it even became known as the American system. The American hand, however, did in fact develop from a continuation of this movement of the forearm and a condensation of the running hand exemplified by Jenkins. Dunton introduced about 1845 the first specimen of what developed into a style that now may fairly claim to rank as the national American hand. It is a style that requires a very fine pen because the down strokes taper from top to bottom. There is a slightly increased slope, a tendency to flourish terminations and a noticeable degree of condensation. It had little success at first and it possibly would have made no progress but for its popularization by the very active Platt R. Spencer, who, in spite of the protests of Dunton, claimed the design as his own and taught it throughout a chain of business colleges that had become established in 44 cities by the time of his death in 1864. The style known as the Spencerian system still has its exponents and when written with care is not a particularly unpleasant letter. Later adaptations of it, somewhat more upright and with less contrast in shading, are still the most widely taught hands in U.S. schools. Nineteenth-century England learned to write from the copybooks of Vere Foster, whose lithographed models expressed edifying admonitions in a flawless current hand of the plainest style. The "Civil Service" hand, an upright version of the same design, also was and is employed. The use of both scripts is declining, however, in part because they became illegible when written with great speed.

Modern Formal Calligraphy.—After World War II there was a notable revival of interest in both formal calligraphy (the writing of manuscript books, addresses, documents, etc.) and informal calligraphy (the writing of a beautiful and legible correspondence hand). This revival owed much to the teaching and example of William Morris (1834–96), who included calligraphy among the many arts and crafts he mastered. Morris keenly admired manuscripts as works of art and formed a notable collection; he also used the resources of the Bodleian library at Oxford and the British Museum to extend his knowledge of scribal technique and method. About 1870 he began to write and illuminate manuscript books, mainly in a round humanistic book hand of the sort used in 15th-century Florence.

The major impetus for the revival of formal calligraphy, however, was provided by the work of Edward Johnston (1872–1944), whose teaching created an international school of scribes and whose textbook, *Writing and Illuminating and Lettering* (1906), has never been superseded. Johnston was guided in his study of manuscripts by Sir Sidney Cockerell, who had been Morris's secretary and librarian; he experimented with a number of scripts before choosing as his basic "foundation hand" a large, handsome variety of Caroline minuscule used in England during the late 10th century. Johnston reconstructed, through close analysis and study, medieval techniques in pen cutting and vellum preparation that he applied to his own work; he rightly decided that the script results from a combination of proper tools, proper materials and proper training, and that true skill cannot be acquired without all three. His single-minded perseverance, his genius as a teacher and his rare ability to write simply and clearly about technical matters, added to his first-rate artistry as a scribe, made him inevitably the centre of a powerful movement. The Society of Scribes and Illuminators, most of whose members were trained by Johnston

or his pupils. demonstrated in its periodic exhibitions that formal calligraphy, rightly used—for the production of unique manuscripts and documents appropriate to owner and occasion—still has a place in modern life.

Among Johnston's pupils were Graily Hewitt, whose manuscripts showed great skill in gilding and decoration; Eric Gill, whose type designs and stone inscriptions owed much to the knowledge of letter forms gained from Johnston; and Anna Simons, who carried his principles to Germany, where they quickly took root. Modern German calligraphers have used not only the Johnstonian foundation hand but a wide variety of others based upon Gothic models, since Gothic current hands and types have survived in the German-speaking world.

Modern German calligraphy, like its prototypes, offers far more scope for invention and decoration than does that based on Caroline or humanistic models. Among the most gifted of 20th-century German calligraphers was Rudolf Koch, of Offenbach, who, like Johnston, inspired and trained a school of followers. Other notable modern European scribes included Rudolph van Larisch, of Austria, Jan Van Krimpen, of Holland, and Akke Kumblein of Sweden.

Modern Informal Calligraphy.—The revival of interest in handwriting, especially in the italic hand, can also be traced back to William Morris and the arts and crafts movement. The first modern manual of the italic was Mrs. Robert Bridges' *A New Handwriting for Teachers* (1898), which showed a hand based on Renaissance models but somewhat overly decorative for successful general use. Graily Hewitt, in his *Handwriting* (1915) and his later Oxford copybooks, displayed a simpler and more powerful hand employing the broad-edged pen. The major impetus for the revival of the italic hand came, however, not from the art schools and the teachers of handwriting but from typographers and artists who were impressed by the articles on italic types and scripts, mostly the work of Stanley Morison, that appeared in *The Fleuron* (1923–30), and above all by the appearance of the first modern reprint of Arrighi's manual, edited by Morison (1926). The italic hand was almost immediately adopted by a number of graphic artists, and among its most vigorous modern champions was Alfred Fairbank, whose writing cards, manuals and anthologies of plates did much to make the italic hand accessible and popular; a comparable role was played by Paul Standard in the United States.

In 1954 a Society for Italic Handwriting was formed in London, and it eventually attracted members throughout the world. It circulated a journal devoted to the subject, and mounted several exhibitions. Fountain pens were developed that approximated the broad pen, and special "calligrapher's papers" were introduced for use with the pens. A great many manuals and copybooks were published, and italic or chancery handwriting came to be taught in many schools, especially in England. Notable collections of calligraphic books and manuscripts have been made, especially at the Victoria and Albert museum, London, under the guidance of James Wardrop, who was himself a gifted calligrapher; and in the United States, at the Newberry library, Chicago, the Pierpont Morgan library, New York, and the Harvard College library, Cambridge, Mass. See also WRITING; PALAEOGRAPHY.

BIBLIOGRAPHY.—For the history of early handwriting in general see B. L. Ullman, *Ancient Writing and Its Influence* (1932); E. A. Lowe, "Handwriting," in *The Legacy of the Middle Ages*, C. G. Crump and E. F. Jacob, eds. (1926); J. Tschichold, *An Illustrated History of Writing and Lettering* (1947); A. J. Fairbank, *A Book of Scripts* (1949, rev. 1960), an excellent inexpensive collection of facsimiles.

Works on Renaissance and modern handwriting and calligraphy include B. L. Ullman, *The Origin and Development of Humanistic Script* (1960); S. Morison, *Latin Script Since the Renaissance* (1938), *Notes on the Development of Latin Script* (1949), "Early Humanistic Script and the First Roman Type," *The Library*, 4th ser., xxiv, nos. 1–2, pp. 1–29 (1943); M. Meiss, "Toward a More Comprehensive Renaissance Palaeography," *Art Bulletin*, xlii, no. 2, pp. 97–112 (June 1960); P. Standard, *Calligraphy's Flowering, Decay, and Restoration* (1917); R. Wellington, *The Irene Wellington Copy Books* (1957) (S. Mo.; J. M. Lv).

CALLIMACHUS (fl. late 5th cent. B.C.), Athenian sculptor, was the originator of the archaistic Neo-Attic style and a specialist in diaphanous draperies. He is given credit for the invention of the Corinthian column and a drill for marble. He made a golden lamp for the Erechtheum. His dancing Laconian maidens was a work of flawless precision, but spoiled by overelaboration of detail, according to Pliny the Elder.

See *The Sculpture and Sculptors of the Greeks* (1950); David M. Robinson, *Olynthus*, vol. xii, p. 356 (1952). (D. M. R.)

CALLIMACHUS (fl. c. 260 B.C.), Greek poet and scholar, was so highly esteemed in antiquity that no other Greek poet except Homer is so often quoted by ancient grammarians. A native of Cyrene in north Africa, son of Battus (hence he calls himself Battiades in *Epigr.* 35 and is so styled by the Latin poets), he first became a schoolmaster in Eleusis, a suburb of Alexandria, but later was introduced to Ptolemy Philadelphus and found employment in the Alexandrian library. According to the lexicon of Suidas his works numbered more than 800, but only six hymns and 63 epigrams survive intact. However, the papyri discoveries made in Egypt during the 19th and 20th centuries have filled many gaps in the text of other poems, of which previously only discontinuous fragments were extant. This is particularly true of Callimachus' chief poetical work, the *Aetia* ("Causes"), a narrative elegy in four books, containing a medley of recondite tales from Greek mythology and history. It included two love stories with happy endings (unusual in Alexandrian poetry), the famous tale of Acontius and Cydippe (*frag.* 67–75 in R. Pfeiffer's edition) and the less familiar one of Phrygius and Pieria (*frag.* 80–83). Another papyrus contains *Diegeseis* ("Expositions") of book 4 and the last *Aetia* of book 3, headed by the first line of each *Aetion*, and proves that in these books Callimachus passed from one *Aetion* to another without any formal connection, but in book 1 and perhaps in book 2 the poet represented himself as obtaining his information from the muses whom he interviewed on Mt. Helicon to which he had been carried in a dream. Ovid imitated this colloquy with the muses in his *Fasti*. In reality Callimachus drew his material from general histories like that of Timaeus or from the chronicles of local historians.

The *Aetia* were probably first published about 270 B.C. and established Callimachus' primacy in elegy (Quintilian calls him *princeps elegiae*), but he also later composed elegies for special occasions, the best-known being the *Lock of Berenice*, translated rather freely by Catullus (66). Also interesting, in a more pedes-

trian mood. were the *Iambi*, a collection of 13 poems, mainly in the iambic or choliambic metre, on topics ranging from literary criticism and social satire to congratulations on the birth of a daughter. There are also fragments from the *Mele* ("Lyrics"), the most striking of which is the funeral ode for Arsinoe, the consort of Philadelphus. Callimachus deemed long epic unsuitable to the age, but his short epic, the *Hecale*, was justly famous. It takes its name from the old lady at whose cabin Theseus spent the night before his struggle with the Marathonian bull. Her homely reception of the hero and their ensuing conversation occupied much of the poem, but many details still remain obscure. The six *Hymns* (five in hexameters and one in elegiacs) exhibit great originality in varying the traditional form. especially ii, v and vi which are dramatic and lyric rather than epic. The *Epigrams* cover a wide range of topics and show that Callimachus was as much a master in this field as he was in elegy.

Callimachus' poetical creed, in particular his insistence on consummate craftsmanship within a relatively small compass, provoked much opposition from his contemporaries. and in a prologue (*frag.* 1) to what seems to be a final edition of his collected poems he answers his critics, whom he nicknames "Telchines" ("malevolent demons"). His quarrel with Apollonius Rhodius, his former pupil, formed part of this controversy. The *Ibis*, a poem in which he may have imprecated unpleasant deaths on Apollonius, is lost, but Ovid's poem with the same name was inspired by it.

Callimachus was also a prolific writer in prose. Here his most famous work was the *Pinakes* ("Tablets") in 120 books, an elaborate catalogue of the Alexandrian library, which laid the foundation of the history of Greek literature; many others, such as his encyclopaedias on special subjects and his collections of *Mirabilia* and the like, are cited by later Greek scholars.

BIBLIOGRAPHY.—O. Schneider, *Callimachea*, 2 vol. (1870 and 1873). For papyri additions and comment see H. Herter in C. Bursian's *Jahresbericht*, vol. lv, pp. 82-217 (1937). For full works, except for a few fragments of verse published in the *Oxyrhynchus Papyri* series from 1953 onward, see R. Pfeiffer, *Callimachus*, 2 vol. (1949 and 1953). 4 selection from the fragments with Eng. trans. and notes by C. A. Trypanis is available in the "Loeb Series" (1958). See also E. Cahen, *Callimaque et son oeuvre poétique* (1929) and *Les Hymnes de Callimaque* (1930); A. Hauvette, *Les Epigrammes de Callimaque* (1907); C. M. Dawson, *The Iambi of Callimachus* (1950). (E. A. B.)

CALLING CARD: see VISITING CARD.

CALLINUS, Greek elegiac poet, active in Ephesus about the middle of the 7th century B.C., appears to have written narrative poems about the period of the Trojan War and the subsequent colonization by the Greeks of the coastal districts of Asia Minor. The only actual quotations which survive, however, deal either with the Cimmerians and the Trerians, nomadic peoples whose raids terrorized all Asia Minor for many years in the 7th century (the Cimmerians actually sacked Sardis c. 652) or with the dangers threatening Ephesus from some unspecified enemy. The longest is an appeal to the young men to cast off their cowardly sloth and prepare to fight, and if necessary die, for their country.

See J. M. Edmonds, *Elegy and Iambus*, vol. i, pp. 40-49, "Loeb Series" (1931); C. M. Bowra, *Early Greek Elegists*, Martin Classical Lectures, pp. 13-16 (1938). (JN. A. D.)

CALLIOPE, the chief of the Muses (*q.v.*), occasionally in late authors the Muse of epic poetry (Gr., "beautiful voice").

CALLISTHENES (OF OLYNTHUS) (c. 360-328 B.C.), Greek historian, was appointed to attend Alexander the Great as historian of his Asiatic expedition on the recommendation of his uncle and former tutor, Aristotle. He offended Alexander by censuring him for the adoption of certain oriental customs and was subsequently accused of being privy to a conspiracy. He was thrown into prison where he died in distressing circumstances, the details of which are in dispute. His death was commemorated by his friend Theophrastus in *Callisthenes or a Treatise on Grief*. Callisthenes wrote a history of Greece from the peace of Antalcidas (387) to the Phocian War (333); a history of the Thocian War; an account (presumably unfinished) of Alexander's expedition; and other works, all of which have perished. It is known that he alluded to the story of Alexander's divine birth, which means that he must have been the first to do so.

The romantic life of Alexander. the basis of all the Alexander

legends of the middle ages, originated during the time of the Ptolemies, but in its present form belongs to the 3rd century A.D. Its author is usually known as pseudo-Callisthenes. although in the Latin translation by Julius Valerius Alexander Polemius (beginning of the 4th century) it is ascribed to Aesopus. There are also Syrian, Armenian and Slavonic versions, in addition to four Greek versions (two in prose and two in verse) which date from the middle ages. Valerius' translation was completely superseded by that of Leo, archpriest of Naples in the 10th century, the so-called *Historia de Proeliis* ("History of Battles"). See also ALEXANDER ROMANCES: *Ancient Sources*.

GH.)

CALLISTO, in Greek mythology, an Arcadian nymph, daughter of King Lycaon and companion of the huntress goddess Artemis; probably a local form of Artemis Kalliste (fairest). She bore Zeus a son, Arcas, the ancestor of the Arcadians, and was transformed into a bear by Zeus himself, or by his consort Hera or by Artemis. Arcas, when hunting, encountered the bear Callisto and would have shot her, had not Zeus, to prevent the crime of matricide, carried up both to the skies, where he placed them as the constellation Ursa Major (Great Bear) and the star Arcturus (bear guard).

CALL MONEY. A money-market term describing short-term (usually less than 24 hours) loans to brokers and dealers in securities, secured by Treasury bills or other securities. An equivalent term in the United States is "call loan." Although the mechanics vary somewhat from country to country, these advances are in principle short-term loans for financing dealers during the short periods of time when transfers of ownership are being effected. Because of the quality and margin of collateral required, these loans are usually considered to stand just below cash in order of liquidity. They are frequently employed by banks to make fine adjustments in loan positions while maintaining relatively high levels of protective liquidity.

Loans of this type are normally repayable on demand, but market practice varies. In the U.S., for example, money-market banks now rarely ask for immediate payment. Elsewhere the call loan, or "money at call" as it is more commonly known, has tended to retain the character of an impersonal money-market obligation. As such, in marked contrast to recent U.S. experience, advances at call have tended to continue as basic money-market devices. Even among loans which are at call, market customs and conventions sometimes distinguish between "day-to-day" money, which is rarely called, and "overnight" or "night" money, which has considerable turnover. (C. R. Pr.)

CALLOT, JACQUES (1592-1635), French artist, one of the first great creative artists to practise the graphic arts exclusively, was born at Nancy, where his father was a minor court official. His career was divided into two parts: an Italian period, c. 1609-21; and a Lorraine period from 1621 until his death. Callot learned the technique of engraving under Philippe Thomasin in Rome. About 1612 he joined Giulio Parigi in Florence. At that time Medici patronage expended itself almost exclusively on *feste*, and Parigi and Callot were employed to make pictorial records of these mannered, sophisticated entertainments. Callot succeeded in evolving a naturalistic style while preserving the artificiality of the occasion. He organized a composition as if it were a stage setting and reduced the figures to a tiny scale, each one being indicated by the fewest possible strokes. This required a very fine etching technique. His breadth of observation, his lively figure style and his skill in assembling a large, jostling crowd, secured for his etchings a lasting popular influence all over Europe.

He had a genius for caricature and the grotesque. His series of plates of single figures, for example the *Balli di Sfessania*, the

Capricci and the *Gobbi*, are witty and picturesque, and show a rare eye for factual detail.

With a few exceptions, the subject matter of the etchings of the Lorraine period is less frivolous and Callot was hardly employed at all by the court at Nancy. He illustrated sacred books, made a series of plates of the Apostles and visited Paris to etch animated maps of the sieges of La Rochelle and the fle de RC. In his last great series of etchings, the "small" and the "large" *Misères de la Guerre*, he brought his documentary genius to bear on the atrocities of the Thirty Years' War. He was one of the first etchers to use the technique of the repeated biting, and often combined graver work with etching. Callot is well known for his landscape drawings in line and wash, and for his quick figure studies in chalk.

Callot died at Nancy, March 24, 1635.

See D. Bechtel (ed.), *Jacques Callot*, (1955). (M. W. L. K.; X.)

CALMETTE, ALBERT (LÉON CHARLES) (1863-1933), French bacteriologist, co-developer of the tuberculosis vaccine BCG, was born at Nice, July 12, 1863. He received his medical degree at Paris in 1886. He introduced a protective serum against snake bite and described the ophthalmic tuberculin reaction.

In collaboration with Camille Guérin, he developed the most widely used vaccine for the prevention of tuberculosis. As the result of a fortuitous observation he found that virulent bovine tubercle bacilli lost their virulence when cultured on a bile-containing medium, but that these attenuated bacilli were still able to confer a certain amount of immunity against infection with either bovine or human tubercle bacilli. This strain is named after its discoverers *Bacillus Calmette-Guérin* or BCG. The vaccine prepared with the live organisms came to be widely used throughout the world, proving its efficacy in reducing the incidence and severity of all forms of tuberculosis.

A director of the Pasteur institute, Calmette defended in numerous scientific publications his most important discovery, which was universally recognized only after his death, which occurred Oct. 29, 1933.

Vaccination in Theory and Practice* (1949); Sol Roy Rosenthal, "Standardization and Efficacy of BCG Vaccination Against Tuberculosis," *J.A.M.A.*, 157:801-807 (March 1955). (D. K.-W.)

CALMETTE, GASTON (1858-1914), French journalist who exposed the financial duplicity of the government. He was born at Montpellier, July 30, 1858. As editor of *Le Figaro* in 1913 and 1914 he originated the bitter attacks on the policy of the minister of finance, Joseph Caillaux (*q.v.*) whom he accused of offering advantages to his friends. Earlier, in the Rochette case of 1911, it was alleged by *Le Figaro* that under the influence of the financier Vereux the course of justice had been delayed. Calmette was fatally shot by Mme Caillaux at the office of *Le Figaro* on March 16, 1914, when incriminating documents on the minister were about to be published. (A. PE.)

CALNE, a market town and municipal borough in the Chippenham parliamentary division of Wiltshire, Eng., 16 mi. S.W. of Swindon on the Bath road. Pop. (1961) 6,559. Lying in the valley of the Calne west of the Marlborough downs, it was the site of a palace of the West Saxon kings. A synod met there in 978 and a witenagemot was summoned in 997. In the Domesday survey Calne was a royal borough and it returned two members to parliament from 1295 until 1832. In the reign of Edward III Flemish weavers helped to make it a large wool centre. The present borough seal dates from 1565 and the area was more than tripled in 1934. The tower of the church of St. Mary the Virgin is by Inigo Jones; the grammar school was founded by John Bentley in 1660. Robert Grosseteste (*q.v.*) and Edmund Rich (see EDMUND, SAINT) were two famous medieval rectors. Bacon curing is the staple industry and there is also milling. Bowood house, 2 mi. S.W., seat of the marquess of Lansdowne, was designed by the Adam brothers (later additions were removed in 1955).

From 1772 to 1780 Joseph Priestly was librarian and literary companion to Lord Shelburne at Bowood.

CALOCHORTUS, a genus of about 40 species of western

North American plants of the lily family (Liliaceae; *q.v.*). They are attractive corm-bearing plants, with linear-lanceolate leaves and showy yellow, white, lilac or blue flowers often spotted in the centre and borne singly or in terminal clusters.

The species are known under several common names, such as mariposa tulip, butterfly tulip, globe tulip, star tulip, mariposa lily (*q.v.*), butterfly lily, sego lily (*q.v.*) and as fairy lantern and pussyears. The sego lily (*C. nuttallii*) is the state flower of Utah. Most of the species are easy to grow in porous, well-drained garden soil but do not stand alternate thawing and freezing.

(J. M. BL.; X.)

CALOMEL, a white powder used in medicine since the 16th century. Once the most popular of cathartics, calomel is also said to stimulate the liver. The recognition of its potential toxicity, together with the development of superior and safer cathartics, resulted in a decline in calomel's use as an internal medicine. It is still used in salves and ointments, having mild antiseptic action. Its use as a fungicide has also declined.

Calomel, or mercurous chloride, Hg_2Cl_2 , occurs in nature as the minor mineral, horn mercury. It is manufactured by subliming mercuric chloride, $HgCl_2$, and mercury, and can also be prepared by heating mercurous sulfate and common salt or by precipitating from a mercurous salt solution by the addition of hydrochloric acid.

Pure, dry calomel is reasonably stable, subliming unchanged at low red heat. The vapour consists of Hg_2Cl_2 molecules, but moisture catalyzes the decomposition into mercury and mercuric chloride, especially when heated. Light causes partial decomposition. This disassociation is the cause of toxicity in samples improperly prepared or stored.

Calomel darkens upon treatment with ammonia, a reaction often used for its identification. It is insoluble in water but is attacked by many oxidizing agents, which convert it into compounds of bivalent mercury. Hot nitric acid converts it to mercuric nitrate, $Hg(NO_3)_2$. In contact with many metals the mercury is displaced.

Solutions of potassium chloride, saturated with calomel, give constant electromotive forces against the mercury electrode. There are three standard calomel electrodes in common use as references in electrochemical investigations (see HYDROGEN IONS). They contain saturated KCl, 1 molar KCl and 0.1 molar KCl, with the values -0.2420 v., -0.2810 v. and 0.3338 v. respectively, when measured at 25° C. against the normal hydrogen electrode (arbitrarily chosen as zero). (W.N. B.)

CALONNE, CHARLES ALEXANDRE DE (1734-1802). French statesman whose efforts to reform the structure of French finance and administration provoked the so-called "revolt of the nobles" in 1787 and made inevitable the summoning of the estates-general that he had hoped to avoid and that led directly to the French Revolution. Born at Douai on Jan. 20, 1734, Calonne had held various legal and administrative appointments from 1757 in French Flanders and in Artois before he first attracted public notice in 1766, when he tried unsuccessfully to overcome the opposition of the province of Brittany to the central government's fiscal policy, thereby incurring the hostility of the parlements. After this he was made intendant of Metz (1768) and of Lille (1774). As the candidate of the prince de Polignac's group of court favourites, Calonne became controller-general of finance on Nov. 3, 1783. His main task was to initiate financial retrenchment and reform after the American Revolution. He reconstituted a sinking fund in 1784, reformed the gold coinage in 1785 and gave his support to the Anglo-French commercial treaty of 1786. He also attempted to revive French credit by a program of extensive public works, including the development of Le Havre and Cherbourg. In 1786 he sought to stave off national bankruptcy by radical reforms as advocated by the Physiocratic school. These included the institution of a proportional land tax levied in kind on the privileged orders as well as on the third estate, the calling of "provincial assemblies" in the *pays d'élection* and the reform of the *corvée* and *gabelle* and the abolition of the internal customs duties. Afraid of the opposition of the parlements, he submitted these proposals to a quasi-representative assembly of

notables in Feb. 1787. The intrigues of his political opponents, Jacques Necker's criticisms and the antagonism of the higher clergy and magistrates caused the rejection of these plans and Calonne's dismissal in April 1787. His revelation of the annual deficit of more than 100,000,000 livres and the failure of his reform schemes ensured the summons of the estates-general in Aug. 1788.

Calonne's subsequent activities were largely devoted to the cause of counter-revolution. He left France in 1787 and became one of the severest critics of the financial and ecclesiastical policy of the Constituent assembly. He published his criticisms in London in 1790 under the title of *De l'état de la France, présent et à venir*. From Dec. 1790 till the fall of the French monarchy he acted as chief minister and adviser to the *émigré* princes. Louis XVI and Marie Antoinette, however, distrusted him, and the suspicion of the Prussian and Austrian governments and the rivalry of the baron de Breteuil (L. A. Le Tonnelier) paralyzed his influence after 1792. After returning to France in 1802, he died on Oct. 29.

CALORIE. The calorie, a unit of energy, was originally defined as the quantity of energy (or heat) necessary to raise the temperature of one gram of water, at constant atmospheric pressure, by 1° C. The kilocalorie (sometimes called the kilogram-calorie or large calorie) is 1,000 cal. The calorific value of foods is usually given in terms of kilocalories and through loose usage the prefix "kilo" is often omitted. The "calories" counted by persons on a reducing diet are kilocalories.

Since about 1925, the calorie has been defined in terms of the joule (see CALORIMETRY: Units). The use of the calorie as a unit of energy is common in those fields of science and engineering where the energy change is thought of in terms of the quantity of heat added to or subtracted from a substance in order to effect a change. Thus the heat capacities of substances, heats of melting and vaporization and heats of reaction associated with a chemical change are usually expressed in terms of calories. (See also HEAT; PHYSICAL UNITS; THERMODYNAMICS.)

On the Celsius temperature scale, formerly called the centigrade scale (the name Celsius was adopted by the General Conference on Weights and Measures in 1948), the melting point of ice is defined as 0° C. and the boiling point of water at atmospheric pressure is defined as 100° C. The quantity of heat represented by the calorie was found by experiment to differ by nearly 1% over the temperature range between 0° and 100° C. and consequently it was necessary to define the temperature at which the specific heat of water is to be taken as 1 cal. Three common definitions have been employed: (1) the 20° cal. (4.1816 joule), from 19.5° to 20.5° C.; (2) the 15° cal. (4.1855 joule), from 14.5° to 15.5° C.; (3) the mean calorie (4.1897 joule), defined as $\frac{1}{100}$ of the heat necessary to raise the temperature of 1 g. of water from 0° to 100° C.

In early calorimetric measurements quantities of heat were measured by comparison with the specific heat of water and it was convenient to define the calorie in terms of the properties of water. Since about 1910 most accurate calorimetric measurements have employed electrical heating, and the energy introduced, expressed in joules, could be determined to high precision from electrical measurements. Prior to the international acceptance of the joule as a unit of heat (1948) there existed a sort of temporary electrical standard, the international joule, which was based on subsidiary electrical standards rather than on the Metre, Kilogram, Second (MKS) system. By 1948 it was possible to determine the absolute values of these units with the necessary precision and to drop the temporary electrical units. The calorie, which had since 1925 been defined in terms of such units, was simply redefined in terms of absolute rather than international joules, and the real values did not change, leaving the mass of thermonuclear data numerically unaltered.

In the United States the thermochemical calorie, defined as 4.1840 joules, is commonly used as the unit for heat capacities, latent heats and heats of reaction. In engineering steam tables the "I.T." calorie, originally defined as $\frac{1}{860}$ int. watt-hr. (4.1868 joules), is internationally used. The name of this calorie, first applied in 1934, derives from the initials of the first and third words of the designation "International Steam Table" or the German equivalent "*Internationale Dampf Tabelle*."

(J. W. ST.)

CALORIMETRY. Calorimetry is the scientific term for the measurement of energy in the form of heat. This term needs to be distinguished from thermometry (*q.v.*) which is the measurement of temperature, or the degree of hotness or coldness. Heat is measured quantitatively by observing the effects that it produces. The most important of these effects for present purposes are: (1) rise in temperature of a substance when heat is added; (2) change in the physical state of a substance as from solid to liquid or from liquid to vapour; and (3) transformation of chemical, electrical or mechanical energy into heat or vice versa.

Many different types of calorimeters have been devised for measuring amounts of heat by observing quantitatively the effects produced or comparing the effects produced when energy in other forms is transformed into heat.

Calorimetric measurements are widely employed in many fields of science and industry. They are routinely used in the measurement of the heating value of coal, oil and natural gas and in the determination of the heat of combustion of foods.

Calorimetric measurements have been used to measure the energy changes in radioactive decay, the binding energies of atoms in molecules and crystals and the energy of interaction between electrically charged particles (ions) in solution, to mention only a few. The measurement of the heat capacities of substances is of importance in the understanding of the atomic vibrations in crystals, the properties of electrons in a metal, the interactions between the elementary magnets in an iron magnet and many other physical phenomena.

It is possible to define thermodynamic properties of a substance which depend only on the pressure, temperature, amount of material and chemical nature of the substance (see THERMODYNAMICS). One such property is the energy, E . In a process carried out at constant volume, under conditions so that no mechanical or electrical energy is involved, the change in the internal energy of a substance is equal to the heat absorbed by the substance. For processes carried out at constant pressure, if the only mechanical or electrical energy involved is the work done against the external atmosphere, the heat absorbed by a substance is equal to the change in another thermodynamic property, the enthalpy or heat content. The enthalpy, H , is $E + pV$ where p is the pressure and V the volume.

Calorimetric measurements are therefore measurements of energy or enthalpy changes associated with changes in temperature of a substance, changes of state (solid, liquid or gas) or changes accompanying chemical reactions. The realization that the heat content of a particular substance in a given state of aggregation is proportional to the mass of the substance and otherwise depends only on the temperature and pressure was first put in categorical form by Sadi Carnot (see HEAT) as the basis of his argument on the motive power of heat by the method of the cycle.

The heat capacity of a substance at constant pressure is the rate of change with temperature of the heat content (or enthalpy). The heat capacity per gram is called the specific heat. Thus the specific heat is the quantity of heat required to raise the temperature of one gram of a substance by one degree. In principle, a calorimetric measurement of the specific heat of a substance consists in introducing a measured quantity of heat and measuring the consequent rise in temperature of the substance. Thus if we add an amount of electrical energy, W , by means of an electrical heater to a substance of mass, m , and observe a temperature rise ΔT , then the specific heat of the substance is given by $W/(m\Delta T)$. The heat added to the substance will be equal to the electrical energy, W , only if there is no heat exchange by conduction or radiation between the substance and its surroundings and there-

fore in accurate calorimetric measurements it is important to have good thermal insulation between the calorimeter and the surroundings and to make corrections for any small heat exchange with the surroundings which may be present. The famous measurements of the "mechanical equivalent of heat" by James Prescott Joule (see below) were measurements of the specific heat of water and other substances in terms of mechanical energy.

The science of thermochemistry (*q.v.*) deals with changes in energy and enthalpy accompanying chemical reactions, and is based on calorimetric measurements. By combining measurements of heat capacities to very low temperatures (in most cases to 15° K., a temperature obtainable with liquid hydrogen) with thermochemical data it is possible to calculate the amounts of the various reactants and products present at equilibrium in a chemical reaction and thus to determine the maximum possible yield, under specified conditions of temperature and pressure, of a desired product. Using the results of calorimetric measurements and the laws of thermodynamics, one can determine, to list only three examples: the maximum amount of useful work obtainable from the reaction of a ton of coal with the oxygen of the atmosphere; the optimum conditions for the fixation of nitrogen through reaction with hydrogen to form ammonia; or the minimum pressure necessary, at a sufficiently high temperature so the reaction rate is not too slow, to make diamonds from coke. The calorimetric measurement of low temperature heat capacities and heats of combustion of substances participating in reactions taking place in biological systems permits the calculation of free energy changes (useful work) available in metabolic processes occurring in living organisms.

Because of the importance of thermochemical data for determining the equilibrium in chemical reactions, numerous measurements have been made, usually employing calorimetric methods, of the heats of tens of thousands of chemical reactions, and the results have been critically reviewed and combined into tables which list, at a selected temperature and pressure, the heat of formation from the elements of several thousand chemical compounds. Since the enthalpy (or heat content) is a property of the substances involved in a chemical reaction the chemist is able, by reference to such tables, to calculate the heats of any reaction between compounds listed in the tables and thus is able to predict the heat effects accompanying a vastly greater number of reactions than those which have been measured directly. An authoritative compilation of such thermochemical data is the U.S. National Bureau of Standards Circular 500, "Selected Values of Chemical Thermodynamic Properties," Washington, 1952.

Early Methods of Calorimetry.—One of the earliest calorimeters devised about 1760 by Joseph Black, consisted of a block of ice hollowed out in the centre and covered with a slab of ice. The method of operation is briefly as follows: A substance of known mass, M_s , is heated to a temperature t_1 , quickly dropped into the ice calorimeter and the cover put on. Sufficient time is

FIG 1.— JOULES APPARATUS FOR THE DETERMINATION OF THE MECHANICAL EQUIVALENT OF HEAT 1878 JOULES ORIGINAL APPARATUS OF 1850 DIFFERED IN MANY RESPECTS

FIG. 2.— ROWLAND'S APPARATUS FOR THE DETERMINATION OF THE MECHANICAL EQUIVALENT OF HEAT. 1879

allowed for the substance to cool to the ice temperature t_0 . The water formed by the heat given up to the ice is removed and its mass M_w , is determined by weighing. Equating the heat given up by the substance to the heat absorbed by the ice, gives the relation

$$M_s(h_1 - h_0) = M_w L$$

where L is the amount of heat required to melt unit mass of ice, called the latent heat of fusion of ice, and $h_1 - h_0$ is the amount of heat given up by unit mass of the substance in cooling from t_1 to t_0 . The mean specific heat, C_m , of the substance over the temperature interval is given by

$$C_m = (h_1 - h_0) / (t_1 - t_0) = M_w L / M_s (t_1 - t_0)$$

The symbol h appearing in the above expression represents the enthalpy (or heat content, per unit mass. It is related to the enthalpy, H, defined earlier by the equation $H = M_s h$.

About 1830 Carnot estimated the heat necessary to heat one kilogram of water by 1° Celsius or Centigrade to be equivalent to 370 kilogram metre (kg.m.), which is about 13% lower than the present accepted value. Carnot planned to determine this quantity experimentally but his early death in 1832 stopped these experiments.

Henri Regnault used a method of calorimetry called the method of mixtures. A substance is heated to some desired temperature and dropped into a calorimeter containing a known amount of water at a known temperature. The rise in temperature of the water serves to measure the amount of heat given up by the substance in cooling from its initial temperature to the final temperature of the calorimeter.

James Prescott Joule used calorimeters in which mechanical energy was transformed into heat by utilizing the potential energy of weights to drive paddles which stirred a liquid and raised its temperature. His experiments began about 1840 and continued up to 1878. He made these experiments with different substances to show that heat was a form of energy quite independent of the substance which was heated. The numerical relation between mechanical energy and heat, known as the mechanical equivalent of heat, or Joule's equivalent, subsequently has been denoted by the letter J. As a further tribute to Joule, all science now honours him by the use of his name for a unit of energy.

Henry A. Rowland, using apparatus similar to that used by Joule but with characteristic attention to detail, made a series of experiments covering the range of temperature from 5° to 35° C. to study the variation in specific heat of water with temperature.

Recent experiments seem to substantiate Rowland's estimate that his results in the range 15°–25° C. would not be changed by as much as 2 parts in 1,000.

Units.—Physical units are treated in a special article on this subject (see PHYSICAL UNITS). Nevertheless, it seems desirable to give some consideration here to the units used in calorimetry.

Heat is related to other forms of energy by the first law of thermodynamics (*q.v.*) which states that the change in energy of a substance is the sum of the heat absorbed by the substance and the energy acquired by the substance because of electrical, mechanical or other work done on it. It is therefore most consistent to use as a unit of heat the unit accepted for other forms of energy. This unit is the joule, and in Oct. 1948 the 9th General Conference on Weights and Measures adopted a resolution recommending the use of the joule as the unit of heat.

For many years, however, quantities of heat could be measured most conveniently and accurately in terms of the temperature rise of a known mass of water. This fact led to the general use of heat units based on the properties of water such as the calorie: that quantity of heat required to heat one gram of water 1° C.; and the British thermal unit (B.T.U.): that quantity of heat required to raise the temperature of one pound of water 1° F. (See CALORIE.)

With the development of accurate electrical standards near the beginning of the 20th century, it became possible to measure energy introduced into a calorimeter electrically more accurately than heat can be measured in terms of the specific heat of water. For a time the international joule, based upon working standards of electrical units was used as the unit of heat. On Jan. 1, 1948, the international electrical units were replaced by absolute electrical units, and the joule (sometimes called absolute joule to distinguish it from the temporary standard, the international joule) became the accepted unit of heat. Nonetheless much scientific data is still expressed, in terms of the older units, the calorie or the B.T.U.

TABLE I.—Specific heat of water in joules per degree Celsius per gram

Temperature °C.	Specific heat	Temperature °C.	Specific heat
0	4.2174	50	4.1804
10	4.1919	60	4.1841
15	4.1855	70	4.1893
20	4.1816	80	4.1961
30	4.1782	90	4.2048
40	4.1783	100	4.2156

These units are now defined, however, not in terms of the properties of water but as being equal to a given number of joules. Thus the thermochemical calorie is by definition equal to 4.1840 joules. In order to convert older data based upon the specific heat of water to the defined calorie a "Table of values considered as the most probable at the present time of the specific

heat of water in joules per degree" was drawn up as a result of the 9th General Conference on Weights and Measures. Some of the values are reproduced in Table I. It is seen from this table that the defined thermochemical calorie differs by only 0.036% from the specific heat of water at 15° C.

In engineering steam tables the I.T. (from the first and last words of Internationale Dampf Tabelle, "International Steam Table") calorie (1.000654 thermochemical calories) and the B.T.U. are often used. The accepted values of 10 of the more commonly used units of energy, each expressed in terms of the others, are given in Table II.

Ice Calorimetry.—Although attempts to measure heat by observing the quantity of ice melted by it were made in the latter half of the 18th century, the first really successful calorimeter based on this principle was that described by Robert Bunsen. A modern instrument, of the type described by Bunsen, provided with a vacuum jacket was first suggested by Hugh L. Callendar in an article on calorimetry in the 11th edition of the *Encyclopædia Britannica*. A layer of ice is formed on the central tube from the air-free water surrounding it. The heat to be measured is liberated in the central tube, or bulb, and the quantity of ice melted by it is measured by the resulting change in volume of the ice-water system as indicated by motion of the mercury meniscus in a graduated capillary tube. A. Schuller and V. Wartha described an ice calorimeter in which the change in volume was measured by weighing the mercury drawn into the system when ice was melted.

An ice calorimeter is usually calibrated by observing the volume or weight of mercury drawn into the calorimeter when a known quantity of heat is added. The calibration factor is given by the relation

$$\frac{\Delta Q}{\Delta M_{\text{Hg}}} = \frac{L}{(V_i - V_w)\rho_{\text{Hg}}}$$

where ΔQ =heat added,

ΔM_{Hg} =mass of mercury,
 L =latent heat of fusion of ice, per gram
 V_i =specific volume of ice,
 V_w =specific volume of water at 0° C.,
 ρ_{Hg} =density of mercury at 0° C.

The possibility of reducing thermal leakage was not fully utilized in the earlier ice calorimeters described in the literature, apparently because the importance of both a high thermal resistance and a low temperature difference between the calorimeter and its environment was not fully appreciated. In the early calorimeters, the bulb was immersed directly in an ice bath so that the thermal resistance between the calorimeter bulb and the ice bath was very small.

The temperature difference between the ice bath and the calorimeter bulb was small but nevertheless appreciable, as a rule, because of impurities in the ice bath and because of the effect of

TABLE II.—Conversion factors for units of energy* (revision of April 30, 1952)

the pressure of the mercury column on the freezing point of the water in the calorimeter.

Even with small temperature differences this caused relatively large thermal leakage. Charles V. Boys in 1887 suggested the use of an insulating air space between the calorimeter and an enclosing vessel surrounded by ice, and showed experimentally that such a device reduced thermal leakage to about one-seventh its value without the air space. C. Dieterici reported the use of a similar device. Ernest Griffiths in 1913 described an ice calorimeter enclosed in an unsilvered vacuum bottle which was closed by a rubber stopper and immersed in powdered ice, and reported a probable error (of a single observation) of 0.08% in the measurement of 140 to 620 cal. T. E. Stern in 1928 described measurements of specific heat by means of a vacuum-jacketed ice calorimeter similar to that suggested by Callendar, and reported a probable error (of a single observation) of 0.1% in the measurement of about 240 cal.

The principal advantages of the ice calorimeter over other types of calorimeters in use are as follows: (1) the heat transfer between the calorimeter and its surroundings can be made very small; this advantage may be considerable where the heat is liberated in the calorimeter over a long period of time; (2) the calorimeter has a high sensitivity (about 0.1 cal.); (3) there has been some question as to the constancy of the calorimeter calibration constant. Since there has been considerable variation of the measured density of ice, there is some doubt that its density is constant. If this doubt is justified, the calibration factor of the calorimeter would not be constant since the amount of mercury drawn depends upon the difference in density between ice and water. However, some of the causes of the variations of the measured density of ice would not affect the constancy of the calibration factor. It does seem possible that strains set up in the ice as it is frozen may require time to be relieved. Although Griffiths stated that he allowed only three or four hours after freezing an ice mantle, Stern claimed that consistent results were not obtained until four days after the ice mantle was formed.

If pure air-free water is used in a Bunsen ice calorimeter, an estimate based on experiments made since 1900 indicates that the intake of 1 gr. of mercury is equivalent to 270.4 int. joules within about 0.1%.

Some of the disadvantages of the ice calorimeter are as follows: (1) the calorimeter must be used at one temperature; (2) accurate accounting must be made of any volume changes in the calorimeter system; (3) there has been some uncertainty as to the constancy of the calorimeter calibration factor.

A number of calorimeters similar to that of Bunsen, but using an organic liquid having a freezing point in the neighbourhood of room temperature have been described in the literature. Although the change in volume upon melting is smaller for such organic compounds than for water, the heat of fusion is also smaller, and in some cases the net result is a greater change in volume per calorie for the organic compound than for water. Thus, H. Sachse in 1929 described a calorimeter using diphenyl ether (melting point 26.5° C.) instead of ice. It was claimed that measurements could be made to 0.1 cal. by observing the motion of mercury in a graduated capillary, and to 0.02 cal. by weighing the expelled mercury.

Aneroid Calorimetry.—For many purposes, particularly for use at extreme temperatures, the type of calorimeter known as the aneroid has been used. Although the term aneroid strictly implies a calorimeter without liquid, it is generally interpreted as meaning a calorimeter in which temperature equalization is produced mainly by metallic conduction rather than by the stirring of a liquid. In the absence of liquids to distribute heat, the calorimeter is free from most of the restrictions imposed by the volatility, freezing point and, sometimes, the immobility of the bath liquid. On the other hand this introduces the disadvantage of depending mostly on thermal conduction and radiation to secure uniformity of temperature throughout the calorimeter in which heat is absorbed.

To secure good results, the calorimeter should be made of

highly conducting material such as copper or silver, with close attention to geometrical design to promote rapid equalization of temperature throughout the calorimeter without unduly increasing its heat capacity. In general, if high accuracy is required, there must be sufficient thermoelements (devices for measuring small electric currents) to integrate temperature differences between the calorimeter and its jacket, the temperatures of which are likely to be less uniform than in a stirred-liquid calorimeter.

One of the early aneroid calorimeters was used by H. C. Dickinson and N. S. Osborne to measure the heat of fusion of water and the specific heat of water and ice. This calorimeter was patterned after an earlier one described by D. R. Harper in 1913 and was made of copper, with a capacity of about 550 ml. and a wall thickness of $\frac{1}{8}$ mm. which served to hasten equalization of temperature on its surface so that the correction for heat leak could be measured more accurately. The mean temperature of the calorimeter was determined by means of a platinum resistance thermometer embedded in a helical groove in the copper and the energy for heating was supplied electrically by means of a constantan heater in a second helical groove in the copper. In order to evaluate the heat leak between the calorimeter and its jacket, it was necessary to use several differential thermocouples.

Low-Temperature Calorimetry.—Calorimeters for use at low temperatures are generally of the aneroid type since it is not practical in most cases to use a stirred-liquid type. Walter Nernst and his collaborators developed an aneroid calorimeter which was used in the early investigation of low-temperature heat capacities. W. F. Giaque and C. J. Egan described a calorimeter used primarily for the investigation of heat capacities and heats of transition, fusion and vaporization of condensed gases. It may be readily adapted to the measurement of the heat capacities of solids. The calorimeter is made of gold or copper with internal vanes to aid in the distribution of heat. On the outside of the cylindrical calorimeter is wound a gold wire which serves both as a thermometer and heater. There is also a thermocouple which serves as the primary standard for temperature measurement. The calorimeter is surrounded by a massive shield of copper and lead whose temperature remains constant while energy is introduced electrically into the calorimeter. In a measurement the shield is adjusted to a temperature slightly above that of the calorimeter. Sufficient energy is introduced into the calorimeter to raise its temperature slightly above that of the shield and the rise in temperature is noted. Before the next measurement, the shield is heated and again set at a slightly higher temperature than the calorimeter. In a typical experiment the temperature increments of individual measurements range from about one degree at 12° K. to six degrees near room temperature. Since the shield is never very different in temperature from the calorimeter the heat interchange between them is small and may be accurately allowed for. This type of calorimeter is called isothermal since the shield temperature remains constant during a measurement.

In an adiabatic low-temperature calorimeter the massive shield of the isothermal calorimeter is replaced by a lighter shield whose temperature may be rapidly varied. A thermocouple is used to indicate the temperature difference between the calorimeter and the shield and while the calorimeter is being heated electrically the shield is also heated so as to minimize the temperature difference. A calorimeter of this type was described by J. C. Southard and F. G. Brickwedde. Both isothermal and adiabatic low-temperature calorimeters are capable of an accuracy of from one to two parts per thousand in the measurement of heat capacity. Above 200° K., where the heat exchange by radiation becomes large, the adiabatic calorimeter is capable of greater precision than the isothermal type.

In the range below 10° K., extreme care is necessary to minimize heat exchange by conduction between the calorimeter and its surroundings. In this temperature range thermocouples or platinum resistance thermometers lose their sensitivity and some other device must be used to indicate the rise in temperature in a heat capacity measurement. Carbon thermometers, suitable for use between 0.1° K. and 20° K., were described by W. F. Giaque, J. W. Stout and C. W. Clark. Thermometers made of germanium

are also sensitive in this region and the preparation and calibration of such thermometers were described by J. E. Kunzler, T. H. Geballe and G. W. Hull.

Calorimetry of Saturated Fluids.—Many problems in thermodynamics are concerned with the properties of saturated fluids, where the term saturated restricts them to conditions where both liquid and vapour are present in equilibrium with each other. As an example the steam tables which the mechanical engineer uses are based on the enthalpy and entropy of saturated liquid water and water vapour.

Osborne developed a systematic method for the calorimetry of saturated fluids and applied it to measurements of the properties of saturated liquid water and water vapour from the freezing point to the critical point. This method makes use of a single calorimetric apparatus with which a system of measurements may be made to determine some of the essential thermal properties of a fluid, in particular the enthalpy H . The calorimeter is provided with two outlet tubes, one at the bottom for introducing or withdrawing liquid and the other at the top for withdrawing vapour. Valves are provided on these tubes for sealing the fluid in the calorimeter and for controlling the rate at which fluids are withdrawn. The calorimeter is surrounded by an envelope, the temperature of which is controlled to prevent any net exchange of heat with the calorimeter. All experiments are made with both liquid and vapour in the calorimeter when saturated fluids are being investigated.

The essentials of this method are as follows. First, consider two experiments (a) and (b) with the same calorimeter, (a) with a large amount of liquid and some vapour to maintain the saturation state and (b) with a small amount of liquid. In these two experiments the calorimeter contains the masses of fluid M_a and M_b respectively, and the quantities of energy Q_a and Q_b are found necessary to heat the calorimeter and its contents from the same initial temperature, t_1 , to the same final temperature, t_2 . The difference of the energies, $Q_a - Q_b$, is used to heat the difference of the masses of the fluid contents, $M_a - M_b$, from one temperature to the other. The quotient of these differences would be equal to the change in enthalpy, H , of the liquid, were it not for the extra vapour in experiment (b). This requires a correction term $-L \frac{v}{v' - v}$ where L is the latent heat of vaporization and v and v' are the specific volumes of the saturated liquid and vapour respectively. This gives the equation:

$$\frac{Q_a - Q_b}{M_a - M_b} = \left[H - L \frac{v}{v' - v} \right]_{t_1}^{t_2} \equiv \alpha$$

Notice that in getting α , by the method of differences in the fillings, not only is the energy correction for the heat capacity of the empty calorimeter eliminated but also other energy corrections which are the same, as long as both liquid and vapour are in the calorimeter. These α experiments are essentially liquid heat capacity experiments.

Consider another type of experiment which may be called a vaporization experiment, for getting the enthalpy of the saturated vapour. Consider a calorimeter nearly filled with liquid and let energy be supplied to evaporate liquid to vapour, most of which is withdrawn through a throttle valve at a rate so controlled as to keep the temperature of evaporation constant. The theory shows that the heat added, ΔQ , divided by the mass withdrawn, ΔM , is equal to the latent heat L plus the correction, $L \frac{v}{v' - v}$. This correction is the energy necessary to vaporize water to fill the space no longer filled with liquid. This gives the equation:

$$\frac{\Delta Q}{\Delta M} = L + L \frac{v}{v' - v} \equiv \gamma.$$

Consider a third type of experiment where liquid instead of vapour is withdrawn as heat is added. Here, liquid is evaporated to fill the space which is emptied. This gives the equation:

$$\frac{\Delta Q}{\Delta M} = L \frac{v}{v' - v} \equiv \beta.$$

This is the same quantity that appears as a correction term in the preceding equations for the heat of the liquid and the heat of vaporization.

These three functions, which can be determined experimentally, may be used to calculate the more familiar functions

$$\begin{aligned} H &= \alpha + \beta \\ L &= \gamma - \beta = H' - H \\ H' &= H + L = \alpha + \gamma \end{aligned}$$

So far these derivations use only the first law of thermodynamics. If the second law with the Clapeyron relation is used, the following equations result:

$$\begin{aligned} \beta &= L \frac{v}{v' - v} = vT \frac{dp}{dT} \\ \gamma &= L + L \frac{v}{v' - v} = L \frac{v'}{v' - v} = v' T \frac{dp}{dT}, \end{aligned}$$

where T is the absolute temperature and p the vapour pressure. This relation gives a way of comparing the calorimetric data with volumetric data providing the vapour pressure slope and the absolute temperature are known.

For the measurements of these properties, a calorimeter is used for containing a sample of fluid while its thermal behaviour is observed. The thermal behaviour is determined by three principal quantities which must be measured: (1) mass subjected to process; (2) energy added to system; and (3) change of state produced. The measurement of mass is relatively simple because the samples are sealed in tight containers with valves, and never opened to the outside when accounting for mass. The measurement of energy is not as simple because no way has yet been found to make calorimeters quite tight for heat. The measurement of the change of state involves the measurement of changes in temperature or pressure.

Flow Calorimetry.—The continuous electric method of flow calorimetry was first reported by H. L. Callendar and H. T. Barnes, and the method was used for measuring the specific heat of water from 0° to 100° C. From 1897 this method has been used for other liquids and gases.

The principle of the method is to add measured electric power to a fluid flowing through the calorimeter at a steady measured rate and to observe the change of state produced. The state of the fluid is determined by its temperature and pressure. The difference in the initial and final fluid temperature in the calorimeter is usually determined with platinum resistance thermometers or differential thermoelements. The power added to the fluid between the initial and final states must include an accounting not only of the electric energy input but also of the energy leak to or from the fluid while in the calorimeter. The heat capacity of the calorimeter does not enter into the measurements but may affect the attainment of a sufficiently steady state for reliable determinations.

The calorimeter used by Callendar and Barnes consisted of a small glass tube about one-half metre long which contained a platinum heater wire and had enlargements at the ends for differential platinum resistance thermometers. Heat leak was minimized by enclosing the heater tube and thermometers in a vacuum jacket. The rate of flow was varied over a ratio of nearly two to one to evaluate heat leakage.

FIG. 3.— CONTINUOUS ELECTRIC CALORIMETER FOR OBSERVING THE VARIATION OF THE SPECIFIC HEAT OF WATER

W. F. Swann used a flow calorimeter for measuring the specific heat of air and carbon dioxide at atmospheric pressure. The heat leak varied from 2% to 20% of the heat added but was determined and corrected.

Karl Scheel and Wilhelm Heuse also measured the specific heat of air and carbon dioxide but used a smaller calorimeter which was better adapted for their measurements with small amounts of other gases. Their calorimeter was constructed chiefly of glass and was used for measurements at one atmosphere of pressure at temperatures from -182° C. up to 20° C. This calorimeter had a simple scheme of radiation shielding which was controlled by the flowing gas and avoided large heat leakages so that the total correction for heat leakage was only a few tenths of one per cent.

L. Holborn and Max Jakob used a flow calorimeter to study the variation of the specific heat of air with pressure at pressures up to 300 atmospheres and at the mean temperature of 60° C. Their calorimeter was large and made of steel to withstand these high pressures but had so large a heat capacity that from three to four hours were required to reach a sufficiently steady state for reliable measurement.

Oscar Knoblauch and his associates made researches over a period of many years, determining the dependence of the specific heat of saturated steam on both temperature and pressure over successive regions covering the range of steam engineering practice.

N. S. Osborne, H. F. Stimson and T. S. Sligh described a flow calorimeter which was used for the determination of the specific heat of superheated ammonia vapour at temperatures from -15° to $+150^{\circ}$ C. and at pressures ranging from 0.5 to 20 atmospheres (atm.). Their calorimeter was designed to minimize heat leakage, by means of two shields: the first at the initial and the second at the final temperature. The temperatures of these shields were controlled by the fluid flow at the initial or the final temperatures. These shields in turn were surrounded by guards. The first guard was maintained at the initial temperature by circulation of the inlet fluid. The second guard was maintained at the final temperature by electric heating. The space between the shields and guards was evacuated to minimize heat leak by gaseous conduction, and the surfaces were of polished nickel to reduce the heat transfer by radiation. The correction for thermal leakage in this calorimeter rarely exceeded 0.2% of the power input.

Bomb Calorimetry.—Heats of combustion of solids and liquids are ordinarily measured by means of a bomb calorimeter. Such an instrument consists essentially of a metal vessel filled with water in which is immersed a "bomb," or gas-tight metal container capable of withstanding an internal pressure of the order of 200 atmospheres, together with some arrangement for stirring the water and a thermometer for measuring its temperature. A measurement of heat of combustion is made by burning a measured quantity of combustible material in the bomb filled with oxygen to an initial pressure of 20 to 35 atm. and observing the resulting rise in temperature of the calorimeter. This temperature rise, when corrected for thermal leakage and other small effects, is proportional to the heat produced by the combustion. A small amount of water is placed in the bomb in order that the space may be saturated initially with water vapour. The water formed in combustion is then condensed to the liquid state, and since the combustion takes place at constant volume, the direct results of bomb-calorimetric measurements are total heats of combustion at constant volume. Such results can be readily converted, however, so as to yield values of total or net heat of combustion at constant pressure.

Although a number of workers had previously made measurements of heats of combustion of gases at constant volume, C. L. Berthelot and M. Vieille appear to have been the first to make such measurements on nonvolatile materials in oxygen under a pressure above that of the atmosphere. Improvements in the Berthelot type of bomb calorimeter were made by various workers, especially by T. W. Richards and his co-workers, and by H. C. Dickinson. Much of the work of W. P. White on the stirred-liquid type of calorimeter is applicable to bomb calorimetry.

The bomb should be made of a material which does not rust

in contact with water, and its interior wall must be resistant to oxidation and to attack by acids, particularly nitric and sulfuric acids, which may be formed in combustion. Various special steels and other alloys have been used for the construction of bombs, and, in cases where the material was not sufficiently resistant to oxidation or attack by acids, bombs have been lined with gold, platinum or porcelain. An improved corrosion-resistant alloy (Inconel) for use in the construction of calorimetric bombs was developed by S. W. Parr about 1915. W. A. Roth used bombs made of a corrosion-resistant steel (austenitic chrome nickel steel V2A) developed at the Krupp works in Germany.

Bomb-calorimetric measurements have applications in the testing of fuels, in the determination of fuel values of foods and in thermochemistry. (See also FUELS; NUTRITION.)

In order to obtain accurate results in bomb-calorimetric measurements it is necessary to determine accurately: (1) the nature and amount of the combustion reaction which takes place in the bomb; the nature, amount and thermal effect of any side reactions; and the energy used to ignite the charge of combustible; (2) the temperature rise of the calorimeter, corrected for heat transfer between calorimeter and environment and for heat of stirring; and (3) the "energy equivalent" of the calorimeter, which is the quantity of energy required to produce unit temperature rise of the calorimeter.

In the bomb calorimetry of fuels the amount of the combustion reaction is determined by weighing the charge of fuel burned. In measurements to determine the heat of combustion per mole of an organic compound it is preferable to determine the amount of the combustion reaction from the mass of one of the products formed; for example, the carbon dioxide, since this procedure will eliminate the effect of inert impurities such as dissolved air or water, and since the molecular weight of the product will be more accurately known than that of the organic compound.

In order to establish the nature of the reactions which take place in the bomb, it is necessary to know the nature and amounts of the impurities in the compound burned, the nature and amounts of the products formed and the states of all reactants and products. It has been found in a large number of cases that combustion in the bomb is substantially complete, so that the products of combustion of substances containing only the elements carbon, hydrogen and oxygen are gaseous carbon dioxide and liquid water. If the substance burned contains nitrogen, or if the oxygen used contains nitrogen as an impurity, some nitric acid will be formed; and if the substance burned contains sulfur, sulfuric acid will be formed. The amounts of such acids are determined and corrections are applied for the heat developed in the reactions by which they are formed. It has been pointed out by E. W. Washburn that in work of high accuracy it is necessary to correct for departures of the gaseous reactants and products from their thermodynamic standard states. The correction varies from a few hundredths of one per cent to several tenths of a per cent depending upon the nature and mass of the substance burned, the volume of the bomb, the initial pressure of the oxygen and the amount of water placed in the bomb. Exact determination of the thermodynamic state of a volatile liquid requires that evaporation be prevented until the instant of ignition. This may be done crudely by the use of gelatine or similar capsules, with independent determination of the heat of combustion of the capsule material. It is done accurately by enclosing the volatile material in a thin glass bulb made with a flexible side so that it can be completely filled with liquid and will not break when oxygen under pressure is admitted to the bomb.

The charge of combustible material is ignited either by a small piece of filter paper or similar material, which is ignited by an electrically heated platinum wire, or by a short length of iron wire which is ignited electrically. In either case the energy used to ignite the charge can be determined in blank calorimetric experiments in which only the filter paper or iron wire is burned, or the energy supplied electrically can be measured by one of several methods and the heat of combustion of the iron wire or other kindler can be calculated from its weight and known heat of combustion per unit weight.

In commercial testing of fuels the temperature rise of the calorimeter is usually measured by means of a Beckmann or other mercurial thermometer. For work of high precision a thermo-electric or platinum resistance thermometer is used. Some workers have minimized heat transfer between calorimeter and surroundings by using the adiabatic method in which the temperature of the "jacket" enclosing the calorimeter is kept approximately equal to that of the calorimeter. However, most modern bomb-calorimetric measurements of high precision have been made by the simpler method in which the temperature of the jacket is kept constant and a correction for thermal leakage and heat of stirring is applied to the observed temperature rise. Accidental differences between the temperature of the jacket and that of the calorimeter, when the attempt is made to keep the two equal, are likely to introduce errors greater than those encountered in making the ordinary corrections for heat loss to a jacket at constant temperature. The constant temperature jacket also avoids much loss of time. Otherwise the jacket has to be cooled for each combustion.

In practically all modern work the energy equivalent, or effective heat capacity of the calorimeter is determined experimentally by supplying a measured quantity of energy to the calorimeter and observing the resulting temperature rise. The calorimeter is thus used to compare an unknown with a known quantity of energy by comparing the corresponding temperature rises. Such a procedure eliminates the effect of the temperature scale used, as well as the effect of calorimetric lags which obey the ordinary law of lag. The energy supplied to the calorimeter in the determination of the energy equivalent may be supplied electrically, and its amount determined from observations of current, voltage and time; or it may be supplied by burning in the calorimeter a known mass of a standard substance, the heat of combustion of which has been measured in terms of electric energy units. The substance most commonly used for this purpose is benzoic acid, the heat of combustion of which has been determined with an accuracy approaching 0.01% by a number of workers.

Combustion Calorimetry of Gases.—Although heats of combustion of gases can be measured by means of a bomb calorimeter, such measurements can be made more accurately with some type of calorimeter in which the gas is burned at constant pressure. Although A. Schuller and V. Wartha made measurements of heat of combustion of hydrogen at constant pressure by means of a Bunsen ice calorimeter, the type of calorimeter most commonly used for such measurements has been the stirred-water type. The gas of which the heat of combustion is to be measured is burned in a reaction vessel immersed in the water of the calorimeter. Oxygen and the gas to be burned are led into the reaction vessel through tubes connected to sources of supply outside the calorimeter. The gaseous products of combustion pass from the reaction vessel through a tube a part of which is ordinarily wound into a helix immersed in the calorimeter water.

Measurements by one of the earliest calorimeters of this type were described by Pierre Dulong. P. A. Favre and J. T. Silbermann in 1852 described a calorimeter embodying some improvements over that of Dulong, including a water jacket separated from the calorimeter by an air space, and an arrangement for stirring the calorimeter water. Most later measurements of heats of combustion of gases, with the exception of those of Schuller and Wartha referred to previously, have been made by means of calorimeters similar in design to that of Favre and Silbermann. The apparatus described by F. D. Rossini embodied a number of refinements not included in similar apparatus described by previous workers, and results accurate to 0.02 or 0.03% have been obtained with it.

The requirements which must be met in order to obtain accurate results in measurements of heats of combustion of gases at constant pressure are quite similar to those mentioned in connection with bomb-calorimetric measurements.

The amount of gas burned in an experiment is determinable from the mass of one of the products formed; for example, water, if the gas burned is hydrogen, a pure hydrocarbon, or any compound containing only C, H and O; or carbon dioxide, if the

gas burned is carbon monoxide. The nature of the reaction which takes place, and the nature and amount of any side reactions, are determined by suitable chemical examination of the gas and oxygen and of the products of combustion. Some of the water formed in combustion will be carried out of the calorimeter as vapour during a calorimetric experiment and some will remain as vapour in the reaction vessel, while the larger part of it will be condensed to the liquid state in the reaction vessel. The amount of water remaining in the vapour state is determined, and suitable correction is made to obtain the final result corresponding to the desired state of the water. The correction to take account of the departures of the gaseous reactants and products from their thermodynamic standard states is much smaller than in the case of bomb-calorimetric measurements, but is required in work of high accuracy. The gas is ignited by means of an electric spark, and the ignition energy is determined calorimetrically in blank experiments. Correction is also applied to the results to take account of any difference in temperature of the calorimeter and the entering gases. The measurement of temperature rise of the calorimeter, the correction for thermal leakage and heat of stirring and the electrical determination of the energy equivalent of the calorimetric system are carried out in the same manner as for a bomb calorimeter.

The Standing Commission on Thermochemistry of the International Union of Chemists (*First Report of the Stdg. Comm. on Thermochemistry of the Int. Union of Chem.*) in 1934 suggested the use of pure hydrogen as a standard substance for determining the energy equivalent in cases where an electrical determination is not convenient.

Fuel Gas Calorimetry.—Probably more laboratories are regularly engaged in determinations of calorific values of gaseous fuels than in any other kind of calorimetric measurement. The requirements as to calorimetric accuracy in such determinations are not as severe as in thermochemical measurements on pure gases, and the calorimeters used are, therefore, designed more for rapid operation than for accuracy. Ordinarily, either a gas calorimeter of the water-flow type or some type of recording calorimeter is used in the testing of gaseous fuels. An accuracy of about 0.5% can be attained with either of these types of calorimeter.

Gas is burned in a water-flow calorimeter at a uniform rate, and the heat produced is absorbed in a stream of water. The mass of water flowing through the calorimeter, during the time that a measured volume of gas is burned, and the resulting temperature rise of the water furnish the data necessary for computing the quantity of heat imparted to the water.

The volume of gas burned is measured by a so-called wet gas meter, and the measured volume is reduced to standard conditions on the basis of a calibration factor for the meter, and observations of the pressure and temperature of the (saturated) gas. The temperature rise of the water is obtained from corrected readings of mercurial thermometers. The mass of heated water collected is determined by weighing. Corrections are applied to the results for heat loss from the surface of the calorimeter, and for the latent heat of the difference in the masses of water vapour entering and leaving the calorimeter. The energy equivalent of the calorimeter does not enter into the measurement because the temperature distribution in the calorimeter remains practically constant during an experiment. C. W. Waidner and E. F. Mueller in 1914 reported the results of an exhaustive investigation of the measurement of calorific values of gases by means of water-flow calorimeters.

In one widely used type of recording calorimeter the gas is burned at a constant rate and the heat produced is absorbed by a stream of air. The rates of flow of gas, air for combustion and heat-absorbing air are regulated by metering devices similar in construction to the ordinary wet gas meter. These metering devices are motor-driven, and are geared together so that the ratio of the rates of flow of gas and air is constant. The temperature rise of the heat-absorbing air is therefore proportional to the calorific value of the gas. This temperature rise is measured by a pair of nickel resistance thermometers, translated into British thermal units per standard cubic foot of gas and recorded graph-

ically. The characteristics of the resistance thermometers are such as to compensate approximately for the effect of changing temperature. The calorimeter is adjusted by the manufacturer so that it will indicate the appropriate calorific value of pure hydrogen. The results of an investigation of this calorimeter were reported by R. S. Jessup.

Respiration Calorimetry.—The term respiration calorimeter has been applied to devices which serve to measure quantities of heat involved in biological processes, particularly those of animals and man. Since these processes generally involve energy in other forms such as chemical and mechanical, a respiration calorimeter generally must be designed to take account of energy in these forms also. This calls for means whereby air and food, if any, can be supplied to a living animal or plant within the calorimeter and the products removed.

The first application of this principle in the United States was at Wesleyan university, Middletown, Conn., in charge of A. D. Atwood and E. B. Rosa, later of the national bureau of standards. Their original respiration calorimeter was similar to that of Max Joseph von Pettenkofer of Munich, Ger., and was used in investigations of nutrition of man which were begun by the department of agriculture in 1894. In the course of its use at Wesleyan university the calorimeter was modified from an open to a closed type. In the latter type the air supplied to the occupant of the calorimeter is circulated in a closed system, being withdrawn, purified and supplied with the necessary replacement oxygen before returning to the calorimeter. This system permitted more accurate measurement of the oxygen absorbed. This apparatus and others modeled after it have been in use by the U.S. department of agriculture in Washington in connection with a variety of biological processes. These applications have included human beings, domestic animals and the processes of ripening of fruits.

Essentially, a respiration calorimeter is an airtight shell surrounded by another so devised that transfer of heat between the two is made negligible or can be measured. Provision is made for supplying the necessary air, food and other essentials and removing the used air and other waste products. The size of the shell depends on the use to which it is to be put. Chemical analysis and measurements of heats of combustion of what goes in and what comes out, together with determination of heat generated within the calorimeter, permit an accurate thermal analysis of the biological processes involved. The heat liberated in the calorimeter commonly is absorbed in water circulated through coils in the calorimeter and is determined by measuring the amount of water and its rise in temperature. Details of construction and measuring techniques necessarily vary greatly, depending on the nature of the measurements required. See also RESPIRATION.

CALPRENEDE, G. DE C. DE LA: see LA CALPRENÈDE, G. DE C. DE.

CALPURNIUS SICULUS, TITUS (fl. c. A.D. 60), Roman poet, was the author of seven pastoral eclogues. These were generally printed together with the four eclogues of Nemesianus (*q.v.*), but in 1854 M. Haupt established with certainty the difference of authorship and date. Very little is known of Calpurnius' life; his name Siculus may indicate Sicilian origin, or may be a conventional indication of his literary debt to the Sicilian Theocritus, originator of pastoral poetry. Again, he may have been the son of a freedman of C. Calpurnius Piso (the leader of the conspiracy against Nero in A.D. 65); a panegyric poem (*Laus Pisonis*) addressed to him is extant, and this may well be by Calpurnius Siculus, though all that can be said with certainty is that it belongs to his period. It has also been ascribed at various times to Virgil, Ovid, Statius and Lucan; of these only the last is a possible claimant. Attempts have been made to identify the characters in the Eclogues with real persons, but these remain little more than hypotheses. Two short and incomplete poems called (from the place of their discovery in Switzerland) the *Einsiedeln* Eclogues are also extant; these certainly belong to the

age of Nero, and are sometimes attributed to Calpurnius Siculus, but without much likelihood.

The *Eclogues* are in the Vergilian tradition, and the influence of Virgil is pervasive. Four of them are rural in type, and three (i. iv, vii) courtly, using the pastoral setting for the praises of the emperor Nero and his achievements. The movement of the hexameter is a mixture of Virgilian and Ovidian rhythm; and the impact which the poems make is agreeable if one grants their imitative nature. They are expressed in a neat and elegant diction, graceful and melodious, remarkably free from the violent rhetoric which characterized much Silver Age poetry. They lack the faults of striving after effect, but they lack its virtues too, and although they contain some contemporary subject matter and references, they add nothing new to the development of Latin literature.

The *Laus Pisonis* is a panegyric poem of the type of the pseudo-Tibullian Panegyricus Messallae, a type practised in the *Silvae* of Statius and later by Claudian and Sidonius. Its diction is fluent and its rhythm smooth; it handles its conventional theme without excessive hyperbole, and is one of the best examples of its kind.

CALTAGIRONE, a town of Sicily, Catania province: lies 75 km. (47 mi.) S.W. of Catania city by road in a picturesque hilly position. Pop. (1957 est.) 45,724 (commune). The upper part of the town joins the lower by a great flight of steps built in the 17th century. All the churches date from the 18th century and there is a big ornamental garden. The town is joined to Catania by road and rail. Ceramics and terra cotta work form the chief industries; agriculture, especially cultivation of cereals, vines and olive and cork trees, is important in the district. The name Caltagirone comes from Qal'at al-Genun (the castle of Genun, the Saracen chieftain who built it). Although it is one of the oldest Sicilian towns, with Siculan, Greek, Roman and Norman remains, its classical name is unknown. The town was badly damaged by earthquake in 1693 and by air raids in 1943. (G. C.)

CALTANISSETTA, a city of Sicily and capital of Caltanissetta province, is situated 1,867 ft. (569 m.) high in mountains west of the Salso valley. 139 km. (86 mi.) by road southeast of Palermo. Pop. (1957 est.) 61,612 (commune). The centre of the city is the Piazza Garibaldi and the modern quarter is to the west. The cathedral and adjoining church of S. Domenico (both 1622) and the Collegiate church (1605) are in baroque style. The Moncada palace (17th century) is baroque, while the palaces of Bordonaro, Benintendi and Lanzirotti are 19th-century neoclassical. Pietrarossa castle has Greek and Norman remains, and the abbey of S. Spirito and Sta. Maria la Vetere church (both 12th century) are Norman. Train and coach services run to other centres. Main industries are sulfur mining and agriculture. There is an institute of mineral technology. Caltanissetta is sometimes identified with the ancient cities of Gibil-Habib or Sabucina, but recorded history does not begin until the Norman occupation in the 11th century. The city passed to Italy in 1860, and in World War II was occupied by Allied forces on July 18, 1943.

(SA. GR.)

CALUMET, the name given by the French in Canada to the peace pipe of the American Indians (Norm. Fr. chalumet, Lat. calamus, a "reed"). This pipe occupied a position of peculiar symbolic significance among the tribes, and was the object of profound veneration. It was smoked on all ceremonial occasions, even on declarations of war, but its special use was at the making of treaties of peace. It was usually about 2½ ft. long, and in the west the bowl was made of red pipestone (catlinite). The pipe

¹This article was originally prepared in collaboration with members of the National Bureau of Standards staff: C. S. Cragoe, H. F. Stimson, R. S. Jessup, D. C. Ginnings, R. B. Scott and F. D. Rossini.

CALUMET, PEACE PIPE OF THE AMERICAN INDIAN

stem was of reed decorated with eagles' quills or women's hair. Native tobacco mixed with willow bark or sumac leaves was smoked. The pipe was offered as a supreme proof of hospitality to distinguished strangers, and its refusal was regarded as a grievous affront. In the east and southeast the bowl was of white stone, sometimes pierced with several stem holes so that many persons might smoke at once.

CALUMET CITY, a city in Cook county, Ill., U.S., on the Indiana state line and adjoining Hammond, Ind., is a part of the Chicago standard metropolitan statistical area. (For comparative population figures see table in *ILLINOIS: Population*.) It is on the outer edge of the Lake Michigan plain 5 mi. from Lake Michigan and 4 mi. from Lake Calumet, strategically located near the Great Lakes-Gulf waterway and Calumet harbour and the heavy industrial area of Gary-South Chicago. Its night clubs, most of them on State street, known as "the strip," have at times attracted some notoriety as places of entertainment for conventioners visiting Chicago, and have been a source of municipal discord.

The city developed as a residential suburb of the industrial belt and until 1924 was called West Hammond. (For the definition of its name see **CALUMET**.) It was incorporated as a city in 1923. In the latter part of the 20th century industrial development within Calumet City itself increased in importance. (D. A. PR.)

CALVADOS, a *département* of northern France, in Normandy, fronts the English channel in the Baie de la Seine between the Cotentin peninsula and the Seine estuary. Area is 2,198 sq. mi. Pop. (1954) 442,991. It lies between the *départements* of Manche and Eure to west and east and is bounded by the *département* of Orne to the south. The *département* of Calvados was formed in 1790 from the districts of Bessin, Cinglais, Hikmois, the Campagne de Caen, Auge and the western part of Lieuvin, and was named from a reef of rocks that stretches along the coast between the mouths of the Orne and Vire rivers. The Aure, Orne, Dives and Touques (from west to east) rivers enter the Baie de la Seine. The Collines de Normandie, crossing the southwest of Calvados, form the highest ground, above 1,000 ft., but most of the *département* is low lying, though the surface is varied by the succession of geological outcrops. Running from south to north, where they are cut off by the coast line, they give an alternation of clay vales and limestone platforms. The coast line is correspondingly varied, with extensive cliff sections and offshore reefs and, elsewhere, sand dunes backed by marshy tracts. Trouville is the chief of several coast resorts. In World War II, from the first landings on the beaches of this coast, the Allied forces penetrated into France in 1944.

Calvados has a damp, mild climate, and the clay vales in Bessin

and Auge provide rich pastures where cattle are fattened and dairying is extensively pursued. Large quantities of butter and cheese are produced, and Pont-l'Évêque is especially well known. The limestone and chalk platforms of the Campagne de Caen and Lieuvin have more arable land, especially devoted to corn, sugar beet and fodder crops. Cider-apple orchards are widespread, and cider brandy (known as calvados) is distilled. The Caen district has for centuries provided fine building stone used in many historic buildings in England as well as in northern France. More recently rich iron ore, occurring in the Silurian rocks in the area south of Caen, has been exploited and is shipped by the canalized Orne or used by local furnaces.

Bayeux, Caen, Lisieux and Vire are the centres of the four *arrondissements* into which Calvados is divided. Caen (*q.v.*), the capital, is the seat of a court of appeal and the centre of an *académie* (educational division). The *département* forms the diocese of Bayeux. There are fine Romanesque and Gothic churches at Caen and elsewhere, and at Falaise in the south is the castle of the first dukes of Normandy, the birthplace of William the Conqueror.

For the history of the region, see **NORMANDY**. (AR. E. S.)

CALVARY, the place where Jesus was crucified. The word comes from the Latin *calvaria*, the Vulgate translation of the Greek *kranion*, "skull" (Luke xxiii, 33). In Matt. xxvii, 33 and John xix, 17 "the place of a skull," to which Jesus was taken for crucifixion, is said to be called in Aramaic *Golgotha*. It evidently lay outside Jerusalem (*cf.* Heb. xiii, 12) on the north side, and near a road (Matt. xxvii, 39). The name suggests a hillock shaped like a skull, or a known place of execution (but John xix, 41, which says a garden was there, seems opposed to this, or a spot where a skull was known to have been found (no evidence supports this). The Holy Sepulchre (*q.v.*) was near (John xix, 42). The location has been sought most often where the Church of the Holy Sepulchre now stands, within the present city walls, but some have favoured the somewhat skull-shaped hillock called "Gordon's Calvary," just north of the Damascus gate.

(F. V. F.)
CALVÉ, EMMA (ROSA EMMA CALVET) (1858-1942), French operatic soprano, best known for her performances in the title role of Bizet's *Carmen*. Born at Décazeville (Aveyron), on Aug. 15, 1858, she spent her early youth in Spain. She studied principally under Mathilde Marchesi and made her debut as Marguerite in Gounod's *Faust* in Brussels (1882). After appearing in Bizet's *Les Pêcheurs de Perles* and Mascagni's *Cavalleria Rusticana* she returned to Spain to study the part of Carmen in which she succeeded Marie Galli-Marié, who created the part, at the Paris Opéra-Comique in 1892. She subsequently sang this part throughout Europe and the United States and her interpretation of it was long considered the model. She bought the chateau de Cabrières at Millau and, after 1925, retired from the stage to teach. She died at Millau on Jan. 6, 1942.

See Emma Calvé, *Sous tous les ciels je chanté* (1940).

CALVERLEY, CHARLES STUART (1831-1884), English poet whose brilliance as a parodist and translator derived from lively wit and unusual skill in imitation, was born at Martley, Worcestershire, on Dec. 22, 1831, the son of the Rev. H. Blyds; his family resumed the ancestral name of Calverley in 1852. At Harrow and Balliol college, Oxford, Calverley was a general favourite; a delightful companion, a distinguished athlete and a brilliant scholar. In 1851 he won the chancellor's prize for Latin verse, but a year later, to avoid the consequences of a college escapade, he migrated to Christ's college, Cambridge. He was elected fellow of Christ's college in 1858, published *Verses and Translations* in 1862 and was called to the bar in 1865; but he was prevented by a skating accident from following a professional career, and during his last years he was an invalid. He died at Folkestone, Kent, on Feb. 17, 1884. The sparkling, witty verses of his *Translations Into English and Latin* (1866), *Theocritus Translated Into English Verse* (1869), *Fly Leaves* (1872) and *Literary Remains* (1885) brought him many imitators.

See *Complete Works*, with a biographical notice by Sir W. J. Sendall (1901).

CALVIN, JOHN (1509–1564), Genevan theologian and reformer, was born at Noyon in Picardy on July 10, 1509, the fourth son of Gérard Cauvin, a man of low birth who rose to be secretary to the bishop and attorney to the cathedral chapter of Noyon. Calvin's mother, Jeanne le Franc, was the pious daughter of a well-to-do innkeeper of Cambrai, whose father, like Gérard, had been received into the Noyon *bourgeoisie*. (The family name seems to have been written indifferently as Cauvin, Chauve, Chauvin, Calvus and, always in the capitulary registers of Noyon, Cauuin. It was Latinized by John for scholarly purposes as Calvinus, and on occasion was used in the anagrammatic forms Alcuinus and Lucanius.)

Early Life. — Destined by his father for an ecclesiastical career, John Calvin was educated in the household of the noble I-hangest family from which for generations had come the bishops of Noyon. In May 1521 he was appointed to the first of several benefices that were to finance his education, undoubtedly receiving the customary tonsure. When the plague threatened Noyon in 1523, Calvin accompanied the three Hangest boys to study in Paris. He attended the Collège de la Marche as an out-student, imbibing early the spirit of humanism from his excellent Latin teacher Mathurin Cordier, who became his lifelong friend and later joined him in Geneva. He may also have learned of Ockhamism from the Scottish teacher John Major. He soon moved to the Collège de Montaigu, a bastion of churchly orthodoxy led by Noel Beda, under whom Erasmus and Rabelais had chafed as students, and where Ignatius of Loyola was soon to study. In college disputations Calvin showed brilliance and unusual precocity. He also acquired a knowledge of medieval thought and a habitual agility and precision of expression that remained with him long after he had forsaken the formal logic of scholasticism as a "science of wind." Enduring friendships were formed at this time, especially with Claude de Hangest, who became abbot of St. Elois in Noyon; Nicholas and Michel Con, sons of the king's Swiss physician, Guillaume Cop, a leading humanist medical scholar and his own kinsman Pierre Robert (Olivétan), translator of the Bible into French. He frequented the home of Guillaume Budé, the most eminent French Hellenist and one of the first (with G. Cop) of the royal lecturers; Bude's sons later became citizens of Protestant Geneva.

Having achieved the master of arts degree, Calvin, in obedience to his father, turned from theology to the study of law. He left Paris for Orléans in March 1528 to hear the lectures of the distinguished jurist Pierre de l'Estoile, and in the autumn of 1539 progressed to Bourges to continue under the Italian Andrea Alciati. Calvin's first published writing is the preface to a work of his friend Nicholas Duchemin defending the conservative L'Estoile against the innovating Alciati. Other close associates—indicating broad interests and a sociable nature in the young Calvin—were François Daniel, François de Connan and the somewhat older Melchior Wolmar, a classicist of Lutheran affinities with whom Calvin began the study of Greek. Calvin's residence at Bourges was cut short by the death of his father in May 1531. He went to Paris, where the "new learning" was at length contesting the supremacy of scholasticism in the university, and there continued the study of Greek with Pierre Danks and began Hebrew with François Vatable, both royal lecturers. In April 1532 Calvin published his commentary in Latin on Sececa's treatise *De Clementia*, dedicated to Claude de Hangest. This writing bears no mark of Protestant interests, but shows him to be a gifted and ambitious young Christian humanist with noticeable sympathies for ancient Stoicism. Soon afterward Calvin returned to Orléans where he finished his doctorate in law and served briefly as proctor for the "nation" of students from Picardy.

Calvin visited Noyon in Aug. 1533 and by October of the same year was settled again in Paris, where the court was now favouring the humanists around Jacques Lefkvre d'Étaples (Faber Stapulensis) under the influence of Margaret of Angoulême, queen of Navarre and sister of Francis I. Calvin's close friend Nicholas Cop in his address as newly elected rector of the university championed this group and used some excerpts from a sermon of Luther in speaking of law and grace. The oration (wrongly at-

tributed to Calvin by early biographers) split the university and precipitated a royal proscription of the "Lutheran sect," causing Cop and Calvin to flee the city. Calvin soon returned briefly to Paris and probably early in 1534 traveled into the more receptive district of Angoulême, where he was the guest of Louis du Tillet, a cathedral canon and son of a notable family. Calvin used the splendid Tillet library during several months of reading and reflection, and traveled to Nérac for his only meeting with the aged Lefkvre, who was living under the protection of Margaret of Navarre.

Conversion to Protestantism. — The "sudden" conversion of Calvin mentioned in the preface to his *Commentary on the Psalms* has been dated by responsible investigators as early as 1528 (E. Doumergue) and as late as the spring of 1534 (J. T. McNeill). A lack of autobiographical writing by Calvin and the wide range of religious opinion in France at the time make a clear solution impossible. He must have had knowledge of the Lutheran version of reform from the time of his first arrival in Paris, which coincided with the burning of Jean Vallière for Lutheran opinions, the condemnation of Luther's writings by the Sorbonne having already taken place. While writing on Seneca he lived at the home of the outspoken Protestant Étienne de la Forge, later martyred. His intellectual associates, however, seem to have been chiefly from the circle of Lefkvre, such as François Daniel and Gérard Roussel, who were to remain within the Roman church. The first act of Calvin indicating a decisively Protestant stand would seem to be that of May 1534. As a holder of benefices he ordinarily would have been ordained about this time, but instead he journeyed to Noyon and resigned the benefices, thereby severing his long-standing tie to the diocese. His movements now become difficult to trace, but he visited Paris, Orléans and Poitiers. The hostile but partly trustworthy 16th-century historian Florimond de Raemond presents uncorroborated accounts of Calvin's activities in Poitiers, including an administration of the Lord's Supper as a Protestant rite. More likely this came after he was a pastor in Geneva.

Calvin's first theological tract, entitled *Psychopannychia* (written in 1534, published in 1542), was not directed against Rome but opposed Anabaptist revival of the idea that the soul of man sleeps between death and the general resurrection. Much more important and of permanent value for understanding Calvin's evangelical orientation is the preface he wrote in 1534 to the French translation of the Bible published a year later by Olivétan.

The year 1534 was thus decisive for Calvin, and subsequently he began to assume intellectual leadership among advocates of Protestant reform. Again endangered in Paris, he went to Angoulême and set out with Louis du Tillet for Basel, where he lived under the pseudonym Martianus Lucanius, welcomed by the Reformation leaders Oswald Myconius, Pierre Viret and Heinrich Bullinger and guided in the study of Hebrew by Sebastian Munster. Though he was exiled, Calvin's interests were with French evangelicals who were being persecuted by Francis I. The king had endeavoured to retain the political support of Lutheran Germany against Charles V by calling his victims Anabaptists. Calvin, indignant, presented a full statement of French Protestant belief under the title *Institutes of the Christian Religion*, prefaced by a respectful yet stinging dedicatory epistle to the king. The book itself (in Latin; no French copy of the 1536 edition has ever been found) was immediately recognized as a superb normative statement of reformed theology, despite the author's youth. Four of the six chapters follow a traditional pattern of instruction giving expositions of the Ten Commandments, the Apostles' Creed, the Lord's Prayer and the sacraments (baptism and Lord's Supper). To these Calvin added a polemic fifth chapter on false sacraments, and a sixth "On Christian Liberty, Ecclesiastical Power and Civil Administration." In this first edition nearly all the themes of Calvin's mature thought are present, although he was to develop, elaborate, reorganize and more than quadruple the bulk of the work through various editions until the final one of 1559.

Geneva. — As the *Institutes* went to press in Basel, Calvin departed for the court of Renée, duchess of Ferrara and cousin to Margaret of Navarre, to try to aid (without success) the cause

of reform there. Returning, as he hoped, to a life of scholarship in Basel or Strasbourg, he was detoured through Geneva by the war between Francis I and Charles V. Calvin's progress was arrested in Geneva when Guillaume Farel, a fiery former pupil of Lefhvre who had succeeded in planting the evangelical standard in that city, demanded and received Calvin's reluctant aid. Calvin began lecturing, inconspicuously and without payment, on Paul's epistles in the church of St. Pierre in Aug. or Sept. 1536, and was later received as a pastor. Farel's position in Geneva had been insecure, partly because of his own limitations as thinker and organizer but especially because religious reform, in the minds of the citizenry, was confused with Genevan political revolt against the duke of Savoy and his vacillating pawn the bishop of Geneva (see GENEVA). Also the reform felt itself harassed by Anabaptist teachers until they were expelled by the city Council of Two Hundred following public disputations in early 1537. Farel remained the leader, but Calvin's influence was increasingly strong, especially in forming a plan of compulsory education and close moral supervision for the entire city. All citizens were required under threat of expulsion to make public avowal of a confession of faith that Farel had written. Frequent and worthy observance of the Lord's Supper was Calvin's rationale for the discipline and the chief ground of insistence that administration of discipline (including the ultimate verdict of excommunication) be solely in the hands of the ministers rather than the magistrates. Severe moral restrictions had been written into Genevan law long before the Reformation, but strict enforcement in the control of the church was a novelty not well received by many of the gay-living and independent citizenry. In this period Calvin composed his brilliant and succinct *Instruction in Faith* as a device for public education. This document was at issue when Pierre Caroli, chief pastor of Lausanne, demanded rather the use of ancient creeds and finally accused the Genevans of Sabellianism and Arianism (*q.v.*).

Caroli, who was to return twice to the Roman communion before he died, was brought before a synod in which the Bernese participated and dismissed on charges of advocating prayers for the early resurrection of the dead and of personal immorality. Calvin's Trinitarian orthodoxy was officially vindicated. His formidable vehemence and erudition in debate before the synod served notice that a new Protestant leader of immense significance was emerging.

Although Genevan elections of Feb. 1537 had supported the Farel-Calvin policies, the opposition came into control one year later. The new leaders represented not an anti-Reformation party but one oriented politically toward Bern because this city was a necessary bulwark against Savoy and because it represented a milder liturgical and moral pattern of reform. (Though Geneva was not yet a member of the Swiss confederation, it had entered into a contract of joint citizenship with Bern as one method of protecting itself against Savoy.) The Bernese rites (including the use of unleavened bread in communion, fonts in baptism, observance of festival days, etc.) were technically matters of indifference to Calvin and his associates, but it was a cardinal principle that the authority for change should rest with the ministers and not with the civil rulers. Early in 1538 the Council of Two Hundred forbade the ministers to exclude anyone from communion, adopted the Bernese rites without consulting the church authorities and refused to delay the matter until the meeting of a general Swiss synod in Ziirich. The ministers, fearing profanation of the sacrament in the uproar, refused to administer it at all on Easter Sunday, 1538, but preached boldly although they had been forbidden to do so and had experienced some personal danger from mob action. The city councils quickly gave Calvin, Farel and their blind associate Corauld three days to leave the city. The Swiss synod arranged a return on milder terms, but the Genevese, with some connivance of the Bern pastor Peter Kunz, refused and the banishment was reaffirmed.

Strasbourg.—Farel settled at Neuchâtel and Calvin at Strasbourg, where, as pastor of a church of French refugees and colleague of Martin Bucer, he spent three of his happiest and most productive years. Sharing the passion of Bucer and Philipp

Melanchthon (whom he met at the diet of Regensburg) for the unity of the church, he attended Charles V's conference on Christian reunion at Frankfurt, and represented Strasbourg at the conference of Hagenau (1530) and the Disputation of Worms (1540–41). In 1539 Calvin published a *Commentary on Romans* and a revised Latin edition of the *Institutes*, which, translated by him into French, became an important early classic (published 1541) of that language. His *Short Treatise on the Lord's Supper* and *Form of Prayer and Manner of Ministering the Sacrament According to the Use of the Ancient Church* represent his decisive liturgical work and show Bucer's influence. In Aug. 1540 Calvin married Idelette de Bure, the widow of Jean Stordeur of Liège, whom he had converted from Anabaptism. In her Calvin found "the excellent companion of my life," a "precious help" in his many labours and illnesses. She died in 1549. Their only child, Jacques, born July 28, 1542, lived only a few days.

Return to Geneva. — During Calvin's absence political and religious chaos threatened in Geneva. An attempt of Cardinal Jacopo Sadoletto to restore Roman Catholicism was frustrated largely by a letter of Calvin, perhaps the finest brief apology for the Reformation ever written. After official communications and deputations were sent from Geneva urging Calvin's return, he reluctantly assented, arriving on Sept. 13, 1541. He now determined to carry out his whole original scheme of reform and to set up in all its integrity that form of church polity which he had carefully matured during his residence at Strasbourg. The "Ecclesiastical Ordinances" thus adopted became influential for Reformed ("Presbyterian") polity subsequently in Europe, the British Isles and America. Its salient features were "four orders of office" (pastors, teachers, elders and deacons) and a ruling body called the consistory (composed of pastors and elders) which guided church affairs. The Genevan government system of councils, embodying both aristocratic and democratic elements, was not changed much by the reform, but the interrelations among the councils shifted and close interaction with the church consistory gave the whole a quite new aspect. Fourteen years of intense struggle and the granting of citizenship to a large new population of religious refugees were needed before the triumph of the new discipline was secure.

(For a more detailed history of the progress of the Reformation in Geneva, see REFORMATION; REFORMED CHURCHES, THE.)

Among the theological controversies of Calvin was that on predestination and election in which his opponents were Albert Pighius and Jerome Bolsec, and that in which Sébastien Castellio was denied ordination because of irregular views of the Holy Spirit and the biblical canon. Michael Servetus, a brilliant eccentric scholar, debated by letter and publication with Calvin, attacking the prime doctrine of Protestant and Catholic orthodoxy, the Trinity. Condemned to burning in Vienne, but escaped, Servetus after a long trial was finally burned at the stake in Geneva, an act typical of the age but one that has placed Calvin's historical image among the persecutors of religious dissent (see SERVETUS, MICHAEL). Calvin was also involved in lengthy but unresolved contention with the Lutherans respecting the Lord's Supper—the Lutherans holding that the body and blood of Christ are present with the elements so as to be consumed by all partaking, even the unworthy; and the Reformed affirming a real but spiritual presence partaken of only by the faithful.

Nor was it only in religious matters that Calvin busied himself; he was consulted on countless affairs great and small that came before the councils—questions of law, police, economy, trade, manufacture and foreign diplomacy. To him the city owed its trade in cloths and velvet, from which much wealth accrued to its citizens; sanitary regulations that made Geneva the admiration of all visitors were introduced by him.

The academy he founded in 1559 with Theodore Beza as rector was a crowning work, the intellectual centre of international Calvinism for many years to come. The curriculum united classical studies, as conceived among the humanists, with reformed theology, showing traces of the conceptions of Budé, Melanchthon and Johannes Sturm of Strasbourg.

Along with these many activities Calvin continuously wrote

theological, exegetical, liturgical, polemical and church constitutional works, many of which carried influential social, political and economic ideas. Beza estimates that Calvin averaged 286 sermons in French and 186 lectures in Latin annually. His wide-ranging correspondence fills ten volumes of the collected works. He published commentaries on the Hebrew and Greek texts of nearly all the books of the Bible, combining techniques of literary, historical and textual analysis with great erudition and penetrating insight.

The incessant and exhausting labours to which Calvin gave himself could not but affect his fragile health. On Feb. 16, 1564, he preached his last sermon, and on April 20 he made his will. On the 27th he received the Little Council, and on the 28th the Genevan ministers, in his sickroom; on May 2 he wrote his last letter—to his old comrade Farel, who hastened from Neuchâtel to see him once again. Calvin spent much time in prayer and died quietly in the arms of Theodore Beza on the evening of May 27. The next day he was buried without pomp "in the common cemetery called Plain-palais," in a spot not now to be identified.

Calvin suffered chronic illness throughout his adult life. He was sparing in his food and simple in his dress; he slept little and was capable of extraordinary intellectual efforts. Possessed of a most retentive memory and a very keen power of observation, he spoke simply, directly, but with great weight. Though he had many acquaintances, he had few close friends. If somewhat severe and irritable, he was at the same time scrupulously just, truthful and steadfast, and commonly cheerful and even playful among his intimates.

Theology.—Fundamental to all Calvin's thought was his conception that the Reformation was not founding something new but was purifying the church and restoring its pristine condition in rejection of scholastic errors and papal heresies. Significantly, the final edition of his *Institutes*, which he conceived as a guide to Bible study, is organized into four books after the sequence of doctrines in the ancient Apostles' Creed—Creator, Redeemer, Spirit and Church—and is buttressed throughout with materials from Church Fathers. The most characteristic thought in his theology concerns the mystery of the grace of God, who redeems sinners although they are unworthy of redemption and incapable of meriting it. The believer, thus, is the undeserving recipient of faith, of sonship and of membership in Christ's body as a sheer gift of the Holy Spirit. The man of faith has been "chosen," or "elect" or "predestined" by God for salvation and may not boast of contributing either his own decision or any good works to procure eternal life.

Following the outline of his own *Institutes* (1559), Calvin's thought might be summarized as follows:

Book I, "On the Knowledge of God the Creator," begins with the inextricable interrelatedness of the knowledge "of God and ourselves" and the positive religious and ethical demands that such knowledge makes upon all men through the revelation in creation and conscience. But since man's sin has blinded him, God has chosen special means to restore him: the revelation known as Scripture, to which God enlightens the mind by the "internal testimony of the Holy Spirit," without which a mere assent of the mind cannot be redemptive. Having established Scripture in a brief excursus (ch. vi-ix), promising to take up the matter later (III, ii), Calvin proceeds to a fairly traditional exposition of the doctrine of the Trinity according to the orthodox formulas, and of the doctrines of creation and providence.

Calvin's special emphases are shown in that he develops the dangers of idolatry in worship (with Rome in mind) as a prelude to discussing the Trinity and in his rigorous insistence that every drop of rain and every thought of man represents a particular expression of the divine will. Here Calvin verges on determinism: a difficult and disputed point especially in view of his strong insistence on human responsibility for every exigency of life, excepting only salvation.

Book II, "On the Knowledge of God the Redeemer in Christ . . .," presents first the need for redemption: man's sin, which has spread corruption through the totality of his being. This is inherited from Adam by every man both as guilt and as a lively

tendency to disobey God, though in such a way as to pervert rather than to abolish the excellent gifts of mind and body enjoyed by all humanity. These remaining gifts, however, are providential and exhibit God's patience but not his gracious will to save. The excellent mathematicians, lawyers and philosophers of antiquity, for all their continuing value, were not (so far as man can judge) men of faith, and mere human excellence will not remove the curse of their sin. A special chapter, prepared for the final edition of the *Institutes* (ch. vi), presents the Old Testament and the Law of Moses as preliminary and specially accommodated forms of the revelation to be made finally clear in Christ, for "the hope of the pious [patriarchs and prophets] has never been placed anywhere but in Christ." The chief use of the Decalogue is not so much to convict sinners as to guide the chosen into faithful obedience. The person of Christ is seen in traditional Chalcedonian terms, but his redeeming activity is freshly formulated as the assumption of Old Testament functions of prophet, priest and king. Christ himself was at the same time the atoning sacrifice both in the perfection of his life and in his voluntary suffering, which God in his mercy chose to accept to cover the sin of men.

Book III, "On the Manner of Receiving the Grace of Christ . . .," presents faith as the "principal work" of the Holy Spirit by which the benefits of Christ are made available to men and "union with Christ" is effected. Thus joined to Christ, the believer has life in him and knows (but with a faithful assurance, not a carnal security) that he is redeemed, having the witness of the Spirit that he is a child of God, and having the promises both "revealed to our minds and confirmed to our hearts" by the same Spirit (III, ii, 7, *et passim*). From faith springs repentance, proceeding from a sincere fear of God, and consisting in the mortification of the flesh and the "old Adam" within us and a vivification of the Spirit. Through faith also the believer receives justification, his sins are forgiven, he is accepted of God and is held by him as righteous, the righteousness of Christ being imputed to him. This imputed righteousness, however, is not disjoined from real personal righteousness, for regeneration and sanctification come to the believer from Christ no less than justification; the two are not to be confused, but neither are they to be separated. The assurance which the believer has of salvation he receives from the operation of the Holy Spirit; but this again rests on the divine choice of the man to salvation in God's eternal free purpose, whereby he has predestined some to eternal life and some to eternal death. The former he effectually calls to salvation, and they are kept by him in progressive faith and holiness unto the end (Bk. III *passim*).

Thus predestination, which Calvin took over chiefly from Augustine, is treated in a unique way, not as an adjunct to the doctrine of God (as in later "Calvinist" theologians) and as a "part of providence" (as in Thomas Aquinas), but as an implicate of grace and faith.

Book IV, "On the Outward Means or Helps by which God Invites Us into the Fellowship of Christ . . .," presents the church and sacraments as gracious means or instruments used by God to support the weakness experienced by all believers. The church is made up of "all the elect from the beginning of the world," fully known only to God, who "knows and has marked those who know neither him nor themselves." Yet this same church is visible to men in every generation as the "whole multitude of men spread over the earth who profess to worship one God and Christ," and who in various particular places preach and hear the Word of God and rightly administer and receive the sacraments. The latter two "marks" of the true church distinguish it, even when it is corrupt (IV, i, 7-11). The chief officers of the church are pastors, who preach the Gospel, administer the sacraments and maintain discipline; and teachers, who lecture in theology and conduct schools in languages and the humanities. With these are joined for the government and discipline of each church certain pious men as a senate of elders, and also deacons, who care for the poor. These officers are elected by the people and ordained by the laying on of the hands of the pastors (iii, 4-16). The sacraments are two—baptism and the Lord's Supper. Baptism (ordinarily of infants) is the sign and seal of membership in the church; it serves

both for the confirmation of faith and as a confession before men. The Lord's Supper is a sacred communication of Christ's flesh and blood, whereby he transfuses his life into believers, uniting by the Spirit "things which are separated in space" when he truly and efficaciously presents his body and blood through the symbols of bread and wine. In the mystery of the Supper a "real participation of him" is enjoyed, yet he is not affixed to the elements or in any way circumscribed (IV, xv-xvii). A great elaboration of polemic material and critical comment on the history of the church makes Book IV the longest section of the *Institutes*. The state is dealt with briefly in the final chapter (xx) showing Calvin's perception that forms of government may change in response to historical circumstances, although whatever the form, rulers are recognized as legitimate only if they provide for true religion among their subjects. Calvin preferred a representative government with an educated populace, but with a strong sustaining aristocratic element to restrain the capriciousness of the many.

BIBLIOGRAPHY.—The standard editions of Calvin's works are that of the Strasbourg scholars J. W. Baum, E. Cunitz, E. Reuss, *et al.*, in the *Corpus Reformatorum*, 59 vol. (1863-1900) and that of P. Barth, W. Niesel and D. Scheuner, *Calvini Opera Selecta*, 5 vol. (1926-52). The bulk of the writings has been published in English by the Calvin Translation Society, 48 vol. (1843-55, reprinted 1947 ff.). See especially J. T. McNeill (ed.), *Calvin: Institutes of the Christian Religion*, Eng. trans. by F. L. Battles, 2 vol. (1959). Further translations are listed and a broad survey of bibliography appears in J. T. McNeill, "Thirty Years of Calvin Study," in *Church History*, vol. xvii, pp. 207-240 (1948), and a continuation by E. A. Dowey, *Church History*, vol. xxiv, pp. 360-367 (1955), and vol. xxix, pp. 187-204 (1960). The most careful and balanced lives of Calvin in English are Williston Walker, *John Calvin, Organizer of Reformed Protestantism* (1906); J. T. McNeill, *The History and Character of Calvinism*, pp. 93-234 (1954). The definitive works are F. W. Kampschulte, *Johann Calvin, seine Kirche und sein Staat in Genf*, 2 vol. (1869-99), which is unsympathetic, and Emile Doumergue, *Jean Calvin; les hommes et les choses de son temps*, 7 vol. folio (1899-1927), which is overly admiring but incomparably thorough and well documented. Especially valuable is P. Imbart de la Tour, *Les Origines de la Réforme*, vol. iv (1935). See also R. N. C. Hunt, *Calvin* (1933); A. M. Hunter, *The Teaching of Calvin*, rev. ed. (1950); F. Wendel, *Calvin: sources et évolution de sa pensée religieuse* (1950). Among Protestant studies of Calvin's thought in English are T. F. Torrance, *Calvin's Doctrine of Man* (1919); E. A. Dowey, *The Knowledge of God in Calvin's Theology* (1952); R. S. Wallace, *Calvin's Doctrine of the Word and Sacrament* (1953); W. Niesel, *The Theology of Calvin*, Eng. trans. by Harold Knight (1956). (E. A. Dp.)

CALVIN, MELVIN (1911-), U.S. chemist, winner of the 1961 Nobel prize in chemistry for research into photosynthesis, was born April 8, 1911, in St. Paul, Minn. He received a B.S. degree from the Michigan College of Mining and Technology, Houghton, in 1931 and a Ph.D. degree from the University of Minnesota in 1935. He then spent two years at the University of Manchester, Eng., as a fellow of the Rockefeller foundation. In 1937 he joined the faculty of the University of California at Berkeley, undertaking additional duties there as director of the bio-organic division of the Radiation laboratory in 1946.

He discovered the chemical pathways that are followed in green plants during the conversion of stored light energy, carbon dioxide and water into the thousands of compounds essential for their growth. The unraveling of the intricate details of photosynthesis is significant since all life on earth is ultimately dependent upon the conversion of sunlight to usable chemical energy.

He also conducted research in the fields of radiation chemistry, organic chelate compounds and the origin of life. (Mu. G.)

CALVINISM means, first, the careful balance of complementary doctrines in the theology of John Calvin (*q.v.*) and, second, the development on speculative or pietistic lines of a selection of these doctrines by his followers and those who claimed, not always defensibly, to be his followers. The unity of Calvin's biblical theology was distorted if not destroyed after his death by Theodore Beza, who reverted in his *Tractationes theologicæ* of 1570 to the medieval scholastic device of placing predestination under the doctrines of God and of providence (whereas Calvin had eventually related it to the work of Christ), thus introducing speculative determinism into the doctrine. Beza also emphasized

literalism in the inspiration of the Bible which brought an attitude to biblical interpretation differing from that of Calvin. William Perkins in England added a pragmatic and pietistic concern for personal sanctification, separated from Calvin's insistence on the objective reality of the church and the sacraments. Continental theologians introduced a "covenant" theology to modify the determinist element in Beza's Calvinism. The Westminster Confession of Faith (1648), still the standard of many English-speaking Presbyterian churches, is influenced by this. The so-called "Five Points" of Calvinism of the 1618 Synod of Dort (*q.v.*) represent the extreme definition of the post-Calvinist type of doctrine. Evangelicals of the 18th century such as George Whitefield (1714-70) emphasized this type together with personal experience of conversion.

Until recently "Calvinistic" in theology has tended to imply this association of ideas. Beza's Calvinism had insisted on Presbyterian church government by "divine right": this churchmanship was adopted in varying degrees by the Reformed Churches of Holland, Germany, France, Hungary, Scotland, the United States and elsewhere. The word "Presbyterian," used to describe a denomination, is synonymous with "Reformed" as applied to continental Presbyterian churches. See also PRESBYTERIAN; REFORMED CHURCHES, THE.

See A. A. van Schelven, *Het Calvinisme Gedurende zijn Bloeitijd*, 2 vol. (1951); J. T. McNeill, *The History and Character of Calvinism* (1954). (B. H.)

CALVINISTIC METHODISM, the popular designation of the PRESBYTERIAN CHURCH OF WALES. Its origin usually is attributed to the religious experience of conversion undergone by the layman Howel Harris (1714-73) in Talgarth church, Brecknockshire, on Whitsunday, May 25, 1735, as a result of which he became an itinerant preacher. About the same time, Daniel Rowland (1713-90), curate of Nantgwnlle and Llangeitho in Cardiganshire, passed through a similar experience, and after the two men had met at Defynnog in Aug. 1737 they were the joint means of starting a nation-wide religious revival. Co-operating at first with some of the more pious clergy and dissenting ministers of Wales and with the leaders of English Methodism, they sought to supplement the normal services of church and chapel by establishing private societies. Doctrinal and personal differences, however, soon appeared. In the dispute between George Whitefield and John Wesley over the doctrine of free grace (1739-41), the Welsh leaders sided with the former, and Methodism in Wales thereby became Calvinistic rather than Arminian. A little later, doctrinal differences between Harris and Rowland over patristianism (the doctrine that the Son was the Father appearing in human form and that the Father therefore suffered on the cross as the Son), reinforced by criticism of Harris' imperiousness and of his association with Madam Griffith of Cefn Amwlch, led to a rupture in 1750, as a result of which Harris retired from active evangelism and established a community or "family" at Trefeca, Brecknockshire; the breach was not healed until 1762. Later still, in 1791, another leader, Peter Williams, was expelled because of his Sabelian views. On the death of the early leaders—who included Howell Davies and William Williams of Pantycelyn, the hymn writer of Welsh Methodism—the leadership of the movement passed into the hands of Thomas Charles (*q.v.*) of Bala, the real founder of the Sunday school in Wales and one of the founders of the British and Foreign Bible society. Hitherto, despite occasional secessions, Methodism had remained a forward movement within the established church, but the death of so many of its clergy supporters, the anomalous position of its lay exhorters, and the threat to its existence from Lord Sidmouth's bill of 1811 (see SIDMOUTH, HENRY ADDINGTON) forced Charles, after some reluctance, to take the decisive step of ordaining nine laymen at the Bala association in June 1811 and 13 at the Llandeilo association the following August.

Calvinistic Methodism thus became a Nonconformist denomination, with its Confession of Faith (1823) and its Constitutional Deed (1826). Its first association was held at Dugoedydd in 1742, the first joint Anglo-Welsh association at Watford in 1713, and the first general assembly in 1864. An act of 1933 secured the

church's autonomy in spiritual matters. Its polity and doctrine are Presbyterian (*q.v.*), and the great majority of its congregations worship in Welsh. In 1960 communicants in its three constituent associations numbered about 150,000 and its ordained clergy about 700.

CALVISIUS, SETHUS (German, *SETH KALWITZ*) (1556–1615), German musician, astronomer and mathematician, whose proposals for reform of the calendar in *Elenchus calendarii Gregoriani* (1612) and treatises on chronology he himself regarded as second to his work as composer. was born at Gorsleben. Thuringia, Feb. 21, 1556. Although poor, he was determined to study, and attended the universities of Helmstedt and Leipzig, where in 1594 he became director of music at St. Thomas' church. In 1611 he declined the chair of mathematics at Wittenberg to remain in Leipzig; and he died there on Nov. 24, 1613'.

Calvisius' chief musical treatise is *Exercitationes musicae duae* (1600 and 1611); he also wrote psalms, motets and hymn tunes, of which the Christmas carol "Joseph lieber, Joseph mein" is well known. His *Opus chronologicum* (1605) expounds a system of chronology based on the records of nearly 300 eclipses.

CALVO, CARLOS (1824–1906), Argentine publicist and historian, was born at Buenos Aires on Feb. 26, 1824. He devoted himself to the study of the law, and in 1860 he was sent by the Paraguayan government on a special mission to London and Paris.

Remaining in France, he published in 1863 his *Derecho internacional teórico y práctico de Europa y América*, in two volumes, and at the same time brought out a French version. The book immediately took rank as one of the highest modern authorities on international law. Between 1862 and 1869 Calvo published in Spanish and French his great collection in 15 volumes of the treaties and other diplomatic acts of the South American republics, and between 1864 and 1875 his *Annales historiques de la révolution de l'Amérique latine*, in five volumes.

In 1884 he was one of the founders at the Ghent congress of the Institut de Droit International. In the following year he was Argentine minister at Berlin, and published his *Dictionnaire du droit international public et privé*, in that city. Calvo died in May 1906 at Paris.

CALVUS, GAIUS LICINIUS MACER (82–c. 47 B.C.), Roman poet and orator, who, as a poet, followed his friend Catullus (*q.v.*) in style and choice of subjects. He was a son of the annalist Licinius Macer. Only 20 meagre fragments of his poetry survive. As an orator he was the leader of the opponents of the florid Asiatic school, who took the simplest Attic orators as their model. Of his speeches 21 are mentioned, the most famous being those delivered against Publius Vatinius, tribune in 59 B.C. Calvus was very short of stature and is alluded to by Catullus as *salaputium disertum* ("eloquent Lilliputian").

For the verse fragments see W. Morel (ed.), *Fragmenta poetarum Latinorum* (1927); for the prose fragments, see H. Malcovati (ed.), *Oratorum Romanorum Fragmenta*, 2nd ed. (1955).

See also H. J. Rose, *A Handbook of Latin Literature From the Earliest Times to the Death of St. Augustine*, 3rd ed. (1954). (E. A. B.)

CALYDON, an ancient town of Aetolia, according to Pliny the Elder 7½ Roman mi. from the sea, on the Euenus (Evinos) river on a site about 6 mi. E. of modern Missolonghi near the village of Evinokorion. It was said to have been founded by Calydon, son of Aetolus; to have been the scene of the hunting, by Meleager and other heroes, of the Calydonian boar; the Calydonians are said to have taken part in the Trojan War. In 391 B.C. it was in the possession of the Achaeans. After the battle of Leuctra (371 B.C.) it was restored by Epaminondas to the Aetolians. Augustus moved its inhabitants to Nicopolis Actia, founded to commemorate his victory at Actium (31 B.C.). The walls of Calydon, now the *Palaiokastro* of Kurtaga on the Evinos, have a circuit of more than two miles. Excavations since 1925 have

revealed remains of a temple of Artemis Laphria ("the Forager").

CALYPSO, in Greek mythology, daughter of Atlas (or Oceanus, or Nereus), a nymph of the mythical island of Ogygia. She entertained Odysseus (*q.v.*) seven years, but could not overcome his longing for home even by a promise of immortality; at last Hermes was sent by Zeus to bid her release him. In later (Italo-Greek) stories she bore Odysseus a son, Auson, or Latinus.

CAM (Cão), **DIOGO** (fl. 1480–1486), Portuguese navigator and explorer, was the first European to discover the mouth of the Congo river; he also explored the west coast of Africa between Cape St. Catherine (1° 52' S.) and Cape Cross (21° 50' S.). His date of birth is unknown. The surviving records of the two voyages made by Cam are brief. In 1482 John II chose him to explore the African coast beyond Point St. Catherine, the farthest point chartered by seamen of Fernão Gomes. Leaving Mina in June (?) 1482, he reached Loango bay (Praia Formosa de S. Domingos) about Aug. 4. A few days later he discovered the mouth of the Congo and set up a stone pillar (*padrão*) to mark the overlordship of his country (this pillar was destroyed by the Dutch when they entered the Congo in 1642). He then sailed a short way upstream and found its banks inhabited by Negroes, like those of the Guinea coast; they appeared willing to trade.

Cam then coasted southward along the present Angola coast and erected a second pillar at Cape Santa Maria (Monte Negro, 13° 26' S.), probably the most southerly point of his first voyage. He returned to Lisbon before April 1484, when John II ennobled him, granted him an annuity and authorized him to add to his coat of arms two pillars in memory of those he had erected.

During his second voyage, Cam revisited the Congo and subsequently erected two more *padrões*, at another Monte Negro (13° 41' S.) and at Cape Cross (21° 50') respectively (all four pillars were later discovered *in situ*; three are now in museums). The date and place of Cam's death are not known with certainty.

See E. G. Ravenstein, "The Voyages of Diogo Cão etc.," in *Geogr. J.*, xvi, pp. 62j–6jj (1900), also xxxi, p. 615 (1908). (E. M. J. C.)

FIG. 1.—CAM ASSEMBLY FOR A LINOTYPE

cam is an indispensable part of the mechanism. Fig. 1 shows a set of cams assembled on a shaft which actuate and control most of the mechanical action of the Linotype, a machine that sets type for books, magazines and newspapers.

The cam itself may take many forms, such as: (1) a disk or plate of desired profile; (2) a plate with a track cut in the face (face cam); (3) cylindrical or conical members with a track cut around the surface; (4) a cylinder or cone with the end cut to a required profile; (5) a sliding wedge of the necessary shape; (6) spiral or lobed bodies for three-dimensional motion; (7) other special shapes.

The follower that is moved by the cam may have a knife edge at the point of contact, a flat or curved face or a roller to

CAM, a part of a machine or mechanism used for transforming rotary or oscillating motion by direct contact (sliding or rolling) into any prescribed motion of a second part known as a follower. This combination is extremely versatile and useful in performing a great variety of jobs in engines, machinery and household appliances. In machinery where automatic control and accurate timing are necessary, the

a very satisfactory profile when done to a proper scale. Analytical procedures which develop mathematical equations for the profile of the cam can be employed readily for some relatively simple types of motion and combinations of cam-and-follower arrangements, but they may become rather cumbersome at times. The use of digital computers reduces the time and effort to design and produce some types of cams, particularly the plate cam.

High speed complicates cam design, since the dynamics of the complete system then affects the operation. Purely kinematic considerations have to be modified to prevent excessive contact stresses and wear, deformation of parts, the follower losing contact with the cam, and vibrations. Such aspects are very important in motion-picture projectors and cameras, high-speed printing

FIG. 5.—CYLINDRICAL CAM WITH OSCILLATING FOLLOWER

reduce friction. It may also be made to move in a straight line or pivoted about a fixed centre.

A few of the typical combinations are shown schematically in figs 2-8. Engine valve cams generally are of the type illustrated in fig 2 and use circular arcs for most of the profile. This characteristic makes a cam relatively easy to machine, but not always the best for high-speed operation. Computing machines and some automatic machinery use three-dimensional cams for more complex relative motions.

Cam design is one example of a case where kinematic synthesis, the putting together of mechanical motions, can be applied easily. In general, the motion of the follower is known and the appropriate profile for the selected type of cam is then designed. The most widely used simple motions of the follower are simple harmonic, cycloidal, constant acceleration and modified constant velocity. Frequently, however, these have to be modified further because of other requirements of the system. Graphical techniques following basic geometrical principles are available which provide

CAMAGÜEY, a province and its capital city, in east-central

Cuba. Although second in area (10,172 sq.mi.), it was the smallest province in population until about 1925. Thereafter, though it remained sparsely peopled, its population grew rapidly (1953 census, 618,256). The province was established in 1879 as Puerto Principe, the former name also of the capital. Its early importance as a cattle-raising centre has continued, with more than 1,000,000 cattle grazing the wide, gently rolling savannas. After 1900, cultivation of sugar cane expanded until the province became a leading sugar producer. Its northern coast consists of a long archipelago of large cays resting on a very wide insular platform and has no bays of importance except Nuevitas at the eastern end. The southern (Caribbean) coast is swampy with no good natural harbours.

The city was founded in 1514 as Santa Maria de Puerto Principe at the site of present Nuevitas, chief sugar port of Cuba. It was moved inland in 1528 to the Indian village of Camagüey. Because of the great production of livestock, sugar and other agricultural products and of chromite in the province. Camagüey has risen to be the largest interior city of Cuba (pop., 1953 census, 110,388). The city is an important communications, trading and industrial centre. It is on the Central highway and connected by rail with Havana, Santiago de Cuba and the ports of Nuevitas, 45 mi. N.E., and Santa Cruz del Sur, 45 mi. S. It has an international airport.

Camagüey retains many traces of colonial architecture, and the old part of the city contains narrow, irregular streets, interrupted by small plazas. Parts of the original cathedral of 1617 have probably survived later alterations. The prosperity of the colonial city evoked assault by buccaneers in 1668.

(D. R. D.)

CAMALDOLESE (COSGREGATIO MONACHORUM EREMITARUM CAMALDULENSIUM, O.S.B.), an independent Benedictine monastic order founded about 1012 by St. Romuald (*q.v.*) of Ravenna, a former Cluniac abbot. Romuald established a colony of hermits at Campo Maldoli (Camaldoli), an upland valley in the Abruzzi, under the Benedictine rule with an eremitical interpretation and strict silence. The monks inhabited huts within an enclosure that contained the common oratory, their regime being very similar to that of the later Carthusians. The fourth prior, Rudolf (prior 1074-87), founded a cenobitic branch in a nearby valley lower down the mountain for sick and elderly monks and those engaged in administration. Later foundations of both types

presses, engines, machine guns and other equipment.

Cams are made by various processes, such as flame cutting, casting, die forging, stamping, powder metallurgy or machining.

Most industrial cams are produced on standard machine tools, with or without special cam-milling attachments, or on specially designed machines. In one method the desired contour is laid out on the cam blank and the machine operator cuts the

FIG. 8.—THREE-DIMENSIONAL CAM

were made, the cenobitic branch reverting to traditional Benedictine practice; the two congregations were reunited in 1935. At the mid-20th century two eremitical congregations exist, the original institute as above, and a reformed body founded in 1523. In the early 1960s there were about 300 monks in 25 houses. The order spread slowly in the middle ages, but more rapidly in Italy and France in the 17th and 18th centuries. Almost all the monasteries have been founded in Italy, with settlements in Brazil and the United States.

Among notable members of the order have been the canonist Gratian, the humanist Ambrogio Traversari, the painter Lorenzo Monaco and Pope Gregory XVI. The original "desert" of Camaldoli, a picturesque site, is still occupied, though the climatic conditions are severe. The head house of the second branch is at Frascati.

Historically the Camaldolese are significant as the first fruit of the great 11th-century monastic reform movement. Romuald, by adding a note of severity to the Benedictine rule and by choosing the eremitic life, initiated and helped to mold a movement that was to give birth to the Carthusians and the early Cistercians.

See A. Des Mazis in A. Baudrillart (ed.), *Dictionnaire d'histoire et de géographie ecclésiastiques*, vol. xi (1949). (M. D. K.)

CAMARGO, MARIE (ANNE DE CUPIS DE) (1710–1770), Belgian ballerina, the most brilliant dancer of the Paris Opéra from 1726 until her retirement in 1751. A technical innovator, noted for her speed and agility, she perfected the *entrechat* and *cabriole* (jumping steps previously executed chiefly by men), and was the first dancer to shorten her ballet skirts to show her twinkling feet and ankles.

Born in Brussels, on April 15, 1710, Camargo studied in Paris under Françoise Prévost, and danced in Brussels and Rouen before her debut at the Paris Opéra in 1726, in *Les Caractères de la Danse*. Her sensational success provoked the jealousy of her aging teacher, Prévost, who relegated her to the ensemble. However, she soon won an unexpected triumph by improvising a spectacular solo when David Dumoulin failed to enter on cue for a demon dance. The incident created a furore, and Camargo went on to consolidate her popularity, eventually dancing roles in 78 ballets and operas. She died in Paris on April 20, 1770.

Among her many admirers was the Comte de Clermont. A fine portrait of her by Nicolas Lancret hangs in the National Gallery, Washington, D.C. (L.N. ME.)

CAMARGUE, the sparsely populated delta of the RhBne in southern France, between the Grand Rhône and Petit RhBne channels, with an area of nearly 300 sq.mi. The highest ground in this flat district is found along the embankments of past and present channels; in the intervening basins are marshes and shallow lagoons that dwindle during the dry summer. The area is notable for its rich bird life, including flamingoes, and the largest lagoon, the Étang de Vaccarès, is a bird sanctuary. The Camargue is exposed to the blasts of the mistral, the wind that sweeps down the RhBne valley.

The Camargue was formerly little used, except for wintering sheep and rearing bulls for the Provençal bullfights, but it has been extensively reclaimed in modern times for viticulture and, during and since World War II, for rice cultivation. The medieval port of Aigues-Mortes (*q.v.*), within the shell of its old ramparts, is a fossil town. Near the mouth of the Grand RhBne, Port St. Louis is an artificial port of modern creation. (AR. E. S.)

CAMARINA, an ancient city of Sicily, situated on the southern coast near the modern village of Santa Croce Camarina, 17 mi. S.E. of Gela. It was founded by the Greek city of Syracuse c. 599 B.C., as an outpost against Gela, but was defeated by the mother city c. 553 in an attempt to assert its independence.

Hippocrates, tyrant of Gela, received the territory of Camarina from Syracuse and restored the town about 491, but it was destroyed in 483 by his successor Gelon and its population transferred to Syracuse; the people of Gela, however, founded it anew in 461. It was abandoned by order of Dionysius of Syracuse in 405 and paid tribute to Carthage. Restored by Tiinoleon of Corinth in 339, it was destroyed by the Romans during the First Punic War in 258.

Remains of the temple of Athena and foundations of houses are still visible.

See B. Pace, *Camarina* (1927).

CAMARINES NORTE, a province in southeastern Luzon, Republic of the Philippines, fronting on the Philippine sea in the western Pacific, with a land area of 829 sq.mi. and a population (1960) of 188,569. It includes the dozen small Calagua Islands, offshore, and several small islets in San Miguel bay. In the western, mountainous section lumbering and gold mining are the chief industries, the main mining district being Paracale in the north. Along the central east coast is the largest lowland, containing most of the agricultural land and population. Coconuts and rice are the chief crops. In the coastal lowland is located Daet, the provincial capital municipality (pop. [1960] 35,571). (J. E. Sr.)

CAMARINES SUR, a province in southeastern Luzon, Republic of the Philippines, land area 2,060 sq.mi. Pop. (1960) 826,640. Off the northern shores are Lahuy, Quinalasag and Butaanan islands, and about 20 other islets. Volcanic peaks are scattered over the region, interspersed by agricultural lowlands. Lumbering, fishing and agriculture are the chief occupations. Most farms are small, and rice and coconuts are the main crops; abaci (Manila hemp) is an important minor crop.

Naga, the provincial capital and an important commercial city on the railroad, was chartered 1948. Pop. (1960) 55,723. It has one of the largest Roman Catholic cathedrals in the Philippines. Farther south are the local trade towns and municipality centres, Iriga, on the railroad (pop. [1960] 75,847) and Nabua, to the west (pop. [1960] 66,819). (J. E. Sr.)

CAMASSIA (QUAMASIA), a small genus of North American bulbous herbs of the lily family (Liliaceae; *q.v.*), with grasslike leaves and showy white to blue or purplish-blue flowers in graceful racemes. The eastern camass or wild hyacinth (*C. scilloides*) grows from 12 to 18 in., bears violet to blue or white flowers and is popular in rock gardens. The common camass (*C. quamash*) and its numerous variants of the western United States has blue, blue-violet or white flowers, and the Leichtlin camass (*C. leichtlini*), also of the western United States and adjacent Canada, has blue-violet to cream-white flowers. The last-named species is perhaps the most popular for the open border, while the first is most suitable for the rock garden. The bulbs should be planted, preferably in groups of eight or more, in the fall and not be disturbed. (J. M. BL.)

CAMBACÉRÈS, JEAN JACQUES RÉGIS DE, DUC DE PARME (1753–1824), French statesman, the legal expert who was second consul with Napoleon Bonaparte and then archchancellor of the empire, was born at Montpellier on Oct. 18, 1753, of a family long associated with the legal profession. At Montpellier he became counselor in the *cour des aides* in 1774 and president of the criminal court there in 1791. Elected to the Convention as deputy (1792), at the trial of Louis XVI he voted for the sentence of death to be delivered but to take effect only if France were invaded. He discreetly kept clear of party quarrels and concerned himself mainly with judicial and legislative matters. The two successive drafts for a civil code which he and P. A. Merlin (Merlin de Douai) produced were not enacted. After Nov. 1794 he became a member of the committee of public safety and occupied himself with foreign affairs, being instrumental in concluding the peace treaties of 1795 with Tuscany, with Prussia, with the Dutch and with Spain. When the Convention was dissolved he became a member of the Council of the Five Hundred, which put him forward, unsuccessfully, as a candidate for the Directory. A third draft for a civil code on which he also collaborated was not debated. As he was not re-elected in May 1797, he turned to practising law privately. Then, in July 1799, he was appointed minister of justice.

Having discreetly assisted Bonaparte and E. J. Sieyès to organize the coup *d'état* of Brumaire (Nov. 1799), Cambacérés became second consul in the following December. In 1802 he helped materially to establish the life consulate for Bonaparte. Though he disapproved of the execution of the duc d'Enghien and of the proclamation of the empire, he has made archchancellor of the empire in 1804 and given the title of duc de Parme in 1808.

He presided over the senate and, as a rule, over the council of state and exercised extended powers during Napoleon's absences. As Napoleon's principal adviser on all juridical matters from 1800 to 1814, he played an important part in formulating the civil code (1801-04) and the four subsequent codes (1804-10). Often consulted on other matters of state, he tried to temper Napoleon's impetuosity, especially in foreign affairs. According to L. A. Thiers, he was against the attacks on Spain (1808) and on Russia (1812).

Excluded from public life at the Restoration (1814), Cambacérés reluctantly returned to it in the Hundred Days, at Napoleon's bidding, when he directed the ministry of justice and presided over the chamber of peers. Exiled at the second Restoration, he lived in Belgium until 1818, when he was allowed to return to France. He died in Paris on March 8, 1824.

Cambacérés was grave and pompous in demeanour but often showed weakness of character. Clear thinking and deliberate in his actions, with a profound knowledge of the law, he was a fluent and persuasive speaker. He had a European reputation as a gourmet who gave superb dinners.

See J. Thiry, *Cambacérés* (1935).

CAMBALUC: see PEKING.

CAMBAY, GULF OF, a trumpet-shaped inlet of the Arabian sea on the west coast of India, narrowing northward between the Kathiawar peninsula on the west and the coast of Gujarat on the east. Its shape and orientation in relation to the southwest monsoon winds explain its high tidal range (40 ft.) and the velocity with which the tides enter. But it shallows rapidly: all its ports have suffered from silting because of flood torrents entering its head; and shoals and sandbanks are treacherous. On the Bombay side, Broach (*q.v.*) is one of the oldest Indian ports and Surat (*q.v.*) is particularly identified with the rise of direct European contacts with India.

CAMBAY town is at the head of the gulf but was never of great significance; all the ports have been supplanted by Bombay and trade is only local. On the opposite side of the gulf, Bhavnagar suffers less from silting and has been modernized to serve as a leading seaport of the Kathiawar peninsula. (L. D. S.)

CAMBERT, ROBERT (c. 1628-1677) can be considered the first French composer of opera as we know it, though the dramatic sense of the word cannot be applied to any of his works. He was born in Paris about 1628 and became a pupil of the harpsichord composer Jacques Champion de Chambonnières. His first stage work, the *Pastorale d'Issy*, was performed in 1659, with text written by the poet Pierre Perrin. The greatest success of these two men came in 1669 when they were granted by Louis XIV the exclusive right to produce operatic performances. They founded the first Académie Royale de Musique and opened it with a performance in 1671 of their masterpiece, the five-act pastoral opera *Pomone*. In 1672 Jean Baptiste Lully managed to gain the royal "opera privilege" from Cambert, and in consequence Cambert left France for England. He arrived in London in 1673 and is said to have become superintendent of music at the court of Charles II. On the French model he founded a Royal Academy of Musick in Covent Garden, which existed for only a short time. He died in London in 1677, supposedly poisoned by a servant. (B. P.)

CAMBERWELL, a southern metropolitan borough of London, Eng., bounded north by Southwark and Bermondsey, east by Deptford and Lewisham, west by Lambeth and extending south to the county of London. Pop. (1961) 174,697.

Camberwell appears in Domesday Book, but the derivation of the name is unknown. It includes the districts of Peckham, Nunhead, Dulwich (*q.v.*), with its well-known college, and parts of Herne Hill and the Crystal palace site. It is mainly residential, but there are varied minor industries including gas works, engineering, printing and bookbinding. Dulwich park (75 ac.) and Peckham Rye common and park (103 ac.) are the largest of several public grounds, and Camberwell green was celebrated for its fairs until 1855. The South London Art gallery in Peckham road was founded in 1898, and the Camberwell School of Arts and Crafts was established the same year. Kings College hospital and the

Maudsley hospital, to which Bethlem Royal hospital is joined, are in Denmark Hill. Robert Browning was born in Southampton Way, Camberwell (1812); Oliver Goldsmith was a schoolmaster in Peckham; and John Ruskin lived at Denmark Hill and designed the east window in St. Giles's church. The borough is divided into two parliamentary divisions, Camberwell Peckham and Camberwell Dulwich.

CAMBIASO (CAMBIASI), **LUCA** (1527-1585), often familiarly known as **IL LUCHETTO**, Genoese painter and the first master of a native school at Genoa. Son of a painter, Giovanni Cambiaso, he was born at Moneglia, near Genoa, on Oct. 18, 1527. His early style was profoundly influenced by the frescoes of Perino del Vaga and Pordenone (1483?-1539) in the Doria palace at Genoa, and there are substantial echoes in his work of Correggio and Veronese; but his mature style was original and distinctive. He executed an immense amount of work in fresco for Genoese palaces and churches sometimes co-operating with his father or, later, with Giambattista Castello (1509?-1569) from whom he learned much about space composition, drawing and colour. Most of his altarpieces and subject pictures remain in Genoa and its neighbourhood.

His turbulent and Mannerist early style gave way to a more calm and measured sense of pattern, and a number of his later "nocturnes" had a profound effect on baroque painting. He was summoned to Spain by Phillip II in 1583 to succeed Castello in painting frescoes at the Escorial. His lively and attractive drawings are very numerous and many show the heads and principal forms blocked out in a broad cubistic manner. He died at the Escorial in Madrid, Sept. 6, 1585. (E. K. WE.; X.)

CAMBIO, ARNOLFO DI: see ARNOLFO DI CAMBIO.

CAMBODIA (CAMBODGE), a far eastern constitutional monarchy which, before achieving full independence in 1955, was a French protectorate and an associate state (1949-55) of the French Union. Practically landlocked, its 66,606 sq.mi. are bordered by Thailand (Siam) to the northwest, by Laos to the northeast and by South Vietnam to the southeast. Its capital, Phnom Penh, stands to the southeast on the Mekong (*q.v.*) river.

Physical Geography. — Formed mainly in a recently alluviated tectonic depression, much of the surface of Cambodia is a low-lying plain round the lake Tonle Sap (Great lake), a natural flood reservoir of the lower Mekong and its distributaries. North of it rises the dry, steep, flat-topped Chaîne des Dangrek (Phanom Dang Raek) sandstone scarp adjoining which to the east are low hills through which the Mekong enters from the north, separating the scarp from outliers of the Chaîne Annamitique. The Cambodian plain is geologically continuous northwestward with the Bangkok plain but to the southwest is edged by the abrupt Cardamom mountains making a rocky coast poorly accessible from land and sea. The plain is regularly flooded over large areas and carries much tropical fresh-water swamp vegetation. The Tonle Sap, nowhere deeper than 6 ft. during the dry season, contains thick aquatic plants which hasten sedimentation and often hinder boats. Settlements are attracted to waterside for the transport facility and to low hills for safety from the extensive floods. The climate is tropical, warm and humid, with heavy summer rains and some cool season rains near the Cardamoms where the rainfall may exceed 250 in. per year. (E. H. G. D.)

Archaeology. — There is no evidence of Paleolithic cultures in Cambodia; such stone implements as are known belong to the Neolithic phase, though they are, in part at least! contemporary with bronze implements in the same region. The objects are from certain kitchen middens, open sites and surface finds; there are also museum specimens of uncertain provenance and age. The material is sufficiently distinct to be grouped as the Somrong-sen culture after a site to the southeast of the Tonle Sap discovered by P. Koques in 1876 and more fully investigated by H. Mansuy. Further researches, notably by Étienne Patte and Paul Lévy, show a wider distribution in the region of the Tonle Sap and its extension northward into Vietnam. In no site has more than one archaeological level been observed. The artifacts include shouldered hoes, axes, adzes, chisels and gouges, with hammerstones, grindstones, polishers, disks, cylinders and bark beaters

and a few knives and scrapers; fishhooks, harpoons, shell ornaments and stone beads are also known. The manufacturing processes include percussion, sawing and polishing; axes show unequal bifacial grinding of the cutting edge, an apparent characteristic of southeastern Asia. Some tools show affinities with the later stage of the Bacsonian culture. All the pottery is handmade, poorly fired and unpainted, decorated with cord patterns, incised geometric designs and arrangements of curved and wavy lines. Some of these patterns, as well as the forms of the vessels, are known from southeastern China. The presence of crucibles with the bronze finds points to some local manufacture, though the types are known from Laos, Burma and Yünnan. The evidence available does not permit precise dating, but it seems unlikely that the sites are much earlier, though culturally less rich, than those of the more northerly Dong-son culture complex.

In the absence of stratified sites, the relation between the Somrong-sen culture and the later phases of Cambodian civilization has not as yet been established. Early Chinese accounts of the life of this region suggest that it cannot have been very different from that exemplified by the material discussed above. Certain sites in the Transbassac, southwest of Saigon, probably represent the earliest considerable western influences upon Cambodian Neolithic and Aeneolithic peoples. These sites, discovered by aerial reconnaissance, were partially investigated by the École Française d'Extrême-Orient during the years 1942-45. They show traces of brick buildings upon heavy granite foundations as well as pile dwellings. There is evidence of a vast system of canals both for irrigation and for navigation between what appear to be settlements of considerable size. The best known of these, Oc Êo, is a rectangle, 3 km. (1.9 mi.) long by 1½ km. wide, about 24 km. (15 mi.) from the sea today. This is connected by canal with another site, Ta Kèo, which seems to have served as its port. It seems almost certain that this great complex of interconnected sites represents the Fou-nan (Fu-nan) of the Chinese texts, first located in this region by Paul Pelliot. Excavations at Oc Êo have revealed evidence for wide trade relations, in southern Asia (confirming, strikingly, the Chinese accounts). There is also evidence that this region, obviously influenced markedly by Indian cultures, shared with other regions of southeastern Asia stone-using techniques hitherto associated in this area with the building of megaliths. The emphasis upon the mountain (Fou-nan = *phnom*, "mountain") in religion and toponymy seems connected with other local widely scattered cults. Finds on the site include gold ornaments, totaling 1,200 g, in weight, some bronze objects, a surprising number of artifacts in tin and lead, intaglios, cameos and terra cottas, vast numbers of beads made of glass and semiprecious stones, with implements and tools of wood, iron and stone.

The inscribed seals, carnelian, bronze and tin have their legends in Sanskrit and date from the 2nd to the 4th centuries A.D. A glass disk shows the bust of a man with Scythian headdress, plaited hair and beard, smelling a flower, a known Sassanian motif. Roman finds include intaglios, some with grylli, and two gold bracteates, one being of Antoninus Pius, datable to A.D. 152. These last almost certainly derive from India. A later Han mirror testifies to Chinese connections. But the indigenous decorative styles, relying upon natural themes with a marked marine and littoral bias, seem to point to a strong Indonesian element in the culture of Fou-nan.

Architecture and Art.—

There follows a further gap in knowledge of Cambodian archaeology, though this can be filled to

some extent, so far as architecture is concerned, by the representations of buildings in low relief on surviving buildings of the earliest Iihmer period and of the last stages of the kingdom of Tchen-la (see below). To this period may belong some nooden Buddhist statuary in the Saigon museum and one or two pieces in stone from the lower Mekong which are strongly Indian in influence. The buildings which survive suggest the adaptation of nooden architectural techniques to buildings in more durable materials. Thus the external roof is constructed in stories which do not reflect the internal vaulting. The predominating horizontal lines suggest nood frame structures. There are, in fact, two styles of building, though both are characterized by single-chamber structures (*prasat*). The more simple is without the large base and the rich ornamentation of the other with its projecting niches on four sides (three with false doors) and its higher, though fener-storied, roofs. To this period, the 7th century belong the temples of Sambor Prei Kuk in Kompong Thom, probably the capital, Içanapura, of Içanavarman I (616-627?) to whose reign are to be assigned also the first buildings of Phnom Bayang. Asram Maha Rosei is of interest because of the fine Harihara image (in the Musée Guimet, Paris) which was found in it and because the building, in stone instead of the more usual brick of this period, was shown by Mauger to be derived from Indian originals which include the cave temples of Ajanta (its undoubted Javanese affinities with the temples of the Dieng plateau being cognate rather than direct). From this region (Phnom Da) came a Vishnu, with two other statues (probably of 6th-century), now at Phnom Penh.

After the Sambor period, which marks the beginning of the decline of direct Indian influence, it is possible to distinguish a period when Cambodian architecture evolved along existing lines (Prei hmgeng period). To this phase belongs the fine Harihara of Prasat Andet. By the second half of the 8th century (Kompong Prah period) the step pyramid style emerges (Ak Yom), though it is clear that by Sambor times the single *prasat* was giving way to quincuncial arrangements of temples. The reproduction of buildings in low relief as suitable ornament for the pediment gives way to garlands and vegetal designs. At Kulen in the 9th century a large group of temples shows signs of a conscious archaism, reflecting styles of the Sambor period, which is a marked feature of Khmer art history. In the styles of Kulen and the succeeding Prah Ko period there are also clear traces of Javanese and Cham influence; these styles recur, characteristically, in the 10th century (Bantéay or Banter Srei), whence in turn the sculptors of the 12th century drew inspiration, as also from Dvaravati (southern Siam) in their Buddhist works. The reign of Jayavarman II saw the establishment of a succession of capitals, one at Prasat Ak Tom, another at Kulen and the fourth at Roluos.

BY COURTESY OF UNITED NATIONS

TEMPLE AT ANGKOR WAT, CAMBODIA: 12TH CENTURY

During the last phase of the 9th century Trapéang Phong (main temple), Prah Ko (879), Bakong (881) and Lolei (893) were erected. These mark the firm establishment of classical Khmer architecture with its groups of buildings on terraced platforms, gradually to be integrated by connecting corridors of increasing complexity (as problems of vaulting were overcome) and by a transition from square to cruciform ground plans for the buildings. The façades are adorned with panels of divine figures, the lintels are more ornate, the Naga theme becomes more prominent and the profiles of the buildings more ambitious. Statuary, too, exhibits the emergence of a Khmer type, freed from the traditions of its Indian originals with their typical *hanchement* (with the weight on one foot and the opposite hip emphasized).

Yaçovarman I moved his capital from Roluos to Siem Reap, where he founded Yasodharapura, the first city of Angkor, with its centre at Phnom Bakheng. The Bakheng period marks the change from brick, with stone embellishments, to stone as the principal building material. Apart from a brief interval when the court moved to Koh Ker (921-944); some 70 mi. N.E. of Angkor, this was to remain the area of the capital for four centuries. To the period immediately after the return from Koh Ker belong the Eastern Mébon and Prh-Rup structures. Bantéay Srei temple follows (967). Next come Ta Kèò, Phimeanakas and the *gopuras* (gateways) of the royal palace (Kléang period). Later in the 11th century the Western Mébon and Baphuon were built, probably by Cdayadityavarman II. Suryavarman II celebrated some years of successful, if transitory, campaigning by the construction of the chief masterpiece of Khmer architecture, Angkor Wat itself, a galleried temple complex adorned in low relief with scenes from the Hindu epics and of the royal court and army, the king himself appearing twice. After a period of setbacks at the hands of the Chams (who sacked Angkor in 1177), the situation was restored by Jayavarman VII. He completed Prah Khan, Ta Prohm and Bantéay Kdei, the latter marking, with parts of Ta Prohm, the transition from the Angkor Wat period to that of Bayon, the last great Khmer building, which formed the centre of the precinct of Angkor Thom with its five gateways constructed by Jayavarman VII as his capital. The great Buddha heads which are carved on the temple towers portray the king as Lokeçvara, a Buddhist deity in great favour among the Khmers. The building underwent many transformations during its construction, which already foretells the rapid decay of Khmer craftsmanship, in part, no doubt, exhausted by wars and by the need for continuous and increasingly ostentatious buildings. The final stages of Khmer architecture are exemplified by Bantéay Chmar and the royal terraces. In addition to these temples, Jayavarman built 121 resthouses and 102 hospitals and numerous roads for the use of pilgrims. A fine statue, almost certainly of this great king, from Angkor Thom, is preserved in the museum at Phnom Penh.

Of Khmer work in bronze, only one example, outstanding both in its artistic and in its technical mastery, can be mentioned here: the head, about 114 cm. high, of a sleeping Vishu, which can be dated to the middle of the 11th century. This is the only surviving specimen of Khmer monumental work in bronze, but it leaves no doubt as to the technical skill of its founders. In stone the Khmer craftsman rapidly achieved independence from Indian models, as can be seen in the earliest datable statues, those from Phnom Da. Thus, though his work was still governed by the fundamentals of Indian iconography, the treatment cannot be confused with Indian work upon similar themes; nor did he adopt all the Indian repertoire, erotic and macabre subjects being almost entirely absent. At least once, in the portrayal of the horse-headed avatar of Vishnu from Kuk Trap (now at Phnom Penh; ? early 7th century) the artist achieved a harmonious blending of the horse's head with the human trunk which is an astonishing resolution of technical and artistic problems. From the 6th until the beginning of the 9th century the craftsman continued the practice of supporting the limbs of his statues by means of a horse-shoe arch or at least a stone bar behind the upper limbs. This requirement seems in part to have been inspired by the reminiscence of Indian work, which seems to prefer high relief to freestanding statuary. But the need to support the multiple limbs

with their attributes and a mistrust in the properties of the available material (certainly justified in the case of schist, a favourite stone) also played parts in this practice. In the early period there is a noticeable trend toward naturalism, but a renaissance under Jayavarman II marks a hieratical tendency in which the forms are markedly more architectural. This tendency continues, though there is an astonishingly dynamic phase which coincides with the move to Koh Ker. With the return to Angkor there develops a period of conscious archaism, which evolves stylistically during the 11th century, but at the beginning of the next century hieratical styles reappear, the statuary being richly adorned with jewels and diadems. Under Jayavarman VII, there is a return to austerity: the benign smile and gestures of the hands replace adventitious aids to religious majesty. At this time, too, statues from the life appear, of the highest merit. But even these rely for their effect upon the traditions of the Khmer artists with their marked preference for hieratical poses and the impressionistic rendering of flesh and musculature. The later statuary shows strong Thai influence, but Thai sculptors in the 16th century were still content to copy Khmer originals of the classic periods. (See also INDIAN ARCHITECTURE: *Malaysia*: Cambodia.)

(A. H. CE.)

History. — Modern Cambodia occupies the territory of an early Khmer kingdom called Fu-nan (Fou-nan) in first Chinese references, founded by migrants from the Indian subcontinent who came during the first four centuries A.D. Although evidence is scanty regarding the numbers of these colonists local inscriptions and early Fu-nan monuments show that they were considerable. The physical difficulties facing Indians traveling to Cambodia were great as their ships were small and their navigation simple. Many came by two sea journeys with a portage across the Kra isthmus. Others arrived by the longer sea route touching the old-established Indian colonies in Sumatra and Java. The settlers seem to have included some who once were colonists in Java and Sumatra. The Indian migration was largely one way; the colonists came to settle and never formed part of an Indian empire. Two-way journeys were facilitated in the South China sea only where the seasonal reversal of winds made it possible to come and go between Cambodia and Java. The cultural contact with India persisted through several centuries despite Siamese kingdoms west of Cambodia becoming stronger and hindering transport in Kra. The Java contact accounts for place names in Cambodia and along the lower Mekong river resembling the Javanese. Cambodian speech, unlike most Indochinese languages, is largely polysyllabic and rendered in a script derived from India.

The Indian colonists intermarried with the indigenous population which was of south Mongoloid stock drawn from what are now east Tibet and Yunnan, the mixture being known as the Khmer race, in which the Indian strain was strong, persisting in physique, language, religion and in techniques of building and farming. Indians introduced the paddy (rice) plant to Cambodia. Contact with imperial China was intermittently close and the reports by imperial Chinese scholars and travelers were the chief historic sources. By transliterating local Indian-type names into Chinese characters these reports create a confusion of Cambodian place and personal names which few can reconcile: Fu-nan and Tchen-la are different Chinese renderings of the same place name, the former descriptive ("southern kingdom"), the latter a rendering of the word "Khmer." Internal struggles in the 9th century led to the consolidation of the country under a dynasty (whose names are south Indian) which used Angkor as capital, though the wat or temple whose famous ruins now stand there was built in the 12th century when the power of the Khmers was also indicated by their wars against Annam (part of modern Vietnam, *q.v.*) and against imperial China (A.D. 1132). The medieval wealth of Cambodia derived from its rice production (large for the times), and from tolls on the luxury caravan trade passing through between India and China. Its wealth drew pressures from the north by way of what is now Laos, and from the west where Thai chieftaincies were consolidating into a strong kingdom in the plains of Siam, then also being opened up to paddy farming. The Khmers suffered repeatedly from domestic instability caused by the varying per-

sonalities heading the semireligious, semimilitary hierarchy. In one weak phase, a Cham (*q.v.*) fleet sailed into Tonle Sap from the lower Mekong to threaten the sacred capital at Angkor. Added difficulties arose from rivalry between the earlier Hindu Brahmins and later proselytizing Buddhists. The king who averted defeat at Angkor (Jayavarman VII, *d.* 1181–c. 1220) later harassed the Champa (*q.v.*) kingdom, and extended Khmer power through Siam as far as the Shan country in Burma and through Kra into what is now Malaya. Such large personal empires were endangered by slow, difficult transport overland and overseas. After this expansion, Mongolian domination over central Asia and China began to be felt, first in intensified attack by the Thais under pressure from the Mongols in Yunnan. The Mongol Khans later attacked Cambodia directly and Kublai Khan drew tribute from the Khmer under Jayavarman VIII (1243–95) at the end of whose reign Thais from the Korat plateau repeatedly penetrated the kingdom.

Thai attacks were increasingly powerful after the mid-14th century so that the royal capital at Angkor was finally abandoned by Suryavarman III (1405–c. 1450) who withdrew toward the Mekong near Phnom Penh. The western and northern frontiers were fatally weakened and repeatedly controlled by Thais during the next four centuries. At the same time the Annamites, with backing from imperial China, were extending southward to the Mekong mouths and westward across the *Chaine Annamitique* to reach the eastern banks of the middle Mekong so that the Khmer gradually lost their eastern borderlands. By the mid-18th century Cambodia was a small and poor rump of the Khmer empire, tolerated by the vigorous Thai and Annamite kings as a buffer state. Cambodia's status was that of a vassal to both kingdoms.

French Domination.—Although Portuguese and Spanish navigators reported visits to Cambodia in the 16th century the country remained off the track of European influence until well into the 19th century. After 1858 when the French, spurred by the extension of British power in Burma, followed their missionaries in Annam with trade and military pressures, Annam ceased to exert direct suzerainty over Cambodia which was left to the mercy of its traditional enemies, the Thais, who took the opportunity to seize the Battambang and Siem Reap provinces. The Annamite claim on Cambodia was then taken up by the French who persuaded Norodom I (1859–1904) to accept for Cambodia the status of French protectorate in order to secure its defense from Thai attacks. The treaty establishing the protectorate was signed by Norodom I on Aug. 11, 1863, and was later ratified by the French government. As a result of these events Cambodia's older political problem of balancing Thai and Annamite power was converted into one of balancing Thai and French rivalry. Siam, as the Thai kingdom was then more generally known, still possessed Battambang and Siem Reap but the Franco-Siamese treaty of 1867 recognized the status of France in Cambodia. Meanwhile in 1866 the capital had been moved to Phnom Penh.

The occupied western provinces remained an issue which both French and Cambodians pressed until, by treaty in 1907, Siam ceded Battambang and Siem Reap. In 1940, taking advantage of French commitments in Europe, the Siamese sent military forces once again into western Cambodia. In this border war, the Japanese, who had not yet entered World War II but were already in 1940 in *de facto* control of much of Indochina, affected to act as arbitrators. In March 1931 they awarded Battambang and Siem Reap to Siam. The disputed provinces changed hands again in 1945, after the defeat of the Japanese in World War II, when Siam handed them back to Cambodia.

Independence Movement.—In 1945 the question arose as to whether the French should or could resume their former status as the protecting power in Cambodia. The monarchy had been maintained through the French and Japanese periods and had shared power with an aristocracy in a manner outmoded elsewhere. It became a constitutional monarchy in 1947 when on May 6 a new constitution was granted as a consequence of the new liberal atmosphere and with the objective of enabling nationalism to focus on the historic monarchy and the person of Norodom Sihanouk, who had succeeded to the throne in 1941, rather than be drawn to Communism. Nationalism in Cambodia had been a force for some

years as evidenced by the risings in 1876 and 1885. The Cambodian aristocracy had maintained an ambiguous position *vis à vis* the French, skilfully exploiting the conflicting interests of Siamese, French and Japanese in turn. During World War II there was established a Cambodian party called Khmer Issarak ("Free Cambodia"), at first sponsored by the Free-French to form an anti-Japanese fifth column. After the war the Khmer Issarak emerged as nationalists and monarchists, able to press and resist the French without embarrassing the king and without suggesting a revolution since the Khmer Issarak initially had no Communist ties. These internal pressures enabled Cambodia to secure many advantages from the French, preoccupied as they were by campaigns in Vietnam and, when independence within the French Union was granted to Vietnam in 1939, Cambodia quickly (on Nov. 8, 1949) received similar status without fighting about it.

Immediately afterward (1950) the traditional pressure of Annamites in Cambodia took a new form. The Vietminh Communists of North Vietnam stimulated the formation of several small Communist groups in Cambodia, linking them with elements of the Khmer Issarak and similar groups in Laos into a united front aiming at internal revolution rather than the actual eviction of the French. The guerrilla war then going on between French and Vietminh forces was extended into Cambodia where North Vietnamese insurgents appeared. Cambodia was already disorganized and politically uneasy as a result of the attempts of the king to deal with his first elected assembly. International alarm at these confusions led to the Geneva conference of 1954 at the conclusion of which, on July 21, both Vietminh and the French agreed to withdraw their forces from Cambodia. Cambodia's frontiers were guaranteed by the Southeast Asia Collective Defense treaty signed at Manila on Sept. 8, 1954. In March 1955 Norodom Sihanouk abdicated and his father, Norodom Suramarit, came to the throne. The former king who had gained much diplomatic and political skill during the complex changes which occurred while he was on the throne then led a party entitled the Socialist People's Community party in a general election. The name of the party suggests a Communist alignment belied by its leadership. At the polls no members of other parties were successful and the assembly contained only supporters of Norodom Sihanouk who became prime minister in Sept. 1955. His first act was to secede completely from the French Union. Since that date Cambodia has been independent in the fullest sense. In foreign affairs its policy has been one of neutralism. Norodom Sihanouk became head of state again after the death of his father on April 3, 1960. (See also **INDO-CHINA**.)

Population.—The population was estimated at 4,740,000 in 1958. Minority groups included 250,000 Vietnamese (often called Annamites) immigrants from the coast who pioneered large paddy farms to the south and east, almost as many Chinese immigrants who handled the marketing of Cambodian rice and fish, and 85,000 Chams to the northeast beyond the Mekong, together with primitive, isolated hill tribes (Stieng, Phnong, Por).

Most of the Cambodian people (about 3,000,000), are descendants of the Khmer, resembling the Siamese and Burmese physically, culturally and linguistically, influenced by medieval south Indian settlers who intermarried freely with the Mongoloid tribes they found in Cambodia. Hindu mythology persists and is prominent in local literature, though the majority of Cambodians now practise Buddhism of the Little Vehicle with supreme authority vested in the king. They are mainly vegetarian, and have well-developed music, dancing and domestic arts. Their way of life is rural, dispersed on low-grade, largely self-contained paddy farms. Many live in houses built on stilts. Cambodian speech, unlike most Indo-Chinese languages, is largely polysyllabic and rendered in a script derived from India. French is widely spoken and is still largely the official language of government and commerce.

Administration.—Cambodia, according to the 1947 constitution, was a hereditary monarchy lineally of male descendants of King Ang-Duong. The constitution was amended in June 1960 whereby parliament could confer the powers of the chief of state on a person chosen by national referendum. Parliament is bicameral and legislative power is vested in a 61-member national

assembly (elected for four years by universal suffrage) and the 24-member council of the kingdom.

The country is divided into 14 provinces: Kompong Cham, Battambang, Kampot, Siem Reap, Kompong Chhnang, Kompong Speu, Takeo, Kratie, Stung Treng, Svay Rieng, Prey Veng, Pursat, Kandal and Kompong Thom. Phnom Penh (*q.v.*), the capital and largest town grew rapidly after independence brought to it administrative departments and foreign agencies. Battambang (*q.v.*) is capital of the lake province.

In the early 1960s there were more than 3,220 primary schools and 40 secondary and technical schools and in addition there was a Buddhist university at Phnom Penh, and teacher's training colleges, schools of law, medicine and administration.

The country, which is divided into five military districts, has a small army, navy and air force.

The Economy.—The economic basis of Cambodia has always been the regular and easy productivity of plains round the shallow Tonle Sap which annually floods more than 2,000 sq.mi. of farm land, naturally replenishing fertility and irrigating paddy. Its historic advantage has not been maintained since changing techniques have left the Cambodian yield far below yields in Japan, Italy and many other countries. The wet farming facilitated by the natural floods was originally pioneered by Hindu colonists who found there the optimum rice growing conditions for their times, enabling them to support large armies and a major monarchy. Rice is supplemented by a large fish catch from the lake, providing a protein food fundamental to rice eaters and, in dried form, another basis for trade. Such remains the economy. Annual paddy production in the early 1960s (from about 2,600,000 ac.) averaged 1,200,000 metric tons, having fluctuated with the unstable position between 800,000 and 1,530,000 tons during the post World War II decade. The acreage harvested has roughly doubled since the 1930s with the increase coming largely from Annamite immigrants opening up new lands along the Mekong distributaries. The oldest and main paddy area is around Battambang where a static phase has been reached. Substantial areas are also under maize (corn). East of the Mekong and near Kampong Cham are rubber plantations. Cattle are raised, mainly for draft, and pigs are shipped to the towns and South Vietnam. Rice exports, more than 250,000 tons annually, are moved downstream across the South Vietnam border to enter international trade at Saigon and Cholon. Insecurity in postwar Indochina greatly reduced the amount of rice exported as Cambodia was the chief Indochinese source before 1940. Fish is caught in Tonle Sap and the annual catch amounts to about 135,000 tons. After 1960 cotton cultivation was attempted but remained a minor interest. Tobacco is grown widely for home use. Chinese immigrants introduced pepper culture to the south around Kampot. Other spices are casually produced in the humid valleys of the Cardamom mountains.

Cambodia currency is the riel, nominally equated with the currencies of Laos and South Vietnam. More than 40% of Cambodian exports in the early 1960s went to other far eastern countries. Imports (about 60%) also came from the far east (chiefly Japan) and about 30% from Europe (chiefly France). After 1954 rubber exceeded half the value of Cambodian exports with rice as next in importance, and textiles, machinery and transport equipment dominated the imports.

The national income in the early 1960s averaged about 2,000,000,000 riels yearly; the national budget exceeded 3,000,000,000. However, these figures do not reflect accurately the significance of the substantial U.S., French and Communist Chinese aid programs, nor the "aid in kind" received under the Colombo plan and Soviet assistance.

Since Cambodia is almost landlocked, commodities must be exported via South Vietnam. For this reason a new port Sihanoukville, at Kompong Som on the Gulf of Bangkok has been built. Rail links from Battambang to Phnom Penh and from Phnom Penh to Saigon are interrupted by the unbridged Mekong. Domestic trade movements are largely by water. Located at the Tonle Sap-Mekong confluence, Phnom Penh is the junction of 900 mi. of navigable waterways in the Mekong and Tonle Sap, where shallow craft handle local trade; from there steamers of up to

3,000 tons carry rice through Mekong distributaries to Saigon for reshipment overseas. Airfields at Phnom Penh and Siem Reap are used by services between Bangkok and Saigon. Three major roads cross Cambodia, all originally designed by the French for strategic purposes: one lies east of the Mekong linking Laos to Saigon, the other two traverse Tonle Sap on the northern and southern sides providing links into Thailand. A further road links Phnom Penh with Kompong Som.

CAMBON, JULES MARTIN (1845-1935), French administrator and diplomat who played a part in European politics as ambassador to Germany before World War I, brother of Pierre Paul Carnbon (*q.v.*), was born in Paris on April 4, 1845. He was called to the Paris bar in 1866, served as captain in the Franco-German War and entered the civil service. He was prefect of the *départements* of Nord (1882) and Rhône (1887) and governor general of Algeria (1891). In 1897 he was transferred to the diplomatic service and appointed ambassador to the United States; in that capacity he negotiated in 1898 the preliminaries of peace on behalf of Spain, after the war with the United States. In 1902 he was sent as ambassador to Madrid and in 1907 to Berlin. In 1898 Paul Cambon became French ambassador in London, and thenceforth the two brothers worked in close accord to frustrate the designs of the war party in Germany. In Oct. 1915 he became secretary-general of the ministry of foreign affairs, a post specially created for him. In Jan. 1919 he was appointed one of the five members of the French delegation to negotiate peace and presided over the peace conference's committees on Czechoslovak, Greek and Polish affairs. He was one of the signatories of the treaty of Versailles and afterward was the chairman of the Ambassadors' conference (1919-31). A writer of distinction, Cambon was elected in 1918 to the French Academy. He died at Vevey, Switz., on Sept. 19, 1935.

See J. Cambon, *The Diplomatist* (1931); Geneviève Tabouis, *The Life of Jules Cambon* (1938).

CAMBON, PIERRE JOSEPH (1756-1820), French revolutionary leader important for his attempt to stabilize the national finances: was born at Montpellier on June 10, 1756. As representative of Hérault in the Legislative Assembly and in the Convention, he was at first sympathetic to the Girondins against such men as Marat. He voted, however, for the execution of Louis XVI and for measures against the *émigrés* and was vehement in his denunciations of Dumouriez, though he opposed the creation of the Revolutionary Tribunal in March 1793 and interceded for the Girondins in June 1793. Thereafter he put his financial acumen to the service of the Montagnards; and the Grand Livre de la Dette

Publique, a register of all the state's creditors, adopted on Aug. 24, 1793, after his report of Aug. 15, was a major contribution to stability (for the financial crisis see for instance ASSIGNATS). Attacked by Robespierre as a reactionary, he replied so forcefully as to precipitate his enemy's downfall (8–10 Thermidor; July 26–28, 1794); but in the ensuing persecution of the Montagnards by Tallien, he was accused of malversation, excluded from the financial committee and eventually driven into hiding until the amnesty of 4 Brumaire (Oct. 26, 1795). He then retired to his estate at Terral, near Montpellier, where he lived quietly for 20 years. Elected to represent Hérault in the Napoleonic chamber of the Hundred Days, Cambon made a final speech against the prospect of a second Bourbon restoration. Then, exiled as a regicide in 1816, he withdrew to the Netherlands, where he died, near Brussels, on Feb. 15, 1820.

See F. Bornarel, *Cambon et la Révolution française* (1905); R. Arnaud, *Cambon, 1756–1820* (1926).

CAMBON, PIERRE PAUL (1843–1924), French administrator and diplomat who as ambassador to London was one of the makers of the Anglo-French alliance, was born in Paris on Jan. 20, 1843, the son of a tannery owner. He was called to the Parisian bar and became private secretary to Jules Ferry during the Commune. In 1872 he was prefect of the *département* of Xube and in 1877 of the Nord. Joining the diplomatic service he was successively resident-general in Tunisia (1882) and ambassador to Madrid (1886) and to Constantinople (1891). In 1898 he became French ambassador in London after the Fashoda incident had embittered Franco-British relations. Cambon set himself the task of improving those relations, and so successful was he that in 1904 he signed with Lansdowne the Anglo-French agreement.

The culmination of his long years of work was reached in Nov. 1912 with the exchange with Sir Edward Grey of the famous letters regarding naval and military co-operation between France and Great Britain in the event of war. Despite anxious moments in the early days of Aug. 1914, Cambon never wavered in his belief in Great Britain, and its participation in World War I on the side of France crowned his lifework. During the war he laboured to smooth away difficulties and allay irritations between the Allied commands. When the peace had been signed at Versailles, Cambon felt that the hour of his retirement had come. He left London in 1920 amid manifestations of regret rarely displayed to the ambassador of a foreign power. He died in Paris on May 29, 1924.

See his *Correspondance 1870–1924* (1940–46) and *Paul Cambon, ambassadeur de France, par un diplomate* (1937).

CAMBORNE-REDRUTH, a large urban district (1934) in the Falmouth-Camborne parliamentary division of Cornwall, Eng. Camborne is about 4 mi. W.S.W. of Redruth, which is 10 mi. N.W. of Falmouth. Pop. (1961) 36,090. Area 34.5 sq.mi. The area is divided into the Camborne, Redruth, Illogan, St. Day and Lanner wards and comprises the villages of Portreath, Four Lanes, Beacon, Troon, Tuckingmill and Carharrack. Richard Trevithick, inventor of one of the first working locomotives, was born in the area, and the safety fuse was invented by William Bickford of Tuckingmill. William bfurdoch invented gaslighting in his house in Redruth. At Camborne is the famous School of Metalliferous Mining. The principal industries are engineering, tin mining; and the making of quarrying and mining machinery and equipment, textiles and safety fuses.

CAMBRAI, a town in northeastern France, the seat of an archbishop and the capital of an *arrondissement* in the *département* of Nord, is 59.5 km. (37 mi.) S.S.E. of Lille, on the main line of the Korthern railway and on the Scheldt river. Pop. (1954) 28,230. In World War I the town was occupied by the Germans from Aug. 1914 until Oct. 1918, and suffered much damage from the fighting (see **CAMBRAI, BATTLE OF**). In World War II it fell to the Germans in 1940, and suffered damage by bombing both then and in 1944. The former cathedral was destroyed after the French Revolution. The present cathedral of Notre Dame was built in the 19th century on the site of the old abbey church of St. Sépulcre. The church of St. Géry (18th century) contains a marble Renaissance rood screen. The triple stone portal, which gave entrance to

the former archiepiscopal palace, is also of the Renaissance period. The Tour St. Martin is an old church tower of the 15th century, much restored and turned into a belfry.

Before 1914 Cambrai was a prosperous industrial town, its chief industry being the weaving of fine fabrics (see **CAMBRIC**); there was also wool spinning and weaving, bleaching and dyeing. The town made a remarkable recovery from the two world wars; it is the centre of a rich agricultural district producing sugar beets, grain, fodder, flax, butter and cattle, and its trade and industry are largely linked with these.

Known in Roman times as Camaracum, the place had until the middle of the 10th century an obscure history, which included invasions by Normans and Hungarians; and from the 10th to the 12th centuries the people were dissatisfied with their bishops, foreigners imposed on them by the emperor. In 1227 the citizens obtained rights which were published by the bishop in the *Loi Godefroy*; but the town and its environs, Cambrésis, which at one time constituted a duchy, continued to be a bone of contention among its neighbours—the counties of Flanders and Hainaut and the kingdom of France, the empire and England—and it frequently changed hands until it was assigned to France by the treaty of Nijmegen (1678). The alliance formed in 1508 by Pope Julius II, Louis XII, the emperor Maximilian I and Ferdinand the Catholic of Aragon, against the republic of Venice, was called the League of Cambrai; and the treaty between France and the empire was signed at Cambrai in 1529. The bishopric, which dates from the 5th century, was raised in 1559 to the rank of an archbishopric, which lasted until the Revolution and was later restored. The bishops were made counts by Henry I (919–936) and dukes in 1510.

See also references under "Cambrai" in the Index volume.

CAMBRAI, BATTLE OF, a British offensive on the western front in Nov.–Dec. 1917, during World War I, carried out by the 3rd army (Gen. Sir Julian Byng), mainly to relieve pressure on the French front. The country, being rolling chalk downland, was specially suitable for tanks, and the battle was the first engagement in the war in which they were effectively used on a large scale. Nineteen divisions were assembled, supported by the tanks (476 in all, of which about 324 took part) and five horsed cavalry divisions. For the initial attack eight divisions, with 1,000 guns, were deployed against three German divisions with 150 guns.

The attack began early on Nov. 20, against the famous Hindenburg position, on a 10-mi. front about 8 mi. W. of Cambrai. Good progress was made at first, but bad weather intervened, and the cavalry could not exploit the advantage. By Nov. 29 the attack had been halted after an advance of about six miles.

On Nov. 30 the Germans counterattacked with 20 divisions. By Dec. 5 the British forces had been driven back—half way to their original positions in the north and about two miles beyond them in the south. Casualties on both sides were about equal—45,000 each. Many authorities believe that a great opportunity was lost by the failure to exploit the initial success.

See J. E. Edmonds, *A Short History of World War I* (1951).

(C. N. B.)

CAMBRIAN SYSTEM, in geology, is the name applied to the oldest group of rocks in which fossils showing recognizable organic structures have been found. Fossils have been discovered in still older rocks; but, with the exception of the fillings of worm burrows, sponge spicules and masses of lime secreted by primitive algae, all are rare and obscure.

The Cambrian period, the time during which these rocks were formed, is estimated to have lasted about 80,000,000 years, beginning about 500,000,000 years ago. The black kolm rock of Sweden, a kind of coal formed from seaweeds, and containing Late Cambrian marine fossils, is the only known sedimentary rock in the world with primary radioactive minerals. The ash of the kolm gives a corrected isotope date of 440,000,000 years; and most Cambrian strata are older than these beds. As the accompanying chart shows, the Cambrian is the oldest period of the Paleozoic era of ancient life. It was named after the Roman name for Wales, Cambria, from pioneer investigations there.

The discussion which follows, divided into four main parts, describes the origins of Cambrian rocks, their indexing or classification into series on the basis of their fossils, the record of life preserved in these fossils and the occurrences of Cambrian rocks throughout the world. A number of cross references to related and supplementary articles are included in the text. Reference to the articles PALEONTOLOGY: *Geological Paleontology* and GEOLOGY: *Paleontology* will provide helpful background material on the identification and classification of series of rocks on the basis of the fossils they contain. For additional information on the forms of life referred to see also individual articles, such as ARTHROPODA; CEPHALOPODA, etc.

Following are the main divisions of this article:

- I. Life of Cambrian Time
 1. Fossil Evidence
 2. Index Fossils
- II. Subdivisions of Cambrian Time
 1. Identifying Subdivisions
 2. The Cambrian Realms
- III. Rocks of the Cambrian
- IV. Distribution of Cambrian Rocks
 1. North America
 2. South America
 3. Europe
 4. Asia
 5. Africa
 6. Australia, Tasmania and New Zealand
 7. Antarctica

I. LIFE OF CAMBRIAN TIME

1. Fossil Evidence.—Plants and animals probably lived in the earth's oceans for at least 1 500 000 000 years before the beginning of the Cambrian period; but all of the Pre-Cambrian animals except the sponges, and all of the plants except the calcareous algae, lacked shells or skeletons, and consequently left no satisfactory record of their former existence. During the Cambrian period many kinds of Invertebrate animals began to encase their bodies in chitinous calcareophosphatic or calcareous coverings. The cystoids and crinoids among the echinoderms, the brachiopods with inarticulate shells (see BRACHIOPODA), the snails and hyolithids (possibly also the pelecypods) among the molluscs, the trilobites and several groups of primitive crustaceans among the arthropods all had acquired preservable hard parts by the end of the Early Cambrian. Some of the true sponges and an extinct spongelike group of animals (the pleospongia) built internal skeletons of spicules and plates of calcium carbonate. Some Early Cambrian marine worms built calcareous or phosphatic tubes in which they lived. In the Medial Cambrian sponges constructed skeletons of siliceous spicules; the Haplozoa (perhaps the ancestors of the starfish and sea urchin) were encasing their bodies in calcareous plates and

Geologic Time Chart

System and Period	Series and Epoch	Distinctive Records of Life	1,000 Years
CENOZOIC ERA			
Quaternary	Recent	Modern man	.
	Pleistocene	Early man	
Tertiary	Pliocene	Large carnivores	70,000
	Miocene	Whales, apes, grazing forms	
	Oligocene	Large browsing mammals	
	Eocene	Rise of flowering plant,	
	Paleocene	First placental mammals	
MESOZOIC ERA

CHARACTERISTIC TRILOBITES OF THE AMERICAN CAMBRIAN: (A) OLENELLUS (B) PARADOXIDES, (C) DIKELOCEPHALUS. SPECIMENS WERE ABOUT 3 IN. LONG

small fishlike creatures (the probable ancestors of the vertebrates) secreted bony plates both within the flesh and on the outer surfaces of the body. By the end of the Cambrian the cephalopods had recognizable calcareous shells, the bryozoa were building chitinous and calcareous exoskeletons or coverings, some hydrozoans and the graptolites had chitinous integuments capable of fossilization under favourable conditions, and the brachiopods with articulated shells of calcium carbonate were abundant.

The shells and exoskeletons of the earliest Early Cambrian brachiopods, snails, trilobites and crustaceans were thin. By the latter part of the Early Cambrian the trilobites had begun to add more lime to the chitinous base of their exoskeletons which became thicker. The exoskeletons of other Medial and Late Cambrian arthropods remained thin. The shells of Medial and Late Cambrian brachiopods especially the articulates, became increasingly thicker, heavier and larger in size. Among most of the molluscs there was little change in shell thickness although the apparent thinness of the snail shell may have been caused by the deposition of aragonite rather than calcite in the shell layers. Late Cambrian cephalopods, though simple in structure had a thicker shell. Many kinds of Cambrian animals, the protozoans, coelenterates, ctenophores, various kinds of worms and many primitive arthropods, had no hard parts at all; and although the bodies of Cambrian jellyfishes, worms and crustaceans were sometimes preserved such fossils are rare and were formed only under exceptionally favourable conditions. A famous example of such preservation occurs in the Middle Cambrian Burgess shale of the Canadian Rockies of British Columbia. On the bedding planes of this fine black shale the soft bodies of many otherwise unknown invertebrate animals and pieces of soft seaweeds were impressed to form shiny carbon films which have retained perfectly the original structures. The fossilized remains of Cambrian seaweeds except for the calcareous (lime secreting) algae are rare, but in Upper Cambrian rocks especially fossil calcareous algae are common and often form large reefs. (see also PALEOBOTANY).

The Cambrian fossils give an imperfect picture of the life of this period. Nevertheless fossils of thousands of different Cambrian animals have been dug up by paleontologists and it is known that the seas of that period teemed with life. Many kinds of trilobites, arachnids, crustaceans and worms crawled over the sea floors or burrowed in the sands and muds. Brachiopods, bryozoans, cystoids, crinoids, sponges, pleospongia and primitive coelenterates lived attached to sand grains, pebbles or shells scattered over the sea bottoms. Other trilobites, crustaceans, jelly fishes, cephalopods and arachnids swam or floated in the waters above the sea floor.

Cambrian plants and animals were primitive as compared with most of those inhabiting the earth today. However, all the major phyla, vertebrate and invertebrate and many of the classes of animals were represented. The most progressive animals known of that time indicate that at least three-quarters of all animal evolution had already taken place in the marine waters (with the vertebrates invading brackish and fresh waters) before the beginning of Cambrian time. Only land animals are unknown. The plants had evolved into many kinds of algae or seaweeds, fungi and other

types living in marine and fresh waters. while lichens and primitive mosses had probably invaded the shores. But the most spectacular part of plant evolution. the development of plants capable of an independent existence on land, took place after the Cambrian *period.

2. Index Fossils. — Trilobites are the best and most abundant Cambrian index or guide fossils, and they are generally used to distinguish the faunal zones of the period. Some characteristic index fossils of Early Cambrian faunas are the trilobite genera: *Olenellus*, *Paedeumias*, *Wanneria*, *Holmia*, *Callavia*, *Strenuella*, *Protolenus*, *Palaeolenus*, *Onchocephalus*, *Antagmus*, *Calodiscus*, *Serrodiscus* and *Bonnia*. The much larger Medial Cambrian assemblages have a greater number of index genera, including *Poliella*, *Albertella*, *Zacanthoides*, *Tonkinella*, *Oryctocephalus*, *Clavaspiddella*, *Glossopleura*, *Ptarmigania*, *Bathyriscus*, *Alokistocare*, *Elrathia*, *Ehmania*, *Solenopleurella*, *Asaphiscus*, *Agraulos*, *Paradoxides*, *Centropleura*, *Olenoides*, *Anomocare*, *Conocoryphe*, *Ctenocephalus*, *Elyx*, *Damesella*, *Drepanura*, *Anomocarella*, *Dolichometopus*, *Eodiscus*, *Peronopsis*, *Phalacroma*, *Goniagnostus*, *Triplagnostus* and *Ptychagnostus*. Late Cambrian faunas have an equally large and varied group of trilobite genera, including *Cedaria*, *Crepicephalus*, *Tricrepicephalus*, *Meteoraspis*, *Coosia*, *Lonchocephalus*, *Dresbachia*, *Coosina*, *Kingstonia*, *Arapahoia*, *Aphelaspis*, *Labiostria*, *Dunderbergia*, *Pterocephalia*, *Blountia*, *Elvinia*, *Irvingella*, *Camaraspis*, *Acrocephalites*, *Dellea*, *Housia*, *Parabolinoidea*, *Taenicephalus*, *Ptychaspis*, *Prosaukia*, *Idahoia*, *Wilbernia*, *Briscoia*, *Saukia*, *Saukiella*, *Dikelocephalus*, *Tellerina*, *Illaeonurus*, *Plethometopus*, *Plethopeltis*, *Entomaspis*, *Rasettia*, *Bowmania*, *Acheilops*, *Olenus*, *Parabolina*, *Peltoura*, *Leptoplastus*, *Eurycare*, *Acerocare*, *Agnostus*, *Homagnostus*, *Kormagnostus*, *Pseudagnostus*, *Litagnostus* and *Glyptagnostus*.

In all. there are about 600 described genera of Cambrian trilobites. The trilobites were more numerous and varied in the Cambrian seas than in the seas of any later period. Some were less than a quarter inch long as adults. while other genera grew to over a foot in length.

About 75% of the fossils found in Cambrian rocks are the remains of trilobites. and represent both their numerous molts and the actual dead animal. About 20% of the fossils are the phosphatic and calcareous shells of brachiopods, and the remaining 5% includes all the other animals represented—the snails and cephalopods, the worm tubes, the few bryozoan, graptolites, hydrozoans and other coelenterates. the reeflike deposits of lime made by the calcareous algae. and the fossil reefs made by the skeletons of the pleospongia, which are abundant locally in Lower Cambrian limestone in Labrador, Nevada, Siberia and Xustralia. See FOSSIL.

II. SUBDIVISIONS OF CAMBRIAN TIME

The Cambrian period is subdivided into three parts. called the Early. Medial and Late Cambrian epochs. The sedimentary rocks deposited during these three epochs are known as the Lower. the Middle and the Upper Cambrian series. Each series can be recognized by its characteristic fossils. called the guide or index fossils.

1. Identifying Subdivisions.—Marine animals can undergo many changes in shell and body structure as a result of evolution in 25,000,000 years. Consequently. in any region where a section of rocks of any one of these series is present. there occurs a succession of fossils which differ from each other enough so that they can be used to distinguish subdivisions (stages and faunal zones characterized by the presence of distinctive fossils) within each series (see PALEONTOLOGY: *Geological Paleontology*). In the United States three stages are recognized in the Cpper Cambrian series. Dresbachian (the oldest). Franconian and Trempealeuan (the youngest). The Middle Cambrian series appear divisible into four stages and the Lower Cambrian series into two. In the United States 16 intracontinental faunal zones have been recognized. In western Europe 11 such faunal zones are recognized. Faunal sequences have been worked out for Siberia. western Canada and Alaska. northeastern Asia, southeastern Asia. Xustralia. northern Africa and southwestern South America. Approximately 7j faunal

zones have been distinguished in the Cambrian system for the whole world.

The existence of faunal realms or regions inhabited by distinct populations of fauna (resulting in biofacies or series of rocks differing in fossil contents from other series of the same age) in the seas during Cambrian time can be determined from the distribution of the various faunal assemblages. Each collection of animals was adapted to a particular environment characteristic of the region in which it lived. Most of these animals could live in no other environment, but a few species could move from one environment to another. Such unrestricted species are very valuable fossils, as they can indicate the contemporaneity of the faunas living in different environments. Some of these species were pelagic planktons (*q.v.*) (animals unable to swim. but floating on the open ocean currents) and hence were carried to all parts of the world (see also ECOLOGY. ANIMAL).

2. The Cambrian Realms.—Four Cambrian biofacies or realms are recognizable: (1) Tethyan realm extending from the Straits of Gibraltar, through the middle east to Indochina and north Xustralia: (2) Extracratonic euixinic (hospitable to life) realm, bordering both sides of the North Atlantic ocean. along the western border of both North and South America and along the eastern border of China and northeastern Xustralia, and in central Asia; (3) Cratonic realm encircling the North American continental land—Laurentia; and (4) Boreal realm bordering the northern shore of the Siberian land mass—Angara.

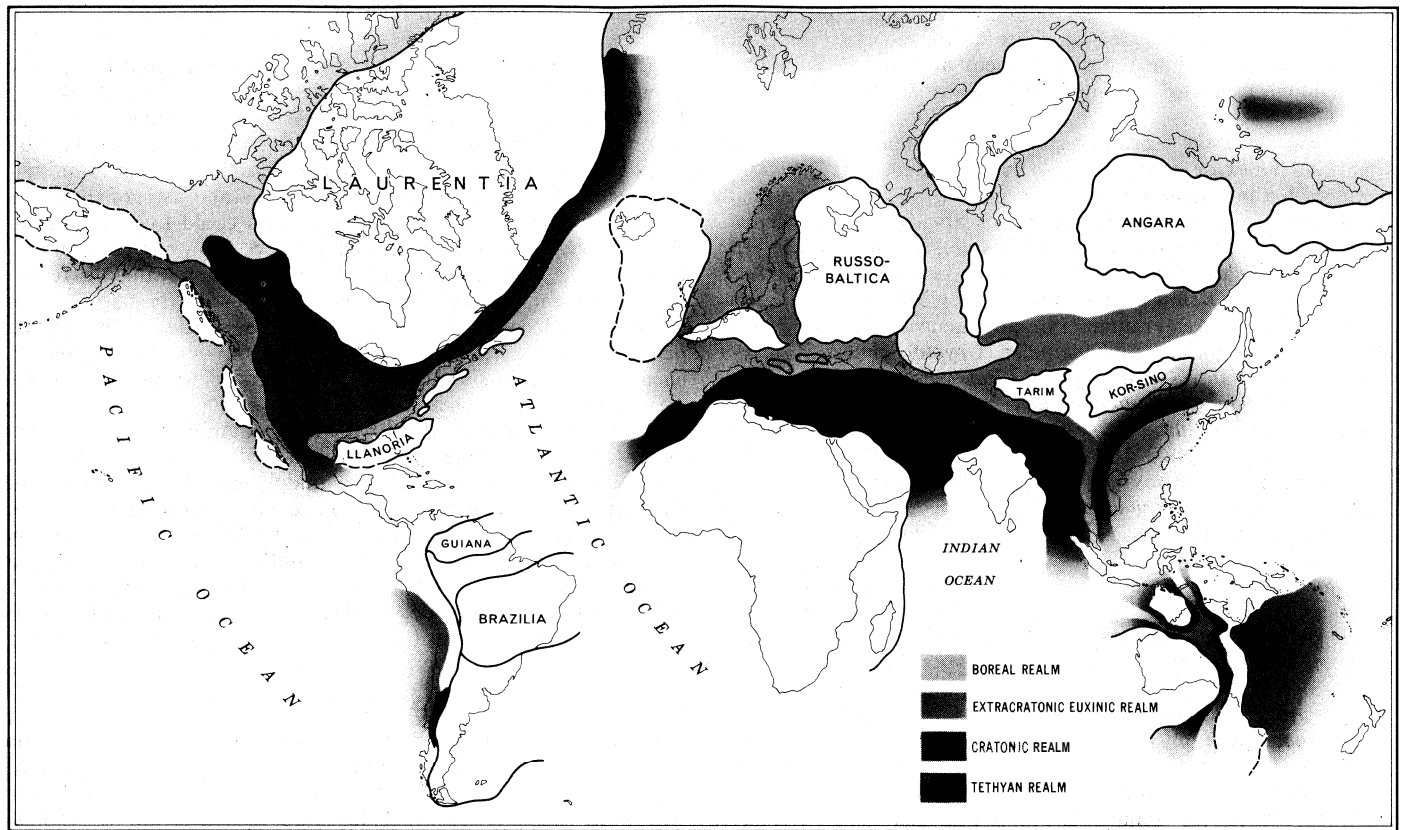

III. ROCKS OF THE CAMBRIAN

Most known Cambrian rocks were originally deposited in shallow to moderately deep marine waters as gravels. sands, muds and limy oozes which later were compacted and hardened into conglomerates, sandstones, siltstones. shales and limestones. In the vicinity of Leningrad and in Estonia there are clays which contain Cambrian fossils but which have never been compacted into shales. In Pakistan there are salt deposits interbedded with marine shales. Few Cambrian fresh water deposits have been preserved. In Great Britain and New Brunswick, however, there are sandstones and shales which may originally have been deposited in lakes and river channels. Pebbles worn and polished by the wind (*Dreikanter*s) are found in Cambrian sandstones in Sweden and the United States (Wisconsin and Texas) which originally formed long sand islands and beaches bordering the seashores.

In Greenland and western North America some Cambrian strata consist of shales in which pebbles and boulders of all sizes are randomly scattered. Such rocks are similar to those formed by glaciers and were thought to indicate Cambrian glaciation. However, they may also be formed by the sliding of masses of mud and broken rocks down steep slopes either on land or below sea level. The few Cambrian rocks of this type are believed formed by submarine mud flows.

Lava flows of Cambrian age are known from Nova Scotia, Labrador, Tasmania, Australia and southern Siberia. Vulcanism in the Cambrian period was restricted to island archipelagoes situated some distance off the shores of the continental land masses. The surface of these islands experienced oscillatory movements, either rising well above sea level or sinking far below it. The surface of the continents was more stable. Broad low plains bordered the shores and merged inland into rolling uplands. In the interior resistant rock masses formed scattered steep ridges or weathered mountain ranges. But there is little evidence that mountain ranges were elevated anywhere during the Cambrian period.

In the earliest Cambrian time the continental lands, coinciding broadly with the present-day areas of North America, central South America, Siberia, the Indian peninsula, central Africa and Xustralia, were large and the shallow seas were restricted to linear basins bordering the margins of the continents. During the Cambrian these seas invaded the borders of the continents, advancing upon the land and retreating sporadically, until in Late Cambrian time marine waters had spread far inland over most of the continents. reducing them to clusters of low islands dotting the shallow interior seas, in which sands, muds and the shells of many primitive animals slowly accumulated.

COMPILED BY CHRISTINA LOCHMAN

THE CAMBRIAN REALMS

Cambrian rocks are found in Greenland, North America, South America, Europe, Africa, Asia, Australia and Antarctica. In the interior of the continents they are remnants of thin sediments once spread widely over the lands flooded by the seas at times of high sea level. In the border regions there are much thicker series of strata. Here the crust of the earth (the sea floor) sank slowly but continuously during the Cambrian, producing a structural trough or geosyncline in which there was room for more and more sediment to be deposited. The amount of sea floor sinking increased progressively outward from the continental interiors to the geosynclines. The strata of the interior range from 0 to 500 ft. in thickness, but many thousands of feet of sediments occur in the geosynclines. They are exposed in the cliffs and canyons of mountain ranges because most of the sedimentary rocks deposited in the geosynclines were later folded into mountains.

IV. DISTRIBUTION OF CAMBRIAN ROCKS

1. North America. — Cambrian sedimentary rocks are exposed in east Greenland, northwest Greenland, Ellesmerland, Newfoundland, Labrador, Cape Breton, New Brunswick, Quebec, Ontario, Maine, Massachusetts, Connecticut, Vermont, New York, New Jersey, Pennsylvania, Maryland, Virginia, North Carolina, Tennessee, Georgia, Alabama, Missouri, Arkansas, Oklahoma, Texas, Illinois, Iowa, Wisconsin, Michigan, Minnesota, South Dakota, Alberta, British Columbia, Yukon Territory, the District of Mackenzie, Alaska, Washington, Idaho, Montana, Wyoming, Utah, Colorado, Nevada, California, Arizona, New Mexico and Sonora, Mex. They are also known to be present beneath the surface, buried under younger rocks, in Kentucky, Ohio, Indiana, West Virginia, Nebraska, Kansas, North Dakota and Saskatchewan.

In most places in eastern North America the rocks are exposed in the belts of the folded Appalachian mountains. Lower, Middle and Upper Cambrian strata are all present in these mountains, and many of the outcropping beds are very fossiliferous. In the northern Mississippi valley and the region west of the Great Lakes the rocks, all of Late Cambrian age, lie nearly horizontally upon the Pre-Cambrian base, and over wide areas are covered by Ordovician

and younger strata. In South Dakota, Upper Cambrian beds are exposed on the flanks of the Black hills. In Arkansas and Oklahoma, Upper Cambrian strata only are present, and crop out in the folds of the Ouachita and Arbuckle mountains. In central Texas the Upper Cambrian beds are exposed on the flanks of the Llano uplift. In western Texas, southern New Mexico, southeastern Arizona, Nevada, Utah, southeastern California and northern Sonora, Lower, Middle and/or Upper Cambrian rocks are found in folded and faulted sections where the Lower Paleozoic rocks have been brought to the surface by crustal movements and uncovered by erosion. In the plateau country of northern Arizona and Utah where the Paleozoic strata are still almost horizontal, Cambrian rocks are exposed in the walls of some of the deeper river canyons, as in the Grand canyon of the Colorado river. In Colorado, Wyoming, Montana, Idaho, eastern Washington, British Columbia, Alberta, Yukon Territory and Alaska they are exposed on the flanks of local uplifts and in the folded and faulted belts of the Rocky mountains. In the Mackenzie district, Cambrian formations crop out in the hills on the eastern side of the Mackenzie river, southwest of Great Bear lake. In many of these areas all three divisions of the Cambrian sedimentary rocks are represented. Some of the most complete, best exposed and most famous of the known Cambrian sections occur in the mountain ranges of the Canadian Rockies. At Burgess pass, British Columbia, is found the outcrop of the unique fossil locality in the Burgess shale previously referred to.

2. South America. — Relatively few outcrop areas of Cambrian rocks have been discovered in South America. All are located on the eastern flanks of the Andes mountains and in the northeastern ranges of the Andean chain. Cambrian rocks are known at a few localities in Colombia. One area of Cambrian strata is known in northwestern Bolivia. In southern Bolivia and southward through northwestern Argentina (Jujuy and Mendoza), Middle and Upper Cambrian strata are exposed.

3. Europe. — Cambrian rocks are widely distributed in Europe. They occur in Norway, Sweden, Bornholm Island in the Baltic sea, Scotland, western England, Wales, Ireland, Ardennes mountains of

northwestern France, Montagne Noire region of southern France, the Pyrenees and elsewhere in Spain, Sardinia, Portugal, the Black forest of Germany, Bohemia, southern Poland, Estonia and the vicinity of Leningrad. Cambrian strata are known to underlie the north German plain and to extend under parts of northern Poland and into western Russia.

In Norway, Scotland, western England, Wales and southeastern Ireland, Cambrian beds are exposed in the folds of the ancient mountains. They contain many fossils. In Sweden, Bornholm island, Estonia and western U.S.S.R. the strata at many localities still lie in the horizontal position in which they were deposited, and their fossils are exceptionally well preserved. In southwestern Germany, the Ardennes and Montagne Noire regions of France, in Spain, Portugal and Sardinia the Cambrian beds have been folded and the fossils are usually badly distorted by movement of the strata. The Cambrian rocks exposed in the Spanish provinces of Leon, Asturias, Aragon and Seville, and in the Portuguese province of Alentejo, are also usually closely folded.

In the U.S.S.R. fossiliferous Upper Cambrian rocks have been discovered in the Arctic Novaya Zemlya Islands and strata with Early Cambrian fossils occur in the southern Ural mountains. The faunas of these sections show relationships with the Siberian realm.

4. Asia.—Much of Siberia is underlain by Cambrian strata. Faunas of the fossiliferous Middle and Upper Cambrian beds of the Kazakh Soviet Socialist Republic belong to the boreal biofacies and show affinities with the North American cratonic realm. Middle Cambrian strata are known on one of the New Siberian Islands (Bennett Island) and on the islands of Emperor Nicholas II Land in the Arctic ocean. Across northern Siberia, Lower and Middle Cambrian strata outcrop extensively in and near the major river valleys from the Yenisei to the Lena. Cambrian rocks, especially Lower Cambrian, are also widely distributed across southern Siberia. They have been found over a wide area in the upper Lena drainage basin, eastward to Lake Baikal and thence northeastward to the Amur valley and the shores of the Sea of Okhotsk. Some of the faunas from these strata have been described by Soviet geologists. Some of the limestones are extensive reefs of pleospongia. Dark shales are common and are characterized by large numbers of trilobites related to the faunas of the extracratonic euxinic realm of western Europe.

Cambrian rocks are found in Korea and in several of the provinces of China—in southern Manchuria, Inner Mongolia, the Shantung peninsula, Shansi, Sinkiang, Hunan and Yunnan. In Korea, Manchuria and Shantung large faunas have been discovered from all three divisions of the Cambrian period which are represented by thick sections of strata. Only Medial Cambrian faunas are known from Shansi. In Yunnan well-preserved Early Cambrian fossils are known, and there is a Late Cambrian faunal sequence showing affinities to the north China assemblages. The few Late Cambrian fossils reported from Hunan are related to the faunas of Late Cambrian age from the eastern Tianshan mountains of Sinkiang— assemblages in dark shale which belong to the extracratonic euxinic biofacies. In Tongking, northern Indochina, Lower, Middle and Upper Cambrian rocks are known, and many of the beds contain large numbers of excellently preserved fossils.

Cambrian rocks are less common in southern Asia. Middle Cambrian, and possibly Lower and Upper Cambrian rocks occur in Kashmir. Lower, Middle and Upper Cambrian strata are present in the Spiti valley in the Himalayas. Lower Cambrian saline deposits are found in the Salt range of western Pakistan. In Iran, north of the Persian gulf, fossiliferous Lower, Middle and Upper Cambrian strata have been found. In Israel, near the southern end of the Dead sea, Lower and early Middle Cambrian strata are exposed in a narrow belt.

5. Africa.—In Morocco in the Anti-Atlas and Cugarta ranges of the southwest, and in the Atlas mountains near Casablanca, Lower and Middle Cambrian rocks are known. Scattered occurrences have been reported elsewhere in northwestern Africa. The Lower Cambrian sandstones, shales and sandy limestones of the Anti-Atlas are richly fossiliferous—with pleospongia reefs and excellently preserved trilobite assemblages containing some of the most primitive genera known. The faunas belong to the Tethyan

biofacies, but also contain a few genera from the western European biofacies, thus enabling a correlation between the two realms. Rocks of undoubted Cambrian age are not known elsewhere in Africa.

6. Australia, Tasmania and New Zealand.—Lower Cambrian strata occur in Northern Territory and South Australia. These beds are world famous for their thick and extensive pleospongia (Archaeocyathid) reefs. Fossiliferous Middle and Upper Cambrian rocks are known in Western Australia, Northern Territory, South Australia, Queensland and Victoria. These fossils have their closest affinities with the southern Asiatic and western European assemblages. Metamorphosed sediments, apparently unfossiliferous, outcropping in New South Wales are considered of probable Cambrian age. Fossiliferous Middle and Upper Cambrian beds and associated volcanic rocks occur in Tasmania; and very late Middle Cambrian strata are known from one area on South Island, New Zealand.

7. Antarctica.—Boulders containing pleospongia have been dredged from the ocean floor near the end of Beardmore glacier south of Ross sea. Early Cambrian beds must underlie the glacier somewhere along its course.

See GEOLOGY; PRE-CAMBRIAN TIME; see also references under "Cambrian System" in the Index volume.

BIBLIOGRAPHY.—General descriptions of Cambrian rocks and fossils and maps showing the position of lands and seas in Cambrian time appear in textbooks on historical geology. More detailed studies are in the following publications: John Rodges (ed.), "El sistema Cámbrico, su paleogeografía, y el problema de su base" (papers mostly in English), Symposium at 20th International Geological Congress, Mexico, 2 vol. (1956); F. Rasetti, "Middle Cambrian Stratigraphy and Faunas of the Canadian Rocky Mountains," *Smithson. Misc. Coll.*, vol. 116, no. 5 (1951); T. CAMBRIC, a plain-woven, staple cotton fabric first made in Cambrai (Flemish: Kameryk), France, and originally a fine linen fabric. Printed cambric was used in London by 1595 for bands, cuffs and ruffs. Modern cambric is made from choice American or Egyptian cotton with textures running from 92 ends and 88 filling picks to 100 ends and 100 picks. Yarns range from 60 to 80 in size or count both ways. Cambric is similar to and often indistinguishable from muslin.

Cambric may be bleached or dyed in the piece. Lower qualities have a smooth, bright finish. It is light in weight, well adapted to sewing, has good body, is well sized and presents a neat, appealing hand and finish. Since cambric launders easily and well, it is ideal for handkerchief linen, children's dresses, slips, underwear and nightgowns.

French cambric is fine textured and is used in neckwear and

scarves when dyed or printed. Superior cotton yarns are used. Irish cambric is an all-linen, plain-woven cloth used for underwear, dresses and handkerchiefs. "Green" (unbleached) yarns are usually used to make the fabric; the product is made completely white by boiling and bleaching. Irish cambric is used for handkerchiefs with coloured yarns employed for border effects. Kid-finished cambric, a soft-finished fabric, is used for dress linings.

(G. E. L.)

CAMBRIDGE, EARLS, DUKES AND MARQUESSES

OF. Under the Norman and early Plantagenet kings of England the earldom of Cambridge was united with that of Huntingdon, and held, among others, by King David I of Scotland as the husband of Earl Waltheof's daughter Matilda. As a separate dignity the earldom dates from 1340 when Edward III bestowed the title on his brother-in-law, William, count (afterward duke) of Juliers. In 1362 (the year after William's death) Edward created his own son, Edmund of Langley, earl of Cambridge (see YORK, EDMUND OF LANGLEY, Duke of). Edmund's elder son, Edward, earl of Rutland (see YORK, EDWARD PLANTAGENET, Duke of), who succeeded his father as duke of York and earl of Cambridge in 1402, appears to have resigned the latter dignity in or before 1414 because in this year his younger brother Richard (c. 1375–1415) was made earl of Cambridge. In 1415 Richard conspired with Henry, Lord Scrope of Masham, and Sir Thomas Grey to assassinate Henry V. The plot was discovered and the earl of Cambridge was executed on Aug. 5, 1415. His title was forfeited, but it was restored to his son Richard (see YORK, RICHARD, Duke of), who in 1415 became duke of York in succession to his uncle Edward. Subsidiary to the dukedom of York, the title was held by Richard until his death in 1460, and then by his son Edward who became king as Edward IV in 1461, when all his honours merged in the crown.

In 1619 James I, wishing to bestow an English title on James Hamilton, 2nd marquess of Hamilton (d. 1625), created him earl of Cambridge, and the title was inherited by his son and successor James, 3rd marquess and 1st duke of Hamilton, who was executed in 1649. In 1651, when William, 2nd duke of Hamilton, died without male issue, his title became extinct (see HAMILTON, MARQUESSES AND DUKES OF).

The title of earl of Cambridge was again bestowed on a member of the royal house when it was granted by Charles II to his brother Henry, duke of Gloucester, in 1659, only to become extinct on Henry's death the next year. Between 1661 and 1677 four sons of James, duke of York (afterward James II), were designated or created earl of Cambridge, but they all died in infancy. When the Act of Settlement was passed in 1701 an English title was needed for George Augustus, electoral prince of Hanover, who became third in succession to the English throne. In 1706 he was created marquess and duke of Cambridge. The title merged in the crown when he became king in 1727, but it was revived in 1801 in favour of Adolphus Frederick, the seventh son of George III.

ADOLPHUS FREDERICK (1774–1850), duke of Cambridge, was born in London on Feb. 24, 1774. Having studied at the university of Göttingen, he served in the Hanoverian army and with the British army in the Low Countries, being severely wounded in 1793. He was created earl of Tipperary and duke of Cambridge in Nov. 1801 and became a privy counselor in 1802. In 1813 he was promoted field marshal and in 1816, after the electorate of Hanover had been raised to the rank of a kingdom, the duke was appointed viceroy. He held this position until the separation of Great Britain and Hanover in 1837. He died in London on July 8, 1850. In 1818 he had married Augusta (1797–1889), daughter of Frederick, landgrave of Hesse-Cassel. He left three children: his successor, George; Augusta Caroline (1822–1916), who married Frederick William, grand duke of Mecklenburg-Strelitz; and Mary Adelaide (1833–97), who married Francis, duke of Teck.

GEORGE WILLIAM FREDERICK CHARLES (1819–1904), duke of Cambridge, was born at Hanover on March 26, 1819, the son of Adolphus Frederick, from whom he inherited the dukedom in 1850. After serving briefly in the Hanoverian army, he became a colonel in the British army (Nov. 1837), served in Gibraltar and Ireland, and in 1842 was appointed colonel of the 17th light dragoons (later

lancers). In 1854, on the outbreak of the Crimean War, he was given command of the 1st division of the Crimean army and was present at the battles of the Alma, Balaklava and Inkerman and at the siege of Sevastopol. He was appointed general commanding in chief in 1856, field marshal in 1862 and (by letters patent) commander in chief in 1887. The Crimean War had exposed the need for reform in the army, but only minor reforms were made before 1868 when Edward (afterward Lord) Cardwell, secretary of state for war, undertook a large-scale reorganization. Cambridge opposed many of his reforms, in particular the abolition of the dual system of control with the subordination of the commander in chief to the secretary of state. The duke was undoubtedly a major obstacle to reform, although he was forced to accept many changes. He disposed of army patronage in the traditional way, promoting men for social rank and seniority rather than for ability. Finally in 1895 Henry Campbell-Bannerman, secretary for war, secured his unwilling resignation. Cambridge was an experienced commander, and concerned with the welfare of his men, but he could not adapt himself to new conditions. He died in London on March 17, 1904.

In 1917 ADOLPHUS CHARLES (1868–1927), duke of Teck, renounced his German titles and was made marquess of Cambridge (see TECK). He was the grandson of Adolphus Frederick, duke of Cambridge, and the brother of Queen Mary, consort of George V. He was succeeded by his son, GEORGE FRANCIS HUGH (1895–), 2nd marquess.

BIBLIOGRAPHY.—Rev. E. Sheppard, *George, Duke of Cambridge* (1906); Willoughby Verner, *Military Life of the Duke of Cambridge* (1905). For the negotiations concerning his resignation see J. A. Spender, *Life of Sir Henry Campbell-Bannerman*, vol. i, pp. 148–154 (1923).

CAMBRIDGE, RICHARD OWEN (1717–1802). English poet and essayist and author of the *Scribleriad*, was born in London on Feb. 14, 1717, and died at Twickenham, Middlesex, on Sept. 17, 1802. Educated at Eton and at St. John's college, Oxford, he went into residence at Lincoln's Inn in 1737. Four years later he married and went to live at his country seat of Whitminster, Gloucestershire. In 1751 he moved to Twickenham, where he entertained a brilliant circle of his famous contemporaries, including Thomas Gray, Charles James Fox and the earl of Chatham. Horace Walpole in his letters makes many jesting allusions to Cambridge in the character of newsmonger. Cambridge contributed 21 papers to the *World* (1753–56), but his chief work is the *Scribleriad* (1751), a mock epic poem satirizing false learning, the hero of which is the Martinus Scriblerus of Alexander Pope, John Arbuthnot and Jonathan Swift.

See *The Works of Richard Owen Cambridge, Esq.*, ed. by his son, George Owen Cambridge (1803).

CAMBRIDGE, a city (from 1951) and a municipal and parliamentary borough, the seat of a university and the county town of Cambridgeshire, Eng., 56 mi. N.E. of London and 80 mi. N.E. of Oxford by road. Pop. (1961) 95,358, including members of the university in residence. It lies immediately south of the fen country, being itself only 20 to 80 ft. above sea level. Most of the city is built on the east bank of the Cam, a tributary of the Ouse. Suburbs extend across the river but modern development to the west has been largely restricted to university expansion; access to open country on that side is quick and easy. Slight hills rise gently on the south (chalk) and west (heavy clay). The borough returns one member to parliament.

Modern Cambridge has been described as "perhaps the only true university town in England." University and college buildings provide nearly all the outstanding features of the architectural scene. The wealth of beauty is great and is no more than hinted at by such outstanding examples as the old court of Corpus Christi, the 15th-century combination room of Peterhouse, the 16th-century President's lodge of Queens' college, the restored 17th-century hall of Clare, the 18th-century Gibbs' building of King's college and Wilkins's early 19th-century layout of Downing college.

The beauty of the city is enhanced by a large number of commons and other open spaces, including Jesus green and hildsummer common, Sheep's green, Lammas land, Christ's pieces, Parker's piece, the university botanic garden (much developed, extended

and improved) and the Backs. The Backs are the landscaped lawns and gardens through which the Cam winds behind the main line of colleges, including Queens', King's, Clare, Trinity, St. John's and Magdalene, and under a series of magnificent bridges of which the Bridge of Sighs (St John's, 1827-31), the stone bridge of Clare with thick stone balls on the parapets (1638-40) and the Mathematical bridge of Queens' are among the best known. East of the Cam is King's parade where the 15th-century university and parish church of Great St. Mary and a line of attractive shops face King's college with its chapel and the university senate house (built between 1722 and 1730 from designs by James Gibbs). King's college chapel (1446-1515), the best-known building in Cambridge, was designed by Henry VI as part of an immense and never fully realized conception. Great buttresses, lofty spires and turrets, a high vaulted roof, heraldic devices and magnificent stained glass windows are notable features of the chapel which is one of the greatest monuments of English medieval architecture.

Among other churches are St. Benet's, with its notable Saxon tower; the restored Norman St. Sepulchre's (one of the four round churches in England); and St. Ednard's King and Martyr, notable not only as a "peculiar" with a parish but also as the church of the Cambridge reformers. It was closely associated with Hugh Latimer and his colleagues and, three centuries later, with Frederick Denison Maurice. The Fitzwilliam museum (1837-41) and the post-World War II engineering laboratory are in Trumpington street, a continuation of King's parade, and the postwar chemistry laboratory and the Scott polar research institute are in the adjoining Lensfield road. The university library building (1931-34) lies west of the river; its design in red brick is a subject of keen local controversy. The Folk museum is in Castle street near Magdalene college.

Cambridge, which is reached by London trains from King's Cross and Liverpool Street stations, has good rail access to the eastern counties and, via Ely and March, to the north. Road access is easy but the city centre is usually thickly congested with traffic. The river is extensively used for pleasure boating, punting and canoeing; larger craft are available for private hire and organized public trips. There is a small airfield, with charter services and flying school, on the Newmarket road. The American memorial cemetery is near the village of Madingley (3½ mi. N.W.).

Cambridge industry is extensive but, from the city centre, is unobtrusive. It includes industries which have depended to considerable extent on university and college connections and orders, as diverse as building, printing and instrument making and others which have also had close links; e.g., radio and electronics. Flour milling, asphalt manufacture and cement making are also important. Several of the large new and secondhand bookshops enjoy international reputations and there are numerous establishments specializing in the sale of antiques.

History.—The site of the earliest settlement was probably at the spot on the Cam river nearest to the sea (at King's Lynn) at which it was possible to cross from the dry land of the midlands to dry land adjoining the fens of the east. The crossing would have been made originally by ford or ferry but a great bridge has existed from a very early date and has been the key to important road junctions. It is the only bridge in England which has given name to a county. The name Cambridge derives from a corruption of the earlier Grantebrycge or Grantabridge. Norman influence displaced *Gr* in favour of *C* and, from the form Cantabrigia, which was commonly used during the early period of university and college development, has come the abbreviation Cantab., still used to distinguish a Cambridge degree or a Cambridge graduate. Granta is the earlier and still alternative river name. Early earthworks, including Castle hill, and Roman remains suggest the existence of a fort on the road between Colchester and Godmanchester and almost certainly there were later two settlements, one on Castle hill which was under Mercian jurisdiction in the period of the Heptarchy, and the other around Market hill, in East Anglia. The Market hill settlement probably grew more rapidly; the Castle hill development reflected the need to control and maintain the great bridge. The progress of amalgamation, which was

spread over several centuries, was thus stimulated by the need for common defense in the face of the Norse invasions. The first written reference to Cambridge occurs in the Anglo-Saxon Chronicle under the year A.D. 875. Two important monastic foundations date from the 11th and 12th centuries respectively: Bantwell priory and the Benedictine nunnery of St. Radegond, which was dissolved and replaced by Jesus college in 1496. Cambridge had a castle and a mint by 1086 and received its first charter in 1201. It has had municipal buildings on part of the modern guild hall site since 1224, a mayor at least since 1231, a coroner since 1256, burgesses in parliament since 1295, a commissioner of the peace since 1380, a town clerk since 1418, a recorder since 1494 and a high steward since 1529. The modern city council consists of a mayor, 14 aldermen and 42 councilors, 6 of the councilors being elected by the colleges and university and 2 of the aldermen elected by the council from among the university and college representatives. Cambridge had an unusually interesting guild history (Corpus Christi college was founded in 1352 by the guilds of St. Mary and of Corpus Christi).

Since the mid-19th century the town has played a pioneer role in the provision of social services, including public libraries, labour exchanges and school dental services and, since World War II, accident prevention. The city council is also represented on the governing body of the Arts Theatre trust which is responsible, *inter alia*, for the theatre, built and presented in 1936 by Lord Keynes. The trustees have carried on his declared intention of making available to a large theatreless region of England the five arts of drama, opera, ballet, music and film.

During the medieval period the Cam was extensively used for water transport, the local wharfing facilities (which have gradually disappeared) being in heavy demand during the annual period of Stourbridge fair. This was held at riverside Barnwell from about 1200 and was one of the greatest of the English fairs. Daniel Defoe wrote a classic account of it, but by the beginning of the 18th century its importance had greatly diminished although it was not finally extinguished until 1934, by which time it was much decayed. The usually four-day Midsummer fair, controlled by the corporation since 1505, is still held.

Outstandingly important additions to the literature of the city's history were made in 1959 by volume III, "The city and University," of the *Victoria History of the County of Cambridge . . .*; and in 1960 by the *Inventory of the Historical Monuments in the City of Cambridge*.

Cambridge faces all the problems of a thriving modern city built around an ancient centre. The *Cambridge Planning Proposals* of 1950 considered, among other topics, traffic and housing problems and formed the basis of part of the *County of Cambridge Plan* approved in 1954. See also CAMBRIDGE UNIVERSITY.

(W. A. MD.)

CAMBRIDGE, a city of Massachusetts, U.S., on the Charles river, opposite Boston; seat of Middlesex county. The population in 1960 was 107,716; in 1950 it was 120,740; and in 1940, 110,879. The decline in population, as in most other cities, was attributed largely to the movement of industry and people to the suburbs on the outer fringes. To offset this trend, attempts were made to achieve more intensified use of the city's limited area, urban renewal and redevelopment, replanning of major highways and provision for parking facilities. (For comparative population figures see table in MASSACHUSETTS: *Population*.)

The original settlement was established by the Company of Massachusetts Bay in 1630 on a site which is now in the vicinity of Harvard square and was at first called New Towne. In 1638, two years following the founding of Harvard college, the name was changed to Cambridge after the English university town. Gov. John Winthrop and others intended the town to be the capital of the Massachusetts Bay colony, but Boston was regarded as offering more advantages both for commerce and defense.

The shaded, irregular streets around Harvard square are full of historic and literary associations. General synods of the New England churches met there in 1637 and 1647 to settle disputed points of doctrine, and from there in 1636 Thomas Hooker's congregation departed for Connecticut. At the outbreak of the Amer-

ican Revolution the first American army camped on what is now the Cambridge common, and from there went most of the detachment which fought the battle of Bunker Hill. Under an elm which stood near the common until 1923. George Washington (according to tradition) took command of the continental forces on July 3, 1775.

The convention which drafted the original constitution of Massachusetts met in Cambridge in 1779-80. In Apthorp house (1760) Gen. John Burgoyne and his officers were lodged as prisoners of war in 1777. Vassall or Craigie house (1759) on Brattle street was occupied by Washington in 1775-76, and later was the home of Henry Wadsworth Longfellow (1837-82). In Elmwood (1767), James Russell Lowell was born and lived all his life. Many other notable literary and scientific figures had Cambridge associations. Among them are Oliver Wendell Holmes, Richard Henry Dana, Louis Agassiz, Asa Gray, Charles Eliot Norton, William James, John Fiske, William Dean Howells and Bernard De Voto.

Old Cambridge, centring at Harvard square, has been to Americans a symbol of culture since the founding of Harvard college. Adjoining the college and residential areas, however, there has developed in the 20th century a commercial centre which ranks high among the cities of the state. Up to mid-19th century there were no factories other than those manufacturing glassware, a few small brickyards and the printing shops around Harvard square. Stephen Daye had set up the first printing press in the colonies in 1639 and the first books printed in the U.S. came from this press. In the early 1870s was begun the reclamation of two square miles of tide-covered marshes for a manufacturing district. Rapid industrial expansion, however, did not begin until 1912 when the opening of the subway to Boston brought the business section of that city within a few minutes of Cambridge; it was further stimulated by the development of motor trucking. By mid-20th century there were about 400 manufacturing establishments.

The leading industries are fabricated metal products, electrical machinery, printing and publishing, the manufacture of candy, bakery and other food products, chemicals, rubber and leather goods. As the city has become an increasingly important centre for scientific and industrial research, the processing and experimental operations of the many research organizations have become a principal activity. This development has been stimulated by the close proximity of Harvard and the Massachusetts Institute of Technology (M.I.T.) with their numerous scientists, laboratories and special facilities. Although the emphasis in the 1960s was on nondurable goods, it was not heavily so. There was a remarkable diversity in the nature of products manufactured. Second in importance was wholesale and retail trade, followed by public utilities and service industries. Although manufacturing provided work for the largest number of employees, the total payroll of the educational institutions was more than twice the sum of the payrolls of the six leading industries.

The industrial growth of the 20th century was advantageous to city finances as an offset to the large proportion of tax-exempt property; at the same time encroachment on the historic, residential and educational areas was checked to a considerable degree by zoning regulations originally adopted in 1924 and completely revised in 1943. A planning board was appointed in 1913; it was provided with a full-time staff in 1945. The presence of educational institutions such as Harvard and M.I.T. helped to stabilize real estate values and to slow down creeping urban blight which has so seriously affected certain neighbouring cities.

Cambridge is often referred to as the university city. In addition to Harvard university (*q.v.*) there is Radcliffe college for women (1879), which has its own endowment, plant and separate corporate organization but is affiliated with Harvard. All instruction at Radcliffe is by members of the Harvard faculty and since 1913 most of the students at both institutions have attended the same classes under the plan of joint instruction. Other older educational institutions of higher learning include the Episcopal Theological school (1867), and the New-Church (Church of the New Jerusalem) Theological school (1866).

In 1916 M.I.T. moved from the site it had occupied in Boston

for 50 years to a 115-ac. campus extending for more than a mile along the Cambridge side of the Charles river basin. This is an independent, endowed institution which offers both undergraduate and graduate programs in all branches of engineering and architecture as well as broad programs in the humanities and social sciences. It also engages in a vast amount of basic research as a major part of its activities. Its research facilities, which are unusual and in some cases unique, include a nuclear reactor, a research laboratory of electronics, a servomechanisms laboratory, supersonic wind tunnels and centres for international: urban and regional studies and for communications sciences. The headquarters of the Smithsonian Astrophysical observatory, Formerly in Washington, D.C., is located in Cambridge. Its major activity is the optical tracking and analysis of satellites.

Until 1846 Cambridge was governed by the traditional New England town-form of government. In that year it was chartered as a city. In 1930, following a reform movement, the voters accepted the council-manager form of government; the council, which appoints the city manager, is elected at large by proportional representation. The school committee is also elected by proportional representation: Cambridge being one of the few U.S. cities using this form of ballot. Another distinctive feature of the city is the cosmopolitan character of its inhabitants.

CAMBRIDGE PLATONISTS, a group of 17th-century philosophico-religious thinkers, who hoped to reconcile Christian ethics and Renaissance humanism, religion and the new science, faith and rationality. Their leader was Benjamin Whichcote (1609-83), who expounded in his sermons the Christian humanism which unites the group. His principal disciples at Cambridge were Ralph Cudworth, Henry More (*q.v.*) and John Smith (1616?-52); Joseph Glanvill (*q.v.*) was an Oxford convert. Nathanael Culverwel, Richard Cumberland (*q.v.*) and the mystic Peter Sterry (1613-72) at Cambridge and John Norris (*q.v.*) at Oxford were influenced by Cambridge Platonism without wholly accepting its moral and religious ideals. Educated as Puritans, the Cambridge Platonists reacted against the Calvinist emphasis on the arbitrariness of divine sovereignty. In their eyes, Hobbes and the Calvinists both made the mistake of supposing that morality could consist in obedience to a will. Morality, they said, is essentially rational; the good man's love of goodness is at the same time an understanding of its nature, which neither God nor man can alter by the exercise of sovereign power. Against both Archbishop Laud and the Calvinists, they denied that ritual, church government or detailed dogmas are essentials of Christianity. To be a Christian is to participate in divine wisdom; men should be left free to choose whatever forms of religious organization they find helpful. The width of their tolerance won them the nickname "latitude men"; they were often condemned as Unitarians or atheists because they placed so much stress on morality and so little on dogma. Their metaphysics derives from Renaissance Platonism, which interpreted Plato in a Neoplatonic light; their more systematic works are clogged with uncritical scholarship. They learned much from Descartes' critique of empiricism, but, fearing that the new "mechanical" theories might undermine the religious conception of the world, they supported, against Descartes, a teleological interpretation of natural processes.

CAMBRIDGESHIRE, an eastern county of England, bounded north by Lincolnshire, east by Norfolk and Suffolk, south by Essex and Hertfordshire and west by Bedfordshire, Huntingdonshire and Northamptonshire. The area of the geographical county, which includes the Isle of Ely, is 867.1 sq.mi.

Physical Features.—All but the southernmost part of the county lies within the fen district, a flat alluvial tract only a few feet above sea level, intersected by innumerable drainage channels. (For its reclamation and physical characteristics see FENS.) In a level country, such minor chalk hills as the Gogmagogs, southeast of Cambridge, or the hillock upon which stand the cathedral and city of Ely, assume an importance far beyond their stature. The scenery of the rolling southern part of the county is more varied, with many villages, farms and scattered woodlands.

The two principal rivers are the Ouse and its tributaries and, in the north by Wishech, the Nen (Nene). For the greater part of their courses within the county these rivers flow slowly between raised banks, the most spectacular of which are two great parallel cuts, the Old and the New Bedford rivers, running northeast for 30 mi. from Earith to Denver sluice in Norfolk. The area between them acts as a flood reservoir; but a new channel constructed after 1960 around the rim of the fen basin, analagous to a ring road, was designed to receive surplus water from all the rivers and convey it into the tidal Ouse below Denver. The dry chalk uplands east and southeast of Cambridge have beech belts and clumps, as seen near Newmarket heath; farther west the clays and greensand flanking the Bourn brook and Cam valleys favour ash and elm; while willows are characteristic of the fens, where buried "oaks" and peat beds bear witness to former forests. Wicken fen is a famous nature reserve; a large mere was made in 1957 to enhance the natural amenities.

The rocks in general strike northeast-southwest and gently dip southeast, the oldest member of the series being the Jurassic Oxford clay of the higher ground running northwest from Cambridge toward Peterborough, where the landscape covers below the great chimney clusters of its brick pits; to the east it forms the floor of the fen basin or, as at Whittlesey or Thorney, rises in low "islands" through the black fen peat. Above it lies either the Coralline Elsworth rock (of which a notable—oolite—exposure, full of shell fossils, occurs at Upware) or Ampthill clay; and above this again, Kimmeridge clay, exposed in the west near Gamlingay and in the north near Ely. Lower greensand comes next: its appearance at the surface (for it is commonly overlaid by the stiff leaden-gray Gault) is especially beneficial for orchards, as at Eversden (noted for its greengage plums). Cottenham and Haddenham in the Isle of Ely. Two industrially important beds overlay the Gault (which is itself worked at Burwell for bricks): the Cambridge greensand, worked for phosphate coprolites a century ago; and the chalk marl for cement. Large pits are worked at Shepreth, Barrington and southeast of Cambridge. Finally there is the chalk, the key to landscape, soil and crop alike in south Cambridgeshire; and the boulder clay, the gray mantle of sludge and debris left by the retreating ice which once covered the whole county.

Early Settlement and History.—Neolithic types of flint implements are very common in parts of the county, implying a prolonged period of occupation in the areas bordering the fens, around Mildenhall (part of the East Anglian heathlands) and along the Cam river southward. Beakers, a type of pottery introduced from the European continent after 2000 B.C., occur in the Anglian river valleys and on the edge of the fens. Throughout the Bronze Age, settlement seems to have been mainly concentrated in the strip east of the Cam from Royston northeastward to Soham, including the chalk escarpment. Hoards of the late Bronze Age come mainly from the borders of the fens and from the Cam valley; several were found in the fens. Inland waterways were evidently important. There is also evidence that raw material (copper and tin) was brought to the region from the southwest along the Icknield way. The forested valleys in the chalk of the south-east were penetrated to some extent.

Invaders reached the region during the early Iron Age, in the La Tène and possibly in the preceding Hallstatt period. Penetration took place by the Wash and also from the south, and the La Tène culture influenced provincial Roman craftsmanship. Population was densest in the fertile valley of the Cam; the southern fens and the forests west of Cambridge were barren. Several hill forts were occupied in the south.

A remarkable feature of the Roman-British period is the wide spread occurrence of finds in what had been marshland as well as on the fen islands. That a good deal of drainage was done is probable (the Car dyke between the Cam and the Great Ouse is of Roman construction), and the forested claylands mere also penetrated. Southern Cambridgeshire lay athwart the main Roman road to the north (Ermine street) whence Akeman street branched northeastward, west of the Cam, to Cambridge and Norfolk.

The earliest English settlements were made in the 5th century. The Anglo-Saxon conquest was followed by a period of contraction but by the time of the Domesday survey the range of settlement was in its essentials that of modern times. The districts corresponding to the counties of Huntingdon and Cambridge were distinguished as the lands of the North Gyrwas and the South Gyrwas respectively. At this period the fen district stretched southward to nithin a few miles of Cambridge; its essential unity is still preserved by its inclusion under one sheriff, chosen in successive years from Cambridgeshire proper, the Isle of Ely and Huntingdonshire. After the treaty of Wedmore, the district was part of the Danelam (*q.v.*). On the conquest of the Danes by Edward in the 10th century it was included in East Anglia (*q.v.*), but in the 11th century was again overrun by the Danes, who burned Cambridge. The Saxon Chronicle records the valiant resistance of the men of Cambridge to the invaders in 1010, when the rest of the East Anglians had fled. The shire system of East Anglia was not definitely settled before the Norman Conquest, but during the Danish occupation of the 9th century the district possessed a certain military and political organization around Cambridge, its chief town, whence probably originated the constitution and demarcation of the shire. At the time of the Domesday Book (1086) the county was divided as now, except that the Isle of Ely, which then formed two hundreds (ancient territorial divisions), meeting at Witchford, is now divided into four—Ely, Wisbech, North Witchford and South Witchford. Cambridge formed a hundred by itself.

Cambridgeshire was included in the diocese of Lincoln until, on the elevation of Ely to a bishop's see in 1109, almost the whole county was placed in that diocese. The Isle of Ely formerly constituted an independent franchise but its privileges were abridged in the reign of Henry VIII, though the bishop still retains certain rights.

From the time of Hereward the Isle of Ely was intimately concerned with the great political struggles of the country. It was defended against Stephen by Bishop Nigel of Ely, who fortified Ely and Aldreth, and the latter in 1144 was held for the empress Matilda by Geoffrey de Mandeville. The Isle of Ely was seized by the followers of Simon de Montfort in 1266, but in 1267 was taken by Prince Edward. The county showed much sympathy with the Reformation. In the Civil War Cambridgeshire was one of the associated counties in which the king had few supporters, but the university helped him with plate and money.

The county is rich architecturally. Norman buildings include Stourbridge chapel, near Cambridge, and the parish church of Thorney, a portion of the church of an abbey founded or re-founded by Aethelwold, bishop of Winchester, as a Benedictine monastery in 972. The lepers' hospital to which Stourbridge chapel belonged was granted a fair by King John. The magnificent cathedral of Ely (*q.v.*) and the rich college buildings and chapels of Cambridge (*q.v.*) are outstanding treasures. At Swaffham Prior there are remains of two churches in one churchyard, the tower of one being good Transitional Norman, the other mainly Perpendicular. Among the many Early English examples the church of Cherry Hinton near Cambridge may be mentioned. The churches of Trumpington and Bottisham are fine specimens of the Decorated style. Monastic remains are scanty. Excluding the town of Cambridge there are no domestic buildings of note with the exception of Sawston hall (1557–84) in the south.

Domesday Book mentions more than 90 mills and numerous fisheries, especially eel weirs in the fens, and as early as the 14th century a flourishing wool industry was noted for its worsted cloths. Both the Black Death (1348–49) and the Wars of the Roses brought grave depressions, several Cambridgeshire towns

obtaining remission of taxation in 1439 on the plea of poverty. In the 16th century the chalklands of the south were growing malting barleys of exceptional quality, as they do today. Activities which have not survived include the weaving of osier baskets, the growing of woad and of saffron and the holding of fairs. Stourbridge fair was once reckoned the largest in Europe, its chief goods being wool, hops and leather; Reach fair was equally renowned for horses. Both are now gone, although the sale and training of bloodstock is still the mainstay of Newmarket (a Cambridgeshire town until transferred to West Suffolk in 1894), where the annual Cambridgeshire horse race is run in October. Racing on the heath dates from Charles II's reign, a traditional association with horses existing from at least four centuries earlier. The drainage of the fens, virtually completed by the middle of the 17th century, brought large new areas under pasturage and cultivation.

Population and Administration.—The population of the administrative county of Cambridge was 189,913 in 1961; that of the Isle of Ely was 89,112. The geographical county of Cambridgeshire includes both these administrative counties. The Isle of Ely was in effect a county palatine under a bishop until 1887. The main centres of population are: Cambridge (95,358), Wisbech (17,512), March (13,119), Ely (9,815), Whittlesey (9,324), Chatteris (5,490), Soham ([1951] 12,999) and Littleport ([1951] 18,300). The municipal boroughs are the city of Cambridge, which is the county town, and Wisbech in the Isle of Ely. The urban districts are Chatteris, Ely (an ecclesiastical city), March and Whittlesey, all in the Isle of Ely. There are 3 rural districts and 127 civil parishes in Cambridgeshire; 4 rural districts and 25 parishes in the Isle of Ely.

The county is in the southeastern circuit and assizes are held at Cambridge. The two administrative counties and the city of Cambridge have courts of quarter sessions. Cambridgeshire is mainly in the diocese of Ely, a few southern parishes being in that of Wisbech. The administrative county, the city of Cambridge and the Isle of Ely return one member each to parliament.

Economy.—With 90% of its total area under cultivation, Cambridgeshire's main interests are agricultural. Wheat comes first, with heavy yields on the fen soils, barleys and a few oats on lighter land. Low rainfall and maximum sunshine favour production of seed. Clover, sainfoin, brassicas and mustard are therefore important crops; the latter is also commonly grown as a catch crop to plow in green. With a large factory at Ely, sugar beet is grown extensively; also potatoes and, on light sandy land, carrots, kale and mangels are grown as cattle feed. Market gardening is common around the borders of the peat fens and the fen "isles"; fruit growing is found especially in the Wisbech, Cottenham and Willingham districts, associated with canning, dehydration and jam-making interests. Other enterprises include pest control and silage production; and farm mechanization is favoured by the large field units of the area. Lime, cement and brick manufacture is carried on and light industries include the production of scientific instruments, radio sets, furniture, containers, paper and books.

CAMBRIDGE UNIVERSITY. The history of the university may be said to begin in 1209 when, following disturbances at Oxford between the scholars and townspeople, a number of the scholars migrated to Cambridge. The majority probably returned to Oxford when order was restored there in 1214, but there is mention of a chancellor at Cambridge in 1226 and when in 1229 Henry III offered asylum in England to the scholars who dispersed that year from Paris. Cambridge was one of the towns to which they repaired. In 1231 the king informed the mayor and bailiffs of the town that the influx of scholars from foreign parts brought honour and profit to the kingdom and that they should be pleased to receive them; to prevent disorder among the scholars he ordered the sheriff to have it proclaimed that no scholar could remain in the town who was not under the supervision of a master.

With its chancellor, masters and scholars the university followed the pattern of Paris and Oxford. The main course of study was based on the traditional trivium and quadrivium. The study of the trivium (Latin grammar, rhetoric and logic) lasted four years and led to the degree of bachelor of arts; the study of the quadrivium (arithmetic, geometry, music and astronomy) lasted three years and led to the degree of master of arts. Degrees in divinity, law and medicine were obtained after further study. The learning and ability of a candidate were tested by disputation.

There were at first no colleges. The students lived in lodgings, or in hostels where a number boarded together, and the maintenance of order was a constant problem. It was partly to provide a remedy that the first college, Peterhouse, was established in 1284. Founded by Hugh de Balsham, bishop of Ely, it was modeled on Merton college, Oxford. Two hostels and an adjoining church were vested in a master and a body of scholars. Certain revenues were appropriated for their maintenance and statutes were made for the regulation of their affairs. Seven more colleges (some of them now extinct or merged with others) were founded in the next 70 years.

During the 13th and 14th centuries, however, the university remained comparatively insignificant. In 1318 Pope John XXII recognized it as a *studium generale* (see UNIVERSITIES) but it boasted no teachers of the order of Oxford's Robert Grosseteste. It was not until Lollardy tainted Oxford's reputation in the 14th century that the tide turned. In 1441 Henry VI founded his splendid college of St. Mary and St. Nicholas (King's college), and three more colleges were founded in the next 60 years. In 1502 Lady Margaret Beaufort, mother of Henry VII, founded a professorship of divinity, the oldest professorship in the university, and appointed John Fisher as the first professor. With his advice she proceeded to refound one college, Christ's, and to found another, St. John's, and through Fisher's influence Erasmus was persuaded to come to Cambridge. In 1511 Erasmus was appointed to the Lady Margaret's professorship and he did much to bring Cambridge to the new learning of the Renaissance. The spirit of the Reformation found early expression in the preaching of such men as Hugh Latimer and Thomas Bilney, and after the election of Thomas Cromwell as chancellor in 1535 the university became staunchly Protestant. In 1540 the king founded the professorships of divinity, Hebrew, Greek, medicine and civil law, and in 1546 he founded what was and still remains the largest college in the university, Trinity college. The university suffered a severe setback under Mary but revived rapidly on the accession of Elizabeth I. In 1570 she gave the university a revised body of statutes and in the following year the university was formally incorporated by act of parliament. The new statutes, which remained in force for nearly three centuries, vested the effective government of the university in the heads of colleges. Membership of the university was no longer envisaged without membership of a college.

Elizabeth's reign saw the growth of a strong Puritan party in the university and two new colleges founded at this time, Em-

A. F. KERSTING

A. F. KERSTING
THE RIVER CAM, WITH ST. JOHN'S COLLEGE IN THE BACKGROUND

manuel and Sidney Sussex, had a marked Puritan bias. Admissions to the university were increasing and after a setback at the turn of the century they averaged 400 a year in the period 1610 to 1635. At the outbreak of the English Civil War, however, the number of admissions declined and it was almost two centuries before they regained their former level.

In 1663 the Lucasian professorship of mathematics was founded under the will of a former member of the university, and six years later the first holder resigned in favour of Isaac Newton, then a young fellow of Trinity. Newton held the chair for over 30 years and gave the study of mathematics a unique position in the university. When the first honours examination in the university came into being in the 18th century it was primarily mathematical. It was called the tripos, after the three-legged stool used formerly at disputations, and candidates placed in the first class were known as wranglers from the style of argument at a disputation.

The 18th century was in many ways a period of stagnation in the university, but the tripos was increasingly respected as a test of ability and to be senior wrangler came to be regarded as a considerable achievement. Until the institution of a classical tripos in 1824 it was the only honours examination in the university and until 1850 the only honours examination that led to a degree. The university became a nursery of mathematicians and many who were senior wrangler in their year were afterward illustrious; for example, Sir George G. Stokes, Arthur Cayley and John C. Adams (*qq.v.*). In 1851 the university instituted tripos examinations in natural sciences and moral sciences.

Other changes were urgently necessary but the reforming party in the university was hampered by vested interests and by the statutes of 1570 which the university had no power to alter. Following the advice of a royal commission of inquiry, which reported in 1852, parliament passed an act in 1856 which put the effective government of the university in the hands of a new body (the council of the senate), appointed commissioners to frame new statutes for the university and colleges and abolished the religious tests for all except divinity degrees. A period of rapid development followed. New lecture rooms and museums were erected, new triposes instituted and new professorships established.

In 1871, with the assistance of the chancellor, William Cavendish, duke of Devonshire, the university established the Cavendish professorship of experimental physics and the building of the Cavendish laboratory was begun. James Clerk Maxwell (second wrangler in 1854) was the first professor. In the same year the Universities Test act removed the religious tests for all lay offices in the university and colleges. Meanwhile there was a marked increase in the number of admissions. From an average of under 200 a year in the 18th century they rose to 400 in the 1820s, 600 in the 1870s and 900 in the 1890s. In 1873 the first college for women, Girton, opened its new buildings in Cambridge.

Expenditure on these developments strained the university's finances. Under the provisions of an act of 1877 statutes were made compelling the colleges to contribute to the university, but the agricultural depression of the last quarter of the century reduced the colleges' rental and they were unable to contribute as much as had been hoped. In 1897 the university resorted to a public appeal for funds but it proved only moderately successful and in March 1914 support was sought from the government. A grant was received the following year. The application had been to the board of education for a grant for the medical school but World War I and its aftermath restricted the university's resources still further and in 1919 application was made to the treasury for a grant for general purposes. A condition of the grant which the university then received was that there should be a comprehensive inquiry into the resources of the university and colleges and the uses made of them. A royal commission was appointed and reported in 1922. In accordance with the recommendations of the report, commissioners were appointed under an act of 1923 to make new statutes for the university and colleges. Among the results of their work were the introduction of a retiring age for university and college officers and the grouping of the teaching staff of the university by faculties.

The period following World War I was remarkable for the number of distinguished men who held university or college appointments; among them may be mentioned Sir Joseph J. Thomson, Lord Rutherford, J. M. Keynes and G. M. Trevelyan (*qq.v.*). The flow of admissions, which had fallen to a mere trickle during the war, rose to 2,400 in 1919 when those whose education had been interrupted resumed their studies. Although the number fell in the following year, the award of scholarships by the government and local education authorities enabled many to come to the university who would not have been able to come before, and the number of admissions remained substantially higher than before the war. In 1938 and 1939 admissions numbered more than 1,900.

During World War II the national need for trained scientists of all kinds led to large numbers of science students coming to Cambridge for short courses lasting one to two years, and the number of admissions rose rather than fell. The retention of conscription after the war prevented an immediate upswing such as occurred in 1919, but in 1948 the number of admissions rose to 2,500, and in contrast with what happened after 1919 admissions in subsequent years remained at a high level. The increase in the teaching and research staff of the university was proportionately even greater.

Constitution of the University.—The university is a self-governing body with the government vested in its own senior members. It cannot amend its statutes without the sanction of the privy council, but subject to the statutes it is free to make ordinances for the management of its affairs. All proposals of any moment are referred to one of two houses, the senate or the regent house. The senate, roughly speaking, consists of all graduates of the university, whether resident or nonresident, above the standing of bachelor. A bachelor of arts who has not previously become a member of the senate by proceeding to any other higher degree may become a member by taking the degree of master of arts, for which he is normally eligible without examination as soon as six years have passed since his first term of residence. University and college officers are eligible for this degree by virtue of their offices. Altogether, the senate includes a large proportion of the university's alumni. The regent house is much smaller, consisting only of members of the senate who hold offices or posts in the university and colleges. The main business of the university is referred for ratification to the regent house and proposals, if opposed, are accepted or rejected by a straight vote! but if the minority is large enough appeal may be made to the senate. The senate considers all proposals for the conferment of degrees and appoints to a number of offices, notably that of chancellor.

The proposals submitted to the regent house and senate originate with a large number of special boards or syndicates, but all proposals to be submitted must have the sanction of the council of the senate, a body consisting of the chancellor, the vice-chancellor, and 16 other members elected by the regent house from among

A. F. KERSTING

KING EDWARD'S TOWER AND TRINITY COLLEGE CHAPEL. CAMBRIDGE UNIVERSITY

themselves. Of these, four must be heads of colleges and four must be professors or readers. In the absence of the chancellor, who is customarily a distinguished nonresident, the chairman of the council is the vice-chancellor. The vice-chancellor is also chairman of the general board of the faculties, which is responsible for advising the university on educational policy and for maintaining the standard of teaching and research, and of the financial board, which is responsible for the management of the property of the university and for the control of expenditure. The vice-chancellor is elected by the regent house, on the nomination of the council, from among the heads of colleges, and holds office normally for two years.

The Colleges.—The statutes of the university recognize 18 colleges for men and 2 for women. The men's colleges in order of foundation are: Peterhouse (1284), Clare college (1326), Pembroke college (1347), Gonville and Caius college (1348), Trinity hall (1350), Corpus Christi college (1352), King's college (1441), Queens' college (1448), St. Catharine's college (1473), Jesus college (1496), Christ's college (1505), St. John's college (1511), Magdalene college (1542), Trinity college (1546), Emmanuel college (1584), Sidney Sussex college (1596), Downing college (1800) and Selwyn college (1882). The women's colleges are Girton college (1869) and Newnham college (1871). Four other foundations may present students for matriculation in the university: Fitzwilliam house (1869), a noncollegiate institution for men, administered by the university; Hughes hall (1885), a foundation for women graduates who propose to become school teachers; New hall (1954), a foundation for women which is intended to become in time a full college of the university; and Churchill college (1960), a foundation for men with a bias toward science and engineering, also intended to become a full college.

No one can become a student in the university except through membership of one of these institutions and no one can remain a student in one of these institutions without matriculating in the university. The teaching and research staff of the university are not required to belong to a college but the great majority have a

college connection. The relationship between the university and the colleges is therefore very close and it is impossible to imagine them existing in isolation. But the colleges, like the university, are self-governing institutions and they remain legally independent of the university. They are subject to university control only to the extent that they cannot make a statute affecting the university without obtaining the consent of the university (besides that of the privy council) and the statutes of the university impose on them certain obligations, for example the payment of an annual contribution for university purposes.

The governing body of a college consists usually of the master (or provost or president) and fellows. The fellows are elected by the governing body and (except at Trinity, Magdalene and Churchill) the master is elected by the fellows. Tenure of a fellowship is usually conditional on the holder engaging in research or occupying a qualifying office in the college or in the university. Such persons are elected as are deemed fittest to become fellows of the college "as a place of education, religion, learning and research."

Apart from the master, the chief officers in a college are the bursar, the dean and the tutors. In most colleges the dean is responsible for the conduct of services in the college chapel and also, with the tutors, for maintaining discipline among the students. The selection of students is largely in the hands of the tutors. Every student in residence is under the supervision of a tutor who stands to him in *loco parentis* and represents him in all his dealings with the university. For the purpose of instruction every student is also under the direction of one or more supervisors concerned with his subject of study. They advise him on his reading and he brings work to them to be corrected and discussed.

Courses of Study.—The normal course for the degree of bachelor of arts (B.A.) lasts not less than three years. There are triposes, or examinations for honours, in 19 subjects. Most of the triposes are divided into two parts which are taken in different years, and in general a candidate must pass both parts of a tripos or two parts of different triposes to qualify for an honours degree. In the case of the natural sciences tripos and the mechanical sciences (engineering) tripos it is possible to qualify by passing only part I. The names of successful candidates are arranged in three classes. A candidate who does not reach the standard for honours may be allowed an ordinary B.A. degree.

There are also courses of study and examinations for the degrees of bachelor of laws (LL.B.), bachelor of music (Mus.B.), bachelor of medicine and surgery (M.B., B.Chir.) and bachelor of veterinary medicine (Vet.M.B.). The courses for the degrees of M.B., B.Chir. (which are taken together) and Vet.M.B. last six years. During the first three years candidates take appropriate papers in the natural sciences tripos. Veterinary students remain in Cambridge for their subsequent clinical training but medical students go to recognized hospitals elsewhere. In each case the final examinations are taken in Cambridge.

The degrees of doctor of philosophy (Ph.D.), master of science (M.Sc.) and master of letters (M.Litt.) are obtained through submission of a dissertation. A candidate must have pursued a course of research lasting three years in the case of the Ph.D. degree and two years in the case of the other degrees. It is not necessary to obtain one of the other degrees before proceeding to the Ph.D. degree.

The degrees of doctor of laws (LL.D.), doctor of medicine (M.D.), doctor of music (Mus.D.), doctor of science (Sc.D.) and doctor of letters (Litt.D.) are awarded to graduates of the university of not less than eight years' standing. Candidates for the LL.D., Sc.D. and Litt.D. degrees must give proof of distinction by some original contribution to their subject. Candidates for the M.D. degree must submit a thesis and may be required to take an examination. Candidates for the Mus.D. degree must give proof of distinction in musical composition. The university also awards the degrees of bachelor and doctor of divinity (B.D. and D.D.), master of surgery (M.Chir.), master of law (LL.M.) and master of music (Mus.M.).

Buildings and Benefactions.—The buildings of the university and colleges, the architectural legacy of seven centuries, form

8. The senate house and Caius college

a magnificent setting for the life of the university. Mention may be made of King's college chapel, begun in 1446; the Great court. Nevile's court and the library at Trinity, dating from the 16th and 17th centuries; the Senate house, finished in 1730; the Fitzwilliam museum, begun in 1837; and the University library, opened in 1934. The gardens of five of the colleges along the river Cam are known as the "Backs," and together they form a unique combination of large-scale architecture, natural and formal gardens and river scenery.

The Fitzwilliam museum was founded under the will of the 7th viscount Fitzwilliam who in 1816 bequeathed to the university his collection of pictures, manuscripts and books, with the sum of £100,000 for the erection of a museum. The collection has been enlarged by many other benefactions and is now one of the finest in Great Britain outside London.

The University library building was erected with the help of a generous grant from the Rockefeller foundation. It contains about 2,000,000 volumes, including many early printed books, and over 10,000 manuscripts. After 1662, with two short interruptions, the library was able to claim a copy of every book published in the United Kingdom.

The roll of the university's benefactors is a long one and, in spite of high taxation in the years following World War II, the sum received annually did not diminish. Many of the larger benefactions, however, now come from firms rather than individuals. While the availability of treasury support is a major factor in determining the university's plans for the future! benefactions continue to play an important part in initiating or assisting new developments. (R. M. Rv.)

CAMBUSLANG, a civil parish of Lanarkshire, Scot., is near the Clyde, 4 $\frac{3}{4}$ mi. S.E. of Glasgow (of which it is a residential suburb). Pop. (1951) 26,861.

Its leading industry is coal mining, and it contains one of the largest steel works in Great Britain. It was the birthplace of John Claudius Loudon (1783-1843), landscape gardener and writer on horticulture. The mining villages of Hallside and Newton are in the parish.

CAMBYSES, the Greek form of Old Persian Kanbujija, the name of two kings of the Achaemenid dynasty of Persia.

CAMBYSES I, son of Cyrus I and father of Cyrus the Great (see **CYRUS**), ruled over Anshan as a vassal of Media from about 600 to 559 B.C. According to Herodotus, he married a daughter of Astyages (*q.v.*).

CAMBYSES II, son of Cyrus the Great, reigned from 530 to 522 B.C. During the lifetime of his father he was in charge of Babylonian affairs. In 538 B.C. he performed the ritual duties of a Babylonian king at the New Year festival and in 530 before Cyrus set out on his last campaign, he was appointed regent in Babylon.

The conquest of Egypt, planned by Cyrus, was the major achievement of Cambyses' reign. Apart from the inscription of an Egyptian, Ldjahorresne, who served under him, the activities of Cambyses in Egypt are known mainly from Greek writers, in particular Herodotus, who drew on Persian and Egyptian sources, both of which were hostile to him. The invasion took place in 525 B.C., during the reign of Psamtik III. Cambyses received

assistance from Polycrates of Samos, from Phanes, a Greek general in the Egyptian army who gave him valuable military information, and from the Arabs who provided water for the crossing of the Sinai desert. After Cambyses had won a battle at Pelusium and captured Heliopolis and Memphis Egyptian resistance collapsed. Upper Egypt was subdued without difficulty and the Libyans and Greeks of Cyrene and Barca made their submission. Psamtik was at first treated leniently but having attempted to raise a revolt was executed.

While in Egypt Cambyses planned expeditions against Ethiopia, the oasis of Amon (Siwah) and Carthage. He himself set out against Ethiopia but after annexing the northern part of the country had to retire because of shortage of supplies. A detachment sent from Thebes captured Al Kharijah (Kharga) oasis but perished in a sandstorm before reaching the oasis of Amon. The attack on Carthage was never attempted as the Phoenicians refused to use their fleet against kinsmen.

Herodotus accuses Cambyses of many atrocities in Egypt, attributing them to madness, but contemporary Egyptian sources suggest that his accusations must largely be discounted. Certainly at the beginning of his rule Cambyses pursued a conciliatory policy. He adopted an Egyptian titulary and visited Sais, the seat of the dynasty he had displaced, to obtain official recognition from the goddess Neith. He sacrificed to the gods of Sais and restored the revenues to their temples.

According to Darius the Great, Cambyses, before going to Egypt, had secretly killed his brother, Bardiya, whom Herodotus calls Smerdis (*q.v.*). The murdered prince was, however, impersonated by Gaumata, a Magian, who in March 522 B.C. seized the Persian throne. Herodotus states that Cambyses heard of this revolt in Syria, while returning from Egypt, and there he died in the summer of 522 B.C., either by his own hand or as the result of an accident.

See G. Posener, *La première domination Perse en Egypte* (1936).
(J. M. M.-R.)

CAMDEN, CHARLES PRATT, 1ST EARL (1714-1794), lord chancellor of Great Britain, who opposed the taxation of the American colonies, was born in London in 1714, the third son of Sir John Pratt, chief justice of the court of king's bench from 1718 to 1721. He was educated at Eton and at King's College, Cambridge. He had been entered at the Inner Temple in 1728, and in 1738 he was called to the bar. After 12 years of struggling practice in the common law courts and on the western circuit, he sprang into prominence in 1752 with his successful defense of a bookseller charged with libel. All his life he was to fight for the principle that in libel it is for the jury to decide the general issue of guilt, and not merely publication. Two years later the elder Pitt appointed him attorney general, whereupon he was elected to parliament for Downton in Wiltshire. His calm mode of speech made little mark in the House of Commons, and his two state prosecutions (of Dr. Hensley for treason and Dr. Shebbeare for seditious libel) were conducted with moderation. In Dec. 1761 he succeeded Sir John Willes as chief justice of the court of common pleas and was knighted, and in 1763 he delivered his memorable judgment in John Wilkes' case, declaring in firm language that general warrants were illegal. This brought him immense popularity, and two years later he was created Baron Camden.

On July 30, 1766, Camden became lord chancellor. He was, however, uncompromisingly opposed to the government's treatment of the American colonies, and ultimately on Jan. 16, 1770, he was dismissed. He continued steadfastly to oppose the taxation of the colonists, and in 1778 he signed the protest of the lords in favour of an address to the king on the manifesto of the commissioners to America. In 1782 he became president of the council under the second marquis of Rockingham, but resigned next year. The younger Pitt restored him to his office in 1784, and he held this until his death in 1794. He was created Earl Camden and Viscount Bayham in 1786. As a judge he was of the first rank, both at law and in equity. He had a powerful intellect, he was eminently judicial, and he was zealous in establishing the liberty of the subject.

BIBLIOGRAPHY.—Lord Campbell, *Lives of the Lord Chancellors*, vol. vi and vii (1868); E. Foss, *Judges of England*, vol. viii (1848-64); H. S. Eeles, *Lord Chancellor Camden and His Family* (1934). (R. E. MY.)

CAMDEN, JOHN JEFFREYS PRATT, 2ND EARL and 1ST MARQUESS (1759-1840). English statesman. whose inflexible policy as lord lieutenant of Ireland led to the rebellion of 1798. was born on Feb. 11, 1759. the only son of the 1st earl, the lord chancellor. Educated at Trinity college, Cambridge, he entered parliament as M.P. for Bath in 1780, and was a lord of the admiralty in the earl of Shelburne's ministry (1782-83) and under William Pitt (1783-89). Thereafter he was a lord of the treasury until 1794 when he succeeded his father as Earl Camden. He was appointed lord lieutenant of Ireland in 1795 and his term of office was noteworthy for the stern repression of revolutionary agitation. After the suppression of the rebellion in which this policy culminated, Camden resigned (1798). In Pitt's last ministry he was secretary of state for war and the colonies (1804-05) and lord president of the council (1805-06). He was again lord president (1807-12) and for a few months he remained a cabinet minister without portfolio. He was created Marquess Camden in 1812 and was chancellor of Cambridge university from 1834 until his death in Kent on Oct. 8, 1840. (A. AL.)

CAMDEN, WILLIAM (1551-1623). English antiquary, a pioneer of historical method and author of *Britannia*, the first comprehensive topographical survey of England, was born in London on May 2, 1551. Educated at Christ's Hospital and St. Paul's school, he was admitted to Magdalen college, Oxford. but moved first to Broadgates hall (later Pembroke college) and then to Christ Church, becoming B.A. in 1573. In 1571 he had moved to London and in 1577 was appointed second master of Westminster school. He was also school librarian and in 1593 became headmaster. In 1595 he published a Greek grammar which was in use for several centuries. In 1589 he was granted the prebend of Ilfracombe and in 1597 was appointed Clarenceux king-of-arms. He was thereby relieved of a schoolmaster's chores and given more time for writing.

From the time he left Oxford. Camden had devoted his leisure to antiquarian studies and spent his vacations traveling the country, collecting material for his *Britannia* (1586), dedicated to Lord Burghley. A topographical survey of England in Latin. without forerunner. except John Leland's shorter work written 30 years before. *Britannia* was an immediate success. It was attacked by Ralph Brooke. York herald. who, motivated by professional jealousy. impugned Camden's scholarship. Camden refuted his critic in the preface to the fifth edition (1600), but issued an improved edition in 1607. The first English translation. that of Philemon Holland, appeared in two parts (1610). and of those that followed, the best are by Richard Gough (1789 and 1806).

Camden planned to write a general history of England. but only published a number of medieval chronicles (*Anglica, Hibernica, Normannica, Cambrica, à veteribus scripta*; 1602), and some of his commonplace collections (*Remaines*; 1605). In 1607 he was commissioned to write an official account in Latin of the gunpowder plot. In the same year he began his *Annales rerum Anglicarum et Hibernicarum regnante Elizabetha*, a history of the reign of Queen Elizabeth I. suggested by Burghley. who had sent him many official documents. The first volume. which took the story down to 1588, was published in 1611. The second, completed in 1617, was not published until two years after Camden's death. Camden's work has been the basis of most later accounts of the reign. Some criticism has been leveled at his treatment of the Mary Queen of Scots episode, and it was alleged that he altered his account to please James I. The work is based on manuscripts in the Cotton collection. The first English editions of the first and second parts appeared in 1625 and 1629 respectively. The best edition is T. Hearne's (1717).

Camden suffered from poor health, and in 1618 he retired to Chislehurst. Kent. He died there on Nov. 9, 1623. Before his death he founded a chair of history at Oxford university. Camden was acquainted with many leading scholars, English and continental. and with most of the prominent figures at court. He sought no high office and refused both the post of master of requests and a

knighthood. The Camden society. founded in 1838, published many useful historical documents and was merged with the Royal Historical society in 1897.

Camden has a special place among English antiquarians. He was the leading historical writer for a generation influenced by the Renaissance and eager to learn of its Roman past. and for a public which included statesmen and ecclesiastics who, for the first time. saw historical precedent as a guide to present action. Whereas his only precursor, Leland. was a solitary eccentric whose work was little known. Camden was an active member of the Society of Antiquaries. founded about 1585, that brought historical scholars together for the first time, and so laid the foundations for the great school of 17th-century historians. Camden was the first to realize the importance of ancient languages in the study of place names. and to make known the existence of Romano-British coins. His work was a model for later writers and his dispute with the herald, Brooke, was to prove the first of a long line of historical controversies.

CAMDEN, an industrial city in south central Arkansas, U.S., 100 mi. S.W. of Little Rock. Camden began as a trading post in 1783. With steamboat traffic up the Ouachita river in 1822. followed by the coming of three railroads, Camden developed as a distribution centre. An earlier settlement was called Ecure à Fabre ("Fabre's bluff"), named after the first permanent white settler. In 1844, when it was incorporated, the name was changed by Gen. Thomas Woodward for his home at Camden, Ala. Evidence of the American Civil War is found at Poison Springs battle-ground. Ft. Lookout, Unknown Confederate Soldiers cemetery and well-kept ante-bellum homes.

Camden's fastest growth began in the 1920s with completion of a year-round navigation system on the river, discovery of the Smackover oil fields and the location of a paper mill in the city. Other Camden industries using the area's timber and mineral resources manufacture bags, bag machines, books, air conditioners, mobile homes, furniture, brick, pottery, soft drink sirups and roofing. For comparative population figures see table in ARKANSAS: *Population*. (W. E. S.)

CAMDEN, a city in New Jersey, U.S., and seat of Camden county. is on the Delaware river opposite Philadelphia, Pa., with which it is connected by a suspension bridge that was opened to traffic in 1926. The site was originally known as Cooper's Ferry. In 1681, the year Philadelphia was founded, William Cooper built a home near the mouth of the Cooper river and named the tract Pyne Point. In 1689 he assumed control over the ferry to Philadelphia. Two other prominent settlers were John Kaighn and Archibald Mickle, for whom streets have been named. Settlement, which was largely by Quakers, was slow, however, and for decades it was claimed that Camden existed out of the necessity for crossing the Delaware in order to reach Philadelphia.

In 1773 interest in real estate grew when Jacob Cooper, a descendant of William, laid out 40 ac. as a townsite. He named the location Camden for Charles Pratt, 1st earl of Camden, whose outspoken opposition to British taxation policies made him popular with the American colonists. The development of the new village was impeded by the American Revolution, as Camden was often held by the British when they occupied Philadelphia.

In the 19th century improvements in transportation brought new growth. While ferry services increased, the advent of the railroad provided the greater impetus. In 1834 the cross-state Camden and Amboy railroad was built and for six years Camden enjoyed better railroad facilities than Philadelphia in reaching the New York city market. By this time, too, the town had achieved its political independence. In 1828 it was set apart from Newton township and incorporated as a city; in 1844 it was selected as a seat of the newly formed Camden county.

Expansion occurred in the years following the American Civil War, a period marked by the inauguration and growth of the

town's important industries. The oldest steel pen company in the U.S., established in 1858, developed in these years, as did a canning plant which opened in 1867 and started marketing condensed soups in 1897. The Victor company, founded in 1894, developed the talking machine. A shipbuilding company was established in 1899 on the south Camden waterfront. Other industries include furniture, chemical products, paper industries machinery, bookbinding, leather, plastics, automobile accessories, plumbing fixtures and electrical appliances.

Among the points of interest are the Walt Whitman house, where the poet spent the last eight years of his life; the Camden County Historical Society museum in the Joseph Cooper, Jr., house, built in 1726; and the Camden divisions of Rutgers, the state university.

Pop. (1960) 117,159. For comparative population figures see table in *NEW JERSEY: Population.* (H. F. WI)

CAMDEN, a city of South Carolina, U.S., 32 mi. N.E. of Columbia; seat of Kershaw county. The first settlers in the area established farms along the nearby Wateree river about 1733. In 1758 Joseph Kershaw established a country store and the community came to be known as Pine Tree Hill. Ten years later the colonial assembly established a court there and the name was changed to Camden, honouring the Englishman Charles Pratt, 1st earl of Camden, a colonial hero by virtue of his fight against the Stamp act. Camden was a major British garrison during the American Revolution and the scene of two of the greatest American defeats. On Aug. 16, 1780, Gen. Horatio Gates, with forces vastly outnumbering those of Cornwallis, lost over 2,000 men, including Gen. Johann Kalb (*q.v.*), in a vain effort to seize the town. On April 19, 1781, a second colonial army under Gen. Nathanael Greene, camping on Hobkirk's hill just outside the town, was caught by surprise and routed by a smaller British force. Andrew Jackson, then 14 years old and a prisoner of the British, watched the battle from the stockade jail. The following month the British, harassed by guerrilla raids, burned and evacuated the town.

Camden prospered as a plantation centre and resort area after the American Revolution. During the American Civil War it was an important Confederate railroad terminus, supply base and hospital. On Feb. 24, 1865, Gen. William T. Sherman entered the town and again much of it was burned. From the American Revolution until well after the Civil War Camden was famous for its duels and provided a school for young men seeking instruction in the code of honour; in the late 19th century dueling was prohibited by law. Camden's fame as a resort area had grown and in the 20th century it was noted for polo, steeplechases, hunts and the fashionable crowds they attracted.

After World War II, the coming of a synthetic fibre plant began to transform it from a city of the old south to one of the new. Industries include textiles, man-made fibres, pulpwood, veneer, lumber and cottonseed oil.

For comparative population figures see table in *SOUTH CAROLINA: Population.* (G. H. CT.)

CAMEL, two species of the genus *Camelus* belonging to the suborder Tylopoda (*q.v.*) in the order Artiodactyla (*q.v.*). The Arabian camel, *C. dromedarius*, has only one hump, but the Bactrian camel! *C. bactrianus*, has two. The limbs are long and the feet have no traces of the second and fifth toes; the wide-spreading soft feet are adapted for walking upon sand or snow. Horny pads on the chest and knees support the weight when kneeling. Although camels ruminant (chew the cud) they are not classified in the suborder Ruminantia because, among other anatomical differences, the stomach differs from that of ruminants. Its third chamber is vestigial and its first, the rumen, has smooth (not papillose) walls, with diverticula, wrongly called "water cells," communicating with it.

Camels are known only as domestic animals and are not found in a truly wild state. The Bactrian camel occurs throughout the highlands of central Asia from Turkistan to Mongolia and although some "wild" herds inhabit various remote districts they are probably descended from animals escaped from domestication. All through that region it is an important beast of burden.

W. SUSCHITZKY

BACTRIAN CAMEL (*CAMELUS BACTRIANUS*)

Although it travels at a slower rate (two to three miles per hour) than the Arabian camel, the Bactrian can maintain this pace for a longer time in caravan, usually averaging 30 mi. per day while carrying a 400-lb. load. The height of the Bactrian is about seven feet at the top of the humps. The Arabian camel, characteristic of India, the near east and north Africa, is likewise primarily important as a beast of burden, though like the other species

it also provides wool, milk, hides and meat. It is longer-legged, lighter-built and shorter-coated than the Bactrian camel. The Arabian camel stands about seven feet tall at the shoulder and when being used for riding can maintain a speed of eight to ten miles per hour for 18 hours. When camels run they pace; that is, they move the two legs on a side forward at the same time. The Arabian camel has been imported into many parts of the world.

Camels can flourish on the coarsest of sparse vegetation and feed on thorny plants, the leaves and twigs of shrubs, and dried grasses that other animals would refuse, though camels are not averse to more attractive food if it is available. When the feeding is good they accumulate in their humps stores of fat, which they are able to draw upon when conditions are adverse not only for sustenance but also for the manufacture of water by the oxidation of the fat, but they do not store water in the miscalled water cells. They are thus able to fast and go without drinking for several days; they have been known to go without water for 17 days and survive. Camels can carry a load of 500 lb. 25 mi. a day for three days without drinking. They lose their body water slowly and can lose up to 25% of their weight by dehydration without ill effects—a much higher percentage loss than man and other mammals can tolerate. They can then regain their lost weight in ten minutes by drinking as much as 25 gal. of water. Other adaptations that enable them to survive in deserts and other unfavourable environments include double rows of heavy protective eyelashes, haired ear openings, the ability to close their nostrils and keen senses of sight and smell.

In the winter camels, especially the Bactrian species, grow thick shaggy coats, which they shed in the spring so that they are almost naked until the new coat starts growing. The female produces one young at a birth after a gestation of 11 months and suckles it for a year; maturity is reached at the age of 10 to 12 years and the life span is 30 to 40 years. Camels are docile and patient when properly trained and handled but are liable to sudden fits of rage, especially in the rutting season. Breeding has been so specialized that the riding camel forms a type quite distinct from the common baggage camel.

Camels originated in North America about 40,000,000 years ago and by 1,000,000 years ago had spread to South America and Asia. They later vanished from the continent of origin and were not seen there again except in zoos until introduced from Asia by the U.S. army in the 1850s as beasts of burden for frontier garrisons in the southwest. The experiment was abandoned, however, and the animals were turned loose. The last wild ones were seen about 1900.

(L. H. M.)

CAMEL CORPS, a military unit mounted on camels for service in the desert. The first Egyptian camel corps was formed in 1884 for the Gordon relief expedition, the personnel being drawn from British units; it was disbanded at the conclusion of the campaign. Later a new camel corps was recruited from Sudanese and Egyptian sources and became a permanent part of the Egyptian army; it fought with credit in the campaigns against the khalifa between 1896 and 1898.

The Bikaner camel corps, an imperial service unit, was raised and maintained by the maharaja of Bikaner, one of the native princes of India. It saw much active service, taking part, without

its camels, in the China expedition of 1900 and in the operations in Somaliland in 1903–04. When World War I broke out it again volunteered to go overseas and served in Egypt.

An imperial camel corps brigade, a composite British, Australian and New Zealand formation, served in Palestine from 1917 to June 1918, when it was reorganized as cavalry. It played a creditable part in the battles of Romani and Gaza and shared in the attack on Beersheba and the subsequent advance to Jerusalem as well as in the Amman and Salt raids.

In the United States a proposal was made after the Mexican War (1846–48) to use camels for crossing the newly acquired arid regions of the southwest. Secretary of War Jefferson Davis favoured their use and in 1855 congress appropriated \$30,000 to purchase camels. They were used briefly on mail and express routes but the project was soon abandoned.

CAMELLIA, a genus of more than 80 species of broad-leaved evergreen trees and shrubs belonging to the tea family and native to Asia. Most garden varieties belong to *C. japonica* but a considerable number belong to *C. sasanqua* and *C. reticulata*. They are esteemed for their dark green foliage and handsome flowers in many forms—single, semi-double, incomplete double and complete double—and colours—white, rose, red or variegated. Different flower forms have been produced by the conversion of stamens into petal-like parts. The blooms open in autumn and winter, and those of *C. sasanqua* are sweet scented.

J. HORACE MCFARLAND CO.

COMMON CAMELLIA (*C. JAPONICA*),

LIAEFLORA

Largely they are grown from cuttings, best made when the summer growth has matured, and to a lesser extent by grafting, shortly before growth starts in spring. They are favourite plants in gardens wherever soil and climate are congenial and in greenhouses.

Good drainage is essential and a mulch of peat, leaves or other coarse vegetable matter three to four inches thick is desirable. Water-spraying the leaves and supplying an even amount of soil moisture are valuable aids in securing good growth and flowering. A soil mixture of good loam, sand, peat and well-rotted manure is suitable. During winter it is best to maintain greenhouse or indoor temperatures of 45° to 55° F. during daylight and 5° to 10° lower at night.

(H. H. HU.)

CAMELOT, the legendary seat of King Arthur's court (see ARTHURIAN LEGEND), variously identified with Caerleon-upon-Usk in Monmouthshire (see CAERLEON), with Queen's Camel in Somerset, with the little town of Camelford in Cornwall and with Winchester.

CAMEO, a term commonly applied to engraved work executed in relief on hard or precious stones, as well as to imitations of such stones in glass, called "pastes," and on the shells of molluscous animals. The cameo is therefore the converse of the intaglio, which consists of an incised or sunk engraving in the same class of materials.

CAMERA, PHOTOGRAPHIC: see PHOTOGRAPHY: Apparatus.

CAMERA LUCIDA AND CAMERA OBSCURA, two simple optical devices used by artists, scientists and others to aid them in drawing, viewing or demonstrating an object by projecting an image of it onto a suitable screen. The camera obscura (Latin

for "dark room") was the first to be introduced and it has been known in one form or another for many centuries. Essentially it consists of a darkened chamber having in one wall a small aperture or a lens, by means of which an image of external bright objects is formed on a screen at the opposite end of the darkened chamber (fig. 1). Artists having difficulty with perspective drawing have used the device from early times to project outdoor scenes or profiles of persons onto a sheet of paper so that they could trace the correct outline before proceeding to paint the scene or the portrait. Astronomers have used the device for projecting images of the

FIG. 1.—DIAGRAM ILLUSTRATING A SOLAR ECLIPSE THROUGH A SIMPLE CAMERA OBSCURA (AFTER RAINER GEMMA-FRISIUS, 1545)

eclipsed sun, the moon and brighter stars. Showmen have made profitable use of it, erecting a room-size camera obscura at a vacation resort before an attractive view. The popularity of the camera obscura began to wane after photography was introduced in 1839 by Louis Daguerre and William Fox Talbot, in whose hands the camera obscura became the familiar photographic "camera."

The camera lucida (Latin for "light room"), invented in 1807 (see below), essentially consists of a small prism of special construction mounted in front of the observer's eye and used in full daylight. By means of this device an image of chosen objects placed in front of the prism is made to appear to be lying on the paper, enabling an artist, naturalist or microscopist to trace the outline of his subject in correct proportions.

THE CAMERA OBSCURA

Early History.—The invention of the original camera obscura, in which a small hole was used to project an image of external objects on a screen in a darkened room (fig. 1), is lost in antiquity. Certainly Aristotle (384–322 B.C.) is known to have been familiar with the fact that an image of the sun could be projected onto a screen through a small aperture in a wall, and that the image would be circular no matter what shape the aperture might have. (The correct explanation of this phenomenon was given by Maurolycus in 1521.) Alhazen (965?–1038), Vitello (d. c. 1290), Roger Bacon (c. 1220–c. 1292) and several other writers of the 13th, 14th and 15th centuries demonstrated familiarity with the principles of the simple camera obscura and many of its applications. Bacon suggested the addition of an inclined plane mirror outside the aperture so that persons passing below the window could be imaged on the screen.

John Peckham, archbishop of Canterbury (1279), commented on the possible use of a camera obscura for observing solar eclipses. Leonardo da Vinci (1452–1519) made accurate drawings of the camera obscura, and seems to have thoroughly understood its action.

Introduction of the Lens—The substitution of a lens for the

FIG. 2.—THE USE OF A CONCAVE LENS IN A CAMERA OBSCURA TO MAGNIFY THE IMAGE

small aperture in the camera obscura, thus converting it into a practical instrument, was apparently first suggested by Girolamo Cardano (Jerome Cardan; 1501-76) in his book *De subtilitate* (1551), then by Daniello Barbaro in *La Pratica della prospettiva* (Venice, 1568), and also by Giovanni Battista Benedetti in 1585. Barbaro further showed that the image must be focused by placing the screen at the proper distance from the lens, and explained how the definition could be improved by stopping the lens down to a small aperture.

Nevertheless, credit for the introduction of a lens in the camera obscura is generally given to the Venetian, Giovanni Battista della Porta (c. 1538-1615), who in 1558 wrote a very popular four-volume book on natural science called *Magia Naturalis* in which he described, among other things, the camera obscura with a small aperture. In the 20-volume second edition of this book (1589), he added as a "great secret which he had intended to keep," a note on the advantages which result from the use of a lens in place of a simple hole.

The image in a camera obscura is, of course, inverted. If a translucent screen is used to catch the image, the observer being on the far side of the screen, then the image will be right-handed and inverted. However, if an opaque screen is used, the observer must either be inside the camera himself or looking into it through a hole at one side, in which case the image he sees will be both inverted and left-handed. It was early recognized that if a plane mirror is used in front of or behind the lens, the left-handedness of the image on an opaque screen will be reversed, giving a correct image.

Modifications and Improvements.—Johann Kepler (1571-1630) well understood the action of the camera obscura, and in fact it was he who introduced the name. In 1600 he began to use the instrument for solar observations, and greatly improved it for this purpose by introducing a negative lens at a suitable distance behind the positive lens to enlarge the projected image (fig. 2). This is the principle of the modern telephoto lens. He is reported to have observed the transit of the planet Mercury across the sun's disk in 1607 by this means.

Even though the telescope was introduced in 1609, astronomers continued to use a camera obscura for solar observations because of the danger to their eyes when looking directly at the sun. In 1611 Johannes Fabricius used a camera obscura without a lens to observe sunspots for the first time.

Robert Boyle (1627-91) seems to have been the first to construct a small portable box-type camera obscura about 1665. It could be extended or shortened like a telescope to focus the image on a sheet of paper stretched across the back of the box opposite the lens. A similar device with an internal mirror to reflect the image onto a screen at the top of the box was described by Johann Zahn in 1685.

A somewhat larger portable camera obscura in the form of a tent was used by Kepler about 1620, and during the following two centuries this form was employed extensively by artists as an aid to perspective drawing. It was made from a pyramidal framework of rods covered with cloth, with the lens at the top surmounted by a plane mirror to reflect a scene onto a horizontal sheet of drawing paper laid on a table inside the tent. The artist would then draw round the objects in the scene and thus determine accurately their relative shapes and sizes. The perspective in many of the paintings made during the past 300 to 400 years is so accurate that some form of camera obscura was most probably used.

It is interesting to note that if the mirror is set so as to look over the artist's head at a scene situated behind his back, then the scene will appear erect and right-handed when projected on the drawing paper.

A somewhat larger form of camera obscura was built in the form of a small cabin in which a lens was mounted in a hole in the roof, with a plane mirror above it at 45° to reflect distant scenes down into the lens, the image of distant objects being projected on a white table inside the cabin. Several people could see the image by standing around the table, and to change the scene it was merely necessary to rotate the mirror holder about the vertical axis of the device. A few camera obscuras of this type are still

in existence at popular vacation resorts as amusement devices.

In 1812 W. H. Wollaston realized that the image quality in the outer parts of the field of this device could be improved by using a meniscus-shaped lens in place of the usual biconvex lens, with a diaphragm or stop on the concave side of the lens to force the oblique rays to pass more normally through it. In this way he developed the flat-field landscape lens, millions of which are manufactured every year for use in box cameras (fig. 3).

The early inventors of photography naturally made use of the box-type camera obscura, since their aim was to "fix" or render permanent the beautiful and interesting views they saw on the

FIG. 3.—DIAGRAM SHOWING WOLLASTON'S APPLICATION OF A MENISCUS LENS TO THE CAMERA OBSCURA

translucent screen. Fox Talbot merely laid a sheet of light-sensitive (photogenic) paper on a piece of glass in the plane of the image, and allowed the light to be recorded by a blackening of the paper.

Since Daguerre used a plain camera without an internal mirror, his positive daguerreotypes were left-handed, and various inventors proposed that a reflecting prism or plane mirror should be mounted in front of the lens to rectify this defect. For the further development of the photographic camera, see PHOTOGRAPHY.

BIBLIOGRAPHY.—J. Waterhouse, "Notes on the Early History of the Camera Obscura," *Photographic Journal*, 25:270-290 (May 1901); J. M. Eder, *History of Photography*, Eng. trans. by E. Epstein, pp. 36-45 (1945); H. and A. Gernsheim, *The History of Photography*, pp. 1-19 (1955).

THE CAMERA LUCIDA

This is a small instrument invented in 1807 by William Hyde Wollaston (1766-1828). It consists of a small four-sided prism mounted on a simple stand at a convenient height above a sheet of paper. By placing the eye close to the upper edge of the prism so that half of the eye pupil is over the prism, the observer is able to see a reflected image of objects situated in front of the prism, apparently lying on the paper (fig. 4); he can then trace the image with a pencil and thus record its appearance accurately. The optical distinction between the camera obscura and the camera lucida is that in the former a real image of external objects is actually projected on the paper by the lens, whereas in the latter a virtual image of the distant object is made to appear to lie on the paper.

The actual use of this instrument is, unfortunately, not as simple as the above brief outline might indicate. For example, if the observer's eye moves as little as $\frac{1}{8}$ in. from its correct position, the light beam reflected by the prism may miss the pupil of his eye entirely. Furthermore, if the distance of the object happens to be different from that of the paper, it will be impossible for the observer to focus both the object and the paper equally sharply at the same time; also, if he were to move his head slightly, there would be a small relative movement between the image and his drawing.

To avoid these difficulties, a selection of weak spectacle lenses is usually provided with the camera lucida which may be inserted between the prism and the paper, as shown in fig. 4, to make the paper appear at the same distance from the eye as the reflected

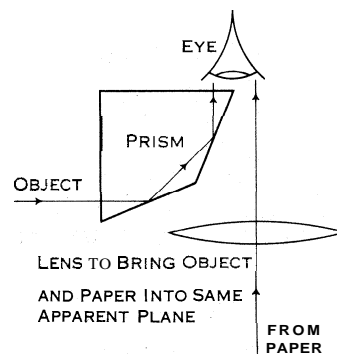

FIG. 4.—DIAGRAM SHOWING THE PRINCIPLE OF THE WOLLASTON CAMERA LUCIDA

image of the object. It will be readily understood that the camera lucida can be used to copy a drawing at its original size, or enlarged or reduced, without distortion, the degree of enlargement being given by the ratio of the distances of the paper and the original drawing from the eye.

In order to give the eye a greater freedom of movement, several modifications of the original Wollaston system were proposed during the 19th century, mainly for use as an aid in drawing the magnified images seen in a microscope. In these devices, a small transparent plane mirror is mounted in front of the eye at an angle of 45° to the direction of the light, so that a reflected image of the subject is seen superposed upon a direct view of the drawing paper, allowing a greater freedom of movement of the observer's eye. Unfortunately, when a single mirror is used the image is inverted and left-handed, but the use of a second mirror in the reflected beam will rectify this. In the original Wollaston form of the camera lucida (fig. 4), the two reflections are combined within a single prism so that no external mirrors are necessary.

In the Abbe form (fig. 5),
particulars introduced without a 1880,

tical microscope, the diagonal transparent mirror is cemented into a small glass cube and mounted close to the microscope eyepiece, the second mirror being supported over the paper by a projecting arm. No equalizing lenses are required because a touch on the fine-adjustment screw of the microscope will serve to bring the microscope image to the same apparent distance as the paper.

CAMERARIUS, JOACHIM (1500-1574), German classical scholar and Lutheran theologian who mediated between Protestants and Catholics at the Reformation, was born at Bamberg on April 12, 1500. He joined the humanist circle of Helius Eöbanus Hesus at Erfurt in 1518 and later became the pupil and friend of Philipp Melanchthon at Wittenberg (1521). He was made professor of classics at Tübingen in 1535. In 1541 Duke Ulrich of Württemberg summoned him to reorganize the University of Leipzig. His classical publications include editions with commentaries of Sophocles, Herodotus, Homer, Plautus and Xenophon, as well as Latin translations of Greek authors. He also wrote a catechism about the classics in Latin verse (*Praecepta honestatis atque decoris puerilis*, 1528) and Latin biographies of Hesus (1553) and Melanchthon (1566). He was present with Melanchthon at the reading of the *Confutatio pontificia* at Augsburg in 1530, and also at a diet there in 1555. In the same year he was the mediator in the dispute over Osiander at Nurnberg. Maximilian II summoned him to Vienna in 1568 to give advice and to order Austrian church affairs. He died at Leipzig on April 17, 1574. His posthumously published *Epistolarum familiarum libri vi* (1583) and *Epistolarum familiarum libri v posteriores* (1595) are valuable sources for the period.

Beiträge zur Kirchengeschichte Deutschlands*, vol. ii, pp. 34-87 (1957); H. Helbig, *Die Reformation der Universität Leipzig* (1953). (C. L. A. R. H.)

CAMERARIUS, RUDOLF JAKOB (1665-1721), German botanist and physician who was the first to demonstrate experimentally that in the absence of anthers (pollen-bearing organs) no seeds are produced by the flower, was born at Tübingen, Feb. 12, 1665, and died there, Sept. 11, 1721. He became professor of medicine and director of the botanic garden at Tübingen in 1668.

De Sexu Plantarum Epistola (1694), Camerarius' best-known

work, contains his observations on the sexuality of plants. (See also *BIOLOGY: History*.) A German translation of the *Epistola* and an account of Camerarius' life and works are given in Camerarius-Mobius, *Über das Geschlecht der Pflanzen* (1899). See J. von Sachs, *History of Botany*, pp. 385-390 (1906).

(J. W. Tr.)

CAMERON, ANDREW CARR (1834-1890). U.S. labour leader and editor, was born on Sept. 28, 1834, in Berwick-upon-Tweed, Eng. After his family moved to the United States he went to work for a Chicago newspaper and became an active member of the typographical union. In 1864 he became editor of a new labour weekly, the *Workingmen's Advocate*. Two years later he helped found the National Labor union, which grew to a membership of over 600,000. The *Advocate* became its official organ, and through it Cameron campaigned for the eight-hour day, the use of arbitration rather than the strike, the amalgamation of farm and industrial workers, co-operatives and currency reforms.

In 1869 he represented the United States at an international labour congress in Basel, Switz. Attempts to form a labour party resulted in the weakening of both the union, which was ultimately absorbed into the Greenback Labor party in 1880, and the paper, which was discontinued. Cameron was editor of the *Inland Printer* and later bought the *Artist Printer*, editing it until he died, May 28, 1890.

CAMERON, JOHN (c. 1579-1625). Scottish theologian, born at Glasgow about 1579, received his early education in his native city. He taught Greek in the university there, lectured at Bordeaux and Sedan and then traveled in Germany and Switzerland. He became a minister of the Protestant Church in 1608 and in 1618 was appointed professor of divinity at Saumur, the principal seminary of the French Protestants. The civil troubles in France drove him to England in 1620, and two years later King James I (VI) appointed him principal of the University of Glasgow. Cameron was prepared to accept episcopacy and was cordially disliked for his support of the king's views on the royal prerogatives. He resigned his office in less than a year and returned to France, becoming professor of divinity at Montauban in 1624. There he made many enemies by his doctrine of passive obedience. He was stabbed in the street in 1625 and died as a result of the attack. His collected works were published (in Latin) at Geneva in 1642, with a memoir by Cappel.

Cameron has a distinct place in the development of Calvinistic theology. He and his followers maintained that the will of man is determined by the practical judgment of the mind; that the cause of men's doing good or evil proceeds from the knowledge which God infuses into them; and that God does not move the will physically but only morally, by virtue of its dependence on the judgment of the mind. This peculiar doctrine of grace and free will was adopted by a number of the more learned among the Reformed ministers who dissented from Calvin.

CAMERON, RICHARD (1648-1680), Scottish Covenanter, founder of a religious sect called Cameronians (*q.v.*) and one of the first to insist on separation from those Covenanters who accepted the indulgence of 1672. was born at Falkland, Fife, and was schoolmaster of his native village until he became chaplain and tutor to Sir William Scott of Harden. In 1673 he began to preach in the open air, under the influence of the Covenanter John Welch, and refused to recognize the rule of an "uncovenanted" king or to accept Charles II's indulgence, which suspended the laws against nonconformists. The number of his followers was severely reduced by their defeat at Bothwell bridge (1679), though many joined him in exile in Holland. Cameron returned at the end of the year and on June 22, 1680, he and his friends, including Donald Cargill (*q.v.*), Thomas Douglas and David Hackston, issued the Sanquhar Declaration, calling for war on Charles II and the exclusion of James, duke of York. With only a small group of men, he was easily taken and killed by royal troops at Airds Moss in Ayrshire on July 22. The prayer he had made before the brief fighting became one of the covenanted songs — "Lord, spare the green and take the ripe."

See J. Herkless, *Richard Cameron* (1896).

FIG. 5 — DIAGRAM ILLUSTRATING THE PRINCIPLE OF THE ABBE CAMERA LUCIDA.

CAMERON, SIMON (1799–1889), U.S. businessman and politician, was born in Lancaster county, Pa., on March 8, 1799. Orphaned at the age of nine, Cameron received little schooling and soon began earning his own livelihood. By the age of 25 he had risen from printer's devil to newspaper owner and editor and to a position of influence in the state Democratic party. Varied business interests—iron manufacturing, banking, insurance and railroads—received his chief attention until 1845 when through his own shrewd manipulations and with the support of Whigs and high-tariff Democrats he was elected to the United States senate. Thereafter his chief business was politics and he became one of the most powerful political bosses the United States has ever known.

In 1857, as the candidate of the new Republican party, but with the aid of Democratic votes which, according to rumour, had been secured by questionable means, Cameron was again elected to the senate. In 1860 he was Pennsylvania's favourite son candidate for president in the Republican national convention and threw his support to Lincoln in exchange for a cabinet post. He was appointed secretary of war but served only 10 months. Despite his demonstrated business acumen and organizing ability he proved unequal to his new responsibility. He administered the war department with such favouritism that in Jan. 1862 President Lincoln transferred him to the post of minister to Russia.

Cameron returned to the United States in 1863 and unsuccessfully sought election to the senate. Four years later he won a seat in the senate and was re-elected in 1873. He served until 1877 when he resigned to make way for his son, JAMES DONALD CAMERON (1833–1918), who had just completed a brief term as secretary of war in Grant's cabinet. "Don" Cameron not only took over his father's senate seat but also assumed control of the state Republican machine—a position and a control that he retained for 20 years.

Upon his withdrawal from the senate, Simon Cameron retired to his farm at Donegal Springs, Pa., where he lived until his death, June 26, 1889.

CAMERON, VERNEY LOVETT (1844–1894), English explorer in central Africa, the first European to cross equatorial Africa from sea to sea, was born at Radipole, near Weymouth, on July 1, 1844. He entered the navy in 1857, taking part in the Abyssinian campaign of 1868 and in the suppression of the east African slave trade. He was selected in 1872 to command an expedition sent by the Royal Geographical society to attempt to make contact with and assist Livingstone and to make independent explorations. But soon after leaving Zanzibar the expedition met Livingstone's servants bearing his body. Cameron continued to Ujiji on Lake Tanganyika and recovered some of Livingstone's papers. He then explored the southern part of the lake and established its outlet by way of the Lukuga river. From there he went west to Nyangwe on the Lualaba, rightly believing this to be the main stream of the Congo system, but he was unable to procure canoes to continue its exploration.

Turning southwest he traced the Congo-Zambezi watershed for hundreds of miles, discovered the sources of the latter river and finally reached the west coast near Benguela, Angola, on Nov. 7, 1875. His book *Across Africa* (1877) made suggestions for opening up the continent, and he later claimed to have originated the idea of a "Cape to Cairo" railway. Cameron was promoted commander, made a companion of the Bath and awarded gold medals of the Royal and Paris Geographical societies. During the rest of his life he was associated with the development of commercial projects in Africa. He was in the middle east in 1878–79 to determine the value of an overland route to India, and advocated the building of a railway from Tripoli to Karachi. With Sir Richard Burton (*q.v.*) he visited West Africa and was joint author of *To the Gold Coast for Gold* (1883). He was killed near Leighton Buzzard, Eng., on March 27, 1894, by a fall from his horse.

See Robert Brown, *The Story of Africa*, vol. ii, pp. 266–79 (1893), a Summary of Cameron's own account of his journey. (R. M. P.)

CAMERONIANS, those of the Scottish Covenanters (*q.v.*) who followed Richard Cameron (*q.v.*) in adhering to the perpetual obligation of the two Scottish covenants of 1638 and 1643 as set out in the Queensferry Paper (1680). On Cameron's death they began in 1681 to organize themselves in local societies all over the south of Scotland, in 1687 they published *The Informatory Vindication*, and by 1690 they numbered several thousands. Though their three ministers then entered the church of the Revolution Settlement, they themselves for the most part remained outside. In 1706 they again obtained a minister, John Macmillan, through whose active itinerant ministry the name Macmillanite came to supersede Cameronian. In 1743 under his leadership they set up a presbytery at Braehead, calling it the Reformed Presbytery; and as Reformed Presbyterians they not only grew in Scotland but also had a considerable effect on Scottish communities overseas, still refusing to take any part in the civil affairs of an "uncovenanted" nation. In 1863 they decided to refrain from taking disciplinary action on those who intended to exercise the franchise. A minority, however, stuck to the strict interpretation of their principles and still do so. Within Scotland the majority united with the Free Church in 1876 and thus became incorporated in 1929 in the reunited Church of Scotland. (See also FREE CHURCH OF SCOTLAND.)

In the British army the Cameronians (Scottish Rifles) are a direct descendant of the "Cameronian guard," which was first used to restore order in the Highlands after the battle of Killiecrankie (1689).

See J. K. Hewison, *The Covenanters* (1913); M. Hutchison, *The Reformed Presbyterian Church in Scotland* (1893). (H. W.A.)

CAMERON OF LOCHIEL, SIR EWEN (1629–1719), Scottish Highland chieftain and a strong supporter of the Stuart cause in Scotland, was the eldest son of John Cameron and the grandson of Alan Cameron, the head of the clan Cameron: which was able to trace its ancestry from the times of King Robert I and King David. Having lost his father in infancy he passed part of his youth with the marquess of Argyll at Inveraray. He left his guardian about 1647 to take up his duties as chief of the clan Cameron, succeeding his grandfather.

In 1653 he was engaged in the earl of Glencairn's rising on behalf of Charles II. In this campaign he won great distinction particularly in his defense of the Pass of Tulloch, at Braemar, against the English forces. For his valour he received a special letter of thanks from the king. After the failure of the campaign Lochiel aided the royalist cause by harassing Gen. George Monck's forces. He came to terms with Monck in 1658, accompanied him to London and was there when Charles II entered the city. He was knighted by Charles in 1681. In July 1689 he was with Viscount Dundee at the battle of Killiecrankie against the forces of William III (a Scots victory, although the rising was soon suppressed). He was too old to join the Jacobite rising in 1715, but his sympathies were with the Stuarts, and his son led the Camerons in battle. He died in Feb. 1719.

Lochiel was of enormous strength and size, and many stories were told of his exploits. Macaulay called him the "Ulysses of the Highlands." It was said, falsely, that he killed, with his bare hands, the last wolf ever seen in Scotland. One who met him when he was 87 reported that "he wrung some blood from the point of my fingers with a grasp of his hand." An incident showing his strength and ferocity in single combat, in which he slew his foe by biting into his neck, was used by Sir Walter Scott as a model for his description of the fight between Roderick Dhu and FitzJames in *The Lady of the Lake* (canto v).

His son and successor, John, attained for sharing in the rebellion of 1715, died in Flanders in 1748. John's son Donald (*c.* 1695–1748), sometimes called "gentle Lochiel," succeeded his grandfather as head of the clan in 1719. He fought for Charles Edward, the young pretender, and captured Edinburgh in Sept. 1745. He was severely wounded at the battle of Culloden on April 16, 1746, but escaped with the prince to France, where he died in 1738.

See Bannatpne Club, *Memoirs of Sir Ewen Cameron of Lochiel* (1842); A. MacKenzie, *History of the Camerons* (1884).

CAMEROONS, a region of west Africa, is bounded west by the Atlantic, northwest by Nigeria, east by Chad and the Central African Republic, south by the Republic of Congo and Gabon and for a short distance southwest by Rio Muni. Area 200,876 sq mi. The coast, with a length of about 220 mi., curves around the Bight of Biafra before turning south. Its chief indentation, named by its Portuguese discoverers Rio dos Camarões (river of prawns), has given the name Cameroon (Fr. *Cameroun*, Ger. *Kamerun*) to the region. From 1884 to 1919 the region was formally a German protectorate. By the treaty of Versailles Germany relinquished sovereignty, the country being administered by France and Britain initially under a League of Nations mandate and after 1946 under the United Nations trusteeship agreement. French Cameroun became an autonomous republic in 1959 and was proclaimed independent in 1960; British Cameroons, after a period of internal self-government within the Federation of Nigeria, was in 1961 divided, the northern districts uniting with Nigeria and the Southern Cameroons with the Republic of Cameroon.

Physical Features.—The greater part of the south and centre of the region is a plateau with a general altitude of 2,000 ft. In the northwest the country is mountainous with three exceptions: immediately north of Cameroon mountain, in the narrow trench of the Benue (Benoue) valley and immediately south of Lake Chad. The Mandara mountains north of the Benue rise to nearly 5,000 ft. Summit altitudes increase southward, being more than 6,000 ft. in the Vogel and Mambila massifs and over 8,000 ft. in the Bamenda highlands. The northern highlands are largely of Pre-Cambrian Basement rocks, but the Bamenda highlands have younger volcanics superimposed upon a Pre-Cambrian foundation, and cones and crater lakes are numerous. A second line of high-

lands branches east, in a northward-curving arc, from the Bamenda highlands past N'Gaoundéré to the Yade massif on the eastern frontier. This highland belt also has peaks exceeding 6,000 ft.

At the seaward end of the mountain ranges, but isolated from them, is Cameroon mountain, the only active volcano in west Africa (eruptions in 1909, 1922, 1954 and 1959). It rises directly from the sea to 13,350 ft., and its western side is one of the rainiest regions of the world. It lies on a line of structural weakness marked by the volcanic rocks of the Bamenda highlands to the northeast and by volcanic islands to the southwest, of which Fernando Po is the nearest. The Cameroons estuary lies southeast of the mountain, with a maximum width of more than 20 mi.

In the area between the two highland belts lie the headwater streams of the Benue and some tributaries of the Logone. The Logone, flowing north to Lake Chad, forms part of the northeast frontier. A tributary of the Benue, the Mayo-Kebbi river, draws off an increasing amount of water from marshes in the middle Logone valley; it might ultimately succeed in diverting to the sea most of the Logone waters: a process which might have grave consequences in the Lake Chad region.

South of the main watershed the drainage is mainly to the sea, the chief rivers being the Nyong and the Sanaga, but the southern part of the Yade massif is drained by the Sanga system to the Congo. There are thus four distinct drainage systems within the region.

Climate.—The climate is tropical, but with the lower temperatures in the highlands much of the region could have been settled by Europeans, unlike most of west Africa. The mean annual temperature varies from 75°–80° F. in the south to 90° in the extreme north, with mean temperatures below 70° over some areas of the southern grasslands. The daily variation is small on the coast, but increases markedly on the plateau. A dry, cool, dust-laden wind (the harmattan) blows from the northeast between November and April in the north and for a decreasing period in the south; for the rest of the year the southwest winds bring moist air from the Atlantic, with rainfall totals varying from 163 in. yearly at Victoria to about 15 in. near Lake Chad. Even Debundscha, on the west side of Cameroon mountain, with an average annual total of nearly 400 in., receives only 9 in. in January, indicating the tendency to a dry season at the beginning of the year.

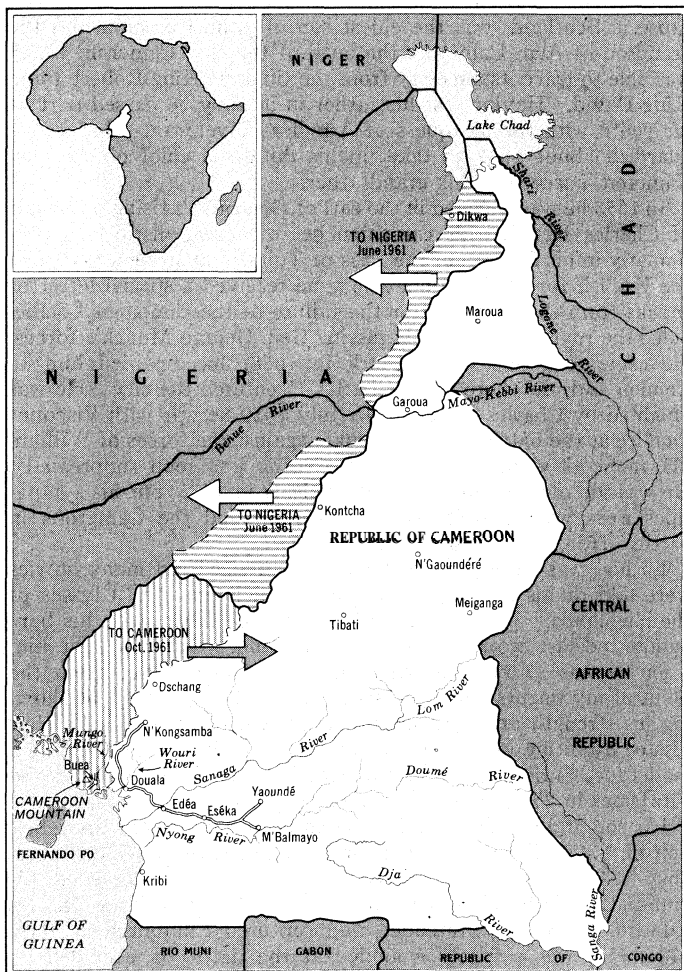

(J. C. PH.)

Vegetation.—Lowlands as far north as 4° to 6° N. latitude are covered by rain forest containing trees up to 200 ft. high, including mahoganies and numerous species of the Leguminosae. Smaller trees include ebonies and wild kola nuts; epiphytic orchids and ferns abound. Oil palms, kapok trees, umbrella trees and scrambling shrubs are often abundant in farmed areas. Forest on swampy ground has raffia palms and tangles of rattans. Coastal mangrove swamps resemble those of southeastern United States.

At altitudes of 4,000 to 8,000 ft. the evergreen forest differs from that of the lowlands; the trees are smaller, of different species, and are festooned with mosses, lichens and other epiphytes; tree ferns sometimes abound in forest enveloped by cloud. The upper limit of evergreen forest is abrupt but varies in altitude depending on the topography. Above it is drier woodland, tall grassland or patches of mountain bamboo. Above about 7,800 ft. in the hinterland and about 10,000 ft. on Cameroon mountain there is short grassland with numerous plants of European affinity. North of the rain forest is savanna woodland with trees 10–60 ft. high which tolerate the annual burning of the tall grass. The species of the savannas are mostly different from those of the rain forest. Strips of dense forest occur along the streams. Thorn woodland, with abundant acacia species, occurs in the far north.

(R. W. J. K.)

Animal Life.—The region has a wide variety of fauna to match the vegetation. In the dense rain forests there are gorilla, chimpanzee and the very local mandrill, as well as the strange aquatic insectivore known as the potamogale, or otter shrew, and the Calahar pottos. About ten species of monkey are also found in the forests and the typical antelopes there are the duikers, or dwarf antelopes. A few elephants survive in the high forest, as well as in the grass woodlands, where baboons and several types

DISPERSION OF THE CAMEROON REGION AFTER THE PLEBISCITES OF FEB. 1961

of antelope are the most common animals. A very few giraffes and black rhinoceroses may still be seen in the far north, and also the rare Cameroons giant eland. Many kinds of rodents, bats and small carnivores, and numerous birds, from tiny sunbirds to the giant hawk eagles and hornbills, are found in both forest and open country.

Found in various localities are many snakes, including some dangerously venomous species, and numerous lizards and frogs, of which the most notable are the hairy frog and the giant frog.

Tsetse flies, carrying both sleeping sickness and cattle disease, are found throughout the forest and also in parts of the grass woodlands, and in these areas it is impossible to keep either cattle or horses. Farther north there is a cattle industry, most cows being of the zebu type, and horses, donkeys and camels are used as beasts of burden. Bees are valuable for honey production only in the open grass woodlands. (G. S. CE.)

The People.—The region is probably the most fragmented part of Africa regarding ethnic and linguistic composition. Though no undisputed ethnic classification has been formulated, the inhabitants may be divided into three main linguistic groups which for the most part tally with the available ethnic evidence; (1) the bulk of the population is Bantu-speaking (about 70 languages and dialects) and inhabits the southern tropical forest; (2) to the north and in the centre live those who speak non-Bantu languages (*i.e.*, Sudanic); (3) between (1) and (2) and especially to the west are found the speakers of countless Bantoid languages which are reminiscent of both major language groups.

The better-known Bantu-speaking tribes are the Duala (*q.v.*), Kpe, Banen, Basa, Yaunde, Bulu and Fang (*q.v.*). The latter invaded the region at the beginning of the 19th century. The non-Bantu tribes are numerous and very diverse. They include the Fulani, Hausa (*qq.v.*), Kanuri and Shuwa Arabs to the north, and in the centre the Kreish, Wute, Laka, Mbum and Mambila, to mention only a few. The Fulani are now a peaceful, nomadic, pastoral people, but in the 18th and 19th centuries they subjugated considerable areas of northern and central Cameroons and set up large Muslim states such as Adamawa. The Hausa and Kanuri form the merchant class and abound in most commercial centres. Group (3) is largely composed of small units, often a single village. Notable exceptions to this, however, are the Bamileke (*q.v.*). They may be considered the main tribe of the northwest part of the region and number approximately 500,000. Some of the better-known Bantoid-speaking tribes are the Tikar, Bamum (*q.v.*), Bali, Banyang and Keaka.

The oldest inhabitants of the region are pygmies, known as Bagieli and Babinga. They live in scattered hunting groups in the forests. See also the section *West Central Africa* in *AFRICA: Ethnography (Anthropology)*. (I. R.N.)

History to 1922.—The Cameroon estuary and the neighbouring coast were discovered toward the end of the 15th century by the Portuguese navigator Fernão do Po. Not until the 17th century were European trading stations, called factories, established. The Duala and other coast tribes, who would not allow strangers inland, took goods on trust from the white merchants and bartered them with the forest tribes for ivory, rubber and slaves. This trust system worked well and continued until the German occupation of the country. The Duala prospered and the "kings" of Akwa and Bell, the chief trading stations, became wealthy merchant princes. By 1800 the coast region was politically under British influence and in 1837 the king of Bimbia ceded part of the country around the estuary to Great Britain. In 1845, at a time when there was still a flourishing trade in slaves between the Cameroons and America, Alfred Saker (1814–80) of the Baptist Missionary society obtained from the Akwa family the site of a mission station. He established another mission station at Bimbia in 1848. When in 1858 the Baptists were expelled from Fernando Po, a colony of freed Negroes from the island was founded in Amba bay, Saker naming the settlement Victoria. In 1868 Woermann of Hamburg established the first German factory in the estuary. Saker reduced the Duala language to writing and before he left the Cameroons in 1876 witnessed the final suppression of the overseas slave trade.

Requests made by the Duala chiefs in 1882 for annexation by Great Britain were refused or neglected, with the result that when Germany started to acquire unappropriated parts of the African coast it was enabled to secure the Cameroons. A treaty with the king of Bell was negotiated by Gustav Nachtigal on July 15, 1884. Five days later the British consul arrived with a mission to annex the country. On July 26 a French gunboat also entered the estuary on a belated annexation mission. Too late to secure the Bell territory, the British government decided to recognize the German claim not only to Bell town but to the whole Cameroons region, which the Germans named Kamerun. Subsequent agreements with Great Britain and France gave the German colony an extension inland to Lake Chad, including parts of the Fulani states of Adamawa and Bornu (*qq.v.*). The Baptist settlement at Victoria passed to Germany in March 1887, when the Baptists were replaced by the Basel mission.

The extension of German authority inland was slow—Lake Chad was reached only in 1902—and was not effected without opposition. In the northern regions under Fulani domination, the African rulers were permitted to retain a good deal of authority. A system of direct administration was gradually extended inland from the coastal districts.

Exploitation of the colony did not prove easy. The early attraction was trade and, despite the development of plantations, trade with the inhabitants remained by far the most important European economic activity throughout the German occupation. The chief products obtained locally in return for European commodities were rubber and palm oil and kernels, collected from the forest, and ivory, the supply of which was soon exhausted. River transport proved impracticable; although 195 mi. of railway were built inland from the coast during 1909–13, traders continued to rely principally on human portage. European planting was concentrated on the slopes of Cameroon mountain, the principal crops being cocoa, palm products and rubber. By 1912, 54,000 ac. were under cultivation, but only about one-fifth of the colony's exports came from plantations and about half was accounted for by rubber collected from forest trees. The colony received considerable grants-in-aid from Germany.

In return for recognizing France's protectorate over Morocco in 1911, the Cameroons received additions of 107,000 sq.mi. of French Equatorial Africa, bringing German territory to the Congo and Ubangi rivers. This territory was returned to France by the treaty of Versailles in 1919.

During World War I British and French troops conquered the Cameroons, and in 1916, after the German forces were defeated, the victors agreed upon a temporary partition, which gave France about nine-tenths of the territory, and the section adjoining Nigeria came under British control. In July 1919 the Cameroons was formally divided by the London declaration signed by Great Britain and France.

Following the treaty of Versailles, the League of Nations in 1922 conferred mandates upon France and Britain for the administration of the two spheres upon which they had previously agreed, subject to the supervision of the League's Permanent Mandates commission. After World War II French and British administration was confirmed by trusteeship agreements approved by the United Nations on Dec. 13, 1946.

(F. R. C.; H. A. W.F.; J. D.F.)

British Cameroons.—The British trust territory consisted of two narrow strips, nowhere more than 100 mi. wide, extending along Nigeria's eastern border and separated at the Benue river by a 45-mi. gap. Pop. (1952–53 census) 1,440,509; area 33,081 sq.mi. In the south, the Cameroons province (9,649 sq.mi.) and Bamenda province (6,932 sq.mi.), with a combined population of 753,658, together formed the Southern Cameroons, with the capital at Buea, (pop. 3,009). The other chief towns in the Southern Cameroons were Bali (pop. 18,272), Kumba (7,778) and the ports of Victoria (3,575) and Tiko (5,337). The northern districts aere (from south to north): the Tigon-Ndoro-Kentu area (1,236 sq.mi.), the southern and northern Adamawa districts (10,965 sq.mi.), separated by the Benue gap, and the Dikma district (5,149 sq.mi.). The chief towns in the northern districts

were Dikwa (pop. 3,010), Mubi and Gashaka.

The economy of the British trust territory depended upon agriculture, with bananas, rubber, hides, palm products, peanuts and cocoa as the principal exports. Bananas, rubber and palm produce were predominantly plantation crops and the remaining exports came chiefly from peasant producers. The main estates, which in 1924 were resold to their former German owners, were in 1939 taken into custody; after World War II they were purchased by the Nigerian government and vested in the Cameroons Development corporation. This had the duty of running the estates on commercial lines while applying profits for the benefit of the inhabitants. By the late 1950s the corporation employed about 25,000 Africans and cultivated about 62,000 ac. of bananas, rubber and oil palms. Bananas accounted for more than half the value of the exports and cocoa for about 30%. Steamship services were maintained between Tiko and the United Kingdom and there were regular air services between Tiko and Lagos and Port Harcourt in Nigeria. Road transport was less developed in the north than in the south and there was no direct link between the two. In the south, the road system joins with those of Nigeria and the Cameroon republic. Education in the Southern Cameroons was likewise more advanced than in the northern districts, with about 400 primary schools, 3 secondary schools, 12 teacher-training schools and 2 vocational and training schools.

Under British trusteeship, the Southern Cameroons was integrated administratively with Nigeria, under a commissioner directly responsible to the governor general of Nigeria for trusteeship affairs in the whole territory including the northern districts. The British system of indirect rule was applied and local government was conducted by native authorities with the advice of administrative officers. Following the introduction of federal government in Nigeria in 1953, the Southern Cameroons became a self-governing region of the federation with its own executive council and legislature, but the north remained administratively part of Nigeria's Northern Region. With the independence of Nigeria imminent, a plebiscite was held in Nov. 1959 under United Nations auspices in the Cameroons northern districts and resulted in a vote to defer decision on their future status. Further similar plebiscites, held separately in the northern districts and in the Southern Cameroons in Feb. 1961, resulted in a vote by the northern districts to join the Federation of Nigeria; the Southern Cameroons voted for union with the Republic of Cameroon. Northern Cameroons became an integral part of Nigeria on June 1, 1961, and Southern Cameroons merged with the Republic of Cameroon on Oct. 1, 1961.

(W. H. I.)

French Cameroun.—The French territory of Cameroun, which had a population (1957) of 3,187,621 and an area of 166,795 sq. mi., was administered from Douala or Duala (pop. 125,000), the chief seaport and commercial centre, until 1921 when the seat of administration was moved to Yaoundé (pop. 58,099) on the central plateau. Other towns of importance as mission stations, markets or subordinate administrative centres were N'Kongsamba (pop. 32,000), Edéa (12,000), N'Gaoundéré, Garoua (15,000) on the Benue river; Maroua in the north, and the hill resort of Dschang near the western border. Kribi (pop. 7,000) was the second port.

French administration of the mandate was accompanied by political and financial autonomy under a French commissioner (later high commissioner). In World War II the territory joined the Free French movement in Aug. 1940 and Douala was for a time the headquarters of Gen. Charles de Gaulle. Under United Nations trusteeship, Cameroun had from 1946 the status of an "associated territory" of the French union. Administratively it was divided into 18 *régions* and its elected territorial assembly exercised wide powers.

In March 1959 the United Nations adopted the French proposal to end the trusteeship status on Jan. 1, 1960, when the territory became the independent Republic of Cameroon.

Republic of Cameroon.—For five years prior to independence the country was troubled by disturbances inspired by the left-wing Union des Populations du Cameroun. Despite the success of the ruling party, the Union Camerounaise, at the 1960 election, ter-

rorism still continued in the western part of the republic, notably in the Dschang district. Good relations were maintained with France, with whom co-operation agreements were signed. Future progress appeared to depend on the economic advantages that would result from the projected extension of the railway northward from Yaoundé, and more generally on the consolidation of the northern districts and their feudal cattle-raising Muslim chiefs with the more modernized southern part.

Administration.—The constitution, modeled on that of the French fifth republic, was approved by popular referendum in Feb. 1960. It provides for a president as head of state, elected by a national assembly for a five-year term, and a premier and cabinet both appointed by the president. The national assembly of 100 members is elected by universal suffrage for five years. Yaoundé is the seat of government.

In the early 1960s about 54% of the school-age group, or 300,000 pupils, attended schools which included about 650 state schools, more than 1,800 private primary schools and 20 secondary schools, 1 *lycée* and 60 vocational centres; about 900 scholars from Cameroon pursued higher studies in France. The forest region was widely converted to Christianity but the east and centre remain chiefly pagan; in the north the population is pagan in the mountains and Muslim in the plains. According to a treaty of co-operation (in trade, diplomacy, defense and culture) signed with France in Nov. 1960, education would continue under the French pattern and the official language would remain French.

Economy.—The economy is essentially agricultural, with stock rearing (1,200,000 cattle) and millet cultivation in the north. The eastern districts are largely forest and the economically important zone lies within 200 mi. of Douala (Duala) in the southwest, where the chief towns are situated and the major export products concentrated: coffee and bananas (largely from plantations) on the western plateaus, and cocoa, coffee, timber and palm products in the southern forest. Cotton growing showed promise in the district southwest of N'Gaoundéré, where bauxite deposits were discovered. Metre-gauge railways built during the German period link Bonabéri (a suburb of Douala) with N'Kongsamba to the north and Douala with Eséka to the east. The Eséka line was extended by the French to Yaoundé and in 1955 the two lines were joined by a bridge of 1,830 m. (6,004 ft.) across the Wouri river. Roads link Cameroon with the Federation of Nigeria and

BABUTE TRIBESMAN PLAYING GUITARLIKE INSTRUMENT, NANGA EBOK VILLAGE, REPUBLIC OF CAMEROON

with the states of former French Equatorial Africa that in 1960 achieved independence as the Central African Republic and the Gabon Republic. The port of Douala has wharfage affording a depth of 23–33 ft. and of a length sufficient to work seven ships together, with a maximum capacity of 1,000,000 metric tons annually. Air services connect Douala with Paris, Marseilles, Madrid and other centres. The Sanaga river dam at Edéa was inaugurated in 1954 to provide electricity for Douala, for the railway and for the aluminum industry.

Current history and statistics are summarized annually in the *Britannica Book of the Year*.

CAMILLO, SAINT, DE LELLIS (CAMILLUS OF LELLIS) (1550–1614), founder of the Ministers of the Sick, was born at Bucchianico in the Abruzzi, Italy, son of an impoverished nobleman, on May 25, 1550. He became a soldier of fortune and was an inveterate gambler. In 1575 he was converted and became a servant and later an assistant at St. James's hospital for incurables in Rome, where he had himself been a patient with the ulcerated leg and the rupture which impeded him all his life. As in all hospitals of the period, conditions were appalling: dirt, neglect and even cruelty on the part of the paid attendants. In 1586 Camillo, who had been ordained in 1584, founded a congregation of priests devoted to hospital service. At first there were 12 members, without vows, working in the hospital of the Holy Spirit, but in 1591 they became a congregation of vowed religious clerks regular, called Ministers of the Sick (*Ministri degli infermi*), wearing a red cross on their cassocks.

Camillo was general of the order until 1607. He insisted on the utmost care for both soul and body of his patients. Though his own health grew worse, he spent himself in superhuman efforts. When he died in Rome on July 14, 1614, there were nearly 300 in his order. He was canonized in 1746, and his feast day is July 18. Members of St. Camillo's order were nursing on the battlefield of Solferino (1859) when J. H. Dunant conceived the idea of the Red Cross.

See C. C. Martindale, *Life of St. Camillus* (1946). (E. I. W.)

CAMILLUS, MARCUS FURIUS (d. 365 B.C.), Roman soldier and statesman who held a triumph four times, was five times dictator and was honoured as the second founder of Rome. His greatest victory was as dictator in 396 B.C. when he conquered the Etruscan city of Veii (*q.v.*): he dedicated to Apollo in the treasury of the Massiliotes at Delphi a golden bowl which survived into later times. In 394 he reduced Falerii (mod. Civita Castellana), contemptuously rejecting the proffered treachery of a Faliiscan schoolmaster. Exiled for misappropriating some booty, Camillus is said to have withdrawn to Ardea until he was appointed dictator when the Gauls had captured Rome (390). He is said to have raised an army and defeated them (and even recovered the gold with which the Romans had bought them off), but his victory was probably invented to counterbalance Rome's defeat by the Gauls at the Allia river in 390. He is said also to have opposed a proposal that the Romans should migrate to Veii. Thereafter he fought successfully (possibly as a result of some reforms in the army) against the Aequi, Volsci, Etruscans and Gauls. Though a patrician (he had, in the interest of the patricians, defeated the rising of M. Manlius, *q.v.*), he was not a diehard; he introduced pay for the army at the siege of Veii, and realizing the need to make concessions to the plebeians, he accepted the Licinian-Sextian laws in 367 (see **ROME**: *Ancient History: The Republic*). Although Roman writers may have exaggerated his achievements, Camillus clearly played a predominant role in Rome's recovery in the decades after the Gallic sack of the city.

See Plutarch, *Lives*.

(H. H. S.)

CAMILLUS and **CAMILLA**, terms of uncertain derivation used in ancient Rome, originally for freeborn boys and girls. later for the attendants on certain priests and priestesses, especially the *flamen* Dialis, the major priest of Jupiter. Such attendants had to be freeborn, under the age of puberty and have both parents alive. They could be children of the priests or priestesses they served.

See Festus, *De verborum significatu*, 93, 2 and 3; Dionysius of Halicarnassus, *Roman Antiquities*, 11, 22.

CAMINO, DA (CAMINESE), an Italian feudal family of the middle ages who ruled for a time in Treviso and adjacent towns. They were probably related to the Collalto, counts of Treviso, and possessed many fiefs—imperial, episcopal and others—in the mark of Treviso, notably in the districts of Belluno, Cadore and Ceneda, of which they became counts. By 1200 they had submitted formally to the commune of Treviso and been accepted as citizens, but since they retained and even increased their feudal patrimony they soon claimed a prominent place among the ruling families of the city, assuming leadership of the Guelf faction. Had it not been for the rival presence of the Ghibelline Da Romano family, the Caminesi might have come to dominate straightway. As it was they first seized power in 1283, after a street fight which ended in defeat for the Ghibellines. With the support of the Collalto and the Avogari (hereditary advocates of the bishop of Treviso), Gherardo da Camino, count of Ceneda and from 1265 captain general of Feltre and Belluno, was then elected captain general of Treviso as well. Gherardo's government was later condemned as tyrannical, especially because of heavy taxation, but that of his son Rizzardo II, who succeeded him on his death in 1306, provoked revolt. In 1311 Rizzardo purchased the office of vicar of Treviso from the German king (later emperor) Henry VII, after which he dropped the popular title of "captain" and began to favour the Ghibellines. This offended the Guelf families and was partly responsible for his murder in April 1312. His brother Guecellone VII, count of Ceneda, who took his place, proved no more acceptable and was expelled in Dec. 1312 at the instigation of the Collalto and the bishop. In 1313 he also lost Feltre and Belluno. By the 15th century the family had died out in all its principal branches.

CAMISARDS, the name given to the French Protestant peasantry of the Cévennes and of Bas-Languedoc who from 1702 to 1705 and for several years afterward carried on an organized military resistance to the government's revocation of the Edict of Nantes. The Camisards (from Languedocian *camisa*, "shirt"; Fr. *chemise*) were so called either because they wore a white shirt over their ordinary clothes for recognition purposes in night fighting, or because, out of concern to symbolize purity, they made a point of changing their linen whenever they halted at a village. They were also called Barbets ("water dogs," a term also applied to the Waldenses), Assemblants, Fanatiques and Houssards or Ozards (as the Hungarian rebels of the same period, led by Ferencz Rakoczy II, were sometimes called "hussars"). They belonged to that Romance-speaking people who made the south of France the most fertile nursing ground of heresy in the middle ages (see **CATHARI**).

In 1686 the pastor Pierre Jurieu had published in Rotterdam his work *L'Accomplissement des prophéties* and his *Lettres pastorales*, a series of brief tracts which were secretly circulated in France.

Speaking of the Apocalypse, Jurieu predicted the end of the persecution of the Huguenots and the fall of Babylon, by which he meant Roman Catholicism! for 1689. The revolution in England seemed a striking corroboration of his prophecies, and apocalyptic enthusiasm took a strong hold on people's minds. In Dauphiné (1688) and in Vivarais (1689) children took to prophesying and whole crowds fell into convulsions and paroxysms of sobbing.

Twelve years later this strange illumination reappeared in the valley of the Ardèche. In spite of ruthless repressive measures it spread with extraordinary rapidity among the Protestants of

Bas-Languedoc and of the Cevennes, whom the intendant Nicolas Lamoignon de Basville was treating with increasing severity. From appeals to repentance the enthusiasts proceeded to swearing revenge, and the "awakening" gave way to revolt. On the night of July 24, 1702, about 40 Cévenols released some young Protestants from the prison at Pont-de-Montvert and assassinated the abbé du Chayla (François Anglade), whom they considered as an odious torturer. They then went through the Cévennes, setting fire to churches and massacring "wicked priests." Their first leader, Esprit Séguier, was caught and burned alive (July 28).

Séguier was succeeded by Gédéon Laporte, an old soldier who, as his troop increased, assumed the title of "colonel of the children of God" and named his camp "the camp of the Eternal." He would lead his followers to battle singing Clément Marot's version of the 68th psalm, "Que Dieu se montre seulement." to the music of Claude Goudimel. The movement was essentially a popular one, its leaders including the goatherd André Castanet, the wool carders Abraham Mazel and Jacques Couderc and the soldiers Catinat (Abdias Maurel, who assumed the name of the great marshal Catinat), Nicolas Jouany and Laurent Ravenel. A sheep gelder, Pierre Laporte, Gédéon's nephew, born at Mas-Soubeyran, proved a determined and astute commander in chief in the Basses-Cévennes, his continual changes of position earning him the nickname of "Pierre Roulante" (rolling stone), abbreviated to Roland or Rolland. Jean Cavalier (*q.v.*), a baker's boy, operated mainly in the lower country; a born strategist, he pinned down successively the armies of Victor Maurice de Broglie and the marshal de Montrevel (N. A. de La Baume). Regular taxes were raised, arsenals were formed in the great limestone caves of the district, the Catholic churches were burned and sometimes the clergy were driven away. Occasionally routed in regular engagements, the Camisards, through their desperate valour, clever tactics and rapid movements, were constantly successful in skirmishes, night attacks and ambushes. The rising was far from being general and never extended to more than 4,000 or 5,000 men, but was made dangerous by the support of the people, whether secret or, as it sometimes was, open. Their knowledge of the mountainous country, covered with forests and without roads, gave the insurgents an enormous advantage.

Montrevel adopted a policy of extermination. Women and children perished in the flames at Moulin de l'Agau near Nîmes (April 1703), and 466 villages were burned in the Hautes-Cévennes alone, the population being for the most part put to the sword (Oct.-Dec. 1703). Recruited mainly at St. Florent (whence the term Florentins), the Catholic militiamen, who took a white cross as their emblem, intensified the massacres and the pillaging. Appointed commandant in Languedoc on March 27, 1704, the marshal de Villars took advantage of the feelings of horror with which the quiet Protestants of Nîmes and other towns regarded the war. The Huguenot baron d'Aigaliers (Jean Jacob de Rossel), undertook to negotiate. Cavalier: who made his submission at Nîmes (May 16, 1704), demanded a large measure of toleration, but Louis XI^l granted only an amnesty, giving the rebels the choice of entering the king's forces or of leaving the country. Most of the Camisards, insisting that the Edict of Nantes should be restored, continued the war. Then Roland was betrayed and killed (Aug. 1704), Jouany surrendered and Ravenel was executed in the sanguinary crushing of the so-called Conspiracy of the Children of God in April 1705. Mazel, having escaped into Switzerland, returned to Vivarais in July 1709 where he made a vain effort to rekindle the revolt. After his death (Oct. 1710) the last of the Camisards were either captured or dispersed.

Shaken by violent convulsions, the prophets of the Cévennes would fall into ecstasies and utter words which they believed to be inspired by the Holy Ghost. The supernatural was part of their life: lights in the sky guided them to places of safety and voices sang encouragement to them. Yet the Camisards were not all visionaries or fanatics, and the prophetic influence, often exaggerated, diminished greatly during the course of the war.

CAMMAERTS, ÉMILE (1878-1953), Belgian poet and writer who as a vigorous royalist interpreted Belgium to the British public, was born in Brussels on March 16, 1878. When he was 30 he settled in England and his writings on English and Belgian themes included translations of John Ruskin and G. K. Chesterton into French. *Discoveries in England (1930)*, *The Laughing Prophet: the Seven Virtues of G. K. Chesterton (1937)* and *Albert of Belgium, Defender of Right (1935)*. During World War I he became known for his poems among which were *Clzants patriotiques et autres poèmes (trans. as Belgian Poems, 1915)* and *Poèmes intimes (1922)*. In 1947 he was made professor emeritus of Belgian studies and institutions at London university. His enthusiasms also embraced nonsense verse, art and religion, on which he wrote *The Poetry of Nonsense (1925)*, *Rubens, Painter and Diplomat (1931)*, *Flemish Painting (1945)*, *The Cloud and the Silver Lining (1952)*, etc. He died at Radlett, Hertfordshire, on Nov. 2, 1953.

CAMÕES (Eng. CAMOËNS), LUÍS VAZ DE (1524-1580), the greatest of Portuguese poets, was born in Lisbon, according to the expression *natural deste cidade* ("native of this city") used in 1613 by Pedro de Mariz, his first, but ill-informed, biographer. In 1607, however, Domingo Fernandes, the bookseller, had dedicated his edition of the poet's *Rimas* to the University of Coimbra, stating that Cambes was born in Coimbra. Successive biographers of various nationalities have enshrouded the little that is known of his life in a bewildering complexity of fantasy and theory unsupported by concrete evidence. A noteworthy exception is the date generally accepted as that of the poet's birth, 1524, which was deduced from the records of the Casa da India brought to light in the 17th century by Camões' over-zealous commentator, Manuel de Faria e Sousa. The most important document extant, however, is the *Carta de perdão a Luis de Camões*, granted in Lisbon on March 7, 1553. This states that the poet was *mancebo* ("a young man"), a gentleman of the king's household and the son of Simão Vaz; that he was then living in Lisbon but was very poor and was going that year to serve in India. He had been arrested for inflicting a sword wound on Gonçalo Borges, one of the king's servants, on the Feast of Corpus Christi, and the *Carta* announced his pardon.

Of Simão Vaz, the poet's father, little is known. He was long confused with his cousin and namesake, whose life is fully documented, and who was the son of João Vaz of Vila Franca, whereas Cambes' father, according to Pedro de Mariz, was the son of Antão Vaz de Camdes and D. Guiomar Vaz da Gama, of the well-known Algarvian Gamas. The same biographer described Cambes' mother as a gentlewoman of Santarém, Ana de Macedo, but other documents give her name as Ana de Sá. The earliest record of a Camdes yet discovered relates to Vasco Pires de Camões, a Galician gentleman who settled in Portugal during the reign of King Ferdinand and fought for the latter's unpopular widow during the conflicts preceding the accession of King John I. If the genealogy is reliable, he was the poet's great-great-grandfather.

The tradition that Camdes studied in Coimbra has persisted unchallenged and the sonnet "Doces e claras águas do Mondego," and, even more! the *canção*, "Vão as serenas águas/do Mondego descendo," bear adequate testimony to his having lived there. He did not, however, study under Bento de Camões, another son of João Vaz, as was at one time thought, for it has now been proved that the Bento who was the first chancellor of the university and the first prior of the famous Augustinian College of Santa Cruz and who died in 1547 was Bento de Almeida or de Abrantes and that Bento de Cambes did not become an Augustinian monk until 1545. It seems unlikely, therefore, that he could have had any influence

on the poet's development, even if the latter were still in Coimbra in 1545.

After finishing his studies Camões went to Lisbon and entered court circles under the patronage of the Conde de Linhares, D. Francisco de Noronha, whose son, António, was his friend and perhaps his pupil. Sometime later, having chosen a military career, he set out for North Africa where he lost an eye. Because of his reference to the *furia rara de Marte* in his well-known *canção*, "Vinde cá, meu tão certo secretbrijo," it has been concluded that he lost it during a battle. From the elegy, "Aquele que d'amor descomedido," it has been deduced that he spent part of this period at Ceuta. His *fuga* ("flight") from Lisbon inspired his earliest biographers to create the hypothesis of a Camões exiled from the court by love. Commentators who allow their imagination to outrun their critical sense will always be able to subscribe to it because in the poems of this period Camões frequently uses the word *desterro* ("banishment") and describes with poignant sincerity the sufferings caused by love.

He returned to Lisbon but in 1553 he was again overseas, this time in India. A letter written after the premature death of D. António de Noronha at Ceuta on April 17, 1553, proves that he went there shortly after receiving the *Carta de Perdão*. In this letter, Camões alludes to the 3,000 days of venomous tongues, worse deeds and biting calumnies, all born in pure envy, that he had spent in Lisbon, and congratulates himself on having known how to escape from the many snares that circumstances laid for him. He adds that in India he finds himself more honoured than the bulls of Merceana and in a quieter atmosphere than that of a preaching friar's cell. His first impression of India was that it was an indulgent mother to the unworthy and a cruel stepmother to the worthy. With time, the impression must have deepened.

He had arrived in Goa after what he describes as six months of very unpleasant life at sea and had to embark again almost immediately with the viceroy to make war on the *Rei da Pimenta* in Malabar. Reference is made to this event in his elegy, "O Poeta Simonides falando." He also took part in one of the expeditions sent to the Straits of Mecca (Bab el Mandebj according to his most famous *canção*, "Junto de um sêco, fero e estéril monte." Later he was appointed *provedor-mor dos defuntos e ausentes* (official responsible for the property of dead and absent Portuguese) in China, but was almost forcibly deprived of this position by the captain of a boat who had previously held it and who tried to take him back to Goa under arrest. Camões escaped this fate as a result of the shipwreck at the mouth of the Mekong river to which he refers in Canto X, stanza 128 of his epic, *Os Lusíadas*. In the same stanza he alludes to the *Injusto mando* ("unjust command") which has baffled all his commentators.

In 1570, Camões was on his way home to Portugal, having served under no less than eight viceroys or governors while he was in India, and just as poor as when he had left Lisbon. He lived for some time in Mozambique where he was visited by the chronicler, Diogo do Couto, who described him as so poor that his friends had to give him food. To enable him to embark for home they had to gather together the clothing he needed and, probably, to pay some debts. He took back with him the manuscript of *Os Lusíadas* which he had only with great difficulty saved from the shipwreck. In Lisbon there were still vestiges of the plague which had ravaged the city during the previous year but this did not deter Camões who had *Os Lusíadas* to publish. This he achieved in 1572, afterward receiving a pension of 15,000 reis, which was not as paltry as has been suggested by some of his biographers, and was transferred to his mother after his death on June 10, 1580, in Lisbon. According to Pedro de Mariz, he was buried in the church of Santa Ana.

Camões' poetical works may conveniently be discussed under three headings: lyric, epic and dramatic. (There was also a manuscript entitled *Parnasso de Luis de Camões* on which the poet had worked during the winter of 1568-69 in Rlozambique. It was described by Diogo do Couto, who later tried in vain to trace it, as a book of much learning.)

The first edition of Camões' *Rimas* was published in 1595, 15 years after his death. The editor, Fernão Rodrigues Lobo Soropita,

had exercised scrupulous care in collecting the poems from manuscript songbooks, but even so he could not avoid the inclusion of some apocryphal poems. The increasing fame of Camões' epic during the political crisis of 1580 to 1640 also swept the lyrics into fame and in the 17th century many efforts, not all of them praise-worthy, were made to unearth more poems. Prominent in this enterprise, but in a manner condemned by modern criticism, was Manuel de Faria e Sousa. Even in the 19th century, the Visconde de Juromenha added to the already excessive collection of lyrics, introducing into his edition of 1860-69 many poems from the songbooks, which were still comparatively unstudied. As a result the sonnets increased from 65 in the first edition to 352 in the Juromenha edition; the *canções* from 10 to 21; the *sextets* from 1 to 5; the odes from 5 to 14; the octets from 3 to 9; the eclogues from 8 to 16; the elegies from 3 to 29; the *redondilhas, motos, esparsas* and *glosas* from 74 to 147. From 170 in the first edition, the number of poems had risen to 593 by 1860.

With Wilhelm Storck, and more especially with Carolina Michäelis, in the late 19th and early 20th centuries there began a critical reaction which led to the elimination of many apocryphal poems. Although a complete restoration of Camões' lyrics appears impossible, scholars continue the work of purifying the texts. Fortunately there are sufficient authentic poems to confirm his position as Portugal's finest lyric poet. If he had remained at court, he would not have reached this high pinnacle despite his consummate artistry. But he exchanged the vanity of court life for the hardships of a soldier's life in Africa and India and this immeasurably enriched his poetry. For he no longer needed to conform to the standards of brevity required in court circles, and, more important still, so profound was the anguish he experienced because of his exile from home and the trials he underwent, that it became an integral part of his being, enabling him to give to *saudade-soleidade* ("yearning fraught with loneliness") a new and convincing undertone unique in Portuguese literature. His best poems vibrate with the unmistakable note of genuine suffering and deep sincerity of feeling. It is this which places him far above the other poets of his era.

Although the *canções* and elegies give the poet's true measure, the *redondilhas* must not be underestimated. In the production of these elegant trifles Camões was inimitable. He rejuvenated the ancient art of glossing by the apparent spontaneity and simplicity, the delicate irony and the piquant phraseology of his verses, and so raised courtly grace in poetry to its highest level. These poems show a Camões who could be happy and carefree.

In their efforts to discover who inspired most of Camões' poems, critics have made, on very slender grounds, many contradictory suggestions, e.g. Isabel Tavares, D. Catarina de Ataíde, D. Francisca de Aragao, the Infanta D. Maria and a young Chinese girl said to have been shipwrecked with him, but the real muse, if the poet had one, remains an enigma. Nor should it be forgotten in trying to resolve the doubt that he himself said in one of his sonnets, "em várias flamas variamente ardia" ("I burnt myself at many flames")

Camões' epic, *Os Lusíadas* ("The Portuguese"), published in Lisbon in 1572, extols the glorious deeds of the Portuguese and their victories over the enemies of Christianity: victories not only over man, but also over the forces of nature motivated by inimical gods. From the 17th century onward, critics have censured Camões for using pagan mythology in a poem exalting the deeds of Christians. Some have claimed that it has an allegorical significance, while Voltaire, in the 18th century, set the tone for neo-classical criticism. Camões was undoubtedly thinking of the *Aeneid* when he conceived the idea for his poem, but in *Os Lusíadas* Bacchus intervenes because he fears that immortality itself is in peril, while Venus, helping the Portuguese, seeks to prolong it by causing them to land on her island and marry her nymphs. The new Argonauts and their progeny will supersede the ancient gods who are only men whom Fama immortalized by blazing abroad their noble deeds (Canto IX, 91-92).

The courage and enterprise of Portuguese explorers had inspired the idea of a national epic during the 15th century but it was left to Camões in the 16th century to put it into execution. It is im-

possible to say for certain when he decided to do so or when he actually began his epic. He wrote the dedication to Sebastian, however, during the prince's minority which ended on Jan. 20, 1568, and, according to Diogo do Couto, was revising his poem during the winter of 1569-70 in Mozambique. The royal licence permitting printing and granting copyright is dated Sept. 24, 1571.

The poem describes the discovery of the sea route to India by Vasco da Gama. After being saved from Mombaça's treachery, the voyagers spend several days in Melinde on the east coast of Africa, and, at the king's request, Vasco da Gama relates the entire history of Portugal from its origins to the inception of their great voyage (Cantos III, IV and V). These cantos contain some of the most beautiful passages in the poem: the death of Inês de Castro, the battle of Aljubarrota, the vision of King Manuel I, the Velho do Restelo, the description of St. Elmo's fire and the waterspout, and the story of Adamastor, a supremely beautiful poetical conception.

When they re-embark the poet takes advantage of leisure hours on board to narrate the story of the Doze de Inglaterra (Canto VI, 43-69). In the meantime, Bacchus, ever ready to impede the progress of the Portuguese in the east, convokes a council of the sea gods and incites them to arrange the shipwreck of the Portuguese fleet. This is prevented by Venus (Canto VI, 85-91) and Vasco da Gama is able to reach Calicut, the end of his voyage. There his brother, Paulo da Gama, receives the king's representative, the *Catual*, on board and explains the significance of the characters depicted on the banners that adorn the captain's ship (Cantos VII and VIII). On their homeward voyage the mariners chance upon the island which Venus has created for them and the nymphs reward them for their labours. One of the nymphs sings of the future deeds of the Portuguese (Cantos IX and X) and the entertainment ends with a description of the universe (Ptolemaic system) given by Thetis and Vasco da Gama, after which the sailors embark once more and the nymphs accompany them on their homeward journey.

In *Os Lusíadas* Camões achieved an exquisite harmony between classical learning and practical experience, delicate perception and superb artistic skill, expressing through them the gravity of thought and the finest human emotions. It was his eulogy of the *vida perigosa* ("dangerous life") and a stern warning to the Christian princes, who, idling their time away in petty struggles, were forgetting Mohammed, the common enemy, who was advancing against Europe (Cantos VI, 95 and VII). In critical periods of their history the Portuguese have found in Camões an inspiring example of strength and endurance.

In his dramatic works Camões tried to combine national and classical tendencies. In *Enfatriões* he accentuated the comic aspect of the myth of Amphitryon; in *El-Rei Seleuco* he reduced the situation found in Plutarch to pure farce; in *Filodemo* he developed the *auto*, a kind of morality play, which Gil Vicente had earlier made popular. But for Camões, comedy was unimportant, a mere curiosity and a recreation to which he could give only transitory attention. Nevertheless, by imposing classical restraint on the Vicentian *auto*; increasing the importance of the plot; transferring the comic element from the characters to the action; and by refining the farce, Camões indicated a possible means of rejuvenating 16th-century comedy in Portugal; but later dramatists, unfortunately, were incapable of following the lead he had given. This, however, is the least important aspect of Camões' poetry. It was his epic and his lyrics, among which are some of the loveliest ever written, that made him one of the greatest poets of 16th-century Europe and have given him a lasting claim to fame.

CAMOMILE (CAMOMILE FLOWERS), a drug consisting of the dried flower heads of certain species of Compositae, once widely used as a home remedy in the form of a tea. Hungarian or German camomile (*matricaria*) is derived from wild plants

Matricaria chamomilla, an annual herb indigenous to Europe and western Asia and naturalized in parts of Australia and the United States. It has a warm aromatic odour and a bitter taste. Its constituents include bitter principles and a strongly aromatic volatile oil that is sometimes used medicinally.

Roman, English or Russian camomile (*anthesis*) is derived from *Anthesis nobilis*, a perennial herb indigenous to southern and western Europe and cultivated for medicinal use in Saxony, France, Belgium and England. It contains bitter principles and a volatile oil similar to that of *matricaria*. Spanish camomile is derived from wild plants of this species. It is richer in active principles but more likely to produce nausea.

The camomiles are said to act as stimulants, allayers of nervous excitement and carminatives.

The name wild camomile is applied to *cotula* (mayweed), the dried plant of *Anthesis cotula*, which is native to Europe but naturalized as a common weed in many parts of North America. It is the most acrid of the camomiles; the juice of the fresh leaves will blister the skin. (V. E.)

CAMORRA, a secret society of the province of Naples in southern Italy. When it began is uncertain, but by 1830 it was publicly known. It originated in Neapolitan jails, its first purpose being protection of prisoners. Former inmates then continued the society outside the jails, notably in the city of Naples. The Camorra grew rapidly in influence and power; its operations included criminal activities of various kinds, such as smuggling, blackmail and ordinary road robberies. The general disorder of Naples was so great and the police so badly organized, that merchants were glad to engage the Camorra to superintend the loading and unloading of merchandise. Because the society was nonpolitical, the government did not interfere with it; indeed its members were taken into the police service, and occasionally they solved crimes that baffled the authorities.

During the decade of reaction which followed the Neapolitan revolution of 1848, many *camorristi* became interested in politics and supported the national and liberal cause. They organized demonstrations against the despotic regime of King Ferdinand II. After the elimination of the Bourbon dynasty and the incorporation of its realm into the United Kingdom of Italy, the political power of the Camorra became truly formidable. It proceeded to abuse this power, and widespread disorder ensued. In 1862 severe repressive measures were inaugurated against the society and continued for several decades. The Camorra struck back by means of political intrigues and acts of brigandage. The authorities countered in their turn with an intensive series of manhunts that started in 1882. Thereafter the Camorra steadily lost ground; its decline was climaxed by the defeat of all its candidates in the Neapolitan elections of 1901.
