Volume 4 BOTHAS TO CARTHAGE

BOTHAS, LOUIS (1862–1919), South African general and statesman, who, as the first prime minister of the Union of South Africa, strove to reconcile the Boers and the British, and to create a unified nation, was born on a farm near Greytown, Natal, on Sept. 27, 1862. In 1869 the family moved to the Orange Free State where Louis was brought up as a typical Boer farmer's son. He had little formal education, and he never acquired much taste for reading or confidence in the use of the English language; but he did possess a natural flair for getting on with people.

In 1884 he took part in the formation of the New Republic in the Vryheid area and settled on a farm to which he took his bride, Annie Emmett, in 1886. The New Republic was incorporated in the South African Republic in 1888, and in 1897 Bothas was elected to the *volksraad* (parliament) where he sided with those who, led by Piet Joubert, were critical of President Paul Kruger's policy toward the *Uitlanders*. But when the South African war broke out in 1899, Bothas, who had been appointed field cornet of Vryheid in 1893, did not hesitate to do his duty by his country.

Service in the South African War.—Bothas gained rapid promotion, and commanded the southern force investing Ladysmith with verve and success. His force ambushed an armoured train, taking Winston Churchill among the prisoners. It was his strategy which drove back General Buller at Colenso, and his determination brought success at Spion Kop and Vaal Krantz. In March 1900, after Joubert's death, Bothas was appointed commandant general of the Transvaal. He could do nothing to prevent Lord Roberts' march to Pretoria because British reinforcements were streaming into the country, and General Cronjé had surrendered with a large force at Paardeberg in Feb. 1900. After the fall of Pretoria he organized guerrilla warfare, and became a brilliant exponent of it. He entered into negotiations with Lord Kitchener at Middelburg in March 1901, but was not satisfied with the terms of the British peace offer and continued the increasingly hopeless struggle. At the conference of representatives of the Boer commandos at Vereeniging in May 1902 he recommended that they should come to terms, since further resistance would be suicidal. This was done, and he was a signatory of the peace agreement.

Prime Minister of the **Transvaal**.—After the war Bothas, assisted by Jan Christian Smuts, took the lead in organizing the

Transvaal Boers for political action. He agitated for self-government and against the importation of Chinese labourers; he became chairman of *Het Volk* ("The People") when the party was founded in 1905; and when self government was granted in 1907 he became prime minister of the Transvaal. He believed that the divisions and bloodshed of the past should be forgotten; that Boer and British South Africa should fuse into a new nation; that the four British African colonies should be united and, like Canada, Australia and New Zealand, should have full control of their internal affairs but be linked with Great Britain and the rest of the empire for defense and for trade. These were probably his hopes even in 1902; the generosity of Sir Henry Campbell-Eannerman and his cabinet in granting self-government to the Transvaal and the Orange River Colony in 1907 made them his ardent convictions, and for the rest of his life he steadfastly adhered to them. His patent sincerity gradually gained him the respect and the confidence of many British white South Africans and of the British government and people.

Although Smuts was mainly responsible for the detailed labours which produced the Union of South Africa, Bothas's personality and tact were also a major factor. He intervened decisively in several crucial debates in the national convention (1908–09) in favour of a unitary and not a federal constitution, for the maintenance of an absolute political colour bar in the northern provinces, and to make Pretoria the administrative capital of the Union. And he, more perhaps than anyone else, persuaded the English-speaking delegates in the convention and a large majority of the English-speaking electorate that union was not a plot for Afrikaner domination of South Africa, but a wise and necessary basis for nationhood and prosperity.

Prime Minister of South Africa.—Bothas was the natural choice as first prime minister of the Union. He assumed the office on May 31, 1910, and held it until his death. He included English-speaking politicians in his Union cabinet, as he had in his Transvaal cabinet, and in the general election of Sept. 1910 his government was given a clear majority. The official opposition was the Unionist party, led by L. S. Jameson and supported by most of the English-speaking voters. In 1911 Bothas founded the South African party, an amalgamation of the anti-imperialist parties which had been in power in the Cape Colony, the Transvaal and

the Orange River Colony before Union.

The challenge to Botha's policy came not from the British but from the Afrikaner side. Already before Union some Afrikaners had thought that Botha's conciliatory policy toward British South Africans and Great Britain was being carried too far; that it endangered the survival of Afrikaners as a distinct national group and sacrificed the interests of South Africa for those of Great Britain. Through his firm hold over the Het Volk party organization, Botha had kept such people under control in the Transvaal colony; but the *Orangia Unie* party in the Orange River Colony was strongly influenced by the former president M. T. Steyn, who was inclined to brood over the past, and led by men like J. B. M. Hertzog, who emerged as a prophet of an Afrikaner revival, unsullied by alien influences. The cracks were papered over when Hertzog joined Botha's government in 1910, but within three years the paper had torn apart and Hertzog had founded an Afrikaner Nationalist party eroding Botha's Afrikaner support.

This process was accelerated during World War I. Botha unhesitatingly accepted the fact that once Great Britain was at war with Germany, so was South Africa; he offered that South Africa should undertake its own defense, so that the imperial troops could be used elsewhere, and when Britain asked that South African forces should deal with the German radio station at Windhoek and occupy German South-West Africa, he agreed. This decision precipitated a rebellion of about 12,000 Afrikaners, led by heroes of the South African War, including C. F. Beyers and C. R. De Wet, and not publicly repudiated by Steyn and Hertzog. Though Botha mastered the rebellion and extended clemency to the rebels, he was thenceforth regarded by extreme Afrikaner nationalists as having missed a glorious opportunity to regain the republican independence which had been lost at Vereeniging.

After the surrender of the last rebels in Feb. 1915, Botha organized the conquest of South-West Africa. He himself took command of the Union forces and his well planned campaign resulted in the surrender of the territory on July 9, 1915. Back in the Union, he had to fight an election in which the Nationalists cast doubts upon his personal integrity and increased their representation in the house of assembly to the point where he became dependent on the support of the Unionists for the measures necessary for the conduct of the war. Botha remained in South Africa, the object of continuous Nationalist criticism; until after the armistice. He then went to Paris, where he supported the claims for the recognition of the dominions as international entities and, with memories of 1902, pleaded for lenient terms for the vanquished. He signed the treaty of Versailles with misgivings and then returned, a sick man, to South Africa. He died in Pretoria on Aug. 27, 1919.

Character.—Like most Boers who had grown up in a 19th-century republican environment, it was natural for Botha to believe that political power in Africa should be a white monopoly; and it was during his premiership that the Natives Land act (1913), limiting the areas in which natives could purchase land, was enacted. He spoke Zulu and Sesuto fluently, and was humane in his personal dealings with Africans, but his vision for the future of his country was of a white minority ruling a nonwhite majority.

Botha's greatness lay in his magnanimous and wholehearted attempt, first to end the century-old friction between Boer and Briton in South Africa by promoting their fusion into a single nation, and second, to draw united South Africa out of its potential isolation into effective membership of the evolving British Commonwealth. His tragedy lies in his gradual alienation from many of his own Afrikaner people, whose exclusiveness he underestimated. See also SOUTH AFRICA, UNION OF: *History*.

BOTHE, WALTHER WILHELM GEORG FRANZ (1891–1957). German physicist, was awarded with Max Born (*q.v.*), the 1954 Nobel prize for physics, for his invention of the coincidence method and his discoveries with this method. Bothe was born at Oranienburg, Ger., on Jan. 8, 1891. He was educated at the University of Berlin, where he obtained his doctorate of

philosophy in 1914. Later he taught in the universities of Berlin, Giessen and Heidelberg.

In 1934 Bothe was appointed director of the Institute of Physics in the Kaiser Wilhelm Institute (later the Max Planck institute) for Medical Research, Heidelberg, and from 1946 he also held the chair of physics in the University of Heidelberg. He introduced coincidence methods into counting techniques in modern physics and with Hans Geiger he applied these methods to study the Compton effect. With W. Kolhörster in 1929 he devised a new method for the study of cosmic rays: by passing these rays through suitably arranged Geiger counters, it was found possible to establish the presence of penetrating charged particles and to define more or less accurately the path of individual rays. In 1930 Bothe discovered an unusual radiation emitted by beryllium bombarded by alpha rays, and this was later identified by Sir James Chadwick as the neutron. He died on Feb. 8, 1957, at Heidelberg. (D. MCK.)

BOTHWELL, JAMES HEPBURN, 4TH EARL OF (c. 1536–1578), duke of Orkney and Shetland (May 12, 1567), was instrumental in the murder of Lord Darnley, second husband of Mary Stuart, whom he himself subsequently married. He was born c. 1536, the son of Patrick, 3rd earl of Bothwell, whom he succeeded in 1556, and of Agnes, daughter of Henry, Lord Sinclair. Although a Protestant, Bothwell supported the Catholic regent, Mary of Lorraine, for whom he led a successful raid into England in Dec. 1558, and seized, in Oct. 1559, £1,000 sent secretly by Queen Elizabeth I to the Protestant lords of the congregation. The queen regent having died in June 1560, Bothwell joined Queen Mary at Paris in September and was sent to Scotland as a commissioner to summon parliament. He was chosen a privy councillor in Sept. 1561, but became involved in partisan feuds and in March 1562 was accused by the deranged earl of Arran of plotting to seize the queen. He was imprisoned in Edinburgh castle, but escaped in Aug. 1562, and after a period of detention in England, reached France in Sept. 1564.

After Mary's marriage with Lord Darnley (July 29, 1565), Bothwell was recalled to Scotland to help suppress the earl of Moray's rebellion. He married Jean Gordon, sister of George, Lord Gordon (afterward restored to his father's forfeited title of earl of Huntly), who thenceforth became his consistent ally. The murder of Mary's secretary, David Rizzio, on March 9, 1566, with Darnley's connivance increased the queen's dislike of her treacherous husband; and Bothwell, whose loyalty and resource during the crisis had done much to preserve her throne, acquired a growing ascendancy over her affections. His appointment as keeper of Dunbar castle (1566) and other marks of royal favour made him the most powerful noble in the south of Scotland and encouraged him to aspire to Darnley's place. The disposal of Darnley was discussed at Craigmillar in Dec. 1566, by a group that included the queen, Bothwell and Lord Gordon; it was later asserted that a murder bond was afterward signed by Bothwell and others. There is undoubted proof that Bothwell himself superintended the preparations for the murder of Darnley at Kirk-O'-Field on the night of Feb. 9–10, 1567.

Public opinion soon accused Bothwell of the crime and Mary of guilty foreknowledge, but after his acquittal at a mock trial on April 12, her intention to marry him was made public; on April 19 he obtained the consent of the leading Protestant nobles. His probably collusive kidnapping of the queen on April 24 was soon followed by his divorce and their marriage on May 15 by Protestant rites. But a coalition of Protestant and Catholic nobles forced them in June to flee to Dunbar, whence they marched in force on Edinburgh, the rival armies meeting on June 15 at Carberry Hill. After Bothwell had been forbidden by Mary to engage in single combat, desertions from the queen's army made her surrender inevitable. Bothwell, however, was allowed to escape; he went north, visited Orkney and Shetland and finally escaped to Karm sound in Norway (then ruled by the Danish kings). He was sent to Copenhagen in Sept. 1567, and removed to Malmo in Scania (a Danish province in Sweden), but King Frederick II, possibly influenced by his offer to restore the Orkneys and Shetlands to Denmark, refused repeated requests for his extradition or execu-

tion. Mary and Bothwell are said to have corresponded at this time; and he may have assented to the annulment (Sept. 1570) of their marriage. After the final collapse of the queen's cause in Scotland, Bothwell was in June 1573 placed in solitary confinement in the castle of Dragsholm in Zealand, where he died, probably insane, on April 14, 1578.

Bothwell's association with Queen Mary proved disastrous to both. As a man of action, he possessed virtues of personal courage and absolute loyalty to the crown, both conspicuously lacking in his leading contemporaries; as a political figure, his lax morality and reckless violence proved fatal to his high ambition. See also MARY (Queen of Scots).

BIBLIOGRAPHY.—*Les Affaires du Comte de Boduel* (Bothwell's account, written Jan. 1568; published 1829); Sir James Melville, *Memoirs*, ed. by T. Thomson (1827); Prince A. Labanoff, *Pièces et documents relatifs au comte de Bothwell* (1856); George Buchanan, *The Tyrannous Reign of Mary Stewart*: ed. by W. A. Gatherer (1958). (J. I.M.)

BOTHWELL, a town in Lanarkshire, Scot., lies on the right bank of the Clyde, 9 mi. E.S.E. of Glasgow. Pop. (1951) 3,180. At Bothwell bridge a monument commemorates the Covenanters who fought in the battle of June 22, 1679, when the duke of Monmouth crushed the Westland rising. The restoration (1898) of the 14th-century chancel of the collegiate church of St. Bride and the renovation (1932) of the early 19th-century nave have provided an impressive setting for the stained glass windows designed by Sir Edward Burne-Jones. A mile beyond St. Bride's, the towers and walls of Bothwell castle (mainly 13th century) crown a river-side cliff of red sandstone. At Orbiston, 2 mi. N.E. of Bothwell, some of Robert Owen's disciples attempted to carry out (1825) his ambitious project of communal living.

BOTOSANI, a town of northeast Rumania in the Suceava region, lies in a rich farming district of northern Moldavia. Pop. (1956) 29,593. Botogani was founded in the 14th century, taking its name from Batu Khan, grandson of Genghis Khan, who occupied the country in the 13th century. The St. George's church dates from 1551. Botogani is an important commercial centre with extensive flour mills. Industrial developments after World War II include factories for textiles, clothing and vegetable oils. The town is on the highway between Bucharest and Chernovtsy, U.S.S.R., and on a branch line from the railway linking them.

BO TREE (BODHI TREE), the name given by the Buddhists of India and Ceylon to the pipal (peepul) tree, or sacred fig (*Ficus religiosa*). It was a tree of this species beneath which the Buddha is traditionally supposed to have attained enlightenment, at Buddh Gaya (q.v.), still the most important site of Buddhist pilgrimage in India. The bo tree at Anuradhapura (q.v.) in Ceylon, grown from a branch of the parent tree sent to Ceylon by King Asoka in the 3rd century B.C., also is venerated by thousands of pilgrims every year. See also FIG.

BOTRYTIS, a minute fungus which appears as a brownish-gray mold on decaying vegetation or on damaged fruits. Under a magnifying glass it is seen to consist of tiny, upright, brown stalks which are branched at the tips, each branchlet being crowned with a naked head of pale-coloured spores. It is very common growing everywhere in the open or in greenhouses, and can be found at almost any season. Some species are known to cause destructive plant diseases. The fungi placed in the genus *Botrytis* are in part stages in the life history of members of the genus *Sclerotinia*. These are characterized by the possession of a *sclerotium*, which is a compact mass of fungal filaments from which a cuplike ascophore arises.

See FUNGI: *Ascomycetes* (*Sac Fungi*).

BOTSARIS, MARKOS (Italian MARCO BOZZARIS) (c. 1788–1823), a hero of the War of Greek Independence, was born at Souli in southern Epirus of a leading Albanian family. In 1803, after the capture of Souli by Ali (q.v.) of Janina, Markos, with the remnant of the Souliots, crossed over to the Ionian Islands, where he ultimately took service in an Albanian regiment in French pay. In 1814 he joined the Greek patriotic society known as the Hetairia Philike. In 1820, with other Souliots, he made common cause with Ali of Janina against the Turkish sultan's government. On the outbreak of the Greek revolt, he fought as a partisan leader in the fighting in western Hellas and was conspicuous in the defense of

Missolonghi during the first siege (1822–23). On the night of Aug. 21, 1823, at Karpenisi, he led 350 Souliots against the 4,000 Albanians who formed the vanguard of the army advancing to reinforce the besiegers. The rout of the Turks was complete, but Botsaris was killed.

BOTTA, CARLO GIUSEPPE GUGLIELMO (1766–1837), Italian-born historian and politician who supported Napoleon, was born at San Giorgio del Canavese, Piedmont, on Nov. 6, 1766. Having graduated in medicine at Turin in 1786, he was in his youth greatly inspired by the ideas of the French Revolution. Arrested as a spy in 1794, he left Italy for France the following year and from 1796 to 1798 served as a doctor in Napoleon's campaigns against Italy and Corfu. He published a history of Corfu in 1799 and in the same year became a member of the Franco-Italian government of Piedmont. An ardent supporter of Napoleon, though he later contributed to his fall, he was elected vice-president of the French legislative assembly in 1808. In 1815 he became a French citizen and was subsequently appointed rector of the academies of Nancy and Rouen. He died in Paris on Aug. 10, 1837. His main work is a fanciful history of the American Revolution, though it is based on contemporary documents and material supplied by Lafayette. An English translation, *History of the War of the Independence of the United States of America*, was published in Philadelphia (1820–21). In this work the American revolutionaries are compared to the French and Washington to Napoleon. Other works were a history of Italy from 1786 to 1814 and monographs on Savoy and Piedmont.

BIBLIOGRAPHY.—C. Dionisiotti, *Vita di Carlo Botta* (1867); C. Pavesio, *Carlo Botta e le sue opere storiche* (1874); Scipione Botta, *Vita privata di Carlo Botta* (1877).

BOTTICELLI, SANDRO (properly ALESSANDRO DI MARIANO DI VANNI FILIPEPI) (1444/5–1510), one of the greatest of the Italian Renaissance painters, was born at Florence in 1444/5, the son of a tanner. The name Botticelli, by which he was generally known, derives from his eldest brother Giovanni, who bore the nickname "Botticello" (little barrel). A tax return prepared by his father in 1458 describes Botticelli as aged 13, backward, and weak in health. At some uncertain date, probably before 1460, he was apprenticed to Fra Filippo Lippi, and a number of his earliest works (among them the Guidi da Faenza Madonna in the Louvre, Paris, and half-length Madonnas in the Museo di Capodimonte, Naples, the Accademia in Florence, the Musée des Beaux-Arts at Strasbourg and the National gallery, London) reflect Lippi's types and compositional schemes.

Before 1470 Botticelli seems to have become associated with the workshop of Verrocchio, and the latter's style is the dominant factor in his first dated work. This is a figure of Fortitude forming part of a series of seven paintings of Virtues (now in the Uffizi, Florence) commissioned to Piero del Pollaiuolo for the Mercanzia at the end of 1469. The commission for the "Fortitude" was withdrawn from Pollaiuolo and allocated to Botticelli in May 1470 at the instance of Tommaso Soderini, perhaps on the instructions of Lorenzo de' Medici; this was the first official recognition of Botticelli's work. To the period about 1470 belongs the S. Ambrogio altarpiece in the Accademia, Florence, and a painting of the Trinity designed for the high altar of the church of the Convertite (Courtauld gallery, University of London). In the four predella panels of this altarpiece (Philadelphia Museum of Art) there appears for the first time the linear figure style with which the name of Botticelli is associated. To the same date may be assigned two small paintings, "Judith With the Head of Holofernes" and the "Assyrians Discovering the Body of Holofernes" in the Uffizi. The nude figure of Holofernes in the latter is in turn connected with a painting of St. Sebastian executed for Sta. Maria Maggiore in 1473–74 (Kaiser Friedrich Museum, Berlin).

Before 1470 Botticelli also executed the first of his many paintings of the Adoration of the Magi, on an oblong panel, in the National gallery, London. A second, circular painting of the same subject in the same gallery is of somewhat later date and was followed in about 1476 by Botticelli's best-known rendering of the subject, a painting in the Uffizi, commissioned for Sta. Maria Novella by Cuaspere di Zanobi del Lama and containing portraits

of members of the Medici family and a self-portrait. Almost a decade later Botticelli painted two more pictures of the Adoration of the Magi. One of these is in the National Gallery of Art, Washington, D.C., and the other in the Uffizi. In both cases the scheme is influenced by the S. Donato a Scopeto "Adoration of the Magi" of Leonardo da Vinci now in the Uffizi. The changes that can be traced in this sequence of paintings form an index to the development of Botticelli's style between about 1468 and 1485.

The commission for the "Fortitude" and the portraits in the Uffizi "Adoration of the Magi" provide the earliest evidence of the association with the Medici that inspired some of Botticelli's greatest paintings. Among these, pride of place belongs to the "Allegory of Spring" and the "Birth of Venus" (both in the Uffizi). The first, painted probably in 1478 for the villa of Lorenzo di Pierfrancesco de' Medici at Castello, owes its title of "Primavera" to a passage in G. Vasari's life of Botticelli. Representing Venus in a flowery meadow against a grove of trees with, on the left, the three Graces and Mercury, and on the right, Flora, a zephyr and the figure of a maiden generally identified as that of Spring, it illustrates a complex humanist program probably drawn up by Marsilio Ficino. Of somewhat later date is the "Birth of Venus," also painted for Lorenzo di Pierfrancesco de' Medici. This, Botticelli's masterpiece, appears to have been inspired by descriptions of the lost "Aphrodite Anadyomene" of the Greek painter Apelles, and to depend primarily on the poem "La Giostra" of Politian. Both paintings were originally planned as Neoplatonic allegories and not as simple narratives, but their enduring fame is due to their lyrical treatment and to their transcendent quality as works of art.

To the same group of Medicean commissions belongs the "Pallas and a Centaur" in the Uffizi, a political allegory dedicated to Lorenzo de' Medici, and the "Mars and Venus" in the National gallery, London. With these works may be grouped a lost cycle of frescoes painted in the villa of Lorenzo de' Medici at Spedaletto near Volterra by Botticelli, Ghirlandaio, Perugino and Filippino Lippi, and two allegorical frescoes from the Villa Lemmi now in the Louvre, generally thought to have been painted in 1486 for the marriage of Lorenzo Tornabuoni and Giovanna degli Albizzi but perhaps rather earlier in date.

The picture of Botticelli as a humanist artist may be completed with reference to 19 woodcuts which he designed for an edition of Dante's *Divine Comedy* with the commentary of Landino, printed at Florence by Lorenzo della Magna in 1481. It is possible that this work was paid for by Lorenzo di Pierfrancesco, and certain that he was responsible for commissioning a later series of 96 drawings illustrating the *Divine Comedy* (now distributed between the Staatsbibliothek, Berlin, and the Vatican library). In these drawings—Botticelli's supreme achievement as a draftsman—the imagery of the *Divine Comedy* is reinterpreted in Neoplatonic terms. Their execution seems to fall within the decade 1485-95. Before the commencement of this series, Botticelli designed the engraving of the "Triumph of Bacchus and Ariadne" (single example in the British museum, London). Concurrently with the latest of the drawings, he painted, for Antonio Segni, the "Calumny" (Uffizi), inspired by Lucian's description of a lost painting by Apelles.

In 1474 Botticelli visited Pisa, in connection with a proposed commission for frescoes in the Campo Santo, and in 1480 executed, on the choir screen of the Ognissanti, a fresco of "St. Augustine in His Study." A companion fresco of "St. Jerome in His Study" was painted at the same time by Ghirlandaio. The virile forms and ambitious space construction of the St. Augustine find a counterpart a year later in a fresco of the Annunciation painted for S. Martino alla Scala, which ranks with Botticelli's most inspired works.

With the experience of these frescoes behind him, Botticelli was summoned to Rome, in the summer of 1481, to undertake, in the company of Ghirlandaio and Cosimo Rosselli, the frescoed decoration of the Sistine chapel, and between this time and Oct. 1482 executed three frescoes of the "Purification of the Leper and the Temptation of Christ," the "Youth of Moses" and the "Desecration of the Sons of Korah." Though filled with incidental beauties, these crowded and conventional designs do not represent the painter's talent at its most felicitous.

Botticelli's development after his return to Florence may be charted in terms of a number of altarpieces. The first of these, a "Virgin and Child Enthroned With the Two SS. John," painted for S. Spirito in 1485, is in the Kaiser Friedrich museum. This was followed by a larger and more ambitious altarpiece painted for S. Barnaba (Uffizi); one panel from the beautiful predella of this altarpiece, the "Vision of St. Augustine," has acquired universal popularity. From the years 1488-90 date the great altarpiece of the "Coronation of the Virgin" in the Uffizi (painted for S. Marco) and an Annunciation in the same gallery painted for the convent of Cestello. Several of Botticelli's best-known paintings of the Virgin and Child in half-length date from these same years. Among these are the "Virgin and Child With an Angel," in the Gardner museum, Boston, and the "Virgin and Child With Young St. John" in the Louvre, as well as two circular panels of the "Madonna of the Magnificat" and the "Madonna and Child With Six Angels," both in the Uffizi. All four paintings are remarkable for their intimate personal sentiment, and those in the Uffizi are at the same time some of the most sophisticated 15th-century examples of the employment of the tondo, or circular, form.

After about 1490 expressive line plays an increasingly important part in Botticelli's style. First apparent in the later Dante illustrations, and subsequently in the scenes from the legends of Virginia Komana and Lucretia (Accademia Carrara, Bergamo, and Gardner museum, Boston) and four scenes from the life of St. Zenobius (National gallery, London; Gemaldegalerie, Dresden; Metropolitan museum, New York), this recourse to visual distortion prepared the way for the late style which Botticelli developed under the inspiration of Girolamo Savonarola, after 1498. The painter's brother, Simone di Mariano, who returned to Florence in 1493 and lived with Botticelli in the Via Nuova, became an avowed follower of Savonarola. Botticelli himself seems to have been associated with the movement only after Savonarola's death in 1498. The influence of Savonarola's teachings and prophecies is directly reflected in two paintings. The first of these, an "Adoration of the Shepherds" in the National gallery, was painted in 1500-01 and contains a Greek inscription in which the period between 1498 and 1500 is identified with the second woe of the Apocalypse. The second, in the Fogg Art museum, Cambridge, Mass., represents the Crucifixion with the Angel of Justice flaying the Florentine marzocco and the Magdalen prostrate beneath the Cross. In addition, a number of Botticelli's late paintings reveal the oblique influence of Savonarola in heightened emotionalism and in expressionistic imagery. The two subjects which appealed particularly to the painter's mystical temper at this time were the suffering Christ (best version in the Accademia Carrara) and the Lamentation over the Dead Christ (best version in the Alte Pinakothek, Munich).

Botticelli died on May 17, 1510, and was buried in the Ognissanti, Florence.

Throughout his life Botticelli was also active as a portrait painter. Notable examples of his portraits exist in the National Gallery of Art, the National gallery, the Uffizi and the Accademia Carrara.

BOTTLE-BRUSH PLANTS comprise two genera of Australian plants, known botanically as *Callistemon* and *Melaleuca*, belonging to the myrtle family (Myrtaceae; *q.v.*). They take their name from the resemblance of the head of flowers to a bottle-brush. Although known in greenhouse culture, they are commonly grown out-of-doors in parts of Florida and California for the beauty of their highly coloured stamens which vary from lemon to crimson. *M. leucadendra* is known as the cajeput or punk tree. Its bark is pale buff and peels off in many thin layers. It is durable and almost impervious to water. (J. M. Bl.)

BOTTLES. This article discusses bottles (defined as narrow-necked rigid or semirigid containers designed to hold liquids or semiliquids) and allied container forms, such as jars, tumblers, jugs, vials, ampoules, and carboys. The material most commonly used in making bottles and these other containers is glass, although after World War II plastics became increasingly important.

History.—The earliest bottles were made from gourds, shells, or animal skins. Wine was transported and stored by the early Egyptians and Greeks in bottles formed by sewing up a goat's skin and leaving the projection of one leg and foot to serve as a vent. The Old Testament refers to the use of skin bottles for wine. Skins are still sometimes used in parts of western Asia to convey and store water. The shell of the bottle gourd is widely used for holding liquids, especially in Africa, where its shape and ornament are often imitated in vessels of pottery. In southern Turkey, crude long-spouted bottles are still carved from pine logs.

Glass.—The use of glass for making containers has been traced back to both the Egyptians and Syrians prior to 1500 B.C. The early Egyptian method consisted of winding strings of molten glass around a core of silica paste on a metal rod, or dipping the core into molten glass. When the glass hardened, the silica paste was dug from it.

The blow pipe method, the first major improvement in the art of making glass containers, was developed shortly before the time of Christ. In this process, which is still used to produce special, high-value glass containers, the glass blower dips the end of a hollow tube into molten glass to collect a gob, and then blows and manipulates the gob to produce a finished object. Metal molds were introduced to speed up the production of mouth-blown glass containers. (See GLASS: Hand Processes.)

Developments in glass manufacturing that contributed importantly to the growth in the use of glass containers were the substitution of hydrocarbon fuels (first coal and later natural gas) for wood and the discovery of lead crystal. The use of hydrocarbon fuels contributed primarily to lowering the cost of glass, while the discovery of lead crystal greatly improved glass quality.

Still another innovation that reduced the cost of glass substantially was the development of the open hearth type of furnace as a replacement for the older pot-type, direct-fired furnace. In the open hearth furnace, gaseous fuel is used, and flames are played directly over the top of the melt.

But the most important development in the history of glass

FIG. 2.—EGYPTIAN BOTTLE MADE OF ROCK CRYSTAL; 9TH CENTURY A.D.

containers up to the early 1960s was the perfection of automatic machinery that manufactures containers continuously. The first automatic machine was commercially introduced in 1903 by Michael J. Owens, its inventor. These machines automatically collect the required amount of glass into a parison (preparation) mold and form the neck or mouth (finish) at the same time. The parison mold is then automatically removed and a full-sized blow mold substituted.

Through the use of automatic machinery in the glass container industry, production rose from 8,000,000 gross in 1899 to about 150,000,000 gross in the early 1960s.

Plastics.—Rigid and semirigid plastic bottles, jars, jugs, carboys and the like were of minor importance in the early 1960s compared with glass containers. In the U.S. in 1959, about 3,500,000 gross of plastic bottles were produced along with a small quantity of plastic vials and jars. The early growth of plastic bottles was stimulated by the use of low-density polyethylene, a flexible plastic material that permitted production of a bottle that could be squeezed to dispense the contents. Squeeze bottles are used mostly for products whose sales will not be decreased appreciably by high packaging costs, or for products in which the squeeze-to-use feature has unique value. High-density polyethylene, a more rigid but tough plastic, was developed in the late 1950s, and its development permitted the production of containers that have thinner walls and cost less than the older squeeze bottles.

Raw Materials and Composition.—**Glass.**—Container glass is made from three major raw materials: silica sand (SiO_2), soda ash (Na_2CO_3), and dolomitic lime ($\text{CaO}\cdot\text{MgO}$). Limes are introduced as raw limestone (CaCO_3) or dolomite ($\text{CaCO}_3\cdot\text{MgCO}_3$). Dolomitic limestone tends to have a high iron content and, in Britain, limestone is usually used for colourless glass manufacture since high-grade supplies are plentiful. Magnesium oxide can then be added in the form of magnesite (MgCO_3). Feldspar is commonly added for its alumina, and borax may be included to supply boron oxide. Minor ingredients aid the melting of the batch or control the colour of the glass. Fused at high temperature (above 2,700° F.), the oxides derived from the raw materials mutually dissolve, making glass of the following range of composition:

SiO_2 (silica, or silicon dioxide)	68%–74%
Al_2O_3 (alumina, or aluminum oxide)	0.2%–5%
CaO (calcium oxide) and MgO (magnesium oxide)	8%–14%
Na_2O (soda or sodium oxide)	13%–16%
B_2O_3 (boron oxide)	0%–1.5%

Iron oxide (FeO) is always present in raw materials, and a green colour results from it unless the glass is decolorized with selenium; the selenium produces a red coloration that masks the green tint of the iron. The faint straw colour that would remain after the masking is covered by adding a trace of cobalt oxide—the glassmaker's "bluing." Arsenic trioxide (As_2O_3) is usually added to oxidize the ferrous iron to the ferric (Fe_2O_3) condition, in which its colour is a paler, more yellowish green. Colourless, or flint, glass cannot be produced if the glass contains more than 0.06% iron oxide.

Besides flint bottles, many coloured ones are made. Amber glass, which protects against the chemical action of light, is made by introducing carbon along with sulfur or a sulfate, thereby generating sulfides in the glass. In the U.S., the carbon is often added as powdered sea coal;—in Britain graphite, coke and powdered coal are commonly used. Iron oxide, in concentrations of 1% or more, makes a green colour that may be reinforced by chromium oxide. Chromium oxide by itself, in a concentration of one pound per

BOTTLES

FIG. 3. — BLOWING-AND-BLOWING PROCESS

ton of glass, produces emerald green. A rich blue results from adding a similar concentration of cobalt oxide.

Glass containers of all sorts must have sufficient resistance to the attack of water and solutions so that the liquids or semi-liquids placed in the containers will not be chemically affected by traces of alkali extracted from the glass. Therefore, soda, which helps to melt the glass but also tends to make it soluble, is kept at a minimum. Lime and alumina increase resistance to attack.

Bottles for medical serums and other sensitive pharmaceuticals are often made from borosilicate glass, in which boron oxide replaces most of the soda, and alumina is used in place of lime, with silica predominating. (See the article GLASS for details on batch mixing, furnaces and melting and annealing operations.)

In the U.S. raw materials for the manufacture of glass containers are inexpensive; in the early 1960s they cost less than two cents per pound. Manufacturing operations cost about three times as much as raw materials. The total cost of finished glass containers mas six cents to eight cents per pound.

Plastics.—The important plastic materials for the manufacture of rigid and semirigid containers are the polyolefins (including both low- and high-density polyethylene), polystyrene, and polyvinyl chloride. These are all thermoplastic resins; that is, they soften on heating and can be readily formed. The important basic raw material for all of these plastics is petroleum, which yields hydrocarbons that are processed into plastics by several chemical transformations. In addition, chlorine is an important element in the manufacture of polyvinyl chloride. In comparison with the starting materials for glass containers, the raw materials for plastic containers were expensive in the early 1960s, costing between 17 and 30 cents per pound. Because of the relatively low temperatures at which plastics soften, the operations for fabricating containers from these materials are considerably simpler than are those for making glass containers. Nevertheless, the fabrication of plastics costs about the same as the raw materials. Finished plastic containers cost roughly 40 to 60 cents per pound—substantially higher than glass containers. The higher cost of plastic containers is offset to some extent by their lighter weight; many more containers can be made from a pound of plastic than from a pound of glass.

Methods of Manufacture.—Glass.—The most common method for manufacturing virtually all glass containers and most plastic bottles (except plastic jars and vials) is blow molding. In this process, a parison that contains enough material to form the finished container is made in the rough shape of the finished container but much smaller. The parison is transferred to a blowing mold in which compressed air forces it out to its final dimensions.

In glass container manufacture, the parison is most commonly made by using compressed air in a gob feeding process as illustrated in fig. 3. The older Owens process operated in much the same way except that the glass was drawn into the parison mold by vacuum from a molten pool (see fig. 4).

The alternate process for manufacturing parison is by pressing. Again, gob-feeding is cus-

FIG. 4. — VACUUM-AND-BLOWING PROCESS

tomary, but instead of using compressed air to form the parison in the mold, a plunger is used. This process is illustrated in fig. 5. The press and blow process is most useful for wide-mouthed containers. Pressing can be used alone—without subsequent blowing—for containers of simple shapes, such as plain jelly glasses.

The speed at which glass containers are produced increased from 30 or 40 per minute prior to World War II to up to 250 per minute in the early 1960s.

Plastics.—In the blow molding of plastic bottles the most common method for manufacturing the parison is by extruding a tube, capturing the semimolten tube in the blow mold and forming the finish, and then blowing (see fig. 6). The other method is to form a parison in an injection mold and then to transfer the parison to the blow mold in a manner similar to the method used in manufacturing glass containers (see fig. 7). The extrusion blowing method is less expensive for large articles because the extruder can be operated continuously if it feeds a number of blow molds. The injection molding process is intermittent, but if the articles to be made are small, many can be produced in one cycle of the injection molding machine. Blow molding is used to make many plastic items in addition to containers because the process can be used for the low-cost production of large objects with narrow openings.

Plastic jars and vials, especially those of small size, are customarily made by injection molding rather than blow molding. Several small-sized, wide-mouthed vials and jars can be produced at each cycle of the molding machine.

Container Characteristics.—Glass.—Glass containers offer chemical inertness, transparency, high rigidity and strength (in some respects), long shelf life, and ease of opening and closing; another advantage is that they can be made in a wide variety of shapes. Disadvantages of glass containers are their comparative fragility, relatively high weight, and the possibility of product contamination through chipping. The cost of delivering glass containers at the packer's plant ready to fill is low, but high shipping weight and the necessity for storing empty containers are factors that add to the total packaging cost when glass is used.

Returnable glass containers are the least expensive liquid-tight containers available; but they have the disadvantage of having to be handled twice by retailers and distributors in each distribution cycle. As a result, in the U.S. there is considerable pressure to replace returnable glass containers with nonreturnable ones. Lighter-weight glass containers were competing in the early 1960s with returnable glass and metal cans. There was a dramatic reduction in the weight of glass containers after World War II. In some cases, weight was reduced by one-third to one-half with little or no sacrifice in strength. This was accomplished by improvements based on careful studies of the chemical and physical properties of glass, the geometry of glass containers, and the effect of coatings that reduce surface scratching. Scratches create points of weakness. The development of lightweight containers and coatings was expected to lead to further economies in glass packaging.

The appeal of glass packages to consumers at the point of sale, which is an important factor in self-service merchandising, is high because of transparency, high gloss, and variety of shapes. Glass

FIG. 5.—PRESSING AND BLOWING PROCESS

containers are convenient to use because they are easy to open and close and because their contents can be heated while still in the container. The fragility of glass containers has been and remains their principal disadvantage. Efforts were being made in the early 1960s to reduce breakage by taking advantage of the inherently high strength of glass (of which only a small fraction was being used). While transparency is an advantage, it raises the problem of having to prevent absorption of ultraviolet rays by products sensitive to this type of radiation. The glass colours available for this use are limited, and the problem has been intensified by the development of lightweight, thin-walled glass containers.

Metal cans are tougher than glass bottles and protect against light. They do not, however, have the point-of-purchase appeal or convenience-in-use of glass packaging, and for a given capacity they cost about the same. Glass and metal compete with one another in the packaging of beer and soft drinks. A major advantage of metal over glass in these areas is nonreturnability.

Plastics.—Liquid-tight rigid and semirigid plastic containers are more expensive than glass. As pointed out earlier, raw materials cost far more for plastics than for glass, and there is no offsetting savings in the fabricating cost for plastic containers. The outstanding general advantage of plastic over glass is greater toughness. Toughness is particularly useful when the package is handled under conditions in which it might be dropped and broken, as are liquid household detergents and other cleaning products. Other features of plastic liquid-tight containers have more specialized appeal; for example, the squeeze-to-use feature. In general, plastic containers do not provide as good a barrier as glass to gain or loss of water vapour, gases, flavour and odour, and when used in relatively heavy, rigid sections they do not have the transparency and gloss of glass. The common thermoplastic materials cannot be heated much higher than the boiling point of water. Consequently, they are difficult to sterilize, cannot be hot-filled as can glass, and their contents cannot be cooked as readily in the package. The development of liquid-tight containers made from thin sheets of plastic by thermoforming instead of from resin by blow molding or injection molding was expected in the early 1960s to eventually lower the cost of plastic containers. It seemed certain that there

be increasing quantities between plastic and glass containers.

Closures.—The closure is an important part of all packages. Except for some, which are closed by crimping the glass at the narrow neck, all glass containers require a separate closure. The commonest form is the screw or lug cap. An important part of all closures

is the cap liner, which is part of the physical barrier between the interior and exterior of the container. Most liners are somewhat resilient and are covered with a high-barrier material to prevent gain or loss of product.

Labels and Decorations.—Labeling and decorating are important operations in the production of glass and plastic containers. The commonest form of label is the glued-on, printed paper type.

In both glass and plastic, increasing emphasis is being placed on integral labels because of their greater attractiveness and reduced chance of label loss. Integral labels can be applied by silk screening a pigmented coating on the container, generally utilizing more than one colour, and following with a heat cure. A later development in labeling of plastic containers was the use of heat transfer labels; these are printed on paper and transferred to the plastic containers by heat.

Integral labels can also be applied to both glass and plastics by

FROM "PLASTICS WORLD"

FIG. 7.—INJECTION-BLOW PROCESS

embossing during the forming processes while the containers are hot. Embossed labels have no colour to differentiate them from the rest of the container.

Markets.—Between World War II and the early 1960s, the market for packaging in the United States and the U.K. grew faster than either the population or the total economy. The principal stimulus for this growth was the development of self-service marketing, which places a selling burden on the package that it does not bear in clerk service marketing. In the U.S. the increase in use of glass containers was somewhat less than the increase for all types of packaging, although somewhat greater than for the total economy. In both countries plastics, on the other hand, because of their newness and special characteristics, grew substantially faster than total packaging and much faster than the economy. While the glass industry in Britain was handicapped during World War II by shortages of labour and raw materials, glass packaging in the U.S. received a major growth impetus during World War II when shortages of metal forced many packers to change from metal to glass containers. Many of the markets that changed to glass remained with it after the war.

More than two-thirds of the glass containers produced in the U.S. in the early 1960s were used for packaging foods and beverages. About one-fourth were used for drugs and toiletries, and the rest were used for household and industrial chemical products. Principal materials packaged in plastic containers were toiletries and household chemicals. Few foods and beverages were packaged in plastics because of lack of barrier properties, lack of consumer

FROM "PLASTICS WORLD"

FIG. 6.—CONTINUOUS-TUBE PROCESS

BOTTLE TREE—BOUCHER

acceptance, and relatively high cost. A sizable increase in the use of plastic containers was expected, however, as soon as their cost could be reduced and improved barrier coatings were developed.

(P. B. BA.)

BOTTLE TREE, the common name, in reference to the shape of the trunk, of various trees of the genus *Brachychiton*, belonging to the cacao or chocolate family (*Sterculiaceae*). Native to Australia, bottle trees are cultivated in southern California and Florida as ornamentals. The flame bottle tree (*B. acerifolium*) is grown especially for its display of brilliant red blossoms that appear during the brief period when the tree is leafless. See *STERCULIACEAE*.

BOTTOMRY (**BOTTOMRY BOND**), a maritime contract in the nature of a mortgage on a vessel, now almost obsolete, used to secure a loan by means of which the vessel is enabled to proceed upon its voyage. Repayment of the loan is conditional on the safe arrival of the vessel, both the security and the right to repayment being lost if the vessel is lost. A similar contract creating a security interest in cargo is called *respondentia*. See *MARITIME LAW*.

(B. CE.)

BOTTROP, an industrial town on the northern edge of the Ruhr in the *Land* (state) of North Rhine-Westphalia, Federal Republic of Germany, is 10 km. (6 mi.) W.N.W. of Essen. Pop. (1959 est.) 110,745. Although first mentioned in the middle ages, it remained a small town until the latter part of the 19th century. The Catholic priory church of St. Cyriakus (1861–62) stands in the centre of the old part of the town on the site of the village church and round it the business district has grown up. St. Martin's (1883) is the chief Protestant church. North of the Altmarkt is the Rathaus (1916) built in neoclassic style with an imposing tower. A bell from the old church of St. Cyriakus (cast in 1425) stands in the Rathausplatz. The industrial part of the town is mainly in the south while to the north are the municipal park and Kölnischer Wald. The local coal mines, employing almost one-half of the industrial workers, produce large amounts of coal and coke. Manufactures include chemical by-products of coal, machinery and structural steel for buildings and bridges. Molding sand is mined and exported. In World War II it was captured by U.S. troops on March 30, 1945.

(F. H. M. K.)

BOTULISM, a kind of food poisoning caused by toxins produced by the bacterium *Clostridium botulinum*, growing in improperly canned foods. The mortality rate is high, and treatment is unsatisfactory. See *FOOD POISONING, BACTERIOLOGICAL.*

BOUAKE, the capital of a district of the Republic of Ivory Coast, W. Africa, lies in a plain covered by a wooded savanna and broken by rocky hills. Pop. (1958 est.) 45,000. The town is a centre of the highly developed Baule (*q.v.*) people. It is divided by the Abidjan-Niger railway; to the north are the residential quarters and to the south the administrative and commercial quarters. Bouaké is also an important junction of roads to Abidjan and Boho-Dioulasso (in Upper Volta) and to the neighbouring republics of Ghana and Guinea. It is a market centre for an agricultural region (rice, yams, maize (corn), coffee, cocoa), and has cotton and tobacco factories. Bouaké was formerly a slave market and in 1896 a post was established there for the pacification of the neighbouring peoples, achieved by 1912.

(J. D.)

BOUCHARDON, EDMÉ (1698–1762), French sculptor and early precursor of neoclassicism, was born on May 29, 1698, at Chaumont, Haute-Marne, and died in Paris, on July 27, 1762. He was a pupil of Guillaume Coustou at Paris. The permanent classical bias of his art was settled during his stay in Rome (1723–33) where his copy of the Barberini "Sleeping Faun" created a sensation. In 1739 he was employed to execute the monumental fountain in the rue de Grenelle (completed 1745), a remarkably classical work for its date. These classicizing tendencies recommended him to the comte de Caylus, the propagandist of the reaction against the rococo style, and brought him the royal commission for the statue of "Amour Taillant son Arc dans la Massue d'Hercules" (Cupid Carving out his Bow from the Club of Hercules). This much discussed work, which took ten years to complete, achieved little success when exhibited at Versailles in 1750: His third major commission, that for the equestrian statue of Louis XV in the centre of the Place Louis XV at Paris, occupied the rest of

his life. The statue was destroyed during the Revolution.

See A. Roserot, *Edmé Bouchardon* (1910).

(F. J. B. W.)

BOUCHER, FRANÇOIS (1703–1770), French painter, whose work has been called the most perfect expression of the rococo taste of 18th-century France, was born in Paris on Sept. 29,

COURTESY OF THE METROPOLITAN MUSEUM OF ART, BEQUEST OF WILLIAM K. VANDERBILT, 1920
"THE TOILET OF VENUS" BY FRANÇOIS BOUCHER. 1751. IN THE METROPOLITAN MUSEUM OF ART. NEW YORK CITY

1703. His father was an obscure painter. François was a pupil of François Lemoyne and worked for an engraver. His first important order was for engravings of 125 drawings by Antoine Watteau for M. de Julienne. In 1723 he won the Royal Academy's first prize, but went to Rome on his own. He spent three years there unrecognized. Back in Paris, he became a member of the Academy in 1734 and was elected to its various offices, including that of director in 1765. After doing illustrations for an edition of Molière's works, he worked for the Beauvais factory, drawing tapestry patterns of farmyard scenes and Chinese subjects.

Boucher's fame in Paris started with the reopening of the Salon in 1737. He painted allegories for the queen's chamber at Versailles. Mme. de Pompadour had him paint pictures for Versailles, Marly and Bellevue. He gave her lessons in drawing and engraving. In 1753 he showed "The Sunrise" and "The Sunset," which Mme de Pompadour bought and which are now in the Wallace collection in London. Inspector of the Gobelins after Jean Baptiste Oudry's death, he produced for that factory the designs for the tapestries of the series entitled "Loves of the Gods." Boucher became Louis XV's first painter in 1763. Toward the end of his life, he was rich, but his talent began to fail and criticisms of his paintings and drawings began to be unfavourable (Grimm, Diderot). He died in Paris on May 30, 1770.

The sale of his art objects after his death brought a large sum. The Wallace collection in London and the Louvre contain the largest number of his works. A portrait of Mme de Pompadour is in the National gallery in Edinburgh, Scot.

See P. de Nolhac, *François Boucher premier peintre du Roi* (1925); M. Block, *François Boucher and the Beauvais Tapestries* (1933).

(M. N. B.)

BOUCHER, JONATHAN (1738–1804), English clergyman who won fame as a royalist in America, was born near Wigton, Cumberland, on March 12, 1738. In 1759 he went to Virginia as a private tutor. After a visit to London in 1762 for his ordination, he became rector of Annapolis, and tutored Washington's stepson, thus becoming a family friend. His royalist views cost him his position: by 1775 he was conducting services with pistols on his pulpit cushion, and he was forced to return to England. He nevertheless dedicated to Washington *A View of the Causes and Consequences of the American Revolution* (1797), consisting of 13 of the eloquent sermons he had preached in America urging loyalty to England, and received a friendly acknowledgment.

Having obtained a pension and the living of Epsom, Surrey, Boucher devoted his leisure to writing and to philology. He contributed to W. Hutchinson's *History of the County of Cumberland*, two volumes (1794 *et seq.*) and compiled a "Glossary of Archaic and Provincial Words," intended to supplement Samuel Johnson's *Dictionary*. It was only published in part, but was later used for Noah Webster's *Dictionary*. He died at Epsom on April 27, 1804.

See *Letters of Jonathan Boucher to George Washington*, ed. by W. C. Ford (1899); *Notes and Queries*, 3rd series, vol. ix (1866) and 5th series, vol. ix (1878).

BOUCHER (DE CRÈVECOEUR) DE PERTHES, JACQUES (1788–1868), French antiquarian, who was largely responsible for establishing the existence of prehistoric man, was born on Sept. 10, 1788, at Rethel, Ardennes. By vocation he was a customs official, like his father, and in 1825 became director of the customhouse at Abbeville, near the mouth of the Somme river. There he began devoting his leisure to archaeology. In the course of his explorations in the Somme valley, he discovered hand-worked flints and other stone tools imbedded in ancient gravels laid down in the Pleistocene, or Ice Age, some of them *in situ* with the bones of extinct mammals. While not the earliest to find evidence of a Stone Age culture, Boucher de Perthes was the first to grasp its revolutionary significance, in an age when Archbishop Ussher's date of 4004 B.C. was widely accepted as the time of creation. In 1838 he presented tools in evidence before the scientific society at Abbeville, but met with disbelief; and his monograph *De l'industrie primitive* (1846) was ignored. In 1859—the year of publication of Darwin's *Origin of Species*—his conclusions were at last upheld by a group of eminent British scientists, including the geologists C. Lyell and J. Prestwich, who visited the excavated sites. His other archaeological studies included *De l'homme antédiluvien et ses oeuvres* (1860) and *Antiquités celtiques et antédiluviennes*, 3 vol. (1847–64). A man of broad interests, he also wrote books of fiction and travel, and works on social and economic questions that reflected liberal views far in advance of his time. He died on Aug. 1, 1868, at Abbeville.

See Lady Prestwich, "Recollections of M. Boucher de Perthes," in *Essays Descriptive and Biographical* (1901); and G. E. Daniel, *A Hundred Years of Archaeology* (1950).

BOUCHES-DU-RHÔNE, a *département* of southeastern France, at the mouth of the RhBne, was formed in 1790 from the western part of Provence (*q.v.*); it is bounded to the north beyond the Durance river by Vaucluse, east by Var, west across the RhBne by Gard, and it fronts the Mediterranean sea for about 120 mi. from the western part of the RhBne delta to the rocky coast beyond Marseilles and La Ciotat. Pop. (1954) 1,048,762. Area 2,026 sq. mi. The triangle of the RhBne delta below Arles, in the southwest of the *département*, is the district known as the Camargue (*q.v.*), a low-lying marshy tract, with extensive lagoons in the depressions between the embankments of past and present distributary channels. East of the main channel of the RhBne is the Rat, boulder-strewn tract of the Crau, formed of coarse material spread out by an earlier Durance from the gap of Lamanon between the main tract of limestone hills and the Alpilles, a westward prong that extends toward the RhBne south of the lower Durance valley. The eastern part of the *département* consists of lowland basins of marls and other Tertiary rocks, set amid scarped limestone hills. They include that of the Etang de Berre, largely filled by a shallow sheet of water with a narrow channel connecting

with the sea, the basin of Aix, and that of Marseilles-Aubagne. Cultivated land shows a very patchy distribution, interrupted by extensive areas of almost soilless limestone, carrying scrub and pinewoods, which provide turpentine.

The extension of irrigation (more than one-third of the cultivated land in the *département* is irrigated, mainly with water derived from the Durance river) allowed the reclamation of considerable areas, especially in the Crau and in the plain north of the Alpilles, for the cultivation of vegetables and fodder crops. In these areas, exposed to the blasts of the mistral, the delicate crops are grown on plots between rows of cypress shelter belts. In the Camargue rice cultivation has been developed. Elsewhere the traditional Mediterranean trilogy of wheat, vine and olive tends to be replaced by specialization upon vineyards, cultivated by smallholders organized in co-operative associations. The wine is not generally of high quality, but Cassis and Palette are well known. Among other fruits, the almond is widely grown, and used for confections which are a speciality of Aix-en-Provence and other places.

Although the ore of aluminum, bauxite, takes its name from the village of Les Baux on the southern edge of the Alpilles, where it was first exploited, the main area of production has shifted to the neighbouring *département* of Var. Behind Marseilles, in the basin of Aix, is a small lignite field round Fuveau and Gardanne, which supplies Marseilles with fuel for electricity generation. Brine evaporation is still carried on at places along the coast of the RhBne delta. The great port city of Marseilles dominates the commercial and industrial life of the *département*. Its industries are especially concerned with refining and processing imported products, such as vegetable oil, grain and sugar. From the mountain-framed lowland into which the old and 19th-century ports and the city are crowded, the port and industrial area were extended after World War II by the development of an *annexe* on the Etang de Berre. At its entrance, Lavera was equipped as a modern oil port, whence oil is piped to great refineries on the shores of the Etang at Shell-Berre and La Mède. An associated development of petrochemical industries was initiated. Mineral oil accounted in 1960 for the great bulk of the tonnage handled by the port of Marseilles, one of the great oil ports and refining centres of western Europe. In other parts of the *département* industry is of subsidiary importance, but rice milling at Arles, naval shipbuilding at La Ciotat, the manufacture of ceramics at Aubagne and cement at La Bédoule, and scattered brick and tile works and food industries may be mentioned.

The Etang de Berre is connected with Marseilles by the Rove canal, which tunnels through the Nerthe mountain. The main Paris-Lyons-Marseilles railway also approaches the city from the northwest by a long tunnel. Farther inland the *dkpartement* is traversed by the main road from the RhBne valley to the Riviera and Italy, along the line of the Roman *Via Awelia*. Aix-en-Provence, first Roman base in Provence, and Salon lie along its line. The ancient Roman cities of Aix and Arles, rich in history and architecture, are important tourist centres, and the fortress ruins at Les Baux and the Camargue village of Saintes-Maries-de-la-Mer also are special attractions for tourists. Near Aix-en-Provence, the home of Cézanne, is the Mont Ste. Victoire, featured in many of his landscapes, and the western part of the *dkpartement* round Arles is depicted in many of the works of Van Gogh.

Marseilles is the capital of the *dkpartement*, divided into three *arrondissements* centred upon Marseilles, Aix-en-Provence, and Arles (*qq.v.*). The *arrondissement* of Marseilles forms the ecclesiastical province of Marseilles, the remainder of the *département* that of Aix. Aix also has the court of appeal and the older part of the University of Aix-Marseilles.

BOUCICAULT, DION (DIONYSIUS LARDNER BOURSIQUOT) (1822?–1890), Irish-L.S. playwright and actor, was born in Dublin on Dec. 26, 1822 or 1820. It is commonly assumed that he was the natural son of Dionysius Lardner, a boarder in their house. In 1837 he began acting and in 1840 submitted his first play to Lucia Elizabeth Vestris at Covent Garden; it was rejected. His second play, *London Assurance* (1841), which foreshadowed the modern social drama, was a huge success. Other early plays were *Old Heads and Young Hearts* (1844) and *The Corsican Brothers*

(1852). In 1853 Boucicault and his second wife, Agnes Robertson, arrived in New York city, where his plays and adaptations were long popular. His *The Poor of New York*, based on the panics of 183; and 1857, had a long run at Wallack's theatre in 1857, and *The Octoroon* (1859) caused a sensation with its implied attack on slavery.

Boucicault and his actress-wife joined Laura Keane's theatre in 1860 and began a series of popular Irish plays—*The Colleen Bawn* (1860), *Arrah-na-Pogue* (1864), *The O'Dowd* (1873) and *The Shaughraun* (1874). After returning to London in 1862, he provided Joseph Jefferson with a successful adaptation of *Kip Van Winkle* (1865). In 1872 Boucicault returned to the U.S., where, except for a trip to Australia that resulted in his third marriage, he remained until his death, Sept. 18, 1890. At the time of his death he was a poorly paid teacher of acting in New York.

As both writer and actor, Boucicault raised the stage Irishman from caricature to character. His major contribution to the theatre, however, was his influence on United States drama.

(S. H.)

BOUCICAUT, JEAN LE MEINGRE, MARSHAL (c. 1366–1421), French soldier distinguished in the wars against the Ottoman Turks and as an exponent of the ideals of chivalry, was the son of another Jean le Meingre (d. 1368) also known as Boucicault and likened to a marshal of France. The younger Boucicault had served in several campaigns, notably at Roosebeke (1382), and been made a marshal by Charles VI in 1391 before he joined the expedition to Hungary (1396). Taken prisoner by the Turks at Nicopolis (Nikopol on the Danube), he was ransomed and in 1399 appeared at Constantinople with 1,400 men and a good fleet to aid the Byzantine emperor against the Turks. He defeated a Turkish fleet at Gallipoli and arrived in the Golden Horn in time to prevent the capture of Glzlat. He held the Turks in check for a year and then returned to France to seek volunteers. He did not return to Turkey, however, and was sent instead to strengthen French dominion in Genoa. His administration was successful but involved him in a brief war with Venice. Genoa threw off the French yoke in 1409 while he was away. Taken prisoner at the battle of Agincourt (1415), he died in England. Boucicault, who was very skilful in the tournament, founded the order of the *Dame blanche à l'écu vert*, a society whose object was to defend the wives and daughters of absent knights.

BIBLIOGRAPHY.—*Livre des faits du bon messire Jean le Meingre dit Boucicault*, ed. by J. A. C. Buchon (1886); J. Delaville-Le Roulx, *La France en Orient: expéditions du maréchal Boucicault* (1886); M. Maindron, *Bécits du temps passé* (1899).

BOUDIN, EUGÈNE LOUIS (1824–1898), French painter, who was pre-eminent as a painter of the moods of water, was born at Honfleur, the son of a sea pilot, on July 12, 1824. The father gave up the sea for a small stationer's shop in Le Havre. Troyon and Millet came to the shop and discovered the boy's talent for art, and Courbet and Alphonse Karr found their way there. Boudin went to Paris to study, and, after a short time, returned to his native place. He was a follower of Corot, and in his turn became the master of Monet.

The Ecole St. Siméon, named after the farm which was its headquarters, dates from 1856. In this colony Boudin was a leader. The group included Millet, Courbet, Diaz, Harpignies, Jongkind, Isabey, Monet and others. Boudin presently moved to Trouville and then married and set up house in Le Havre. From 1875 onward he exhibited at the Salon but without attracting much notice until his "Corvette russe" was bought by the state for the Luxembourg gallery in 1888. In 1896 the "Rade de Villefranche" was bought for the same gallery, and Boudin, then over 70, received the Legion of Honour. He died at Deauville on Aug. 8, 1898.

Boudin's best work was in his small canvases. As the painter of tidal rivers he was outstanding, and Corot called him the "master of the sea." A large number of his sketches are at Le Havre.

BOUDINOT, ELIAS (1740–1821), U.S. lawyer and public official, was born in Philadelphia, Pa., on May 2, 1740. He practised law and became a member of the revolutionary party at the

outbreak of the American Revolution, serving first as deputy in the New Jersey provincial assembly, and then as one of New Jersey's representatives in the continental congress. He was president of that body from Nov. 1782 to Oct. 1783. After the establishment of the national government he was for six years (1789–95) a member of the national house of representatives. He became director of the U.S. mint at Philadelphia in 1795, succeeding David Rittenhouse, and served for 10 years. He was the first president of the American Bible society, and in reply to Thomas Paine's *Age of Reason*, published the *Age of Revelation* (1790). He died at Burlington, N.J., on Oct. 24, 1821. (E. E. R.)

BOUÉ, AMI (1794–1881), Austrian geologist who was one of the pioneers in geological research, was born in Hamburg, Ger., on March 16, 1794. He received his early education there and in Geneva and Paris. In Edinburgh he came under the influence of Robert Jameson, whose teachings in geology and mineralogy inspired his future. Boué was thus led to make geological expeditions to various parts of Scotland and the Hebrides and in 1820 he issued his *Essai géologique sur l'Écosse*, in which the volcanic rocks in particular were carefully described. He settled for some years in Paris, being one of the founders of the Société Géologique de France in 1830 and its president in 1835. In 1841 he settled in Vienna and became naturalized as an Austrian. He died there on Nov. 21, 1881.

Boué published important papers on the geology of the Balkan states (1859–70), *Mémoires géologiques et paléontologiques* (1832) and *La Turquie d'Europe*, four volumes (1840).

BOUFFLERS, LOUIS FRANÇOIS, DUC DE (1644–1711), marshal of France, distinguished in the last of the Dutch Wars, in the War of the Grand Alliance and in the War of the Spanish Succession, was born Jan. 10, 1644, of an old Picard family that held the marquisate of Boufflers in Ponthieu. As a guards officer he was at the first French landing in Algeria, at Djidjelli (1664). In 1669 he bought the colonelcy of the royal dragoons, a new arm much favoured by the king, Louis XIV, who noted the young colonel's exploits. After good service under Turenne and under François de Créquy on the German frontier, Boufflers was made colonel-general of dragoons (1679–92) and promoted lieutenant-general (1681). Wounded in the trenches at Mons in 1691, he was made colonel of the French Guards (1692–1704). With that high honour he was made marshal of France in 1693 and created duc de Boufflers in 1694.

In 1695, when he shared the army command in Flanders with the marshal duc de Villeroi, Boufflers was the soul of the defense of Namur, where 8,000 of his garrison perished before he surrendered. In 1702, in command of the main French army, he began with a sharp blow at the Dutch before Nijmegen but was then maneuvered out of the Rhine-Meuse area by Marlborough. In 1703 his cavalry raid on the Dutch near Antwerp checked their plan. He was appointed to command the royal bodyguard in 1704.

Boufflers had been governor of Lille since 1694, and in 1708, when Marlborough and Prince Eugène of Savoy were threatening it, he asked for leave to take up his post there. He did so just before the siege began (Aug. 1), and with 14,000 men he made another memorable defense. On Dec. 9 he marched out from the citadel with the full honours of war. The next year he volunteered to help the marshal duc de Villars, his junior, and in the battle of Malplaquet (q.v.) found himself in command when Villars was wounded; he led the household cavalry with great spirit, took the decision to retreat and kept the army in such control that he reported defiantly that they were ready to fight again. He died at Fontainebleau on Aug. 22, 1711. (I. D. E.)

BOUFFLERS, STANISLAS JEAN, CHEVALIER DE (1738–1815), French man of letters, described as "the Voiture of his age," was born in Lorraine on May 31, 1738. His mother, Marie Catherine de Beauvau-Craon, marquise de Boufflers, was the mistress of the duke of Lorraine, Stanislaw Leszczyński (the dispossessed king of Poland), at whose court in Lunéville the boy was brought up. While studying theology at Saint-Sulpice in Paris, he wrote *Aline, reine de Golconde* (1761), the charming tale of a milkmaid, Aline, who after a series of improper adventures becomes queen of Golconda. This tale won immediate

success in fashionable circles but led to his expulsion from Saint-Sulpice, whereupon he joined the Knights of Malta so as to combine qualification for ecclesiastical benefices in Lorraine with the freedom of a military career. For the next 24 years he was either campaigning in Europe (often with the Austrian armies) or establishing his reputation for wit in the Parisian salons! where in 1777 he fell in love with Éléonore de Jean de Manville, comtesse de Sabran. To restore his finances he served two terms (1786 and 1787) as governor of Senegal, where he showed interest in developing the country's resources but was reluctant to exploit the slave trade. Elected to the Académie Française in 1788, he was deputy for the nobility of Nancy in the states-general of 1789, but emigrated to Prussia in 1791. With the loss of his benefices his celibacy became pointless, and he married Mme de Sabran at Breslau in 1797. Returning to France in 1800, he supervised an edition of his complete works (1803). He died in Paris on Jan. 18, 1815.

There are editions of Bouffler's *Contes* and of his *Poésies diverses* by Octave Uzanne (1878 and 1886) and of his letters to Mme de Sabran by Paul Prat (1891).

See N. H. Webster, *The Chevalier de Boufflers* (1916).

BOUGAINVILLE, LOUIS ANTOINE DE (1729-1811), French navigator, commander on land and at sea, colonial organizer and explorer who, in his voyage of circumnavigation (1766-69), made important discoveries in the Pacific ocean, was born in Paris on Nov. 11, 1729. He showed an early aptitude for mathematics and published a treatise on integral calculus (1754-56). Having entered the army at the age of 24, he went to Canada in 1756 as aide-de-camp to the marquis de Montcalm and distinguished himself in the war against England. Bougainville then undertook to colonize the Falkland Islands for France at his own expense. He established his colony in Jan. 1764, but in Jan. 1765 Commodore John Byron planted an English colony in another part of the islands, and the French government agreed to cede the group to Spain in April 1767. Bougainville, commissioned by his government to make a voyage of discovery round the world, sailed in Dec. 1766 in the frigate "La Boudeuse" accompanied by a store-ship. He traversed the Straits of Magellan and sailed northwest to the Tuamotus. He visited Tahiti, discovered in June 1767 by Capt. Samuel Wallis, and named it *La Nouvelle Cythère*. Sailing west he touched at Samoa (*Archipel des Navigateurs*) and the New Hebrides (*Les Grandes Cyclades*). He then took a westerly course toward New Holland, in waters not previously navigated by any European ship. On the fringes of the Great Barrier Reef he turned north without sighting Australia and passed through the Louisiade archipelago and the edge of the Solomon Islands to New Britain. Since his men were now suffering from scurvy and his ships needed a refit, he repaired to Buru in the Moluccas (Sept. 1768), and thence to Batavia. In March 1769 he arrived at St. Malo, having lost only seven men since leaving France.

On his return Bougainville was promoted *chef de vaisseau* (1770) and appointed secretary to the king (1772). In 1779-82, as *chef d'escadre*, he served in North America; and after the French defeat at the battle of the Saints, off Martinique (April 12, 1782), he was court-martialed and banished from court. He returned to the army, and after the peace he settled in Paris. He obtained the rank of vice-admiral in 1791; and in 1792, having escaped from the massacres of Paris, he retired to his estate in Normandy. He was chosen a member of the Institute at its formation, and became a member of the board of longitude. Napoleon I made him a senator, count of the empire and member of the Legion of Honour. He died in Paris on Aug. 31, 1811.

Bougainville was characterized by courage and resource in action, by urbanity in personal relationships and by a scientific cast of intelligence. His name was given to the largest of the Solomon Islands and to the strait between Malekula and Espiritu Santo islands of the New Hebrides group. The South American climbing plant *Bougainvillea*, often cultivated in greenhouses, is also named after him.

Bougainville's *Voyage autour du monde* (1771) was translated into English by J. R. Forster (1772). His personal papers were dispersed by sale in London in 1957. (R. A. SN.)

BOUGAINVILLE, the largest of the Solomon Islands (*q.v.*), is situated near the northern end of the chain and, together with Buka, forms part of the Australian trust territory of New Guinea (*q.v.*). Measuring 127 mi. by 49 mi., Bougainville has a rugged and heavily forested mountainous core containing two active volcanoes. Mt. Balbi (8,502 ft.) and Mt. Bagana (5,730 ft.). On the east coast there is a narrow plain in the vicinity of Kieta, the chief settlement, and there are situated most of the coconut plantations that constitute the island's principal economic activity. The native population numbers about 40,000. The island was named for the French explorer, Louis Antoine de Bougainville (*q.v.*).

(D. W. F.)

BOUGAINVILLEA, a genus containing a dozen or more South American shrubs, often woody climbers, belonging to the four-o'clock family (Nyctaginaceae). The leaves are simple, petioled, alternate, ovate to elliptic-lanceolate and commonly entire. The small and inconspicuous flowers are enclosed by showy mauve, magenta, purple or red corollalike bracts that constitute the decorative value of the plants. Formerly *Bougainvillea glabra* and *B. spectabilis*, with their varieties, constituted the forms chiefly known in cultivation in the United States, but *B. trolli*, with its several varieties, is now also widely grown. All the species are highly sensitive to frost and thus can be grown successfully outdoors only in regions that are essentially frost free. They may be grown in greenhouses, however, where the climate does not permit year-round outdoor culture.

The young stock, obtained from half-ripened or old wood, can be started in pots and grown in the field during summer. During early autumn the potted plants must be lifted and brought into the greenhouse. Under proper care these plants should bloom the following spring. In most of Florida, along the coast of the Gulf of Mexico and in southern California, bougainvillea is used extensively as a porch cover, on pergolas! arches and as hedge or fence plants.

They may also be planted at the base of trees, up which they climb to make beautiful displays of colour. All species and varieties withstand drought extremely well and may be pruned heavily without risk of injury. (J. RI. BL.)

BOUGHTON, GEORGE HENRY (1833-1905), Anglo-U.S. painter, born on Dec. 4, 1833, near Norwich, Eng., was brought up in Albany, N.Y. After studying art in Paris during 1861-62, he settled in London and was much influenced by Frederick Walker. His pictures of early American colonial life and scenery were especially characteristic, and subject pictures such as "Weeding the Pavement" (Tate gallery, London) had a great success. Boughton executed many fine book illustrations, notably those for *Rip Van Winkle* (1893) and *Knickerbocker History* (1886). He became a royal academician in 1896, and died in London on Jan. 19, 1905.

(D. L. FR.)

BOUGHTON, RUTLAND (1878-1960), English composer of opera, whose work was influenced by the Wagnerian concept of the music drama, was born at Aylesbury, Buckinghamshire, Jan. 23, 1878. He studied at the Royal College of Music in 1900 but was otherwise self-taught. He had the idea of writing a series of works based on Arthurian legends, and of creating a festival theatre for their performance at Glastonbury. After a long struggle (1914-24) with inadequate resources he abandoned the attempt to establish the theatre, but had some success in London and elsewhere. His most popular work was the tuneful romantic opera, *The Immortal Hour* (1913), which had a run of 216 performances in Lon-

BOUGIE—BOUILLON

don in 1922. Among his other successes were *Bethlehem* (1915), *Alkestis* (1922), *The Queen of Cornwall* (1924) and *The Lily Maid* (1934). After 1939 little was heard of his music, but this did not discourage him from composing, and between 1943 and 1946 he wrote two more Arthurian music dramas, *Galahad* and *Avalon*. Besides operas, he wrote choral works, symphonies, concertos and chamber music. He published a book on Bach (1907) and, with Reginald Buckley, his partner in the Glastonbury scheme, *The Music Drama of the Future* (1908). He died in London. Jan. 25, 1960. (Co. MA.)

BOUGIE, a seaport in the Sétif *département* of Algeria, with the finest position on the Algerian coast: lies at the mouth of the Wadi (river) Sahel-Soummam, sheltered from the winds of the west and north by the peninsula of the Jabal Guraya and Cape Carbon. Its deep and majestic gulf is dominated by the well-watered mountains of the east of the Djurdjura Kabylia and of the Babor Kabylia. Formerly centre of a subprefecture, it became chief town of a prefecture; it is, however, a secondary port. Pop. (1954) 29,750 of whom 6,340 were Europeans; 42,830 including the rural Kabyle suburbs. The upper town, much altered by the French, is built on the slope of the Guraya; the lower and more modern town containing the business and industrial quarter lies east of the railway station and of an old Spanish fort, and along the road to Algiers. Bougie is linked by rail and road with Algiers, Constantine and Bône and by coastal road with Philippeville. It is an important market town for the Kabyles (*q.v.*). The port exports the iron ore from the mines of the Guergour and the Babor, the phosphates of the Jebel Mzaita (south of Sétif), the wine of the Soummam valley, the olive oil and cork of the Kabyle areas, and the grain of Sétif. Its imports were confined mainly to building materials and fuels but the arrival of the Sahara oil pipeline from Hassi Messaoud in 1959, changed the trend of its commerce.

The Roman *Saldæ*, probably on this site, and the Arab town which succeeded it were small, but the town gained importance after 1067 when the Hammadite sultan En-Nasir chose it as his capital, and merchants and corsairs enlivened the port, then closed by the "Saracen gate," which still exists. It declined after conquest by the Almohads in 1152, but revived under the Hafsiids of Tunis from the 13th to the 15th centuries, when it had naval shipyards, privateering and trade with Europe. Spanish occupation (1510–55) achieved its ruin. Algiers, chosen as capital by the Turks, hindered Bougie's revival, and in 1833 when occupied by the French there were only about 2,000 inhabitants and a few fortifications and ruins. (J.-J. Ds.)

BOUGUER, PIERRE (1698–1758), French scientist, took part with C. M. de la Condamine in an expedition to measure an arc of the meridian near the equator in Peru (1735–43) and used the results in a new determination of the figure of the earth (*see* GRAVITATION), a full account of this operation being given in 1749 in *La Figure de la terre*. Born at Croisic in lower Brittany on Feb. 16, 1698, he succeeded his father, Jean Bouguer, as regius professor of hydrography at Croisic and in 1730 became professor at Le Havre. As a hydrographer he wrote on ships, maneuvering and navigation. He might also be called a geodesist and a physicist. As a physicist he worked on problems connected with the passage of light through the atmosphere and on photometry. He constructed tables of atmospheric refraction based on his own theory and the adopted refraction on the horizon, and at 26° altitude. He made some of the earliest measurements in astronomical photometry and investigated the absorption of light in the atmosphere, the results of which inquiry he published in his *Essai d'optique sur la gradation de la lumière* (1729). In optics he constructed an early form of the instrument later called the heliometer. Bouguer died at Paris on Aug. 15, 1758. (J. JN.)

BOUGUÉREAU, ADOLPHE WILLIAM (1825–1905), French painter, whose academic renderings of allegorical religious and genre themes were highly considered by his contemporaries, was born at La Kochelle on Nov. 30, 1825, and died there on Aug. 18, 1905. From 1843 to 1850 he studied at the *École des Beaux-Arts*. and in 1850 divided the Grand Prix de Rome scholarship with P. J. A. Baudry.

On his return from Rome in 1855 he was employed in decorating

several great houses, deriving inspiration from the frescoes at Pompeii and Herculaneum. Bouguereau took a medal of honour at the Paris exhibition of 1878 and in the Salon of 1885. Most of his works, especially "The Triumph of Venus" (1856) and "Charity," were popularly known through engravings. His subjects and formulas received severe criticism after the general acceptance of impressionist trends.

BOUHOURS, DOMINIQUE (1628–1702), French grammarian and literary critic, notable as an extreme purist, was born in Paris on May 15, 1628. Having taken vows as a Jesuit in 1662, he was entrusted with the education of the sons of the duc de Longueville and subsequently with that of the marquis de Seignelay, Colbert's son. His first book (1665) was an attack on the Jansenists of Port-Royal. He began to advance his ideas on the French language in *Les Entretiens d'Ariste et d'Eugène* (1671), but this book, which also included another attack on Port-Royal, was banned by the government. Thereafter he developed his linguistic and literary doctrine in a series of works. In the name of purity of language he required such caution and circumspection in the choice of words and in sentence-building as would in practice make great writing no longer possible. This was made clear enough in the *Lettres . . . sur le sujet de la Princesse de Clèves* (1678; on Mme de La Fayette's masterpiece), which were written by J. B. du Trousset de Valincour but inspired by Bouhours. Bouhours had great influence in his time and was the teacher of the Jesuits who were later to edit the *Journal de Trévoux*. He died in Paris on May 27, 1702.

See A. Adam, *Histoire de la littérature française au XVIIe siècle*, vol. v (1956); also G. Doncieux, *Un Jésuite homme de lettres au XVIIe siècle* (1886). (A. E. A.)

BOUILLON, a town in Belgium, province of Luxembourg, known for the ducal title connected with it. Bouillon in the 11th century was held by the counts of Ardennes, five of whom, between 1012 and 1069, were invested with the dukedom of Lower Lorraine by the German kings. As Bouillon was their principal stronghold, it became usual to designate these dukes, loosely, as dukes of Bouillon, though Bouillon itself was not a duchy. Godfrey the Hunchback (d. 1076) left Bouillon to his nephew Godfrey, who pledged it in 1096 to the bishop of Liège to raise funds for his crusade. Thereafter the bishops of Liège occasionally styled themselves dukes of Bouillon. In 1482, however, Guillaume de La Marck got Bouillon in pledge from Liège and installed his brother, Robert I (d. 1487), lord of Sedan, as chatelain. Robert II (d. 1536) had to restore Bouillon to Liège in 1521, but Robert IV (d. 1556), with French support, began to style himself duc de Bouillon in 1548 and actually got possession of the place in 1552. His son, Henri Robert de La Marck (d. 1574), had to restore Bouillon to Liège again in 1559, but he and his son Guillaume Robert (d. 1588), continued to style themselves dukes of Bouillon. Their heiress, Charlotte, brought the title to her husband, Henri de La Tour d'Auvergne (1555–1623), in 1591.

As sovereigns of Sedan, Henri and his successor, Frédéric Maurice (1605–52), were particularly formidable to the French government whenever they chose to conspire against it. Frédéric Maurice lost Sedan in 1642 when his role in the conspiracy of Cinq-Mars came to light, but during the Fronde the French government, in order to conciliate him, undertook to promote his claim to Bouillon as soon as practicable. Accordingly, French troops having taken the place (1676), his son Godefroy Maurice (1641–1721) was set up by Louis XIV as independent sovereign there (1678). The next dukes of Bouillon, in direct succession, were Emmanuel Théodose (1668–1730), Charles Godefroy (1706–71), Godefroy Charles Henri (1728–92) and Jacques Léopold (1746–1802). The last named—who was to lose Bouillon in 1794 when it declared itself a republic (it was annexed to France next year)—had always been sickly, so that his father had in 1786 recognized as eventual heir an English naval lieutenant: Philip D'Auvergne, a descendant of the medieval counts of Auvergne. On the defeat of Napoleonic France, D'Auvergne in Aug. 1814 set himself up as sovereign in Bouillon, but the congress of Vienna in Nov. 1815 gave the place, with Luxembourg, to the Netherlands. D'Auvergne killed himself in 1816, and the ducal title was adjudged in 1818 to Charles de

Rohan, duc de Montbazou (a great-grandson of Charles Godefroy), in whose family it remains. On the partition of Luxembourg in 1831. the town of Bouillon passed to Belgium. Pop. (1955 est.) 3,063. (J. G. R.-S.)

BOULAINVILLIERS, HENRI, COMTE DE SAINT-SAIRE (1658-1722), French political writer, who deplored equally the rise of the absolute monarchy and the idea of government by the people. He was born on Oct. 21, 1658, at St.-Saire, Normandy, where he spent most of his life, devoting his time to historical research and becoming acquainted with the duc de Saint-Simon. His systematic though paradoxical mind was admired by Voltaire. Though the manuscripts of his works were known to his contemporaries none of them was published during his lifetime. He wrote several works on the history of the French nobility, extolling the excellence of the feudal system. His writings on economic affairs were practical and instructive. His books were quoted both by those who defended the principle of authority, and later, with more effect, by the revolutionaries. He was also interested in occult sciences: prophesied the date of death of Louis XIV and wrote a life of Mohammed. He died in Paris on Jan. 23, 1722.

See R. Simon, *Un révolté du grand siècle* (1948).

BOULANGER, the name of several French artists: JEAN (1606-1660), a pupil of Guido Reni at Bologna, who had an academy at Modena; his cousin JEAN (1607-1680), a celebrated line engraver; the latter's son MATTHIEU, another engraver; LOUIS (1807-1867), a subject painter, friend of Victor Hugo and director of the imperial school of art at Dijon; the best known, GUSTAVE RODOLPHE CLARENCE (1824-1888), a pupil of Paul Delaroche, a notable painter of oriental and Greek and Roman subjects and a member of the Institut de France (1882), who decorated the Foyer de la Danse of the Paris Opéra with terpsichorean subjects; and CLEMENT (1805-1842), a pupil of J. A. D. Ingres.

BOULANGER, GEORGES ERNEST JEAN MARIE (1837-1891), French general and minister whose political activities constituted a grave danger to the republican regime in the 1880s, was born at Rennes on April 29, 1837. He entered the army in 1856, served in Algeria, Italy and Cochin China (Indochina) and in the Franco-German War. He was made a brigadier general in 1880 on the recommendation of the duc d'Aumale (Henri d'Orléans), and his expressions of gratitude on this occasion were remembered against him in 1886, when, as minister for war, he erased the duke's name from the army list as part of the campaign against the princes of formerly sovereign dynasties residing in France.

Boulanger became director of infantry in 1882 and two years later was appointed to command the army in Tunisia, but was recalled because of differences of opinion with Pierre Paul Cambon, the political resident. Returning to Paris, he began to take part in politics under the aegis of Clemenceau and of the Radical party. In Jan. 1886 he entered Charles de Freycinet's government as minister for war.

By introducing reforms for the benefit of all ranks and by courting popularity openly, Boulanger came to be accepted by the people as the man destined to avenge France's defeat in the Franco-German War. He thus became a tool in the hands of the groups hostile to the existing republican dispensation. On Freycinet's defeat in Dec. 1886, Boulanger was retained at the ministry of war by the new prime minister, René Goblet, though Clemenceau by this time had withdrawn his patronage from the obviously too compromising general. On Goblet's retirement from office in May 1887, the Paris populace clamoured for their "brav' général," but Maurice Rouvier, who had long been hostile to Boulanger, refused to include him in his government, and the general was sent to Clermont-Ferrand to command the XIII corps. A Boulangist "movement," however, was now in full swing. The Bonapartists (except the empress Eugénie) had attached themselves to the general, and the royalists were led to support him by the duchesse d'Uzès (Marie Anne Clémentine de Rochechouart-Mortemart), who contributed large sums to the general's political fund.

Boulanger was deprived of his command in 1888 for coming three times to Paris without leave and in disguise, and for visiting

Prince Napoleon at Prangins in Switzerland. His name was removed from the army list, but almost immediately he was elected deputy for the Nord. In June 1888 his proposals for revising the constitution were rejected by the chamber, whereupon he resigned. An altercation with Charles Floquet led to a duel (July 13) in which the elderly prime minister inflicted a severe wound on the general. Neither this humiliation nor Boulanger's failure as an orator checked his followers' enthusiasm, and throughout 1888 his personality dominated French politics.

In Jan. 1889 Boulanger was returned for Paris by an overwhelming majority, and he became an open menace to the parliamentary constitution, which he sought to modify to suit his ambitions. But a new government under Pierre Tirard, with Ernest Constans as minister of the interior, decided to prosecute Boulanger, and within two months the chamber was requested to waive the general's parliamentary immunity. To his friends' astonishment, Boulanger fled from Paris on April 1, going first to Brussels and then to London. He was tried in *absentia* for treason by the senate as high court and condemned on Aug. 14, 1889, to deportation. In the elections of 1889 and 1890 his supporters received a setback, and public enthusiasm for his cause dwindled away. On Sept. 30, 1891, Boulanger committed suicide in Brussels at the cemetery of Ixelles, over the grave of his mistress, the vicomtesse de Bonnemain.

BOULDER, a city of Colorado, U.S., on Boulder creek, just east of the continental divide, 30 mi. N.W. of Denver, at an elevation of 5,354 ft.; the seat of Boulder county. (For comparative population figures see table in COLORADO: Population.) Protected by mountains from the winter winds, and cooled in summer by breezes from glaciers to the west, the average monthly mean temperature ranges from 32.5° F. (Jan.) to 73.6° F. (July); the sun shines almost every day.

The water supply comes from the Arapahoe glacier, which is owned by the city, thus making Boulder perhaps the only city in the nation with such a water supply. The Rocky Mountain National park of 378 sq. mi. is 40 mi. to the northwest and the Roosevelt National forest lies a few miles west. Boulder canyon and others in the vicinity have great scenic beauty, and the city owns 6,000 ac. of mountain park lands.

The first settlement there was made late in 1858, and placer gold was discovered nearby in 1859. The town was laid out in 1859; the first city charter was secured in 1871; and a city-manager form of government was adopted in 1917.

The city adjoins a rich agricultural area. Once supported by mines of coal, precious and rare metals, the city later attracted important industrial and research organizations. For several years after 1900 most of the tungsten mined in the United States came from the Nederland region, 18 mi. W. of Boulder.

The Colorado chautauqua, one of the oldest and largest independent chautauquas in the country, has its permanent grounds on a site 400 ft. above the city.

The University of Colorado, incorporated in 1861 and opened in 1877, is in Boulder, except for its medical school which is in Denver. The university buildings are constructed of native sandstone. The university has an annual enrollment of more than 10,000 students. (L. R. HA.)

BOULDER CLAY (TILL): see GLACIER.

BOULE, (PIERRE) MARCELLIN (1861-1942), French geologist, paleontologist and physical anthropologist, a specialist on fossil man, was born Jan. 1, 1861, at Montsalvy. Educated at Tououse and Paris as a geologist, his interests broadened to include paleontology and eventually human paleontology. He became lecturer on geology at Paris and then assistant professor at Clermont-Ferrand. In 1892 he was appointed laboratory assistant at the French National Museum of Natural History, where he served as professor from 1902 to 1936. In that capacity he made extensive studies on human fossils from Europe, north Africa and Palestine, and he reconstructed the first complete Neanderthal skeleton (1908), from Chapelle-aux-Saints. His broad background

enabled him to correlate geological and archaeological evidence in establishing a chronological sequence for remote eras.

He was president of the French Geological society; founder of the Institute of Human Paleontology and of the *Annales de Paléontologie*; and editor of *L'Anthropologie*. He received the Legion of Honour (commander) and many academic honours. He died July 4, 1942, at Montsalvy.

Boule's best-known work was *Les Hommes fossiles* (1921; 1952); his monograph, "L'Homme fossile de la Chapelle-aux-Saints," in *Annales de Paléontologie* (1911-13), remains a model of its kind. Among his many other works were *La plateau de Lanomezan* (1895); *Les volcans de la France centrale* (1900); and *Les Grottes de Grimaldi* (1906-19). (L. C. B.)

BOULE, in ancient Greece the council of a city or other body politic (as distinct from the general assembly, or ecclesia). Each Greek league or confederacy also had a council, sometimes called boule but more often called *synhedrion* (see ACHAEAN LEAGUE; BOEOTIA; GREECE: *History*). The name boule was more often used for the council of a democratic state, whereas gerousia was normally reserved to an aristocratic council, but there is no sharp distinction between the two terms. The councilors were respectively called *bouleutai* and gerontes, but other names were also used (*timouchoi* at Massalia, *probouloi* at Delphi, etc.). This article gives a general survey of the development of the institution of the boule; for further details on aristocratic councils see GEROUSIA.

Kings in archaic Greece, as elsewhere, were surrounded by a council of elders. A gerousia (according to one interpretation) is alluded to in Mycenaean documents. In Homer the elders, who ate on formal occasions with the king, also had judicial functions. It is not known how the kings chose their councilors. In Sparta, under the dual kingship, the 28 gerontes were elected by the people from among those over 60 years old; the Spartan gerontes led and controlled the deliberations of the assembly and had wide judicial powers, but the assembly was summoned by the kings or, later, by the ephors. In purely aristocratic states the council was supreme. At least in some cases it perpetuated itself by electing the magistrates of the city and co-opting former magistrates. According to one theory, the Areopagus (*q.v.*) in Athens before Solon (*q.v.*) worked on these principles. The individual councilors were appointed for life and were not accountable to the general assembly for their actions.

Transition to democracy was effected either by modifying the old councils or by replacing them with new ones or by opposing a new council to the old one. In Corinth (*q.v.*) after the fall of the tyrants at the end of the 6th century B.C. there seems to have been a council (perhaps yearly) of 80, of whom 8 functioned in turn as chairmen. In the 5th century Argos had an aristocratic council of 80 together with a more democratic council. In Athens in 594 B.C. Solon did not abolish the Areopagus, but (according to one view) transferred the elections to the assembly and created a new boule of 400 to guide the work of the assembly. The new boule was later (508 B.C.) connected by Cleisthenes (*q.v.*) with his new ten tribes and increased to 500 members. Coexistence of two councils was probably also to be found in Chios, at least from about 550 B.C., and Solon may have based his reform on Ionian models. A gerousia and a boule are found together in Hellenistic Cyrene and elsewhere.

The individual cities of the Boeotian league *c.* 395 B.C. had four councils; each of them took its turn in preparing the business to be put before the other three. One-fourth of the councilors acted as the real boule; the others had the function of a primary assembly. This type of organization must have inspired the Athenian project for the so-called "constitution of five thousand" in 411 (see THERAMENES). At Delphi, in the 4th century B.C., 30 yearly councilors were divided into two groups, each in charge for six months of the general conduct of affairs; another group of councilors (under the name of *prytaneis*) was in charge of finances throughout the year. There were also two secretaries, making a total of 40 members; councilors could be re-elected.

The Athenian boule, after the reforms of Cleisthenes, was elected by lot every year, except during the brief periods of oligarchic reaction in 411 and 404 B.C. Each tribe provided 50 coun-

cilors who were at least 30 years old; a certain number of councilors was allotted to each deme of the tribe in rough proportion to its size. The functions of the council were defined (and perhaps limited) by the oath for the members introduced in 501 B.C. A man chosen by lot was not obliged to serve. Since poorer citizens might be unwilling to serve, this explains why, especially in the 4th century B.C., men of property prevailed in the council, though property qualifications did not operate before 322 B.C. The councilors were paid (in the 4th century, 5 obols). They met (normally in the special building, *bouleuterion*) every day of the year except on feast or unpropitious days. The councilors belonging to each tribe functioned in turn as a general purposes committee for a tenth of the year; they summoned the others and prepared the agenda for the council. They were called *prytaneis* and were presided over by an epistates. One-third of the *prytaneis* sat in permanence in a building of their own, the *tholos*. The epistates would change every day, keep the seal of the state and the key to the treasury for the day; he was what might be called the one-day president of the Athenian republic. In the 5th century the epistates also presided over the assembly; in the 4th century the presidency of the assembly was left to a man chosen by lot from the councilors who were not *prytaneis*.

The most important task of the Athenian boule was to draft the deliberations for discussion and approval in the assembly. The draft (not necessarily a recommendation) was called *probouleuma*. The assembly could not discuss a topic unless the boule had passed a formal resolution. But any Athenian in the assembly could amend the *probouleuma* and make new proposals; he could also privately ask the boule to put an item on the agenda. There were moreover constitutional rules for the inclusion of certain routine items of business in the agenda for certain meetings of the ecclesia. The *probouleuma* regulated, but did not impede, the private initiative of any Athenian. The council was assisted by one and later by more than one secretary, provided by lot in turn from each tribe; after about 360 the secretary was no longer a member of the council. The boule could fine up to 500 drachmas or initiate a trial in the judicial courts. It controlled the farming of public revenues and it dealt with debtors to the state; it controlled the maintenance of the fleet and of the cavalry; judged the fitness of the magistrates-elect; it received foreign ambassadors and advised the strategoi in military matters. It could be given special powers by the assembly in an emergency. The boule, even after Ephialtes (*q.v.*), never totally replaced the Areopagus in political importance. The Areopagus recovered influence in Hellenistic and even more in Roman times when the Areopagus and the boule shared the government of the city, the boule being the minor partner. In the Hellenistic age property qualifications were intermittently required for the councilors, and their number was increased to 600 in 307 B.C., to 650 in 229, and again returned to 600 from 200 B.C. until the age of Hadrian, when the number of 500 was restored; later still the number went up to 750. The Athenian boule is still mentioned in sources of the 4th century AD.

The Athenian system largely influenced the organization of the councils of other cities in the Hellenistic period but other types survived or were newly introduced. In Argos and Rhodes the council remained in office only six months and in Cyrene the members seem to have sat for two years, and the council to have been renewed by halves every year. Under the Roman emperors annual election gradually became purely formal and eventually disappeared. By the end of the 3rd century A.D. the councils were everywhere permanent bodies. Hereditary membership gradually replaced the recruitment of councilors by lot or election or selection by magistrates. The councils of the east became increasingly similar to the *curiae* of the western part of the empire (see CURIA).

(A. D. Mo.),

BOULLE (BOULE; incorrectly БУЛ), **ANDRÉ CHARLES** (1642–1732), French cabinetmaker, who gave his name to a fashion of inlaying, bouille or buhlwork, was born in Paris on Nov. 11, 1642. The son of Jean Boule, a member of a family of cabinetmakers, he became very famous and was indeed the second cabinetmaker—the first was Jean Macé—who acquired individual renown. At the age of 30 he had already been granted one of those lodgings in the Louvre set apart for the most talented artists employed by the crown. Boule was given the deceased Jean Macé's own lodging by Louis XIV. In the patent conferring this privilege he is described also as "chaser, gilder and maker of marquetry."

As a young man Boule had studied drawing, painting and sculpture. Some of his drawings, influenced by Charles Le Brun and Jean Bérain, are preserved in the Louvre and the Musée des Arts Décoratifs in Paris. A collection of fine works of art was lost when his workshops caught fire in 1720.

Boule was employed for several years at Versailles, where he produced what was regarded as his most remarkable work: the flooring in "wood mosaic," the paneling and the marquetry in the private study (no longer existing) of the Grand Dauphin. Boule received numerous commissions from the French royal family, princes, noblemen and financiers in France and from foreign courts throughout Europe. He died in Paris on Feb. 29, 1732.

Though the type of marquetry named after him is derived from Renaissance models, Boule elaborated it with a skill never surpassed. His furniture, sumptuous and full of colour, often has an architectural quality. Some examples have inlays of brass on tortoise shell or tortoise shell on brass; others have inlays of natural woods portraying landscapes with figures, flower pieces or arabesques. Splendid bronzes sometimes added the crowning touch to his work. There are four magnificent wardrobes in this style in the Louvre; and the Wallace collection, London, contains exceptionally fine examples of his manner.

Boule's style was continued successfully in France during the 18th century and also under Napoleon III. Such was its popularity that any piece with some copper inlay on a black or red ground came to be described as "buhl."

See H. Havard, *Les Boule* (1893); François de Salverte, *Les Ébénistes du XVIII^e siècle* (1953).

(S. Gr.)

BOULLONGNE (BOULOGNE), the name of a family of French painters. **LOUIS** (1609–1674), who was one of the original members of the Academy of Painting and Sculpture (1648), became celebrated under Louis XIV. His traditions were continued by his children: **GENEVIÈVE** (1645–1708), who married the sculptor Jacques Clérion; **MADELEINE** (1646–1710), whose work survives in the "Trophées d'armes" at Versailles; **BON** (1649–1717), a successful teacher and decorative artist; and **LOUIS DE** the younger (1654–1733), who copied Raphael's cartoons for the Gobelins tapestry, and besides taking a high place as a painter was also a designer of medals.

BOULOGNE, JEAN DE: see VALENTIN, LE.

BOULOGNE (BOULOGNE-SUR-MER), in the *département* of Pas-de-Calais in northern France is on the English channel at the mouth of the Liane, 125 km. (78 mi.) N.N.W. of Amiens by road and 45 km. (28 mi.) S.E. of Folkestone by sea. Pop. (1954) 43,936. Boulogne stands upon hills skirting the east bank of the Liane, with the industrial quarter, Capécure, on the west bank. Haute Ville, the older part of the town, on the top of a hill, is a comparatively small oblong surrounded by 13th-century ramparts with boulevards outside. There are the law courts, chateau, and *hôtel de ville* (18th century) and a bell tower (13th and 17th centuries). At some distance to the northwest is the church of Notre-Dame (1827–66), a well-known place of pilgrimage, on an old site. The modern town—the much larger Basse Ville—stretches from the foot of the hill to the harbour. The public buildings include a museum of antiquities with a fine collection of Greek vases and Alaskan masks; galleries of painting and drawings; china and ceramics and natural history. The public library contains more than 120,000 volumes as well as valuable manuscripts, many richly illustrated. The Colonne de la Grande-Armée,

begun in 1804 and completed under Louis-Philippe, commemorates Napoleon's projected invasion of England. The harbour is at the mouth of the Liane and is divided into two main parts, an outer, deep-water harbour and an inner port with docks for fishing: passenger and cargo boats, and wet and dry docks. Boulogne is the third French port for passenger traffic and the first for car ferry traffic to Folkestone and Dover. It is the chief fishing port of France, herring and mackerel being the most important catches. There are foundries! cement factories: ceramic works, fish curing and canning factories, shipbuilding and the manufacture of pens, pencils, ropes, fishing nets, canvas and shoes. Jute, manganese ore, coal, wine, fuels, timber, machinery, woven goods of silk and wool are imported, while ferromanganese, wines, brandy, woven goods, stone and cement are exported.

Boulogne is on the site of the Roman harbour of Gesoriacum, later called Bononia. It was destroyed by the Normans in 882, but rebuilt about 912. In the days of the Carolingian kings it was head of a countship, long in dispute between Flanders and Ponthieu. It belonged to the house of Ponthieu from 965 to 1234, and then to Brabant and Auvergne until seized by Philip the Good, duke of Burgundy, in 1119. In 1477 Louis XI of France reunited it to the crown. In 1544 Henry VIII of England took the town by siege but it was restored to France in 1550. From 1566 to the end of the 18th century it was the seat of a bishopric. During the Napoleonic Wars, from 1803 to 1805, Napoleon I assembled a large army there with the hope of invading England, but Nelson's navy bombarded the harbour and eventually Napoleon gave up the attempt at invasion. In World War I the first British forces landed there on Aug. 12, 1914, and the town and port were under British administration until 1918. In World War II Boulogne was occupied by German forces on May 25, 1940, and became a German submarine base. During the occupation it was made part of the German "West Wall." It was liberated by Canadian forces on Sept. 18, 1944. The war damage to the harbour was very severe but regular passenger cross-channel services were resumed in 1946.

See also references under "Boulogne" in the Index volume.

(HE. H.; F. S.-Bo.)

BOULOGNE-BILLANCOURT (BOULOGNE-SUR-SEINE: the former name was fixed by decree in 1925), a town of north-central France, in the *département* of Seine, on the right bank of the Seine, southwest of Paris and just outside the former fortifications. Pop. (1954) 93,280. The town has the Gothic church of the 14th and 15th centuries (restored 1863) of Notre-Dame de Boulogne-sur-Mer. The settlement had previously been called Menuls-lès-St. Cloud. Boulogne-Billancourt is connected by the underground railway and bus with central Paris. It is a centre of the automobile, aircraft and film industries. Metal boxes and food products are made, and laundering is carried on. For the neighbouring Bois de Boulogne see PARIS.

BOULTER, HUGH (1672–1742). English archbishop of Armagh, the virtual ruler of Ireland at the height of the Protestant ascendancy, was born in London on Jan. 4, 1672. Educated at Christ Church, Oxford, he entered the church and rose rapidly under the patronage of the earl of Sunderland. In 1719 he was made chaplain to George I and then bishop of Bristol. In 1724 he reluctantly accepted his appointment as archbishop of Armagh and primate of all Ireland. He soon became the government's chief adviser in Ireland, and was 13 times a lord justice.

Boulter's policy in Ireland was based on the conviction that the English interest must be supreme. He used his control of patronage to secure the advancement of Englishmen to high ecclesiastical and political offices. He condemned policies which gave the discordant groups in Irish politics a common cause for opposition. Convinced of the danger of the enormous Roman Catholic majority, he made the penal laws more stringent (1728), prohibiting Catholics from voting and excluding them from the legal profession. He also promoted a scheme to found schools to bring up orphans and poor children as Protestants. Under his auspices the Incorporated society was founded in 1733 by royal charter, and chartered schools were built, but the militant Protestantism of the scheme doomed it to failure in Ireland.

Boulter's talents were above all administrative, and within the

limitations of his English and Protestant outlook he ruled Ireland well. Aware of the disastrous economic situation he encouraged agricultural development, introducing a bill to prevent the wholesale conversion of arable land to pasture, and tried to reform the coinage, combating both English indifference and Irish opposition, led by Jonathan Swift. Despite his preoccupation with politics, he did much to reform the Irish (Anglican) Church, trying to prevent pluralism, dividing up unwieldy parishes, and encouraging the building of new churches. He augmented the benefices of the poorer clergy, and left the bulk of his estate to this cause. His generosity to the poor of Dublin earned him popularity, especially during the famine of 1739–40. Boulton remained primate until his death in Ireland on Sept. 27, 1742.

See Ambrose Philips (ed.), *Letters of Hugh Boulton* (1769–70).

BOULTON, MATTHEW (1728–1809), English manufacturer, engineer and artist, an outstanding leader in industrial development who introduced James Watt's steam engine, was born on Sept. 3, 1728, at Birmingham. After managing his father's hardware business, in 1762 he built Soho manufactory, near Birmingham, and with John Fothergill produced gilt and silver buttons, buckles, Sheffield plate, etc. He founded the Birmingham assay office in 1773.

In 1768 Boulton made the acquaintance of James Watt. When John Roebuck, founder of Carron ironworks and owner of coal mines! became bankrupt, Boulton accepted Roebuck's share in Watt's first steam engine patent (1769) as repayment of a debt. In 1775 Boulton took Watt as partner in the steam engine business and obtained a 25-year extension of the patent. Assisted by William Murdoch, they established the steam engine industry by initially erecting pumping engines on Cornish mines. Boulton foresaw great industrial demands for steam power and wrote, "People in London, Manchester and Birmingham are steam mill mad." He urged Watt to design the double-acting rotative engine, patented in 1782. The Watt engine (1788) for driving lapping machines at Boulton's factory is in the Science museum, London. In 1786 Boulton applied the steam engine to coining machinery and in 1790 he patented his coining press; he also supplied machinery to the royal mint. He became a fellow of the Royal society in 1785 and established a theatre in Birmingham in 1807.

By 1800, when Matthew Robinson Boulton and James Watt, Jr., took over their fathers' business, almost 500 steam engines had been installed in the British Isles and abroad. Boulton died on Aug. 17, 1809, at Birmingham.

See H. W. Dickinson, *Matthew Boulton* (1937). (AR. S.)

BOUNCING BET, the common soapwort (*q.v.*) (*Saponaria officinalis*), which has become very widely naturalized in waste grounds and along roadsides in the eastern United States.

BOUNDARIES, the indicated limits of an area. Some areas are privately owned and therefore nonpolitical in nature. The boundaries that come most frequently to the attention of the public are political, especially the boundaries of sovereign states.

In ancient Greece and Rome and during the middle ages there were no fixed boundary lines between political communities. The limits of a state's jurisdiction were vague; there were border zones or marshes but no fixed lines. In those days a frontier was merely a place where a state had put a halt to its authority; it had no recognition in public international law. The need for fixed boundaries arose as the modern states of western Europe developed to take the place of the Holy Roman empire. This development placed the populations of neighbouring states in close proximity to each other, so that it became imperative to know the limits of jurisdiction. Exact boundaries were not possible, however, until the sciences of geography and cartography had reached the point where they could furnish data needed for delimitation and demarcation.

The period of the Renaissance, with its stimulus to the study of mathematics, topography and descriptive geography, made this needed information increasingly available. To some extent the demand for fixed boundaries was met during the 17th and 18th centuries by the doctrine of natural frontiers, which maintained that a nation's territory should extend to a designated river, mountain, lake or some other natural impediment

to population movements and relations. With its emphasis upon simplification, the French Revolution brought fresh strength to the contention that boundaries should be fixed and definite. After that time great progress was made both in the science of boundary making and in the actual establishment of definite boundaries.

There are two processes involved in boundary making. First, there is the delimitation of the boundary, the definition on paper of the course which the line shall take; and, second, demarcation.

Delimitation. — Delimitation is normally a diplomatic procedure, except that where a boundary dispute has been submitted to an international court! it is done by arbitral or judicial bodies. Even when this is true, the authority of the tribunal may be traced back to a diplomatic agreement in the form of a treaty or a *compromis*, an agreement to abide by a decision.

Diplomatic delimitation of a boundary may be on a bilateral or multilateral basis. An illustration of the former is provided by the negotiations between Mexico and the United States in 1848, resulting in a definition in the treaty of Guadalupe Hidalgo of the mutual boundary between them. Increasingly, however, negotiations for the delimitation of boundaries have been on a multilateral basis because of the more general recognition that matters of this nature affect the relative power positions of many nations. After the Second Balkan War the boundaries of the Balkan states were defined in a conference held at London in which the large powers took part. In 1919 the Paris peace conference fixed the boundary lines of European states for the post-World War I period.

Following World War II negotiations were on a multilateral basis, with the large powers dominating even more openly than in 1919; the Council of Foreign Ministers, designated to write preliminary drafts of the peace treaties, was unable to agree on some boundaries.

There are five main considerations taken into account in the process of delimitation—strategic, ethnic, economic, geographic and historic. The strategic conception is that a line shall be drawn in such a way that the security of some one or more nations will be strengthened. When delimitation is undertaken by a peace conference, it is the security of some one or more of the victors that is uppermost, and the defeated nation is obliged to acquiesce. It is generally admitted that modern methods of warfare—atomic bombs! aircraft, tanks and other mechanical devices—decrease the practical utility of strategic frontiers.

Ethnic considerations played an important part in the delimitation of boundaries after World War I. An effort was made to find lines that would separate national groups as effectively as possible. To do this, population statistics were consulted or plebiscites were prescribed. Following World War II less stress was given to ethnic facts and more to strategic.

In addition to strategic and ethnic considerations, negotiators take into account economic, geographic and historic facts: so that a line will be as sound as possible from these points of view. After 1919, however, these factors were given somewhat less weight than strategic and ethnic considerations.

Demarcation. — After the delimitation of a boundary has been completed, demarcation should follow. This is the process of applying the documentary definition of the boundary to the earth's surface, and setting up monuments and buoys at selected points along the line. As a rule this work is done by a commission especially selected for the purpose. The boundary between the United States and Canada is unusually well marked. Many boundaries, however, have not been marked at all.

When a boundary is located in a river, it is understood to be at the *thalweg*, the middle of the navigable channel, rather than at the middle of the river. At times this doctrine of the *thalweg* is applied to other water boundaries, such as lakes and straits. When the boundary is a mountain range, it is common to take the water divide as the line. See also WATERS, TERRITORIAL: HIGH SEAS; MARE CLAUSUM.

BOUND BROOK, a borough of Somerset county, N.J., U.S., on the Raritan river. 34 mi. S.W. of New York city. With South Bound Brook and Middlesex it comprises an urban area. (For comparative population figures see table in NEW JERSEY: *Population*.) The town is primarily residential with quiet tree-shaded streets and parks. Many residents commute to work in industrial enterprises located nearby.

In 1681 all the land now occupied by Bound Brook was transferred by deed from two Indian chiefs to Philip Carteret and six other men. Settlement soon followed, but the borough was not incorporated until 1891.

The area is rich in American Revolutionary history and several interesting colonial houses survive. The Staats homestead in South Bound Brook was the headquarters of Baron von Steuben during the Revolutionary War. Col. Philip Van Horne's house, known as Convivial hall because of the famed hospitality of the colonel and his five daughters, was occupied for a time by Lord Stirling and later by "Light-Horse Harry" Lee. George Washington's army twice camped on the hills behind the village, known as the heights of Middlebrook, and the site is kept as a historical monument. It is said that there Washington first (1777) unfurled the Stars and Stripes as the national flag. (W. L. CA.)

BOUNDS, BEATING THE, an ancient custom, dating at least from Anglo-Saxon times, formerly observed in many English parishes and intended, at a time when maps were rare, to familiarize the members of a parish with the position of its boundaries. A procession of the parish priest, the churchwardens and the parochial officials headed a crowd of boys who, armed with sticks, beat the parish borderstones. Originally the boys themselves were often beaten, or bumped on the boundary stones to help them to remember. The object of taking boys was to ensure that witnesses to the boundaries should survive as long as possible. The procession took place on Ascension day or during the preceding Rogation (*q.v.*) days (sometimes called "ganging days" or "gang week" in the north of England from the "gang" or procession) and was always marked, in England, by a parish-ale or feast, which assured its popularity. Beating the bounds had a religious side in the practice which originated the term "rogation," as the accompanying clergy used to beseech (Lat., *rogare*) God's blessing on the parish lands for the ensuing harvest. Much of the religious ceremonial was prohibited in the course of the Reformation, but the injunctions of Elizabeth I provided that "at the time accustomed the curate and substantial men of the parish walk about their parishes as they were accustomed, and at their return to church make common prayer." The ceremony became increasingly secular, but was fairly widely observed until the end of the 19th century. It is not altogether extinct, being continued, for example, in the city of London at the Tower, and in the parish of St. Dunstan-in-the-East.

"BOUNTY," MUTINY OF THE (1789): see BLIGH, WILLIAM.

BOURASSA, HENRI (1868–1952), pioneer Canadian nationalist politician and journalist, was born at Montreal, Sept. 1, 1868. A grandson of Louis Joseph Papineau, leader of the democratic movement in Lower Canada from 1810 to 1837, he became mayor of Montebello (Labelle district) at the age of 22. He represented Labelle in the federal house of commons from 1896 to 1907 as a Liberal, but he gradually became an independent nationalist. He resigned in protest against Canadian support of the imperialist cause in the South African War, but was immediately re-elected. He was the first prominent politician to advocate that Canada should become a completely separate nation under the crown—an idea which became a reality before his death. Bourassa's opposition to the exploitation of Quebec, or of Canada, by U.S. business firms drew him into co-operation with the Conservatives in both provincial and federal politics. He opposed the Liberal government in Quebec as a member of the legislative assembly from 1908 to 1912.

One of Bourassa's most enduring accomplishments was the establishment in 1910 of a daily French language newspaper in Montreal, *Le Devoir*. In 1911 he campaigned vigorously against the naval policy of the Liberals, and in 1917 against military conscription, introduced by the Conservatives. In 1925, as an Independent, he was again elected to parliament for Labelle, which he represented until his indifference to local political patronage led to his defeat in 1935 by a Liberal party member.

Disillusioned with both major parties, Bourassa in 1944 advocated support for either the Bloc Populaire Canadien or the Co-operative Commonwealth Federation. His career was a combination of religious conservatism and social radicalism. He died Aug. 31, 1952, at Outremont, on the island of Montreal.

(G. O. R.)

BOURBAKI, CHARLES DENIS SAUTER (1816–1897), French general who served with distinction in Algeria, the Crimea and Italy but was unsuccessful as a commander in chief during the Franco-German War. He was born at Pau on April 22, 1816, the son of a colonel who lost his life in the War of Greek Independence. After studying at the military school at La Flèche and at Saint Cyr (1834–36), Bourbaki joined the Zouaves in Algeria. He showed considerable valour in battle, notably at Sétif (1840), and in 1842 was promoted captain. After a brief period in 1845 as aide-de-camp to King Louis Philippe, he went back to Algeria to take charge of the *bureau arabe* at Blidah. In 1851 he was colonel of the zouaves. During the Crimean War he fought with great bravery in the battle of the Alma and was promoted brigadier-general. Wounded during the capturing of Sevastopol, he returned once more to Algeria, becoming a general of division in 1857.

Bourbaki took part in the campaign in Italy in 1859 and assumed command of the 2nd division at Grenoble in 1860. Appointed aide-de-camp to Napoleon III in 1869, he commanded the imperial guard in 1870 and was engaged in the fighting around Metz after the outbreak of the Franco-German War. Sent by Marshal A. F. Bazaine to England to negotiate with the empress Eugénie, he was afterward unable to return to Metz and offered his services to the provisional government at Tours. In Oct. 1870 he was put in command of the army of the north but was subsequently transferred to the army of the east. Having won a victory over the Germans at Villersexel (Jan. 9, 1871) he tried to break through the German lines and to raise the siege of Belfort, but after three days' fighting suffered a severe repulse before Héricourt. Without munitions, lacking sufficient food supplies and leading an exhausted army, Bourbaki was incapable of action. On Jan. 26 he attempted to commit suicide and was replaced by Gen. C. Clinchant.

After the war he commanded the XIV corps and was governor of Lyons. Placed on the reserve in 1881, he twice tried unsuccessfully to enter parliament. He died at Bayonne on Sept. 23, 1897.

See G. Felix, *Le Général Bourbaki* (1898).

(L. G.)

"BOURBAKI, NICOLAS," the collective pseudonym of a group of French mathematicians who began in the late 1930s to write a treatise on mathematics as a whole. About 24 volumes had appeared by 1960. Bourbaki's work is characterized by rigid adherence to the axiomatic method, strictly logical arrangement, insistence on the utmost generality, and carefully chosen terminology which has often been at variance with prevailing usage. Much of Bourbaki's terminology has, however, been generally adopted, his point of view has been widely accepted, and his work has determined the direction of much mathematical research.

An example of the axiomatic method is furnished by the theory of groups (*q.v.*). The theorems of abstract group theory can be interpreted at will as theorems about groups of rotations, groups of numbers, groups of permutations of the roots of equations, etc. The development of a branch of mathematics from axioms is at least as old as Euclid, although the idea of detaching the axioms completely from any interpretation came much later. It had often been applied before Bourbaki, although never on so grand a scale.

Another feature of Bourbaki's approach is his classification

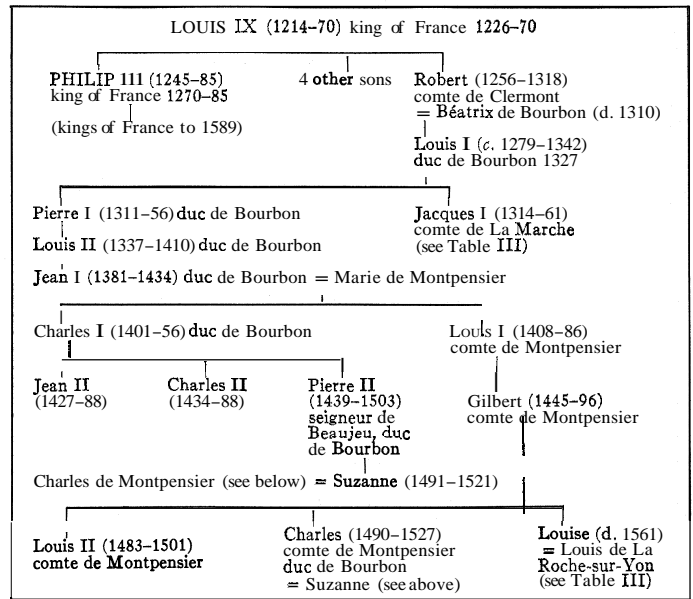

of mathematics. Instead of dividing mathematics into the traditional fields, Bourbaki divides it into parts characterized by their types of structure: for example, algebraic structure, such as the structure imposed on the real numbers by the operations of addition and multiplication; order, such as the structure imposed on the real numbers by the relation of inequality; and topology, such as the structure imposed on the real numbers by the concept of limit.

The parts of Bourbaki's treatise that had appeared by 1960 were supposed to constitute a portion of the first part of the whole, namely "the fundamental structures of analysis." They dealt with the theory of sets, algebra, general topology, functions of a real variable, linear topological spaces and integration.

The Bourbaki group has kept its exact membership secret. However, it is generally believed that among its original leaders were such well-known mathematicians as H. Cartan, C. Chevalley, J. Dieudonné and A. Weil; younger mathematicians such as J. Dixmier, R. Godement, J. L. Koszul, P. Samuel and J. P. Serre joined the group from time to time, while older members became inactive. The constant changes in membership have tended to preserve the youthful spirit that characterized the enterprise from its inception. (R. P. Bo.)

BOURBON, the name of one of the greatest formerly sovereign houses of Europe (Spanish BORBÓN; Italian BORBONE). To cite only their sovereign titles, Bourbon princes, in the period 1572-1931, were kings of Navarre, of France, of Spain, of Naples and Sicily (or of the Two Sicilies), of Etruria and of the French; and dukes of Parma and of Lucca. A branch of the house also in-

TABLE I.—The Bourbon Descent from Louis IX: Ducs de Bourbon and Comtes de Montpensier

herited the pretension to the imperial throne of Brazil. The house of Bourbon, with its many branches, is itself a branch

TABLE II.—The Bourbon Kings of France, with the House of Orleans to 1830

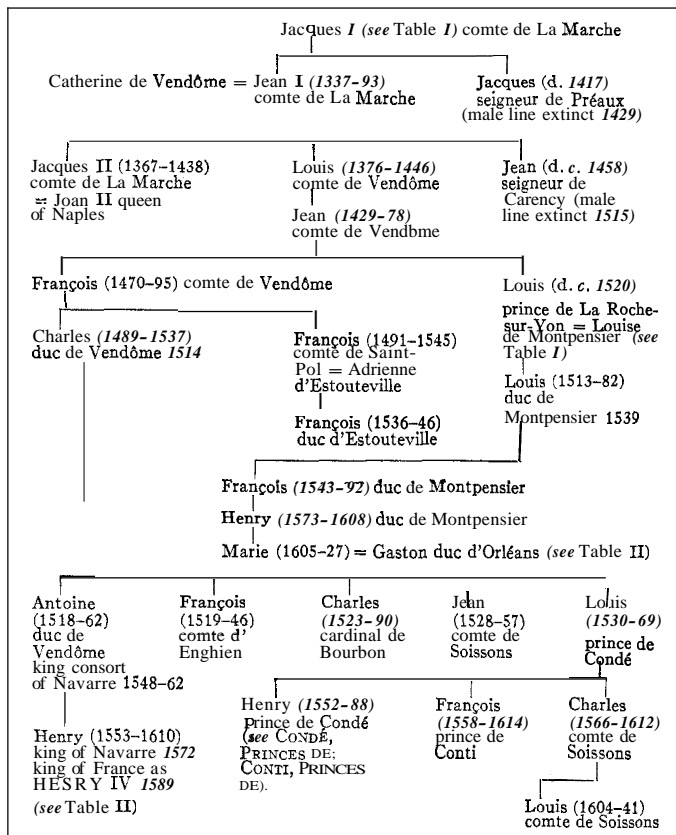

TABLE III.—The Branch of La Marche-Vendôme, to Henry IV, with the Second Line of Montpensier

of the house of Capet (*q.v.*), since Louis IX of France, a Capetian of the direct line, is the ancestor of all the Bourbon princes through

his son Robert, comte de Clermont, who married the heiress of the ancient lords of Bourbon (see BOURBONNAIS) and whose son Louis, likewise the ancestor of the whole house, was created duc de Bourbon in 1327 (see Table I). The senior male lines of the first duke's descendants, who had moreover acquired by marriage the countship of Montpensier, became extinct in 1527, so that the succession is through a junior line, that of La Marche-Vendôme (see Table 111), from which all the sovereign branches of the house, as well as the princes de Condé and the princes de Conti (*q.v.*) descend. After two Bourbons of this line had been kings consort (Jacques II, comte de La Marche, in Naples—a title not uncontested—and Antoine, duc de Vendôme, in Navarre), Henry de Bourbon, the head of the house, became not only king of Navarre (*q.v.*) in 1572 in succession to his mother but also king of France as Henry IV in 1589 as head of the whole house of Capet on the extinction of the male line of the Valois dynasty (see FRANCE: History). From Henry descend not only the two French branches but also the Spanish, Parmesan, Neapolitan-Sicilian and Brazilian.

The senior line of France runs in direct succession from Henry IV to Louis XVII and is then resumed in Louis XVIII, Charles X and the latter's grandson the comte de Chambord, who was pretender as "Henry V" (see Table II).

On the extinction of the senior male line of France in 1883, the headship of the house of Bourbon—and of that of Capet—passed to the Spanish line. The Bourbon Philip V's accession to the Spanish crowns in 1700 was based on his descent from two Habsburg infantas—daughters of Philip III and of Philip IV of Spain and wives respectively of Louis XIII and Louis XIV of France (see Table 11)—and was sanctioned by the testament of the last Habsburg king of Spain, Charles II (see SPAIN: History; SPANISH SUCCESSION, WAR OF THE).

Philip V, as a Capetian, introduced the Salic law of succession to the Spanish monarchy in 1713, but his great-grandson Ferdinand VII, who had no sons, revoked this in 1830 in favour of his elder daughter Isabella. His brother Don Carlos, who would have been his heir by Salic law, protested against this revocation,

TABLE IV.—The House of Orléans from 1830

and on Ferdinand's death the first of the Carlist wars broke out (see CARLISM).

The extinction of the Carlist male line in 1936, however, combined with the fact that Isabella had in 1846 married the eldest son of the next brother of Ferdinand VII and of Don Carlos, made Isabella's descendant, the conde de Barcelona, both the head of the house of Bourbon and the rightful pretender to Spain according to Salic law. (See Table V.)

If all male descendants of Charles IV of Spain (other than those whose families have renounced their rights) became extinct, the headship of the house of Bourbon would pass to the Neapolitan-Sicilian branch, as descended from Charles III of Spain, who had conquered Naples and Sicily in 1734-35 and transferred them to his son Ferdinand on succeeding to Spain in 1759 (see Table V; Table VII; NAPLES, KINGDOM OF). If likewise the Neapolitan-Sicilian branch died out, the next heads of the house would be the pretenders to the duchy of Parma, descended from Charles III of Spain's brother Philip (see Table V; Table VI). Both Charles and Philip were entitled to Parma through their mother Isabella Farnese, heiress of the original dukes of Parma (see FARNESE). Charles in fact had been duke of Parma from 1731 to 1735 but had to renounce the duchy to secure general recognition as king of Naples and Sicily. Philip did not secure recognition as duke till 1748.

The junior branch of the house of Bourbon is that of Orléans, descended from Philippe, brother of Louis XIV of France (see Table II). Louis Philippe, duc d'Orléans, became de facto king of the French in 1830, as a result of the July revolution. If his

descendants are now recognized as de jure pretenders to the crown of France, with priority over the claims of the Spanish, Neapolitan-Sicilian and Parmesan branches to it, this is because the non-Bourbon European powers, before consenting to recognize the Bourbon accession to Spain, had required that Philip V should renounce for himself and his descendants all rights to the French crown. Thus, with the Spanish branch and its Neapolitan-Sicilian and Parmesan subdivisions excluded, the house of Orléans could claim the French succession as by right after the death of the comte de Chambord in 1883. The claim of a junior branch of the line of Orléans to Brazil came about through the marriage of the comte d'Eu to Isabella, heiress of the last Brazilian emperor. The descendants of this marriage form the house of Orléans-Braganza or Bourbon-Brazil. (See Table IV.)

The political history of the house of Bourbon is part of the history of Europe and of the several states over which Bourbons reigned and need not be discussed here (see also biographical articles on members of the family). The dates on which the various sovereign branches were deposed, restored and deposed again can be seen in the tables. Dynastic co-operation was most effective in the 18th century, when the Bourbons of France and Spain allied themselves in the "Family compacts" (1733, 1743, 1761), least effective during the French Revolutionary and Napoleonic Wars and in the 19th century, despite the regularity of intermarriage of Bourbon with Bourbon.

In the accompanying tables (1) the names of sovereigns are mostly anglicized (*e.g.*, Philip instead of Felipe), but those of other persons are generally given in the original form, except

TABLE V.—*The Spanish Bourbons*

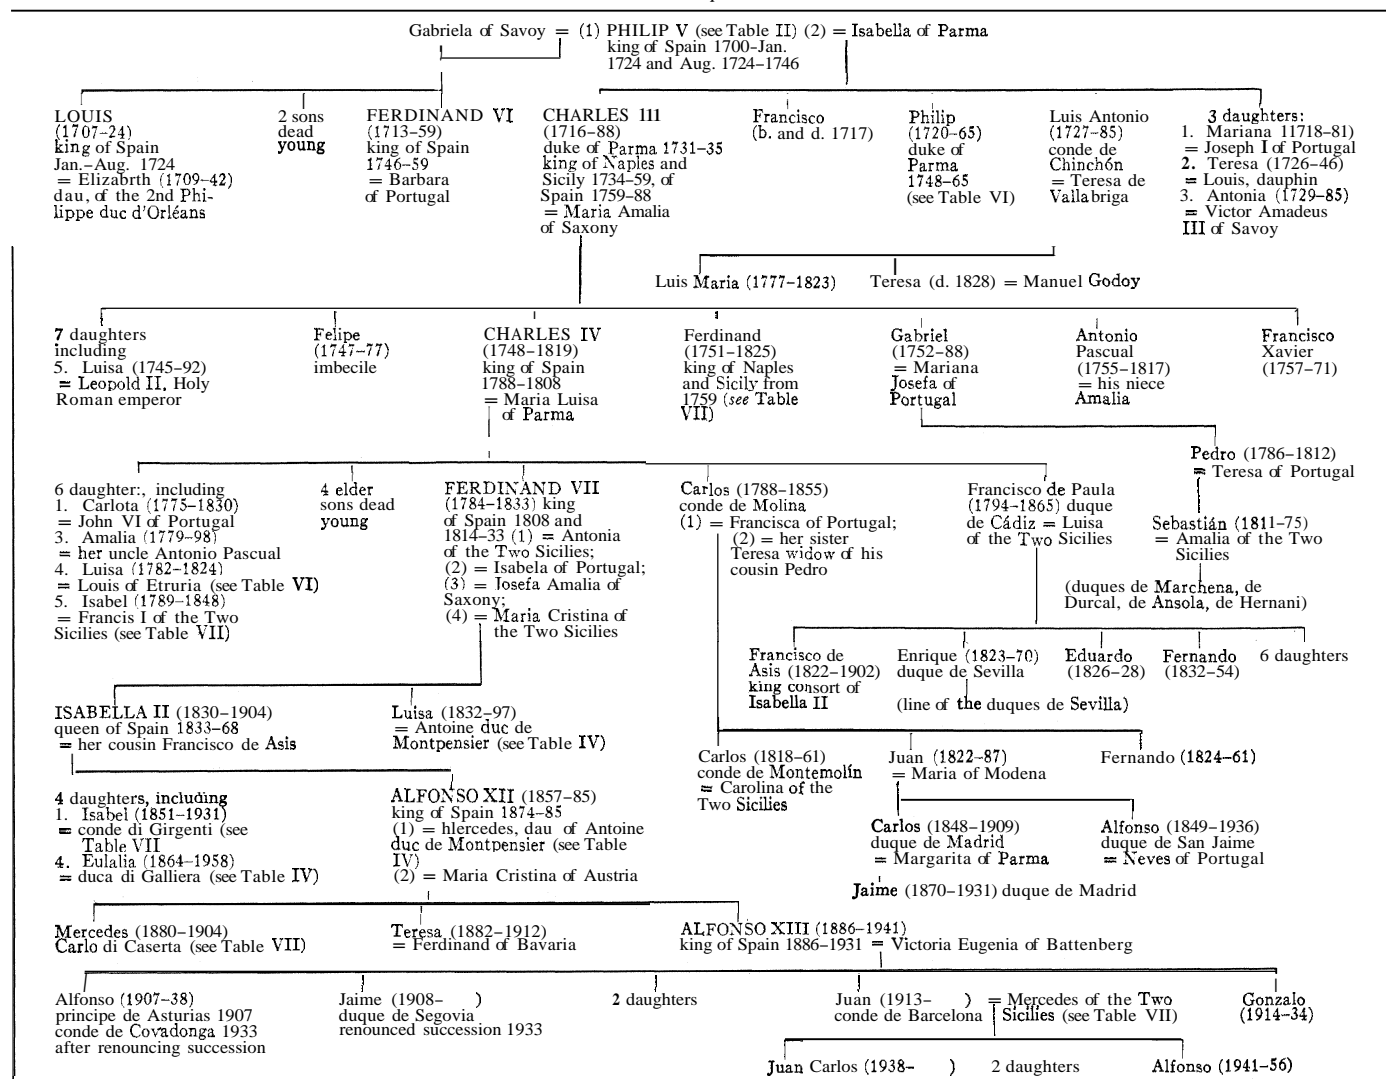

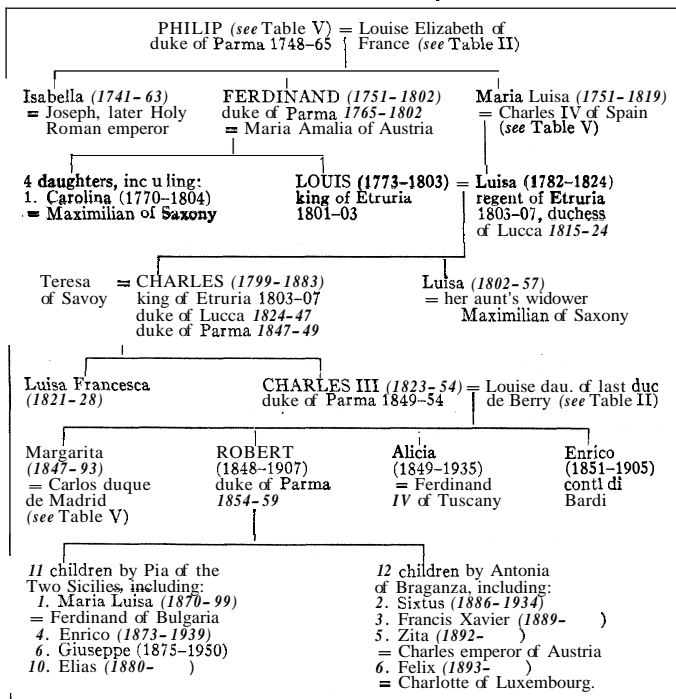

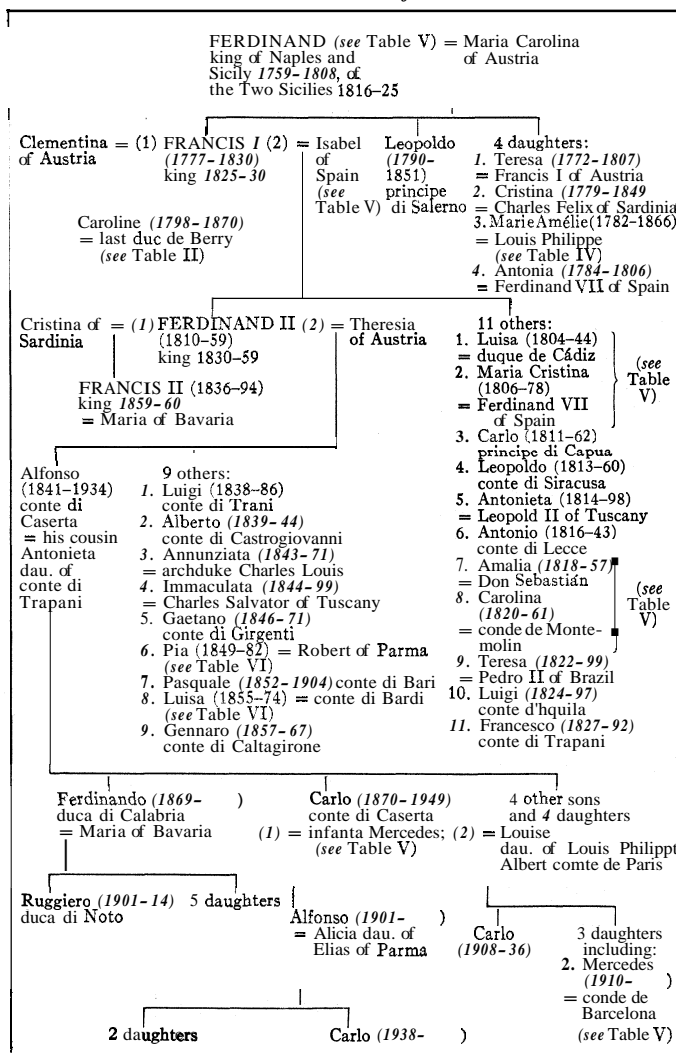

TABLE VI.—*The Bourbons of Parma*TABLE VII.—*The Bourbons of the Two Sicilies*

occasionally where princesses, having married into another country, are better known under that country's name (*e.g.*, Marie Amélie, queen of the French: instead of Maria Amalia); and (2) the first name Maria has in many cases been omitted from such compounds as Maria Amalia, Maria Antonia, Maria Luisa, Maria Teresa, Maria de las Mercedes, etc.

Something must finally be said about the bastard branches of Bourbon (not indicated in the tables). The oldest surviving one of these is that of Bourbon-Busset, descended from Louis de Bourbon (d. 1482), prince-bishop of Libge, another son of Charles I duc de Bourbon. Of the numerous bastards of Henry IV and Louis XIV, the most important were legitimated. The second Bourbon house of Vendôme begins with César (1594-1665), duc de Vendôme, Henry IV's eldest son by Gabrielle d'Estrées. Henry (1601-82), duc de Verneuil, was the son of Henry IV and the marquise de Verneuil. Of Louis XIV's five children by Louise de La Vallière, two were legitimated, namely Louis (1667-83), comte de Vermandois, and Marie Anne (1666-1739), known as Mademoiselle de Blois until her marriage with Louis Armand, prince de Conti.

The children of Louis XIV and the marquise de Montespan, all legitimated, were: Louis Auguste (1670-1736), duc du Maine, whose last direct heir died in 1775; Louis César (1672-83), abbé de Saint Germain-des-Près; Louis Alexandre (1678-1737), comte de Toulouse, whose son Louis Jean (1725-93), duc de Penthievre, was the father of Louis Alexandre (d. 1767), prince de Lamballe, and of Louise Marie Adélaïde, mother of the future king Louis Philippe; Louise Françoise (1673-1743), called Mademoiselle de Nantes until her marriage with Louis III de Condé; Louise Marie (1676-81), Mademoiselle de Tours; and Françoise Marie (1677-1749), known as the second Mademoiselle de Blois until her marriage with Philippe, duc de Chartres, the future duc d'Orléans and regent.

See also references under "Bourbon" in the Index volume.

(J. G. R.-S.)

BOURBON, CHARLES, DUC DE (1490-1527), constable of France, is often presented to the popular French historical imagination as the symbol of treason and ingratitude, though in fact his conduct was largely justified by the change in his king's treatment of him. Born at Montpensier on Feb. 17, 1490, the second son of Gilbert, comte de Montpensier, head of a junior branch of the house of Bourbon (*q.v.*), Charles benefited by a rapid succession of deaths: his father's (1496) was followed by his eldest brother's (1501); and finally, in 1503, his father's cousin Pierre II, duc de Bourbon, died leaving no male heir. Charles, who moreover proceeded to marry Pierre's daughter Suzanne, thus inherited the domains of the ducal line of Bourbon as well as those of Montpensier. At the age of 15, in 1505, he was one of the most powerful men in France.

Charles now started a brilliant military career. He was at the siege of Genoa in 1507 and took part in the battle of Agnadello in 1509. Appointed constable of France on the accession of Francis I, he contributed greatly to the victory at Marignano, which made his young king master of the Milanese. At 25, laden with honours by the king, Charles was governor of the Milanese in the king's name. He took effective measures to defend the province against the Holy Roman emperor Maximilian.

Then the constable began to lose the king's favour. Various explanations have been advanced for this change. The king's envy may indeed have been excited by the splendour of Charles's life at Moulins, capital of his duchy in the Bourbonnais, but above all it seems to have been the king's mother, Louise of Savoy, who worked against Charles. According to one story, Louise had been in love with the constable, but he had scorned her advances and rejected the proposal of marriage made by her after his wife's death (1521). It is certain in any case that Francis, who had neglected to pay his salary to the constable since his investiture, instituted proceedings in the *parlement* of Paris to recover the inheritance of the senior branch of the Bourbon family from him (1522-23). As the king's case was bad in law, the *parlement* suspended judgment but ordered the property to be sequestered, thus constituting the crown a trustee.

BOURBON—BOURDALOUE

Thereupon Charles turned to negotiate with the emperor Charles V and with Henry VIII of England. At one time they even considered a partition of France, whereby the emperor would take Languedoc, Burgundy, Champagne and Picardy, the constable would add Provence and Dauphine to his own domains of Bourbonnais and Auvergne, and the king of England would have the rest of France, from Normandy to Guienne. Francis got wind of this simple project, but failed to stop Charles from escaping to the Franche-Comté. Passing into the emperor's service at the head of an army of German mercenaries, Charles then repelled a French attack on Italy (April 1524), invaded Provence and captured Toulon, but was halted before Marseilles (Aug.-Sept. 1524). Falling back on Lombardy, he fought in the battle of Pavia (Feb. 24, 1525), in which Francis was taken prisoner by Charles's soldiers. The treaty of Madrid (1526), whereby Francis recovered his liberty, guaranteed Charles's free return to France and the restitution of his possessions, but Francis did not keep his word.

To offset this disappointment, Charles V made the constable governor of the Milanese, the post that he had held ten years earlier as the representative of the king of France. Left without resources by the emperor for the upkeep of his army, the constable, in the spring of 1527 led his pillaging troops across central Italy to Rome. He was killed in the first assault on Rome (May 6, 1527), just before the capture and sack of the city.

BIBLIOGRAPHY.—The life of the constable de Bourbon to 1521, by his secretary G. de Marillac, with the continuation of it by A. de Laval, is printed in *Pantheon littéraire*, ed. by A. Desrez (1836). See also the romanticized life by N. Baudot de Juilly, *Histoire secrète du constable de Bourbon* (1696; new ed. 1947); and C. Hare, *Charles de Bourbon* (1924).

BOURBON, LOUIS HENRI DE BOURBON-CONDÉ, DUC DE (1692–1740), French statesman, the first prime minister of Louis XV's reign, was born at Versailles on Aug. 18, 1692, the son of Louis de Bourbon-Condé (Monsieur le Duc). After the death of Louis XIV, he was placed by the regent, the duc d'Orléans, at the head of the regency council where he distinguished himself mainly by his opposition to the legitimized princes. In general he played little part in politics during Louis XV's minority, preferring to occupy himself in the speculation engendered by the financial system of John Law. In 1719, however, he met the marquise de Prie (Agnès Berthelot de Pléneuf), who soon became his acknowledged mistress and diverted to politics the energies he had been accustomed to dissipate in the chase. After the death of the duc d'Orléans on Dec. 2, 1723, Bourbon became first minister, but he remained completely under the influence of his mistress. The ministry was a disastrous one; increased taxation, repressive police measures and rigorous laws against the Protestants made the regime unpopular in France, while the ending of the betrothal of Louis XV to the infanta nearly led to war with Spain and was directly responsible for the Austro-Spanish *rapprochement* of 1725. In June 1726 a plot to secure the dismissal of A. H. de Fleury (*q.v.*) failed, and it was Bourbon himself who was dismissed. Exiled to Chantilly, he interested himself in chemistry and natural history until his death there on Jan. 27, 1740. (B. J. R.)

BOURBONNAIS, an old province of France, covering approximately the same area as the modern *département* of Allier. Bounded on the north by Nivernais and Berry, on the south by Auvergne, on the east by Burgundy and Forez and on the west by Berry, Bourbonnais included parts of lands held in pre-Roman times by certain Gallic tribes—the Arverni, the Aedui and the Bituriges Cubi—and later divided between Aquitania and Lugdunensis. The territory, a creation of the feudal period, was gradually carved out of neighbouring provinces by the sires or lords of Bourbon (the modern Bourbon-l'Archambault). These sires were descended from Aimon I (10th century), whose son or grandson Archambaud I or II (d. c. 1034) set up the dynasty of Archambaud. Archambaud IV (d. 1095) was succeeded by his brother Aimon II Vaire-Vache (d. 1110), whose great-granddaughter Mathilde I married Guy of Dampierre (d. 1216) as her second husband. Their descendants form the line of Archambaud-Dampierre: Archambaud VII the Great (d. 1242), his son Archambaud VIII (d. 1249) and the latter's two daughters, Mathilde II

(d. 1262) and Agnès (d. 1287 or 1288). Agnès, by her first husband, Jean, second son of Hugh IV of Burgundy, had a daughter, Béatrix, who in 1276 married Robert, comte de Clermont, sixth son of Louis IX of France. Their son Louis, created duc de Bourbon in 1327, was the ancestor of the great sovereign dynasty of Bourbon.

Bourbonnais was confiscated by the French crown in 1527 on the death of the rebellious constable Charles, duc de Bourbon, and attached to the crown in 1531. In the 18th century different parts of Bourbonnais formed parts of five dioceses, those of Bourges, Clermont, Autun, Nevers and Limoges. The principal towns of Bourbonnais were Moulins (the capital), Gannat, Montluçon and Lalapalisse. The province had a military government with headquarters at Moulins. For judicial purposes it came under the *parlement* of Paris.

BOURCHIER, THOMAS (c. 1412–1486), English cardinal and archbishop of Canterbury, was notable during the Wars of the Roses for his attempts to maintain peace and the stability of the church first by compromise and later by supporting whichever king was in power. He was a younger son of William Bouchier, made count of Eu (1419) for his services to Henry V, and of Anne, heiress of Thomas of Woodstock, duke of Gloucester, the youngest son of Edward III. Thomas Bouchier went to Oxford university in about 1425 and was chancellor of the university from 1434 to 1337. While bishop of Worcester (1435–43) and of Ely (1443–54), he was often at court and was frequently in demand as a confidant and arbitrator. His avoidance of political faction made his election as archbishop of Canterbury (1454) acceptable to all parties during the tense months (1453–54) of Henry VI's insanity. Chancellor from 1455–56, he organized the temporary pacification of 1458 and the abortive compromise settlement (Oct. 1460) of Richard duke of York's claim to the throne. He supported Edward IV unswervingly throughout his reign and was repaid by numerous grants, the king obtaining for him a cardinal's hat (1467). After Edward's death he accepted the usurpation of Richard III, and it was probably in naive good faith that he persuaded Elizabeth Woodville to give up her second son, Richard, duke of York, to join his brother, Edward V, in the tower of London. Bouchier crowned Richard III in July 1483 and his supplanter, Henry VII in Oct. 1485. He died at Knole, Kent, on March 30, 1486.

See *Registrum Thome Bourghier Cantuariensis archiepiscopi*, ed. by F. R. H. Du Boulay (1957) for the most recent appraisal and bibliography. (A. R. M.)

BOURDALOUE, LOUIS (1632–1704), French Jesuit, held by many to have been the greatest of the 17th-century court preachers who in those days filled a public role comparable with that of the modern newspaper, was born at Bourges on Aug. 20, 1632. He became a Jesuit in 1648 and very soon manifested his gift for oratory. After preaching in the provinces, he was sent to Paris in 1669 where he preached in the church of Saint Louis. He soon earned the title of "king of preachers and preacher of kings." Bourdaloue disliked the custom of flattering funeral orations for the great, but the one he preached on the great Condé was so effective that it changed the life of the prince's son and successor, Henri Jules, who called it "the finest and most Christian panegyric that has ever been pronounced." Bourdaloue has been compared with the greatest orators of all ages. Louis XIV preferred Bourdaloue on an old theme to anyone else on a new one.

He was inevitably contrasted with J. B. Bossuet, though their styles and matter were very different. Bourdaloue always wrote out his sermons, which were careful logical expositions with much psychological insight into human nature. He never flattered his congregations, but his beautiful voice, speaking easily and rapidly, kept them spellbound. Bossuet, whose sermons depended to some extent on the stimulus of the occasion, has been called a lyrical preacher in contrast with Bourdaloue's more carefully prepared dialectical expositions. Yet Bossuet reads better today than Bourdaloue, who owed much to the beauty of his voice and the saintliness and attraction of his personality. Bourdaloue died in Paris on May 13, 1704.

See E. Griselle, *Bourdaloue, histoire critique de sa prédication*, 3 vol.

(1901–06); F. Castets, *Bourdaloue* (1904).

(M. D. L. B.)

BOURDELLE, ÉMILE ANTOINE (1861–1929), French sculptor and painter, in whose works the heroic energy and exaggerated, rippling surfaces of Rodin mingled with the flat, decorative simplifications of Greek archaic and Romanesque art, was born in Montauban, Oct. 30, 1861. He studied at the École des Beaux-Arts in Toulouse, then went to Paris in 1885. After studying with Jean Alexandre Falguière, J. B. Carpeaux and A. J. Dalou, he entered the studio of Auguste Rodin, who was to remain one of the chief influences of his artistic life. The masterpiece of his early period was the monument of the "Defenders of 1870–71," (1893–1902). In 1900 he created a crucial work, the "Head of Apollo," whose majestic dignity and broad planes recalled Greek early classic works. In 1910 he achieved his first triumph in the salon with "Heracles the Archer," which again owed much to archaic art, although the pose is far more sinuous and the musculature more exaggerated. In this year he also created a Moses-like "Head of Rodin," as well as busts of Rembrandt and Ingres (1910–12). In 1912 he executed reliefs for the Théâtre des Champs Élysées in a compact, planar style. The subject was "Apollo and His Thought," accompanied by dancing muses. The year 1914 marked the creation of another masterpiece, the "Dying Centaur," which represented for him the defeat of paganism. His "Monument to Alvéar" (1923), in Buenos Aires, consisted of the equestrian subject flanked by four allegorical figures. Among his most satisfying works were his small studies, such as "Apples" (1917) or "Self-Portrait" (1908). He died in Paris on Oct. 1, 1929. (L. W. N.)

BOURDON GAUGE: *see* PRESSURE GAUGE.

BOURG (BOURG-EN-BRESSE), capital of the *de'partement* of Ain, eastern France, and formerly capital of the province of Bresse, is situated on the Reyssouze, a tributary of the Saône, in flat country to the west of the Jura mountains, 61 km. (38 mi.) N.N.E. of Lyons by road and about 70 km. (43 mi.) W. of Geneva, Switz. Pop. (1954) 20,878. The church of Brou, on the boulevard named after it in the southeast of the town, is a remarkable late Gothic monument (1506–32). Marguerite of Bourbon, wife of Philip of Savoy, made a vow to rebuild Brou priory, but died before she was able to fulfill it, and her daughter-in-law, Marguerite of Austria, built the church and monastery in memory of her husband Philibert le Beau of Savoy. The three mausoleums ornamented with the marble effigies of the two Marguerites and Philibert, the rood loft, the oak stalls, the stained glass and the reredos in the Lady chapel are masterpieces of the style. The Ain museum is housed in the buildings of the former priory, which has three cloisters. Notre Dame church was built in different periods, but mainly in the 16th century (nave, choir and stalls). There are some old houses of the 16th and 18th centuries. Bourg is a road and rail junction, standing at the crossing of the road from Paris to the Riviera by the Route Napoléon over the Alps with that from Bordeaux to Geneva and on the main line from Paris to Turin. There is considerable tourist trade and the town has iron and cable works, furniture factories and trade in grain, cattle and Bresse poultry. Neolithic remains have been found. Bourg has had a market since the 11th century and in 1250 the inhabitants were granted a charter of franchise. In 1272 the district of Bresse passed to Savoy by marriage. In 1601 it was annexed to France. In World War II when it was occupied by the Germans from Nov. 1942 until Sept. 1944, it was a centre of the Resistance movement. (AM. M.)

BOURGAULT-DUCOUDRAY, LOUIS ALBERT (1840–1910), French composer and musicologist who influenced his contemporaries by his researches on folk music. Born at Nantes, Feb. 2, 1840, he studied at the Paris Conservatoire, where he won the Prix de Rome (1862), and where (1878–1908) he was professor of the history of music. He wrote operas, symphonic works and chamber music, but his fame rests on his *Trente mélodies populaires de Grèce et d'Orient* (1876), *Trente mélodies populaires de Basse Bretagne* (1885) and *Quatorze mélodies Celtiques* (1909), which fostered a new approach to folk music in France by giving it in its original modal setting. He thus anticipated 20th-century music, being one of those who provided Debussy with the

evocative archaism that through him became an essential element in modern musical style. He died at Vernouillet (Seine-et-Oise), July 4, 1910. (F. E. G.)

BOURGEOIS, LÉON VICTOR AUGUSTE (1851–1925), French statesman and ardent promoter of the League of Nations, winner of the Nobel peace prize in 1920, was born in Paris on May 29, 1851. Having studied law, he entered the civil service in 1876 and in 1887 rose to the position of prefect of police for the Seine *département*. He began his political career next year when he defeated Gen. Georges Boulanger in the Marne *département*, for which he then became deputy. He was a member of several governments from 1888 onward and prime minister from Nov. 1, 1895, to April 21, 1896. He fell from power in the constitutional struggle over the senate's right to veto budgetary supply. Minister of foreign affairs in Ferdinand Sarrien's government from March 14 to Oct. 19, 1906, he was responsible for French policy at closing stages of the Algeciras conference. Having already distinguished himself at the peace conference at The Hague in 1899, he was nominated a member of the permanent court of arbitration there in 1907. He was minister of foreign affairs in Alexandre Ribot's two-day government in June 1914. Thereafter he was minister without portfolio until he became minister of labour in Aristide Briand's government (1916–17). He had been elected to the senate in 1905 and was its president from 1920 to 1923.

Bourgeois had been one of the first to suggest a league of nations and so was appointed by the French government as its representative in the special committee of the Paris peace conference that prepared the covenant of the League of Nations. On the League's being constituted, he became France's principal representative, both in the council and in the assembly, until 1923, when approaching blindness forced him into retirement. In 1920 he was awarded the Nobel peace prize. He died at the château d'Oger, near Ppennay, on Sept. 29, 1925. His publications include: *La Politique de la prévoyance sociale*, two volumes (1914–19), *Le Traité de 1919 et la Société des Nations* (1920) and *L'Oeuvre de la Société des Nations* (1920–23).

See M. Hamburger, *Hommes politiques: Léon Bourgeois* (1932).

BOURGEOISIE, a French term that referred originally to the inhabitants of walled towns in the middle ages. Such townspeople made their living by practicing the medieval arts and crafts. They occupied an intermediate position in the economic and social scale between the landlords and the peasantry in the open country. With the introduction of mechanical power into urban industry and the growth of the factory system the medieval handicraftsmen began to divide into two classes—employers and employees—and the growth of a new kind of class consciousness tended to restrict the idea of bourgeois to the employers. Thus arose a more modern system of economic and social classification which emphasized the distinction between bourgeois (or capitalist) and proletariat (*q.v.*). This distinction became politically important in the first part of the 19th century in the course of the reaction against the indiscriminating democratic idealism that flourished during the French Revolution.

Later, Marxist communists built a pretentious system of social and political philosophy on this distinction between *bourgeoisie* and proletariat. That the attempt to create a comprehensive philosophy of history and politics on this narrow basis was excessively unrealistic is demonstrated by the subsequent struggles between different schools of socialism and communism. Karl Marx's early collaborator, Friedrich Engels, made the first breach in the Marxist system when he admitted the importance of evolution as well as revolution in the development of human society. The successors of Marx and Engels, from Karl Kautsky and Lenin to Joseph Stalin and Nikita Khrushchev, were forced to make increasing concessions to the stubborn facts of modern industrial and political life. The original simplicity of the Marxist scheme of social classification yielded to a growing recognition of the baffling complexity of modern society and politics.

In the most advanced capitalistic countries there is a strong tendency to revert to one of the oldest schemes of social and political classification. Aristotle's system of politics emphasized

the distinctions among three classes—upper, middle and lower—and stressed the importance of the middle classes in a well-ordered state. But in contemporary politics these major classes are highly complex, and there is no part of them which can be identified as the *bourgeoisie*. The word itself retains its practical utility chiefly in discussions of art and manners. In Great Britain and the United States *bourgeoisie* had nearly disappeared from the vocabulary of political writers and politicians by mid-20th century.

(A. N. H.)

BOURGES, a city of central France, capital of the *département* of Cher, is situated almost in the exact middle of the country, 196 km. (122 mi.) S.S.E. of Paris by road. Pop. (1954) 45,372. Bourges is built on a plateau in marshy country crossed by several streams, tributaries of the Cher. The medieval town with its winding streets was enclosed by fortifications, traces of which remain. The modern town with its industries extends to the north, east and west. The summit of the hill on which Bourges is built is crowned by the cathedral which dominates the city. Dedicated to St. Etienne, it is one of the most beautiful Gothic cathedrals in France. It was begun at the end of the 12th century and completed in 50 years, but some additions were made later. It has five magnificent doorways flanked by two asymmetrical towers: the Tour de Beurre on the north (Renaissance) and the Tour Sourde (13th century). The interior has five aisles—the inner aisles are remarkably high—and no transepts, and contains, among many works of art, exquisite stained glass windows of the 12th to the 17th century, those of the 13th century being particularly beautiful. Beneath the choir there is a splendid 12th-century crypt and traces of the 9th-century Carolingian church. The palace of Jacques Coeur (*q.v.*), the Hôtel Lallemand, the palace of John, duke of Berry (*q.v.*), and the magistrate's court were built in the 15th and 16th centuries using the Gallo-Roman fortifications. The Cujas house, built in 1515, is the Berry museum. The Ursuline convent (17th century) is used as the law courts. Two gardens, those of the town hall and Près-Fichaux, set off these fine buildings of the capital of the former province of Berry (*q.v.*).

Bourges is a centre of the aircraft industry and manufactures tires, spirits, biscuits and clothes. It is also the capital of a rich agricultural district famous for its corn, sheep, beef and wines. The old Berry canal is no longer used, the commercial traffic going by road and rail. The archbishop of Bourges bears the title *Primat des Aquitaines, Métropolitain et Patriarche*. The ancient Avaricum, capital of the Bituriges, Bourges was conquered in 52 B.C. by Julius Caesar despite the brave defense by Vercingetorix. Caesar noted in his commentaries that it was almost the most beautiful place in Gaul. St. Ursin brought Christianity to Bourges in the 3rd century. The city was destroyed many times after the end of the Roman occupation. Charlemagne unified Berry and made Bourges the capital of Aquitaine. Charles VII stayed there from 1422 to 1437 during the Hundred Years' War and Joan of Arc spent the winter of 1429–30 in the city. In 1438 the Pragmatic Sanction (*q.v.*) was signed at Bourges. Louis XI, in 1463, endowed his birthplace with a university which became famous for its teaching of Roman law, especially by Jacques Cujas (*q.v.*), but it has long ceased to exist. In this town John Calvin was converted to the ideas of Martin Luther. In World War II Bourges was occupied by the Germans from June 1940 to Aug. 1944.

(S. Po.)

BOURGET, PAUL CHARLES JOSEPH (1852–1935), French Catholic and conservative writer whose voluminous output included novels, short stories, plays, poetry, criticism and travel books, was born in Amiens on Sept. 2, 1852. The son of an eminent mathematician, Bourget studied at the Lycée Louis-le-Grand, the École des hautes Etudes and the Sorbonne. He found medical studies too much for his sensitive nerves but passed his *licence-2s-lettres* brilliantly and embarked on a literary career in imitation of Balzac's heroes.

He began as a poet: *La Vie inquiète* (1875), *Édel* (1878) and *Les Aveux* (1882), reflecting varied influences, are sincere but uninspired. Now forgotten, these poems were then admired: some were set to music by Debussy. Encouraged by Taine, whose thought deeply influenced him, Bourget turned to criticism and

published *Essais de psychologie contemporaine* (1883) and *Nouveaux Essais* (1886), brilliant analyses of the sources of contemporary pessimism. He also contributed many articles to the liberal republican dailies *Le Parlement* and *Le Journal des débats* (1880–86), only a few of which, including impressions of travel in Britain and Ireland, were collected (*Études et portraits*, two volumes, 1889). Meanwhile he published psychological novels: *L'Irréparable* (1884), *Cruelle énigme* (1885), *Un Crime d'amour* (1886), *André Cornélis* and *Mensonges* (both 1887). Set in fashionable society and written in reaction against Zola's naturalism, they are based on a no less deterministic psychological theory derived from Taine. But in *Le Disciple* (1889), his most important novel, Bourget broke with Taine by showing how determinism undermines morality and may lead to crime.

A period of uncertainty followed. Bourget married (1890), traveled in Italy (*Sensations d'Italie*, 1891) and in the United States (*Outre-mer*, 2 vol., 1895), and published further psychological novels, in cosmopolitan settings: *La Terre promise* (1892), *Cosmopolis* (1892), *Une Idylle tragique* (1896). He was elected to the Académie française in 1894 and was a prominent *anti-dreyfusard*.

In 1901, Bourget was converted to Roman Catholicism and thereafter wrote primarily in support of the church and the monarchy. *L'Étape* (1901), *Un Divorce* (1904), *L'Émigré* (1907), *Le Démon de midi* (1914), etc., although called by Bourget *romans à idées* are really *romans à thèse* and have fallen into merited disfavour, like his political plays *La Barricade* (1910) and *Le Tribunal* (1911). His short stories and *nouvelles* are still worth reading however: they include *Pastels* (1889), *Complications sentimentales* (1898), *Drames de famille* (1900), *Le Justicier* (1919) and *De Petzts faits vrais* (1930). Bourget was always an excellent critic: *Pages de critique et de doctrine*, two volumes (1912), *Quelques témoignages*, two volumes (1928) and *Au service de l'ordre* (1929) contain much valuable writing. He died on Dec. 25, 1935, in Paris. A man of great personal integrity, Bourget was generous to young writers. Like his more gifted friend Henry James, he was devoted to his art and deeply interested in its technique. But his dogmatism was disastrous for his creative writing.

Mansuy, *Paul Bourget* (1961). (L. J. Ac.)

BOURGUIBA, HABIB (1903–), first president of the Tunisian republic, was born at Monastir, near Sousse, on Aug. 3, 1903. Educated first in the Sadiqiya college at Tunis, he later took a law degree and a diploma in political science at Paris. Soon after his return to Tunis he founded (1930) and edited a nationalist newspaper in French. In 1934, when the more active members of the Destour, or nationalist, party seceded and founded the Neo-Destour party, he became first secretary-general of the new body, which was banned by the French authorities the same year. A period of forced residence during 1934–36, first at Borj Leboeuf on the edge of the Sahara, later on the island of Djerba, was ended by the liberal policy of the Popular Front government in France. In 1938, however, he was again arrested, and proceedings in the court of cassation in Paris were still pending at the outbreak of World War II. On May 27, 1940, he was transferred to the part of France subsequently held by the Vichy government. Freed by the Germans in 1942, he was sent by them to Rome. There he resisted efforts to secure from him a declaration of support for Axis aims. Allowed back into Tunisia in 1943, he made approaches to the Free French, which were ignored, and in 1943 he escaped in disguise to Egypt. The next six years (apart from seven months from Sept. 1949, when he was able to visit Tunisia and carry on an intensive propaganda campaign) were spent in extensive journeys in the middle east, the far east, Europe and the United States for the purpose of publicizing the Tunisian cause.

Returning to Tunisia during a period of *détente* in 1951, he was in 1952 once more arrested after a hardening of the French atti-

tude and imprisoned until 1954. He was then again released and so enabled to direct the Tunisian delegation from behind the scenes during the negotiations for the internal autonomy promised by the French prime minister, P. Mendès-France. Two days before the actual signing of the conventions establishing Tunisian autonomy he made a triumphal re-entry into Tunisia (June 1, 1955), but he was unwilling to become prime minister until the full independence of Tunisia was recognized (March 1956). In 1957, when the monarchy of the bey of Tunis was abolished, Bourguiba was elected president by the unanimous vote of the constituent assembly. Bourguiba showed himself averse to violent solutions, preferring to attain his aims by diplomacy. In internal matters he favoured social reform; in foreign affairs he showed a marked preference for association with the west.

See TUNISIA: *Tunisian Nationalism*. (N. BA.)

BOURIGNON, ANTOINETTE (1616–1680), Flemish religious enthusiast, who believed herself to be the "woman clothed with the sun" (Rev. xii), was born at Lille on Jan. 13, 1616. She began life a Catholic, but took to self-imposed retirement, penance and mortification. Later she tried convent life and the management of an orphanage; both were failures because of her distrust of human nature and her harsh, autocratic disposition. She soon became convinced that she was directly illuminated by God for the reforming of things temporal and spiritual, and accordingly began to attack every form of religious organization.

She attracted many followers in the Netherlands and France, and especially in Scotland, where her doctrines were denounced by the Presbyterian general assemblies of 1701, 1709 and 1710. She died at Friesland on Oct. 30, 1680.

Her works, which exhibit a curious medley of opinions, were collected by her disciple, Pierre Poiret (1679), who also published her life (1679).

See A. van der Linde, *Antoinette Bourignon, das Licht der Welt* (1895); A. R. Macewen, *Antoinette Bourignon, Quietist* (1910).

BOURNE, FRANCIS (1861–1935), English cardinal, archbishop of Westminster, who, although lacking the personal magnetism of his predecessors, was a strong leader of Roman Catholics, pursuing policies he considered right for church and state, often in face of adverse criticism. He was born at Clapham, London, on March 23, 1861, and was educated at Ushaw college, St. Edmund's college, Ware, St. Sulpice in Paris! and Louvain university. (His book *Ecclesiastical Training* [1926] shows admiration for St. Sulpice and its methods.) After ordination in 1884, he worked at Blackheath, Mortlake and West Grinstead, before his appointment in 1889 as rector of St. John's seminary, £-onersh. In 1895 he became a monsignor and in 1896 coadjutor-bishop of Southwark. He was made archbishop of Westminster in 1903 and came into prominence in 1908 when the Blessed Sacrament procession he had planned through the streets during the Eucharistic congress was banned for fear of disturbances; he countered this by having the benediction given from the loggia of the cathedral. He became a cardinal in 1911, and from then on his influence grew, his patriotism finding full scope during the war. He championed the rights of the Arabs in Palestine, upheld Catholic claims in education, condemned violence in Ireland, denounced the general strike, reproved the modernists and was lukewarm toward the Malines conversations inaugurated by Désiré, Cardinal hiercier (q.v.) and Lord Halifax. He took the liveliest interest in university education, preferring Catholics to attend the national universities rather than to attempt to set up one of their own, and likewise favoured their joining existing political parties instead of forming a Catholic party. He opened many new parishes and favoured splitting up dioceses, if this made for greater progress. Cardinal Bourne died on Jan. 1, 1935.

See T. Hooley, *A Seminary in the Making* (1927); E. J. Oldmeadow, *Francis, Cardinal Bourne*, 2 vol. (1940–44). (J. W. DU.)

BOURNE, in physical geography, a variation of the term burn applied to small streams in Scotland, is the term applied to the intermittent streams that are common features of the chalk and limestone country of south England. Drainage there is slow, and after the land becomes saturated (as it does during the winter season) a heavy rain causes streams to develop where at other

times they do not occur. These are the winter bournes that appear as place names in the Salisbury Plains, Winterbourne Gunning being an example.

Bourne in the sense of boundary is a different word; the first use of it in English is in Lord Berners' translation of Froissart's *Chronicles* (1523). The word was used several times by Shakespeare, and the figurative meaning of limit or goal of a traveler comes from the well-known passage from Hamlet (1602), "the undiscovered country, from whose bourne no traveler returns."

BOURNEMOUTH, a parliamentary and county borough, and seaside resort, in the county of Southampton (Hampshire), Eng., 105 mi. S.W. of London by road. Pop. (1961) 153,965. Area 17.9 sq.mi. The present centre of the town occupies the valley of the Bourne, a little stream which goes past the pavilion rockery. The sandy beach of Poole bay is here backed by considerable sandstone cliffs scored with deep picturesque dells or chines. The town is of modern and remarkably rapid growth, though the site was occupied from prehistoric times. It is said that there was no house on the site when the Dorset squire Lewis Tregonwell, the founder of Bournemouth, paid a visit in 1810 before building a summer residence there. By 1841 Bournemouth consisted of 26 buildings including a church, a hotel, a boarding house and a library; the sheltered position and mild climate were beginning to attract attention. In 1851 the population was only 695, and in 1858 the only barber came from Christchurch twice weekly. A wooden pier was constructed in 1861 and, ten years after the railway came in 1870, a second pier was built. When the town was incorporated in 1890 the population had risen to 37,000. Suburbs rapidly extended inland and along the shore in both directions, much building having taken place after 1918 (when it became a parliamentary borough); e.g., at Pokesdown, Southbourne, Westbourne, Branksome Park and Canford Cliffs. The heath vegetation and pines which flourish in the sandy soil were largely replaced by houses, but the municipality checked further destruction by protecting existing trees and planting new ones. Hengistbury Head, a prehistoric site and the southern arm of Christchurch (q.v.) harbour, was added to the borough in 1932. Many new parishes were formed and churches built. The boundaries of the borough now include Boscombe, Pokesdown, Southbourne, Kinson and Holdenhurst. Bournemouth, with Christchurch, sends two members to parliament.

There are six miles of sandy bathing beach and five miles of promenade including Cndercliff drive. There are more than 1,400 ac. of public parks and pleasure gardens within the borough. Notable buildings include the pavilion (1929), the municipal college and central library (opened 1913), the winter gardens (originally built in 1876) which were opened as a new concert hall in 1917 and are the headquarters of the Bournemouth Symphony orchestra (established 1893), and the Russell Cotes art gallery and museum. There are also four theatres. Bournemouth is mainly a residential and resort town and has few industries apart from catering throughout the year for visitors and conferences. Its position halfway along the south coast of England, on the Hampshire-Dorset border, makes it a good centre for visits to Winchester, the New Forest, Salisbury, Wilton, Stonehenge, Shaftesbury, Cranborne, Yeovil, Dorchester and Lulworth cove.

Mary Shelley and her father and mother. William Godwin and Mary Wollstonecraft, are buried in the graveyard of St. Peter's church which also commemorates John Keble, an inhabitant of Bournemouth. Robert Louis Stevenson also lived in the town from 1884 to 1887.

BOURNONITE, a mineral sulfosalt containing antimony, lead and copper, of interest as an example of twinning and for the beautiful cross- and wheel-shaped crystallizations it affords. The crystals are orthorhombic and are generally tabular in habit. Usually the crystals are twinned on a face of the prism; the twinned individuals are nearly at a right angle, giving cruciform groups, and when often repeated the grouping has the appearance of a cogwheel. The mineral was first described from Cornwall in 1804 by the French mineralogist, comte de Bournon, after whom it was named. Because of its unusual appearance, it also has been known as wheel ore (Ger. *Rädelerz*.) It is opaque and has a bril-

liant metallic lustre with a lead-gray colour. The hardness is 2.5 and the specific gravity 5.8. The formula is $PbCuSb_3$.

(Cl. F.)

BOURNONVILLE, AUGUST (1805–1879), Danish dancer and choreographer, who directed the Royal Danish Ballet for nearly 50 years, was born in Copenhagen on Aug. 21, 1805. He studied under his father, Antoine Bournonville, before going to Paris for further training under Auguste Vestris and Pierre Gardel.

After appearances at the Paris Opéra and in London, Bournonville returned to Copenhagen in 1829. The following year he became virtual dictator of Danish ballet. In 1836 he staged his own version of *La Sylphide*, a ballet by Filippo Taglioni, with his pupil and protégée, Lucile Grahn, in the title role. *Le Toreador*, produced in 1840, had a Spanish theme, and *Napoli*, given in 1842, was based on his impressions of a trip to Italy. His *Konservatorzet* (1849) is the only surviving ballet to show classical dance exercises as practiced in the classroom in the early 19th century.

A strong dancer with excellent elevation, and an accomplished mime, he emphasized these qualities in his ballets. His influence on Danish style, technique and choreography has been deep and long-lasting. Many of his ballets, such as *Napoli*, *La Ventana*, *Kermesse i Brügge*, *Et Folkesagn*, *Konservatoriet* and *La Sylphide* have remained in the repertoire for more than a century.

From 1861 to 1864 Bournonville directed the Swedish Royal Opera, at Stockholm. He staged several of his works in Vienna in 1855–56. His international fame, however, has derived chiefly from increasing recognition of his choreographic genius as exemplified in revivals by the Royal Danish Ballet for tours and festivals, since 1950. He died on Nov. 30, 1879. (L.N. ME.)

BOURRÉE, a French name for a dance common in Auvergne and in Biscay in Spain; also a term for a musical composition or a dance movement in a suite, somewhat akin to the gavotte, in quick time with two beats to the bar.

BOURSAULT, EDMÉ (1638–1701), French man of letters, active in the literary world of mid-17th-century Paris, was born at Mussy L'Évêque, now Mussy-sur-Seine (Aube), in Oct. 1638. He composed light verse which appeared in the collection *Délices de la poésie galante* of 1663, engaged in journalism (editing a sequel to Jean Loret's gazette in 1665) and wrote plays, some of them polemic. He replied to Boileau's first *Satires* with a *Satire des satires*, written in 1666 and published in 1669. This was later recast as a play, the public performance of which seems to have been prevented by Boileau. One of his plays, *Le Médecin volant* (1661), used Molière's material and another, *Le Portrait du peintre* (1663), attacked *L'École des femmes*, provoking Molière to reply in *L'Impromptu de Versailles*. Other plays performed included *Le Mort vivant* (1662), *Les Nicandres ou les menteurs qui ne mentent point* (1664) and *Les Amours de Germanicus* (1673), one of the last plays to be acted at the Marais theatre. Boursault died in Paris on Sept. 15, 1701.

See H. Carrington Lancaster, *A History of French Dramatic Literature in the Seventeenth Century, part III. The Period of Molière, 1652–1672*, 2 vol. (1936); A. Adam, *Histoire de la littérature française au XVII^e siècle*, vol. 3 (1952). (W. G. ME.)

BOURSE: see STOCK EXCHANGE.

BOURSE, ESAIAS (1630–1673), Dutch painter, whose interiors with figures were painted with great precision and with exquisite quality of colour, was born in Amsterdam. He was a follower of Pieter de Hooch. His paintings are exceedingly rare; many of them pass under the names of Vermeer van Delft and Pieter de Hooch. Two of the paintings ascribed to the latter (one bears the false signature) at the Rijksmuseum in Amsterdam are now recognized as being the work of Bourse. The Wallace collection in London has his masterpiece, an interior with a woman and a child in a cradle, reflecting something of the feeling of Rembrandt, by whom he was influenced. Other important examples are at the Rijksmuseum and at Aix-la-Chapelle. "Boy Blowing Soap Bubbles" is in the Berlin museum.

BOUSSAC, MARCEL (1889–). French textile manufacturer, industrialist, race-horse breeder and owner, was born at Châteauroux on April 17, 1889. The second son of Louis Boussac,

draper and clothing manufacturer, he took over the family business at the age of 18. The great cotton industry that was to grow out of this relatively small beginning was built on two main factors: the organizing ability and business memory of its promoter and the principle of self-sufficiency in business (the Boussac organization, for example, became its own bankers and insurance brokers). While still at Châteauroux, his first master move was a mercileless war on the "black look" in France; its result was the introduction for the first time of colour into the clothes of the ordinary French family. In 1910, with the equivalent of £20,000 patrimony, he set up business in Paris in the traditional textile quarter of the city: no. 21, Rue Poissonnière, was later to become the nerve centre of the immense business organization known as Les Établissements Boussac. To prove his theory of "democratic luxury" he created, between World Wars I and II, the Toile d'Avion chain of stores in Paris. In the world of *haute couture* he launched the House of Dior in 1947. Boussac also manufactured domestic electrical equipment and acquired the Paris daily paper *L'Aurore*. Horse breeding and racing, his hobby, brought him world-wide fame on the turf. (P. W. HE.)

BOUSSINGAULT, JEAN BAPTISTE (1802–1887), French chemist and pioneer in agricultural research, was born in Paris and spent his early manhood in South America. On his return to France he held the chair of chemistry at Lyons, and then the chair of agricultural and analytical chemistry in Paris. His most important work, which was translated into other European languages, was *Agronomie, chimie agricole, et physiologie* (1860–74; 2nd ed., 1884). His writings included papers on the quantity of nitrogen in different foods, the amount of gluten in different wheats, investigations on the question of whether plants can assimilate free nitrogen from the atmosphere (which he answered in the negative), the respiration of plants, the function of their leaves, the action and value of manures, and similar subjects.

BOUSTROPHEDON, a term descriptive of a peculiar form of writing common among the early Greeks. The direction of writing was alternately right to left and left to right in horizontal lines, or conversely, left to right and right to left. It was a transition between the earlier right to left writing and the later left to right style. The term was derived from two Greek words meaning "ox," and "to turn," from the resemblance of the writing to the winding course taken by oxen in plowing. There is a variety, known as serpentine boustrophedon, in which the posture of the letters is inverted as well as the direction, with the result, in some letters, of canceling out the change of direction.

See J. Whatmough, *Prae-Italic Dialects*, pp. 222, 523 (1933).

(J. WH.)

BOUTENS, PIETER CORNELIS (1870–1943), one of the most outstanding of Dutch poets in a sublime and elevated style, a mystic and a classical scholar, was born at Middelburg on Feb. 20, 1870. He studied classical languages at Utrecht and established himself at The Hague as a private tutor and man of letters. His early poems were influenced by the aesthetic view of life and of "art for art's sake" held by the school of Dutch poets writing after 1883. Later, however, largely through his study of Plato, his own art developed in the direction of philosophical mysticism. In his collected volumes *Praeludiën* (1902), *Stemmen* (1907), *Carmina* (1912) and many others, he portrays in beautiful and symbolic language the eternal desire of the soul. His mastery of metrical forms and subtle intuition made him an ideal translator of Homer, Aeschylus, Sophocles, Plato, Goethe, Rossetti, Wilde and others. He also adapted the Persian poems by Omar Khayyam. Because of his participation in literary organizations Boutens was greatly esteemed and internationally known during his lifetime. He died at The Hague on March 14, 1943.

See D. A. M. Binnendijk, *Een protest tegen den tijd* (1945); H. J. C. Grierson, *Two Dutch Poets* (1936) which gives a short account of Boutens' work, and translations of some poems. (Gd. W. HS.)

BOUTERWEK, FRIEDRICH (1766–1828), German philosopher and literary critic, was born at Oker, in Lower Saxony, on April 15, 1766. He studied law at Göttingen but became a disciple of Rant in 1790 and published *Aphorismen, den Freunden der Vernunftkritik nach kantischer Lehre vorgelegt* in 1793.

Later, however, he abandoned the Kantian position, being dissatisfied with its formalism, and inclined to the views of F. H. Jacobi (see Jacobi's letters to him; Gottingen, 1868). Bouterwek became extraordinary professor of philosophy at Gottingen in 1797 and ordinary professor in 1802. He died at Gottingen on Aug. 9, 1828.

His chief works are *Ideen zu einer allgemeinen Apodiktik*, two volumes (1799); and *Geschichte der Poesie und Beredsamkeit seit dem Ende des 13. Jahrhunderts*, 12 volumes (1801-19), notable for its treatment of Spanish literature. Other works were *Aesthetik*, 2 parts (1806); *Lehrbuch der philosophischen Vorkenntnisse* (1810); *Lehrbuch der philosophischen Wissenschaften* (1813); novels, including *Graf Donamar*, three volumes (1791-93); and poetical compositions.

See G. Struck, *F. Bouterwek* (1919).

BOUTHILLIER (LE BOUTHILLIER), a French family, originally from Angoumois, that rose to prominence in the 17th century with the four sons of the advocate Denis Bouthillier (d. 1622), who were childhood friends of Armand Jean du Plessis, the future cardinal de Richelieu. These sons were: Claude (see below); Denis, whose son Armand Jean, abbé de Rancé (*q.v.*), was the founder of Trappist monasticism; Sébastien, bishop of Aire from 1622 to 1625; and Victor, bishop of Tours from 1640 to 1670.

CLAUDE BOUTHILLIER (1581-1652) was one of Richelieu's principal adjutants. Secretary of state from 1628, he became superintendent of the finances jointly with Claude de Bullion in 1632 and sole superintendent in 1640. In this capacity he canceled a large class of exemptions from the *taille*, but he used his influence on several occasions to help individuals in disgrace or misfortune. He was especially valuable as a mediator between Richelieu and members of the royal family, as Richelieu could not always rely even on Louis XIII's support. Richelieu made him an executor of his will, and in Louis XIII's will he was nominated a member of the regency council. When this will was annulled, he resigned the superintendence (June 1643). He died in Paris on March 13, 1652.

LÉON BOUTHILLIER (1608-52), comte de Chavigny, was Claude's son. Designated secretary of State in 1632, he was in 1635 also made chancellor in the household of Gaston, duc d'Orléans, to watch over his conduct. Nominated, with his father, to the regency council in Louis XIII's will, he bitterly resented Jules Mazarin's monopoly of Anne of Austria's favour when she became sole regent and he was deprived of his secretaryship of state. Governor of the château de Vincennes, he was arrested there in Sept. 1648 as dangerous to the government, but the *parlement* of Paris took up his case as an example of arbitrary arrest and he was released in October. In the Fronde (*q.v.*) he was one of the prince de Condé's advisers against Mazarin, and in April 1651, during Condé's predominance, Anne made a show of taking Chavigny as prime minister. By July, however, he no longer dared to present himself at her council. As Condé's fortunes declined, Chavigny made secret overtures to Mazarin. Condé, hearing of these during the Fronde's last days in Paris, furiously reproached Chavigny, who, shocked and chagrined, fell ill and died (on Oct. 11, 1652).

(J. G. R.-S.)

BOUTS, DIERICK (DIRK, DIERIC, THIERRY; last name sometimes given erroneously as STUERBOUT) (*c.* 1400-1475), painter of the early Netherlandish school, was born at Haarlem where he was probably active for a number of years before going to Louvain in 1445(?). As some of the early works show the influence of Rogier van der Weyden, he may have worked at Brussels before settling in Louvain. From 1457 his name appears almost every year in the archives of Louvain up to his death in that city on May 6, 1475. No authentic works of this master are known, both painted toward the end of his life. One was ordered by the Confraternity of the Holy Sacrament for the church of St. Peter at Louvain in 1464. The picture is a triptych whose wings are divided into two smaller panels, one above the other. The central panel represents the "Last Supper," and the artist seems to have introduced his own portrait and that of his sons in the background. On the wings are shown four scenes from the Old Testament foreshadowing the Holy Sacrament; *i.e.*, the "Feast of the Passover," "Elijah in the Desert," the "Gathering of Manna,"

"ELIJAH IN THE DESERT" FROM THE WINGS OF THE TRIPTYCH OF THE "LAST SUPPER" BY DIERICK BOUTS. 1464-67. AT THE CHURCH OF ST. PETER, LOUVAIN, BELG.

and "Abraham and Melchisedek." The other authentic work is a series of four huge panels, which the artist undertook for the town hall at Louvain. He only completed one of these and died before the completion of the second. These two pictures are now in the Brussels gallery. They represent an episode from the legend of the emperor Otto III.

These works reveal a master of harmonious colour schemes, a landscape painter who placed his figures in three-dimensional spaces, correctly constructed according to the rules of perspective. He observed nature closely and his drawing as a portraitist was precise and full of character. His rendering of human anatomy was primitive and his compositions were somewhat angular, lacking the grace which his contemporary Rogier van der Weyden gave to his pictures. Probably Bouts's earliest extant painting is the little altarpiece at Madrid representing the "Annunciation," the "Visitation," the "Nativity" and the "Epiphany." Then comes the large triptych in the cathedral at Granada representing the "Descent from the Cross," the "Crucifixion" and the "Resurrection," a copy of which is in the Colegio del Patriarca at Valencia. Other early works are: the "Entombment" (on canvas) in the National gallery, London, and the "Pietà" in the Louvre, Paris. The following works were probably painted after the move to Louvain: "Moses and the Burning Bush" in the Johnson collection at Philadelphia; the "Virgin Enthroned between St. Peter and St. Paul" in the National gallery; the triptych in Munich, known by the name of "The Pearl of Brabant," representing the "Adoration of the Magi," "John the Baptist" and "St. Christopher"; a pair of panels, probably the wings of a triptych of the "Last Judgment," both at Lille, representing respectively Paradise and Hell; and the triptych of the "Martyrdom of St. Erasmus" at St. Peter's, Louvain. Of several versions of the half-length figure of the "Madonna Holding the Child," the one in the National gallery is among the finest. Of portraits the most notable is in the National gallery, dated 1462, and believed by some to be a self-portrait.

The Altman collection in the Metropolitan museum, New York, and the Friedsam collection in the same museum, also contain a portrait.

After his death his two sons, Albert and Dierick, carried on his tradition in Louvain.

BOUTS-RIMÉS, "rhymed line-endings," is the name given in European literatures to the making of a verse with a modicum of sense in it from given end-rhymes in a given order. *Bouts-rimés* are said to have been invented by the minor French writer Dulot in the 17th century. Alexander Dumas (*père*) invited French poets and versifiers to try their skill with given sets of rhymes and he published 150 of the results in 1865. Dante Gabriel Rossetti and William Rossetti improved their ingenuity and rhyming facility by filling in verses from *bouts-rimis*, and the former is said to have been able to produce a "sonnet" in from five to eight minutes. (J. W. T.)

BOUTWELL, GEORGE SEWALL (1818-1905), U.S. statesman. was born in Brookline, Mass., on Jan. 28, 1818. He was reared on a farm but at an early age entered upon a mercantile career at Groton, Mass. There he studied law but was not admitted to the bar until 1862. He served as a Democratic leader in the lower house of the state legislature in 1842-44 and again in 1847-50. With the help of "Free-Soil" votes he was elected governor of Massachusetts in 1851 and 1852. The passage of the Kansas-Nebraska act in 1854 finally alienated him completely from the Democratic party; thereupon he became one of the founders of the new Republican party in the state. He played an influential role in the Republican national convention of 1860, and two years later, after passage of the war tax measures, he was appointed the first commissioner of internal revenue by President Lincoln. He was a member of the national house of representatives from 1863 to 1869, and in 1867 acted as one of the radical Republican managers of President Johnson's impeachment trial. He served as secretary of the treasury in President Grant's cabinet in 1869-73 and as U.S. senator from Massachusetts in 1873-77. Under an appointment by President Hayes he prepared the second edition of the *United States Revised Statutes* (1878). As a vigorous opponent of the acquisition of the Philippine Islands by the United States, he became president of the Anti-Imperialistic league and a presidential elector on the Democratic ticket in 1900. He died at Groton, Mass., on Feb. 27, 1905. He published various volumes, including *The Constitution of the United States at the End of the First Century* (1895) and *Reminiscences of Sixty Years in Public Affairs* (1902). (N. A. G.)

BOUWARDIA, a genus of 30 species of handsome, evergreen, greenhouse shrubs, belonging to the family Rubiaceae, mostly native; of tropical America. The flowers are in terminal, many-flowered, flat clusters; the corollas are tubular, with a spreading four-lobed limb. The cultivated kinds are mostly of hybrid origin: the first was crossed at Parsons nursery, Brighton, Sussex, about 1837. Since then many different horticultural forms have originated, some of them fragrant and once very popular florist's flowers. In the United States *B. humboldtii*, a beautiful fragrant white-flowered shrub from Mexico, is widely grown for the florist trade, as is the red-flowered *B. ternifolia*. Usually forced for winter bloom, they need a warm greenhouse and rich soil. (N. Tr.)

BOUVIER, JOHN (1787-1851), U.S. jurist, was born in France in 1787. In 1802 his family emigrated to the United States, settling in Philadelphia. Bouvier became a citizen of the United States in 1812 and was admitted to the bar in 1818. He is best known for his able legal writings. His *Law Dictionary Adapted to the Constitution and Laws of the United States of America and of the Several States of the American Union* (1839, revised and brought up to date by Francis Rawle, under the title of *Bouvier's Law Dictionary*, 1897), has always been a standard later editions

of which were issued in 1916, 1926 and 1934. He died in Philadelphia on Nov. 18, 1851.

BOUVINES, BATTLE OF, a decisive victory won at Bouvines, a village in Flanders south of Lille and west of Tournai, on July 27, 1214, by the French under King Philip II Augustus over the forces of the coalition formed against him. This coalition, grouped round the emperor Otto IV and King John of England (who was desirous of reconquering the French provinces that he had lost to Philip), comprised several French vassals displeased by Philip's policy, particularly Raynald (Renaud), count of Damartin and of Boulogne, and Ferdinand, count of Flanders.

The plan of campaign had been minutely designed by the coalition. In the south, after landing at La Rochelle, John was to stir Aquitaine and Anjou to revolt and then to march against Paris. Meanwhile, from the north, the imperial army, reinforced with Flemish militia, a contingent of English mercenaries and the troops of Raynald and Ferdinand, likewise would march on Paris.

The first part of this plan collapsed when John was defeated at La Roche-aux-Moines early in July 1214. Thereafter Philip had greater freedom of action and resolved to take the offensive.

Otto, who had failed to synchronize his invasion of France with John's in the spring, was entrenched at Valenciennes. Philip, instead of moving straight at Otto through Douai, moved round to the northward of him through Lille and Tournai. But on reaching Tournai, Philip realized that Otto, aware of his movement, had made his troops march on to Mortagne at the junction of the Scarpe and the Scheldt, a fortified place, quite unassailable. Philip then moved again toward Lille. The imperial forces attacked the rear of the French when the vanguard had just crossed the Marcq at the bridge of Bouvines. Both armies then secured their positions on the highest part of the plateau. The left wing of the imperial army was composed of Ferdinand's Flemish troops, its centre of Germans under Otto's command, and its right wing of Raynald's knights and the English mercenaries under William Longsword, earl of Salisbury. On the French side, the king was in the centre, supported by his picked cavalry, with Guillaume de Barres; on his left his brother Robert commanded, on his right the military churchman Guérin, bishop of Senlis.

It was on the French right that the attack was launched, and the Flemish corps was completely disorganized after three hours. In the centre, however, the French *milices des communes*, weary of their march and of being drawn up in battle array, were encircled by the imperial infantry and knights. Philip himself was unhorsed, but was eventually extricated from serious danger. Guillaume de Barres, getting round the German cavalry, reached the emperor, who fled from the field. Lastly, on the left of the French, Raynald held out fiercely against the attack until he was captured. The French king's victory was then complete: Raynald and Ferdinand were his prisoners and the fugitive Otto was no longer able to resist the claims of his rival, Frederick II, to the empire. The battle marks the acme of the reign of Philip Augustus.

See C. Oman, *History of the Art of War in the Middle Ages*, vol. i (1924); F. Lot, *L'Art militaire et les armées au moyen âge en Europe et dans le Proche Orient*, vol. i (1946). (M. Pac.)

BOVET, DANIEL (1907-), naturalized Italian pharmacologist, was awarded the Nobel prize for physiology and medicine in 1957 for his production of a synthetic form of curare (the substance used by South American Indians to poison the tips of their arrows), which proved of great use in inducing muscular relaxation in surgical operations. Born in Neuchâtel, Switz., of French parents on March 23, 1907, Bovet studied in Geneva, and, from 1932, at the Pasteur institute in Paris where he became head of the laboratory for therapeutical chemistry in 1937. In 1947 he was appointed head of the pharmacological section of the Istituto Superiore di Sanita in Rome.

Bovet was responsible for a series of discoveries in chemical pharmacology which led to important advances in medical practice. By his work on sulfanilamide (1935-37), on aryloxyethylamine derivatives, and on anilino-ethyl-diethylamine he opened the way to the discovery of the important antihistamine drugs, of which mepyramine (1944) was his own outstanding achievement. In 1947 his investigations into synthetic substitutes for tubocurarine

led to his discovery of gallamine triethiodide, and in 1949 he produced suxamethonium iodide, a useful short-acting drug. These discoveries had a revolutionary effect on anesthetic practice.

BOVIANUM, the name of two ancient Italian towns.

BOVIANUM UNDECIMANORUM (modern Boiano, 11 mi. S.W. of Campobasso in the *regione* of Abruzzi e Molise) was the chief city of the Pentri Samnites, on the road from Beneventum to Corfinium. Remains survive both of the lower Roman town and of the upper Samnite city, where there are walls of the type of masonry known as Cyclopean. Both the Roman and the modern town lie on the plain. Bovianum was captured by Rome about 311 B.C. during the second Samnite War (328–304) and was temporarily the capital of the Italians in the Social War (90–89 B.C.), after which Sulla reduced it to a village. In the 1st century A.D. it became a colony for the veterans of the 11th legion (Undecima), whom Vespasian settled there; hence its name Undecimanorum.

BOVIANUM VETUS (near the modern Pietrabbondante, 5 mi. S. of Agnone and 19 mi. N.W. of Campobasso), the chief town of the Caraceni Samnites, was conquered by Rome in 298 B.C.

BOVIDAE, a family of the mammalian order Artiodactyla comprising cattle, sheep, goats, antelopes and other even-toed hoofed ruminants with hollow unbranched horns. Horns, always present in males and commonly in females, consist of a horny sheath covering a bony core that is a fixed part of the skull. Unlike the antlers of deer, the horns of Bovidae are never shed. Bovids are essentially grazing animals, but many are browsers as well. The family originated between 20,000,000 and 25,000,000 years ago in Europe or northern Asia and spread over most of the northern hemisphere during the Pleistocene. Africa now is headquarters of the family. Asia is also well-stocked with Bovidae. Few forms survived in Europe and a few, the bison, musk ox, mountain sheep and mountain goat, moved into North America.

The subfamily Bovinae includes the domestic cattle, or oxen; the extinct European aurochs, which were ancestral to modern cattle; the domesticated Indian zebu; the southern Asiatic gaur, gayal and banteng, the last two existing in wild and domestic states; the pygmy buffaloes of the Philippines and Celebes; and true buffaloes, of which there are a number of wild and domestic forms in Africa and southern Asia. Remnants of the North American bison or "buffalo" and its near relative, the European wisent, still survive in parks and special refuges. All bovines are large and heavy bodied. The horns, which are present in both sexes, are rather smooth and are placed well behind the eyes with their bases projecting outwardly to the sides of the head.

The African subfamily Strepicerinae includes the kudu, bushbuck, nyala, bongo and the tallest of antelopes, the eland. The horns of strepicerines are more or less twisted and project upward and to the back of the head; facial markings and transverse body stripes are usually present. Two Indian relatives of this group are the nilgai and the small duikerlike four-horned antelope.

African duikers form another subfamily, the Cephalophinae. Duikers are small- to medium-sized antelopes with short spikelike horns and well-marked odoriferous facial glands that produce a strong-smelling secretion in males.

The Reduncinae includes the waterbuck, kob, lechwe, reitbok and rehbok, all African. The horns, confined to males, are strongly annulated (ringed) and curve back before turning upward. The end of the muzzle (muffle) is naked; facial glands are small or absent.

The Hippotraginae includes the sable and roan antelopes of the genus *Hippotragus*, characterized by long scimitar-shaped horns, and four species of *Oryx*, of which the gemsbok, beisa and algalz are African, while the beatrix oryx is confined to Saudi Arabia and Iraq. The addax is an African hippotragine with twisted horns.

The Alcelaphinae is African. Males and females bear lyre-shaped horns. In the hartebeest, topi, blesbok and sassaby, the horns rise above the head. In the gnu they are curved against the head.

The Antilopinae comprises moderately sized antelopes with compressed lyrate or recurved horns or cylindrical and spiral horns. The muffle is hairy, facial and interdigital odoriferous glands are

present and the cheek teeth are narrow as in goats. Members of the group include the Indian black buck, the African and Asiatic gazelles and the African springbok, gerenuk, dibatag and impala.

Several small African antelopes of uncertain affinities but with large facial glands and rather short, straight horns are sometimes classified with the Antilopinae. One of these antelopes, the little klipspringer, stands on the very tips of its toes in walking and jumping from rock to rock and along the face of sheer cliffs. Another, the oribi, is a plains dweller characterized by a naked area beneath each ear. Others are the steinbok, which lacks dewclaws, and the dik-dik, a tiny antelope with thickened muzzle, hairy muffle and short horns.

Another heterogenous group of bovids are the so-called goat antelopes. Most of them resemble each other more in habitat preferences than in anatomical characters. In many respects, however, they stand between true antelopes on the one hand, and goats and sheep on the other. Included are the Asiatic goral, serow and chiru, the southern Russian saiga, the chamois of Europe and Asia Minor and the North American Rocky Mountain goat.

True goats and sheep compose the subfamily Caprinae. In goats, horns are pear-shaped in outline at the base and curve backward or are spirally twisted. Facial glands are absent, the muffle is hairy, a beard is usually present and males have a strong odour. Wild and domestic forms of the common goat, the tahr, ibex, tur, markhor, bharal, udad and takin are included in the goat tribe. The sheep tribe is distinguished by the absence of beard, the presence of small facial glands, absence of strong odour in the males, and horns that are triangular in outline at the base and curve backward or, when fully developed in males, backward and downward with the tips everted. Wild sheep include the mouflon, argali and Rocky Mountain sheep. The arctic musk ox may be related more closely to true bovines than to sheep and goats but the animal is generally classified with the Caprinae.

See **ARTIODACTYL** and also the separate articles on the various members of the Bovidae. See also references under "Bovidae" in the Index volume.

(PH. H.)

BOVILLAE (near the modern Frattocchie, 12 mi. S.E. of Rome in the Italian *regione* of Lazio) was an ancient town of Latium and a station on the Via Appia. It was a colony of Alba Longa and one of the 30 cities of the Latin league. After the destruction of Alba Longa about 600 B.C., the religious cults associated with the Latin league were transferred, according to tradition, to Bovillae, including the cult of Vesta and that of the *gens Julia* or family of Julius. In inscriptions found at Bovillae, moreover, "Alban Vestal virgins" are mentioned, and in imperial inscriptions the inhabitants of Bovillae are called *Albani Longani Bovillenses*. The cult of the *gens Julia* made Bovillae important when the family rose to power under Julius Caesar. In A.D. 16 the shrine of the family worship was dedicated anew and yearly games in the circus were instituted. Bovillae was the scene of the murder of P. Clodius Pulcher by Milo in 52 B.C.; Clodius had a villa above the town, to the left of the Via Appia. Remains of buildings of the imperial period—the circus, a small theatre and edifices probably connected with the post-station—still may be seen southwest of the Via Appia.

BOW AND ARROW. The bow is one of the oldest of all projectile weapons and exists in great variety, some nations, especially in Asia, having evolved special forms with great skill and ingenuity. Bows could be made of one material, generally a stave of wood (self bow), or of more than one piece of the same material joined together (built bow), or of several materials, such as wood, horn and sinew glued together (composite bow).

Self bows are thicker in the middle (called the handle) where held by the bowman's hand and taper toward the tips, which are notched to hold the string looped over them. The arrow is fitted to the string by its head which has a "nock" (notch) and is then drawn back, bending the bow until a maximum tension is produced, whereupon it is released. Arrow heads of great antiquity have been found in many countries where specimens of bows have not survived: many possible arrow heads of knapped flint, roughly shaped, have been found dating from Paleolithic times, and others, finely finished, from Neolithic times.

The bow is mentioned several times by Homer, and in the Old Testament Ahab met his death when a man "drew his bow at a venture, and struck the king of Israel between the joints of his harness." Rameses II, pharaoh of Egypt, and Ashurbanipal, king of Assyria, are represented on stone carvings as shooting their bows from chariots. The Romans were not great archers.

In Europe the bow usually took the form of the self bow and was at first short, being drawn to the chest only. Very few English bows have survived but a few were recovered from the wreck of the "Mary Rose" sunk in 1545. A bow dug up on the site of Berkhamsted castle, Hertfordshire, and now in the British museum, London, almost certainly dates from the dauphin of France's siege of 1216.

It is to Wales that the origin of the English longbow is usually accredited. The longbow was as tall as a man and the arrow about half that length, the famous cloth-yard shaft. The bow was held with outstretched arm and the arrow drawn back to the bowman's ear. An English archer could shoot six aimed shots a minute and his effective range was about 200 yd., though an arrow could go twice as far in the right hands. Yew trees were planted with official encouragement and the making and sale of bows was strictly supervised. The best bows were made of yew, but they were also made of witch hazel, hickory, ash and elm. The arrows were feathered (fledged) as a rule with goose feathers, though peacock feathers were sometimes used for gayness. In England the bow was superseded by firearms during the 16th century.

In Europe the crossbow (*q.v.*) was preferred to the longbow; its use did not require the same physique or training and its range was greater. The crossbow consisted of a short bow mounted horizontally on a stock or tiller, leveled to the shoulder when aiming. It was more powerful than the longbow, but slower to load. In its simplest form the crossbow had a bow of wood and was drawn (spanned) by muscular tension, the bowman placing his foot in a stirrup fixed to the middle of the bow and drawing the string upward by hand. The crossbow with composite bow was much stronger and more effective. Made of layers of horn and wood glued together and covered with parchment, it was bent mechanically by a goat's foot lever or by a rack and is traditionally the bow used by William Tell. Crossbows are often richly decorated and were much used for shooting game. The windlass crossbow was the largest and most complicated and was more often used in siege warfare than in the field. It is still used for target shooting.

The prod or stonebow, a light crossbow which shot small bullets from a pocket in the centre of the string, was used solely for hunting and was still being made in Lancashire as late as the middle of the 19th century. A less important variety was the slurbow, where the shaft is guided within a barrel set along the tiller with slits along the sides for the string. The Saracens of Spain devised a very small crossbow of steel which could be concealed in the user's sleeve and was sometimes spanned by means of a screw in the base of the stock. In contrast certain countries developed very large bows; the archer lay on his back holding the bow horizontally and placing both feet in the middle.

Composite bows were used throughout Asia, the basic materials being horn and sinew, as the right kind of wood was not available in sufficient quantity. The Turks made some of the best bows ever fashioned: short and with the curve of the bow reversed, they shot light arrows very great distances and some specimens are signed and dated. The Japanese built bows are also of a high class, some of them being very long, even to the height of 8 ft., but they also made small bows of horn or whalebone. The Japanese examples of good quality are sometimes signed by the maker. The accessories to the bow, such as the bow case and quiver, are often elaborately decorated.

The natives of the Andaman Islands in the Bay of Bengal produced very large and broad bows. The bow in Africa was generally small, partly because it was not used as a rule in open country. The Eskimos used composite bows of wood and bone backed by sinew, very similar to the Asian bow. Bows were also used by the natives of Polynesia and New Zealand, but not by the Australian aborigines. The North American Indians used bows before they

were introduced to firearms, their bows being either self bows or of wood backed by sinew.

The bowstring varies in material and in the way in which it is fastened to the bow. The English longbow usually had one of linen or hemp. Eastern bows were often strung with silk, spun or unspun, or mohair. Dwellers in warm, well-forested parts use a strip of rattan or bamboo, or a worked string of some vegetable fibre, but animal sinew or a strip of hide is widespread, especially with the Asiatic bow. Rattan or bamboo strings, being intractable, are often attached indirectly to the stave by a separate flexible loop, but with other bowstrings direct attachment is more common, the string being threaded through a hole in the bow, secured by a firm lashing, or looped over the ends and stopped from slipping by a shoulder, notch or other projection.

Arrows were governed by the bows from which they were shot: the English longbow had a wooden arrow; in Melanesia and elsewhere the pointed heads of the cane arrows were dipped in poison; the crossbow bolt or quarrel was much shorter than that of the longbow and was flighted with strips of leather or light wood rather than feathers. An arrow may be made all in one piece, a wooden stick with one end pointed and hardened in the fire, or it may be composed of two pieces, a shaft of reed, cane or light wood with a heavier sharpened foreshaft. More commonly a separate head of stone, bone, shell, metal, etc., is fixed to the shaft or foreshaft. The head may be tanged or socketed and fixed by lashings or cementing or both; the head can be made loose so that it stays in the wound when the shaft is extracted. Feathers or bits of leaf, leather or fur are added to light arrows to steady the flight, but arrows with heavy foreshafts are occasionally unfeathered. The steel points of arrows show a great variety of design, some being broad and flat with large barbs and others being crescent-shaped for the decapitation of birds. The head of the crossbow quarrel is usually small, solidly made and of polygonal section.

The arrow may be loosed in various ways. The easiest release is by holding the butt end of the arrow between the index finger and thumb and pulling the bowstring back with it. In the secondary release the arrow is still held by the index finger and thumb, but the other fingers help in pulling the string. In the so-called Mediterranean release the thumb takes no part; the nocked arrow is fitted to the string, which is drawn by the fingers. This is the loose of modern archers, as well as some of the most primitive peoples, the Vedda and the Eskimo, and it occurs in a modified form in the Andaman Islands. The Mongolian release is the opposite. Here the fingers are idle (save for steadying the arrow) and the thumb alone, protected by a ring or glove, does the work. This is universal in Asia and parts of Africa, and some of the oriental drawing-rings of ivory, jade and precious stones are of great beauty. See ARCHERY. See also references under "Bow and Arrow" in the Index volume.

BOWDICH, THOMAS EDWARD (1791–1824), English traveler and author who prepared the way for the opening-up and annexation of the Gold Coast in Africa, was born at Bristol on June 20, 1791. In 1814 he became a writer for the African Company of Merchants, stationed in the Gold Coast at Cape Coast. In 1817 he went to Kumasi as the scientific member of a mission to Ashanti where he conducted negotiations so successfully that the way was prepared for the commercial opening-up of the interior. His *Mission From Cape Coast Castle to Ashanti* (1819, reissued in 1873), the earliest account of Ashanti by a European,

BOWS AND ARROWS OF THE WORLD

gave fascinating details of the kingdom of Ashanti at the height of its splendour. He gave his collections of African works of art, insects and reptiles to the British museum. On his return Bowditch publicly attacked the management of the Africa committee and was in considerable measure responsible for the British government's decision to abolish the company and take over the administration of the Gold Coast in 1821. Between 1820 and 1822 Bowditch lived and studied in Paris, where he mixed freely with Georges Cuvier, Alexander von Humboldt and other scholars. He left Paris to undertake a trigonometrical survey of the Gambia, but soon after his arrival he was taken ill, and died of fever at Bathurst on Jan. 10, 1824.

Bowditch published several papers, including an *Essay on the Geography of North-Western Africa* (1821) and an *Essay on the Superstitions, Customs, and Arts Common to the Ancient Egyptians, Assyrians, and Ashanties* (1821). (R. W. SL.)

BOWDITCH, NATHANIEL (1773–1838), American mathematician and astronomer whose works on navigation are among the most useful ever written, was born at Salem, Mass., on March 26, 1773. He made four long voyages (1795–99) and, being an excellent navigator, commanded a vessel (1802), instructing his crews in lunar and other observations. He edited J. H. Moore's *The Practical Navigator* and in 1802 published the *New American Practical Navigator*, based on Moore's work, which was adopted by the U.S. navy department and went through numerous editions. Bowditch also undertook a translation of P. S. Laplace's *Mécanique céleste*. He later refused professorships at several universities and died at Boston on March 16, 1838.

BOWDLER, THOMAS (1754–1825), English "purifier" of Shakespeare for family reading, was born at Ashley, near Bath, on July 11, 1754. After years spent in medicine, travel, philanthropic work and some study of the education of children, in 1818 he produced *The Family Shakespeare*. The Shakespeare, which went through four editions before 1824, omitted "those words and expressions . . . which cannot with propriety be read aloud in a family" because of their indecency or impiety. Attacked by the *British Critic* (1822), Bowdler argued that words exciting "an impression of obscenity" were not to be spoken, written or printed; and if printed they "ought to be erased." An expurgation of Gibbon's *History* (1825), earlier selections from the Old Testament (1822) and his promotion of the Proclamation society against impiety and vice show the same bias. The word "bowdlerize" was first used in print in 1836 and has become a term of abuse. It is questionable, however, whether Bowdler did as much harm as the "adaptors" of Shakespeare (then still staged) or even the generally accepted Lamb's *Tales*. He died at Rhyddings, south Wales, Feb. 24, 1825. His dates are worth stressing, for he is often thought to be typically Victorian. (G. A. O.)

BOWDOIN, JAMES (1726–1790), political leader of Massachusetts during the era of the American Revolution. He was born in Boston of French Huguenot descent on Aug. 7, 1726, and graduated from Harvard in 1745. A merchant by profession, he also had a distinguished career as a public official. He was a member of the Massachusetts general court (1753–56) and of the council (1757–74, 1776–77). He was delegate to the first continental congress in 1774, president of the constitutional convention of Massachusetts, 1779–80, member of the state convention to ratify the federal constitution, 1788, and governor of Massachusetts, 1785–87. During the revolutionary crisis, he boldly spoke out for American independence and worked closely with such popular leaders as Samuel Adams (*q.v.*) and James Otis (*q.v.*). He published important papers stressing the economic advantages to be enjoyed by a free America. In the critical post-Revolutionary period, he was a stabilizing force in Massachusetts political life. As governor, he took prompt action to suppress Shays' rebellion.

A man of wide cultural interests, Bowdoin was a prominent scientist whose specialties were physics and astronomy. He wrote numerous scientific articles (including one on electricity in collaboration with Benjamin Franklin) and corresponded with many notable American and English scientists. He was a founder of the American Academy of Arts and Sciences (1780) and served as its first president. He was a member of several other learned societies,

including the famous Royal Society of London, and the recipient of honorary degrees from Harvard and the University of Edinburgh. He died in Boston on Nov. 6, 1790. Bowdoin college in Maine was named in his honour. (L. L. Tu.)

BOWEN, CHARLES SYNGE CHRISTOPHER BOWEN, 1ST BARON (1835–1894), a great English appeal judge, was born on Jan. 1, 1835, at Woolston, Gloucestershire, the son of a clergyman. From Rugby he went to Oxford and became a fellow of Balliol in 1857. He was called to the bar at Lincoln's Inn in 1861. Soon after he had begun to make his mark he was briefed against the claimant in the famous "Tichborne case," both in the civil and criminal trials. Bowen's services to his leader, Sir John (afterward Lord) Coleridge, in the former helped to procure for him the appointment of junior counsel to the treasury when Sir John was attorney general. In 1879 his acceptance of a judgeship in the queen's bench division gave him leisure. His subtle intellect and gentle irony were wasted upon common juries; but when, in 1882, he was raised to the court of appeal he was more at home. In Aug. 1893, Bowen was made a lord of appeal. But his health had broken down; he never sat to hear appeals, and he gave but one vote as a peer; his last public service was to preside over the commission which sat in Oct. 1893 to inquire into the Featherstone riots. He died on April 10, 1894.

Lord Bowen's judicial reputation rests upon the decisions delivered by him in the court of appeal, which are remarkable for their lucid interpretation of legal principles as applied to the facts and business of life and the advice given to the house of lords. He made translations of Virgil's *Eclogues*, and of the *Aeneid*, books i–vi, and his pamphlet, *The Alabama Claim and Arbitration Considered from a Legal Point of View*, showed that even in a legal discourse he was still a lover of style.

Sre Sir Henry Stewart Cunningham, *Lord Bowen* (1897).

BOWEN, NORMAN LEVI (1887–1956), U.S. geologist, was one of the great pioneers in experimental petrology, particularly in the field of phase equilibrium studies on silicate systems. Born in Kingston, Ontario, on June 21, 1887, he was educated at Queen's university, Kingston, and the Massachusetts Institute of Technology, Cambridge. He joined the Geophysical laboratory of the Carnegie institution of Washington, D.C., in 1912, serving in a research capacity until he retired in 1952, except for his occupancy of the chair of mineralogy at Queen's university, 1919–20, and of the chair of petrology at The University of Chicago, 1937–47. His memoir *The Evolution of the Igneous Rocks* (1928), with its emphasis on a physicochemical approach to problems of petrogenesis, came to exert a profound influence on petrologic thought in the ensuing decades. He initiated on his return to Washington in 1947 a program of study on silicate systems with volatiles, particularly water. These researches contributed greatly to the understanding of the origin of granite and to problems of metamorphism, to which subject his earlier work at Chicago on the progressive metamorphism of siliceous limestones and dolomites had made a great advance. He died in Washington on Sept. 11, 1956. (C. E. T.)

BOWER, FREDERICK ORPEN (1855–1948), English botanist, known for his research and publications on the Pteridophyta, particularly the ferns, was born at Ripon, Yorkshire, on Nov. 4, 1855. He was educated at Repton and at Trinity college, Cambridge, and later at the universities of Würzburg and Strasbourg. In 1882 he became lecturer in botany at the Royal (now Imperial) College of Science, London, where he was associated with Thomas Huxley. In 1885 Bower was appointed regius professor of botany at the University of Glasgow, a post he held until his retirement in 1925. Bower was one of the principal exponents of the "antithetic" or "interpolation theory" of alternation in the life cycles of Pteridophyta. His principal works include *The Origin of a Land Flora* (1908); *The Ferns*, 3 vol. (1923–28); *Size and Form in Plants* (1930); and *Primitive Land Plants* (1935). His many distinctions included the Linnaean medal (1909) and the Royal medal and Darwin medal of the Royal society (of which he was a fellow). Bower was president of the Royal Society of Edinburgh (1919–24) and of the British association (1930). He died on April 11, 1948. (J. Wn.)

BOWER, WALTER (1385–1449), Scottish chronicler and abbot of Inchcolm, in the Firth of Forth, author of the *Scotichronicon*, the first connected attempt at a history of Scotland, which expanded and continued the work of John of Fordun (*q.v.*), was born at Haddington. Bower probably entered religion at St. Andrews, and may earlier have taken degrees in theology at Paris. He was provided to his abbacy in 1417 and thereafter is frequently named in papal and royal records, as an unsuccessful claimant of the abbacy of Holyrood (1420), as an opponent of peace with England (1432) and as present in parliament and acting as its auditor. His care for the records of his abbey is responsible for their partial preservation. The *Scotichronicon* was undertaken at the instigation of his patron, Sir David Stewart of Rosyth, in 1441, and finished in 1447, the last date mentioned in it. Even when he leaves fabulous history, Bower is not entirely reliable, but without his 16 books (of which five and part of the sixth at least are the work of Fordun, with Bower's alterations and interpolations) the history of Scotland in the 13th and 14th centuries would lack many familiar landmarks. He is known to have used Andrew Wyntoun (*q.v.*), as well as Fordun. First printed by T. Hearne (1722), and then by W. Goodall (1759), from late 15th-century manuscripts, it exists in a number of copies. The manuscript at Corpus Christi college, Cambridge, appears to be the author's manuscript. The work was edited, with translation, by W. F. Skene in *The Historians of Scotland*, vol. i and iv (1871–72). (A. A. M. D.)

BOWERBANK, JAMES SCOTT (1797–1877), English naturalist and paleontologist, whose studies on the history of sponges is especially noteworthy, was born in Bishopsgate, London. Until 1847 he was an active partner in the family business (a distillery) but kept his interest in natural science. About 1836 he and six others founded "The London Clay club." His *A History of the Fossil Fruits and Seeds of the London Clay* appeared in 1840. Bowerbank was the originator of the Palaeontographical society. His great work, *Monograph of the British Spongiadae* (1864–82), except for the last plate, was completed shortly before his death, March 8, 1877.

BOWERBIRD, the name applied to birds of the family Ptilonorhynchidae, containing about 17 species like stout thrushes, 8 to 14 in. long. Although the females are usually dull, the males often sport brilliant plumage approaching that of their close relatives, the birds of paradise (*q.v.*), though without decorative plumes. Ten species occur in New Guinea, others in eastern Australia. In jungle or brush they construct courtship bowers or "runs" of sticks, decorating floor or entrance with small bones, shells and brightly coloured berries, flowers or feathers. Both sexes use bowers as a playground, and males fight, display or "dance" for the females.

The satin bowerbird (*Ptilonorhynchus violaceus*), abundant in the wooded mountains of southeastern Queensland, eastern New South Wales and Victoria, builds a walled corridor usually facing north and south though often hidden in the jungle. The "blue" males—lustrous bluish or purplish black—prefer lavish decorations of blue bits of glass or blue flowers, the greenish females and young males prefer green to decorate the bower entrance. Two blotched eggs are laid in a bulky nest 6 to 40 ft. up in bush or tree that may be some distance away from the bower.

The regent bowerbird (*Sericulus chrysocephalus*) is the most brilliantly plumaged bird in Australia, gorgeous in black and orange-yellow. Common in the McPherson ranges, Queensland, it rarely constructs a bower. Some species build no bower at all; one surfaces a bare spot with leaves to form a "circus ring." The gardener bowerbird (*Amblyornis inornatus*) of New Guinea builds a roofed bower, three feet wide, of orchid stems near the foot of a small tree, and covers the floor and entrance with moss, ornamented with fresh flowers and berries, which are replaced by fresh ones as they fade. See also COURTSHIP OF ANIMALS; BIRD. (G. F. Ss.)

BOWFIN, a fresh-water fish (*Amia calva*) of North America, also known as grindle, mudfish or dogfish; it is the only living representative of its family, the Amiidae, which dates back to the Cretaceous period (beginning about 130,000,000 years ago). The bowfin is a voracious fish found in sluggish waters from the Great Lakes southward to the Gulf of Mexico. Because it may eat large

numbers of game fish it is sometimes considered a pest.

The elongate bowfin is mottled green coloured and has a long dorsal fin and strong conical teeth. The female reaches a length of 30 inches; the male is smaller and is distinguished by a black spot circled with orange on the tail. (C. Hu.)

BOWIE, JAMES (1796–1836), hero of the Texas revolution, was born in Logan county, Ky., in 1796. The family moved to Missouri in 1800 and to Rapides parish, La., in 1802. At the age of 18, James left home, cleared land and sawed the timber into lumber for current income. He later sold the land and engaged in the slave trade with two of his brothers, John and Rezin. James and Rezin later bought and improved a sugar plantation, Arcadia, on Bayou La Fourche and introduced steam power for grinding cane. Rezin was elected to the Louisiana legislature and James spent much time in New Orleans society where he learned French and Spanish and had his portrait painted. About 1826 the two brothers speculated in Spanish land grants in Arkansas. James is said to have killed a man in a duel and then to have gone to Texas in 1828. He is also reputed to have been the inventor of the Bowie hunting knife. At Bexar (San Antonio), Bowie became friendly with the vice-governor, Don Juan Martin de Veramendi. He obtained citizenship papers and about 15 eleven-league grants of land, and married the Veramendis' daughter, Ursula, in 1831. The restrictive law of April 6, 1830, helped interest Bowie in the early Texas revolutionary movement. He took part in several battles and then with volunteers joined Col. William B. Travis in the Alamo (*q.v.*), disputing leadership with him. But he fell ill and was found dead on his cot after the Alamo fell (March 6, 1836). (T. P. MA.)

BOWKER, RICHARD ROGERS (1848–1933), U.S. editor and publisher, is known for his development of professional library standards. Born in Salem, Mass., on Sept. 4, 1848, he graduated from the College of the City of New York, became literary editor of the New York Evening Mail and later of the New York Tribune and founded the R. R. Bowker company, which specializes in the publication of bibliographical materials. He was instrumental with Frederick Leypoldt and Melvil Dewey in organizing the American Library association in 1876 and in founding the Library Journal, which he edited for more than 50 years; he also edited or published the Annual Library Index, the American Catalog and Publishers' Weekly. A champion of authors' rights, he was an authority on copyright and wrote two books on copyright history, literature and law. He organized the earliest list of state documents and other important bibliographies and wrote books on business, politics, education, religion and economics.

A proponent of civil service reform, Bowker drafted the first national civil service reform plank. He also helped to form the Independent Republican, or "Mugwump," movement in 1879. He died Nov. 12, 1933, in Stockbridge, Mass.

See Edward McClung Fleming, R. H. Bowker, *Militant Liberal* (1952), which contains a bibliography.

BOWLES, SAMUEL (1826–1878), U.S. journalist, who made the Springfield (Mass.) Republican a leading national newspaper, was born in Springfield, Mass., on Feb. 9, 1826, and died there on Jan. 16, 1878. With the exception of a brief period in Boston, he devoted his life to the Republican, established as a weekly by his father, also Samuel Bowles (1797–1851), in 1824 and published as a morning daily after 184j. He is credited with being one of the leaders in the new journalism, giving his paper a national reputation by the vigour, incisiveness and independence of its editorial utterances and the concise and convenient arrangement of its local and general news matter. Then and later the Republican office was a sort of school for young journalists, especially in the matter of pungency and conciseness of style, one of Bowles' maxims being "Put it all in the first paragraph." During the controversies resulting in the Civil War he was a general supporter of the Whig and Republican parties, but he was later independent in politics. On travels for his health, he wrote letters to the paper describing the west, which were collected in *Across the Continent* (1865) and other books. Bowles's son, another Samuel Bowles (1851–1915), became a third editor of the paper.

See George S. Merriam, *Life and Times of Samuel Bowles*, 2 vol.

(1885), virtually a history of American political movements after the compromise of 1850; Gamaliel Bradford, "Samuel Bowles," in E. H. Ford and E. Emery (eds.), *Highlights in the History of the American Press*, pp. 178-194 (1954).

BOWLES, WILLIAM LISLE (1762-1850), English poet and critic chiefly remembered for his influence on the young Coleridge, was born at King's Sutton, Northamptonshire, on Sept. 25, 1762. He was educated at Winchester and at Trinity college, Oxford, and took orders in 1792. He subsequently held livings in Wiltshire. He died at Salisbury on April 7, 1850.

In 1789 Bowles published *Fourteen Sonnets* and *Verses to John Howard*, both received enthusiastically by Coleridge and his circle. The sonnets express the fluctuations of the poet's sensibility at the sight of "Dover Cliffs" or the sound of "The Bells, Ostend." Their somewhat tremulous emotional sensitivity recalls Cowper, but they lack Cowper's tough practicality and preoccupation with morality and personal salvation. Bowles loves to capture "the light that never was on sea or land,"

Presenting fairy vales, where the tired mind
Might rest beyond the manners of mankind

and it is this that links him with the Romantic poets. In *Biographia Literaria* Coleridge says that his own ideas on poetry were fixed by arguing in favour of Bowles who, with Cowper, he characterizes as "the first who combined natural thoughts with natural diction; the first who reconciled the heart with the head." Bowles's principal longer poems are *The Spirit of Discovery* (1804), *The Missionary of the Andes* (1815), *The Grave of the Last Saxon* (1822) and *St. John in Patmos* (1833).

In 1806 he published an edition of Pope's works with notes and essays which, under a mask of judicial impartiality, attacked the poet's moral character and poetic principles. Bowles's opinions were attacked by Byron in *English Bards and Scotch Reviewers*, I, 327-384, and in 1819, a defense of Pope's poetical character by Thomas Campbell sparked off a war of pamphlets sustained largely by Byron, which continued until 1826 and was known as the "Pope and Bowles controversy." Bowles had asserted that natural objects and basic passions were intrinsically more poetic than the products of art and manners; a forest was more poetic than a garden, religious awe than love of society. His opponents cited products of art which were undoubtedly poetic—the most telling example was a man-of-war taking the water—and the controversy developed along these arbitrary lines, producing considerable heat but little criticism of permanent value. Bowles's *Poetical Works* were edited by G. Gilfillan (1855).

See J. J. van Rennes, *Bowles, Byron and the Pope-Controversy* (1927). (J.N. C.)

BOWLEY, SIR ARTHUR LYON (1869-1957), British statistician, outstanding for the application of sampling techniques in social inquiries, was the last survivor of the original group of teachers at the London School of Economics and Political Science. He was born at Bristol on Nov. 6, 1869, and was educated at Christ's hospital and at Trinity college, Cambridge, where he gained the Cobden prize with his pioneer work, *A Short Account of England's Foreign Trade in the Nineteenth Century* (1893). From 1895 to 1919 he combined part-time teaching in statistics at the London School of Economics with posts in mathematics and economics at University college, Reading. From 1919 until his retirement in 1936 he was the first holder of the chair in statistics in the University of London. Later he was director of the Oxford University Institute of Statistics (1940-44). His work ranged over a wide field of theoretical, economic and social statistics and his writings were very numerous. Bowley was prominent in the affairs of the Royal Statistical society from 1895, of the International Statistical institute from 1903 and of the London and Cambridge Economic service from 1923. He was elected a fellow of the British academy in 1922 and was knighted in 1950. He died at Haslemere, Surrey, on Jan. 21, 1957. (R. G. D. A.)

BOWLING is a game in which a ball is rolled down a long, narrow lane toward a group of wooden pins, the object being to knock down more pins than an opponent. The game is quite different from the sport of bowls, or lawn bowls, in which the aim is to roll the bowls near a stationary ball called a jack; but there are

many points of similarity and their history is complicated by the fact that the name "bowls" has been used for several games (see BOWLS)

HISTORY

The history of bowling may be traced back 7,000 years. Sir Flinders Petrie, British Egyptologist, reported finding in the grave of an Egyptian child implements for playing a game decidedly similar to modern tenpins. The date of the Egyptian child's burial was placed at 5200 B.C. According to Sir Flinders, the games were full developed, both as board games and bowling at pins, or skittles.

Stone Age artifacts indicate that early men and boys played some sort of bowling game in which large pebbles and rocks were rolled at pointed stones or sheep joints which served as pins. The ancient Polynesians, according to Malcolm Rogers of the San Diego (Calif.) museum, participated in an ancient game of bowling in which small elliptical balls and round, flat disks of stone, about 3½ to 4 in. in diameter, were used. One rule of this game, called Ula Maika, set the distance the stones were to be bowled at 60 ft., the same specification used in tenpin bowling today.

Germany.—Bowling has been played for centuries in Germany and the Low Countries. Written records of A.D. 300 state that bowling originated in the monasteries of continental Europe, where it was part of a religious ritual. The peasants of those days habitually carried a club, even when visiting church. It is said that the priests, in an effort to dramatize a point and develop a visual religious explanation, told the people that the clubs could represent evil or the devil. The club was stood in a corner, and the peasant rolled a large stone or ball at it. If he succeeded in hitting it, he was praised; should he fail, he was instructed to lead a better life. The priests, according to the account, became intrigued with the idea of hitting the club or *kegel* themselves and took turns at trying. Soon others tried their skill, and a game was born. Later the nobility and landed gentry took up this form of recreation. By the middle ages, bowling was a universal and very popular game in Germany. It held an important place with the people in village gatherings and celebrations, and wealthy burghers participated in the game on their own private bowling lanes.

England.—As the game spread to England, the people became equally enthusiastic about bowling, so much in fact that Edward III became concerned about it. In 1365 he passed an edict forbidding "the hurling of stones" and other sports because he feared that the practice of archery (important for military purposes) would suffer because of the people's fascination with games. About two decades later, Richard II's reign saw these laws renewed with penalties being levied against those who bowled in public establishments. Far from dying out, however, the game became popular with the nobility, and by 1530 Henry VIII ordered bowling lanes added to his residence at Whitehall in order to indulge his fancy for the game.

Various forms of bowling were played in the different European countries through the years. The number of pins varied from 3 to 15, balls differed in size and weight, and there were differences in the distances they were rolled. The basic principle of rolling a ball at pins remained the same: however, among the different

names of bowling games were skittles, half-bowl, Basque *quilles* and German *Kegelspiel*, or ninepins.

Ninepins was universally popular among the Germans and Dutch and was first bowled upon a bed of clay. Later a single board, about one foot in width, was laid upon the clay, and the ball was rolled upon this narrow lane.

United States.—The early Dutch settlers of New York brought the game of ninepins to America with them. It was first played in the new world upon the green, and in 1732 the square north of New York's Battery was leased as a bowling green and still bears this name. In Washington Irving's famous tale of Rip Van Winkle, the strange beings Rip meets in the mountains are playing ninepins, and the noise of their balls striking the pins sounded like distant thunder.

Bowling grew to tremendous popularity in the U.S. during the early part of the 19th century. The game of ninepins reached the peak of favour in the 1840s, according to the *Western Bowlers*

Journal Bowling Encyclopedia. In New York city, there were lanes (the game had moved indoors from the bowling green) on nearly every block on Broadway from Fulton street to 14th street. In 1849 there were four lanes located uptown and, in surprisingly modern fashion, on the third floor of a building.

As ninepins grew in popularity, so did gambling upon the outcome of the games. Matches for money were made with increasing frequency, and the game fell into the control of gamblers. For this reason, it was outlawed, first in Connecticut and later in New York. Because only the game of ninepins had been outlawed, not bowling itself, the idea was conceived about 1842 of adding another pin to the nine-pin setup to circumvent the law. Thus was born the game of tenpins, which has grown in popularity to become a major sport in the United States and many other countries. Adding a tenth pin changed the arrangement of pins on the lane from the diamond formation of ninepins to the triangle formation of tenpins.

In 1875 and again in 1890, organizations were formed to control the game, but they were short-lived. On Sept. 9, 1895, another group met to form a governing organization for the sport. Among them were skilled bowlers, bowling-alley proprietors (commercial establishments were flourishing by that time) and representatives of bowling equipment manufacturers. Their purpose was to draw up universally acceptable rules and regulations for tenpins and to develop uniform standards for lanes and equipment so that bowlers everywhere could play under equal and well-known conditions. The American Bowling congress (A.B.C.), as the new organization was named, grew and flourished as did the game of tenpins itself.

The American Bowling congress is the governing body of male bowlers only. By 1916 a sufficient number of women were participating in the game to warrant the formation in November of that year of the Woman's International Bowling congress (W.I.B.C.). An American Junior Bowling congress was also established for boys and girls of high school age.

Parallel with the increase in participation in the game was the growth and development of the commercial bowling establishment in the United States. From four- and six-lane houses frequented primarily by men, many have become huge, gaily decorated, well-lighted sports establishments where the whole family plays the game of tenpins. Modern bowling establishments have 20, 36 or as many as 40 lanes on a single floor. A 64-lane establishment was built with lanes in a continuous line unbroken by pillars. Most of them have refreshment counters, locker rooms where bowlers may store their equipment throughout a season, comfortable spectator seats and sales counters for bowling supplies such as balls, bags and shoes. Modern electrical equipment will clean a ball for the bowler, detect a foul (stepping over the foul line), throw scores on a screen so spectators may follow a game and return a ball to the bowler from the pits; semiautomatic and automatic machines set up the pins after a ball is thrown.

SPECIFICATIONS FOR BOWLING EQUIPMENT

Equipment has been completely standardized through American Bowling congress specifications so that bowlers everywhere compete under equal conditions.

A bowling lane is 60 ft. long from the foul line to the centre of the head pin and must be no less than 41 in. nor more than 42 in. wide. Behind the foul line is an approach of no less than 15 ft. and usually 16 ft. where the bowler takes 3, 4 or 5 steps before rolling the ball. Pins are set in a 36-in. triangle with a spacing of 12 in. from the centre of one pin to another. First is the no. 1 or head pin and behind it a row of two pins, followed by a row of three and another row of four pins to account for all ten.

On each side of a bowling lane are nine-inch gutters (nine and one-half inches on lanes that are 41 in. wide), which guide the ball down to the pit if it should be

FIG. 2—THE STANDARD FOUR-STEP DELIVERY

misthrown and leave the lane. Each pair of lanes has a ball return, a narrow track to allow the ball to be returned to the bowler from the pits after each throw.

The lane itself is constructed of maple and pine planks fastened tightly together with the narrow edges upward and coated with finish for a smooth and continuous surface. To prevent any possibility of lanes being slotted to guide the ball to the pins, the American Bowling congress allows a tolerance of only $\frac{4.0}{1,000}$ in. in levelness. Periodic inspections of bowling lanes are made by A.B.C. officials to ensure conformity with all specifications.

Pins.—Bowling pins are made to equally rigid specifications. A pin must be made of sound, hard maple and weigh not less than 2 lb. 14 oz. nor more than 3 lb. 10 oz. The ten pins in a single set must not vary more than 4 oz. in weight. Each pin must be 15 in. high and the diameter at the base $2\frac{1}{8}$ in., increasing to $4\frac{3}{4}$ in. at the belly and diminishing to $1\frac{3}{4}$ in. at the neck. Only pins meeting such specifications may be used in A.B.C. sanctioned play.

Pins originally used in bowling were simple wooden clubs, thick at the base and tapering to the top. These were later turned in the form of a smooth cone, varying in diameter and length according to local tastes. The cone was superseded by a pin shaped like a small keg, flat on both top and bottom. Eventually the shape of a champagne bottle was adopted as standard for pins.

Bowling Ball.—The development of the bowling ball is an interesting bit of evolution. Centuries ago, round stones were used. Later wood was used, in part attributable to the interest in the game by the Flemings who were skilled craftsmen. In later years, iron and rubber balls were tried. With the advent of the power lathe, wooden bowling balls could be turned out, smooth and true. Lignum vitae, a hard tropical wood, was the most popular. Wooden balls were palmed (thrown without finger holes), but in some localities of Europe slots for fingers and a hole for the thumb were tried. About 1890, the two-hole grip (one for the middle finger and one for the thumb) was introduced in the U.S. The three-hole grip is now the most popular type.

Modern A.B.C. requirements for bowling balls are that they must be made of nonmetallic composition material and must have a circumference of not more than 27 in., and the weight must be between 10 lb. and 16 lb. To keep competition equal for all bowlers, balls must be so constructed and drilled that no less than six sides are in proper balance.

Range Finder.—Through the years many bowlers developed the habit of dropping the ball on a certain board of the lane as a guide point for its travel to the pins. To assist bowlers in this search for accuracy, the range finder was introduced. This is a system of markers imbedded in the lane to guide both footwork in the approach and delivery of the ball on a given spot. A row of markers is located at the far end of the approach to help the bowler start from the same spot each time. Another row just before the foul line helps indicate the stopping position for the feet. Two more rows out on the lane, one 7 ft. and the other 13 to 16 ft. beyond the foul line, allow the bowler to send his ball on exactly the same path each time he rolls it.

PLAYING THE GAME OF TENPINS

Bowling was recognized as the second greatest participant sport in the United States by the late 1950s. (Fishing is usually ranked first.) It received great impetus during World War II when many members of the armed forces tried the game for the first time during recreation periods. Industry, geared for defense work, encouraged employee leagues as a means of building morale. In the 1941-42 season, for example, the American Bowling congress records showed 68,226 teams representing factory, automotive and

aviation workers. Many U.S. women defense workers tried the game for the first time and stayed with it through the years in housewives' leagues. It continued to grow in popularity after the war.

Unlike many others, bowling is a sport that can be played at all ages. One man, Harry Steers of Elmhurst, Ill., bowled in the annual American Bowling congress tournaments for more than 50 years.

Children's leagues are in operation, using special lightweight balls on regulation lanes. Bowling has also become an organized school and college sport in many areas and national intercollegiate tournaments are held annually. The various athletic conferences, such as the Big Ten and Eastern Intercollegiate conference, also sponsor tournaments in which teams from member colleges compete.

Millions of adult men and women bowl in thousands of leagues throughout the United States. Many skilled bowlers of 70 years or over actively compete in the game. Since skill is the great prerequisite of bowling, rather than great physical stamina, and since team play develops many social hours of good fellowship, there are, as noted previously, no real age limits to the game.

The game is usually played by one individual against another or by one team against another. Teams are ordinarily composed of five persons, and a number of teams are organized into a league to compete against each other on a definite schedule. There are usually about 12 teams in a league, although the figure may vary either way. League officers are elected, and league business is run according to parliamentary procedure and a set of bylaws. Most

U.S. leagues apply to either the American Bowling congress or the Woman's International Bowling congress for sanction, or approval. Among other benefits, the sanction makes teams from the league eligible to compete in the annual tournaments staged by the A.B.C. and the W.I.B.C.

Aside from accuracy which must be developed by practice, bowling is a relatively easy game to play. A minimum of equipment is necessary for the player, and it is inexpensive compared with many other sports. A bowling ball, a pair of bowling shoes and a bag in which to carry them are all that are needed. Lanes, pins and all other equipment are provided by the bowling establishment on the basis of a small charge per line (game) for play. Bowling lanes furnish house balls and rental shoes. Thus it is not necessary to buy any equipment to bowl, and many thousands of casual bowlers do not. Experts at the game recommend, however, that a bowler who has serious intentions of improving his skill obtain his own ball with the holes custom fitted to his hand and finger size.

The action of rolling a bowling ball consists of taking several quick walking steps while the hand which grips the ball drops to the side, swings backward and then forward again just as the last step is taken. It is at this instant that the ball is released with the momentum of the body helping to propel it. Three, four or five steps are taken. A four-step delivery is the most popular and the one recommended by experts. For a right-handed bowler, the last step is taken on the left foot which slides a little toward the foul line just as the hand comes forward with the ball. Good practice requires that the arm follow through after the ball is released to help give it proper direction toward the pins.

The ball can travel toward the pins in any one of four paths—a straight line, a hook, a curve or a backup. A straight ball is recommended for beginners. The more skilled throw a hook ball by turning the hand just at the instant the ball is released. A hook ball usually sends the pins tumbling in more active fashion

than a straight ball with the result that some pins hit by the ball will knock over other pins as they fall.

A number of excellent bowling instruction books have been written to summarize and illustrate the many different techniques of footwork, delivering the ball, follow-through, etc. (see Bibliography). Many bowlers have improved their knowledge of the fundamental techniques of the game with such instructional books. Personal instruction on the lanes is also helpful and in the larger cities many bowling establishments offer free professional instruction.

A line, or game, of tenpins is divided into ten frames. Two balls or throws are allowed for each frame, but when the first ball rolled knocks down all ten pins the frame is concluded with one ball.

Scoring the Game.—Scoring is based on the number of pins knocked down per frame, plus a bonus system of strikes and spares. If the first ball of a frame knocks down four pins and the second ball knocks down four more, the score for the frame is simply 8. If all the pins are knocked down by two throws, a spare is scored. This makes the score for that frame 10 plus the number of pins knocked down with the next ball rolled. A strike is scored when the first ball rolled knocks down all ten pins. For a strike frame, the bowler gets 10 plus the number of pins knocked down with his next two throws. A strike in the tenth or last frame gives the bowler two extra balls; a spare in the tenth frame gives him one extra ball. A perfect score, achieved by strikes in all ten frames plus the two extra balls at the end, is 300.

In addition to marking the number of pins on the bowling score sheet, the accomplishment of the frame (strike, spare, error or split) is also marked in the smaller of the two squares that are used to score each frame. The strike mark is an X; for a spare it is a diagonal line (/); a dash (—) is used for an error and an O for a split (two or more pins widely spaced).

Score for a Sample Game.—To clarify further the system of scoring, the principles are applied here to several sample frames.

If, for example, the bowler rolls two balls in the first frame and gets only six pins, he marks 6 in the large square and the error symbol in the small square.

In the second frame, he gets three pins with the first ball and all the rest with the second ball. Then he marks the spare sign in the small square and nothing in the large square, remembering that he will get 10 plus what he knocks down with his next ball.

On the next ball—the first of the third frame—he gets a strike. So the scoring goes like this: 10 for the spare, plus ten pins on his next ball, *i.e.*, 20; 20 plus the 6 in frame one totals 26, to be marked down as the score for the second frame. Since there was a strike in the third frame, only the strike symbol is marked in the small square. In the fourth frame he gets another strike so he doesn't put a score in the third frame box until after the next ball.

In the fifth frame he gets only six pins with the first ball and two with the second and no split to mark. So there is an error for the fifth frame to be marked in the small square. Now it is time to do some adding to fill in the scores for frames three and four. In frame three, the bowler adds 10 for the strike, plus the total from the next two balls (10 more for the strike in the fourth and 6 for the first ball in the fifth), plus the 26 already in frame two. This finally allows 52 to be marked in for the third frame. Now, he can also fill in the score for the fourth frame by adding 10 for the strike, plus 8

for the next two balls (the error) to the 52 from frame three. The score up to this point is 70. Since a total of only 8 was made in the fifth frame, this can be added at once to give 78 through the fifth frame. The remaining frames of the game are scored and marked in the same fashion.

BOWLING TOURNAMENTS

Highlight of the year for many U.S. bowlers is the annual American Bowling congress tournament for men and Woman's International Bowling congress tournament for women. Both are held in different cities each year and draw individual and team entries from all over the nation. The first A.B.C. tournament was held at Chicago, Ill., in 1901 with an entry of 41 teams and a prize list of \$1,592. The tournaments, whose participants and prize money increased greatly through the years, were held annually thereafter with the exception of 1943, 1944 and 1945 during World War II.

The prize fund is developed from contestants' entry fees for the tournament and is distributed to the various teams and individuals on the basis of performance in the tournament events.

The four basic events are for five-man teams, two-man teams, individuals and all-events (a combination of the first three). A.B.C. tournament play in the 1950s covered a period of more than two months with continuous bowling every afternoon and evening. A classic division to represent professional bowlers was instituted in 1961.

W.I.B.C. tournaments for women bowlers include the same four events. It was started in St. Louis, Mo., in 1917 with eight teams competing. Three games are bowled for each of the four events in both the A.B.C. and W.I.B.C. tournaments.

A.B.C. Tournament Records.—A record total in the A.B.C. all-events was rolled by Ed Lubanski of Detroit, Mich., in 1959 when he scored 700 pins for his five-man team, 652 for his two-man team and 764 in his individual contest for a grand total of 2,116 pins, exceeding the previous record of 2,070 pins set by Max Stein of Belleville, Ill., in 1937. Lubanski bowled on the Pfeiffer Beer five-man team of Detroit which scored 3,243 pins in the 1959 tournament. The first classic division championship (1961) was won by the five-man Brentwood Bowl team of San Francisco with a score of 5,983 for six games. A two-man record was set by Steve Nagy and Johnny Klares of Cleveland, O., who scored 1,453 pins in 1952. The individual record score of 775 pins was rolled by Lee Jouglaard of Detroit in 1951. Other outstanding A.B.C. champions include John Koster of Nyack, N.Y.; Joe Wilman, Berwyn, Ill.; Don Carter, St. Louis, Mo., who was elected the first president of the Professional Bowlers association, organized in 1958; and "Junie" McMahon, Fair Lawn, N.J.

W.I.B.C. Tournament Records.—Among woman bowlers, a W.I.B.C. tournament "five-man" team record was achieved by the Bill Snethkamp-Chrysler team of Detroit, with a total of 3,030 in 1959. A two-man team record for women was made in 1955 by Marion Ladewig and Wyllis Ryskamp, both of Grand Rapids, Mich., with 1,264. A singles game record in W.I.B.C. tournament play was made in 1934 by Marie Clemensen of Chicago, with 712 pins. In 1959 Pat McBride of Grand Rapids set an all-events record of 1,927, topping Marie Warmbier's record of 1,911 set in 1935.

All-Star Tournament.—A new kind of tournament was started in 1942 to determine the national individual match game champion. This title was determined for many years by unofficial challenge matches and was sometimes in dispute. From 1942 top bowling stars of the U.S. competed in a grueling 100-game tournament over a ten-day period. It is an extremely severe test of tenpin skill, physical stamina and mental alertness and became the leading test of individual bowling prowess. The bowlers competed for the Bowling Proprietors' Association of America individual match game championship.

Wilman, McMahon, Carter and Nagy, mentioned previously, also won individual match game titles at various times. Other champions in this tournament included Connie Schwoegler, of Madison, Wis.; Ned Day, West Allis, Wis.; Andy Varipapa, Hempstead, N.Y.; Dick Hoover, Akron, O.; and Bill Welu and Harry Smith, St. Louis.

Competition for women was added to the All-Star tournament in 1949. The winner for five successive years was Marion Ladewig who completely dominated women's bowling during that period in a fashion seldom achieved by any athlete in any sport. During the 1951 tournament, her average was 211, a margin of two pins per game better than the winner in the men's division. Trailing in second place through the first two days of the 1951 finals, Mrs. Ladewig unleashed a burst of scoring never before seen in championship women's tournament competition. Her first two games for that third day were 255 and 279, followed by 247, 227, 247, 224, 255 and 247 for an eight-game total of 1,981 pins and an average of more than 247 a game.

Mrs. Ladewig's five-year reign was ended in 1955 by Sylvia Wene of Philadelphia, Pa., who won the women's All-Star competition. In 1957, however, Mrs. Ladewig led the women bowlers for the sixth time in eight years, and in 1959 she again won the women's All-Star championship. In the same year, Mrs. Ladewig and LaVerne Carter of St. Louis won the women's national doubles championship at Rego Park, N.Y. Mrs. Ladewig also won W.I.B.C. titles in 1959 and in 1960.

A.B.C. Hall of Fame.—To honour the men with the greatest accomplishments in the game of tenpins, the American Bowling Congress Hall of Fame was established in 1941. Ten years later, Hall-of-Fame member Hank Marino was elected "Bowler of the Half Century" by the elections board in one of the highest tributes to be paid to a bowler's accomplishments in the game of tenpins.

OTHER GAMES OF BOWLING

In addition to the universally popular tenpins, there are several other varieties of bowling played. In the United States, for the most part their popularity is confined to rather specific geographical areas of the country. Among these games are duckpins, rubberband duckpins, candlepins, five back and barrelpins.

The most popular game, duckpins, is played along much of the U.S. eastern seaboard with special concentration in Baltimore, Md., and Washington, D.C. The regulation duckpin is only $9\frac{1}{8}\frac{3}{4}$ in. in height and $4\frac{1}{8}$ in. in diameter at its widest part. Ten duckpins are used in the game. The ball is small, without finger holes, and measures 5 in. in diameter with a maximum allowable weight of 3 lb. 12 oz. Three balls are allowed in each frame of a ten-frame game; there is no bonus for making all ten pins with three balls; other rules are similar to those of tenpins. The National Duck Pin Bowling congress was founded in 1927.

The rubberband duckpin game is concentrated chiefly in the area around Pittsburgh, Pa. The pins are the same height as regular duckpins but have a rubberband $1\frac{1}{8}\frac{3}{4}$ in. wide set into a slot around the belly of the pin. This gives them additional action when they are hit by the ball. The ball is the same size as that for duckpins but must weigh no more than 3 lb. 8 oz. Only two balls are allowed for each frame of a ten-frame game; other rules are similar to those of tenpins.

Candlepins (a candlepin is a long, narrow cylinder, tapered to both ends) enjoys its greatest popularity in the New England states and eastern Canada. Three balls are allowed as in duckpins. Five back and barrelpins are played in New York.

The U.S. game of tenpins is played in many countries of Europe (Great Britain, Germany, Norway, Sweden and Finland), in Central and South America and in Japan. (J. J. W.)

BOWLING GREEN, a city of Kentucky, U.S., 118 mi. S.W. of Louisville, at the head of navigation on the Barren river; the seat of Warren county. (For comparative population figures see table in KENTUCKY: Population.)

The city is the centre of a rich agricultural area and a market for strawberries, tobacco, grain, livestock and poultry. Its industries produce auto parts, photoflash bulbs, air compressors, cloth-

ing and building materials. Bowling Green College of Commerce and Western Kentucky state college (1906) are located in Bowling Green. Mammoth Cave National park, 30 mi. N.E. of the city, and Lost River and other nearby caves attract thousands of tourists annually.

Warren county was established in 1796. Two years later a town was established around the courthouse square. There is a tradition that Robert Moore's bowling alley on the open green suggested the city's name. Bowling Green was incorporated in 1810; a new charter was granted in 1858.

During the American Civil War it was on the right flank of the first line of Confederate defense in the west, and for a time was the headquarters of Gen. Albert Sidney Johnston. (J. C. CR.)

BOWLS, one of the oldest of outdoor pastimes; in the U.S. often called lawn bowling. The aim is to roll the bowls near a stationary ball called a jack. The game is therefore quite different from the modern sport of bowling, but the points of similarity are obvious and both are of very ancient origin; the earliest known forms are discussed in BOWLING. Tracing the later history of the two games is complicated by the fact that in early modern English the word "bowls" was used to mean both the present game and the game of skittles or ninepins (and also perhaps billiards). and in many early references to bowls it is difficult to determine which form is meant.

It is certain, however, that the game of bowls, at least in a rudimentary form, was played in the 13th century. A manuscript of that period in the Royal library, Windsor (No. 20, E iv.), contains a drawing representing two players aiming at a small cone (instead of an earthenware ball, or jack). Another manuscript of the same century has a picture—crude, but spirited—of a game which more closely resembles the present game. It shows three figures and a jack. The first player's bowl has come to rest just in front of the jack; the second has delivered his bowl and is following after it with one of those eccentric contortions still not unusual on modern greens, the first player meanwhile making a repressive gesture with his hand as if to urge the bowl to stop short of his own; the third player is depicted as in the act of delivering his bowl.

The Game in England.—As the game of bowls grew in popularity in England it came under the ban of king and parliament, both fearing that it might jeopardize the practice of archery, then so important in battle; statutes forbidding it and other sports were enacted in the reigns of Edward III, Richard II and other monarchs. Even after the invention of gunpowder and firearms had made the bow obsolete as a weapon of war, the prohibition was continued. A statute of 1511 in the reign of Henry VIII confirmed previous enactments against unlawful games. By a further act of 1541—which was not repealed until 1845—artificers, labourers, apprentices, servants and the like were forbidden to play bowls at any time except Christmas, and then only in their master's house and presence. It was further enjoined that anyone playing bowls outside of his own garden or orchard was liable to a penalty of 6s. 8d., while those possessed of lands of the yearly value of £100 might obtain licences to play on their own private greens. In Mary's reign (1555) the licences were withdrawn, the queen or her advisers deeming the game an excuse for "unlawful assemblies, conventicles, seditions, and conspiracies."

The amount of skill demanded by the game increased considerably in the 16th century, when biased bowls were introduced. "A little altering at the one side," says Robert Recorde, the mathematician, in his *Castle of Knowledge* (1556). "maketh the bowl to run biasse waies." And Shakespeare (Richard II, act iii, sc. 4) causes the queen to remonstrate, in reply to her lady's suggestion of a game at bowls to relieve her ennui, "Twill make me think the world is full of rubs, and that my fortune runs against the bias." This passage is interesting also as showing that women were accustomed to play the game in those days. It is pleasant to think that there is foundation for the familiar story of Sir Francis Drake playing bowls on Plymouth Hoe as the armada was beating up the channel, and finishing his game before tackling the Spaniards. Bowls, at that date, was looked upon as a legitimate amusement for Sundays—as indeed were many other sports. When John Knox

visited Calvin at Geneva on Sunday, it is said that he discovered him engaged in a game; and John Aylmer (1521–94), though bishop of London, enjoyed a game on a Sunday afternoon but used such language "as justly exposed his character to reproach." The pastime found favour with the Stuarts. In the *Book of Sports* (1618), James I recommended a moderate indulgence to his son, Prince Henry, and Charles I was an enthusiastic bowler although unfortunately he encouraged, by example, wagering and playing for high stakes, habits that ultimately brought the green into general disrepute. Even the Puritans could not suppress betting. So eminently respectable a person as John Evelyn thought no harm in bowling for stakes, and once played at the Durdans, near Epsom, for £10, winning match and money, as he triumphantly notes in his *Diary* for Aug. 14, 1658. Samuel Pepys repeatedly mentions finding great people "at bowles." But in time the excesses of gambling and drinking attending the game, which became associated almost exclusively with taverns, rendered it unfashionable.

Developments in Scotland.—After a long interval salvation came from Scotland, where the game became organized with a code of laws. There, along with its winter analogue of curling, bowls may be considered, much more than golf, a national game. Yet it was not until well into the 19th century that the pastime acquired popularity in that country. It had been known in Scotland since the close of the 16th century but greens were few and far between. There is a record of a club in Haddington in 1709, of Tom Bicket's green in Kilmarnock in 1740, of greens in the grounds of Heriot's hospital, Edinburgh, prior to 1768, and of one in Peebles in 1775. (These are, of course, mere infants compared with the Southampton [Eng.] Bowling green, founded in 1299, which still uses the green on which it has played for centuries and continues the quaint custom of describing certain successful players as "sir.") As the game grew in popularity in Scotland the need was felt for a uniform code of laws and in 1848–49 a committee was appointed to draft one. The body delegated its functions to its secretary, W. W. Mitchell (1803–84), who prepared a code that was immediately adopted as the standard laws. The Scots were also pioneers in laying down level greens of superlative excellence. Not satisfied with seed-sown grass or meadow turf, they experimented with sea-washed turf and found it answered well. The enthusiasm as well as skill with which the game was conducted in Scotland at length proved contagious; thus Scottish bowlers saved the game. Clubs in England began to consider the question of legislation and to improve their greens. Moreover, Scottish emigrants introduced the game wherever they went and colonists in Australia and New Zealand established many clubs which; in the main, adopted Mitchell's laws; clubs were also started in Canada and in the United States, in South Africa, India, Japan and Hong Kong. In Ireland the game took root very gradually.

A Lead From Australia.—Further efforts to organize the game were made in the last quarter of the 19th century, but this time the lead came from Australia. The bowling associations of Victoria and New South Wales were established in 1880, and it was not until 1892 that the Scottish Bowling association was formed. Then in rapid succession came several independent bodies—the Midland Counties (1895), the London and Southern Counties (1896), the Imperial (1899), the English (1903) and the Irish and Welsh (1904). The multiplicity of organizations in England proved a hindrance, so in 1905 the various organizations joined the English Bowling association. Visits to the United Kingdom of teams of bowlers from Australia and New Zealand in 1901, and from Canada in 1904, demonstrated that the game had gained enormously in popularity. Since then accredited teams of players from Australia, New Zealand, South Africa, Canada and the United States have visited Great Britain at regular intervals and British teams have returned those visits.

Bowls in the U.S.—Bowls was the chief pastime of the early settlers of New York; a reminder of that fact is the small park at the lower end of Broadway near the Battery called Bowling Green. The game as it was played in 1700–1800 is portrayed on a stained glass window at the rear of the corridor of the Bowling

Green building, 11 Broadway. Lawn bowling spread from New York and Boston to many cities along the Atlantic coast; a bowling green was built on the estate of George Washington at Mount Vernon in 1732 and enjoyed great prosperity. The game was considered the leading sport until the Revolutionary War but after the war became practically nonexistent for 100 years.

In 1879 Christian Schepflin of Dunellen, N.J., formed a club called the Dunellen Bowling club, thereby bringing about a revival of the sport. The game took on a slow but steady growth, gradually moving westward. A club was formed in the San Francisco area in 1899 by a group of the St. Andrews society. The American Lawn Bowling association was organized in Buffalo, N.Y., in 1915 with the first national tournament held at Franklin field in Boston, Mass., in 1918.

The American Lawn Bowling association joined the International Bowling board in 1938, thereby becoming affiliated with the game's governing body throughout the world. The present American Lawn Bowling association organization is divided into five divisions, the eastern (New York, New Jersey, Pennsylvania and New England states), the central (mid-western states), the southeast, the southwest and the northwest.

The **Green**.—Bowls are played on a level green; there is no prescribed size but 40 or 42 yds. square is generally recommended. In constructing a green, the ground should be excavated to a depth of about 18 in., thoroughly drained and then filled with layers of crushed rock or cinders, soil and sand before the final covering of turf. Surrounding the green is a shallow space called a ditch. Beyond the ditch are banks, usually laid with turf. A green is divided into spaces usually 18 to 21 ft. in width, commonly called rinks. These are numbered in sequence on a plate fixed in the bank at each end opposite the centre of the space.

How the Game Is Played.—Every player uses four bowls (of lignum vitae wood or a composition material) in single-handed and in doubles games, three in triples or a three-on-a-side match and two in the rink game or four players to a side. Every bowl must have a certain amount of bias, which was formerly obtained by loading one side with lead but is now imparted by making one side more convex than the other, the bulge showing the side of the bias. No bowl must have less than No. 3 bias—that is, it should draw about 6 ft. to a 30-yd. jack on a first-rate green. The diameter of the bowl shall not be less than $4\frac{3}{4}$ in. or more than $5\frac{1}{8}$ in. and its weight must not exceed $3\frac{1}{2}$ lb. The jack, to which the bowler plays his bowls, is round and not less than $2\frac{1}{2}$ in. in diameter. The player delivers his bowl with one foot on a rubber mat which must be at least 24 in. by 14 in. An end is completed when each player has rolled all the bowls he is playing with (that is, four, three, or two). In scoring, all the balls of one team nearer the jack at the finish of an end than the nearest ball of the opposing team count one point each. In team play game consists of any number of ends, usually 18 or 21; in singles play game is 21 points.

In theory the game is very simple, the aim of the player being to roll his bowl so as to cause it to rest nearer to the jack than his opponent's, or to protect a well-placed bowl, or to dislodge a better bowl than his own. The four players in a rink are known as the lead, second, third (or vice-skip) and skip (or captain), and their positions, at least in matches, are unchangeable. The lead places the mat and rolls the jack. He also bowls first and is chosen to fill that position because of his skill in drawing (rolling) his bowl close to the jack. The second man, also, must be able to draw accurately. His official duty is to mark the game on a scorecard or blackboard. The third player, who does any measuring that may be necessary to determine which bowl or bowls may be nearest the jack, holds almost as responsible a position as the captain, whose place, in fact, he takes whenever the skip is temporarily absent. The skip plays last; it may be that he has to draw a shot to save the end, or even the match, or to lay a block, or to "fire"—that is, to deliver his bowl almost dead straight at the object, with enough force to overcome the bias.

Some Essential Rules.—Every newcomer to the game should learn to play both forehand and backhand. It must always be remembered that the biased side of the bowl is kept to the inside

of the rink and that the forehand-backhand reference depends on a left-handed or right-handed bowler. In throwing the jack there must be a clear distance of not less than 25 yd. between the mat and the jack. A bowl which touches the jack during its original course on the green is called a toucher and is distinguished by a chalk mark. If a toucher is driven into the ditch it remains a "live" bowl; other ditch bowls are accounted dead and are removed to the bank. If the jack is driven beyond the limits of the rink it is counted dead, no score is recorded and the end must be replayed, usually in the same direction.

BOWMAN, ISAIAH (1878–1950), U.S. geographer and university president, early established an international reputation by compiling the first comprehensive work published on the physiographic divisions of the United States (*Forest Physiography*, 1911) and by carrying out extensive field studies in the Andes (1907, 1911, 1913). Born at Waterloo, Ont., on Dec. 26, 1878, he was graduated from Harvard (B.S., 1905) and Yale (Ph.D., 1909) universities. After teaching at Yale for ten years (1905–15) he served for 20 years as director of the American Geographical Society of New York (1915–35), and later was president of The Johns Hopkins university, Baltimore, Md. (1935–48).

By enlarging its membership, staff and program, he made over the previously rather small American Geographical society into an institution of world-wide influence, and launched it on a 25-year project of mapping all of the American continents south of the United States and on collaborative studies of pioneer settlements, polar geography and many other matters. At Johns Hopkins he effected substantial administrative changes, and new departments of geography, oceanography and aeronautics were established during his administration.

At the Paris Peace conference of 1918–19 Bowman served as territorial adviser to Pres. Woodrow Wilson and the U.S. commission; his best-known book was *The New World: Problems in Political Geography* (4th ed., 1928). Pres. F. D. Roosevelt consulted Bowman on matters of scientific and national policy, and during the Roosevelt administrations he served on many governmental advisory committees. He participated in the Dumbarton Oaks (1944) and San Francisco United Nations (1945) conferences. Bowman was a fluent writer, the author of some dozen books and more than 200 periodical articles, addresses and minor publications. He died at Baltimore, Md., on Jan. 6, 1950.

BOWMAN, SIR WILLIAM (1816–1892), English physician who was the British leader in ophthalmology when that subject entered its brightest period, was born at Nantwich, Cheshire, on July 20, 1816. He was an outstanding general anatomist, a brilliant surgeon and one of the leaders in the application of the compound microscope, then new and at a time when T. Schwann had just enunciated the cell doctrine. Bowman was first apprenticed to Joseph Hodgson, surgeon to Birmingham General hospital, where he acquired his first microscope. In 1837 he joined the medical department of King's college, London, and was awarded the fellowship of the Royal society at the early age of 25. During this period he published important papers on the structure and action of voluntary muscles, the minute anatomy of the liver and the structure and function of the kidneys. While working as assistant surgeon to King's College hospital, London, in 1840, his clinical interests turned particularly to the eye and in 1846 he was appointed assistant surgeon to the Royal London Ophthalmic hospital

(later Moorfields Eye hospital), becoming full surgeon in 1851, the year which saw the discovery of the ophthalmoscope by Helmholtz.

He wrote many important papers and an early work, *The Physiological Anatomy and Physiology of Man* (1845–56), published jointly with R. B. Todd, was the pioneer work on physiology with histology. He was president of the ophthalmological section of the seventh international medical congress (1881) and of the newly founded Ophthalmological Society of the United Kingdom (1880–83), which founded an annual eponymous lecture in his honour. Knighted in 1884, Bowman died near Dorking, Surrey, on March 29, 1892.

(F. W. L.)

BOWRING, SIR JOHN (1792–1872), English author, linguist and diplomat, who was prominent in many spheres of mid-Victorian public life, but is chiefly remembered as the friend and literary executor of Jeremy Bentham. A member of a long-established Devonshire family, he was born on Oct. 17, 1792, at Exeter, where the foundations of his linguistic abilities were laid during his early career in a merchant's house. He devoted much time to the study of foreign literature, especially that of eastern Europe, and his first published works included *Russian Anthology* (1820–23); *Ancient Poetry and Romances of Spain* (1824); *Servian Popular Poetry* (1827); *Specimens of the Polish Poets* (1827); *Sketch of the Languages and Literature of Holland* (1829); and *Poetry of the Magyars* (1830). Bowring was a great friend of Jeremy Bentham and became an editor of the latter's *Westminster Review* in 1825. Subsequently, as Bentham's literary executor, he published *Jeremy Bentham's Life and Works* in 11 volumes (1843). From 1835–37 and 1841–49 Bowring was a member of parliament. In the house of commons he was a supporter of free trade, the repeal of the Corn laws and of penal reform, and an opponent of flogging in the army. He was also a strong advocate of the introduction of the decimal system into England and, with the support of the prince consort, secured the issue of the florin as an intended first step in this direction. Compelled by economic necessity to take up a diplomatic career, in 1849 he was appointed British consul at Canton and superintendent of trade in China, a post which he held for four years. Knighted in 1854, he was again sent the same year to Hong Kong as governor, invested with the supreme military and naval power. It was during his governorship that a dispute broke out with the Chinese over the case of the "Arro"; and the irritation caused by his highhanded policy led to the second war with China. In 1855 he visited Siam, and negotiated with the king a treaty of commerce. Bowring's last employment by the British government was as a commissioner to Italy in 1861, to report on British commercial relations with the new kingdom. He died at Claremont, near Exeter, on Nov. 23, 1872. His other writings include *Mznor Morals for Young People*, 3 pt. (1834–39); *The Influence of Knowledge on Domestic and Social Happiness* (1840?); *The Kingdom and People of Siam*, 2 vol. (1857); *A Visit to the Philippine Isles* (1859); and the posthumous *Autobiographical Recollections of Sir John Bowring* published by his son, Lewin Bowring, in 1877.

BOWYER, WILLIAM (1699–1777), English printer and scholar, known as "the most learned printer of the 18th century," was the son of William Bowyer, an eminent London printer and patron of the type-founder William Caslon. The younger Bowyer was born in London on Dec. 19, 1699, and, while at St. John's college, Cambridge, began to assist his father in correcting proofs. In 1722 he became a partner, continuing the correcting work while his father ran the mechanical side, and when the elder Bowyer died in 1737 his son carried on the firm. In 1729 they had been appointed printers of the house of commons' votes and in 1736 were appointed printers to the Society of Antiquaries, Bowyer being elected a fellow the same year. He contributed many papers which, together with other writings, were collected and published in 1785 by John Nichols (*q.v.*), "his apprentice, partner and successor."

Bowyer was a prolific writer and printer, producing many literary and religious critical works. The extensive notes on M. Bladen's translations of *Caesar's Commentaries* (1750) were his and in 1763

he edited and printed a two-volume Greek testament. In 1761 he became printer to the Royal society and in 1767 was appointed to print the rules of parliament and the journal of the house of lords. In the same year he moved the expanding business from Dogwell court to Red Lion passage. He died in London on Nov. 18, 1777, leaving many charitable bequests to be administered by the Stationers' company.

BOX: see BOXWOOD.

BOX ELDER, the name commonly given in the eastern United States to a species of a maple (*Acer negundo*), with pinnately compound leaves, numerous varieties of which are planted for shade and ornament. See MAPLE.

BOXER REBELLION: see CHINA: History.

BOXING, in modern times, is the art of attack and defense with the fists in which the contestants wear padded gloves, fight bouts of three-minute (or occasionally among amateurs two-minute) rounds, do not wrestle and otherwise generally observe the code (see below *The Bare-Knuckle Era*) set forth in the Marquess of Queensberry rules. The boxer depends upon his ability to land hard and often with his own fists and avoid the blows of his opponent.

The terms "pugilism" and "prize fighting" in 20th-century usage are practically synonymous with "boxing," though the first indicates the ancient origins in its derivation from the Latin *pugil*, "a fighter with the cestus (a hand covering)," related to the Latin *pugnus*, "fist," and in turn from the Greek *puξ*, "with clenched fist"; while "prize fighting" emphasizes the pursuit of the sport for gain. Samuel Johnson in his *Dictionary* (1756) defined a prize fighter as "one that fights publicly for a reward."

EARLY HISTORY

Undoubtedly men resorted to their fists to settle arguments as a matter of course for many centuries before anyone thought of staging bouts for the entertainment of others. There is evidence that boxing existed in ancient Crete, where a civilization was established by about 1500 B.C. Centuries before the arrival of the Greeks, boxing was known in the Aegean. And no sport was older and more popular throughout ancient Greek history than pugilism. The epics of Homer celebrate the deeds of fist fighters, and Theocritus describes an exciting bout between Amycus and Polydeuces (trans. by James Henry Hallard):

So, when their fists were bound with thongs of force-giving ox-skin,
Coiling the long bands round their arms, they met in the mid-ring,
Breathing slaughter against each other. . . .

The descriptions of fighting in ancient Greece are not evocative of Queensberry skill. The Greeks believed in fine development of physical as well as mental abilities. But the young Greek was always conscious of his possible role as a soldier or warrior and it was with this sort of destiny in mind that he exercised. Therefore, the fighting the Greeks did was largely to prove their courage, strength and endurance—not their agility or cleverness. They fought in the open air, bounded by spectators, with no resined surface to glide upon, no corners or ropes to employ in their strategy. As a matter of fact, they moved very little for agility might have been construed as cowardice. It was, however, accepted practice to maneuver an opponent so that he would face the sun. For the rest, the opponents stood close together and belaboured one another with swinging, clubbing blows. The object seemed to be as much to prove that they could "take it" as that they could deliver punishment. They did not employ straight punches at all. There were no rounds—the bout continued until one of the fighters admitted himself beaten.

In the early days fighters wore thongs of soft leather bound about their fists and (often) two-thirds of the way up their forearms to protect hands and wrists. Beginning in the 4th century B.C. harder leather was used for the thongs, with the result that they became weapons as well as protection. And finally, late in the history of the Roman empire, the Greeks adopted the hand covering called the cestus, which was studded with iron or brass nuggets and was used in battles to the death in the Roman arenas. The famous bronze statue of a Greek pugilist at the Museo delle

Terme in Rome shows an athlete with the hard thongs bound about his hands and forearms. It has the thickened nose and hemorrhaged (cauliflower) ears which still mark many professional boxers.

Although fist fighting was supposed by the Greeks of the classic period to have been a feature of the mythological games at Olympia, it was not actually introduced into the historic Olympic contests until the XXIII Olympiad (688 B.C.) after the re-establishment of the famous games by Iphitus about 880 B.C. Onomastus of Smyrna was one of the first Olympic victors. A sport called *pankraton* ("complete contest"), which combined boxing and wrestling, was introduced in the XXV Olympiad (652 B.C.). In the XLI Olympiad boxing competition for youths was added. There were no weight divisions, and size and strength were prime qualifications for the pugilist always.

The first Greek fighters were not paid; glory was the only reward they sought. Later wealthy men trained their slaves as boxers and had them perform for special entertainments. In the 1st century of Christianity Romans forced their cestus-clad slaves to bludgeon one another to death in a gruesome perversion of sport for the entertainment of crowds who thronged to arenas to see the kill. With the rise of Christianity and the concurrent decline of the Roman empire, pugilism as entertainment apparently ceased to exist for there is no record of it. When knighthood was in flower it was a poor fellow indeed who did not do his battling with horse, sword, armour and all the other trimmings.

THE BARE-KNUCKLE ERA

With the rise of London as a major city came a type of encounter called a prize fight. Prize fighters were strong men of different sections of the city, whose admirers were willing to bet that they could beat one another and arranged fights to settle the issues. The fighters performed for whatever purses were agreed upon plus stakes (side bets). At first there were few tactics which were not allowed. Wrestling was permitted and it was common to fall on a foe after throwing him. It also was common practice to hit a man who was down. The fighters wore no gloves of any kind and welcomed variations upon punching because their hands could not take the hard punishment implicit in delivering many hard punches consecutively. Nevertheless, one man by 1719 had so far captured public imagination that he was acclaimed champion of England. His name was James Figg (*q.v.*) and he held the title for a span which may have been as great as 15 years, turning back during this time an Italian challenger named Tito Alberto di Carni. Despite the appearance of this foreigner in the records, for years the only outstanding fighters were English. Occasionally an Irishman or American came to London to ply his trade. These invasions became more frequent as the popularity of prize fighting (and the size of prizes offered) increased.

The first fighter greatly to aid the sport itself was Jack Broughton (1704-89), a 200-lb. Englishman who won the championship of his country sometime between 1734 and 1740 (versions differ) and lost it in 1750 to a foul, unskilled brawler named Jack Slack. Broughton's reign was long enough and his character good enough to win a new respect for prize fighting. He preferred to discard the barroom techniques which his predecessors favoured and rely primarily on his fists. (He did, however, like all fighters of the time, also use wrestling holds.) He brought some degree of order out of a brawling chaos not only by the way he fought but by a set of rules which so clarified the proper conditions for a bout that they governed boxing, with only minor changes, until 1838 when the more detailed London Prize Ring rules superseded them. Under Broughton's rules, a round continued until a man went down; after 30 seconds of rest he had to square off a yard from his opponent or be declared beaten; he could not hit an opponent who was down or grasp him below the waist.

Broughton capitalized upon his good name among sportsmen by conducting classes in "the mystery of boxing. . . that wholly British art," as he advertised it for gentlemen at his Haymarket academy in 1747. To attract pupils, he devised "mufflers," ancestors of modern boxing gloves, with the assurance that these would be used in all bouts to protect against bruised faces and hands. This con-

tribution alone establishes his importance to modern boxing. Slack, however, inaugurated a period of dishonesty and foul play in which one fixed bout followed another and sportsmen lost faith entirely in the sport. Finally it was re-established in good repute by Tom Johnson, who became champion in the 1780s and finally lost the title, in an unquestionably honest bout in 1791, to Ben Brain.

The man who succeeded Brain was the first scientific fighter in the history of pugilism. He was an English Jew named Daniel Mendoza (1763-1836) who weighed only 160 lb. (a middleweight by modern standards) but beat the best and biggest fighters in England. Mendoza had good, quick footwork and a swift straight left (a jab). By combining agility with the bothersome jab, he easily befuddled his lumbering opponents. After losing his title to John Jackson, known as "Gentleman Jackson," in 1795, Mendoza opened a school in London at which he coached young noblemen in fighting techniques. Jackson was a clever boxer, although he achieved his championship by grabbing Mendoza's long hair with one hand and clubbing the smaller man with the other. But his chief interest was to use boxing as a way to meet and hobnob with the gentry of his time. He was a masterful teacher and claimed among his pupils Lord Byron, who referred to him in *Hints from Horace*:

And men unpractised in exchanging knocks
Must go to Jackson ere they dare to box.

Jackson's chief contribution, in the transformation of prize fighting into boxing, was to gain friends of distinction for the sport of fist fighting—people who were interested in seeing it progress and who could give it a badly needed aura of respectability. It is significant that the Pugilistic club was organized in Jackson's rooms. The organization attempted to create orderly procedures to be followed at every fight and raised funds for making matches and for prizes. At the first meeting Sir Henry Smith presided and many noblemen, including Lord Yarmouth, were present.

Of the bare-knuckle champions who followed, the first to assure himself sports immortality was Tom Cribb (1781-1848), and he did so largely by defeating two American-born former slaves, Bill Richmond (1763-1829) and Tom Molineaux (1784-1818). Richmond was the first man born in America to win acclaim in England as a first-class pugilist. Gen. Earl Percy, who commanded some of the British troops occupying New York, discovered Richmond's talents and took him to England in 1777. Cribb beat Richmond in 90 minutes in 1805. Later, after winning the English championship, he twice beat Molineaux in his greatest performances.

In 1839 the new London Prize Ring rules were first used in a championship fight, the one in which James ("Deaf") Burke lost the English title to William Thompson ("Bendigo"). These rules (revised in 1853) provided for a ring 24 ft. square and bounded by ropes. When a fighter went down the round ended. He was helped to his corner. Time was called after 30 seconds and if he could not get unaided to a mark in the centre of the ring by the end of 8 additional seconds, he was declared "not up to scratch" and beaten. Kicking, gouging, butting with the head, biting and low blows were all declared fouls. The London rules governed pugilism in England and America for over 50 years.

By 1860 America had produced a number of good fighters. One of them, the handsome John C. Heenan, was not content with the championship of the United States. He challenged English champion Tom Sayers. They met at Farnborough, Eng., April 17, 1860. There was a great difference in weights—195 lb. for Heenan to the Englishman's 149 lb.—but Sayers held Heenan to a 42-round draw, the last five rounds fought after a crowd entered the ring.

Although the Heenan-Sayers bout attracted a good deal of attention, the brawling which distinguished old-time pugilism continued to alienate most of the better people of England and it became apparent that if a widely popular sport was to emerge and endure it would have to be extracted from rather than preserved in the hurly-burly of prize fighting. When John Graham Chambers of the Amateur Athletic club devised a new set of rules he tried to emphasize the aspects of pugilism which Daniel Mendoza had first exploited—that is, the science and skill of it. These attributes were expected to draw a better class of patron than the old London rules.

The rules appeared in 1867 and differed from the London rules in four major respects: contestants wore padded gloves; each round consisted of three minutes of fighting followed by a minute of rest; wrestling was illegal; any fighter who went down had to get up unaided within ten seconds and, if he could not do so, was declared knocked out of time and the fight was over.

John Sholto Douglas, 8th marquess of Queensberry (1844-1900), had lent his name to Chambers' rules so that they would be associated with the nobility. At first professionals regarded them askance and thought practitioners of the new code somewhat effete. But gradually, although championships among professionals continued to be decided by the London rules, more and more fighters who were quick with their hands and feet and preferred punching to wrestling learned the Queensberry style. Prominent among these was James ("Jem") Mace (1831-1910) who, though weighing only 160 lb., won the English heavyweight title in 1861 through judicious use of a good left jab and a quick pair of feet. Having proved that he could win under the London code he was more or less free to do as he pleased and he chose to do two things which had a vast influence on the course of boxing history. The first was to go abroad to fight. The second was to show growing interest in the Queensberry style of fighting. In regard to the first move, Nat Fleischer explains its background in his book *The Heavyweight Championship* (G. P. Putnam's Sons, 1949):

At this time the good people of England, following the example of their blessed Queen Victoria, were in a state of almost orgiastic virtue. A reform wave swept the country. The clergy preached sulphurous sermons against the "ruffians of the ring." Prize fighting was becoming daily a more perilous pastime as the magistrates, falling in line with the popular trend, imposed heavier and heavier jail sentences on persons brought before them who were in any way associated with the ring.

A great exodus followed. [Ned] O'Baldwin, Tom Allen, Joe Wormald, Joe Goss, and a host of lesser lights sailed for the United States. In a sense, they were jumping out of the frying pan into the fire, for the transatlantic brand of Victorianism differed only in detail from the native variety. The fistic tide, nevertheless, set strongly toward the United States.

It was only a matter of time before Mace arrived, too. He actually was at his best when sparring with gloves. His enthusiasm for glove fighting gave the Queensberry code a real advantage, for it was generally conceded that there was nothing effete about Jem Mace. Jem fought his last bout in 1890, in England. Meanwhile, both the London and Queensberry rules were followed by a new generation of fighters in America and the time for decision between them was near.

Queensberry rules had gained favour steadily. Jack McAuliffe, who held the American lightweight title 1885-96, learned these rules and largely fought under them, although sometimes using skintight gloves instead of padded ones. "Nonpareil" Jack Dempsey, the first world middleweight champion, fought under both London and Queensberry rules but saw the latter gain in popularity toward the end of his reign (1884-91).

John L. Sullivan (*q.v.*), who claimed the world's heavyweight championship, was more famous and ruled a more popular division than either McAuliffe or Dempsey and it was, therefore, up to him to make the move which finally aligned professional fighters on the side of the Queensberry rules. He did so not out of a desire to benefit sport. He did so because he felt he could not afford to do otherwise.

Having won the American heavyweight title at the age of 24, Sullivan squandered remarkable speed of hands and feet on the London era, when these qualities were less appreciated than might later have been the case. Luckily, he also had great strength and a mighty punch. These latter qualities made and kept him a bare-knuckle champion. Public authorities had, however, grown increasingly hostile to pugilism. In 1889, when Sullivan defended against Jake Kilrain in the last heavyweight championship bare-knuckle fight to be held in America, prize fighting (London rules) was illegal in every state of the union. Subsequent to the Kilrain fight Sullivan was arrested and plagued with legal actions which interfered with his making a living for the next year. He complained that it cost him \$18,670 to settle for the Kilrain match. Therefore when at the age of 34 a dissipated, slow John L. agreed to defend his title against quick, clever "Gentleman Jim" Corbett,

Sullivan insisted on Queensberry rules. John L. lost to the epitome of Queensberry skill. Corbett in a five-year reign (1892-97) proved that a big man could be highly scientific. He launched boxing on a lucrative new era.

MODERN BOXING

Divisions. — In Sullivan's time the welterweight, featherweight and bantamweight divisions also were active although the weight limits varied with the champions, since it was then a champion's prerogative to adjust the weight to suit his own convenience, as long as he did not go to extremes. The light heavyweight class, called cruiserweight in Great Britain, was created in 1903 to include all boxers weighing over the middleweight limit and not more than 17½ lb. In 1910 the flyweight class was created in Britain, recognized also in the United States, to provide an official division for the smallest boxers. The weight limit was set at 108 lb., later changed to 112 lb. The divisions became heavyweight (over 175 lb.); light heavyweight or cruiser eight (over 160 lb. and not over 175); middleweight (over 147 lb. and not over 160); welterweight (over 13½ lb. and not over 147); lightweight (over 126 lb. and not over 13½); featherweight (over 118 lb. and not over 126); bantamweight (over 112 lb. and not over 118); and flyweight (not over 112 lb.). Following World War I and World War II boxing was so popular in the United States that two other divisions, junior lightweight (class limit 130 lb.) and junior welterweight (140 lb.) also existed briefly.

Economic Impetus. — When the bruisers of Victorian times left England, they went not only to the United States but to Australia and Canada and, occasionally, to continental Europe. The reasons that professional boxing became centred in the United States were chiefly two: an expanding economy made it possible for promoters to conduct bouts fairly regularly for the entertainment of factory hands, miners, lumberjacks and the other workers who flooded into the new country demanding excitement in their off hours; and successive waves of immigration provided husky, hungry boys who had little education and were willing to fight for quick cash. Boxing became, as it remains, a short cut to riches and social acceptance for those near the foot of the economic ladder.

The famines which drove thousands of Irish to seek refuge in America furnished important raw material for the greatest era professional boxing has known. Before 1915 the Irish had become dominant in every division from heavyweight through bantamweight. Oppression, especially in big cities, sent into the ring whole neighbourhoods of Irish-American boys. Terry McGovern, "Philadelphia" Jack O'Brien, Mike ("Twin") Sullivan and his brother Jack, Packey McFarland, Jimmy Clabby, Jack Britton — these were only a few of the colourful, courageous and highly skilled boys who made a profession of boxing.

Meanwhile, the American Negro, free but discriminated against in the land of his birth, turned to boxing also, hoping quite literally to fight his way to the top. And foreign-born Negroes (such as Peter Jackson, Sam Langford, Joe Walcott and George Dixon) came to capitalize on the boxing boom. Lightweight Joe Gans, born in Baltimore, was perhaps the cleverest boxer, pound for pound, in professional annals. He became a world champion (1902-08), as did heavyweight Jack Johnson (1908-15). German, Scandinavian and central European immigration, which increased after the political troubles of 1848, also contributed greatly to this golden age of boxing in the United States.

Polish-American Stanley Ketchel and German-American Billy Papke, Frank Klaus and Frank Mantell dominated the middleweight division 1908-13. Danish-American Battling Nelson and German-American Ad Wolgast ruled the lightweights 1908-12. Such outstanding Jewish fighters as Joe Choynski, Abe Attell, Battling Levinsky, Harry Lewis were active, but even more outstanding Jewish fighters were active from 1915 to 1930, when Benny Leonard, Sid Terris, Lew Tendler, Al Singer, Maxie Rosenbloom and Max Baer were in the ring.

Beginning about 1920 Italian-Americans assumed an importance in boxing. Their influence has continued great and has produced such champions as featherweight and lightweight Tony Canzoneri,

heavyweight Rocky Marciano, featherweights Johnny Dundee (nicknamed the "Scotch Wop") and Willie Pep.

The influence of the Negro was continual from the 19th century, although prejudice against him at times was great. John L. Sullivan found it convenient to "draw the colour line" in refusing to defend against Peter Jackson, and Jack Dempsey would not fight American Negro Harry Wills. But during his professional career Joe Louis (*q.v.*) won complete acceptance and his reign as heavyweight champion (1937-49) was one of the most popular in boxing history. Greatly encouraged, and further prompted by the rigours of depression years, Negroes flooded into the ring beginning in the mid-1930s to start a domination comparable to that enjoyed by the Irish prior to 1910. Outstanding among them were Henry Armstrong, who held the featherweight, lightweight and welterweight titles simultaneously; Ray Robinson, welterweight and middleweight champion; Archie Moore, light heavyweight champion; and heavyweight champions Ezzard Charles, "Jersey" Joe Walcott and Floyd Patterson.

Purses.—John C. Heenan and Tom Sayers fought for \$2,500 a side and a championship belt in 1860. John L. Sullivan fought Corbett in 1892 for a \$2 5,000 purse and a \$10,000 side bet. The man who made boxing big business was George ("Tex") Rickard, its first great promoter. After staging the world's lightweight championship bout between Joe Gans and Battling Nelson to publicize the mining town of Goldfield, Nev., in 1906, he saw that boxing as a spectacle had great potentialities. Through clever press agency Rickard made it fashionable to be seen at ringside at major bouts. Five of the fights he promoted for Jack Dempsey (*q.v.*), heavyweight champion 1919-26, drew over \$1,000,000 in receipts. They were the two bouts against Gene Tunney (1926 and 1927) and a match each against Georges Carpentier of France (1921), Luis Angel Firpo of Argentina (1923) and Jack Sharkey (1927). A natural showman and gambler, Rickard made an art of boxing ballyhoo, playing on people's prejudices in pitting Negro against white (Gans-Nelson and Jack Johnson-Jim Jeffries), alleged slacker against war hero (Dempsey-Carpentier) and American against foreigner (Dempsey-Firpo). His fortunes were tied to Dempsey's, however, and after Jack's retirement he lost over \$150,000 on Gene Tunney's 1928 title defense against Tom Heeney of New Zealand.

In the depression years which followed, receipts from boxing shows dwindled greatly. The financial centre of boxing remained the United States, although the bout between Primo Carnera of Italy and Paulino Uzcudun of Spain fought in 1930 in Barcelona drew more (\$110,000) than all but a few U.S. bouts that year. In 1935 Mike Jacobs, who had been associated with Rickard, signed Louis to a contract and thus launched a new boxing boom. With Louis fighting exclusively for him, Jacobs had the best drawing card since Dempsey. In two years he was promoting for Madison Square Garden in New York. Louis fought in three bouts that grossed over \$1,000,000: Max Baer (1935); Max Schmeling (1938); and Billy Conn (1946). In 1945 the receipts from a year of boxing at Madison Square Garden exceeded \$2,000,000 for the first time.

When James D. Norris and Arthur Wirtz succeeded Jacobs as America's outstanding promoters (1949) with their International Boxing club, boxing was undergoing a great change brought about by televising of bouts. Attendance fell off sharply for all but the most attractive matches, people preferring to watch televised bouts at home or in theatres. Therefore receipts from the crowd attending became steadily of less importance. When Rocky Marciano defended his heavyweight title against Archie Moore in 1955, the attending crowd paid \$948,117. But television receipts gave the bout a gross of \$2,248,117. Some lucrative bouts also were being staged outside the United States. British light heavyweight Freddie Mills drew \$200,000 and \$182,000 respectively in London bouts against Americans Gus Lesnevich and Joey Maxim. In 1953 English Randy Turpin drew \$238,000 in London against French Charles Humez. When Thai bantamweight Chamrern Songkitrat developed into a contender for the world championship, he drew receipts of over \$200,000 in 1954 Bangkok bouts against Australian Jimmy Carruthers and Frenchman Robert Cohen.

Individual boxers made fortunes, especially in the years before income taxes were levied on their earnings. Gene Tunney made almost \$1,000,000 from the second Dempsey fight. Dempsey himself earned \$2,402,500 in eight title bouts. But the \$2,722,000 which Joe Louis earned in 27 title bouts was heavily taxed.

Spread of Boxing.—As the English traveled they took boxing with them to the nooks and crannies of the world. It had attained some popularity in continental Europe before World War I but this popularity increased when American soldiers, who learned boxing as part of their training for bayonet fighting, showed great enthusiasm for the sport. Boxing was a feature of the Inter-Allied games held in Paris in 1919 and not many years afterward future world heavyweight boxing champions Primo Carnera and Max Schmeling of Germany launched their professional careers. The sport gained popularity more slowly in sections of Asia. In Thailand it developed alongside a traditional native sport similar to the old French savate, in which blows were delivered with feet as well as hands.

During the first half of the 20th century, world champions from the following countries other than England and the U.S. were crowned: Canada, Germany, Italy, France, Ireland, Greece, Australia, Philippine Islands, Cuba, Mexico, Panama, Spain, Puerto Rico, South Africa, Hawaii, Algeria, Wales, Tunisia, Scotland, Japan and Argentina.

SUCCESSION OF MODERN WORLD HEAVYWEIGHT CHAMPIONS

1882	John L. Sullivan (bare-knuckle title)	1930	Max Schmeling
1892	James J. Corbett (Queensberry title)	1932	Jack Sharkey
1897	Bob Fitzsimmons	1933	Primo Carnera
1899	James J. Jeffries (retired undefeated 1905)	1934	Max Baer
1906	Tommy Burns	1935	James J. Braddock
1908	Jack Johnson	1937	Joe Louis (retired undefeated 1949)
1915	Jess Willard	1949	Ezzard Charles
1919	Jack Dempsey	1951	Jersey Joe Walcott
1926	Gene Tunney (retired undefeated 1928)	1952	Rocky Marciano (retired undefeated 1956)
		1956	Floyd Patterson
		1959	Ingemar Johansson
		1960	Floyd Patterson

Changing Styles.—Styles of boxing underwent great changes after 1892, became highly individual and generally less circumscribed by convention. The classic style, popular at the turn of the century, was fought from a straight stand-up stance, with the emphasis upon straight blows and long-range boxing. The straight left jab was used prominently both in attack (to pile up points and wear an opponent down) and in defense (to beat the opponent to the punch). Scientific boxing was an art appreciated as such by the fight fans of that time. Corbett, not a heavy puncher, was adept at blocking (stopping a punch with his gloves or arms); slipping (avoiding it by moving his body while keeping his feet stationary); ducking; feinting; parrying (knocking a blow aside); and side-stepping. His own attack was comprised of sharp, quick punches that were timed to keep his opponent off balance. Young Griffo, Australian claimant of the world featherweight title, was such a clever defensive boxer that he could stand on a handkerchief and avoid the blows of an attacker who enjoyed freedom of movement. Lightweight Joe Gans glided on perfectly co-ordinated feet as he blended skill and power into a smoothly efficient style. With these men and their contemporaries, boxing was very much a defensive skill as well as an offensive one.

With the increase in popularity of the sport as a spectacle, however, the crowds began more frequently to demand the knockout. When Jack Dempsey was heavyweight champion he and promoter Rickard demonstrated that there was no substitute for a knockout punch at the boxing box office. Dempsey did more, too. He helped to revolutionize the style of boxing.

Dempsey was a beautifully co-ordinated athlete who kept on the offensive almost continually, bobbing up and down and moving from side to side as he delivered short, swinging blows out of a crouch at blinding speed. His constant movement and the speed of his attack constituted his defense. He had little patience with

the jab and less with long-range fighting, preferring the infighting to which his powerful, short hooks were adapted. This spectacular style of boxing as practised by Dempsey had a wide appeal because it often resulted in a knockout and because it reduced defensive maneuvering, which had to be understood to be appreciated, to an absolute minimum. The wider the boxing audience became, the less it cared for the refinements of the old school, the more it roared for the knockout.

Because crowds paid to see heavy punching, professional boxers, especially in the United States, began to stress aggressiveness and punching, even if they had to "take two to land one." The typical stance became a slight crouch (not so pronounced as Dempsey's) and there was an increasing emphasis on infighting. Cleverness was not lost for featherweight Willie Pep, who won the world title in 1942 and again in 1949, and Ray Robinson, who won the welterweight title in 1946 and the middleweight title in 1951 (twice), in 1955, in 1957 and in 1958, rank among the all-time great tacticians of boxing. Joe Louis was an expert boxer as well as a paralyzing puncher. There have been still others. With the advent of home television in the late 1940s, the emphasis went still more to punching. Housewives and clerks who had never been to boxing bouts now were part of the audience. They were chiefly interested in a good show—that is, plenty of action. The refinements of skilled boxing did not interest them enough to make skill a requisite for the bouts they saw.

Amateur.—From the time when the old English bare-knuckle champions began teaching their sport to English gentlemen, there have been enthusiastic amateur pugilists. At first they fought for the pure pleasure of it. Warren Barbour, an extremely competent heavyweight, won the U.S. championship in 1910 but refused to turn professional although some fight experts were confident he could beat the great Negro champion, Jack Johnson. In 1919 another promising American heavyweight, Edward Eagan, won the national title and also refused to become a professional. But the amateur ring nevertheless increasingly became a training ground for professional boxing.

The British Amateur Boxing association was established in 1884 to control amateur boxing in Great Britain. The Amateur Athletic union, established in 1888 in the United States, began that year to conduct annual competitions. Annual collegiate competitions have provided some contenders for A.A.U. honors. In 1923 still another amateur competition was started by a Chicago newspaper. Called the Golden Gloves (the name was first used in New York in 1927), it grew quickly into a national competition rivaling the A.A.U. Such world professional champions as Joe Louis, Ray Robinson, Joey Maxim, Floyd Patterson, Ezzard Charles and Rocky Marciano got valuable experience in amateur competition.

Boxing in seven divisions was introduced into the modern Olympic games in 1904. In 1920 light heavyweight competition was added and in 1952 the classes became ten with class limits as follows: flyweight, 112 lb.; bantamweight, 119; featherweight, 125; lightweight, 132; light welterweight, 139; welterweight, 147; light middleweight, 156; middleweight, 165; light heavyweight, 178; heavyweight, over 178. The spread of amateur boxing is reflected by the number of countries represented by boxers winning Olympic titles over the years (see OLYMPIC GAMES).

RULES

Professional.—Uniformity has been notably lacking in the rules under which professional boxing matches are conducted in different countries and in different states of the United States. Generally speaking, however, bouts take place in a "ring" which is 20 to 24 ft. square and surrounded by three strands of ropes. Each bout is comprised of rounds of three minutes of fighting followed by a minute of rest. Rounds range in number from 4 to 20, with 15 the usual length of a championship fight. Padded gloves, ranging from six to eight ounces in weight are worn by the fighters. Fouls include hitting below the belt, butting with the head, hitting with one hand while holding the opponent with the other, hitting an opponent who is down and using the "rabbit punch," a blow delivered to the base of the skull. Penalties for these infractions vary greatly. In the United States a "no foul"

rule was adopted after Max Schmeling won the heavyweight championship on a foul claim of doubtful validity in 1930. Under this rule all fighters must wear protective cups. If a boxer strikes below the belt he is only penalized by loss of the round unless his infraction is flagrant and repeated, in which case he is disqualified. Outside the United States a low blow usually brings disqualification.

In general, United States referees permit more infighting and are less strict about holding, butting and other roughing up at close range than European officials. A bout can end in a knockout when a boxer is knocked down and does not regain his feet before the count of ten (seconds), in a technical knockout, when a boxer is judged by the referee incapable of defending himself even though he has not been counted out; in a draw; in a decision, when a bout goes the scheduled distance and is won on points; or in a no contest, when the referee feels that for some reason the boxers are not putting up a good bout. In the United States in bouts that go the scheduled distance a referee and two judges have equal votes in determining the winner, in some states the vote being in terms of points scored; in some, rounds won; and in some, both. In Britain and most of continental Europe the referee has the whole responsibility.

Amateur.—The rules for conducting amateur boxing are very similar in Great Britain, the United States and continental Europe, although there are some national idiosyncrasies. Perhaps the most notable is that United States referees permit much more infighting and clinching than the others and go between the boxers to cause them to break up a clinch, instead of expecting them to break on voice command. Bouts are fought in rings 16 to 20 ft. square and eight- to ten-ounce gloves are used. Bending below the waist is prohibited by international rules because it may lead to butting with the head. The voting, under international rules is done entirely by three judges, the referee simply supervises the fighting. Here again the rules of the A.A.U. specify otherwise for United States amateur bouts. There two judges and the referee score each bout by rounds and points and vote for the winner. In 1952, however, the A.X.U. did adopt the ten divisions accepted under international rules and began conducting competitions in them.

TECHNIQUE

Stance and footwork are the basis of good boxing for they make it possible for the boxer to keep his balance while punching and moving. The left foot of the right-handed boxer should be a step ahead of the right, the toes of both feet pointed slightly toward the right. Both knees are bent slightly. The weight of the body rests largely on the right leg. The right heel lifts when a punch is delivered. In advancing the left leg leads the right follows. In retreating the reverse takes place. The chin is usually sunk slightly behind the left shoulder. The left hand is advanced ready to strike or parry, and the right hand is held close to the body sometimes in front of the chin.

The left jab is delivered by straightening the left elbow with a snap. It is the key blow of boxing used in both attack and defense. Other basic punches are the left and right hooks delivered with bent elbow, the right cross—a straight punch delivered with the right hand, and left and right uppercuts—short, swinging blows that come up from the direction of the ring floor. Swings which are longer than hooks are delivered also with bent elbows but are not usually so effective since a good boxer can avoid them. When a boxer has co-ordinated footwork with punching he is able to get the maximum body weight behind each punch. He is never off balance. Chief targets for the knockout punch are the chin, the temples and the stomach.

(M. M. W.)

BOXING DAY, the name given in Great Britain to the first weekday after Christmas, on which Christmas "boxes" or presents, are given to errand boys, postmen, etc. It is a bank holiday (*q.v.*).

BOXWOOD, the mood obtained from the genus *Buxus*, the

principal species being the well-known tree or shrub *B. sempervirens*, the common box, in general use for borders of garden walks, ornamental parterres, etc. Even more important in gardens is the dwarf variety *suffruticosa*, which does not too rapidly overgrow the proportions of the parterre. The cold-hardier *B. microphylla koreana* is used in northern gardens. The other source of the ordinary boxwood of commerce is *B. balearica*, which yields the variety known as Turkey boxwood. The common box is grown throughout Great Britain (perhaps native in the chalk hills of the south of England), in the southern part of the European continent generally, and extends through Iran into India, where it is found growing on the slopes of the western Himalayas. Only a very small proportion of the wood suitable for industrial uses is now obtained in Great Britain. The box is a very slow-growing plant, adding not more than one and one-half or two inches to its diameter in 20 years, and on an average attaining only a height of 16 ft. with a mean diameter of 10½ in.

JOHN MARKHAM

COMMON BOX (*BUXUS SEMPERVIRENS*)

The leaves of this species are small, oval; leathery in texture, and of a deep glossy green colour. *B. balearica* is a tree of considerable size, attaining to a height of 80 ft., with leaves three times as large as those of the common box. It is a native of the islands of the Mediterranean, and grows in Turkey, Asia Minor and around the shores of the Black sea. The wood of both species possesses a delicate yellow colour; it is very dense in structure and has a fine uniform grain, which has given it unique value for the purposes of the wood engraver. A large amount is used in the manufacture of measuring rules, various mathematical instruments, flutes and other musical instruments, for turning, for inlaying and for small carvings. The use of boxwood for turnery and musical instruments is mentioned by Pliny, Virgil and Ovid.

BOYACÁ, a densely-settled department in the Andes mountains of eastern Colombia. Area 23,217 sq.mi.; pop. (1961 est.) 844,890. Most of the population lives in the cool uplands of the Andes, cultivating potatoes, wheat, barley, haba beans and the lesser Andean root crops under a system of tenancy inherited from the colonial era. Dense forests on mountain slopes yield fine wood. Besides the capital city of Tunja, the principal towns are Chiquinquirá, Sogamoso and Moniquirá. A few miles south of Tunja, near the village of Boyacá, was fought the decisive battle in New Granada's war for independence on Aug. 7, 1819. The famous Muzo emerald mines are located in the western part of Boyacá. At Paipa, 30 mi. north of Tunja, there are famous mineral springs. Colombia's first integrated iron and steel plant (capacity 122,000 tons) was built at Paz del Río, 5 mi. N. of Sogamoso at an elevation of nearly 9,000 ft. Iron ore, coal and limestone are in ample supply but major consuming markets are so distant that the project has frequently been criticized as uneconomic. The larger part of the department of Boyacá lies within the llanos or low plains between the Andes and the Orinoco river. This vast area was for a time separated from Boyacá as the Comisaría de Casanare, but it was reincorporated into Boyacá in 1950. (Js. J. P.)

BOYAR (Russ. boyarin, plur. *boyare*). The boyars formed the upper stratum of society and of the state administration in medieval Russia. In Kievan Russia of the 10th–12th centuries they constituted the senior group in the princely retinue (*drushina*), occupying the higher posts in the armed forces and in the civil administration. The boyar council (*boyarskayu дума*) usually advised the prince in all important matters of state, although its com-

position and competence were not defined by law. In Novgorod, despite its democratic constitution, the prosperous boyars were influential in political life and in the local economy. In the north-eastern Russian principalities, during the 13th and 14th centuries, the boyars formed a privileged class of rich landowners who were also the prince's aides and councilors; they retained, however, the right to leave their sovereign and enter another prince's service without losing their landed estates.

From the 15th to the 17th centuries the boyars of Muscovy formed a closed aristocratic caste that surrounded the throne of the grand prince (later the tsar) and ruled the country together with him. They were drawn from the ranks of about 200 families descended from former appanage princes whose possessions had been annexed by Moscow, from old Moscow boyar families, or from aristocratic newcomers from other lands. The rank of boyar did not belong to all members of these families, but only to those senior members to whom the tsar granted this title. Below the boyars stood the group of *okolnichie*. Together they formed the boyar council, which, together with the tsar, directed all internal and foreign affairs of the state. According to the code of laws (Sudebnik) of 1550, the decisions of the boyar council, as confirmed by the tsar, were recognized as the normal form of legislation. The boyars and *okolnichie* served as heads of the most important government offices (*prikazy*), as governors of the most important provinces, as military commanders and as chiefs of the most important foreign embassies.

The tsar, however, did not have a free hand in the choice of his chief aides. He was bound by the peculiar aristocratic custom called *mestnichestvo*. This was a complicated system of service-relationships between the aristocratic families of Muscovy. They were ranked in a definite genealogical order according to their relative seniority, while posts in the civil and military administration were arranged in a similar hierarchical scale. In filling the highest posts in his army and administration, the tsar had to consider not so much the candidate's personal merits but rather his genealogical seniority as defined by earlier precedents. *Mestnichestvo*, which hampered the choice of the right man for the right position and caused endless quarrels among the boyar families over seniority, was finally abolished in 1682.

After Ivan the Terrible's reign and the "time of troubles," the social and political importance of the boyars declined throughout the 17th century. Peter the Great abolished the very rank and title of boyar and made state service the sole means of attaining a high position in the bureaucratic hierarchy.

(S. G. P. U.)

BOY BISHOP, according to a custom widespread in the middle ages, was chosen in connection with the festival of Holy Innocents. In England the boy bishop was elected Dec. 6, the feast of St. Nicholas, the patron of children, and his authority lasted till Holy Innocents' day (Dec. 28). The boy and his colleagues took possession of the cathedral and performed all the ceremonies and offices except Mass. Several ecclesiastical councils had attempted to abolish or to restrain the abuses of the custom, before it was prohibited by the council of Basel in 1431. It was, however, too popular to be easily suppressed. In England it was finally abolished by Elizabeth I. An analogous custom survived until late in the 18th century in Germany, where on March 12, in honour of St. Gregory, the patron of schools, a schoolboy was elected bishop. See also **FOOLS, FEAST OF**.

See E. K. Chambers, *The Medieval Stage*, vol. i, pp. 336–371 (1903).

BOYCE, WILLIAM (1710–1779), one of the foremost English composers of church music, notable also for his symphonies and as an organist and musical editor. He was probably born in London in 1710, and was a chorister under Charles King at St. Paul's cathedral, and later a student of Maurice Greene, the organist there. He became organist of the Oxford chapel, Vere

street, London, in 1734. Other appointments about this time included that of conductor of the Three Choirs festival (1737).

Boyce's career as a composer was closely related to his many official positions. He became composer to the Chapel Royal in 1736 and many of his anthems and church services were written for use there and at the London churches of which he was *organist*—St. Michael's, Cornhill, 1736–68, and All Hallows, Thames street, 1749–68. He also composed secular music for the stage, an early example being the music for Lord Lansdowne's masque, *Peleus and Thetis*, first produced in 1740. The serenata *Solomon* (1743) is among the best of such works; it contains the once-popular tenor scena "Softly rise, o southern breeze." His next published work was *Twelve Sonatas for two Violins with a Bass* (1747), which achieved an instant and lasting popularity. In about 1745 he began the publication of the first of several volumes of the collection of his own songs and cantatas, *Lyra Britannica*. In 1749 he received his doctorate of music from the University of Cambridge for his setting of William Mason's ode and of the anthem *O be joyful* for the duke of Newcastle's installation as chancellor. In the same year he wrote the music for *The Chaplet*, "a musical entertainment" by Moses Mendez, which long remained popular. The next year, 1750, saw a revival of Dryden's *Secular Masque*, with music by Boyce, including the well-known *Song of Momus to Mars*. In 1751 came another musical entertainment by Mendez and Boyce—*The Shepherd's Lottery*.

On Greene's death in 1755, Boyce succeeded him as master of the King's Band of Music and thereafter composed the music for the annual new year and birthday odes by the poet laureate. In 1758 he became one of the organists at the Chapel Royal and in 1759 he composed the music for the pantomime, *Harlequin's Invasion*, by Garrick, which includes his most famous song, *Heart of Oak*. In 1760 appeared his Eight *Symphonys*, orchestral works selected from his odes, operas, etc. They had some success, but ten years later, when he published a second set, the *Twelve Overtures*, the more exciting symphonies of the Mannheim school were in vogue and Boyce's shapely and tuneful "ancient style" symphonies were regarded as out of date. Meanwhile, he had begun to publish his famous collection of *Cathedral Music*, 3 vol. (1760–73). Based in part on materials collected by Greene, it was a landmark in the history of church music, the first collection since the Restoration, and the first to be printed in score. Boyce performed his work well by the standards of his time, and his collection, which covered three centuries, was only superseded in the mid-19th century.

Boyce had been long afflicted by deafness, and in 1769 he gave up all appointments except that at the Chapel Royal. He was still able to teach, however, and his pupils included the child prodigies, Charles and Samuel Wesley. He died in London, Feb. 7, 1779.

As a man Boyce was respected and loved. As a composer, his fame long rested mainly on his church music; his anthems are still sung. Later, the vigour of his symphony-overtures was increasingly recognized and many have been reprinted and performed. Some, arranged by Constant Lambert, were used for the ballet *The Prospect Before Us*, first produced at Sadler's Wells, London, in 1940.

See his *Overtures*, ed. by G. Finzi, in *Musica Britannica* (1957).

(Cs. Ch.)

BOYCE THOMPSON INSTITUTE FOR PLANT RESEARCH, INC., of Yonkers, N.Y., was founded and endowed by Col. William Boyce Thompson of Yonkers. The institute was formally opened on Sept. 24, 1924. It is a foundation for research on plants and plant products, insecticides and fungicides. The results of the foundation's research are published.

The greenhouses and other growing chambers give accurate control of growth conditions for plants, including light (quality, daily duration and intensity), humidity, temperature and carbon dioxide concentration of the air. This apparatus is on sufficiently large scale to permit plants to be grown to maturity in large numbers. Special attention is given to adequate equipment so that researches may be carried forward with facility and accuracy. The laboratories are adequately equipped for researches in physiology, pa-

thology, morphology and anatomy, biochemistry, microchemistry, physical chemistry, entomology, organic chemistry and plant breeding. While the laboratories are equipped and manned on the basis of techniques, the problems are generally attacked as projects, focusing all techniques on them necessary for their solution, even adding new lines of technique for particular problems when needed.

The institute has sufficient land available for field plots so that laboratory findings can be tested out on a field basis. A large arboretum gives adequate opportunity for the study of problems of forest and ornamental plants, including propagation, diseases, insect pests, soil adaptation and hardiness.

The institute has held the view that research on plants should contribute alike to science and to practice and that real progress in either requires a fundamental attack. It is world famous for its researches in certain phases of plant science. These include chemicals for forcing dormant plant organs and the effect of such chemicals upon plant metabolism: germination and storage of seeds, especially those offering difficulties in practical fields such as conservation, forestry, horticulture and seed trade; plant hormones and other chemicals that regulate plant development, movement and metabolism; virus and yellows diseases of plants; and synthesis of cellulose by plant cells and structure of primary cell walls.

(R. Cro.; X.)

BOYCOTT, CHARLES CUNNINGHAM (1832–1897). English estate manager who achieved notoriety during the agitation over the Irish land question when he became the originator of the word "boycott." Born in Norfolk on March 12, 1832, the son of a parson, he retired from the army with the rank of captain and in 1873 became agent for the earl of Erne's estates in County Mayo, Ireland. The Land league, formed in 1879 when bad harvests threatened a new famine (see IRELAND: *History*), soon told Boycott that he must reduce rents and in 1880 made a concerted demand for a 25% reduction. In Sept. 1880, after Boycott had attempted to serve writs for eviction, C. S. Parnell urged that without resort to violence the tenants should avoid any communication with those who refused their demands. This tactic was first used on Boycott, and its success was demonstrated when he needed the help of 50 volunteers from Ulster, working under an armed escort of 900 soldiers, to harvest his crops. Boycott left Ireland the same year, but conditions quickly eased after Gladstone's Land act of 1881 had set up fair rent tribunals. Boycott became an agent for estates in Suffolk in 1886 and died there on June 19, 1897.

After 1880 the term "boycott" soon came into common use and was at first used to describe all forms of nonviolent intimidation; it is now generally synonymous with "sending to Coventry."

(D. G.)

BOYD, the name of an old and distinguished Scottish family, one member of which, SIR ROBERT BOYD, had fought with William Wallace and Robert I (the Bruce), and later acquired the barony (1592) and earldom (1661) of Kilmarnock.

ROBERT BOYD (d. c. 1481), Lord Boyd, a son of Sir Thomas Boyd (d. 1439), was created a peer c. 1454 and was one of the regents of Scotland during the minority of James III. He secured the person of the young king in 1466 and was appointed governor of the realm (1466) and chamberlain (1467). He arranged the marriage (1469) between James III and Margaret, daughter of Christian I, king of Denmark and Norway, which secured the cession by Norway to Scotland of Orkney and Shetland. But Boyd's great power aroused jealousies, and he was attainted of treason and sentenced to death in Nov. 1469; he escaped to England, and died c. 1481, probably at Alnwick, Northumberland.

THOMAS BOYD (d. c. 1473), earl of Xrran, Robert Boyd's eldest son, received his title in April 1467, on his marriage with Mary, sister of James III, and was principal envoy to Denmark for the negotiations of 1468–69. On his return with King James's bride in July 1469 he learned of his family's fall from power and escaped with his wife to Denmark. He was forfeited by parliament in Nov. 1469, and is thought to have been dead by 1474, the date of his widow's marriage to Lord Hamilton, from whom the Hamilton earls of Xrran were descended.

ROBERT BOYD (c. 1517–90), Lord Boyd, was prominent in Scot-

tish politics from his succession to the title in 1551 or 1558. At first he favoured the reformed religion, but was afterward a trusted adviser of Mary Stuart and supported her at the battle of Langside (1568). During the queen's captivity he was often employed on diplomatic errands and was suspected of participation in the murder of the regent Moray. He was in favour under the regent Morton, but was banished to France in 1583 for a short while, for his share in the raid of Ruthven, a plot to seize James VI. He died on Jan. 3, 1590.

Several descendants of the 1st Lord Boyd held the office of chamberlain of Kilmarnock. THOMAS BOYD (c. 1547–1611), Lord Boyd, resigned his whole estate to James VI, and on Jan. 12, 1592, was granted the lordship and barony of Kilmarnock. His great-grandson WILLIAM BOYD (d. 1692), Lord Boyd of Kilmarnock, was created earl of Kilmarnock on Aug. 17, 1661, and the barony was merged in this title until both were forfeited by the attainder of his great-grandson, WILLIAM BOYD (1705–46), 4th earl of Kilmarnock, who was captured fighting for Charles Edward, the Young Pretender, at the battle of Culloden in April 1746. He was beheaded on Aug. 18, 1746.

William Boyd's second but first surviving son, JAMES BOYD (1726–78), succeeded to the estates but not to the title of his father. On the death of his maternal great-aunt, he became, in 1758, 15th earl of Erroll, adopting the Erroll family name of Hay. The barony of Kilmarnock was revived in favour of WILLIAM GEORGE HAY (1801–46), 18th earl of Erroll, and the title Lord Kilmarnock was thereafter used by the eldest son of the earl of Erroll. JOSSLYN VICTOR HAY (1901–41), 22nd earl of Erroll, was succeeded in the earldom of Erroll by his daughter, and in the barony of Kilmarnock by his brother, GILBERT ALLAN ROWLAND HAY (1903–), who resumed the name of Boyd.

BOYDELL, JOHN (1719–1804), English publisher, engraver and lord mayor of London, whose good taste and liberality as a publisher of engravings exerted an extensive influence on English art, was born at Dorrington, on Jan. 19, 1719. At the age of 21 he went to London and was apprenticed for seven years to an engraver. In 1746 he published a volume of views in England and Wales and started in business as a print seller. He was sheriff in 1785, and in 1790 became lord mayor of London. In 1786 he published, by subscription, a series of prints illustrating Shakespeare's plays. The pictures from which these were made were commissioned from the most famous artists of the day and were exhibited in Boydell's own gallery in Pall Mall. In 1802, the year of the production of Boydell's *Shakespeare*, the gallery contained 102 pictures, including canvases by Reynolds, Romney, Opie, Barry, Fuseli, Angelica Kauffmann, Stothard and others. Toward the close of his life Boydell sustained severe losses and was compelled to dispose of his Shakespeare gallery by lottery. He died on Dec. 12, 1804, in London.

BOYD-ORR, JOHN BOYD ORR, 1ST BARON, of Brechin Mearns, in the county of Angus (1880–), British scientist and authority on nutrition who was awarded the Nobel peace prize in 1949. Born at Kilmaurs, Ayrshire, Scot., on Sept. 23, 1880, he was educated at Glasgow university, where he went on to the study of nutrition after enrolling as a theological student. In 1914 he went to Aberdeen university as director of the Institute of Animal Nutrition and in 1929 founded the Imperial Bureau of Animal Nutrition at Rowett. Boyd-Orr first became well-known following the publication of *Food, Health and Income* (1936), the report of a dietary survey by income groups made during 1935. It showed that the cost of a diet fulfilling basic nutritional requirements was beyond the means of half the British population and that 10% of it was badly undernourished. The findings of this report and of others conducted by the Rowett institute formed the basis of the British food rationing system during World War II, when Boyd-Orr was a member of the cabinet's scientific committee on food policy and held the chair of agriculture at Aberdeen. In 1945, the year in which he became rector of Glasgow university and a member of parliament for the Scottish universities, he was elected director-general of the United Nations Food and Agriculture organization (FAO). He held this post until 1948, and his Nobel award the following year was generally considered

to have been due to his work with the FAO. Knighted in 1935, he received a barony on Jan. 1, 1949. His writings include *The National Food Supply and Its Influence on Public Health* (1934); *Nutrition in War* (1940); *Fighting for What?* (1942); *Food and the People* (1943); *Food—the Foundation of World Unity* (1948); and *The White Man's Dilemma* (1953).

BOYE, KARIN MARIA (1900–1941), the leading woman poet of Swedish modernism, was born at Goteborg on Oct. 26, 1900. She studied at the universities of Uppsala and Stockholm, became a leading figure in the Clarté socialist movement inspired by Henri Barbusse and worked on *Spektrum*, a review propagating psychoanalytical theory and modernistic literary views. Her five collections of poems (beginning with *Moln*, 1922) show the evolution of her outlook and style from the simple expression of a middle-class girl's dreams and a young radical's eager acceptance of life to bolder images, wider perspectives and feeling for the tragic problems of mankind. Among her novels are *Kris* (1934), based on her discovery of her own deviant sexual inclinations, and *Kallocain* (1940), which describes the insupportable oppression of a totalitarian society of the future.

Karin Boye committed suicide at Alingås on April 24, 1941.

(L. G. G. T.)

BOYER, JEAN PIERRE (c. 1773–1850), president of Haiti. A mulatto, he was born in Port-au-Prince and educated in France. After the first Haitian revolts, he served under Gen. André Rigaud, who ruled part of southern Haiti and opposed Toussaint L'Ouverture (q.v.). He fled to France after Rigaud's defeat, returned with the French army in 1802, and then joined the revolt that established Haiti's independence. He was private secretary to Alexandre Sabes Pétion and then chief of the presidential guard. When Pétion died, Boyer's friends in the army forced the senate to elect him as president for life.

Boyer occupied northern Haiti after Henri Christophe's death in 1820 and in 1822 conquered the former Spanish colony of Santo Domingo, thus becoming ruler of the entire island. In 1825 France recognized Haiti's independence in return for a promise, not fully carried out, to pay a \$30,000,000 indemnity. Boyer was honest and able but his autocratic policy made him unpopular in later years, especially among the younger generation. He was ousted by a revolution in 1843 and died in poverty at Paris, July 9, 1850. He was responsible for much important legislation including the basic law codes of Haiti. See also HAITI: *History*.

(D. G. Mo.)

BOYLE, ROBERT (1627–91), English natural philosopher, was one of the founders of modern chemistry. He was the 7th son and 14th child of Richard Boyle, the great earl of Cork, and was born at Lismore castle, Ire., Jan. 25, 1627. While still a child he learned to speak Latin and French, and he was only eight years old when he was sent to Eton. In 1638 he went to travel abroad with a French tutor. Visiting Italy in 1641, he remained during the winter of that year in Florence, studying the "paradoxes of the great star-gazer" Galileo. On returning to England in 1644 Boyle devoted his life to study and scientific research, and soon took a prominent place in the band of inquirers, known as the "Invisible College," who devoted themselves to the cultivation of the "new philosophy." They met often in London, at Gresham college; some of the members also had meetings at Oxford, and Boyle went to reside in that city in 1654. Reading in 1657 of Otto von Guericke's air pump, he set himself, with the assistance of Robert Hooke, to devise improvements in its construction, and with the result, the "machina Boyleana" or "pneumatical engine," finished in 1659, he began a series of experiments on the properties of air. An account of the work was published in 1660 as *New Experiments Physico-Mechanical Touching the Spring of Air and Its Effects*.

Among the critics of the views put forward in this book was a Jesuit, Franciscus Linus (1595–1675), and it was while answering his objections that Boyle enunciated the law that the volume of a gas varies inversely as the pressure, which among English-speaking peoples is usually called after his name, though on the continent of Europe it is attributed to E. Mariotte, who did not publish it till 1676. In 1663 the "Invisible College" became the

"Royal Society of London for improving natural knowledge," and the charter of incorporation granted by Charles II named Boyle a member of the council. In 1680 he was elected president of the society, but declined the honour from a scruple about oaths. In 1668 he moved to London, where he died on Dec. 30, 1691.

Boyle's great merit as a scientific investigator is that he carried out the principles which Bacon preached in the *Novum Organum*. Yet he would not avow himself a follower of Bacon or indeed of any other teacher. He performed experiments in the hope of effecting the transmutation of metals, and he was instrumental in obtaining the repeal, in 1689, of the statute of Henry IV against multiplying gold and silver. With all the important work he accomplished in physics—the enunciation of Boyle's law, the discovery of the part taken by air in the propagation of sound, and investigations on the expansive force of freezing water, on specific gravities and refractive powers, on crystals, on electricity, on colour, on hydrostatics, etc.—chemistry was his peculiar and favourite study. His first book on the subject was *The Sceptical Chemist*, published in 1661, in which he criticized the "experiments whereby vulgar Spagyristy are wont to endeavour to evince their Salt, Sulphur and Mercury to be the true Principles of Things." He advanced toward the view that matter was ultimately composed of "corpuscles" of various sorts and sizes capable of arranging themselves into groups, and that each group constituted a chemical substance. He distinguished between mixtures and compounds and showed that a compound might have different qualities from those of its constituents. He studied the chemistry of combustion and of respiration and made experiments in physiology, where, however, he was hampered by the "tenderness of his nature" which kept him from anatomical dissections.

Besides being a busy natural philosopher, Boyle was interested in theology, and in 1665 would have received the provostship of Eton, if he had taken orders. He learned Hebrew, Greek and Syriac in order to pursue his scriptural studies and spent large sums on biblical translations. By his will he founded the Boyle lectures, for proving the Christian religion against "notorious infidels, viz., atheists, theists, pagans, Jews and Mahomedans," with the proviso that controversies between Christians were not to be mentioned.

(See also CHEMISTRY: *History of Chemistry*.)

An incomplete and unauthorized edition of Boyle's works was published at Geneva in 1677, but the first complete edition was that of Thomas Birch, with a life, published in 1744, in five folio volumes, a second edition appearing in 1772 in six volumes, quarto. Boyle bequeathed his natural history collections to the Royal society, which also possesses a portrait of him by the German painter, Friedrich Kerseboom (1632–90).

BOYLE (MAINISTIR NA BÚILLE), a town in County Roscommon, Republic of Ireland, 106 mi. W.N.W. of Dublin and 24 mi. S.S.E. of Sligo by road. Pop. (1956) 1,835. It is situated on both banks of the Boyle, a tributary of the Shannon, between Loughs Gara and Key, at the foot of the Curlew hills. Three bridges connect the two parts of the town. Trade is mainly agricultural. To the north of the town stand the extensive ruins of a Cistercian abbey founded in 1161 and suppressed in 1569, including remains of a cruciform church, with early Gothic and Romanesque arches carved in beautiful detail down the long nave. There is a large dolmen by the road toward Lough Gara; many prehistoric remains, including dugout boats, have been found in the lake. Boyle was incorporated by James I.

BOYLE'S LAW, a relation, discovered by Robert Boyle, between the pressure, p , and the volume, v , of a gas, viz., $pv = \text{constant}$, at constant temperature. See BOYLE, ROBERT; KINETIC THEORY OF MATTER: *The Gas Laws*; THERMODYNAMICS: *Frictionless Adiabatic Expansion*; ELASTICITY: *Boyle's Law*.

BOYLESVE, RENE (real name RENÉ MARIE AUGUSTE

TARDIVEAU) (1867–1926), French novelist who influenced many other writers, including Proust, was born in La Haye-Descartes (Indre-et-Loire), April 14, 1867, and was educated in Poitiers, Tours and Paris. His studies of both liberal and fine arts, science and law, did not lead to his entering a profession. After ten years in unimportant jobs, he wrote, under his mother's maiden name, his first novel, *Le Médecin des dames de Néans* (1896) in which the essential Boylesve is already to be found, and which anticipated Proust in style. There followed *Le Parfum des îles Borromées* (1898), a bitter book which he softened in tone and cut by nearly half in the definitive edition (1907). *Sainte-Marie-des-Fleurs*, an autobiographical love story, had appeared in 1897. Then came the powerful series known as the *romans tourangeaux*—*Mademoiselle Cloque* (1899), *La Becquée* (1901), *L'Enfant à la balustrade* (1903; Eng. trans. *The Child at the Balustrade*, 1929) and *La Jeune Fille bien élevée* (1909)—which although ostensibly works of imagination, reveal Boylesve as the historian par excellence of rural and urban society in the west of France during 1870–1900—a historian and at the same time, a poet.

Mention should also be made of his most famous and least understood work, *La Leçon d'amour dans un parc* (1902), which purports to be the daring story of an 18th-century love affair, but is fundamentally a novel about a child's education. His least known work, *Le Bel Avenir* (1905), is of interest because it was always his own favourite. His last novels were *Mon Amour* (1908), *Le Meilleur Ami* (1909) and *Madeleine jeune femme* (1912; Eng. trans. *A Gentlewoman of France*, 1916) which is probably his masterpiece, though not his most attractive work. He also wrote many short stories, collected in *La Marchande de petits pains pour les canards* (1909) and *Bonheur à cinq sous* (1917). Boylesve was elected to the Académie Française in 1918. He died, Jan. 14, 1926, in Paris. Among his posthumous works are *Opinions sur le roman* (1929) and *Feuilles tombées*, ed. by É. Gérard-Gailly (1927)—the latter an important fragment of his private journal, which shows rare critical and introspective gifts, and *Profil littéraires* (1961). (E. G.-GÄ.)

BOYNE (AN BOINN), a river in the Republic of Ireland rising in the Bog of Allen, near Carbury in County Kildare, and flowing in a northeasterly direction past Trim, Navan and Slane to enter the Irish sea 4 mi. below Drogheda. With a total length of 70 mi., it is noted for its salmon fishing and its lower reaches are navigable by coastal shipping. It figures largely in Irish history. The Bronze Age burial tumuli at Knowth, Newgrange and Dowth along its course are of the highest archaeological interest and importance. Slane is intimately associated with St. Patrick and with the introduction of Christianity to nearby Tara, the seat of the Irish kings.

Battle of the Boyne.—On July 12 (new style; July 1, old style), 1690, the forces of King William III and the former king James II came to battle on its banks. James, failing to take Derry and Enniskillen, had left Ulster as a bridehead to William and had wasted his best Irish regiments in England and France. He assembled in the Oldbridge area, south of the Boyne, 7,000 French infantry, some regular Irish cavalry and untrained Irish infantry and dragoons—altogether about 21,000 men. William led the Dutch Blue Guards, two regiments of French Huguenots, some English, and contingents of Danish, Prussian, Finnish and Swiss mercenaries—altogether about 35,000 men. Fearing encirclement by William's cavalry which crossed the Boyne at Rosnaree on the left and at Oldbridge toward the right, James fled hastily from the battle and from the country. The battle was William's but the Jacobite army successfully withdrew to carry on the war for another year in Ireland. The battle of the Boyne is celebrated in northern Ireland by Orangemen as a victory for the Protestant cause on July 12, which is actually the old style date of the more decisive battle of Aghrim (*q.v.*). See GRAND ALLIANCE, WAR OF THE. (U. G. F.)

BOYS' BRIGADE, THE, was founded on Oct. 4, 1883, by William Alexander Smith (1854–1914) for "the advancement of Christ's Kingdom among Boys, and the promotion of habits of Obedience, Reverence, Discipline, Self-respect and all that tends toward a true Christian manliness." As secretary of the Sunday school of the Free Church mission in Glasgow, Scot., Smith

recognized that the task of Christian teaching would be much easier and more effective if a greater discipline could be imposed upon the Sunday school pupils. Accordingly he formed, under the name of the Boys' Brigade, a company of about 30 boys wearing a simple uniform over their ordinary clothes and meeting weekly for drill as well as for Bible class on Sundays. The movement spread quickly throughout the United Kingdom and extended later to the United States, Africa, the West Indies and other countries.

Every company of the brigade is connected with a church or other Christian organization, and the vicar or minister usually holds the rank of chaplain. Each company meets weekly for religious instruction, generally as a Sunday Bible class conducted by the officers. In addition to the weekly drill parade the program includes physical training, gymnastics, athletics, bands, first aid, wayfaring, educational subjects and holiday camps. There are certificates and badges for most of the subjects taught, the highest award being the Queen's badge. Boys may join at the age of 11 and remain members until they are 18. The more than 4,000 companies (most of them in England) and 3,300 Life Boy teams have a total membership of all ranks of 250,000. The Boys' Brigade is governed by an executive committee responsible to the brigade council whose annual meeting is open to all officers.

(D. J. W.-H.)

BOY SCOUTS. The Boy Scout movement was started for the purpose of training boys in the essentials of good citizenship, and it arose in 1908 after the appearance of a book *Scouting for Boys* written by the then inspector general of cavalry in the British army, Lieut. Gen. R. S. S. Baden-Powell (*q.v.*), then more widely known in England as the defender of Mafeking in the South African War. Baden-Powell had intended his ideas to be used by existing youth organizations, but it was soon obvious that a new movement had come into being and, although it had been started in Great Britain for British boys, it very quickly spread to other countries. Chile was the first to take up scouting after Great Britain, and Canada, Australia, New Zealand and South Africa were the first in the commonwealth, but by 1910 it had spread to Sweden, France, Norway, Mexico, Argentina and the U.S.

Foundation and Principles.—It has been said that scouting began with a man, an island and a book. Certainly with the publication of the book the Boy Scouts came into being, but before this Baden-Powell had held an experimental camp on Brownsea Island in Poole harbour, Dorsetshire, during which he put into practice his ideas on the training of boys. These had accumulated from the experiences of his own life—his school days at Charterhouse, his holidays with his brothers trekking, canoeing and sailing, his life as a soldier in India and Africa—supplemented by ideas beyond his time and a notable skill in tracking and reconnaissance.

Baden-Powell's idea of training boys was that they should organize themselves into small natural gangs of six or seven under a boy leader—the patrol and the patrol leader. Their training would be complementary to their ordinary education: such things as mapping, signaling, knotting, first aid and all the skills that would arise from camping and similar outdoor activities. But, and perhaps most important of all, to become a scout a boy must promise that on his honour he would do his best to do his duty to God and his country (or sovereign), to help other people at all times and to obey the scout law, itself a simple code of chivalrous behaviour easily understood by the boy.

In every country where scouting exists the same basic pattern remains: a promise and a law, with such small variations as national traditions and culture demand; an emphasis on the delights of the outdoor life and the pursuit of outdoor activities such as camping, swimming, sailing, climbing, canoeing, gliding and exploring caves; a progressive training rewarded by the granting of certain badges; and the daily good turn which from the beginning took the fancy both of the general public and the boys themselves. In every country, too, the highest point of proficiency is marked by the award of a special badge; *e.g.*, the Eagle scout badge in the United States and the Queen's scout badge in Great Britain. From the beginning the left handshake, together with some form of the fleur-de-lis badge and of the motto "Be Prepared," were adopted as the signs of being a scout. The club meetings of the

earlier days soon developed into troop nights with their own atmosphere and ethos. Underlying all, has remained that training in observation on which Baden-Powell placed so much stress.

Development.—The scout movement was intended for boys from 11 to 14 or 15, but it was soon realized that programs for younger and older boys were needed. By 1916 Baden-Powell had solved the problem of the younger boy by the introduction of wolf cubs, or of cub scouts as they are called in the United States, with their own motto of "Do Your Best," their own uniform, their own badges and system of training. Once again this was taken up by other countries with possibly more modifications than had been so with the original scouting. In Great Britain and many other European countries the wolf cub pack is based on Rudyard Kipling's *Jungle Books*. In the United States parent participation is a much more essential part of the cub program, and other countries have their variations without departing far from the basic idea of the wolf cub pack as a preparation for the scout troop.

Troops for handicapped scouts were started for the blind, deaf and dumb, the crippled and the spastics in 1925, and, with modifications in the scout program, scouting has shown its true greatness for these boys.

The older boys were served by a section of rover scouts and later by what are known in the United States as explorer scouts, in Great Britain as senior scouts and in France as raider scouts, all of whom carry on their scouting with realistic expeditions on sea and land, at home and abroad. Scouting for older boys emphasizes personal fitness, social, vocational and cultural activities, and a sense and practice of citizenship and service to the community.

Sea scouts had been started in Great Britain in 1910, and the idea spread. Air activities of various kinds were included in the scout program in some countries during the 1930s, but it was not until 1941 in Great Britain and 1939 in the United States that air scouts became a recognized section. The explorer scout program in the United States, which was expanded to cover such diverse interests as science, auto mechanics, emergency service and conservation, with membership geared to enrollment of high-school age boys, includes the 127,000-ac. Philmont Scout ranch in the Rocky mountains near Cimarron, N.M.

From the early days Baden-Powell had seen the necessity of training the responsible and enthusiastic volunteers who are scoutmasters, and in the early 1920s he developed a system of training in camp known as the wood badge training, which, with its headquarters at Gilwell park in Epping forest in England, has been copied with little local variation throughout the world.

International Events.—Scouting spread rapidly throughout the world. The outbreak of World War I six years after its introduction retarded scout development little. It was indeed a testing time for the young movement through which, in every country where it existed, it came with flying colours. In the early 1920s its international character became increasingly apparent. In 1920 the first international scout meeting, or jamboree, was held in London. It was on this occasion that Sir Robert Baden-Powell was acclaimed chief scout of the world by virtue of his unique position as the acknowledged founder of the movement.

World jamborees, held approximately every four years, are gatherings of thousands of scouts representing their countries and camping together as one family whatever their colour, class or creed. From the beginning the scout movement has been non-military, nonpolitical, interdenominational and interracial. In these camps the scout law is the only rule, and the boys give a fine example of happy living and kindness and tolerance. For the rover scouts there have been similar camps known as moots. There have been indabas, or international camps for scoutmasters, and there are also agoons, which are international camps for the handicapped boys. There have also been innumerable national camps which parties of scouts from neighbouring countries attend. Possibly it has been these smaller camps, rather than the vast jamborees, which have helped most to keep the scout law of international brotherhood before the national movements.

International Organization.—One outcome of the 1920 jamboree was the formation of the Boy Scouts' international con-

ference and committee, and the foundation of the Boy Scouts international bureau. The purpose of the conference is to promote world unity of purpose and common understanding in the fundamental principles of scouting as set out by the founder. The conference, which ordinarily meets biennially, is composed of six delegates from each country in which there is at least one registered scout association, all countries having equal status and voting power. An international committee of 12 members which functions as the permanent central committee of the world movement is elected by the conference and is empowered to act between meetings of the full conference. The international bureau, under its director, is the permanent secretariat of the conference and committee and, after being established in London and remaining there for some years, was moved in 1958 to Ottawa, Can. It should be emphasized that each country, under its own chief scout, is autonomous.

The essential rightness of the programs and principles of scouting has been proved by its continuity and by its attraction to an increasing number of boys of all the five continents. Wherever scouting is allowed boys flock to become scouts. Scouting was not permitted under the fascist regimes in Italy and Germany, nor was it later allowed under communist regimes, but elsewhere it continued to attract and expand; by the 1960s there were about 8,500,000 active members in the world as a whole. Scouting's essential ideas—the development of a boy's initiative and self-dependence, the development of a spirit of selflessness and helpfulness to others to make him a modern good Samaritan, not only willing to help others, but able by his training to do so even at the risk of his own life, the idea of brotherhood among the nations, which is inherent in scouting—remained as fundamental as they were when the movement began. The details (of scout uniform, for example) might vary from country to country and might change from decade to decade, but the spirit of scouting—its adventure and helpfulness to others—still continued to inspire and attract boys against the background of an everchanging world. (RN)

BOZRAH, the ancient name of three cities in western Asia.

1. **BOZRAH**, a stronghold in northern Edom, important between 1200 and 600 B.C., often identified as al Busayrah, a village lying some 3,000 ft. above sea level on the Edomite plateau halfway between the Dead sea and the ruined town of Petra in southern Jordan. The modern village is close to the ancient Roman road that ran from Damascus through Petra to the Gulf of Aqaba. The prophets Isaiah and Jeremiah equate Bozrah with Edom; it was the home of Jobab, the second known king of Edom (Gen. xxxvi, 33).

2. **BOZRAH** (Lat. Bostra; Gr. Bosorra and Bosora; mod. Bosra or Busra), a ruined city in the Hauran region of southwestern Syria, 67 mi. S. of Damascus and 22 mi. S.E. of Der'a. While it achieved its greatest fame as the site of a key Roman fortress east of the Jordan river, Bozrah was a city of the Nabataeans (*q.v.*), possibly the Bosora of I Macc. v, 26. The emperor Trajan, conqueror of Nabataea, made the city capital of the Roman province of Arabia in A.D. 106. Trajan's highway, which ran through Bosra to the Gulf of Aqaba (*see above*), is still traceable. Under the emperor Alexander Severus (A.D. 222–235) the city became a Roman colony and then achieved the title "metropolis" under the emperor Philip (244–249), a native of the city. It became the see of a bishop early in the 4th century but fell to the Arabs in 636. The crusaders captured it in the 12th century but failed to hold it, and in the same century earthquakes, together with Turkish misrule brought decline. Monumental remains—temples, theatres, triumphal arches, aqueducts, reservoirs, churches, mosques, a 13th-century citadel—stretch over the modern site. (*See BASHAN; ARABIA, ROMAN PROVINCE OF.*)

3. **BOZRAH**, a city of Moab (*q.v.*) mentioned in Jer. xlviii, 24, possibly the Bosor or Beshor of the tribe of Reuben but not definitely located. (J. S. I.)

BRAAK, MENNO TER (1902–1940), who, with E. du Perron and S. Vestdijk, occupied an influential position among Dutch critics before World War II, was born at Eibergen, Gelderland, Jan. 26, 1902. After studying history in Amsterdam, he taught in Rotterdam. In 1931 he founded the independent

periodical *Forum*, and in 1933 became literary and dramatic critic of *Het Vaderland*, a leading Hague daily. In *Het Carnaval der burgers* (1930) he defended originality and vitality against convention and in *Démasqué der schoonheid* (1932) he attacked the cult of aestheticism in literature. As a critic, Ter Braak denounced mediocrity. The influence of Nietzsche is evident in *Politicus zonder partij* (1934), which unmasks the underlying falsity of so-called spiritual values, and in *Van oude en nieuwe Christenen* (1937), which propounds the theory that all mass movements are basically inspired by resentment.

Ter Braak's respect for the freedom of the personality made him the enemy of National Socialism and when the Netherlands were occupied, he committed suicide at The Hague (May 14, 1940). His *Verzameld Werk*, seven volumes, was published in 1949–51.

BRABANT, one of the nine provinces of Belgium, consisting of three administrative *arrondissements* (Brussels, Louvain and Nivelles), 31 judicial cantons, and 348 communes. Pop. (1955 est.) 1,887,782. Area, 1,268 sq. mi. It is the most densely populated province (1,489 per sq. mi.) because of the considerable urbanization; outside the towns density is from 400 to 500 per square mile. The rural population lives in numerous prosperous-looking nucleated villages, but there are occasional large individual farms.

Brabant occupies the central part of the low plateau of Belgium, rising southward from about 60 ft. above sea level in the north to 545 ft. in the south. Paleozoic slates and quartzites underlie the plateau at no great depth in the centre and south, and the rivers have cut down their valleys through the newer overlying strata, exposing these older rocks. Porphyritic diorites are mined at a number of places, notably at Quenast and Tubize, for roadmaking materials. The greater part of the plateau is covered with Eocene rocks, mainly Flanders clay to the west of the Senne valley and sands to the east, with some patches of Oligocene sands to the southwest of Brussels and Pliocene sands west of Louvain. In the broad river valleys much alluvium has been deposited, and in addition a widespread cover of *limon* lies on the interfluves.

The main rivers of the eastern Scheldt basin, the Senne, Dyle and Gette, flow in a north-northeast direction until each is picked up by the east-west line of the Demer-Dyle-Rupel river system, hence flowing to the lower Scheldt. Their valleys are broad shallow troughs, separated by the gentle interfluves of the plateau surface.

This area is of great importance agriculturally. The *limon* resting on sand has developed into brownish loams of excellent quality, while on the valley floors the soils are derived from alluvium. Large hedgeless fields grow wheat and sugar beets, producing high yields through intensive use of fertilizers. In 1958 about 58% of the total area of the province was arable, of which one-third grew fodder crops and nearly two-fifths cereals. In the neighbourhood of Brussels (*q.v.*), the provincial capital, concentration is on market gardening, pig and poultry farming, the production of flowers and nursery cultivation. To the northwest of the city, between Berchem (*q.v.*) and Asse, vast areas of glass-houses produce early vegetables and flowers, while others in the southeast specialize in grapes, particularly in the communes of La Hulpe, Hoeilaart and Overijssel (Overijse). Northeast of Brussels, in the Demer valley, the district known as Petit Brabant has warm, light soils, a transition between the sandy loams farther south and the coarser sands and gravels of the Kempen heathlands near Antwerp. When heavily fertilized these grow early vegetables: peas, asparagus, potatoes, carrots and chicory, especially between Mechelen and Diest. Greenhouse produce, bush and orchard fruits, and flowers are also grown. Cattle raising for both meat and dairy purposes is widespread because of the dense urban population. Nearly 10% of the province is wooded, the largest area being the Forêt de Soignes to the southeast of the city.

The industrialization of Brabant is considerable. The outstanding area is Brussels and its suburbs. The Flanders textile industry has spread eastward into Brabant: in Brussels, Braine-l'Alleud,

Nivelles and Anderlecht. In the Senne valley Halle (French, Hal) and Tubize have miscellaneous metallurgical, textile and food-processing industries. At Clabecq, a large integrated iron and steel plant is situated in the Sennette valley, 15 mi. S. of Brussels, on the banks of the Brussels-Charleroi canal. Farther east is a host of smaller towns, many within the Brussels orbit, sharing the well-developed industrial life of Belgium. Louvain (*q.v.*) (Flemish, Leuven), pop. (1955) 34,206, stands on the banks of the Dyle in a well-marked gap through the northern edge of the Brabant plateau. It is a market town for the surrounding agricultural countryside, with food-processing industries (brewing, milling, the manufacture of potato starch, and vegetable canning). It also has a number of metallurgical industries, especially agricultural machinery plants, chemical works, tanneries and sawmills. The Leuven-Dyle Canal links the town with the Rupel and the lower Scheldt. Vilvorde (Flemish, Vilvoorde), pop. (1955) 29,316, is situated where the Senne cuts through the edge of the plateau. The manufacture of fertilizers, vegetable oils, glue, starch and leather is established on the banks of the Willebroek canal in the suburbs, and there are textile and glove factories. Farther east is Tirlemont (Flemish, Tienen) in the Gette valley, pop. (1955) 22,617, which has the largest sugar refinery in Belgium, and flour mills, tanneries, starch factories and a citric acid plant.

For the history of Brabant see BRABANT, DUCHY OF; BELGIUM: History.

BRABANT, DUCHY OF, the name of a duchy in the southern Low Countries, now a province of the kingdom of Belgium. In the early middle ages there existed a *pagus Brabantensis*, whose name was later given to the much larger duchy that included it. The oldest centre of the duchy was in the region of Louvain and Brussels, and the counts of Louvain and Brussels built up the duchy into an important territorial principality. The history of Brabant is connected with that of the duchy of Lower Lorraine, which in the course of the 11th century was split into a number of small feudal states. The counts of Hainaut, Namur, Luxembourg and Limburg asserted their independence, and the territory of Libge passed to the bishops of that city. The remnant of the duchy, united since 1100 with the margraviate of Antwerp, was conferred in 1101 by the emperor Henry IV, with the title of duke of Lower Lorraine, upon Henry, count of Limburg. On the emperor's death his son, Henry V, who in 1106 had rebelled against his father, gave the title to Godfrey I, the Bearded, count of Louvain and Brussels, and for three generations the representatives of the rival houses contested the possession of the ducal dignity in Lower Lorraine. The issue was decided in favour of the house of Louvain by Duke Godfrey III in 1159. His son, Henry I, the Warrior (1183–1235), abandoned the title of duke of Lower Lorraine and assumed in 1190 that of duke of Brabant. Strictly speaking this date marks the beginning of the duchy of Brabant. Godfrey's successors were Henry II (1235–48), Henry III (1248–61), and John I (1261–94). These were all able rulers. Their usual place of residence was Louvain. In 1283, John I bought the duchy of Limburg from Adolf of Berg and secured his acquisition by defeating and slaying his competitor, Henry of Luxembourg, at the battle of Woeringen (June 5, 1288). From then onward there was a personal union between the two duchies, which conserved their individuality and separate institutions. The battle of Woeringen was an important episode in the expansionist policy of the dukes of Brabant, who tried to secure control of the territories along the great commercial axis of Bruges-Cologne, a policy that was thwarted by the counts of Flanders in the west and the prince-bishops of Libge in the east. John II (d. Oct. 27, 1312) granted the charter of Cortenberg on Sept. 27, 1312. By it the imposition of grants (*beden*) and taxes was strictly limited and regulated, and its execution was entrusted to a council, appointed by the duke for life, whose duty it was to consider all complaints and to see that the conditions laid down by the charter concerning the administration of justice and finance were not infringed. He was succeeded by his son, John III (1312–55), who in 1354 granted the great charter of its liberties, called La Joyeuse *Entrée*. (See JOYEUSE ENTRÉE.) This great constitutional charter gave Brabant

an exceptional position among the principalities of the Low Countries and allowed it to play an eminent role in later centuries in the resistance against absolutism.

On the death of John III, the ducal dignity passed to his daughter and heiress, Johanna (d. 1406). Wenceslas of Luxembourg, her husband, assumed the style of duke of Brabant in right of his wife and by the sanction of La Joyeuse *Entrée*, which he swore to uphold (Jan. 3, 1356). Johanna's title was, however, disputed by Louis II of Male, count of Flanders (d. 1384), who had married her sister Margaret, and a war broke out in 1356 between Wenceslas, supported by the guilds, and Louis, who upheld the burgher-patrician party in the Brabant cities. After the death of Wenceslas (1383) his widow continued to rule over the two duchies of Luxembourg and Brabant but was obliged to rely on the support of the house of Burgundy in her contests with the turbulent city guilds and with her neighbours, the dukes of Jilich and Gelderland. In 1390 she ceded her duchies to Philip the Bold of Burgundy, the husband of Johanna's niece Margaret of Flanders (d. 1405), keeping only the usufruct to herself. Of the three sons by this marriage John the Fearless succeeded to Burgundy, and Anthony to Brabant on the death of Johanna in 1406. On the extinction of the line of Anthony (1430) the duchy of Brabant became the inheritance of the elder branch of the house of Burgundy, in the person of Philip III, the Good, of Burgundy, son of John. From this time onward the history of Brabant is merged with that of the other territories of the Netherlands, united by a personal union under the dukes of Burgundy and their successors. The duchy conserved, however, its own central institutions and laws. Philip III's granddaughter Mary (d. 1482), daughter and heiress of Charles I, the Bold, (d. 1477) married the archduke Maximilian and so brought Brabant with the other Burgundian possessions to the house of Habsburg. Brussels, the chief city of Brabant, became under the Habsburg regime the residence of the court and the capital of the Netherlands.

In the course of the Dutch war of independence (1568–1648) the province of Brabant became separated into two portions. In the southern and larger part Spanish rule was maintained, and Brussels continued to be the seat of government. The northern (smaller) part was conquered by the Dutch under Maurice and Frederick Henry of Orange (1597). At the peace of Miinster (1648) this portion, which was known as Generality Land and now forms the Dutch province of North Brabant, was ceded by Philip IV to the United Provinces and was placed under the direct government of the states-general. The southern portion, now divided into the provinces of Antwerp and South Brabant, remained under the rule of the Spanish Habsburgs until the death in 1700 of Charles II, the last of his race.

BRABANT, NORTH (NOORDBRABANT), the largest province of the Netherlands, adjoined by Belgium to the south, the islands and peninsulas of Zeeland to the west and Limburg to the east, and bounded on the north by the Merwede and the Meuse (Maas) rivers. Area 1,894 sq.mi. The provincial capital is 's Hertogenbosch. From coastal marshlands in the northwest the land rises gently southeastward to a maximum of 135 ft. The surface ranges from silt and clay near the coast and alluvium along the Meuse and its tributaries to sands and gravels that cover most of the province; these coarser materials are largely terrace deposits of the Meuse and Waal and include bare sand dunes; e.g., near Drunen. Considerable heathlands remain and there are patches of high bog, the largest being in the Peel (marshy land) southeast of Deurne. Colonization of these dry sandy areas began

early. Neolithic finds at four sites are followed by Bronze Age and numerous Iron Age remains; there were Roman camps along the Meuse. After the dark ages the division between east and west in North Brabant (discernible in two different Iron Age groups) was continued in political divisions: to the west the Barony of Breda, and to the east the Meirij of 's Hertogenbosch (Bois-le-Duc); the affinities of the west still lie with Belgium and France, those of the east with the Rhineland.

In 1957 the population was 1,425,732. its density less than the Dutch average; nearly all the inhabitants are Roman Catholic. The coastal lands, partly flooded in 1953, are fertile and arable, producing wheat and sugar beet; the riverine lands are more acid, often poorly drained, and mostly permanent pasture. The southern heaths contain many recently planted conifers; agriculture on these poor soils is restricted, and mixed farming is general. Cattle are the chief livestock; rye, oats, potatoes and buckwheat are the chief crops. Extensive areas of heath were reclaimed for arable land or pasture in the 19th century and several new colonies, e.g., Helenaveen, were established in the raised bogs of the Peel where the sale of peat was combined with horticulture and cattle raising. Reclamation slackened after 1900; emigration from rural areas has been heavy and more than one-half the population now lives in towns. Formerly Bergen op Zoom was the centre of the marshlands, Breda (*q.v.*) of the riverlands and 's Hertogenbosch of the inner sandy areas. All retain their market functions and Bergen op Zoom, like several other centres, refines sugar beets; but now the largest settlements in the province are Tilburg (*q.v.*), a woolen textile centre, and Eindhoven (*q.v.*), the sixth largest Dutch town (pop. [1957 est.] mun. 157,621), an industrial centre for the manufacturing of radios: electrical appliances and vehicles.

BRABAZON, HERCULES BRABAZON (1821–1906), English watercolourist whose fresh and sensitive sketches have been prized, was born in Paris on Nov. 27, 1821, the younger son of Hercules Sharpe. He succeeded his elder brother in the Brabazon estates, County Mayo, Ire., and under the will of his uncle adopted the surname of Brabazon. Educated at Harrow and Trinity college, Cambridge, he studied painting by copying the English water-colourists William Müller, David Cox and Peter De Wint. Brabazon's later style approached that of Turner, with an even freer use of body colour. He made many sketches on his travels in Europe and Egypt. An amateur and a country gentleman, he was reluctant to exhibit or sell his work. In 1891 he showed at the New English Art club and was elected a member. He died at Battle, Sussex, on May 15, 1906.

See C. L. Hind, *Hercules Brabazon Brabazon* (1912). (D. L. Fr.)

BRAC̄ (It. BRAZZA), an island in the Adriatic sea, forming part of the People's Republic of Croatia, Yugos. Pop. (1961) 14,218. Area 153 sq.mi. The inhabitants speak the čakavski dialect of the Serbo-Croatian language. Though rugged and mountainous, the island yields an abundance of olives, figs, almonds, saffron and chrysanthemums (from which an insect powder is produced), as well as wines of a good quality. The main industries are fishing, silkworm rearing, and stone, slate and marble quarrying. The marble is exported all over the world. The island has no fresh water, which in the summer months is brought from the mainland. The principal village is Supetar (pop. [1953] 1,859) and a tourist trade was beginning to develop by 1960.

The island has been dominated in turn by the pirates of Almissa, by Dubrovnik (Ragusa), Venice, the Holy Roman Empire, Hungary, Bosnia, Napoleon's Illyria and Austria. with one brief period of autonomy. In 1918 it was incorporated in Yugoslavia. During World War II it was occupied for a time by the Italians. Partisans and Allied special forces drove the Germans out of Brač in 1914.

(V. DE.)

BRACCIANO, LAKE (LAGO DI BRACCIANO), lies in the Sabatini mountains 25 mi. N.W. of Rome, Italy. The classical *Lacus Sabatinus*, it was formed from a group of volcanic craters. Mineral hot springs along its shores recall its earlier geological history. The surface, which has a total area of 22 sq.mi., is at 538 ft. above sea level. The maximum depth is 525 ft. and diameter about 5½ mi. The lake, which has the Arrone river for an outlet

on its southeast side, is known for its eel. The lake towns of Bracciano and of Anguillara Sabazia preserve their magnificent late medieval castles. There is a seaplane base at Vigna di Valle on the south shore.

(G. KH.)

BRACCIO DA MONTONE (1368–1424). Italian *condottiere*, distinguished both as a soldier and as one of the first of his profession to try to found a state. Born of a noble Perugian family, he learned the profession of arms under Alberico da Barbiano, first of the great Italian war captains. Braccio and Muzio Attendolo Sforza (*see* SFORZA), also a pupil of Alberico, were lifelong rivals and left their names to rival schools of warfare. Braccio likewise had great ambitions. He began to satisfy them in papal territory, where between 1416 and 1419 he seized power in Perugia and most of Umbria. In 1420 he was granted legitimate title to rule as vicar by Pope Martin V. Not content with this, he went on to seek further land and dominion in southern Italy, but was defeated and severely wounded in the battle of Aquila (June 2. 1424). Refusing food and drink, he died three days later.

See W. Heywood, *A History of Perugia* (1910). (P. J. J.)

BRACE, CHARLES LORING (1826–1890), U.S. reformer and pioneer social welfare worker, was a founder and for 37 years executive secretary of the Children's Aid Society of New York city. Born in Litchfield, Conn., June 19, 1826, of a Hartford family long prominent in religious and political life, he was educated at Yale university and at Union Theological seminary in New York; asked to become the head of "a mission to children" in 1853, he spent the remainder of his life in the Children's Aid society. In 1872 he wrote an unconsciously autobiographical account of it as *The Dangerous Classes of New York, and Twenty Years' Work Among Them*, which established him as a world authority. At his death a leading sociologist estimated that Brace's influence had aided over 300,000 children.

In 1882 Brace published *Gestn Christi: a History of Humane Progress Under Christianity*, a review of "certain practices, principles and ideals—now the richest inheritance of the race—that have been either implanted or stimulated or supported by Christianity." This became a significant contribution to the literature supporting the growing social gospel movement. He also wrote on comparative religion, European and American travel, knew and corresponded with many of the great figures of his time and contributed extensively to the *New York Times* and several journals of opinion and current affairs. He died Aug. 11, 1890.

His daughter Emma Brace edited *The Life and Letters of Charles Loring Brace* (1894). (C. H. Hs.)

BRACEGIRDLE, ANNE (c. 1663–1748), English actress, a pupil of Thomas Betterton (*q.v.*), was born about 1663, probably in one of the midland counties. Her talents were first noted in 1688 when she played Lucia in Shadwell's *The Squire of Alsatia* at Drury Lane.

Such antithetical playwrights as William Congreve and Nicholas Rowe wrote leading parts for her. For the heroines of Congreve's artificial comedies she could turn on "the Charms and Attractions of a conscious Beauty" (Colley Cibber) when she played Xraminta in *The Old Bachelor* or Mirabel in *The Way of the World*; but she had also a feeling for Rowe's pathetic sentiments when she acted Selima in *Tamerlane* or Lavinia in *The Fair Penitent*. One of her most famous roles, however, was that of Statira in Nathaniel Lee's *The Rival Queens*.

She left the stage in the prime of her life, about 1707, when she began to be eclipsed by the rising star of Anne Oldfield (*q.v.*). Mrs. Bracegirdle enjoyed, perhaps undeservedly, a reputation for virtuous character extraordinary in an actress of the period. It was believed during her life that she was married to Congreve, who left her a legacy of £200.

(A. M. N.)

BRACHIOPODA, a phylum of small bottom-dwelling marine invertebrate animals that have a shell composed of two valves. Some brachiopods superficially resemble clams; however, the valves are unequal, and lie above and below the soft body, instead of being nearly equal and on the right and left sides of the body as in clams. Between the valves are the fleshy parts of the animal including two coiled arms (brachia), one on either side of the mouth, that direct food-bearing currents toward the mouth.

The name brachiopod, from the Greek meaning arm-foot, was first proposed by A. M. C. Duméril (1806), who assumed that the brachia were locomotive organs like the molluscan foot. Brachiopods, commonly known as lampshells for their fancied likeness to early Roman oil lamps, are found throughout the oceans of the world, but are much more rare today than they were in past geologic history (see *Paleontology* below). In southern Japan and the Philippine Islands species of *Lingula* are used for food, either the pedicle (stalk for attachment) or the whole animal being boiled. Because of their preservation in rock strata, especially of the Paleozoic era (from 225,000,000 to 600,000,000 years ago), fossil brachiopods are useful to geologists in determining the age of certain strata.

Geographical Distribution.—More than 200 species of modern brachiopods representing 73 genera are known. Several species are known in American waters from Maine to Florida and from Alaska to Mexico. Brachiopods are common about the West Indies. They inhabit the Mediterranean, the northwest coast of Africa and the waters around the British Isles. Off the Philippine, Japanese and Hawaiian islands many species are known. New Zealand, Australian and Antarctic waters also yield numerous species.

The majority of brachiopods—about 60%—are shallow-water dwellers (less than 100 fathoms, or 600 feet) but some of these range into deep water. More than 35% of modern brachiopods occupy waters deeper than 100 fathoms and a few live in the deep sea abyss (2,900 fathoms). *Lingula* is confined to water less than 25 fathoms deep.

Morphology and Habits.—In all brachiopods the two valves are situated on the front (ventral, or pedicle, valve) and back (dorsal, or brachial, valve) of the animal, the former valve usually being the larger. Brachiopods are grouped into two classes, Inarticulata and Articulata (see Classification below), based on the presence or absence of a hinge and on shell composition and embryology.

Inarticulata.—In the Inarticulata the valves are joined by a complicated system of muscles. Except during the Cambrian period, Inarticulata have always been less numerous than Articulata. *Lingula*, both modern and fossil, is linguiform (tongue-shaped) in outline and lens-shaped in profile. Another living inarticulate, *Discinisca*, is circular in outline and conical in profile. In general the Inarticulata deviate little from these two forms. *Lingula* shells are chitinophosphatic, *i.e.*, they are composed of alternating layers of chitinous material and calcium phosphate covered by a smooth periostracum, while in *Discinisca* overlapping layers of the same substances are set at a small angle to the surface. Members of the superfamily Craniacea, unlike other inarticulates, have pitted, calcareous shells. Inarticulate valves are commonly brown to black, but some species of *Lingula* have green blotches. Ornament usually consists of concentric growth lines, but some species are radially marked. The Inarticulata seldom measure over an inch in length and many fossil representatives are tiny.

Lingula makes a vertical burrow 2 to 12 in. long and attaches its pedicle by mucus to the sand in the bottom of the burrow (fig. 1). By extension of the pedicle, part of the shell projects above the surface, disappearing instantly when the animal is alarmed. *Lingula* burrows usually occur in mud flats exposed at low water. *Glottidia* (fig. 1), a relative of *Lingula*, moves by wriggling the pedicle.

The soft parts of the Inarticu-

FIG. 1.—SAND TUBES FORMED BY BRACHIOPODS

(A) Section of tube of *Lingula* showing attachment of shell by extended pedicle (dotted line indicates position of shell when retracted); (B) tube of *Lingula* seen from surface; (C) *Glottidia pyramidata* with wormlike pedicle attached to sand tube

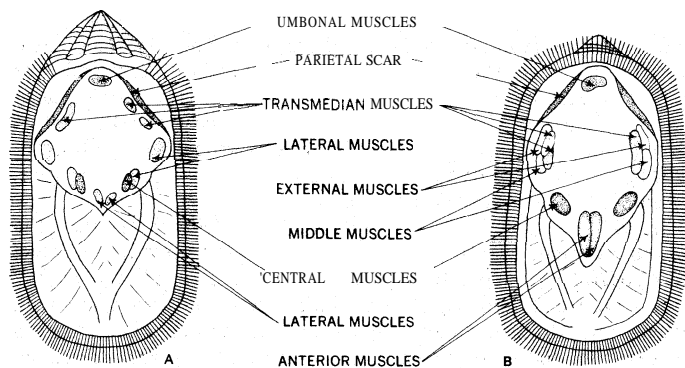

FIG. 2.—INNERSURFACES OF *LINGULA* VALVES SHOWING MUSCLE ATTACHMENTS: (A) VENTRAL VALVE; (B) DORSAL VALVE

lata are similar to those of the Articulata but vary in having a terminal anus and a more complicated muscle system. The shells open vertically but slide laterally as well. Chitinous bristles (setae) fringe the shell, forming three tubes anteriorly, two side ones for incoming, food-bearing currents and the middle one for discharging wastes.

Articulata—Most of the Articulata have calcareous shells joined by teeth (in the ventral valve) and sockets (in the dorsal). These brachiopods are usually small, but some measuring 6 to 15 in. in one dimension are known. The Articulata are usually lens-shaped in profile but the outline varies. The shells are usually light-colored, grayish or dark brown, but some are salmon to red, occasionally with bright red radial bands. Fossil Terebratuloidea with colour patterns occur as early as the Devonian period.

The shell is smooth or variously ornamented by radial ribs (costae), concentric bands, or both. Many genera are spiny-shelled. Most Articulata develop a median fold on the dorsal valve, rarely on the ventral, which facilitates passage of incurrent and excurrent streams.

Many Articulata attach by their fibrous pedicle or cement their ventral valve to a firm object. When cemented, the brachiopod usually becomes misshapen, oysterlike (*Leptodus*), or conical (*Prorichthofenia*). Some extinct Articulata, attached when young, broke away to lie loose on the sea floor. *Echinauris* and others like it, had no pedicle but lived supported by their spines.

The Shell.—General Anatomy.—Posteriorly the shell (fig. 3) tapers to a beak. The swollen portion in front of the beak is called the umbo. The hinge may be short or extended. Length is measured from beak to anterior margin; width is at right angles to this, and thickness is the greatest distance at right angles to both. In many genera a palintrope, or shelf, with curved or plane surface (interarea) lies between the beak and hinge line. The ventral palintrope is divided medially by the delthyrium, a triangular pedicle opening. This may be partially or completely closed by deltidial plates growing from the delthyrial margins; or it may be closed by a single plate, the pseudodeltidium, anchored to the delthyrial edges. The teeth occur at the antemarginal ends of the delthyrium and may be buttressed by dental plates separated or united with a septum to form a spondylium.

The dorsal valve contains brachial attachments called crura, curved processes diverging from the beak. In some ancient forms the crural bases bound a deltoid cavity, the notothyrium, in which the diductor muscles are attached on the floor or to a ridge, or boss (cardinal process). The notothyrium may be closed by a solid plate (chilidium). In advanced genera a hinge plate bearing the diductor muscles occurs between the crural bases. It is divided when incomplete, but forms an undivided, flat or concave hinge plate when continuous. This plate is commonly supported by a median septum in the dorsal valve. The sockets are located between the inside shell wall and the outside of the crural bases. In many specialized genera the crura support loops or spires (brachidia), the inner skeleton of the food-gathering organ.

Structural Detail.—The mantle secretes the shell by successive additions at the anterior margin. Thickening occurs by deposition over the inner surface. The relatively simple structured chitino-

phosphatic shell, characteristic of most Inarticulata, was described earlier. The calcareous shell, of all Articulata and some Inarticulata, is more complex in structure, being composed of three layers: (1) an outer thin, chitinous periostracum (not seen in fossils); (2) a middle lamellar layer; (3) an inner prismatic layer. The two inner layers are composed of calcite (calcium carbonate).

Three groups of Articulata are recognized on details of shell structure: (1) Punctate, with inner layers pierced by tiny holes, or puncta, into which minute projections of the mantle (caeca) penetrate, thus increasing the surface of the mantle, the main respiratory organ; (2) Pseudopunctate, in which taleolae, minute rods of calcite, project into the inner layers, often beyond the inner surface, and shell exfoliation leaves deep pits (pseudopunctae) simulating puncta where these rods are torn out; (3) Impunctate, having neither puncta nor taleolae (see *Classification* below).

The Animal.—**Soft Parts.**—The fleshy body is divided transversely by a body wall into a posterior visceral cavity (coelom) filled with coelomic fluid and an anterior mantle cavity filled with sea water (fig. 4). The visceral cavity contains the U-shaped digestive canal, four reproductive glands and "liver," held in place by mesenteries. Extensions of the coelom (pallial sinuses, fig. 4) into the mantle lodge the sex organs. The mouth leads into an esophagus, and this into a saclike stomach terminated by a blind intestine. The "liver," or digestive gland, surrounds the stomach. Waste is excreted through the mouth. The nervous system, circling the esophagus, sends nerves to other parts of the body.

The mantle, or brachial, cavity is lined by the thin, shell-secreting fleshy mantle, externally fringed by tactile setae. Within the mantle cavity is lodged the lophophore (fig. 4), a simple or complicated, commonly horseshoe-shaped, loop whose ciliated cirri direct food-bearing currents to the mouth, located between the branches of the lophophore.

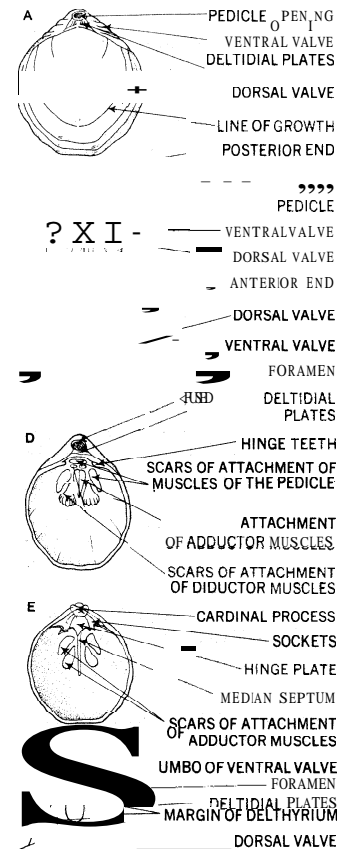

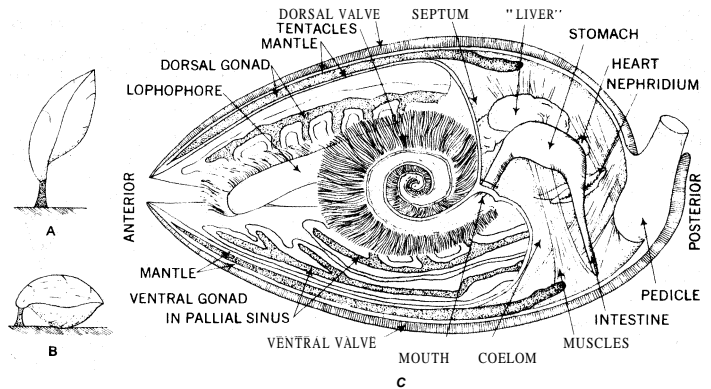

FIG. 3.—SHELL OF A BRACHIOPOD. Exterior of shell: (A) dorsal view; (B) lateral view; (C) anterior view. Interior: (D) ventral valve; (E) dorsal valve. (F) Diagram of pedicle opening in *Rhynchonella*: delthyrium becomes filled with plates, leaving foramen open

Musculature.—The shell opens by contraction of flabellate diductor muscles (fig. 3, 5) which extend from near the centre of the ventral valve to the hinge plate or cardinal process under the dorsal beak. The dorsal valve rotates on a line joining the hinge teeth. Contraction of the diductors stretches the adductors, two muscles in the ventral valve that fork in passing to the centre of the dorsal valve. When the tension of the diductor muscles is released the stretched adductors contract and close the valves. Besides adductors and diductors, pedicle muscles, or adjustors, extend from the ventral valve to the pedicle. These adjust the shell on the pedicle. The muscles leave attachment scars on the inside of the shell that are important in classification.

Reproduction and Development.—The sexes are separate; ova and sperm are discharged into the mantle cavity through funnel-shaped nephridia, two (sometimes one) on either side of the mouth. Fertilization takes place in the mantle cavity or outside. In a few genera the larvae develop inside the female in brood pouches formed by a fold of the mantle. Five articulates and one

that is known in detail or brachiopods develop inside the female in brood pouches formed by a fold of the mantle. Five articulates and one

FIG. 4.—(A, B) BRACHIOPODS ATTACHED TO SEA BOTTOM; (C) INTERNAL STRUCTURE OF MAGELLANIA, SHOWING SHELLS CUT TO MID-LINE WITH MANTLE AND LOPHOPHORE OF LEFT SIDE REMOVED

larvae develop cilia and swim freely for about 12 days; the *Terebratella* swim freely for a shorter time. During this time three regions develop, after which the larvae attach by the tail region which becomes the pedicle. The lobes of the second, or thoracic, region envelop the first, or head region and form two thin, chitinous semicircular plates, the embryonic shell, or protegulum. This develops into a punctate calcareous shell ornamented by fine costae. In *Lacazella* the head of the larva bears four eyes.

The dorsal mantle lobe develops more rapidly than the ventral, and the inner surface bears a shell plate continuous with another on the dorsal side of the thoracic segment. The mantle then inverts, the dorsal mantle plate becoming the external shell and the thoracic plate forming the incipient pseudodeltidium. The ventral valve is thought to be secreted by the rudimentary mantle lobe. A similar inversion of the mantle lobes occurs in *Argyrotheca*, but no thoracic shell plate is formed. In *Lingula* threefold differentiation into regions does not occur. The free-swimming stage may last a month or six weeks, and pairs of cirri on the embryonic brachia protrude, thus serving as swimming organs. The cuticular shell plate, formed over the dorsal and ventral mantle portions, is

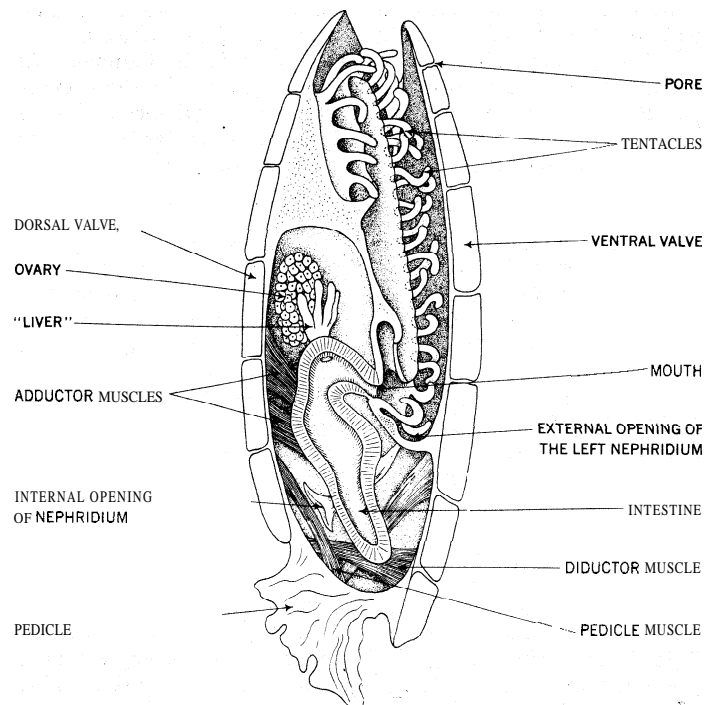

FIG. 5.—INTERNAL STRUCTURE OF A RECENT BRACHIOPOD (*ARGYROTHECA CORDATA*)

Longitudinal section with mantle, its tubular extensions and the epidermis omitted

circular in outline, but a fold forms posteriorly to divide the shell into dorsal and ventral valves. These thicken and the fold of thin cuticle serves for a time as a hinge. The pedicle is formed from the ventral mantle fold and not from the caudal region as in *Terebratulina* and *Terebratella*.

Paleontology.—Brachiopods were an abundant form of life in the Paleozoic era but later became subordinate. Nearly 30,000 species, distributed among over 1,700 genera (including 129 inarticulates) have been described. No brachiopods are known prior to the Cambrian period; the Inarticulata thrived during the Cambrian and part of the Ordovician but later declined, occupying a subordinate position ever since. Some *Lingulacea*, *Craniacea* and *Discinacea* have survived with little change since the Ordovician.

Even in the early Cambrian highly organized primitive Articulata occurred, indicating a long previous development. The great development of the *Trimerella* and *Pentamerioidea* and appearance of the *Terebratuloidea* occurred in the Silurian. The Devonian and Carboniferous periods saw the expansion of the *Spiriferoidea* and *Productoidea*.

some productoids attaining a width of 15 in. In the Permian many bizarre types of cemented brachiopods occurred among the *Orthotetacea* and *Productoidea*, possibly foreshadowing their extinction.

Besides the *Rhynchonelloidea* and *Terebratuloidea* a few *Chonetoida*, *Spiriferoidea* and *Punctospiracea* of the Articulata survived the widespread extinction culminating in the Permian. All *Spiriferoidea* and *Punctospiracea* became extinct with the Jurassic. In the Mesozoic the *Rhynchonellacea*, *Terebratuloidea* and *Terebratelloidea* flourished, but by the Cenozoic the first group declined, the last two surviving as the commonest modern brachiopods.

CLASSIFICATION

The first mention of brachiopods in a published work appeared in 1596 when J. Bauhin figured a *Rhynchonella* from the early Jurassic of Württemberg. Ten years later Fabio Calonna described *Concha anomia diphya* which he considered to be a pelecypod but is really the brachiopod *Pygope*. In the 18th century several authors figured the Recent species, *Crania anomala* and *Terebratolina retusa*. G. L. C. Cuvier, however, in the early 19th century first suggested their separation from the Pelecypoda. Subsequent investigation of internal structure and development and increasing knowledge of fossil forms established the brachiopods as a phylum.

The classes generally adopted are Inarticulata and Articulata proposed by T. H. Huxley in 1869. C. E. Beecher (1891) divided Brachiopoda into four orders based on the kind of pedicle opening and shell development. *Atremata* and *Neotremata* belong to the Inarticulata, while the *Articulata* include the *Protremata* and *Telotremata*. In 1927 J. A. Thomson added *Palaeotremata* to the *Articulata*, and proposed major divisions approximating Huxley's terms based on embryology; *Gastrocaulia* (Inarticulata); *Pygocaulia* (Articulata). Adequacy of Beecher's orders *Protremata* and *Telotremata* was questioned by G. A. Cooper (1944). (Extinct forms are followed by an asterisk.)

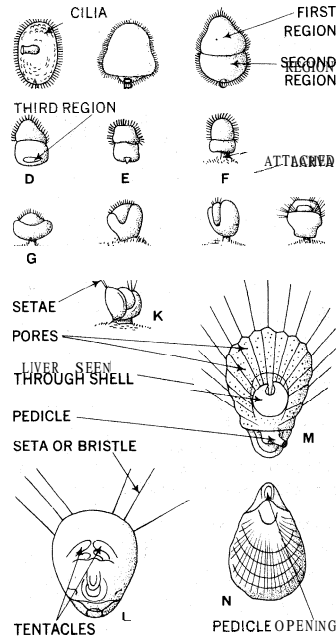

FIG. 6.—DEVELOPMENT OF TEREBRATULINA (A-M GREATLY MAGNIFIED) BY COURTESY OF THE SOCIETY OF NATURAL HISTORY BOSTON

(A-E) stages of free swimming larva; (F-I) attachment of larva to substrate, showing second region gradually enclosing first; (J, K) appearance of bristles and horny valves; (L) formation of permanent setae and, within shell, tentacles and other structures; (M) later stage in which setae correspond in position with first formed ribs of shell; (N) adult shell, natural size

CLASS INARTICULATA (GASTROCAULIA)

Valves usually chitino-phosphatic, fastened by muscles only. Intestine long, ending in anus. Pedicle developing within valves of first shell (protegulum) and later protruded.

Order I. *Atremata*. Valves gape apically, pedicle attached to ventral valve, forming a pedicle groove. Growth mainly lateral and anterior. Superfamilies: *Obolacea**, *Lingulacea*, *Trimerellacea**.

Order II. *Neotremata*. Pedicle, when present, emerging from a foramen at or near the ventral apex. Growth, at least in ventral valve, on all margins. Superfamilies: *Paterinacea**, *Siphonotretacea**, *Acrotretacea**, *Discinacea*, *Craniacea*.

CLASS ARTICULATA (PYGOCAULIA)

Articulated valves, always calcareous; anus absent in modern genera. Pedicle developed from caudal segment of embryo and seldom enclosed in the protegulum. Classification unsatisfactory.

Order III. *Palaeotremata*. Primitive, articulation and delthyria not fully developed. Superfamilies: *Rustellacea**, *Kutorginacea**.

Order IV. *Protremata*. Delthyrium open or closed by a pseudodeltidium. Brachial processes primitive.

Order V. *Telotremata*. Delthyrium closed partially or completely by deltidial plates. Crura or brachidium present.

Discovery of deltidial plates and a loop-bearer in the *Protremata* casts doubt on these orders. Cooper (1944) suggested a convenient but nongenetic arrangement based on shell structure:

Impunctate Articulata: Suborders and superfamilies: *Orthoidea**, *Clitambonitoidea**, *Pentamerioidea**, *Triplesioidea**, *Rhynchonelloidea* (with *Rhynchonellacea*; *Stenosclimatacea**), *Atrypoida**, *Spiriferoidea** (*Spiriferacea**; *Rostrospiracea**).

Pseudopunctate Articulata: Suborders and Superfamilies: *Strophomenoidea** (with *Plectambonitacea**, *Strophomenacea**; *Orthotetacea**), *Oldhamioidea**, *Productoidea** (with *Strophalosia* and *Productacea*), *Chonetoida**.

Punctate Articulata: Suborders and Superfamilies: *Dalmanelloidea**, *Thecideoida*, *Punctospiracea**, *Terebratuloidea*, *Terebratelloidea*.

BRACKEN (BRAKE), a genus of ferns (*Pteridium*), the sole species (*P. aquilinum*) of which is widely distributed throughout the world in temperate and tropical regions. The species is represented by 12 varieties, 4 of which occur in North America and Great Britain. Var. *pubescens* grows from Alaska to Mexico, east to Wyoming, Colorado and Texas. Var. *latiusculum*, growing also in northern Europe and eastern Asia, occurs from Newfoundland to Minnesota, south to Oklahoma and Tennessee. Var. *pseudocaudatum* grows from Massachusetts to Florida, west to Missouri and Texas. Var. *caudatum*, a West Indian plant, grows in southern Florida. Var. *typica* is common in Great Britain. This species has a perennial, black rootstock, which creeps extensively underground and at intervals sends up fronds. These fronds may reach a height of 15 ft. or more, and, although dying in autumn, often remain standing throughout the winter, affording in some regions cover for game. The fronds are used for thatching and occasionally as fodder. (R. M. T.)

BRACKET FUNGUS. The term "bracket" has been given to those hard, woody fungi that grow on trees or timber in the form of semicircular brackets. They belong to the order *Poly-poreae* of the *Basidiomycetes*, distinguished by the layer of tubes or pores on the undersurface within which the spores are borne. The mycelium, or vegetative part of the fungus, penetrates into the tissues of the tree, causing more or less extensive wood rots (see DRY ROT); the "bracket" represents the fruiting body and

produces innumerable spores which gain entrance to other trees by some wound or cut surface. Many of these woody fungi persist for several years, and a new layer of pores is superimposed on the previous season's growth.

It has been estimated that a fruiting body of *Fomes applanatus*, the commonest of the bracket fungi, having a pored surface of one square foot liberates 30,000,000,000 spores in 24 hours, and the period of spore discharge for this species is approximately six months.

BRACKLEY, THOMAS EGERTON, VISCOUNT (c. 1540–1617), English lawyer and diplomatist, better known as

LORD CHANCELLOR ELLESMERE, secured the independence of the court of chancery from the common law courts, formulating thereby nascent principles of equitable relief. An illegitimate son of Sir Richard Egerton of Ridley, Cheshire, he was educated at Brasenose college, Oxford, and was called to the bar by Lincoln's Inn in 1572. He found early favour with Queen Elizabeth who made him one of her counsel after hearing him plead against the crown. Thereafter his promotion was rapid: solicitor general (1581), attorney general (1592) and master of the rolls (1594), an office which he retained when he became lord keeper of the great seal (1596) and which he held until Elizabeth's death.

But Egerton was more than a mere lawyer and Elizabeth entrusted him with many diplomatic missions. He was a firm friend of Robert Devereux, 2nd earl of Essex, but endeavoured in vain to effect his reconciliation with Elizabeth, being unable to dissuade him from rebellion in 1601. After the accession of James I in 1603, Egerton was created Baron Ellesmere and became lord chancellor. He gave indiscriminating support to James's conception of the royal prerogative, coming into frequent collision with the house of commons, which he also offended by his attempt to control its composition in Goodwin's case (1604). He was equally indiscriminating in his support of James's ecclesiastical policy.

Ellesmere's career closed with a victory gained over the common law and his formidable antagonist, Sir Edward Coke (*q.v.*), the chief justice of the King's Bench. The chancellor's court of equity originated as a tribunal to decide cases not served by the common law—to relax and correct its rigidity and insufficiency. The two jurisdictions were often rivals, the common-law bar often complaining of the arbitrary powers of the chancellor, who had set aside common-law decrees, and the equity lawyers censuring the failures of justice at common law. The disputes, concerning which the king had already in 1615 remonstrated with the chancellor and Coke, came to a crisis in 1616, when the court of chancery granted relief against judgments at common law. This relief Coke and other judges declared to be illegal and a writ *praemunire* (*q.v.*) was brought against the parties concerned in the suit in chancery. The grand jury, however, refused to bring in a true bill, in spite of Coke's threats, and the dispute was referred to the king, who after consulting his counsel and taking Francis Bacon's advice, decided in favour of equity (Earl of Oxford's case). The chancellor's triumph was great, and from this time the equitable jurisdiction of the court of chancery was unquestioned. In June 1616 he supported the king in his dismissal of Coke in the case of *commendams* (royal permission to a bishop to retain, on promotion, his former living—a practice Coke was opposed to), and he agreed with Bacon that it was the judge's duty to communicate with the king before giving judgments in which the king's interests were concerned. On March 3, 1617, he delivered up to James the great seal, which he had held for the unprecedented term of nearly 21 years. In 1616 he had been created Viscount Brackley, and he declined an earldom on his deathbed. He died on March 15, 1617.

Lord Chancellor Ellesmere is a striking figure in the long line

PHOTOGRAPH, JOHN H. GERARD
BRACKET FUNGI (*POLYPORUS RESINOSUS*) GROWING ON A TREE TRUNK

of illustrious English judges. He ignored all communications from suitors, and it was doubtless to Ellesmere (as weeding out the "enormous sin" of judicial corruption) that John Donne, who was his secretary, addressed his fifth satire. Universally esteemed as an equity lawyer, he gained the admiration of William Camden, was extolled by Bacon, his protégé, and by Ben Jonson. His personal integrity was such that he reconciled the common lawyers to the implications of the Earl of Oxford's case. He hoped to see a codification of the laws, and had greater faith in judge-made law than in statutes, advising parliament (Oct. 27, 1601) "that laws in force might be revised and explained and no new laws made." Ellesmere's conception of the duties of his office was traditional. He considered that "the office of the chancellor is to correct men's conscience for frauds, breach of trust, wrongs and oppressions of what nature soever they be and to soften and mollify the extremity of the law." He reformed the administration of the court of chancery and of the star chamber; delays were reduced and fees restricted, although he allowed the masters in chancery too great a discretion. In 1609 he published his argument in the case of the Post Nati (Calvin's case) where the exchequer chamber had held that Scottish persons born after the accession of James I were natural-born subjects of the king of England; it appears to be his only certain work. Other works have been ascribed to him, most probably wrongly, including *The Privileges and Prerogatives of the High Court of Chancery* (1641); *Certain Observations Concerning the Office of the Lord Chancellor* (1651); *Observations on Lord Coke's Reports*, ed. by G. Paul (c. 1710).

See Lord Campbell, *Lives of the Lord Chancellors*, vol. ii (1845; 4th ed. 1857); W. S. Holdsworth, *A History of English Law*, vol. v, 3rd ed. (1945) (G. H. J.)

BRACKNELL, a new town (*see* NEW TOWNS) in Berkshire, Eng., lying within the jurisdiction of Easthampstead rural district council, 11 mi. E.S.E. of Reading and 29 mi. W.S.W. of London by the road through Staines. Old Bracknell had little importance until the 19th century when the Windsor-Wokingham road was built and caused congestion in the Wokingham cattle market, with the result that the Bracknell cattle market became and remained the principal one in east Berkshire. When the new town was formed in 1949, the population of about 5,000 was engaged in brickmaking, timber yards, dairying and metalwork. Bracknell, which was to have a planned population of 25,000 and an area of 2.9 sq. mi., had 20,380 residents by 1961 and many new industries which included the manufacture of gasoline pumps, boilers, tools, ball bearings, furniture and clothing.

A college of further education and a county library were planned for the central area of the town. The town rests on London Clay in the northwestern portion; the remainder, where there are coniferous trees, is largely on Bagshot Sands deposits.

BRACQUEMOND, FÉLIX HENRI (properly FÉLIX JOSEPH AUGUSTE) (1833–1914), French engraver and painter, a leading engraver both of his own designs and those of old and modern masters, was born in Paris on May 22, 1833. Trained as a trade lithographer, he produced plates after the works of artists from Hans Holbein to Eugène Delacroix (and later Gustave Moreau). As a painter his public career began in 1852 when he exhibited at the Paris Salon; by then he had entered the studio of J. Guichard, a pupil of J. A. D. Ingres and Delacroix and master of Berthe Morisot.

Bracquemond numbered Edouard Manet and the young Impressionists, some of whom he instructed in engraving, among his friends. He also designed textiles and bookbindings and painted on porcelain. He died in Paris on Oct. 29, 1914. (D. C. T. T.)

BRACON (BRATTON, BRETTON), **HENRY DE** (d. 1268), English judge and writer on English law. His real name was Bratton, and it is only after his death that his name appears as Bracton. He seems to have entered the king's service as a clerk and he began to appear as a justice in 1245. From 1248 until his death in 1268 he was steadily employed as a justice of assize in the southwestern counties, especially Somerset, Devon and Cornwall. During the earlier part of this period he was also sitting as a judge in the king's central court which was soon to be distinguished as

the king's bench. From this position he retired or was dismissed in or about 1257, shortly before the meeting of the "mad parliament" at Oxford in 1258. In 1267 he was a member of a commission appointed to hear the complaints of the disinherited partisans of Simon de Montfort. Like most of the lawyers of his time, Bracton was a priest; he held several livings and ecclesiastical appointments in the diocese of Exeter.

Bracton's fame rests on two works: the *Note Book*, which is a collection of cases; and the *Treatise on the Laws of England*, which he never finished but of which Sir W. S. Holdsworth wrote, in *A History of English Law* (Methuen and Co. Ltd., London, 1936), that it "had no competitor either in literary style or completeness of treatment till Blackstone composed his commentaries five centuries later." Two principal characteristics of importance in the development of the common law must be noted, namely: (1) the emphasis on practice and procedure; and (2) the dependence on decided cases (see also ENGLISH LAW). There are various editions of the treatise.

Some indication of the extent to which Bracton's reputation has stood the test of time was given in 1923 when a stone commemorating him as "Author of the first systematic treatise on the Laws of England" was presented to the dean and chapter of Exeter cathedral where he was buried.

Bracton's Note-Book was edited by Frederic Maitland (1887); *Selected Passages from the works of Bracton and Azo* was published by the Selden society (1895); and Bracton's *De Legibus et Consuetudinibus Angliæ* was edited by George Woodbine, 2 vol. (1915-22).

See Sir W. S. Holdsworth, *A History of English Law*, vol. ii and vi, new ed. (1936, 37); "The Bracton Memorial," *Law Times*, vol. 155, pp. 302-303 (1923). (W. T. Ws.)

BRADDOCK, EDWARD (1695-1755), British general, was born in London, Eng. He joined the Coldstream Guards in 1710 and served in Holland during the siege of Bergen op Zoom in 1747. He was appointed major general in 1754 and arrived in Virginia the following February to command all British forces in North America against the French. Although hampered by administrative confusion and lack of resources, after several months of preparation he undertook to attack Ft. Duquesne (Pittsburgh, Pa.) in an extremely arduous wilderness expedition. His force cut a road westward from Cumberland, Md., the first road across the Allegheny mountains. George Washington, then Lieut. Col. of Virginia militia, was among the 700 provincials and 1,400 British regulars under his command. Braddock's force safely crossed the Monongahela river and reached a point only 8 mi. from Ft. Duquesne. The forward column of 1,459 officers and men, being short of Indian scouts, was ambushed in a ravine by 254 French and 600 Indians on July 9. Wounded during the ensuing slaughter and riot, Braddock died four days later and was buried at Great Meadows, Pa. See also FRENCH AND INDIAN WAR.

See L. McCardell, *Ill-Starred General: Braddock of the Coldstream Guards* (1958); L. H. Gipson, *The British Empire Before the American Revolution*, vol. vi (1946). (W. R. SL.)

BRADDOCK, a borough of Allegheny county, Pa., U.S., on the Monongahela river, 10 mi. S.E. of Pittsburgh; part of the Pittsburgh standard metropolitan statistical area. (For comparative population figures see table in PENNSYLVANIA: *Population*.)

John Frazier traditionally is regarded as the first settler (1742); his cabin is said to have been the first built by a white man west of the Alleghenies. Incorporated as a borough in 1867, Braddock's growth was primarily a result of the industrialization of the Pittsburgh region in the post-Civil War period. Most of the work force is engaged in primary steel production. Braddock was named for Gen. Edward Braddock (q.v.), who in 1755 was ambushed there by the French and Indians. (P. R. J.)

BRADDON, MARY ELIZABETH (1837-1915), English novelist, best known for her popular melodrama, *Lady Audley's Secret*, was born in London, Oct. 4, 1837. Her first novel was *The Trail of the Serpent* (1861). In 1862 she produced her three-volume novel *Lady Audley's Secret*, originally written serially at the request of John Maxwell for his magazine *Robin Goodfellow*. A lurid story of crime in high society which yet did not transgress

Victorian ideas of propriety, it was a sensational financial success. She subsequently married John Maxwell, published over 70 further novels, and edited several magazines. Although she may have owed some of her success to the fact that critical attacks on her novels merely served to increase her sales, in her later novels especially she shows a capacity for social satire and a skill in conveying atmosphere which causes regret that her talent for storytelling should have overpowered her latent sense of style. Her last novel was *The Green Curtain* (1911). She died at Richmond, Surrey, on Feb. 4, 1915.

BRADÉ, WILLIAM (c. 1560-1630), English violist and composer who was one of the most important of the group of English musicians living in Germany in the early 17th century. He worked in many places in Germany (including Berlin, Götterf, Hamburg, Halle and Güstrow), and also at Copenhagen, and finally returned to Hamburg in 1626. His music, which greatly influenced his German contemporaries, including S. Scheidt and J. H. Schein, is often unorthodox: his more experimental dance suites incorporate, among other features, unusual rhythms, which tend to obscure the normal characteristics of the dance forms. However, he also composed suites in which the dance types are clearly differentiated. His music, largely consisting of dance suites and fancies (called *canzoni*) was published between 1607 and 1621 in contemporary collections at Hamburg, Lubeck, Berlin and Antwerp. He died at Hamburg, Feb. 26, 1630. (A. D. F.)

BRADFORD, JOHN (1510?-1555), English Protestant martyr, was born at Manchester. He was deputy paymaster at the siege of Montreuil (1544) and studied law in the Inner Temple (1547), when, influenced by a fellow student, Thomas Sampson, he "sold his chains, rings, brooches and jewels of gold," giving the proceeds to the poor. Determined then to study theology, he entered St. Catherine's hall, Cambridge (1548), received his M.A. degree (1549) and was appointed a fellow of Pembroke hall. Nicholas Ridley, bishop of London, ordained him deacon and made him his chaplain (1550) and a prebendary of St. Paul's (1551); as a chaplain (1553) to Edward VI, he became a popular preacher. Soon after Queen Mary's accession he was imprisoned on a charge of sedition (Aug. 1553), examined, mainly on his eucharistic beliefs (Jan. 1555), and burned as a heretic before a large crowd at Smithfield on July 1, 1555, in his last moments encouraging his young companion, John Leaf.

See A. Townsend (ed.), *The Writings of John Bradford* (1848-53).

BRADFORD, WILLIAM (1590-1657), governor and historian of the Plymouth colony in colonial America, was born at Husterfield, Yorkshire, Eng., probably in March 1590. A year after Bradford's birth, his father died and he was reared by his grandfather and uncles who trained him in farming. At the age of 12, Bradford read the Scriptures and, against his friends' advice, became a Separatist (see CONGREGATIONALISM). He joined the harassed nonconformists when they migrated to Holland in 1609 in search of religious freedom. In spite of his comparative youth, Bradford became a leader of the group of Pilgrims who sailed to America in 1620. A passenger on the "Mayflower," he signed the Mayflower compact, helped locate the spot for settlement, and after recovering from serious illness, was unanimously elected governor in 1621 upon the death of Gov. John Carver. Though he urged rotation in office, he was re-elected 30 times, serving every year except five from 1621 to 1656.

Under Bradford's judicious guidance, Plymouth was put on a sound basis both economically and politically. Some historians have objected to the broad extent of the powers exercised by Bradford in the first years of the Plymouth settlement. Others, more realistically, have shown that under his leadership Plymouth was essentially democratic, that the powers he exercised were given to him by the people in annual elections: and that the people could have chosen another governor had they been dissatisfied.

A self-taught man, a Calvinist and a congregationalist, Bradford was skilled in languages and literature. No portrait of him exists, but the inventory of his estate shows a man who liked fine, colourful clothes. He married twice and was the father of four children. He died at Plymouth on May 9, 1657. Bradford's *History of Plymouth Plantation, 1620-1647*, a journal of the

Pilgrims, ranks among the major literary achievements of his time and remains our best source of knowledge of the Pilgrims. Though not published until 1856, contemporary historians such as Morton, Hubbard, Mather, Prince and Hutchinson used it in manuscript form. Bradford also wrote several *Dialogues* and some poetry, and collaborated with Edward Winslow in writing the journal known as Mourt's *Relation*.

See also MASSACHUSETTS: *History*.

See Samuel Eliot Morison (ed.) *Of Plymouth Plantation* (1952); Bradford Smith, *Bradford of Plymouth* (1951). (B. K. B.)

BRADFORD, WILLIAM (1663–1752). American colonial printer, was born in Leicestershire, England, on May 20, 1663. He learned the printer's trade in London and in 1682 emigrated to Pennsylvania, where in 1685 he introduced the "art and mystery" of printing. His first imprint was an almanac, *Kalendarium Pennsilvaniense or America's Messenger* (1685). In 1690, with William Rittenhouse (1644–1708) and others, he established in Roxboro (Pa.), now a part of Philadelphia, the first paper mill in America. In the spring of 1693 he moved to New York, where he was appointed royal printer for the colony, a position that he held for more than 50 years. On Nov. 8, 1725, he issued the first number of the *New York Gazette*, the first paper established in New York and from 1725 to 1733 the only paper in the colony. Bradford died in New York on May 23, 1752.

See NEWSPAPER: *Early Papers in Philadelphia and New York*.

BRADFORD, WILLIAM (1827–1892), U.S. marine painter whose pictures attracted much attention by reason of their novelty and colour effects, was born at New Bedford, Mass. He was a Quaker and a self-taught artist, painting the ships and the marine views he saw along the coast of Massachusetts, Labrador and Nova Scotia; he went on several arctic expeditions with Isaac Hayes and was the first American painter to portray the frozen regions of the north. His "Steamer 'Panther' in Melville Bay, under the Light of the Midnight Sun" was exhibited at the Royal Academy in London in 1875. Bradford was a member of the National Academy of Design, New York; he died in that city on April 25, 1892. His style was somewhat influenced by Albert van Beest, who worked with him at Fairhaven for a time, but Bradford is observant of minute detail whereas Beest's aim was general effect. John Greenleaf Whittier's poem "Amy Wentworth" was inspired by a Bradford painting and is addressed to him.

BRADFORD, a city, municipal, county and parliamentary borough: in the West Riding of Yorkshire, Eng., 9 mi. W. of Leeds by road. Pop. (1961) 295,768. Area 38.9 sq.mi. The centre of Bradford is in a small valley opening southward from that of the Aire and the outskirts extend into the surrounding hills. Bradford's situation on the lower eastern spurs of the Pennines had much to do with its history and development.

Bradford is mentioned as having belonged before 1066 to one Gamel and appears to have been almost destroyed before 1086. By that time it had been granted to Ilbert de Lacy, in whose family it continued until the death of Henry de Lacy, earl of Lincoln, in 1311. Already Bradford was becoming an important market centre. A charter for a market every Thursday was granted to Edmund de Lacy in 1251 and a fair of five days' duration was granted in addition in 1294. The *inquisitio post mortem* taken in 1311 shows that the earl had there a hall or manor house, a fulling mill, a market and a fair. Edward IV granted or confirmed to certain feoffees, in whom he had vested his manor of Bradford, a market on Thursdays and two yearly fairs. The church of St. Peter, which occupies the site of a previous Norman church, dates from 1458 and has a fine original roof of oak. After the diocese of Bradford was formed in 1919, out of those of Ripon and Wakefield, the parish church of St. Peter was made the cathedral.

The grammar school existed in the 16th century and received a charter of incorporation from Charles II.

From the mention of a fulling mill in 1311 it is possible to surmise that woolen manufacture had already begun. By the reign of Henry VIII it had become an important industry and added much to the status of the town. John Leland in his *Itinerary* says that Bradford is "a praty quik Market Toune. It standith much by clothing." Toward the end of the 17th and beginning of the

18th century the woolen trade decreased, and worsted manufacture began to take its place. On the introduction of steam power and machinery the worsted trade advanced with great rapidity. The first steam-powered mill in Bradford was built in 1798; by the early 1960s there were about 400 mills serving the textile and clothing industry alone.

In 1836 Titus (later Sir Titus) Salt developed the alpaca manufacture in the town: mohair was shortly afterward introduced; and the great works at Saltaire were opened. Later, S. C. Lister (Lord Masham) introduced the silk and velvet manufacture, having invented a process for manipulating silk waste whereby what was previously treated as refuse was made into goods that could compete with those manufactured from the perfect cocoon. The Bradford wool exchange is the chief wool-buying centre, and Bradford's commercial relations with South America and Australia are very important. It is the chief centre for wool-combing and the worsted industry and has a conditioning house for testing all kinds of textiles. The local water—much of which is brought from the Nidd valley about 32 mi. away—after draining through peaty soil, is very soft and consequently is specially suited to wool washing and other manufacturing processes. There are deposits of coal and iron in the vicinity.

The technical college was opened in 1882. The Mechanics' institute was founded in 1825, and in 1871 the present building, near the town hall, was opened. The Cartwright Memorial hall contains an art gallery and museum and commemorates Edmund Cartwright (q.v.).

Other public buildings are Bolling hall (14th century), the ancestral home of Edith Bolling, wife of Pres. Woodrow Wilson, and opened in 1915 as a museum of English social history. St. George's hall (1853), the wool exchange (1867), the Gothic town hall (1873), the market hall (1878) and Britannia house (1933). The Margaret McMillan Memorial Training college for the training of infant and nursery teachers was completed in 1956. Most of the buildings in Bradford are built with freestone quarried locally, which blackens easily under the influence of smoke. There are about 2,000 ac. of parks and open spaces.

Bradford was incorporated in 1847, created a county borough in 1888 and a city in 1897. The council is presided over by a lord mayor, a dignity conferred in 1907. The borough returned two members to parliament from 1832 until 1885, when three were returned. Since 1918, four members represent Bradford.

(W. H. Lm.)

BRADFORD, a city of McKean county, Pa., U.S., near the northern border of the state, 85 mi. S.E. of Buffalo, N.Y., on the forks of Lunenburg creek. (For comparative population figures see table in PENNSYLVANIA: *Population*.)

Bradford is the commercial and industrial centre of Pennsylvania's richest oil field. The first oil well was drilled in 1861 and commercial oil production began in 1875. Production increased rapidly to a peak in 1881 when the area was producing 40% of the world's output. Production declined at the end of the 19th century, but increased after 1906 when a flooding process was introduced. After mid-20th century there were 35,000 wells in production in the county.

The city's principal industries centre about the oil industry and include the refining of oil (two pipelines also carry oil to the seaboard), and the production of greases, gasoline, oil well supplies, tools and machinery. Lumber, brick and wooden articles are manufactured from the products of the surrounding hills. Cutlery, carbon brushes for electrical machines, steel sections, cigarette lighters, paper containers and component parts for television are also manufactured in Bradford.

Bradford was established about 1827 by settlers from New England. It was called Littleton after Col. Lebit C. Little, an early resident, until 1873 when it took the name Bradford for the New Hampshire town from which many early settlers came. It was incorporated as a borough in 1873, and chartered as a city in 1879.

The 65,000-ac. Allegheny state park is 3 mi. from Bradford. The Cornplanter Indian reservation, the only remaining Indian reserve in Pennsylvania, is 15 mi. to the west. (W. A. C.)

BRADFORD-ON-AVON, an urban district in the West-

bury parliamentary division of Wiltshire, Eng., on the Bristol Avon 9 mi. E.S.E. of Bath. Pop. (1961) 5,757. Its houses of gray Cotswold stone rise up the steep sides of the valley, and the river is spanned by a nine-arched medieval bridge on which is a chapel.

Bradford was the scene of a victory of Cenwalch of Wessex over rebels in 652. A monastery existed there of which St. Aldhelm was abbot when he was made bishop of Sherborne in 705. In Abbey yard—probably the site of the monastery—stands the Saxon church of St. Lawrence, considered by Edward Freeman to be "the most perfect surviving church of its kind in England, if not in Europe." It consists of a nave, chancel and porch and was only rediscovered in 1856 when it was carefully restored. Up to the string-molding it is almost certainly St. Aldhelm's original fabric. In 959 the witan (*q.v.*) or witanagemot was held at Bradford. The monastery was sacked by the Danes in 1003, but the abbess of Shaftesbury, to whom the monastery and manor was given for refuge in 1001, held the manor until the Reformation.

Bradford appears as a borough in Domesday Book. The town was at one time the centre of the west of England wool trade and was famous for its broadcloth and mixtures, the waters of the Avon being especially suitable. Flemish merchants settled there during the reign of Edward III. Despite the introduction of weaving machinery in the 17th century and the great prosperity of the 19th century, there came a decline in the 1840s; the last cloth mill in Bradford closed in 1905.

The main industry is rubber with subsidiaries such as the making of ledgers. The 12th-century parish church of Holy Trinity has had continued additions; the 14th-century stone-tiled tithe barn, one of the best in the country, is preserved as a museum of agricultural implements; Kingston house, restored and called the Hall, was built about 1600 and later used for a time as a wool store.

BRADLAUGH, CHARLES (1833–1891), English free-thinker and radical, prominent during the second half of the 19th century for his championship of individual liberty, was born at Hoxton, London, on Sept. 26, 1833, the son of a poor solicitor's clerk. He earned a living by odd jobs, and came into contact with a group of freethinkers who were disciples of Richard Carlile.

At the end of 1850 he enlisted as a soldier, but in 1853 was bought out with money provided by his mother. He then found employment as a lawyer's clerk, and gradually became known as a free thought lecturer, under the name of "Iconoclast." He edited the *National Reformer* for several years from 1860, and displayed much resource in legal defense when the paper was prosecuted by the government on account of its alleged blasphemy and seditious in 1868–69. The passing of the Evidence Amendment act in 1869 was the result of another legal contest (1867–69) as to whether Bradlaugh, being an atheist, and so unable to take the oath, could give evidence in a court of law. Bradlaugh played a prominent part in the republican movement which enjoyed a certain amount of popular support in the early 1870s. In 1874 he became acquainted with Mrs. Annie Besant, who soon became co-editor of the *National Reformer*. In 1876 the Bristol publisher of an American pamphlet, on the population question, called *Fruits of Philosophy*, was indicted for selling a work full of indecent physiological details, and, pleading guilty, was lightly sentenced; but Bradlaugh and Mrs. Besant took the matter up, in order to vindicate their ideas of liberty, and aggressively republished and circulated the pamphlet. In the prosecution which resulted they were convicted and sentenced to a heavy fine and imprisonment, but the sentence was stayed and the indictment ultimately quashed on a technical point. The affair, however, had several side issues in the courts and led to much prejudice against the defendants, the distinction being ignored between a protest against the suppression of opinion and the championship of the particular opinions in question.

Mrs. Besant's close alliance with Bradlaugh terminated in 1885, when she drifted from secularism, first into socialistic and labour agitation and then into theosophy as a pupil of Mme Helena Blavatsky. Bradlaugh himself took up politics with increasing fervour. He had been unsuccessful in standing for Northampton in 1868, but he was returned by that constituency to parliament

as an advanced radical in 1880. A long and sensational parliamentary struggle now began. He claimed to be allowed to affirm under the Parliamentary Oaths act, and the rejection of this pretension, and the refusal to allow him to take the oath on his professing his willingness to do so, terminated in Bradlaugh's victory in 1886. But this result was not obtained without protracted scenes in the house of commons. In July 1880 Bradlaugh was unseated; in Aug. 1881, having been re-elected, he attempted to force his way into the house, but was ejected. In 1882, at the opening of the session, he entered the house and, producing a Bible from his pocket, administered the oath to himself. After several re-elections and exclusions, and much litigation, Bradlaugh was victorious in Jan. 1886, when the new speaker insisted on his being allowed to take the oath. When the long struggle was over, the public had gradually got used to Bradlaugh, and his transparent honesty and courageous contempt for mere popularity gained him increasing respect. He died in London on Jan. 30, 1891. Hard, arrogant and dogmatic, with a powerful physique and a real gift for popular oratory, he was a natural leader in causes which had society against them, but his sincerity was as unquestionable as his combativeness.

BRADLEY, FRANCIS HERBERT (1846–1924), influential British philosopher prominently associated with the Absolute Idealist movement. He was born in Clapham (London; then in Surrey), on Jan. 30, 1846, a son of the Rev. Charles Bradley, an Evangelical preacher of some note who fathered 22 children in all. He was educated at Cheltenham, at Marlborough and at University college, Oxford, where he took second-class honours in Greats. He was elected to a fellowship at Merton college in 1870. Shortly afterward he fell ill of a kidney disease which made him a semi-invalid for the rest of his life. He retained his fellowship at Merton, which involved no teaching duties, until his death on Sept. 18, 1924. Three months before, he had been appointed to the Order of Merit, being the first philosopher to receive that distinction. He was unmarried.

Bradley came upon the British philosophical scene at a time when the empiricist theories of J. S. Mill and others were under attack from writers sympathetic to the ideas of Kant and Hegel, and much of his early work consisted in pressing home this attack. In *Ethical Studies* (1876; 2nd ed., 1927), his first major book, he exposed the confusions of the doctrine of utilitarianism as held by Mill; and in *The Principles of Logic* (1883; 2nd ed., 1922, corrected 1928), where his mastery of philosophical prose is at its most evident, he trenchantly denounced the slovenly psychologism and uncritical reliance on the principle of the association of ideas which was all that the empiricists could offer in the way of a logic. In both works Bradley acknowledged his debt to German writers and disclaimed originality, but he was never the simple "Hegelian" that some critics took him to be. Thus while one of the most striking essays in *Ethical Studies*, that on "My Station and its Duties," was devoted to a brilliantly persuasive exposition of the Hegelian conception of "social ethics," Bradley did not hesitate to point out the shortcomings of this doctrine if taken as a complete account of the moral life; and in *The Principles of Logic*, where, without accepting formalism, he tried to treat logic as a special science distinct from psychology on the one hand and from metaphysics on the other, his break with Hegelian doctrine, if not with Hegelian ways of thinking, was still more obvious. Professing to write "from a level not much above that of common sense," he tended to treat topics independently and without much system; there was, moreover, manifest throughout the work a persistent suspicion of thought in all its forms as a source of mere abstractions, a suspicion which Bradley perhaps derived from R. H. Lotze. Later, under the influence of Bernard Bosanquet, Bradley repudiated some of the central ideas of this book, but his emphasis on the ultimate "failure" of thought remained.

Bradley's work in the fields of ethics and logic made him, much

against his will, the leading figure in a particular philosophical school, and this fact is of importance in assessing the effect of his third and most ambitious book, his "metaphysical essay" *Appearance and Reality* (1893; 2nd ed., 1897). Bradley's followers expected from this book a demonstration of the spiritual nature of the universe, a vindication of the truths of religion and of the superior reality of the soul. What they got was, in the author's own words, "a critical discussion of first principles," meant "to stimulate inquiry and doubt." Reality was indeed spiritual; it was, said Bradley, a harmonious system of experience, a spiritual unity in diversity. But though this result was certain, to demonstrate it in detail was beyond human capacity. If nothing else ensured this conclusion, it was made inevitable by the fatally abstract nature of human thinking, once again insisted on. Immediate feeling could give us an idea of reality as a harmonious whole, individuated yet undivided, but the idea could not be worked out at the conceptual level. The outlook for any constructive metaphysics was accordingly bleak. Nor could Bradley's admirers find much consolation in his treatment of religion and the self. Religion, he declared, was "not final and ultimate" but, in the end, a matter of practice: the philosopher's absolute had little to do with the God of religious men. As for the self, the idea was beset with at least as many difficulties as any other popular metaphysical notion. To say that souls were the only realities, or that they were more real than other things, was definitely false.

The immediate effect of *Appearance and Reality* was thus to encourage rather than to answer doubt; and in general it has been the negative and critical side of Bradley's thought which has proved influential. Bertrand Russell and G. E. Moore, who led the attack on idealism in the early years of the 20th century, had each benefited from his sharp dialectic; important parts of the new logic which these philosophers introduced were already to be found in Bradley. Not that Bradley himself was prepared to accept their criticisms or ways of thinking: on the contrary, he protested to the last that they and other critics misrepresented him. But, rightly or wrongly, he failed to establish his position on this point. He is valued less for his conclusions than for the manner in which he reached them: for his determination to let nothing stand in the way of an honest enquiry into truth.

Besides the fields mentioned above, Bradley did notable work in philosophical psychology, while his early essay on *The Pre-suppositions of Critical History* (1874) is still worth consulting.

BIBLIOGRAPHY.—Bradley's psychological essays and minor writings were put together in *Collected Essays*, 2 vol. (1935). In addition to the works named in the text he himself published *Essays on Truth and Reality* (1914). For biographical details see A. E. Taylor, "Francis Herbert Bradley," in the British Academy's *Proceedings*, 1924-25 (1926). See further: B. Bosanquet, *Knowledge and Reality* (1885); J. H. Muirhead, *The Platonic Tradition in Anglo-Saxon Philosophy* (1931); C. A. Campbell, *Scepticism and Construction* (1931); R. W. Church, *Bradley's Dialectic* (1942); J. Pucelle, *L'Idéalisme en Angleterre* (1955). (W. H. W.)

BRADLEY, GEORGE GRANVILLE (1821-1903), English headmaster and liberal Anglican clergyman, was born at High Wycombe on Dec. 11, 1821. He was educated at Rugby school under Thomas Arnold and then at University college, Oxford, where he became a fellow in 1844. At once he returned to Rugby, whence, having proved his ability both as teacher of classics and administrator, in 1858 he took orders and succeeded his former Rugby colleague G. E. L. Cotton as head of Marlborough college, a new public school which was then in an unsatisfactory condition. He soon eliminated disorder, improved finances and raised teaching to equality with the best. Subsequently, as master of University college (1870 to 1881), he elevated both the personal quality of its students and their academic standards. In 1881 he succeeded his close friend A. P. Stanley as dean of Westminster abbey, the buildings and finances of which his efforts restored. He died in London on March 13, 1903.

Bradley's works include the standard *Life and Letters of Stanley* (1892) (with R. E. Prothero), two sets of lectures on *Ecclesiastes* (1885) and *Job* (1887) and a revision (published in 1881) of

Thomas Arnold's *Latin Prose Composition*.

See F. D. How, *Six Great Schoolmasters* (1904). (G. F. A. B.)

BRADLEY, JAMES (1693-1762), English astronomer and third astronomer royal, who discovered the aberration of light, was born at Sherborne, Gloucestershire, and educated at Balliol college, Oxford. His early astronomical observations were made at the rectory of Wanstead in Essex, under the tutelage of his uncle, the Rev. James Pound (1669-1724), and he was elected a fellow of the Royal society on Nov. 6, 1718. He was appointed Savilian professor of astronomy at Oxford in 1721. His discovery of the aberration of light, made while attempting to detect a stellar parallax, was communicated to the Royal society in Jan. 1729, but he withheld announcement of the supplementary discovery of the nutation until Feb. 14, 1748, when he had tested its reality by careful observations during an entire revolution (18.6 years) of the moon's nodes. He succeeded Edmund Halley as astronomer royal in 1742 and while holding that office made fundamental contributions to both the instruments and techniques of observational astronomy. He observed the eclipses of Jupiter's satellites for many years to correct the existing tables, which he then used to make accurate determinations of the longitudes, from Greenwich, of Lisbon and New York. He retired in broken health in 1761 to Chalford, Gloucestershire, where he died the following year, on July 13. His observations, which are often considered to mark the beginning of the modern era in physical astronomy, were the subject of an ownership dispute, but were finally published in two volumes (1798-1805) at Oxford.

See S. P. Rigaud, *Miscellaneous Works and Correspondence of James Bradley, D.D.* (1832). (O. J. E.)

BRADLEY, JOSEPH P (1813-1892), justice of the U.S. supreme court from 1870 to 1892, whose opinions dealing with the commerce clause of the constitution (art. 1, sec. 8) were of notable significance. He was born at Berne, near Albany, N.Y., on March 14, 1813. A farm boy with an insatiable thirst for learning, he managed to find a way to Rutgers college and thence to the New Jersey bar. He grew to be both a reflective master of the law and an active participant in large undertakings; the Camden & Amboy railroad was his most important client. In 1870 he was appointed to the supreme court and assigned to the 5th (southern) circuit, where he at once came to grips with the problems of Reconstruction. His advent made a bare majority to sustain the validity of the legal tender legislation of the Civil War. In the electoral commission of 1877, it was his decisive vote that made Rutherford B. Hayes president. Each of these episodes produced unwarranted partisan charges. As to the power of congress to enforce racial equality, under the postwar amendments, his original views "were much modified by subsequent reflection." In 1883, in the civil rights cases: he held invalid the statute wherein congress had forbidden discrimination on grounds of colour in inns, public conveyances and places of amusement: the 14th amendment is directed at state, not private action. Throughout his 22 years on the court, Bradley was the great exponent of the proposition that the commerce clause makes the nation a single free-trade area—a design which parochial legislation may not defeat. He was influential in bringing the court to uphold state regulation of the rates of railroads and grain elevators. His was one of the most acute and powerful minds in the court's entire roster. Bradley died on Jan. 22, 1892, in Washington, D.C. His *Miscellaneous Writings* were compiled and edited by Charles Bradley (1902).

BIBLIOGRAPHY.—Five essays by Charles Fairman approximate a bibliography: "Mr. Justice Bradley's Appointment to the Supreme Court and the Legal Tender Cases," *Harvard Law Review*, 54:977-1034, 1128-55 (1941); "The Education of a Justice: Justice Bradley and Some of His Colleagues," *Stanford Law Review*, 1:217-51 (1949); "What Makes a Great Justice?—Mr. Justice Bradley and the Supreme Court, 1870-92," *Bacon Lectures on the Constitution of the United States*, 425-485 (1953); "The So-Called Granger Cases, Lord Hale, and Justice Bradley," *Stanford Law Review*, 5:587-679 (1953); "Mr. Justice Bradley," *Mr. Justice*, pp. 69-95, ed. by A. Dunham and P. B. Kurland (1956). (C. F. N.)

BRADLEY, OMAR NELSON (1893-). U.S. soldier, commander of the 12th army group in Europe during World War II, was born in Clark, Mo., on Feb. 12, 1893. On graduation from the United States Military academy in 1911 he was commissioned

second lieutenant of infantry. At the opening of World War II he was commandant of the Infantry school, later commanding the 82nd and the 28th divisions. In 1943 he led the 2nd corps in north Africa and in the Sicilian campaign. In the fall of that year he took command of the U.S. 1st army in the United Kingdom and started planning for the Normandy invasion. He led the 1st army in the landings in France and in the early battles of 1944, relinquishing this command in August to assume command of the 12th U.S. army group. Under his leadership, the 1st, 3rd, 9th and 15th armies, the largest force ever placed under a U.S. army group commander, carried on operations in France, Luxembourg, Belgium, the Netherlands, Germany and Czechoslovakia.

From 1945 to 1947 Bradley was administrator of veterans' affairs, and from 1948 to 1949 chief of staff of the U.S. army. He was the first chairman of the joint chiefs of staff after unification of the armed services, 1949-53, and was promoted to the rank of general of the army while in that post. In 1951 he published a volume of reminiscences, *A Soldier's Story*. (F. C. P.E.)

BRADMAN, SIR DONALD GEORGE (1908-), Australian cricketer, perhaps the most remarkable batsman of all time. was born at Cootamundra, New South Wales, on Aug. 27, 1908. He perfected his timing and quickened his eyesight by hitting a soft ball against a corrugated water tank and first played for New South Wales in 1927. Bradman scored 6,996 runs in test matches, in which his average of 99.94 runs was unparalleled. His judgment bordered on the miraculous and this, allied with incredibly deft footwork, enabled him to pulverize good-length bowling. In England in 1930, when he made the then test record of 334, no bowler could subdue him, but sticky wickets (rain-affected pitches) and fast, short-pitched "body-line" balls, as bowled by H. Larwood in Australia in 1932-33, momentarily checked him. A brilliant outfieldsman and a shrewd and successful captain, he retired from first-class cricket in 1948 and was knighted in 1949. See also CRICKET.

BRADSHAW, JOHN (1602-1659), president of the "high court of justice" which tried Charles I. was the second son of Henry Bradshaw, of Marple and Wibersley in Cheshire and was baptized on Dec. 10, 1602. He was admitted into Gray's inn in 1620 and was called to the bar in 1621, becoming a bencher in 1647. On Sept. 21, 1643, he was appointed judge of the sheriff's court in London. In Oct. 1644 he was counsel, with William Prynne, in the prosecution of Lord Maguire and Hugh Macmahon, implicated in the Irish rebellion; in 1645 for John Lilburne in his appeal to the lords against the sentence of the star chamber; and in 1647 in the prosecution of Judge David Jenkins. In 1647 he was made chief justice of Chester and a judge in Wales, and on Oct. 12, 1648, he was presented to the degree of sergeant-at-law. On Jan. 2, 1649, the lords threw out the ordinance for bringing the king to trial, and the small remnant of the house of commons which survived Pride's Purge (see ENGLISH HISTORY) determined to carry out the ordinance on their own authority. The leading members of the bar of both parties having refused to participate in the proceedings, Bradshaw was selected to preside. The king refused to plead before the tribunal, but Bradshaw silenced every legal objection and denied to Charles an opportunity to speak in his own defense. Bradshaw also conducted the trials of several royalists, including the duke of Hamilton and Lord Capel. He was appointed, in 1649, attorney general of Cheshire and North Wales and chancellor of the duchy of Lancaster, and on March 10 he became president of the council of state. When, after the expulsion of the long parliament (April 1653) Oliver Cromwell came to dismiss the council, Bradshaw is said, on the authority of Edmund Ludlow, to have confronted him boldly and denied his power to dissolve the parliament. He refused to sign the "engagement" drawn up by Cromwell pledging members of the parliament of 1654 to support the Protectorate, and in consequence withdrew from parliament. After the abdication of Richard Cromwell, Bradshaw again became a member of the council of state and on June 3, 1659, was appointed a commissioner of the great seal. He died on

Oct. 31, 1659, and was buried in Westminster abbey.

BRADWARDINE, THOMAS (c. 1290-1349), archbishop of Canterbury and savant, noted as a theologian and mathematician, called the "profound doctor." was educated and taught at Oxford, where he became professor of divinity and chancellor. In 1335 he left the university and successively held important church offices. After serving as chancellor of the diocese of London, he became a chaplain of Edward III during the early part of the Hundred Years' War. He distinguished himself by his apostolic labours among the soldiers and served as a peace commissioner in 1347. Returning to England he became archdeacon of Lincoln in 1347, and after a contested election, archbishop of Canterbury in 1349. He was struck down by the Black Death 40 days after his consecration. Among his disciples were Nicholas of Autrecourt, John Wycliff and John of Mirecourt.

Bradwardine's most famous work was a treatise on grace and free will entitled *The Cause of God Against Pelagius*, in which he so stressed divine concurrence with all human volition that his followers concluded from it a universal determinism. Bradwardine also wrote works on mathematics: entitled *Speculative Geometry; Practical Arithmetic; Proportions . . . ; and Squaring the Circle*, printed 1495-1530, as well as an unpublished *Art of Memorization*.

See W. F. Hook, *Lives of the Archbishops of Canterbury*, vol. iv. (D. D. McG.)

BRADY, MATHEW B. (c. 1823-1896), probably the best known photographer in U.S. history, was born in New York state, as he himself said, "in the Lake George country about 1823-24." Through his friendship with William Page, the artist, he met Samuel F. B. Morse, who taught him to take daguerreotypes. In 1844 Brady opened his first New York gallery. Although Brady's name is synonymous with famous battlefield pictures of the Civil War, his career prior to the war is as important to history as his battlefield accomplishments.

As early as 1844 Brady won awards for his skilful daguerreotypes. In 1851 he was awarded a medal for a collection of 48 uncoloured daguerreotypes which he exhibited at the Crystal Palace exhibition in London. It was not only his skill as a photographer which won him everlasting fame, but also his plan, begun in 1845, to take portrait photographs of every great man and woman. The scope of his career is shown by his collection of presidential portraits; he photographed every president of the United States from John Quincy Adams, the sixth president, to William McKinley, with one exception, William Henry Harrison, who died only a month after his inauguration in 1841.

To cover the Civil War, Brady spent his entire fortune of almost \$100,000 to hire and equip a corps of photographic teams which covered every phase of the conflict and became the forerunner of the 20th-century newsphoto services. Many of his photographers later photographed the west for the Union Pacific railroad and as official photographers for government railroad surveys.

Although his main activities were directing his cameramen from his Washington office and supervising the operation of his fashionable galleries in New York and Washington, Brady also photographed the battlefields. He was at the first battle of Bull Run in 1861 and at Antietam in 1862 and photographed the battlefields of Gettysburg shortly after the battle had ended; he was at Fredericksburg in 1862 and was under cannon fire at Petersburg in 1864. He also took the memorable photographs of Abraham Lincoln and of Robert E. Lee at Lee's house in Richmond after he had surrendered his army to Ulysses S. Grant at Appomattox.

The Civil War project ruined Brady financially. To meet one bill he gave the creditor a set of his war views. In the financial panic of 1873 he was forced to sell his New York gallery and became bankrupt. He was unable to pay the storage bill for his negatives, and the plates were sold at public auction on July 31, 1874, when they were purchased by the war department for \$2,-840.

Through the efforts of Gen. Benjamin F. Butler and James Garfield, later president, congress finally appropriated \$25,000 for Brady. He continued with his Washington gallery but most of the work was done by assistants and his nephew, Levin Handy.

On Jan. 15, 1896, Brady died alone and forgotten in the alms ward of the Presbyterian hospital in New York city.

See James D. Horan, *Mathew Brady: Historian With a Camera* (1955); Roy Meredith, *Mr. Lincoln's Camera Man* (1946). (Js. D. H.)

BRADY, NICHOLAS (1659–1726). Anglican clergyman and poet. author. with Nahum Tate (*q.v.*), of a well-known metrical version of the Psalms. was born at Bandon, County Cork, on Oct. 28, 1659. He graduated at Trinity college, Dublin, and became prebendary of Cork. In 1690 Brady prevented the burning of the town of Bandon, after James II had given orders for its destruction. He soon afterward settled in London, where he held the livings of Clapham and Richmond.

Brady and Tate's *New Version of the Psalms* was licensed in 1696 and largely displaced the old version of T. Sternhold and J. Hopkins. Among Brady's other works was a blank verse translation of Virgil's *Aeneid* (1726). He died at Richmond, Surrey, on May 20, 1726.

BRADY, WILLIAM A. (1863–1950), U.S. actor, manager and motion-picture producer, was born in San Francisco, Calif., June 19, 1863. He made his debut as an actor there in 1882 and by 1888 was touring with his own company. He had considerable success as Svengali in *Trilby*. In New York city, at the Manhattan, 48th Street and Playhouse theatres, he produced over 250 plays, including *Way Down East*, an all-star revival of *Uncle Tom's Cabin*, and *Street Scene*. Grace George, his second wife, starred in many of them. An early motion-picture producer, he was president of the National Assembly of the Motion Picture Industry, 1915–20. He died Jan. 6, 1950, in New York.

ALICE BRADY (1892–1939), Brady's daughter by his first wife, Rose Marie Rene, after a period in operetta, became a leading actress in straight plays. One of her greatest performances was as Lavinia in *Mourning Becomes Electra* (1931). She also acted in a number of motion pictures. (B. Hr.)

BRAEMAR, a district in southwest Aberdeenshire, Scot., extending 24 mi. from Ballater (east) to Glen Dee (west), with a breadth of 3 to 6 mi. Glen Dee lies among hills from 1,000 to nearly 3,000 ft. high. The villages and clachans (Gaelic for hamlets) from 600 to more than 1,000 ft. above the sea, have pure, bracing air. The deer forests comprise the royal forests of Balmoral and Ballochbuie, Glen Ey forest, Mar forest and Invercauld forest. Castles, mansions and lodges, mostly in Scottish baronial style, include Balmoral (*q.v.*) and Abergeldie castles belonging to the crown, Invercauld house, Braemar castle, Mar lodge and Old Mar lodge. Braemar (officially Castleton of Braemar) is the foremost village, the capital of the Deeside highlands. The well-known Braemar gathering for highland games is held in August in Princess Royal park near the village. Not far from the spot where the brawling Clunie rivulet joins the Dee the earl of Mar raised the standard of revolt in 1715. His seat, Braemar castle, reputed to be a hunting lodge of Malcolm Canmore, was forfeited along with the estates. The new castle built by the purchasers in 1720 was later acquired by Farquharson of Invercauld, who gave the government the use of it after the battle of Culloden.

BRAG, an old English game which is an ancestor of poker (*q.v.*). From 3 to 12 may play, using the regular 52-card pack. There are three wild cards, called braggers—ace of diamonds, jack of clubs and nine of diamonds. The dealer antes and then deals three cards to each player, face down. Each player in turn may drop, call or raise; if no player calls, dealer collects one chip from each. At the conclusion of betting there is a showdown. Three of a kind and pairs are the only combinations of value, and natural cards outrank equal combinations made with a bragger. (For example, three natural aces would beat an ace, jack of clubs and nine of diamonds.) There are several variants: including one in which all jacks and nines are braggers. (R. L. Fy.)

BRAGA, (JOAQUIM) TEÓFILO (FERNANDES) (1843–1924), Portuguese literary historian, Republican statesman, and poet the first to attempt a complete history of Portuguese literature, was born at Ponta Delgada in the Azores on Feb. 24, 1843. His family was Catholic and monarchist by tradition but he himself soon became noted for his intransigent republicanism

and anticlericalism at Coimbra university where he graduated in law in 1868.

After attempting to secure a professional chair in law, Braga became professor of modern literatures in the *Curso Superior de Letras* in Lisbon in 1872. Of a buoyant, pugnacious temperament, he wrote profusely on literary, social, historical and political subjects, and produced some verse. He was influenced by French 19th-century writers and his *Visão dos Tempos* (1864) was inspired by Victor Hugo's *Légende des siècles*. Jean Michelet stirred his nationalist enthusiasm for the medieval and popular elements in literature, and later he was a firm upholder of Auguste Comte's positivism. Braga's investigations ranged widely over the whole of Portuguese literature but, owing to his lack of a sense of proportion and his determination to fit the facts to his own sociological and philosophical theories, the valuable material he accumulated is often swamped by digressions and theorizings which have lost much of their validity. Nevertheless, a number of his works remain important: his *História do Romantismo em Portugal* (1880) is still the most comprehensive picture of the Romantic period, and his studies of Almeida Garrett, *Garrett e o Romantismo* (1904) and *Garrett e os Dramas Românticos* (1905), are valuable, as are also the books on the 18th-century poets, *Bocage, sua vida e época literária* (1877) and *A Arcádia Lusitana* (1899), and his *História da Poesia Popular Portuguesa* (1867).

An unswerving Republican, Braga became president of the provisional government which set up the Republic of 1910; he held the presidential office again in 1915. In spite of blindness he never lost enthusiasm and was planning another major work just before his death, at Lisbon, on Jan. 28, 1924.

See J. de Carvalho, "Teófilo Braga," in *Perspectiva da literatura portuguesa do século XIX*, vol. II (1948); A. J. Saraiva and O. Lopes, *História da literatura portuguesa* (1954). (N. J. L.)

BRAGA, a city in the district of the same name and the capital of Minho province in northern Portugal, stands at the head of a railway from Oporto, about 30 mi. N.E. of that city. Pop. (1960) 98,012 (mun.). The city is an archiepiscopal see. Braga is the Roman Bracara Augusta, capital of the Callaici Bracarii, or Bracarenenses, and a centre for military roads. In the early 5th century it was taken by the Suevi and about 485 by the Visigoths. The city is noted as the place where the Visigoths renounced the Arian and Priscillianist heresies. Its archbishops are primates of Portugal and long claimed supremacy over the Spanish church.

From the Moors, who captured Braga early in the 8th century, the city was retaken in 1040 by Ferdinand I, king of Castile and Leon; and from 1093 to 1147 it was the residence of the Portuguese court. Its 12th-century cathedral was rebuilt during the 16th century in the blend of Moorish and florid Gothic styles known as Manueline. The church of Santa Cruz has a handsome façade, which dates from 1642. There are several convents and a library containing many rare books and manuscripts. On a hill about 3 mi. S.E. stands the celebrated sanctuary of Bom Jesus do Monte, visited at Whitsuntide by many thousands of pilgrims, and about one mile beyond it is Mt. Sameiro (2,535 ft.), crowned by a colossal statue of the Virgin Mary and commanding a magnificent view of the mountainous country, which culminates in the Serra do Gerez, on the northeast.

The principal manufactures of the city are firearms, jewelry, cutlery, cloth and felt hats. Large cattle fairs are held in June and September.

BRAGA DISTRICT has an area of 1,054 sq.mi.; pop. (1960) 617,162.

BRAGANZA (Port. BRAGANÇA), the name of an administrative district and its capital in the extreme northeast of Portugal. The city, an episcopal see since 1764, is situated on a branch of the Sabor river, 8 mi. S. of the Spanish frontier, and consists of a walled upper town, containing the castle and cathedral, and of a lower or modern town. Area (district) 2,527 sq.mi.; pop. (1960) district 238,588; town 38,387 (mun.).

Historically, the town is important as the seat of the house of Braganza which provided the kings of Portugal from 1640 to 1910 and the emperors of Brazil from 1822 to 1889. Afonso (d. 1461), an illegitimate son of John I of Portugal, was made duke of

Braganza in 1442, having previously acquired considerable estates and hereditary rights by his marriage with Beatriz, daughter of the constable, Nuno Álvares Pereira. Successive dukes—Fernando I (d. 1478), Fernando II (d. 1483), Jaime (d. 1532), Teodósio I (d. 1563), João I (d. 1583), Teodósio II (d. 1630) and João II—enlarged their patrimony by matrimonial alliances. João I, moreover, married Catherine, a niece of King John III of Portugal and, after 1580, a claimant to the Portuguese throne (*see* PORTUGAL: *History*). Finally, when the national revolution of Dec. 1, 1640, terminated the union with Spain, João II became king of Portugal as John IV. Subsequently the title duke of Braganza was borne by the heir presumptive to the throne. The new dynasty lasted until the deposition of Manuel II and the proclamation of a republic on Oct. 5, 1910.

Meanwhile, with the proclamation of Brazilian independence in 1822, the house of Braganza had provided two heads of the new empire. Pedro, the elder son of John VI of Portugal, was emperor from 1822 to 1831, and his son, Pedro II, was emperor from 1831 until his deposition on the proclamation of the Brazilian republic in 1889. With Pedro II's death in 1891 the male line of this branch of the family became extinct. (For the house of Orléans-Braganza or Bourbon-Brazil *see* BOURBON.)

Manuel II, who died in England, without issue, on July 2, 1932, bequeathed the possessions of the house of Braganza to the Portuguese state. The property was made into a quasi-autonomous administrative unit, supporting the Fundação da Casa de Bragança. This foundation supports a library, museum and lecture centre housed in the palace of Vila Viçosa, which from the 16th century was the principal residence of the Braganza family.

(DA. A. P.)

BRAGG, BRAXTON (1817–1876), Confederate officer in the American Civil War, was born at Warrenton, N.C., March 22, 1817. After graduating from West Point in 1837 he served as an artillery officer in the Seminole Wars of 1837 and 1841, and under Gen. Zachary Taylor in the Mexican War. In 1862, as a major general in the Confederate army he led a bold advance from eastern Tennessee across Kentucky to Louisville. Tactically the ensuing battle of Perryville (Oct. 8) was a draw; unwilling to fight to a decision, Bragg withdrew into Tennessee. Though he was bitterly censured, the personal favour of Pres. Jefferson Davis kept him at the head of the army of Tennessee, and on Dec. 31, 1862, and Jan. 2, 1863, he fought the indecisive battle of Murfreesboro (or Stone River) against Rosecrans. In the campaign of 1863 Rosecrans constantly outmaneuvered the Confederates and forced them back to the border of Georgia. Bragg, however, inflicted a crushing defeat on his opponent at Chickamauga (Sept. 19–20) and for a time besieged the Union forces in Chattanooga. But large forces under Grant were concentrated upon the threatened spot, and the great battle of Chattanooga (Nov. 23–25) ended in the rout of the Confederates. Bragg was now deprived of his command, but President Davis made him his military adviser. In 1864, he led an inferior force from North Carolina to Georgia to oppose Sherman's march. In Feb. 1865, he joined Gen. Joseph Johnston, and he was thus included in the surrender of that officer to Sherman.

In spite of his want of success Bragg was a brave and at times a skilful officer, but he lacked the resourcefulness, dash and craftiness of Lee. His irritability prevented him from securing the loyalty from subordinates that military commanders need, but the Confederates had in the west no organizer to equal him. Bragg's greatest military fault was in not following up his successes. His victories were fruitless.

After the war Bragg was a civil engineer in Alabama and Texas. He died at Galveston, Tex. on Sept. 27, 1876.

See Don C. Seitz, *Braxton Bragg, General of the Confederacy* (1924); Bragg Manuscripts, Western Reserve Historical Society. (G. D. L.E.)

BRAGG, SIR (WILLIAM) LAWRENCE (1890–), British physicist, worked with his father Sir William Henry Bragg (*qv*), in the study of crystals by means of X-ray diffraction. He was born on March 31, 1890, in Adelaide, Austr. He received his education at Adelaide university and Trinity college, Cam-

bridge, where he became a fellow in 1914. After receiving his degree from Cambridge, he joined his father in the study of X-ray diffraction. As a result of the Braggs' work, the structures of many kinds of crystals were discovered with the aid of the X-ray spectrometer. "For their services in the analysis of crystal structure by means of X-rays" the Braggs were awarded the Nobel prize for physics in 1915.

During World War I the younger Bragg served as technical adviser on sound ranging in the map section of British army headquarters in France. He was elected to the Royal society in 1921, and he was Langworthy professor of physics at the Victoria university of Manchester, Eng., from 1919 to 1937. During 1937–38 he was director of the National Physical laboratory, and in the latter year was made Cavendish professor of experimental physics at Cambridge. In addition to various papers on crystal structure, he published with his father *X-Rays and Crystal Structure* in 1915. Other writings include *The Crystalline State* (1934); *Electricity* (1936); and *Atomic Structure of Minerals* (1937).

BRAGG, SIR WILLIAM HENRY (1862–1942), British physicist, is best known for studies of crystal structure by means of X-ray diffraction. He was born at Wigton, Cumberland, July 2, 1862, was educated at King William's college, Isle of Man, and Trinity college, Cambridge. In 1886 he was appointed professor of mathematics and physics at Adelaide, Austr., where he carried out his earlier researches in radioactivity. In 1909 he was appointed Cavendish professor at Leeds and in 1915 Quain professor of physics in the University of London. His researches upon various radioactive phenomena and his power of lucid exposition brought recognition from scientific bodies both at home and abroad; in 1906 he was elected a fellow of the Royal society; in 1915 he received the Nobel prize for physics and the Barnard Gold medal (Columbia university), both of which distinctions he shared with his son William Lawrence Bragg (*qv*).

The joint work of father and son went far toward elucidating the arrangements of atoms and crystals, an achievement rendered possible by their development of the X-ray spectrometer.

In 1923 he was appointed Fullerian professor of chemistry at the Royal institution and director of Davy-Faraday research laboratory; subsequently he became director of the Royal institution. He was president of the British Association for the Advancement of Science, 1928–29, and from 1935 to 1940 was president of the Royal society. He died March 12, 1942.

In addition to many publications, chiefly upon radioactivity and crystallography, in the *Philosophical Magazine* and the *Proceedings of the Royal Society*, he also wrote *The World of Sound* (1920); *Concerning the Nature of Things* (1923); and *The Universe of Light* (1933).

BRAGI, according to Norse mythology, is a god of poetry and the son of Odin. Evidence that he actually was worshiped is scant, and some authorities believe that he should be identified with the poet Bragi Boddason the Old, who worked in Norway in the 9th century.

(G. T.-P.)

BRAHE, Swedish noble family, descended in the female line from the Danish family of Brahe and a senior member of the Swedish nobility through marriage into the house of the Vasas. PER BRAHE (1520–1590), the nephew of Gustavus I Vasa, wrote a historical work *Per Brahe den aldres fortsatning af Peder Svarts kronika* (pub. 1897) and *Oeconomia* (1677 and 1920), a manual for young noblemen. Created count of Visingsborg in 1561 by Eric XIV Vasa, he was the first Swedish count.

PER BRAHE the younger (1602–1680), a grandson of Per Brahe, was born on Feb. 18, 1602, at the castle of Rydboholm, near Stockholm. During the war with Poland he served in Prussia from 1626 to 1628 and was a colonel of horse from 1628 to 1631. At the diet of 1629 Brahe was president of the nobility (*lantmarskalk*) and became a privy counselor (*riksråd*) in 1630. From 1632 to 1644 he was a member of the regency council for Queen Christina, concluding the armistice with Poland of 1633. As governor general of Finland from 1637 to 1641 and from 1648 to 1654 he reformed the administration, promoted urban, commercial and agricultural developments and founded the university of Åbo (Turku) in 1640, being its chancellor from 1646 to 1680. Between 1641 and 1680 Brahe was lord high chancellor and as such

was an influential member of the regency council from 1660 to 1672 for Charles XI. He died on Sept. 12, 1680, at his castle of Bogö sund, near Stockholm.

Per the younger's brother, Count NILS BRAHE (1604–1632), was born at Rydboholm on Oct. 14, 1604. He served as a general under Gustavus II Adolphus and was appointed a colonel of the "yellow regiment," the king's renowned life guard, in 1631. He distinguished himself at the crossing of the Rhine at Oppenheim (Dec. 1631) and at the battle of the Lech (April 1632). At the battle of Lützen (Nov. 16. 1632) where he commanded the Swedish centre, he was mortally wounded and died on Nov. 21, 1632, at Naumburg. The marriage of his son, Adm. Count NILS BRAHE the younger (1633–1699), to a daughter of C. G. Wrangel, the lord high constable, brought Skokloster castle, near Stockholm, to the family.

Count MAGNUS BRAHE (1790–1844), a close friend of Charles XIV John (the former French marshal Bernadotte), exercised a secret but preponderant influence on public affairs from 1823 onward, being marshal of the kingdom from 1834 to 1844. When the last count MAGNUS BRAHE (1849–1930), died, Skokloster and Rydboholm castles, with their great art collections, passed to the family of von Essen, related to the Brahes by marriage; the earlier archives from both castles are however in the Swedish public record office (*riksarkivet*) in Stockholm.

BRAHE, TYCHO (1546–1601), Danish astronomer, the discoverer of the "new star" in Cassiopeia and one of the great practical astronomers of the later Renaissance, was born on Dec. 14, 1546, at the family seat of Knudstrup in Scania, Den. He studied at Copenhagen, Leipzig, Rostock and Augsburg, and in 1571 was permitted by his maternal uncle, Steno Belle, to install a laboratory at his castle of Herritzvad, near Knudstrup, where on Nov. 11, 1572, he discovered the famous "new star" in the constellation Cassiopeia. His observations were published in *De Nova Stella* (1573), in which he proved that the star was beyond the moon, contrary to the general belief.

He gave lectures in Copenhagen, by royal command, in 1574 and traveled to Germany and Italy in 1575. He returned to Denmark in the following year when Frederick II granted him the island of Hven, near Copenhagen, together with ample means to found an observatory there. In return, Tycho acted as astrologer and almanac maker for the royal family. The corner stone of Uraniborg ("castle of the sky") was laid in 1576 and the finished building provided working spaces, living quarters and instruments on a scale much greater than had previously been available to astronomers. Craniborg, together with a later building, Steliaborg, is the forerunner of the great modern observatories.

The appearance of the new star in 1572 had given Tycho the idea of forming a precise star catalogue which, together with most of his other work, was carried out on Hven between 1576 and 1596. In 1596 Frederick was succeeded by Christian IV who was less tolerant of Tycho's arrogance and heavy drain on the royal treasury. Tycho's pensions having been withdrawn, he left Denmark in 1597 and finally reached Prague in June 1599, where he was assured of favour and protection by the emperor Rudolph II, who granted him the castle of Benatky, near Prague, together with an ample pension. Although most of his instruments were moved from Hven to Prague, and Kepler joined him in Jan. 1600, very few observations were made and Tycho died there on Oct. 24, 1601.

Tycho's principal work, *Astronomiæ instauratæ Progymnasmata*, 2 vol. (1602–03), was edited by Kepler. The first volume treated of the motions of the sun and moon and gave the places of fixed stars—this number was increased to 1,000 by Kepler in 1627 when he published his "Rudolphine Tables." The second

volume, which had been privately printed at Ilraniborg in 1588 with the title *De Mundi aetherii recentioribus phaenomenis*, was mainly concerned with the comet of 1577 which, Tycho showed, as he had for the new star, possessed no appreciable parallax and was therefore an extra-terrestrial phenomenon. This volume also includes an account of the Tyconic system in which a middle ground was sought between the Ptolemaic and Copernican systems. The immobility of the earth was retained from the Ptolemaic system but the other planets were made to revolve around the sun, which, with these planets, annually circuted the earth. In both the Tyconic and Ptolemaic systems, the sphere of the fixed stars performed a diurnal rotation. Tycho, in correspondence, tried to convert Galileo from the Copernican system on the basis of the fact that his precise observations showed no sensible relative motion of the fixed stars, but Galileo was unconvinced and groups Tycho with Aristotle and Ptolemy in his *Dialogue on the Two Systems of the World*, although he expresses admiration for Tycho's observational results.

In *Astronomiæ instauratæ Mechanica*, Tycho published at Wandbeck, in 1598, a description of his instruments, together with an autobiographical account of his career and discoveries, including the outstanding one of a new variation in the motion of the moon. His *Epistolæ Astronomicae*, printed at Uraniborg in 1596, were embodied in a complete edition of his works issued at Frankfurt in 1648. He was the first to allow for the effect of refraction, by the earth's atmosphere, on astronomical observations and introduced methods for the correction of instrumental errors and the averaging of accidental errors. He substantially corrected the received value of nearly every astronomical quantity and his observations on Hven are characterized by their accuracy and his observations on Hven are characterized by their accuracy

BRAHMA AND BRAHMAN. Brahma (masculine) is the first member of the Hindu trinity, the creator-god whose Vedic prototype was Prajapati, the lord of the creatures. The other members of the trinity are Vishnu and Shiva, and with the rise of Shivaism and Vishnuism in the Epic period as the two most popular cults, the importance of Brahma declined (see also HINDUISM: Gods). Only one prominent temple dedicated to Brahma remains, that at Pushkar, near Ajmer, India.

The familiar picture of Brahma is that of a four-faced and four-armed bearded deity seated on a lotus seat below which is placed a swan. The four faces represent the four Vedas, the chief Hindu scriptures. The sacrificial spoon, a string of beads and a manuscript that he holds in his hands indicate that he is the God of wisdom and piety. His consort is Sarasvati, the goddess of learning. He is known as the lotus-born and the first-born, and he is described as the grandfather of gods and men. His mind-born sons, the sages Sanaka, Sanandana, Sanatana and Sanatkumara, are the exemplars of the path of renunciation, while his worldly sons such as Daksha are charged with the duty of perpetuating the species.

Brahman (neuter) is the supreme reality that upholds the universe. Originally the word probably meant "prayer" or "speech" from the root *brh*, "to burst forth." It also means that which is great and mighty. The seers of the Upanishads seem to have arrived at the conception of Brahman when inquiring into the origin of the objective universe. When they adopted the method of subjective investigation, they concluded that the root principle is Atman (the soul or self). Finally Brahman is identified with Atman, and defined in one of the Upanishad texts as "that whence all beings come into existence, wherein they reside and where unto they return at the end."

Brahman is thought of in two ways: as the all-inclusive sustaining spirit of the universe: or as the reality of which the universe is only the surface appearance. The former is the cosmic view (*saprapanca*) according to which Brahman is endowed with attributes (*saguna*), postulated by the theistic schools of Vedanta. The latter is the acosmic view (*nishprapanca*) which considers Brahman to be unconditioned and attributeless (*nirguna*) and is held to be a more adequate view of Brahman by the absolutist

schools. Since Brahman is the unconditioned reality, it can be indicated only negatively as "not this, not this." This, however, does not mean that Brahman is "nothing." It is the plenitude of being (*sat*), consciousness (*chit*) and bliss (*ananda*). Although both the theistic and the absolutistic standpoints are to be found in the Upanishads themselves, the most outstanding exponents of these in the systematic period of Indian philosophy were respectively Ramanuja in the 11th century A.D. and Shankara in the 9th century A.D. (See also INDIAN PHILOSOPHY.)

Of the two conceptions, that of the personal God Brahma and that of the impersonal Absolute Brahman, it is difficult to say which was earlier. The seeds of both are to be found even in the Rigveda.

The term Brahma also refers to one of the four principal priests that officiate at Vedic sacrifices. His functions are to supervise the ritual acts and to set right any mistakes. The expression *brahmana* means (1) the parts of the Veda which are concerned with sacrifices (see BRAHMANAS); (2) one who has realized Brahman; (3) "a Brahman"; i.e., member of the Brahman caste.

BRAHMAGUPTA (588–c. 660), Hindu mathematician and astronomer. He set forth the astronomical system of Brahma in verse form, the *Brahma-sphuta-siddhanta* (c. 628).

Two of the chapters in this work are devoted to mathematics, including an arithmetical progression, a quadratic equation and proofs of various geometrical theorems on the right-angled triangle, on areas of triangles and quadrilaterals and on surfaces and volumes. These two chapters were translated into English by H. T. Colebrooke in his *Algebra, with Arithmetic and Mensuration, from the Sanskrit of Brahmagupta and Bhāscara, preceded by a dissertation on the state of science as known to the Hindus* (1817). Another translation is given in P. C. Sengupta, *The Khandakhādya, an Astronomical Treatise by Brahmagupta* (1934).

(O. Oe.)

BRAHMAN, the highest-ranking group in the Hindu hierarchy of hereditary castes (see CASTE [INDIAN]). The elevated position of the Brahman goes back to the first millennium B.C. when the Aryans who had settled in northern India were already divided into Brahmans or priests, warriors, traders and husbandmen, and menials, and the Brahmans had gained prominence among the three upper classes known as "twice-born." Since then there has been no fundamental change in their position and they still enjoy great prestige and many advantages, though their claim to tangible privileges is no longer officially admitted. The basis of the age-old veneration of Brahmans is the belief that they are inherently of greater ritual purity than members of other castes and that they alone are capable of performing certain vital religious tasks. The study and recitation of the sacred scriptures was traditionally reserved for this spiritual élite and for centuries all Indian scholarship was in their hands.

Because of their high prestige and their intelligence and learning, Brahmans wielded influence even in secular affairs, and although political power lay normally with members of the warrior caste they acted frequently as advisers and ministers of ruling chiefs. During the period of British rule Brahmans largely retained their role as intellectual leaders—at first in the service of government and later in the nationalist movement. After India achieved independence (1947) Brahmans continued to lead the Congress party, and dominated the central government, but in many states there developed a reaction against their dominant position in the administration, and in southern India, where Brahmans were particularly firmly entrenched, an anti-Brahman movement gathered considerable strength. This does not, however, affect their traditional position as priests, ministering both in temples and at domestic rites. Every orthodox Hindu of clean caste must have a Brahman family priest (*purohita*), to whom he pays customary dues in return for services at weddings, funerals and other ceremonial occasions.

The ritual purity of the Brahmans is maintained through the

observance of numerous taboos, many of which relate to diet and contact with lower castes. Most Brahman castes are strictly vegetarian and their members must abstain from certain occupations. They may not plow or handle any impure material, such as leather or hides, but they may farm and do such agricultural work as does not offend against these specific restrictions. They may also accept employment as domestic servants and many well-to-do Hindus have Brahman cooks, who are useful because members of all castes may eat the food they prepare.

Orthodox Brahmans spend much time on religious practices, which consist of recitations and prayers, a daily ritual bath and the regular worship of household deities. Brahmans never bow to other castes but others bow to them in recognition of their high ritual status. At an early age boys are invested with a sacred thread made of three strands of cotton, which is worn next to the skin over the left shoulder. Those who have undergone this initiation rite are known as *Duija* ("twice-born"). Most Brahmans are strict in the observance of marriage rules, and while polygamy is permitted traditionally to Brahman men, Brahman women who have been widowed or deserted by their husbands are not allowed to remarry. Well into the 19th century Brahman widows sometimes committed *sati* or self-immolation on the husband's funeral pyre, a pious act approved by public opinion.

The Brahmans of India are divided into ten main territorial divisions, five of which are associated with the north and five with the south. The northern group consists of Saraswati, Gaur, Kanauj, Maithil and Utkal Brahmans and the southern group of Maharashtra, Andhra, Dravida, Rarnata and Gurjara Brahmans. Within each of these groups there are sectarian divisions based on an emphasis on the study of specific Vedas, and also endogamous subcastes, most of which have local associations. Each of these subcastes is again divided into exogamous clans or *gotra*, believed to consist of the descendants of certain legendary saints or *rishi*. Despite this variety of sects and regional divisions, Brahmans represent the only caste group whose status is constant throughout India, and recognition of their supreme ritual status is one of the marked features of Hindu unity. Outside India Brahmans are also found in Nepal and in small numbers in the Tamil-speaking parts of Ceylon. See BRAHMA AND BRAHMAN; HINDUISM.

See also references under "Brahman" in the Index volume.

(C. v. F.-H.)

BRAHMANAS, treatises in prose explaining the significance of the Vedas as used in ritual sacrifice (see SANSKRIT LANGUAGE AND LITERATURE). The word *brahmana* (otherwise signifying "a Brahman") is derived from *brahma* in its Vedic sense of devotion or prayer.

The Brahmanas belong to the period 800–500 B.C., a time when the collections into Samhitas ("books") of the sacred hymns had acquired a position of sanctity. They represent a digest of accumulated teachings, illustrated by myth and legend, on various matters of ritual and on hidden meanings of the sacred texts. Assuming complete familiarity with the ritual, they do not form a guide to sacrificial procedure. The oldest Brahmanas are found in the Krishnayajur Veda, where the Samhita is interspersed with prose comments. In the Katha and Maitrayaniya schools such comments form the only extant Brahmana, whereas the Taittiriya school has a supplement, in three books, entitled the Taittiriya Brahmana. The last portion of the Taittiriya Brahmana (together with the beginning of the Taittiriya Aranyaka) has been incorporated bodily from the prose portions of the Katha Samhita. The treatises designated as Aranyaka, "forest treatises," represent a subsequent development in brahmanical discussion, being more theosophical in content, and were either to be studied by pious Brahmans who, having retired to the forest, no longer partook in ritual sacrifice, or else were to be imparted by teacher to pupil in the forest; i.e., away from the village. Aranyakas act as a link between Brahmans and the Upanishads, the latter often being inserted in the Aranyaka.

The Samaveda owns numerous Brahmanas, but properly there are two, the Panchavimsha ("25 book"), Tandya or Praudha Brahmana of the Rauthuma school and the Jaiminiya Brahmana of the Jaiminiyas or Talavakaras. They show almost complete

accordance in their exposition of the *gavamayana* ("going of cows" ceremony), the *jyotishtoma*, *ukthya* and *atiratra* (Soma [*g.v.*] ceremonies), the *dvadashaha* ("12 days' rite") and finally the different rites lasting from 1 to 12 days. The last chapters of the *Shadvimsha* (26th book), called *Adbhuta Brahmana*, as also the conclusion of the *Jaiminiya Brahmana*, describe the atonements required where mistakes or evil portents have occurred during sacrifices. The *Jaiminiya* wanders into digressions, quoting long anecdotes, whereas the *Panchavimsha Brahmana* adheres more rigidly to the order of the sacrifice, indulging occasionally in statements hostile to the *Kaushitaki* school of the *Rigveda*. The *Kaushitaki* (or *Shankhayana*) *Brahmana*, in 30 chapters, explains the religious significance of the *agnyadhana* (setting up the sacrificial fire), *agnihotra* (daily morning and evening sacrifice) the new and full moon rites and the *chaturmasyas* (four months' rites). The bulk of the *Brahmana*, as also that of the *Rigvedic Aitareyins*, is then occupied with the *agnishtoma*, the one-day rite of the *Soma*. The *Xitareya Brahmana*, in eight books of five chapters each, also treats the *gavamayana* and the *dvadashaha*. The remaining three books deal with the *agnihotra* and the rites for the installation of kings.

The *Xitareya* and *Kaushitaki Aranyakas* begin with some ritual, but turn to speculation concerning the world-soul under the names of *prana* and *purusha*, a theme dealt with in the *Kaushitaki Upanishad* which, like the *Aitareya Upanishad*, is contained in the *Brahmana*.

To the *Shuklayajur Veda* belongs the *Shatapatha Brahmana* (of 100 paths), consisting of 100 lessons. Ranking next to the *Rigveda* in importance, this *Brahmana* survives in two slightly differing recensions, the *Kanva* and the *Madhyamdina*, following the order of the *Samhita* exactly, the first nine (*Madhyamdina*, ten) sections corresponding to the first 13 divisions of the *Samhita*. The remaining sections, besides complementing the earlier portions, introduce elements more connected with domestic ritual; the last section introduces the *Brihadaranyaka* which in turn concludes with the *Brihadaranyaka Upanishad*.

Finally to the *Atharvaveda* belongs the comparatively late *Gopatha Brahmana*. Relating only secondarily to the *Samhita* and borrowing considerably from other *Samhitas* and *Brahmanas*, it is partly concerned with the role played by the *Brahman*, the priest who presides over sacrificial procedure (see *SANSKRIT LANGUAGE AND LITERATURE*).

BRAHMANISM: see *HINDUISM*.

BRAHMAPUTRA (Tibetan. *TSANGPO*; Chinese, *YA-LU-TS'ANG-PU CHIANG*), a great river of Tibet, northeastern India (Assam) and East Pakistan, with a total length of about 1,800 mi. Its source, in about 82° 10' E., 30° 30' N., is in a great glacier mass in the *Kailas* range of the *Himalayas*, just south of the lake called *Gunkiyud Tso* in western Tibet. Tributaries join the infant river from near the pass of *Maryum La* (16,900 ft.), which separates its basin from the *Manasarowar* lake district, in which two other great Indian rivers, the *Indus* and *Sutlej*, have their source. The river flows through southern Tibet for about 700 mi., keeping a course roughly parallel to, and 100 mi. from, the main chain of the *Himalayas*. It is known there as the *Tsangpo*, meaning in Tibetan "the purifier," but this is not a distinctive name, for it is applied to any large river: the Tibetans themselves call it by different names in different parts of its course. It receives many tributaries of which the most important are: on the left bank, the *Raka Tsangpo*, which joins it west of *Zhikatse*, and the *Kyi Chu*, on which stands *Lhasa*; on the right bank, the *Nyang Chhu*, which flows by the large trade centre of *Gyantse* and joins the *Tsangpo* at *Zhikatse*. *Zhikatse* is the principal place on the *Tsangpo* itself and the second town of Tibet, with the great monastery of *Trashi Lhumpo*, formerly the seat of the *Tashi Lama*.

From *Lhatse Dzong* (*Janglache*) in 87° 37' E. to a day's journey below *Tsethang* (11,850 ft.) 50 mi. S.E. of *Lhasa* the *Tsangpo* has a wide navigable channel. It is one of the most remarkable inland systems of navigation in the world, for boats navigate it for 400 mi. at a height of 12,000 ft. and more above sea level. The boats are coracles made of hide stretched over frameworks of slender branches. Large ferry boats, shaped like oblong boxes, ply

in some places. Elsewhere there are suspension bridges made mainly of bamboos and in a few cases with heavy chains: some have a 300-ft. span.

At *Tsela Dzong* the *Tsangpo* is joined from the north by the *Gyamda*, 2 mi. wide at the point of junction. Further east at *Pe* (9,680 ft.) the river is still a broad placid stretch of water. 660 yd. wide. Then turning abruptly to the northeast and north it makes its way by a succession of stupendous gorges between the huge mountain masses of *Gyala Peri* (23,458 ft.) and *Namcha Barwa* (25,446 ft.), which are in one place only 8 mi. apart. Through these deep narrow gorges the *Tsangpo* rushes tumultuously down in a series of cascades and rapids, turning the flank of the range in a hairpin bend. It takes up from the north the *Po Tsangpo*, a swift torrent 80 yd. wide, and then, turning to the south and southwest, emerges from the foothills as the *Dihang*. It flows into Indian territory across the *North East Frontier* agency (administered by the governor of *Assam* as agent for the president of *India*) and into *Assam* proper west of *Sadiya* town. Near *Sadiya* it receives from the north the *Dibang* and the *Sesiri* and from the east the *Luhit*, which, as it flows in the same direction as the main river, is wrongly called by the *Assamese* the *Brahmaputra*. From the point of junction the mighty river, which is now for the first time known by the Indian name of *Brahmaputra*, *i.e.*, the son of *Brahma*, rolls majestically down the *Assam* valley for 450 mi. Its channels oscillate from side to side over a bed about 6 mi. wide and it forms many islands, one of which, *Majuli*, has an area of 485 sq.mi. In times of flood it overflows its banks and resembles an inland sea.

Sweeping round the spurs of the *Garo hills*, the river enters the alluvial plains of *East Pakistan*, through which it flows for another 150 mi. until it joins the *Ganges* at *Goalundo*. From the confluence of the *Tista* to *Goalundo* it is called *Jamuna*. The united stream of the two rivers then flows southeast under the name of the *Padma* and makes its exit into the *Bay of Bengal* by the broad estuary of the *Meghna*. Till the end of the 18th century the *Brahmaputra* flowed through the centre of the district of *Mymensingh* to join the *Ganges* near *Bhairab Bazar*, but early in the next century, as this channel became choked with silt, the stream deserted it and moving westward across the friable soil of the delta cut its channel along the western boundary of *Mymensingh*.

It has well been said that the *Brahmaputra* for its size and utility ranks among the most important rivers in the world. It is 250 mi. longer than the *Ganges*. It drains an area of 361,000 sq. mi. and its flood discharge during the rainy season, when its level rises 30 to 40 ft., has been estimated at 500,000 cu.ft. per second. It not only builds up land, but also fertilizes it and distributes its produce. It is the highway of commerce through the fertile valley of *Assam* and *East Pakistan*. Unbridged throughout its length in *Indian* and *Pakistan* territory it is navigable by steamers as far as *Dibrugarh*, 800 mi. from the sea.

The upper course of the *Brahmaputra* has long an unsolved mystery; it was even thought at one time that the *Tsangpo* might be the upper channel of the *Irrawaddy* and might thus have no connection with the *Brahmaputra*. The explorations of *Kintup*, an *Indian* surveyor, along the *Tsangpo* as far as *Pemakochung* in 1884 and of *J. F. Needham* up the *Dihang* in 1886 first established the identity of the *Tsangpo* and *Brahmaputra* beyond reasonable doubt. *Capt. C. G. Rawling*, with *Capt. C. H. D. Ryder*, *Capt. H. Wood* and *Lieut. F. M. Bailey* marched up the *Tsangpo* from *Zhikatse* to its source in 1904-05; but its course from *Pemakochung* through the *Himalayas* to its debouchment in the *Abor hills* of *Assam* remained a mystery. It was known that after flowing at a level of 12,000 ft. on one side of the range it reappeared at 1,000 ft. on the other; and it was thought that there might be tremendous waterfalls hidden in the mountains. Exploration was barred by the hostility of mountain tribes, but in 1913, after the *Abor* expedition had inspired them with wholesome respect, *Bailey* and *Capt. H. T. Morshead* explored 100 mi. of the river and found marvelous gorges and rapids but no falls higher than 30 ft. A gap of 50 mi. still remained, but in 1924 *Capt. F. Kingdon Ward* found that in this part of its course also the river descends not by great waterfalls but by rapids and cascades pent in towering cliffs and

narrowing in one place to a width of 30 yd. See SIANG FRONTIER DIVISION. See also references under "Brahmaputra" in the Index volume.

(L. D. S.)

BRAHMO SAMAJ ("Association for the Worship of God"), a protestant theistic movement within the fold of Hinduism, was founded in Calcutta in 1828 by Ram Mohan Roy (*q.v.*). It does not accept the authority of the Vedas, has no faith in avatars and does not insist on belief in *karma* and rebirth. It discards Hindu rituals, adopts some Christian practices in its worship and, influenced by Islam and Christianity, denounces polytheism, idol worship and the caste system. It has no authoritative canon of its own and relies more on reason than on faith. It has preserved neither the comprehensiveness and philosophic depth of orthodox Hinduism nor the concrete appeal of the older theisms connected with the worship of Vishnu, Siva and Sakti.

Whereas Ram Mohan Roy wanted to reform Hinduism from within, his successor, Devendranath Tagore, broke away in 1850 by repudiating Vedic authority and making reason and intuition the basis of Brahmoism. However he tried to retain some of the traditional Hindu customs, and a radical group led by Keshub Chunder Sen (*q.v.*) seceded and organized the Brahmo Samaj of India in 1866. The new branch became eclectic and cosmopolitan and was also most influential in the struggle for social reform. It sponsored the Band of Hope temperance society, encouraged the education of women and campaigned for the remarriage of widows and for legislation to prevent child marriages. When Keshub arranged for his daughter to marry the prince of Cooch-Behar, though both parties were under age and he was thus violating his own reformist principles, many of his followers rebelled and in 1878 formed a third *samaj*, the Sadharan Brahmo Samaj. While Keshub attempted to establish a new universal religion called Nava Vidhan (the New Dispensation), the Sadharan Samaj gradually reverted to the teaching of the Cpanishads and carried on the work of social reform. Although the movement has lost force in the 20th century—by the second half of the century it embraced only 0.2% of the Indian people—it has been partially successful in that its fundamental social tenets are now accepted by Hindu society.

See Sitanath Tathvabhusan, *The Philosophy of Brahmaism* (1909); Sivanath Sastri, *History of Brahmno Samaj*, 2 vol. (1911-12)

(D. S. Sa.)

BRAHMS, JOHANNES (1833-1897), German composer and one of the great masters of classical musical forms, was born at Hamburg, on May 7, 1833.

Life.—His father, Johann Jakob Brahms, of peasant ancestry, settled in Hamburg in the 1820s and made his living as a musician, playing the double bass at weddings and dances, in coffee houses and music halls. When Johannes, his eldest son, revealed remarkable musical talent as a child, it seemed the obvious thing to destine him for the same profession. Fortunately a better-equipped musician, Otto Cossel, became interested in the gifted child, and some years later Cossel's teacher, Eduard Marxsen, took charge of his musical education and gave him an equally sound training in the rudiments of composition as in the techniques of piano playing. Johannes was an accomplished pianist and already a composer of distinctive style when he set out, aged 19, in 1853 on his first adventure, a concert tour with the violinist Eduard Reményi, a Hungarian political refugee; and this journey was to be a decisive event in the young musician's career. He met Joseph Joachim, who, his senior by only a couple of years, was already famous as a violinist and became one of his closest friends; and Joachim gave him a letter of introduction to Robert Schumann at Dusseldorf who, as much as his wife Clara, the famous pianist, was enormously impressed by that young visitor's genius.

Under the heading *Neue Bahnen* ("New Paths") Schumann wrote a sensational article for the *Neue Zeitschrift für Musik* in

Leipzig, the periodical he had founded and edited many years before, in which Brahms was proclaimed as the coming man, the great prospective master who would lead music to new and glorious achievements. That generous appreciation of a young, totally unknown beginner by an acknowledged master is rare in the history of music. Better auspices for the opening of an artist's career would be difficult to imagine. Schumann's recommendation provided instant attention and interest for his protégé and a publisher for his first works, which appeared by the end of that same year, 1853. Already on that occasion young Brahms showed his self-critical seriousness by suppressing some of the works Schumann had recommended for publication to his own publishers, Breitkopf & Härtel in Leipzig. The three pianoforte sonatas, the Scherzo in E flat minor, the first book of songs which he did publish at that time, are amazingly original and mature for a composer of his youth and his lack of practical experience, and worthy of an artist whose whole output throughout his life was guided by a conscience of incomparable objectivity and vigilance.

The young composer's career, after such a dazzling opening, was somehow hindered for a number of years, probably by personal as much as external causes. In February 1854, on learning of the mental illness that was to end in Schumann's death two years later, Brahms moved to Dusseldorf in order to help Clara and her children in those tragic circumstances, and he stayed there for several years, living on piano lessons, working incessantly but publishing only a few works. These, his formative years, mere continued in Hamburg, where he returned after Schumann's death in 1856; during them he shaped his style and developed his technique by the most comprehensive study of the great masters. His personal situation at that time was by no means satisfactory: except for a modest temporary appointment at the court of Uetmold, where he gave piano lessons and was in charge of a choral society for some months of the winter, he had to live on private teaching and could not find a suitable position of any kind.

Performances of his music were few and rarely successful until, in 1862, a visit to Vienna resulted in a radical change of his circumstances: he could present himself there with a number of important, mature works—the Serenade in D major, the Pianoforte Quartets in G minor and A major, the Variations on a Theme by Handel for piano, the String Sextet in B flat major—and he made an immediate and decisive impression as a composer, a performer and a personality. He was appointed conductor of the *Vienna Singakademie*, an oratorio society. That appointment did not last very long, nor did a later one as conductor (1871-74) of the most prominent concert institution in Vienna, the *Gesellschaft der Musikfreunde*. But he had found in Vienna the surroundings that, for the musician as for the man, seemed as congenial as possible, and Vienna remained his main residence henceforth. After the tremendous success of his *Requiem* in 1868, his fame rose, giving him, in a few years, a dominating position in the musical life of central Europe and secure material conditions. A confirmed bachelor, he lived comfortably in Vienna during the winter, traveling usually in spring when he would appear as a performer, playing and conducting mainly his own works, and retiring for prolonged summer vacations, usually to the Swiss or Austrian Alps, where he was totally absorbed in his creative work. The external events of his life are in no way memorable; its reality is the mountain range of great works he created during those years of quiet, single-minded devotion, unaffected by honours of all kinds and an almost mythical fame, as simple and unassuming as ever in his personal habits. His indefatigable creative activity, after a life of robust health, was cut off by the first attack of the deadly disease, a cancer of the liver, to which he finally succumbed, after nearly a year's illness, in Vienna on April 3, 1897.

Aims.—With contributions of momentous importance to practically all branches of music with the exception only of opera, Brahms has taken his place alongside the very greatest composers of the past, and general appreciation of his work seems to have become even greater in the 20th century than it was at the time of his death. If comparatively little of his work has faded so far, this is certainly as a result of his own strict censorship, which never allowed anything to pass that might fall short of his own

fastidious claims. For example, a pianoforte trio in E flat, composed when Brahms was in his 50s, delighted two of his most expert and respected friends, Clara Schumann and Theodor Billroth, yet it never appeared, because the composer judged it unsatisfactory. An extraordinary awareness of his own limitations or shortcomings was probably the reason for a prolonged period of apprenticeship, of assiduous studies that followed the publication of his first works. Like some of his predecessors, such as Schumann or Chopin, and with similar resulting difficulties, Brahms had grown up with the piano as his main medium of musical communication. Not without continued struggle was he able to master the problems of different instrumental combinations, the secrets of string technique, of orchestral, of choral writing. His correspondence with his much more experienced friend Joachim during those formative years, which, strictly speaking, were only concluded with the *Requiem*, shows on every page the ardent desire to learn and an incredible humility. The most ambitious work of that period, the Pianoforte Concerto in D minor, went to Joachim over and over again for criticism and advice, and the composer is never satisfied, always feeling keenly the gap between his monumental vision and its actual realization. Throughout these years, in company with Joachim, whom he tried to stimulate in his activity as a composer, he continued to train himself systematically in the most involved and scholastic techniques of counterpoint, feeling this to be the most essential foundation of the art of composition, with the final result of an unsurpassed mastery of writing. Like Schumann's and Chopin's, Brahms's idiom appears already amazingly personal in the very first works he published. All the same there is a steady development of style, progressing throughout his long creative career. But there is hardly any wavering of the course he pursued: his principles, his ideals seem to have been set from the start. Glancing chronologically through his works, one is struck by the methodical deliberation with which he established himself in one branch of music after another, with a never-failing sense of responsibility and an uncanny consciousness of the individual problems involved.

Style.—An artist's style results from a complicated interaction of two basic components: his artistic heritage and his own gradually emerging individual way of expression. This applies to Brahms as it applies, say, to Beethoven or Schubert. If in the case of Brahms the traditional, the inherited elements of form and style seem to predominate, at least at a superficial examination, this is due in part to a peculiar historical situation. Brahms was the first great composer who grew up at a period when, as never before in the history of music, the heritage of the past, and even of the remote past, had become a vital factor in the growth and gradual development of a musician's mind and consciousness. The complete edition of Bach's works that began to appear in 1850 was a more important event for Brahms than anything that happened in the field of music during his lifetime, and early in his 20s his keen interest in the music of the 16th and 17th centuries, of Giovanni da Palestrina, Orlando di Lasso and Heinrich Schutz, added another layer of the utmost importance to his background. In the language of his maturity, Brahms is a romanticist with unmistakable classical and preclassical features; in his vocal music, especially in his music for unaccompanied voices, the style of the golden age of vocality, of the masters of the 16th century, has made a noticeable imprint; and his fondness for the German folksong—in point of fact a romantic fashion of his early years—adds an element of melodic obviousness and simplicity to the intricate, subtle structure of his songs. With all that, there is never any feeling of eclecticism: the complicated genetic components of his music are amalgamated with an unsurpassable sense of style and with a noble, virile expressiveness that permeates every strain of a rich, impeccably controlled texture.

From his deep study of the masters, Brahms, with ever-increasing consciousness, became aware of the organic connection of the present with the past, of music as a living continuity. He saw and felt himself as a humble descendant of a glorious ancestry whose achievements, impossible to equal, imposed a tremendous task on the latecomer and an almost crushing sense of responsibility. There is an unbridgeable chasm between this kind of phi-

losophy and the convictions of the radical progressive party, the neo-German school, presided over by Liszt, and propagating the "music of the future." Against such tendencies Brahms maintained a stubborn opposition throughout his life. He found sparks of spirit and originality in Berlioz, whom he met in Leipzig in 1853. He fully understood Wagner's genius, both as a dramatist and a musician, and he liked to call himself "the best Wagnerian," although he could never swallow Wagner's theories and loathed his grandiloquence and extravagance. But Liszt, whom he found incomparable as a pianist, he refused to take seriously as a composer and, time and again, speaks of his music as "snindle." This feud caused the only deplorable act of rashness in his life of which we know: a declaration he circulated among his friends, intended as a public pronouncement against the "music of the future" and its representatives and against the claim to general acceptance of their ideal of descriptive music as realized in Liszt's and his disciples' symphonic poems and program-symphonies. Owing to some indiscretion the draft was published prematurely by a Berlin newspaper with only the signatures of the proposers, Johannes Brahms, Joseph Joachim and two others, and so the whole enterprise lamentably misfired, with the only result of exposing Brahms to a lifelong vendetta with the "musical futurists" and their very active supporters in the press. It was the first and the last time in his life that he became involved in public polemics. Thereafter he remained silent, even after some spiteful personal attacks by Wagner.

In Brahms's early style—as represented in the three pianoforte sonatas (1851–53) or the Pianoforte Trio in B major (1854)—the impression of romantic exuberance prevails. The music is imbued with the spirit of the German romantic poetry of Joseph Eichendorff or Johann Ludwig Uhland. Here is the point of intersection where young Brahms, with the ecstatic expressiveness of his music, stands by no means far from his antipode, Wagner. The slow movement of the Sonata in F minor (1853), quite in line with the poetic tendencies of the neo-German Lisztians, even bears a love poem by Sternau as an inscription. By a strange coincidence, the movement actually contains a striking allusion to an episode in Wagner's *Mastersingers* (*Der Vogel, der heut' sang*), written ten years later. At this stage, however, the young composer's control of form and texture is not yet sufficiently reliable to avoid occasional lapses. It took him another ten years to impose on his work the strict discipline of classical form that he felt to be essential. Many years later, he rewrote the grandest, most ambitious work of his early years, the Trio in B major of 1854, which had never fully satisfied him. The totally reconstructed new version—considerable parts are cut down to the roots and redeveloped with new thematic material—was published in 1891, one of the most striking demonstrations of a great master's critical approach to an immature work of genius.

Works.—Still, during his 20s, Brahms seems sometimes to stand undecided between the romantic and the classical ideals, between extravagance of expression and formal restraint. Only toward the end of that period does the synthesis seem to be achieved, the conflicting forces brought into balance. He has successfully mastered the problems of instrumental and vocal style and technique, but he still balks at what he regards as the most demanding tasks, the string quartet and the symphony. With the growing practical experience of his activity as a conductor of choral and orchestral music in Vienna, he achieves the first great climax of his creative life, *Ein Deutsches Requiem*. As his most monumental conception, this work is one of his most popular achievements; as to frequency of performance, it has found its place alongside the foremost standard works of its kind. The Requiem—not a work written for the church but a kind of sacred oratorio on words from the Scriptures—opens a period during which Brahms concentrated particularly on choral and orchestral composition: *Rinaldo* (1868), *Rhapsodie* for contralto and male chorus (1869), *Schicksalslied* (1871) and *Triumphlied* (1871) followed the Requiem and some years later came *Nänie* (1881) and *Gesang der Parzen* (1882). Brahms was 40 when he published his first two string quartets and 44 when, 15 years after he had made his first drafts, he completed his First Symphony. Hans Bülow, the greatest conductor of that

time, hailed it as "the 10th," a true successor of Beethoven's nine symphonies. Preceded (1873) by the Variations on a Theme by Haydn, the symphony is the first of a galaxy of symphonic works in which Brahms fully expressed his genius for highly organized instrumental music. As a symphonic composer, he stands on Beethoven's shoulders. This applies as much to the structure as to the whole conception of symphony as an art form. In his First Symphony, the progress from the stress and strain of the first movement to the jubilant triumph of the finale corresponds to a similar curve of emotion in Beethoven's Fifth and Ninth. When he made use of the archaic device of a *passacaglia* ("variations on a ground bass") in the finale of the Fourth Symphony, he himself pointed out, in justification of himself as it were, that Beethoven had used a similar technique in the finale of the *Eroica* symphony. What he has added to Beethoven's pattern of possibilities is mainly based upon the polyphonic component of his style. Brahms's process of inventing is always stimulated by contrapuntal elements. In the first movements of the First, Second and Third symphonies, the opening main subjects are contrapuntal inventions, subject and countersubject in a close construction that works as a thematic accumulator, a shaping force of dynamic power. More than on Beethoven's "thematic work," with motive cells germinating and coalescing, Brahms's process is based on variation of motives, on the infinite possibilities of widening, condensing, transforming a phrase.

The four symphonies, the two overtures, the second piano concerto in B flat, the violin concerto and the concerto for violin and violoncello have become classics in the most exact sense. The same term can be applied to the chamber music, the songs, the piano music, motets and part songs, the creations of his mature years. When Bülow in the 1880s proclaimed his belief in "the three great Bs"—Bach, Beethoven and Brahms—he anticipated a valuation which has hardly seemed exaggerated.

Achievement.—It is undeniable that Brahms, as sturdy and original a character as any of the very great, was rather a preserver than an innovator. This is a result of the historical situation in which he found himself, with his deep consciousness of a glorious tradition and as the last exponent of the great creative period that, from Bach to Brahms, has contributed more than any other to our living musical heritage. Intrinsic parts of his greatness are the modesty with which he accepted his position and the energy and honesty of his struggle for perfection that seemed almost out of reach to the latecomer. The philosophical skepticism and pessimism of the late 19th century found their noblest expression in the work of this composer, whose belief in the immortality of great music and the sovereignty of human thought was his religion.

BRAHUI, a tribal confederacy in Baluchistan, West Pakistan, with about 150,000 members, mostly nomadic goat herdsman, distributed from the Bolan pass through the Brahui hills to Cape Monze on the Arabian sea. The Brahui language (*q.v.*) is a far northwestern outlier of the Dravidian family of languages, all of whose other members are located in peninsular India; it has borrowed heavily from Sindhi, but remains in unexplained isolation among Indo-Iranian dialects, to which it bears no genetic relationship. Physically the Brahui tribesmen resemble their Balochi and Pathan (*qq.v.*) neighbours, for the confederacy has been a highly absorptive one. The Brahui tribes are all Muslim by creed and Sunnis by sect, Muslim rites being thickly overlaid upon social customs which are essentially Indian. Women are not strictly secluded.

The Brahui tribes are organized along Balochi lines, owing a loose allegiance to the Brahui khan of Kalat, the "Fort," which

has long been knit up with the confederacy's destinies. A group of seven or eight endogamous lineages form what is believed to be the original Brahui nucleus and constitute about one-eleventh of the Brahui population. These nuclear lineages claim descent, as do the Balochi tribesmen, from Mir Hamza, the Prophet's uncle, who according to orthodox Islamic tradition left no issue. First among the nuclear lineages stands the Ahmadzai, the ruling lineage, and last among them, the Rodeni, of semiservile descent. To this nucleus have been affiliated many indigenous and captive peoples, their lineages classed as Baloch, Pathan, Persian, Jat, etc., according to the reputed origin of its ruling set. Thus the Pathan group among the Bangulzai comprises Rind-Balochi and Arab lineages. Even the nuclear Brahui lineages are of similarly mixed origin.

Documentary knowledge of Brahui history begins with the capture of Kalat by the Moguls and its recapture by the Brahuīs with Pathan aid, in the 15th to 16th century. Incessant warfare with Balochi and Jats ensued, but eventually, in the 17th century, Mir Ahmad, founder of the Ahmadzai lineage, welded or rewelded the various tribes into a confederacy. Under Nasir the Great, who took the title of khan, the confederacy attained its zenith in the 18th century (*see* BALUCHISTAN: *History*). On that ruler's death in 1795 anarchy revived and the confederacy disintegrated, the Pathan elements taking a full share in its disruption, but closely followed by the Balochi and Persians. Modern Brahui history shows repeated fission.

BIBLIOGRAPHY.—Sir Denys Bray, *Census Report of India*, vol. iv, *Baluchistan* (1913), *The Life-History of a Brahui* (1913) and *The Brahui Language*, 2 vol. (1909–34). (M. Ma.)

BRAHUI LANGUAGE. Spoken in Baluchistan in West Pakistan, the grammatical system discloses the secret of its parentage. The use of suffixes, most of which are traceable to the same source as Dravidian (in southern India), the essential forms of the personal pronouns and striking analogies in the pronominal terminations of the plural in the verb, in the formation of the casual, and, above all, in the organic negative conjugation, all show that the language has sprung from the same source as the Dravidian group. "It has freely absorbed the alien vocabulary of Persian, Balochi, Sindhi and other neighbouring languages, but its grammatical system has preserved a sturdy existence." *See* also DRAVIDIAN LANGUAGES.

BRAID, JAMES (1795–1860), Scottish surgeon and scientific investigator of hypnotism, was born in Fifeshire, educated at Edinburgh and practised in Manchester. Braid's interest in mesmerism was aroused in 1841 when he attended several *conversazioni* of an itinerant mesmerist. Initially skeptical toward the phenomenon of mesmeric sleep, he began his own experiments; he became convinced that genuine sleep can be induced by a fixed stare at a bright inanimate object. In 1843 he published his *Neurypnology, or the Rationale of Nervous Sleep, Considered in Relation with Animal Magnetism*, introducing the term neurohypnotism or hypnosis and proving conclusively that hypnotic "phenomena are induced solely by an impression made on the nervous centers" without any fluid or other influence passing from operator to patient. By this means he hoped to "acquire a power of rapidly curing many functional disorders," otherwise deemed incurable and generally labeled "nervous complaints." He reported successful treatment of *tic douloureux*, paralysis, aphasia, rheumatism, headache, palpitation, skin diseases and other functional and organic diseases and advocated the use of hypnotism in surgery to alleviate anxiety and pain. At first his views met with violent opposition, but they were later taken up by Paul Broca, J. M. Charcot, A. A. Liébault and H. Bernheim and thus provided a major impetus to the development of the French school of neuropsychiatry. Braid died at Manchester on March 25, 1860. *See* also HYPNOSIS. (I. V.)

BRAID, JAMES (1870–1950), British golfer and one of the greatest players of his time, was born at Earlsferry, Fife, Scot.,

on Feb. 6, 1870. He learned golf as a caddie and wished to become a professional, but his parents apprenticed him to a joiner. In 1893 he became a club maker in a large department store in London and two years later achieved sudden fame by halving with the reigning champion, J. H. Taylor. In 1896 he became professional at the Romford golf club and quickly established himself as a player of note. He won the open championship five times: Muirfield (1901 and 1906); St. Andrews (1905 and 1910); Prestwick (1908); and the *News of the World* match-play tournament four times.

Braid, H. Vardon and Taylor were the dominating figures of the game in the early years of the 20th century and they were known as "the great triumvirate" (see *GOLF: History*). In 1905 Braid played with Sandy Herd a famous foursome over 72 holes against Vardon and Taylor, the latter pair winning by 13 to 12. He was professional at Walton Heath, Surrey, for over 45 years. Braid died in London on Nov. 27, 1950. (B. DN.)

BRĂXLA (formerly **IBRAILA**), a Danubian port of southeast Rumania in the Galați region, lies in flat country on the west bank of the Danube, 106 mi. from its mouth at Sulina and 229 km. (142 mi.) N.E. of Bucharest. Pop. (1956) 101,424. Brăila is mostly a modern town compactly built; its principal building is the cathedral of St. Michael. Electric streetcars intersect the town and link it with the salt Lake Sdrat, 6 mi. S.W. Brăila is connected by rail with Ploești and Bucharest, and with Galați (20 mi. N.N.E.). It is the second largest port of Rumania, being accessible to seagoing ships and having a large grain and warehousing capacity.

Brăila is an important industrial centre, with metalworking, textile, clothing, footwear and food-processing factories. At Chișcani, 5 mi. S.S.W., pulp and paper are made from reeds. There are a state theatre and a museum of art.

Brăila is first mentioned in a document of 1368 issued by the prince of Walachia and permitting merchants of Brașov to transport their goods on the Danube through Brăila. In 1554 it was conquered by the Turks who built five concentric walls around it. By the treaty of Adrianople following the Russo-Turkish war of 1828–29, Brăila was returned to Walachia. A little upstream of the city are remains of the piles of a bridge attributed by doubtful tradition to Darius (c. 500 B.c.).

BRILLE, LOUIS (1809–1852), to whom the blind owe their alphabet, was born in Coupvray, France. At the age of three, while cutting leather in his father's shop, the knife slipped and plunged into his eye. Sympathetic ophthalmia and blindness followed.

In 1819 he went to Paris with a scholarship to attend the Institution National des Jeunes Aveugles, whose founder, Valentin Haüy, first discovered that the blind could decipher texts in embossed Roman letters. In 1821 Charles Barbier, an artillery captain, exhibited there an apparatus by which a message, coded in dots and dashes, was embossed on thin cardboard. At age 15 Braille worked out an adaptation that adequately met the needs of the sightless. After extending his six-dot code to musical notation, he published expositions of his system in 1829 and 1837.

Braille became a dedicated teacher in his school and a talented church organist. For the last 17 years of his life he was ill with tuberculosis. His remains, sent to Coupvray, were returned to Paris in 1952 to rest in the Pantheon.

BRAIN. The brain is that part of the central nervous system that is lodged in the skull or, if the invertebrates are included in the definition, the head. This article deals almost exclusively with the brain of man; it does not include the invertebrates and considers the brain of the lower vertebrates only in so far as it can throw light on the structure of the human brain. The article is organized as follows:

- I. Anatomy of the Brain
 - A. Development of the Brain
 1. Early Stages
 2. Further Differentiation
 3. Hindbrain and Roof Plate

4. Midbrain and Thalamencephalon
5. Development of the Pituitary Body
6. Pineal Organ or Epiphysis
- B. Comparative Anatomy
 1. Cyclostomes
 2. Fishes
 3. Amphibians and Reptiles
 4. Birds
 5. Monotremes
 6. Marsupials and Insectivores
 7. Higher Mammals
- C. Anatomy of the Adult Human Brain

1. General Structure
2. Membranes of the Brain
3. Ventricles
4. Medulla Oblongata
5. Pons Varolii
6. Cerebellum
7. The Midbrain
8. Cerebral Hemispheres
9. Cerebral Cortex
10. Weight of the Brain

II. Physiology of the Brain

- A. Vertebrate Evolution
 1. Increased Integration
 2. Control of Environment
 3. Hindbrain
 4. Midbrain
 5. Forebrain
 6. Developmental Stages
 7. From Subhuman to Human
- B. Experimental Investigations
 1. Lessons of Animal Behaviour
 2. Reflexes
 3. The Cerebral Cortex
 4. The "Motor" Cortex
- C. The Brain Stem
 1. Brain Stem Reflexes
 2. Sensory Conduction Through the Brain Stem
 3. Motor Conduction Through the Brain Stem
 4. Regulation of the Internal Environment
 5. Regulation of the Central Nervous System
- D. Nutrition of the Brain

I. ANATOMY OF THE BRAIN

The anatomy of the brain is of interest primarily because in the central nervous system, perhaps more than anywhere else, morphology sets certain easily seen limits to function. Nerve cells can do only one thing: send out rather uniform signals. For a given cell these signals will all be of roughly the same strength, determined by the amount of energy developed in that cell and having no clear relation to the energy of the impulse that releases that cell. This survey of the anatomy of the brain deals very briefly with the first stages of its development, then its comparative anatomy and, finally, the anatomy of the adult human brain.

A. DEVELOPMENT OF THE BRAIN

In all vertebrate embryos the central nervous system originates as an axial thickening of the ectoderm covering the dorsal surface of the embryonic area. This is the neural or medullary plate and is continuous on each side with the ectoderm that will become the epidermis. The edges of the neural plate soon become raised, so that the axial band is converted into a longitudinal groove. This is the medullary groove and already at its anterior end shows three enlargements that are separated by two constrictions. These indicate the site of the primary divisions of the embryonic brain, namely, the forebrain or prosencephalon; the midbrain or mesencephalon; and the hindbrain or rhombencephalon. There is also an indication on each side of the forebrain of the optic vesicle.

The medullary groove later becomes converted into a closed tube, which is named the medullary or neural canal, by the folding inward and union of its edges. The union begins in the region of the neck and extends headward and tailward. The lumen of this tube is dilated at the head to form the ventricles of the brain, while in the rest of its extent it remains narrow and forms the central canal of the spinal cord. As the margins of the medullary groove unite to form the medullary canal, a continuous lamina of epithelium grows outward on each side of the spinal cord and posterior part of the brain. This is the neural crest. It afterward becomes segmented and gives origin to the sensory ganglia on the posterior

roots of the spinal nerves, the sensory fibres of the spinal nerves, and the ganglia and nerve fibres of the sympathetic system. It takes part in the formation of some of the ganglia and nerve fibres of the cranial nerves. The neural crest cells appear also to give rise to pigment cells, thus explaining in a simple way why so many animals are lighter on the belly than on the back. (*See NERVOUS SYSTEM; EMBRYOLOGY, HUMAN.*)

The hypoglossal (last cranial) nerve, which in the adult is a purely motor nerve for the muscles of the tongue, in the embryo has a posterior or sensory root with a rudimentary ganglion upon it (Froriep). This afterward disappears, but its temporary presence in the embryo indicates that the nerve was primarily composed of both motor and sensory fibres and that it is homologous with the spinal nerves.

1. Early Stages.—In the early stages of development the brain presents certain flexures which involve the longitudinal axis of the neural tube. The first of these is the cephalic flexure, which is a forward bend round the anterior end of the notochord. It is followed by the cervical flexure at the junction of the brain with the spinal cord, which is also in a forward direction. Between is the pontine flexure, which is in the reverse direction and does not involve the whole thickness of the neural tube.

The stage with three primary vesicles soon becomes modified by subdivision of the forebrain into an anterior telencephalon and a posterior diencephalon (including thalamencephalon); the hindbrain also divides into the metencephalon and myelencephalon. The telencephalon gives rise to the olfactory lobes and hemisphere vesicles. The thalamencephalon forms the region of the brain surrounding the posterior part of the third ventricle behind the foramen of Monro. It includes the thalamus proper, divisible into a sensory dorsal and a motor ventral part, the pineal organ and the habenula dorsally and the hypothalamus and the cerebral lobe of the pituitary ventrally. The metencephalon comprises the pons Varolii, part of the fourth ventricle and the cerebellum; the myelencephalon corresponds to the medulla oblongata.

In transverse section the developing medullary tube is seen to consist of left and right lateral plates, between which is the central canal of the spinal cord. The lateral plates are joined at their dorsal margins by a thin roof plate and along their ventral margins by a similar thin floor plate. These close in the central canal behind and in front. A cross section of the canal at this stage of development is diamond-shaped, with the dorsoventral diameter much longer than the transverse diameter. The wide angles on each side of the diamond correspond to a longitudinal groove on the inner surface of each lateral plate. This is the posterior median sulcus (sulcus limitans) and runs the whole length of the spinal cord. It is continued forward on the floor of the fourth ventricle, to the sides of the aqueduct of Sylvius in the midbrain. Its end in the thalamencephalon is not quite clear. The groove marks off the ventral or basal part of the brain and spinal cord, which gives origin to motor nerve fibres, from the dorsal or alar part, which receives the sensory fibres.

2. Further Differentiation.—The developing neural tube shows three important zones: an inner or germinal zone, a middle or mantle zone and an outer or marginal zone. The germinal zone is characterized by actively dividing nuclei. The middle zone forms the central gray matter of the cord and contains a large number of oval nuclei embedded in the supporting tissue. The marginal zone consists at first only of a fine network of supporting or neuroglial fibres. Later, it is traversed by white medullated fibres forming the columns of white matter.

These zones are present in the early stages throughout the whole extent of the neural tube, but the primary relations are considerably modified in the brain by the migration of nerve cells and nerve fibres from one zone into the other. Thus the inner zone forms the ependyma or lining membrane of the central canal of the spinal cord and ventricles of the brain. In certain places in the brain, however, the ependyma is invaginated into the cavities of the ventricles and modified so as to form the choroidal epithelium. Moreover, that part of the gray matter that forms the cortex of the cerebral hemispheres and of the cerebellum is situated on the surface of the brain, superficial to the white matter.

This is brought about by the migration of cells from the mantle zone into the superficial strata of the marginal zone. White fibres may also invade the territory of the gray matter, as in the formation of the internal capsule. Portions of gray matter may thus be displaced from their original position, so that the primary position of the parts becomes obscured.

In the later stages of development the primary flexures of the brain become, to a large extent, straightened out, and the whole form of the brain becomes modified by the enlargement of the cerebral hemispheres.

3. Hindbrain and Roof Plate.—In the hindbrain a remarkable change occurs in the position of the lateral walls of the neural tube, whereby their dorsal margins formed by the alar laminae become widely separated. Each lateral plate is rotated outward through an angle of 90° by a hinge movement, as in opening a book. The surfaces originally directed toward the median plane thus become directed dorsally and now form the floor of the lozenge-shaped fourth ventricle. The sulcus limitans still separates the basal (motor) and the alar (sensory) region, but these, instead of being ventral and dorsal, are now internal and external.

The roof plate also becomes greatly modified, becoming thinned out and stretched so as to form a delicate epithelial lamina, which is blended with the overlying pia mater. A part of this membrane becomes infolded just behind the cerebellum to form the choroid plexus of the fourth ventricle. The anterior part of the roof plate with the adjoining portion of the alar lamina becomes thickened to form the cerebellum, which is thus connected with the sensory tracts and, more especially, with incoming impulses from the vestibular portion of the eighth cranial nerve. Median and lateral openings in the roof of the fourth ventricle are formed, secondarily, by a breaking down of the epithelial membrane. The cerebrospinal fluid is thus able to pass from the ventricles into the spaces of the subarachnoid tissue outside (*see Ventricles, below*).

4. Midbrain and Thalamencephalon.—The midbrain in a ten-millimetre human embryo is characterized by the relatively large size of its central canal and its prominent position on the surface of the brain. At a later stage, owing to the growth through it of tracts of nerve fibres from the cerebral hemispheres, cerebellum and pons Varolii, the walls of the canal become greatly increased in thickness, and the lumen becomes relatively small. Moreover, in the later months of fetal life, the midbrain becomes completely covered over and concealed by the backward growth of the corpus callosum and cerebral hemispheres.

The thalamencephalon appears to undergo less change from the primary form of the neural tube than either the midbrain or hindbrain. In the early stages of development the roof of the thalamencephalon is exposed on the superficial aspect of the brain. About the third month, however, the cerebral hemispheres, with the developing corpus callosum and fornix, grow backward over the thalamencephalon, mesencephalon and cerebellum, carrying with them a covering of pia mater. This fuses with the pia mater, covering the thalamencephalon so as to form a triangular fold, the velum interpositum, or tela chorioidea, from which the choroid plexuses of the third and lateral ventricles are formed.

The hemisphere vesicles are at first quite small and open by a relatively large aperture, the foramen of Monro, into the third ventricle. The latter is limited in front by a thin membrane, the lamina terminalis, so named because it at first forms the anterior end of the brain. Later the hemispheres grow forward on each side of it, and it is left at the bottom of the great longitudinal fissure. As the hemispheres enlarge forward, upward and backward, nerve fibres are developed between them, which cross in or near the lamina terminalis. These form the anterior commissure, the hippocampal commissure of the fornix, and the corpus callosum.

5. Development of the Pituitary Body.—The pituitary (or hypophysis) has two parts: an oral or anterior lobe, glandular in structure; and a cerebral or posterior lobe, composed of neuroglia. The organ is present in all vertebrate animals and is developed very early. Thus in the human embryo of four weeks the oral portion appears as a flattened, flask-shaped diverticulum, the pouch of Rathke, which arises from the ectoderm of the primitive mouth cavity or stomodeum. This comes in contact with the neural ecto-

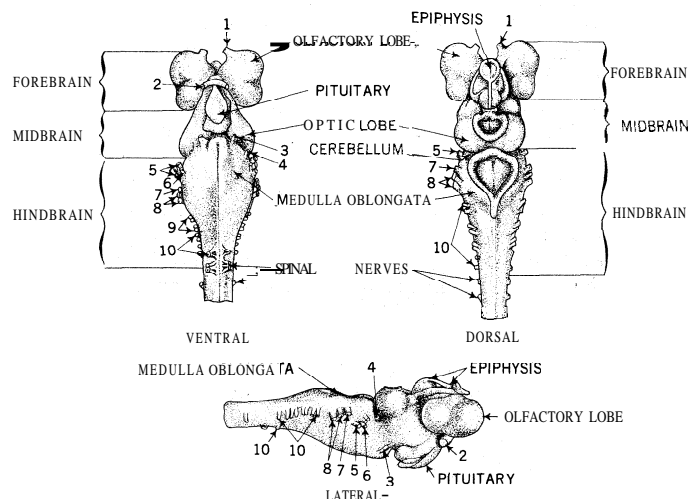

derm, forming the floor of the third ventricle behind the optic decussation and in front of the anterior end of the notochord. Later the neural ectoderm gives rise to a hollow diverticulum, the posterior lobe, which is connected to the brain by a funnel-shaped stalk, the infundibulum. The infundibulum then becomes surrounded on the front and sides by the vesicular part of the pouch of Rathke. That part of the pouch that comes in contact with the cerebral lobe is called the paraneural part or pars intermedia.

The parts on each side which become applied to the infundibular part of the floor of the third ventricle are the lateral or tuberal lobes. The vesicular part of the pouch soon becomes cut off from the roof of the mouth cavity by the degeneration of its stalk. About the seventh or eighth week the vesicle becomes further modified by the outgrowth from it of numerous branching processes which invade the surrounding tissue. The processes are at first hollow and lined by epithelial cells. Later the mesodermal tissue between the processes becomes vascularized, and the lumina of the processes and the main central cavity gradually become obliterated. The cavity of the posterior lobe also disappears, with the exception of a small recess in the floor of the third ventricle, which corresponds to the attachment of the infundibulum. In the adult the interior of the posterior lobe is occupied by a loose network of supporting neuroglia and contains no nervous tissue, except fibres of the sympathetic system which accompany the vessels.

The meshes of the network contain a clear fluid. In the paraneural part or pars intermedia, the epithelium is frequently arranged in the form of closed vesicles containing colloid material, and this substance has sometimes been observed in the posterior lobe and in the region of the third ventricle, close to the infundibulum more especially in those animals in which the lumen of the cerebral lobe persists and remains in continuity with the cavity of the ventricle. The origin of the pituitary gland presents one of the most interesting problems of comparative embryology, references to the literature on which will be found in any of the standard works on zoology and embryology mentioned in the bibliography. (See also PITUITARY BODY)

6. Pineal Organ or Epiphysis.—The pineal body of the human brain is a small conical structure that springs from the posterior part of the roof of the third ventricle and projects backward over the superior quadrigeminal bodies. It consists of rounded epithelial cells that are arranged in an alveolar manner. Between the alveoli or follicles is a supporting tissue enclosing thin-walled blood vessels and frequently containing also deposits of calcareous salts. These form small spherical bodies which show, on section, a concentric laminated structure. They are known as brain sand and in old subjects are commonly found also in the choroid plexuses, pia-arachnoid and other parts of the brain.

The pineal body of man is a vestigial organ which represents a more highly evolved apparatus in lower types of living vertebrates

FIG. 2.—BRAIN OF A SHARK (SCYLLIUM): (1-10) CRANIAL NERVES

and probably a still more highly evolved apparatus in certain extinct reptiles, such as the *Ichthyosaurus*. In one living reptile, the tuatara (*Sphenodon*), the pineal apparatus consists of two distinct organs—a glandular organ, the epiphysis, which is the structure present in the human brain, and a sensory organ, the pineal eye; this is situated in the parietal foramen, a central aperture in the vault of the skull, immediately beneath the scales covering the surface of the head.

In some of the lower vertebrate animals the pineal organ is bilateral, and it is believed that the ancestors of vertebrate animals possessed a pair of parietal eyes which may have been serially homologous with the paired vertebrate eyes. Transitional stages in the evolution of the pineal body from a bilateral to a mesial organ have been shown in amphibians.

B. COMPARATIVE ANATOMY

In the lowest types of vertebrate animals the brain is tubular in form and resembles an early developmental stage of the brain in higher vertebrates. In the small lancelet or amphioxus (*q.v.*) the brain consists of a median cerebral vesicle, the cavity of which is continuous with the central canal of the spinal cord. In the larval stage an opening lined by ciliated epithelium, the anterior neuropore, lies at the bottom of a funnel-shaped depression, the infundibulum of the pituitary body. There are only two pairs of cranial nerves, both of which are sensory. It should be remembered that the lancelet lives in mud and hardly ever moves about.

1. Cyclostomes.—In the cyclostomes, of which the lamprey (*Petromyzon*) may be taken as an example, the brain is easily distinguished from the spinal cord. There is distinction into forebrain, midbrain and hindbrain. There are well-developed eyes with optic nerves ending in optic lobes (fig. 1). In the larva the fibres of the optic nerves, instead of crossing to the optic tract and lobe of the opposite side, as in higher vertebrates, appear to pass back to the optic lobe of the same side. It is probable, however, that in the later stages of development a decussation of some of the deeper fibres occurs in the floor of the fourth ventricle. The forebrain presents on each side two hollow vesicles, the olfactory lobe of large size and a rudimentary cerebral hemisphere behind. The two cerebral hemispheres are joined across the median plane by the lamina terminalis, in which there is a small anterior commissure.

On the dorsal aspect of the thalamencephalon are two oval masses, the habenular ganglia. The right of these is much larger than the left. There is an epiphysis and also an indication of an

additional outgrowth in front of the pineal organ, the paraphysis. The pituitary body is formed from a single median pouch, the pituitary sac, which opens primarily on the ventral aspect of the head, between the olfactory sac in front and the primitive mouth behind.

Later the pituitary sac sends out small follicular processes that fuse with the infundibulum and form, with the latter, the compound pituitary gland. In the course of development the original openings of the pituitary and olfactory sacs are displaced from the ventral to the dorsal aspect of the head.

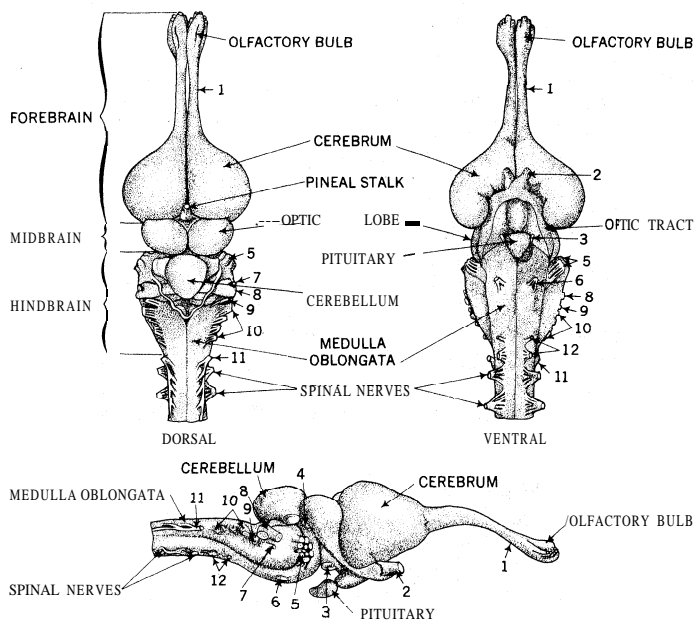

In the hindbrain a rudimentary cerebellum is present, which appears as a transverse bar at the anterior boundary of the roof of the fourth ventricle. The choroid plexuses are well developed and consist of three invaginations, an anterior from the roof of the third ventricle, a middle in relation with the midbrain, and a posterior from the roof of the fourth ventricle.

2. Fishes.—The Chondrichthyes, to which belong the sharks and the rays, are the lowest vertebrates that swim freely about in the water. Although the eyes are fully developed, smell is probably the dominant sense, since the olfactory bulbs and tracts are enormous and project as large hollow outgrowths from each side of the forebrain. There is also a remarkable development of the cerebellum (fig. 2). The cerebellar cortex is often highly convoluted. The cerebral hemispheres are much larger than in the lamprey, the corpus striatum is developed and a roof plate or pallium is present; but as yet there is no differentiation of cortical layers. There is only one pineal stalk. The fibres of the optic nerves cross one another as compact bundles.

The brain of the Teleostei, or fishes having a bony skeleton, is in some respects not so far advanced as that of the cartilaginous fishes. The cerebral hemispheres and olfactory lobes are small. The optic lobes are enormously developed, however, and the optic nerves cross one another completely.

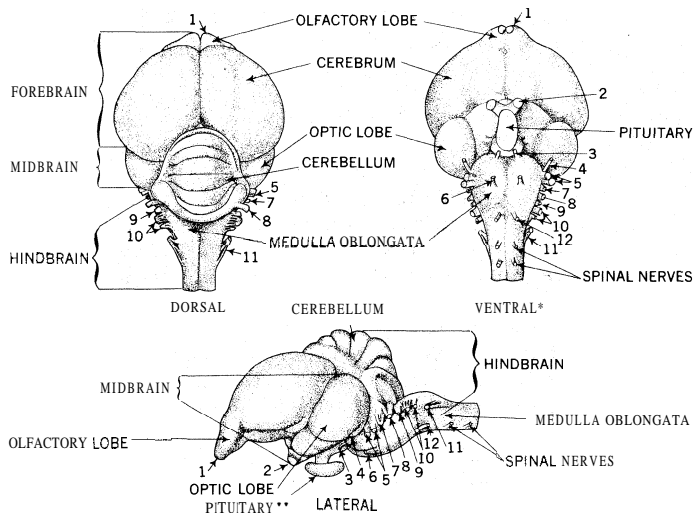

In the mud fishes, or Dipnoi, the brain is elongated and tubular in form, the olfactory lobes large and the cerebellum small. The brain, as might be expected, resembles in some respects that of the Amphibia.

The cranial nerves and their nuclei are arranged in two columns: a dorsal or, in the fourth ventricle, lateral one; and a ventral or medial one. In the spinal cord the two roots unite and form together the peripheral nerve. In the brain they remain separate, the anterior root giving rise to the innervation of the mesoderm, the posterior root giving sensory and visceromotor innervation to the skin and the internal organs, including the muscles of the gill

FIG. 4. — BRAIN OF A PIGEON: (1-12) CRANIAL NERVES

arches. But the cranial nerves were numbered before this was clearly understood. The anterior roots in higher forms are four in number: the 3rd pair or oculomotor, the 4th or trochlear, the 6th or abducens and the 12th or hypoglossal nerve. The posterior roots are the 5th or trigeminal, the 7th or facial, the 9th or glossopharyngeal, the 10th or vagus and the 11th or accessory nerve. The 1st or olfactory, the 2nd or optic and the 8th or acoustic are nerves that go to special sense organs and are neither anterior nor posterior roots.

3. Amphibians and Reptiles.—In the Amphibia the brain is tubular and does not show any distinct advance on the type characteristic of fishes; in some respects, e.g., the development of the cerebellum, it is distinctly inferior to that of *Scyllium*. The olfactory lobes are large and in the frog's brain are fused in the median plane. In the lamina terminalis there is an anterior or ventral commissure and a dorsal or hippocampal commissure. The formation of the latter corresponds to the appearance of a small layer of cells in the superficial stratum of the median wall of the pallium. This is regarded as the first indication of the hippocampal cortex. The epiphysis that is present in the larva disappears in the adult animal. There is a well-developed infundibulum and hypophysis. The optic tracts and lobes are of large size. The cerebellum appears as a small transverse bar in the anterior part of the roof of the fourth ventricle and closely resembles that of the human embryo at the fourth week.

In the Reptilia (fig. 3) the cerebral hemispheres are more highly differentiated. The mesial surface of each hemisphere shows an upper hippocampal zone, a lower olfactory tubercle and an intermediate part, the paraterminal body or precommissural area. On the upper part of the outer or lateral surface is a limited area, termed by G. Elliot Smith the neopallium. This is the forerunner of the neocortex, which forms the main part of the cerebral hemispheres in the higher mammalia. Below the neopallium is the pyriform lobe, which is olfactory in function and corresponds to the uncus of the human brain. The corpus striatum is large, and there is an indication of differentiation into caudate nucleus, globus pallidus and putamen. In the Lacertilia the pineal organ is more highly developed than in any other living vertebrate animal. There is, however, no evidence of its use as an organ of sight.

4. Birds.—In birds (fig. 4) the cerebral hemispheres, optic lobes and cerebellum are large. The surface of the cerebral hemispheres is smooth, and their bulk depends largely on the great size of the corpus striatum. The cerebellum consists of a large central lobe or vermis, crossed by a series of parallel fissures, and on each side a small but well-defined flocculus. The olfactory lobes are extremely small, and, judging from the early development and large size of the optic vesicles and the optic nerves and tracts, vision is the dominant sense.

5. Monotremes.—In the lowest Mammalia, represented by the

duckbilled platypuses and the spiny anteaters, the cerebral hemispheres are well developed. They extend forward over the olfactory lobes and backward over the thalamencephalon, midbrain and cerebellum. Convulsions and fissures appear. There are a dorsal and a ventral commissure, fimbria and gyrus dentatus. The cerebellum is well developed, presenting numerous folia and a conspicuous flocculus. In the spiny anteater, which is nocturnal in its habits, the optic nerves are extremely small, but there is an enormous development of the olfactory bulbs and tubercles.

6. Marsupials and Insectivores.—In the Marsupialia the type of brain varies much, apparently according to the habits of the different species. Thus in the Tasmanian devil (*Sarcophilus*), described by G. Elliot Smith as an "offal eating animal," there is an enormous development of the olfactory bulbs and the region of the brain termed rhinencephalon; in kangaroos (Macropodidae) there is a great development of the neopallium and cerebellum.

The Insectivora are remarkable for the very large size of their olfactory organs and for the fact that they possess a corpus callosum. Most of the lower mammals are macrosomatic; *i.e.*, have a well-developed olfactory organ. In the mole the optic nerves and tracts and the superior corpora quadrigemina are poorly developed. The influence on the brain of change of habit in two members of the same family, the jumping shrew and the tree shrew, is striking.

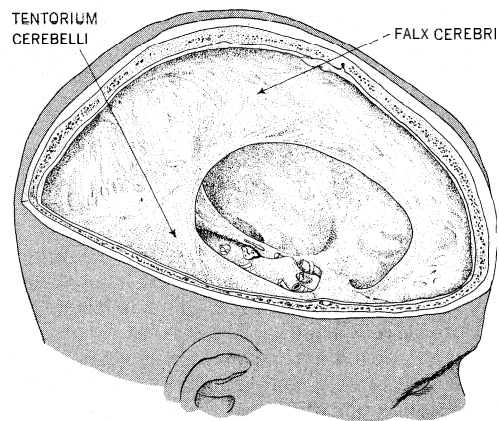

7. Higher Mammals.—The surface of the brain in mammalian animals varies greatly with regard to the convolutionary pattern. In some the hemispheres are smooth, *e.g.*, the manatee, the lesser anteater and the marmoset; in others highly convoluted, *e.g.*, whales, dolphins and certain ungulates, such as the elephant; others are intermediate in this respect. The degree of convolution is partly dependent on the size of the body. As a rule large animals have highly convoluted brains, small animals smooth brains. There is also a definite relation between the number of white fibres in the centre of the hemispheres and the number of nerve cells in the gray cortex on the surface.

In some animals, *e.g.*, the Cetacea, with a highly convoluted pattern, the gray cortex is very thin. In the higher types of animals it is usually thicker and much more highly differentiated. Primates are macrosomatic; *i.e.*, have a poorly developed organ of smell. The brain of the chimpanzee closely resembles the convolutionary pattern of the human brain. In most apes there is an extension forward of the striate (visual) and peristriate areas of the cortex on the outer side of the occipital lobe. This encroaches on and overlaps the parietal lobe and occipitoparietal fissure. It thus produces a transverse or lunate sulcus. This is the simian fissure or affenspalte and is sometimes represented in the human subject by a small and variable fissure which usually lies some distance behind, and external to, the external parieto-occipital fissure and is not continuous with it. The human brain is distinguished anatomically from that of the higher apes by its large size and great development of the parietal regions. Mentally, man is distinguished from the apes by the faculty of speech and by much greater powers of reasoning, concentration and appreciation. (See MAMMALIA; PRIMATES.)

C. ANATOMY OF THE ADULT HUMAN BRAIN

1. General Structure.—The lowest part of the brain, the medulla oblongata, is continuous through the foramen magnum with the spinal cord. The brain and spinal cord constitute the central nervous system, whereas the nerves passing to and from the central nervous system form the peripheral cerebrospinal system. (See also NERVOUS SYSTEM; SPINAL CORD.) The nervous

FIG. 5.—SAGITTAL VIEW OF HUMAN BRAIN PAN SHOWING MEMBRANOUS PARTITIONS BETWEEN HALVES OF THE BRAIN

system also includes certain nerve centres and nerve fibres that, without our conscious knowledge of the processes concerned, control the vital functions of the body, such as circulation of the blood and respiration. This system, since it acts to a large extent independently of the will, has been termed the autonomic system. It includes the sympathetic and parasympathetic systems. Through communicating branches the brain is capable of influencing organs that are supplied by the autonomic system; *e.g.*, the salivary glands and heart, both of which may be acted on by fear, hunger, etc. Ordinarily, however, the functions of the internal organs are carried out without the person's being conscious of the processes involved.

The halves of the brain are separated by membranous partitions (fig. 5) that are continuous with the three membranes covering the substance of the brain. If the membranes are removed, the brain's surface is seen to be moist and of a grayish-white colour. It is characterized by sinuous foldings of the superficial stratum or cortex. These are the gyri or convolutions, and they are separated by grooves or sulci. The main part of the brain is subdivided by a deep longitudinal fissure into right and left hemispheres. The hemispheres are connected by transverse bands of nerve fibres called commissures. The largest of these crosses the middle of the great longitudinal fissure and is called the corpus callosum. In addition to the hemispheres and cerebellum, the brain comprises the interbrain or thalamencephalon, the midbrain or mesencephalon, the pons Varolii, which forms a transverse bridge between the two cerebellar hemispheres, and finally the medulla oblongata, which is situated below the pons and cerebellum and connects these with the spinal cord.

2. Membranes of the Brain.—These are an outer, tough, fibrous layer, the dura mater; a thin, intermediate, weblike tissue, the arachnoid; and a soft, vascular inner covering, the pia mater. (See also MENINGES AND CEREBROSPINAL FLUID.)

The dura mater lines the cranial cavity. On its outer surface are meningeal arteries and veins that serve for the nutrition of the bone. If the dura mater is torn in an injury to the skull, an effusion of blood may occur between the dura mater and the bone, which may, by exerting pressure on the underlying brain, cause paralysis of the opposite side of the body. The inner surface of the membrane which is in relation with the brain is smooth and moist. The dura mater also forms partitions between the hemispheres of the brain and cerebellum. These septa are folds of the dura mater and consist of two layers, blended where they touch but separated along the attached borders of the septa to form venous channels or sinuses, by which blood and also excess of cerebrospinal fluid is drained from the brain into the great veins of the neck, which carry it back toward the heart.

The secretion from the pituitary gland is also carried away into the general blood stream by small venules, which open into the neighbouring cavernous and other venous sinuses. Absorption of the cerebrospinal fluid is carried out, to a large extent, by small villous processes of the arachnoid membrane, which

project into the venous sinuses and spaces of the dura mater and are most numerous in the neighbourhood of the sagittal sinus. If this absorption is prevented or retarded, the intracranial pressure of the cerebrospinal fluid rises, and one form of hydrocephalus (*q.v.*) results. In old age the arachnoid villi enlarge to form Pacchionian bodies. Between the dura mater and the subjacent arachnoid membrane is an interval called the subdural space. It contains a small quantity of fluid that serves to lubricate the smooth inner surface of the dura mater.

Beneath the dura mater is the arachnoid membrane! which, although thin, is not permeable to fluids. It is separated from the pia mater by the subarachnoid space. This is traversed by a network of delicate fibrous bands. The meshes of this network are filled by the subarachnoid cerebrospinal fluid, while the larger thin-walled cerebral arteries and veins covering the surface of the brain lie in the thin bands of fibrous tissue forming the net.

The pia mater is the delicate vascular membrane which forms the immediate investment of the brain and dips down into the fissures between the convolutions. It contains the smaller arterioles and venules which supply the subjacent cortex of the brain. A large triangular fold of pia mater (*velum interpositum*) is included in the great transverse fissure lying between the corpus callosum and *fornix* above and the roof of the third ventricle and optic thalami below. This pyramidal fold contains the two great cerebral veins of Galen, which drain the blood from the interior of the brain. Vascular fringes at the margin of the fold project into the lateral ventricles, and similar fringes project from the under surface of the fold into the third ventricle. These fringes are the choroid plexuses of the lateral and third ventricles, and a similar choroid plexus is found in the roof of the fourth ventricle. They are covered by a secretory layer, called the choroidal epithelium, which secretes the cerebrospinal fluid.

In the lower part of the roof of the fourth ventricle are three openings in the arachnoid membrane: a median, the foramen of Magendie; and two lateral, the foramina of Luschka. These form a communication between the cerebrospinal fluid in the ventricles of the brain and that contained in the subarachnoid space. Obliteration of these openings by meningitis produces an obstructive hydrocephalus, in which the accumulation of fluid is entirely intraventricular.

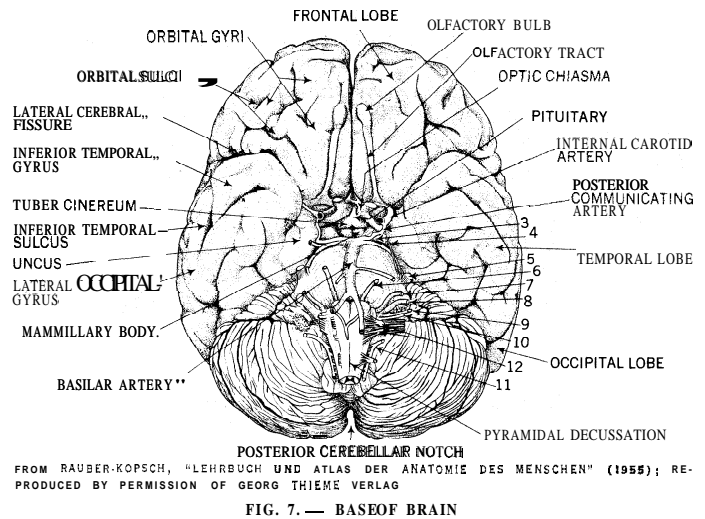

3. Ventricles.—These are cavities containing fluid situated in the substance of the brain and lined by a thin membrane, the ependyma. The true ventricles are four in number, namely, the right and left lateral ventricles, which are contained in the cerebral hemispheres; the third ventricle, situated in the thalamencephalon; and the fourth ventricle, in the hindbrain. Each lateral ventricle is connected with the third ventricle by a small opening, the interventricular foramen of Monro; and the third ventricle is joined to the fourth by a narrow channel, the aqueduct of Sylvius in the midbrain. The fourth ventricle communicates below with the central canal of the spinal cord and with the subarachnoid space by the foramina of Magendie and Luschka.

The cerebrospinal fluid, which is contained in the ventricles and subarachnoid space, acts as a mechanical support to the brain

FIG. 7.—BASE OF BRAIN

and spinal cord; it also takes the part of the tissue fluid and lymph found in other parts of the body.

The blood is supplied to the brain by two paired arteries: the two internal carotids and the two vertebral arteries. These are in communication with each other at the base of the brain, where they form the so-called circle of Willis, which, however, in about 25% of all cases is incomplete. The details do not matter too much, but it should be pointed out that the venous return is arranged not alongside the arteries as almost everywhere else in the body but through a system of dural sinuses that go to the jugular foramen and from there to the internal jugular veins. (*See ARTERIES; VEINS.*)

4. Medulla Oblongata.—This is situated in the lower and posterior part of the cranial cavity (fig. 6). It appears to be a direct continuation upward of the spinal cord but differs from this in the arrangement of the fibres composing the nerve tracts and in the disposition of the gray matter. It contains the important vital centres known as the cardiac, vasomotor and respiratory centres. These are situated in the lower part of the floor of the fourth ventricle. Longitudinal bundles of nerve fibres connect the medulla oblongata with the pons Varolii, and two diverging bundles of fibres called restiform bodies join it to the cerebellum.

The principal longitudinal tracts which connect the pons with the medulla on each side are: (1) the pyramidal tract, (2) the medial longitudinal bundle; and (3) the medial lemniscus or fillet.

Pyramidal Tracts.—The pyramidal tracts consist of motor fibres, each of which descends from the motor area of the cerebral cortex through the internal capsule, midbrain and pons to the anterior part of the medulla. Here they form two parallel strands, one on each side of a median vertical groove. In the lower part of the medulla oblongata the greater number of the fibres of the pyramidal tract cross over to the opposite side of the spinal cord, where they form a bundle of descending fibres called the crossed pyramidal tract. The remaining fibres are continued downward on the same side of the cord as the direct pyramidal tract. Eventually these fibres also cross to the opposite side. (*See SPINAL CORD.*) The crossing of the motor nerve fibres in the medulla oblongata is called the decussation of the pyramids (fig. 7); and since, with few exceptions, all motor fibres, and also sensory fibres, cross to the opposite side, each cerebral hemisphere dominates the muscles of and receives sensory impulses from the opposite side of the body.

Medial Longitudinal Bundles.—These are paired tracts of nerve fibres which have their cells of origin in the vestibular nuclei of the brain stem, and end in the nuclei of the muscles of the eyes and those for the neck muscles of the same and the opposite side. By means of these tracts the position of the eyes and the head can be adjusted to each other, and coordinated in such a way that the eyes remain fixed on a given object, regardless of the position of the head.

Medial Fillets (Lemnisci).—Each medial fillet is a longi-

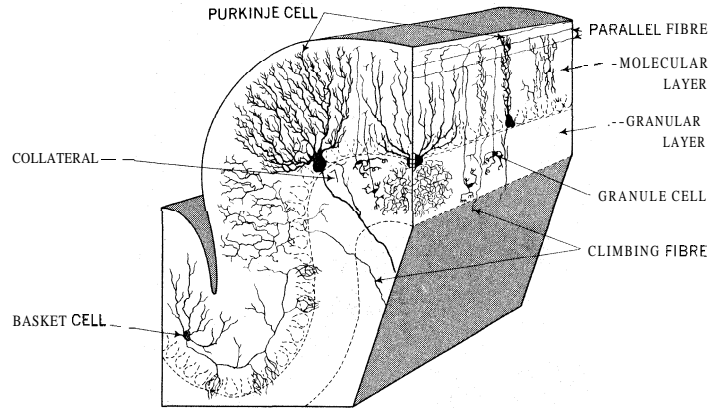

tudinal tract of ascending sensory fibres lying close to the median plane between the pyramidal tract and the medial longitudinal bundle. The fibres of the right and left tracts cross the median plane, forming the sensory decussation. This lies above the level of the motor or pyramidal decussation.

The sensory impulses coming from the spinal cord end in cell-stations in the medulla: the gracile and cuneate nuclei. It is from these that the superficial arcuate fibres; which pass to the cerebellum, and the deep arcuate fibres (medial fillets) take origin. The latter thus form one link or relay in the main sensory tract to the cortex.

Immediately lateral to the pyramidal tract on the anterior aspect of the medulla is an oval swelling, the olive. The olive lies over a folded lamina of gray matter in the substance of the medulla; this is the inferior olive. It is connected with the opposite cerebellar hemisphere by fibres that cross the middle line and reach the cerebellum by means of the restiform body. The superficial origin of the cranial nerves from the 3rd to the 12th is shown in fig. 7; the nuclei from which the motor fibres originate and those in which the sensory fibres terminate lie in the substance of the medulla and pons. Like the spinal nerves, they are connected by tracts of nerve fibres with the opposite cerebral hemisphere.

5. Pons Varolii.—This area lies between the medulla oblongata and midbrain on the ventral side (fig. 8). It forms, by its posterior surface, the upper half of the floor of the fourth ventricle. It contains the nuclei of origin or termination of the 5th, 6th, 7th and 8th cranial nerves. A conspicuous band of transverse fibres lies superficially and crosses beneath or ventral to the pyramidal fibres, which pass through the pons from the internal capsule and midbrain to the medulla oblongata. Some of the transverse fibres, however, lie more deeply and intersect the longitudinal fibres of the pyramidal tract. Most of the transverse fibres arise from nuclei of the pons which are connected with the cortex of the frontal and parietotemporal lobes of the cerebrum on the same side and, crossing the mid-line, eventually reach the cortex of the opposite cerebellar hemisphere. The most important longitudinal tracts of nerve fibres traversing the pons are the pyramidal tracts, the longitudinal bundles and the ascending sensory fibres of the medial and lateral fillets. The lateral fillet is the main auditory tract which ascends to the midbrain.

6. Cerebellum.— This consists of a central part, known as the vermis, and two lateral hemispheres (fig. 8). Each hemisphere is connected with the brain stem by three peduncles: (1) the inferior or restiform body to the medulla; (2) the middle or brachium pontis; (3) the superior or brachium conjunctivum. The last-named joins the cerebellum to the midbrain and conveys efferent fibres, one bundle leaving the cerebellum and ascending to the contralateral red nucleus and to the thalamus, another bundle

FROM VON MÖLLENDORF-BARGMANN, "HANDBUCH DER MIKROSKOPISCHEN ANATOMIE DES MENSCHEN," ED. IV, T. 8, KLEINHIRN VON JANSEN UND A. BRODAL (1958); REPRODUCED BY PERMISSION OF SPRINGER-VERLAG, BERLIN-GÖTTINGEN-HEIDELBERG

FIG. 9. — DIAGRAMMATIC SECTION OF CEREBELLAR CORTEX

going finally to the reticular substance of the medulla oblongata.

The cerebellum receives impulses from the equilibratory organ in the middle ear; from muscle spindles, from the exteroceptors of the skin, from the eye and from the ear (acoustic organ), as well as from the cerebral cortex. These impulses reach the gray matter of the cortex of the cerebellum and are believed to pass from there to the dentate nucleus, a convoluted lamina of gray matter situated in the substance of each cerebellar hemisphere. From this a relay of fibres ascends to the opposite red nucleus and thalamus (see below for midbrain). The superficial surface of the cerebellum differs from that of the cerebral hemispheres. In place of convolutions, the vermis and hemispheres of the cerebellum are crossed by numerous transverse fissures, which mark off a series of folds or folia. The general arrangement of these is seen in a median section through the vermis, which presents a branched appearance called the arbor vitae. The surface of the cerebellar hemispheres and central lobe is subdivided into lobes and lobules by deep fissures, a full description of which must be sought in textbooks of anatomy.

The cortex of the cerebellum consists of a superficial stratum, the molecular layer; an intermediate layer: which contains the cell bodies of branched Purkinje cells (fig. 9); and an inner deep stratum, the granular layer, which rests upon the central white matter. The latter is formed by medullated nerve fibres, which course to and from the gray matter. The Purkinje cells are remarkable for their large size and extensive connections. The cell bodies are pear-shaped and arranged in a single layer. From the outer end of each cell arise processes that branch out in the molecular layer.

These processes (or projections), are the dendrites, and the branching takes place chiefly in a plane at right angles to the longitudinal axis of the folium in which it lies. The dendrites of the Purkinje cells are intersected at right angles by parallel fibres that run in the direction of the folium. These fibres are derived from axons of the granule cells in the inner stratum of the cortex, which pass outward and divide in the molecular layer in a T-shaped manner into right and left branches. The bodies of the Purkinje cells, moreover, are surrounded by a network of fibres that originate from basket cells in the molecular stratum; and the Purkinje dendrites are also accompanied by delicate climbing fibres: which are afferent nerve fibres from the white matter.

Although areas of the cerebellar cortex cannot be mapped out by response of particular groups of muscles to electrical stimulation, it is possible on morphological grounds, by means of experimental work and by the tracing of tracts of nerve fibres entering the cerebellum, to locate areas of the cortex according to the fibres which they receive from particular parts. Thus it is generally admitted that the head and neck are represented in the anterior part of the vermis, the trunk in the posterior part and the limbs in the apical region of the vermis and hemispheres. References to literature on cerebellar localization will be found in

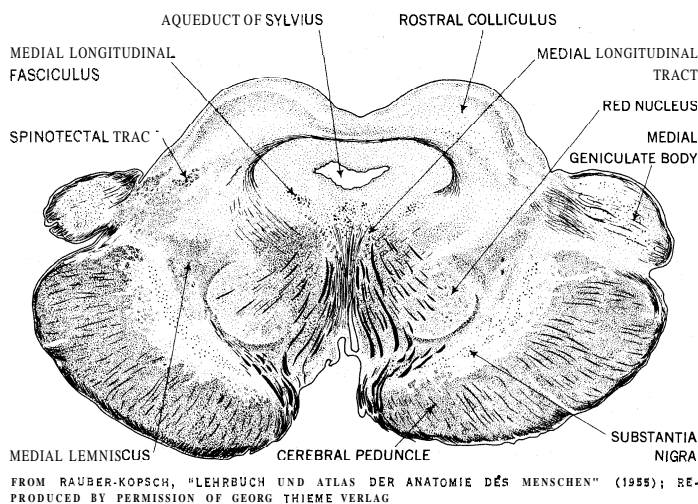

FIG. 10.—SECTION THROUGH UPPER PART OF MIDBRAIN

C. J. Herrick. *An Introduction to Neurology* (1927); H. Woollard, *Recent Advances in Anatomy* (1927); and Jansen and Brodal, *Aspects of Cerebellar Anatomy* (1954).

7. The Midbrain.—The midbrain (mesencephalon) connects the pons and cerebellum with the forebrain (fig. 10). It is traversed by the aqueduct of Sylvius. The part that lies above the aqueduct, called the roof plate or tectum, is subdivided by a cruciform sulcus into four rounded swellings. These are the colliculi or corpora quadrigemina. The upper pair of these bodies receives nerve fibres from the retina, which reach them through the optic tracts. They are concerned in the regulation of the movements of the eye and in the pupillary reflexes. The lower pair serves as a cell station in the path of the auditory impulses which pass from the cochlea to the cortex of the temporal lobe. The gray matter in the roof of the aqueduct receives an important tract of nerve fibres from the spinal cord, known as the spino-tectal.

A similar bundle, the spinothalamic tract, also traverses the midbrain. Both tracts convey the more primitive sensations of pain, heat and cold to the receptive centres in the brain. These have been described by Head as protopathic sensations, to distinguish them from the finer and more recently evolved sensations of touch, which he terms epicritic. The latter ascend in the posterior columns of the spinal cord to the gracile and cuneate nuclei. From these a relay of nerve fibres ascends through the medulla oblongata and, crossing in this to the opposite side of the brain, passes as the medial fillet through the pons and midbrain to the thalamus. From the thalamus another relay of fibres carries the sensory impulses to the cortex of the brain. These fibres diverge as they traverse the white matter of the brain, thus forming part of the corona radiata.

The most ventral part of the midbrain forms the crura cerebri. These are two diverging limbs which ascend as it were from the pons Varolii to the right and left cerebral hemispheres. They are partly the pyramidal tract that descends from the motor area of the cerebral cortex to the opposite side of the spinal cord and partly the cortico-pontine fibres which pass from the frontal and temporal lobes to the pons. Behind or dorsal to the crura is a lamina of pigmented nerve cells (substantia nigra) that separates the pes pedunculi from the tegmentum. The latter consists of two symmetrical halves connected by a median raphe. This is traversed by decussating fibres, the greater number being the cerebellar fibres already mentioned as issuing from the dentate nucleus, traveling by the superior peduncle to the midbrain and then crossing to the red nucleus of the opposite side and to the thalamus.

From the red nucleus a tract of nerve fibres descends to the spinal cord, where it forms connections with the motor cells in the gray matter of the anterior cornua. (See SPINAL CORD.) This is the rubrospinal tract of Monakow. Large in lower forms, it dwindles into an insignificant strand of a few fibres in man,

showing that the kind of control exercised by the cerebral cortex changes in the course of mammalian evolution. The red nucleus is also connected with the central ganglia of the brain, in the first place with the inferior olive. By means of these connections, it is believed that the cerebral hemispheres control the more reflex movements carried out by the spinal cord, such as balancing movements and the maintenance of posture.

In the tegmental part of the midbrain are also situated the longitudinal association tracts, known as the dorsal and medial longitudinal bundles; the fountain decussation, which connects nuclei in the superior quadrigeminal body of one side with the nuclei of cranial nerves of the opposite side of the brain; and, finally, the nuclei and roots of origin of the 3rd, 4th and part of the 5th cranial nerves in the gray matter surrounding the aqueduct of Sylvius. (See NERVE.)

8. Cerebral Hemispheres.—One of the most distinctive features of the human brain is the large size of the hemispheres and the high degree of specialization in the microscopic structure of the cortex. The surface of each hemisphere is subdivided, for descriptive purposes, into lobes and lobules. Certain fissures and lines which are arbitrarily drawn between these are employed for demarcating the boundaries of these areas. The names of the principal fissures and lobes are indicated in figs. 11 and 12, and it will be necessary only to draw attention to certain of the more important ones. Thus the central fissure, or fissure of Rolando, is situated on the lateral surface and separates the frontal from the parietal lobe. The lateral fissure or fissure of Sylvius marks off the temporal lobe from the parietal and frontal lobes. On the median surface are the callosomarginal, parieto-occipital and calcarine fissures, which limit the frontal, limbic, parietal and occipital lobes.

The central, or Rolandian, fissure marks the posterior limit of the important motor area of the cortex. Electrical stimulation of particular parts of this area produces definite movements of groups of muscles, the action of which is normally initiated and controlled by the part stimulated. Injury to the same part causes paralysis of the corresponding muscles.

The cortex of the occipital lobe which surrounds the posterior part of the calcarine fissure is the visuosensory area for reception of visual impulses from the retina. The visuosensory area is surrounded by a marginal zone which extends on to the outer aspect of the occipital lobe, termed the visuopsychic area. (See VISION OR SIGHT.)

The middle part of the first temporal gyrus and the adjacent gyri on the lower lip of the fissure of Sylvius are concerned with hearing. The auditory area of the brain receives sensory impulses by way of the auditory radiation from the medial geniculate body of the same side. These, the lower auditory centres, are connected with the opposite ear by means of the lateral fillet.

The front part of the hippocampal gyrus, with its hooklike end, the uncus, is the higher cortical centre for the sense of smell.

FIG. 12. — MEDIAL SIDE OF LEFT CEREBRAL HEMISPHERE

This is the most primitive of the special senses. It is closely associated with the sense of taste and is both relatively and absolutely more highly developed in lower types of vertebrate animals than in man. That part of the brain which is concerned in the sense of smell, and also in certain complex emotional responses, is called the rhinencephalon. In addition to these, there is a large area behind the central fissure that extends forward onto the motor area. This is the cutaneous sensory, or tactile, area.

The areas of cerebral cortex lying between the special and cutaneous sensory areas are believed to function as association centres between the different senses and as centres in which the memory of associated sensations is stored. The prefrontal region is connected by association fibres with all the various sensory and motor areas and, more especially, with that part of the adjacent motor area which is concerned with the movements of the eyes. It is therefore believed that this part of the cortex may control skilled movements which are dependent on impulses reaching the brain from the eyes and which require close attention and a knowledge or memory of past experiences—for instance, such movements as those of the lips and tongue, or of the hand, which have given man the powers of speech and of writing. If the upper and lower lips of the fissure of Sylvius are separated, a triangular area of submerged cortex will be exposed. This is the island of Reil, or insula. It lies over the outer aspect of the corpus striatum, and the lips of the fissure which overlap it are called the opercula insulae. In the human fetal brain, and the brains of most animals, part of this area of the cortex is exposed.

The basal ganglia are masses of gray matter embedded in the cerebral hemispheres. They include the optic thalami and the caudate and lenticular nuclei. The optic thalamus is a receptive centre for primary sensory impulses, and an important cell station in the path of sensory messages to the cerebral cortex. The caudate and lenticular nuclei, with the white matter which surrounds the lenticular nucleus, form the corpus striatum. The white fibres lying to the inner side of the lenticular nucleus are called the internal capsule; those to its outer side form the external capsule. The former consists of sensory fibres passing to the cortex, motor fibres of the pyramidal tract passing from it, and association fibres passing between the nuclei. (See fig. 13.)

9. Cerebral Cortex. — The cortex is the stratum of gray matter that covers the central white matter of the hemispheres. It consists of nerve cells, nerve fibres, blood vessels and a supporting tissue, the neuroglia. It exhibits a definite stratification into layers of nerve cells and nerve fibres. In sections of the fresh brain, the main strata are easily recognizable by the unaided eye, and more especially so in the visual cortex, or area striata. Various zones may be distinguished in this way, and it is found that the naked eye appearances correspond closely with the finer details revealed by microscopic preparations.

The superficial lamina, or outer fibre layer, is largely composed of nerve fibres running tangentially to or parallel with the surface. Many of these fibres are branches of the peripheral processes of

small and large pyramidal cells contained in the subjacent strata of the cortex; others are the terminal branches of nerve fibres passing into the cortex from the white matter. These are called corticopetal fibres and originate from nerve cells in the central ganglia or from other parts of the cerebral cortex. The nerve fibres of the superficial lamina, and other strata in which the fibres are arranged tangentially, serve as association fibres, connecting different areas of the cortex with one another. They also connect fibres conveying sensory impulses reaching the cortex from the central ganglia or other parts with the cells which give rise to the efferent or outgoing impulses. Certain of these efferent, corticofugal fibres spring from the basal ends of the large pyramidal cells of Betz, present in the motor region of the cortex and other smaller pyramidal cells. Some efferent fibres remain on the same side as their origin and pass to distant parts of the cerebral cortex, while others cross, by the corpus callosum, to the cortex of the opposite cerebral hemisphere.

In animals the degree of lamination and differentiation of the nerve cells in the cortex appears to correspond with the stage of evolution attained by the particular species. The cortex is thicker and more highly evolved in man and the higher types of mammals than in lower forms. In the development of the cortex, stratification begins about the sixth month of fetal life, when the convolutions first appear, and differentiation continues not only during the later months of fetal life but for a considerable period after birth. The more superficial strata containing the pyramidal cells are developed latest.

10. Weight of the Brain. — The weight of the brain varies with age, stature, body weight, sex and race. It is also influenced by congestion of the blood vessels, degenerative changes and atrophy. At birth the brain weighs approximately 380 g. and is 12.4% of the body weight. The entire brain, with the pia-arachnoid, of an adult British male weighs approximately 1,409 g., or 49.6 oz.; that of a female, 1,263 g., or 44.5 oz. The average stature and body weight of the female, however, are less than those of the male, and when these factors are allowed for, the size and weight of the brain in the two sexes are approximately equal. The influence of age on brain weight is considerable. The growth of the brain is very rapid during the first three years but slightly less rapid up to the 7th year, when it is not far off its full weight. After this the increase is very gradual, its prime being usually attained in males by the 20th year and in females somewhat earlier. From this period onward, in both sexes, there is a continuous diminution in the average brain weight of approximately 1 g. per year.

Tall persons have heavier brains than short persons, but, relative to their height, short persons have larger heads and brains than tall persons. Many men of conspicuous ability have had

brains of large size, *e.g.*, Georges Cuvier, 1,830 g., but on the other hand the brain of Anatole France, who died at the age of 80, weighed, without the membranes, only 1,017 g.; by adding 60 g. for the weight of the membranes and 61 g. to allow for shrinkage due to age, his brain may be estimated to have weighed, at the age of 20, no more than about 1,138 g. Averages calculated from groups, *e.g.*, scholarship winners and persons of average and below average ability, show statistically that there is only a very slight correlation between large size of head and a high intelligence.

(R. J. G.; G. v. B.)

II. PHYSIOLOGY OF THE BRAIN

If by physiology of the brain is meant the study of the biological function of that organ, the state of exact knowledge regarding it is still extremely inadequate, although there exists a vast body of detailed fact. Inferences as to function drawn from morphological and phylogenetic data are therefore a permissible and welcome help, although often of the nature of suggestion rather than demonstration. It is with the vertebrate brain that the following account is concerned.

The brain is that part of the nervous system that is constructed upon and evolved alongside the distance receptors. The importance of this is that it means ability on the part of the animal to react to an object when still distant from it and allows an interval for preparatory reactive steps; this can go far to influence the success of the animal's behaviour in regard to that object. The reactions initiated and guided by the distance receptors are all steps toward final adjustments, which latter are consummations often of critical importance for the existence of the animal (*e.g.*, attainment of food) or of its species (*e.g.*, fertilization). This time interval and its series of steps, along with the vicissitudes of relation between things of changing position reacting one on another at a distance, conspire to give to the distance receptor reflexes a multiformity and a complexity unparalleled by the reflexes initiated from other receptors. This interval affords much more copious opportunity for adjustment and side connection as occasion demands. It gives freer play for the affixing of new-conditioned, *i.e.*, individually acquired, reflexes to the primal inborn reflexes. Further, the time interval allows opportunity for variations of behaviour to be failures and yet recovered from and, conversely, allows greater chance for successful reaction variations to be selectively preserved.

A. VERTEBRATE EVOLUTION

As we pass from lower vertebrates to higher, we find, broadly taken, a progressive increase in the relative size of the brain. This fact stands related to two features which characterize the vertebrate evolution and seemingly also that of other phyla as well. One of these features is that, broadly speaking, the course of vertebrate evolution has tended to produce a more and more unified individual, an individual of greater functional solidarity, although still consisting of individually living cell units. Consistently with the two main biological requisites of the individual animal life, namely, its preservation and that of its species, the closer functional welding of the parts of the animal individual into an integrated whole seems, as we look along the vista of geological time and of geographical spread, to have been a steady outcome of evolution.

The other feature is not unrelated to the foregoing one. It is that evolution, though with checkered history, has resulted in animal forms possessing successively greater dominance over their environment. Organisms are commonly spoken of as "lower" and "higher." The lower are usually the simpler, the higher the more complex; but the lower need not the less perfectly fulfill their primary biological requisites: preservation of self and species. There are brachiopods that have without visible change maintained themselves in and upon their environment from the era of the earliest fossil-bearing rocks till today, and they are lower animals. Such commerce with and maintenance in the environment must be as admirably adjusted as any imaginable so far as concerns persistence of life. Yet, in the course of time, evolution has produced animal forms which pursue a far richer and more manifold

commerce with the environment, and some of these dominate the environment more variously and extensively than others, including their own ancestry, have done. In this sense they are higher forms. The earliest animal forms have included none of these highest, and some of the very latest are also the very highest forms achieved. As judged by dominance of the environment, man, although quite a recent form, is the highest as yet. The key to this evolutionary feature is furnished largely by the evolutionary history of the brain and its functions.

1. Increased Integration— A factor, and in some respects a decisive one, both in the accomplishment of greater functional solidarity of the animal and of its higher mastery over the environment, is the progressive development in the nervous system of a dominant part. The organization of the central nervous system is thus enhanced as an integrator of the animal in its life of external relation. The integration combines, into great unitary harmonies, reactions originally scattered and local and semi-independent acts. It organizes the several segments and segmental regions into a well-knit individual. The establishment in the central nerve cord of, so to say, a headquarters station for receipt of calls from many directions and for dealing through subsidiary parts of the nervous system with the motor machinery of the animal, as a whole, imbues the organism with individuality of a higher kind. It is this that the advent of the brain foretells. The progressive development of the brain increasingly secures advantages.

The success seems partly a matter of mere increase of centralization. The receptor apparatus of the head acquires increased coordinative guidance of the body. The body tends to become a locomotor and, later, a secondary prehensile train and a digestive appanage attached to the head, with, as inalienable possession, the reproductive organs. The brain in this respect merely takes with further specialized success the general role assigned to the nervous system from its earliest appearance and onward throughout evolutionary history, namely, the welding of the body's component parts into one consolidated mechanism facing as a united entity the changeful world about it. The work of this kind done for the "higher" animal by its brain presents the acme of animal integrative achievement. Hence is it that each of us, though made up of myriads of cell lives individually feeding and breathing, and of manifoldly differing activities, constituting scores of organs, yet appears to himself a single entity, a unity experiencing and acting as one individual. That the particular body system which is specialized for integration, and whose sole function is integration, and that that portion of it where integrative function is at its highest should be the seat of mind, even from the dim mental beginning, and that mind should remain there localized and despite all mental growth stay restricted in seat there along millions of years, on into ourselves today, indicate the scope and crowning importance of nervous integration and the brain.

2. Control of Environment.— In regard to attainment of wider mastery over the environment, no less than in respect of organizing the individual, phylogenetic development of the brain has played a decisive part. The more numerous and extensive and the better co-ordinated the responses made by a creature to the actions of the world around upon its receptors, the more completely will the bundle of reflexes (which from one standpoint the creature in its life of external relation is) figure the complexity of the environment and meet widely and successfully its situations. And at the root of the success of the brain as an integrator there lies something more than is represented in its expressing merely a more highly organized centralization.

Over and over again in the evolution of the brain there is insisted the importance, for the process of integration, of connecting together nerve structures that might or do react concurrently but are originally unconnected. The simultaneous components of a "reflex-figure" (C. S. Sherrington, 1906) tend to stamp in a neural pattern. The functional "reflex-figure" with its simultaneously reacting parts proceeds along with (as its structural counterpart) a neural pattern which may become innate or be an individual acquirement; *e.g.*, mammalian cortex.

A keystone of the principle of integration is that the concurrent

activity of related parts results in more than the simple sum of the activity of the separate component parts. Thus, in psychical integration, the single touch gives experience of itself alone. But a double simultaneous touch, *e.g.*, compasses, gives experience of two touches and, which is new, an untouched space between. The integration results in more than the mere sum of the components. Again, the unocular field gives experience of some amount of "depth"; but when in combination with the other unocular field to a binocular, there is yielded such an enhancement of the third dimension as amounts to a new result, the "depth" of stereoscopic vision. And in the vertebrate after advent of the brain the animal's reactive behaviour shows in increased measure the important quality of modifiability by experience, using this last term without of necessity any psychological connotation. Late in vertebrate development in a restricted number of forms, all mammalian and nearly related one to another, and relatively very recently evolved, this modifiability of behaviour has become greatly more effective. Its highest outcome appears perhaps as the rational guidance of human conduct.

It is not of course that either the fuller integration of the individual animal or the higher animal's wider dominance of the environment is the result entirely of the brain or of the cerebral adjunct "mind." Contributory to the latter result has been the mechanism (partly nervous) for ensuring a constant temperature environment for the tissues of the body, enabling the individual's activity to be uninterrupted by season and largely independent of latitude; also contributory has been the gestation arrangement which protects the young within the mother until a relatively late stage, providing exceptional prenatal care for the offspring. Nevertheless the extreme importance of the contribution by the brain is shown by the degree of dominance over the environment obtained by man as compared with that of other, even the highest other, placental mammals.

The vertebrate brain consists of a hindbrain, midbrain and forebrain.

3. Hindbrain.—The hindbrain, as traced upward from the lamprey, shows two main functional divisions. Of these, one, the basal, closely resembles the spinal cord of which it is the continuation in the posterior head segments. In air-breathing vertebrates this basal portion contains a centre regulating the movements which ventilate the lungs. This mechanism presents the interesting physiological feature that while "reflex" in the sense of being driven and controlled by nervous impulses arriving at it by well-recognized afferent nerves, it is also activated and partly regulated by stimuli arising autochthonously within it. This intrinsic stimulation is perhaps generated and is certainly influenced by the chemical condition (degree of acidity) of the blood. Another centre in this basal part of the hindbrain is, in higher vertebrates, one which influences the general circulation of the blood, by regulating the contraction of the muscles of the arterial tubes and to some extent of the heart itself. There lie also in this region reflex centres which maintain postural contraction of the extensor muscles of the limbs and trunk in response to passive stretch of these muscles. In the erect attitude of the animal these muscles are subjected by the weight of superincumbent parts to stretch, and they are termed antigravity muscles; this hindbrain region, therefore, executes a crude reflex standing, traces of which can be executed even by the isolated spinal cord itself (dog). Further forward still this part of the hindbrain receives the nervous impulse from the labyrinth organs and enables still more perfect reflexes of standing.

Cerebellum.—The hindbrain has further an important roof portion, the cerebellum, so called because in man it seems, on gross inspection, a small replica of the great cerebral hemispheres in front. The cerebellum has its cradle, ontogenetically and phylogenetically, in the primary receiving stations of the receptive nerve from the labyrinth, an organ largely controlling the postures of the head in regard to the vertical (line of gravity). The activity of the primitive cerebellum rests further on nerve tracts from the spinal cord. It acts on the muscles of the body. Traced up from the fish through amphibians and reptiles to birds, the relative size of the cerebellum differs in even nearly allied groups but bears evi-

dent proportion to range and power of skeletomuscular motility. In forms that crawl and creep it is small, but in the great swimmers and fliers it is large, even very large. With the mammalian series, however, a steady progress in cerebellar size occurs along with ascension to higher forms and culminates in the ape and man. Two large lateral developments are added to the pre-existent, unpaired median portion. Each of these lateral additions is functionally an annex of the new mammalian neopallium of the contralateral cerebral hemisphere, and with this latter go considerable developments in the median (paleo) cerebellum also. The surface sheet of the cerebellum has a peculiar and characteristic minute structure, found in both the paleocerebellum and the neocerebellum, although the history of the two seems so different and though the genesis of the neocerebellum is separated by many millions of years from that of the paleocerebellum. To all appearances the neural chains of the cerebellum are a collateral path that, as regards those of the paleocerebellum, belongs to the afferent limbs of reflex arcs actuating skeletal movements but, as regards those of the neocerebellum, belongs to the efferent central path of "volitional" movements.

The excitability of the cerebellar surface by electricity was once denied, but later studies confirmed that considerable areas of the surface are truly excitable by electrical stimuli. The excitable field is paleocerebellar and causes inhibitory relaxation of certain active postures; *e.g.*, of extension-abduction of limb. Destruction of the paleocerebellar region, which receives in mammals proprioceptive spinal tracts, causes exaggeration of the stretch reflexes of the limb extensors. Disease with cerebellar defect in man produces its most obvious detectable results in the field of willed muscular acts. The accuracy of execution of the movement is impaired by overshoot, abruptness of start and stop, ill-sustained contraction and undue liability to fatigue. Cerebellar ataxia seems to contain the following three factors: (1) diminished fineness of postural adjustment; (2) excessive intensity of postural activity; and (3) complication of the two foregoing by voluntary efforts at correction.

Function of the Cerebellum.—Acute unilateral damage of the cerebellum in man brings as characteristic symptoms: (1) the tendency to fall sideways toward the side of injury, especially if the eyes are closed; (2) the hand in reaching toward a point goes too far or stops too short; (3) in alternating movements the limb on the side of the lesion cannot alternate its phases with normal quickness and accuracy—it starts late and ends late for each phase; (4) with eyes shut the limb tends unconsciously to slip from an adducted into an abducted posture; and (5) the position of the limb is often misperceived, its degree of abduction being underestimated. There is, however, no impairment of skin sensations or of superficial or deep pain sensation. Strangely enough, congenital absence, total or almost so, of the cerebellum has been found in persons who have lived their lives without suspicion of any nervous defect. How the defect is compensated remains unanswered.

Obviously the function of the cerebellum is still obscure, although it is a large organ, weighing in man more than the entire spinal cord. Proprioceptive receipts seem at the base of paleocerebellar function and suggest for it an adjusting co-operation in the execution of muscular acts, the acts themselves being initiated and directed by centres other than the paleocerebellum, probably mainly those of the midbrain. The neocerebellar function may be inferred to be similar in character to that of the paleocerebellum but to be adjuvant to movements of a newer physiological order (voluntary), initiated and directed by the neopallium (cerebral cortex). The neopallium in activating these movements probably activates collaterally the associated neocerebellar co-operation. The status of the cerebellum in the motor acts seems merely that of an executive instrument of them; the purpose and object of them are none of its affair. Cerebellar reactions are unconscious. The destruction of the cerebellum entails no loss of sensation, although cerebellar disturbance may occasion some proprioceptive misperception.

4. Midbrain.—The midbrain, like the hindbrain, is made up of centres intrinsically its own, as well as of conducting tracts merely passing through it to connect centres extrinsic to it. Its main

intrinsic apparatus is collected in its roof. This receives a great afferent path from the retina and also from the receptive centres of the hindbrain and spinal cord. It distributes efferent paths to neighbouring motor stations, including those of the eye muscles; many of these paths decussate. It sends also some longer paths forward to the forebrain and backward into the spinal cord. It has also rich intrinsic interconnections. By means of its midbrain the mammal, even after destruction of the forebrain, is able to execute and maintain the erect posture and with better adjusted muscular tone than by means of the hindbrain alone. It is able further to assume the erect posture from other positions passively imposed upon it. It can right itself. The mere motor execution of these reflexes is a matter of high complexity. Maintenance of standing involves duly adjusted simultaneous activation of many hundreds of thousands of motor units. The righting reflexes themselves are chain reflexes. In a chain reflex the result of a foregoing reflex's execution is to evoke execution of the next succeeding one. This means due and successive activations of appropriate different great combinations of motor units reaching at last the "standing complex," which forms an equilibrium, and, until disturbed, an end point. (See also EQUILIBRIUM, ANIMAL.)

The cat retaining the midbrain but deprived of the forebrain reacts to sounds, although without giving indication of the direction whence they come. The midbrain is in fact a large exchange where messages from the retina are associated with those from various other receptive nerves of the head and, via the spinal tracts, from the body (especially skin). In responding to these messages the midbrain uses efferent paths by which it can operate upon motor centres, especially of the eyes and mouth and also of the neck and body. Severe impairments of motility and of normal posture are therefore produced by injury of the midbrain roof. Although relatively large in lower vertebrates, the midbrain becomes relatively dwarfed in the mammalian brain. There is some evidence that in the course of vertebrate evolution along the mammalian branch the intrinsic importance of the midbrain as a dominating centre becomes smaller, not only relatively but absolutely. The supreme control of behaviour becomes located progressively more forward, passing from the midbrain (most fishes) to the thalamus and corpus striatum (reptiles and birds) and then to the cerebral cortex (mammals).

5. Forebrain.—In the forebrain four main constituents are strikingly distinguishable. They are the thalamus, olfactory lobe, corpus striatum and pallium. The latter three belong to the endbrain, so called because it is the actual terminal piece of the nerve cord itself.

Thalamus.—Throughout the vertebrate series the thalamus is a structure for correlating messages relayed up from receiving stations corresponding with all the various classes of receptor organs of both head and body; eminently so with the retina, whence the term optic thalamus. Besides providing machinery for interconnecting these and bringing their receipts to bear on the motor centres of the midbrain and hindbrain, it is itself a relay station for transmissions to the corpus striatum. Whereas in mammalia the neopallium is large, the thalamus becomes a relay station for routes thither, and on an enormous scale. In lower mammals it is subdivided into regions (nuclei) each preponderantly representative of some specific set of receptors (retinal, auditory, tactual-proprioceptive, etc.) and each in give-and-take connection with especially some one field of the neopallium (cerebral cortex). In higher apes and man the subdivisions become more complex still. The thalamus of lower vertebrates certainly mediates the simpler types of modification of behaviour by trial-and-error learning; after removal of the whole forebrain the frog, for instance, is incapable of acquiring a very simple maze adjustment. But the feeding chain reflex remains, the retinal reflex orients the frog to the fly and, if the fly moves again, the simultaneous spring and snap reflex follows, to be followed, if successful, by the swallow reflex. The thalamus is of itself quite incompetent in the hen for the instinctive behaviour of the maternal uprearing of the chick.

In close association with the thalamus is an underlying structure, the hypothalamus, among whose ascribed functions is nervous

regulation of the mechanism (vascular, glandular, etc.) by which in animals of constant temperature (birds, mammals) the body temperature is maintained steady despite environmental changes, a result contributing enormously to evolutionary success. In addition to this so to say essentially vegetative function, the hypothalamic region is concerned with visceral nerve relays, putting them in touch with taste and smell (from in front) relays. It is therefore relatively large in lower vertebrates, while the thalamus, analogous with it but in an exteroceptive and somatic rather than a visceral field, gains on it in higher vertebrates. In the bird the thalamic forebrain independently of the cerebral hemispheres seems to operate large reflex reactions to injurious agents and to hunger, thirst and temperature and possibly elaborates mental concomitants of these. But even in the highest mammals tonic activities of the sympathetic, essentially a visceral, system are traceable to this region. The nexus between sympathetic and visceral reactions on the one hand and affective and emotional mental experience on the other makes the close relation between thalamus and hypothalamus the more significant.

The dog or cat deprived of the forebrain except the thalamus does not react even when hungry to food placed before it. The muzzle has to be dipped into the food or the food put into the mouth for the feeding to occur. Food doctored with quinine, etc., is rejected. Pain stimuli to skin, etc., evoke biting, barking, miaowing and withdrawal of the threatened part. Yet in all this defensive behaviour there may be little or no indication of the locality of the offending stimulus. The animal, it has been inferred, can experience pain; it is not, however, able to acquire the simplest conditioned reflex. Its behaviour is confined to the stereotyped inborn reflexes. Its reflex behaviour is modifiable, however, to the extent that having hurt one foot it limps upon three legs until the hurt foot is healed. Its reactions, indicative of pain, may possibly be pseudoaffective reflexes without psychical adjunct. But there is evidence from clinical studies that pain is among the reactions of the thalamus. Affective and emotional disturbances are recognized as part of the syndrome of thalamic disease. The inference is therefore that the cerebral seat of mind does in some measure include—and so to say overlap upon—the thalamus, even in higher mammals. (See also THALAMUS.)

Olfactory Lobe and Corpus Striatum.—Of the three great components of the endbrain (cerebral hemisphere) one is the olfactory lobe, the reflex centre for the organ of smell, whose afferent nerve is so to say the segmental nerve for this region. Another is the corpus striatum, a large correlating centre, of easily recognizable beginnings in fish and of further development in reptilia. In birds it becomes the largest element of the hemisphere, whereas in mammals although large it is relatively dwarfed by the development of the pallium, especially the neopallium of higher mammals. Birds, therefore, offer best opportunity for detecting striatal function, the more so perhaps since in them the olfactory region is greatly reduced. In the pigeon, destruction of the hemispheres other than the corpus striatum leaves the feeding, mating and rearing reflex acts, as well as walking and flying with avoidance of obstacles, intact but open to occur with less discrimination of stimuli. Conditioned reflexes can be acquired and attached to the innate ones: feeding or avoidance. But if the corpus striatum is destroyed, the hen loses irrecoverably her maternal behaviour of incubating and rearing. So, similarly, the hawk caged with mice turns its gaze toward them when they move, but on their ceasing to move reaction ceases on the part of the bird. Neither does their movement excite attack upon them. The bird will starve in presence of its natural prey. It seems clear that in birds the corpus striatum operates complex though stereotyped behaviour and provides in some measure acquisition of individual modification (by experience) of such behaviour.

Passing to the lower mammals, the corpus striatum is relatively smaller than in birds. Conformably with mammalian ancestry some of the corpus striatum is ancient and olfactory and probably serves higher correlations of smell with taste and touch for locomotor and head reflexes involved in feeding. Another part, also ancient, receives exteroceptive and proprioceptive tracts (from the thalamus) but no olfactory; it operates movements through

an emissive path to the midbrain. To these old parts there is a new addition of undetermined function. The cat, with neopallium lost but corpus striatum (and archipallium) retained, localized the direction of sounds. In man destructive disease within the corpus striatum is thought responsible for the syndrome of Parkinson's disease, characterized by tremor and tonic spasm.

Pallium (Cerebral Cortex).—In fish and many amphibians the pallium is nonexistent or present only in traces. It exists clearly though rudimentarily in reptiles. In view of the great importance ultimately assumed by the pallium it is well to remember that, in entire absence of a pallium, not only is complex instinctive behaviour but also modification of innate behaviour by individual experience clearly evidenced in fishes and lower amphibians, not to speak of Invertebrata.

From early reptilian stock came, it is held, the mammalian stock, as did, independently and somewhat later in geological time, the birds. In the course of bird evolution the pallium has progressed little or not at all, perhaps in correspondence with the avian lack of olfactory development, the pallium tracing its origin partly to nerve centres for smell. In mammals on the other hand the pallium taken over with primitive potentialities has proceeded to large and ultimately in some forms (apes and man) enormous development. Hence a progressive divergence might be expected between the courses of development of behaviour in birds and mammals, respectively. The progress of bird behaviour to its highest types might be expected to show little qualitative difference from behaviour of the paleocephalic type. Comparison of birds with bony fishes reveals in both groups a great diversity of specialized forms with specialized behaviour evolved by hereditary organization, behaviour highly and rigidly stereotyped and fixed in character and little imbued with individual plasticity. In this respect both groups resemble the insects. The fish, however, reveals more individual modifiability, *e.g.*, docility, than does the insect; and the bird on the average leads individually a more diversified life and has more power for conditioned molding of innate instinctive behaviour than has the fish. Yet, there is a similarity of the behaviour of the two. Nothing essentially new in behaviour, not even in instinctive type, sunders the later group from the earlier.

Mammalian behaviour, on the other hand, in its course of evolution reveals attainment of certain additional new types of reaction, types different perhaps even radically from anything paleocephalic. Indications of this are the replacement in some respects of "trial-and-error" learning by methods of "seeing through" or of "stopping to think" about a situation. Another is the "tool-dom," if one may so call it, of man. And there is the specific human behaviour involving concepts and symbolic thinking and employing complex speech. Of all this the development of the pallium is the correlative.

Neopallium.—The pallium that the mammalian stock derived directly from its reptilian ancestry is an associating mechanism for receipts relayed to it from olfactory organs on the one hand and receptive organs of the mouth and muzzle on the other. This, called the archipallium, therefore promotes in some way the behaviour reactions in regard to feeding, including the food finding. No sooner, however, has the mammalian career of the pallium been entered on than a further formation adds itself to the archipallium. This is the neopallium, a correlation mechanism of still more decisive and capital importance, destined in man to exceed in size the total rest of the central nervous system. In man it is the seat of all that is exclusively human in the mind. It is a structure in which are brought together paths from less comprehensive correlating centres; *e.g.*, those of the thalamus. The archipallium correlates receipts from the olfactory distance receptor with others from the skin, mucous membrane and muscles of the mouth region. The neopallium working on a grander scale brings together receipts from all the various species of receptors, distance receptors and others alike.

But it is never reached by any receptive nerve immediately; it is reached only through relay systems that climb to it via successive correlating mechanisms. The receipt patterns that enter the neopallium (cerebral cortex) are therefore always greatly changed from those furnished to the first receiving stations by the groups

of receptor nerves themselves. Yet, as is clear in the more primitive mammals, just as the thalamus shows some subdivision into regions individually concerned with receipts predominantly of one kind of source, retinal, auditory, cutaneous, etc., in the neopallium connected with the underlying thalamus there are individual territories which receive patterns composed predominantly of receipts traceable to one kind—be it this or that—of receptive source. There is thus some localization of function in the neopallium in correlation with some at least of the sets of receptor organs, or, psychologically put, some at least of the modalities of sense. Vision is an instance.

6. Developmental Stages.—It is of interest and a help toward broad evaluation of the place of the brain in the scheme of life to trace, so far as possible, the steps in biological history that were specially momentous in favouring or determining the vertebrate brain's evolution onward to its capital development in man.

One of these steps is judged to have been the emancipation from an aquatic existence achieved partially by amphibians with conversion of paired fins into limbs and development of lungs for air breathing. The body's greater need for support in air than in water made of the limb a jointed motor prop for locomotion with movement of diverse direction and with fingers and toes for clasping and other use. The limb and the evolving nervous system conspired so to say to draw advantage from this. The conquest of the land completed by the reptiles was accompanied by relative increase of the forebrain. The land may be regarded as a habitat of more varied difficulty and opportunity. Yet, launched from that stock, the primitive mammal was completely equipped for a land existence. Its forebrain as judged from primitive existent forms was able, and grew more so, to learn with fewer repetitions and better retention; not only so, but its warm constant body temperature provided for cerebral and other activities uninterrupted by seasonal abeyance. One great branch of this stock, developing a mechanism (placenta) of nutrition and protection for the young within the mother's body (ultimately in the human case nine months long), entered into active and successful competition with other land forms and, indeed, upon great competition within itself. We learn, by comparison of the fossil members of this great group with its present members of similar kind, that even with regard to allied forms the cerebral neopallium has become relatively much larger since the Early Tertiary period. That is to say that in this group the modern individual has relatively more neopallium than had its ancient ancestor of like form and body bulk.

7. From Subhuman to Human.—The ancestry proper of man is thought traceable to some shrewlike placental that became arboreal in habit. Modes of arboreal life put a premium on movements of varied range and accurate adjustment of both limbs and body and also on sight. The evolving of a limb as a tool for uses additional to locomotion gives opportunity for limb and brain to interact. Physical opportunities beget mental opportunities, and conversely. Fruits picked and insects caught will be handled and examined under combined touch, muscular sense and sight. The hand became a testing organ additional to and of greater range than the snout. Some lemurlike type arose, followed by some monkeylike type. The brains corresponding with these are known, and their increased scope of reaction and behaviour can be judged. Parts of the brain concerned with sight and manual dexterity increase greatly in transition from the lemurs up to the ape. The freeing of arm and hand from exclusively locomotor use and their employment for grasping and presenting objects to the eyes and mouth, along with correlative change of the visual axes to parallelism, greatly amplifying and enhancing stereoscopic vision, are thought to have been of great moment for advance toward the human stage of brain. A core of three-dimensional space neighbouring upon and centred at the animal then became visually, tactually and proprioceptively explorable by and familiar to experience on a scale of accuracy hitherto unapproached in animal life. Correlated with this is perhaps the curiosity characteristic of monkeys. The free hand itches to be employed. Later some form belonging to the ape group, though not any existent ape, with anthropoid characters, came to live less in the trees and indeed far more on the ground, probably on the grasslands. With this

went a greater attainment of the erect position, a more complete freeing of the arm and hand as a universal tool and a loftier point of vantage for the stereoscopic gaze. So an immediately sub-human and then, less than 500,000 years ago, a human brain was reached.

B. EXPERIMENTAL INVESTIGATIONS

1. Lessons of Animal Behaviour.—Lloyd Morgan showed that the newly hatched chick pecks at things of all sorts, as well as food, and that it learns to feed by profiting from the experience of the gustatory results of its random pecking. For this behaviour in the bird the corpus striatum in absence of the pallium suffices; it forms an instance of a modifiable behaviour in which one (a pleasurable) result stamps in the step which led to it, while another (an unpleasurable) result eradicates itself by stamping out an act which led to it. Similarly, the dog, caught by too hot a morsel, fights shy of a next one. In the case of the dog, more than the corpus striatum is at work; the pallium is necessary. Those who study the functions of the pallium look largely to animal behaviour as their key. The behaviour tests consist chiefly in training or learning of one kind or another: a simple form of maze with alternative paths, one leading to food and another not, or one evoking an electric shock and the other not; food that can be reached only by opening the tilt latch or other fastening of a spring; or the learning by experience that some stimulus, *e.g.*, a sound, signals the coming of food or some other event with which in the animal's training it has been regularly associated. Such observations touch somewhat the same topics as do many of the anecdotes of sportsmen and animal lovers. They have the difference, however, that laboratory observers control carefully the conditions surrounding an observation, simplify its factors, exclude extraneous variables, describe the resultant behaviour as objectively as possible and arrange the experiments so as to permit quantitative statement.

In a good deal of this work it is customary to apply the term reflex to the acts of the normal animal; *e.g.*, dog. Previously the application of the term reflex in physiology and in medicine was to reactions, through the nervous system, that in man were known to be, or that in animals there was cogent reason to believe were, unaccompanied by mental experience. The extension of the term reflex to such an act on the part of one's dog as its coming when called by name may be taken to mean not that the observer denies that mental action attaches to the dog's behaviour but that the observer explicitly disregards it and is studying the behaviour solely as neuromuscular bodily reaction, hoping thus to study the brain, much on the lines along which the spinal cord may be studied.

2. Reflexes.—All purely spinal and hindbrain and midbrain reflexes of the placental mammal seem to be innate. They are transmitted by heredity and are the common property of the species, often of the genus. They include not only such simple acts as mastication, swallowing, the blink reflex, the knee jerk, the scratch reflex, crude sexual acts, etc., but also standing, stepping, the falling cat's righting reflex, etc. They may develop only in maturity, but they are innate. Built up into chain reflexes, they form the basis of much instinctive behaviour.

Besides this type of reflex reaction the individual animal is able to develop other responses operating through its central nervous system. Thus, when the skin of the foot is subjected to a hurtful electric shock, retraction of the foot ensues. If along with or just preceding this some other stimulus, *e.g.*, a sound, is given, then after a number of regular repetitions of this concurrence, the sound itself evokes the retraction of the foot. The response to such an associated stimulus is called an associated or conditioned or individual reflex. The associated reflex is (in the dog) a response for which the neopallium is a *sine qua non*. In entire absence of the neopallium (cerebral cortex) the dog is incapable of acquiring any such responses and loses any such as it has already acquired. A dog's normal everyday behaviour is largely composed of such responses which the common happenings and experiences of its life as an individual from puppyhood onward have taught it. By loss of the pallium this stock of reactions is woefully reduced; it cannot maintain even its base existence. Its behaviour is cut down to a few rigidly fixed reactions. This is exemplified by Pavlov's decor-

ated dogs, which were not able even to feed unless food was placed in the mouth, and by J. G. Dusser de Barenne's cats, although one of those, in which the archipallium had been spared, still found its food by smell and fed itself.

By means of the pallium any agent which acts on a receptor can by training become a signal evoking a particular movement or a secretion. The training required is that the agent act several times concurrently with the act of movement or secretion, or immediately before it or, which is much less favourable, just after it. The movement or secretion to which the extraneous stimulus becomes attached as a signal is called the ground act or unconditioned reflex. In using the latter term it must be remembered that the protective movement in response to a hurtful stimulus is not itself entirely a reflex in the usual physiological sense of that term.

It is true that in the protective ground act there is a kernel of reaction evocable even when only the spinal cord remains, and it is therefore purely reflex. But to this in the protective act evoked by a similar stimulus in the intact animal there is much added. In this latter case cerebral and cortical reactions are superadded to the reflex. The ground act is therefore a behaviour response far more complex than that which is usually denoted physiologically a reflex. If we face the full biological situation, it includes, instead of merely a pure physiological reflex, a large psychical reaction as well. It must, so to say, reverberate through wide regions of the pallium (cerebral cortex). Similarly, the secretion of the saliva in response to food in the mouth has been greatly used as a ground act (Pavlov), and in terming it an unconditioned reflex it must be remembered that although secretion of saliva can after severe curtailment of the nervous system be obtained as a pure reflex, it yet, as obtained in the feeding response of the intact animal, is but one component of an immense reaction with emotional and other mental accompaniments inevitably involving wide regions of the pallium. These ground acts as reactions to the essential stimulus, *e.g.*, food in the mouth for salivation, are innate inherited reactions, although possessing cortical extensions. The attaching of them to other stimuli, by training in the individual, constitutes the so-called conditioned reflex of Pavlov and the individually acquired reflex of Beritoff and also involves the pallium.

At commencement of the acquiring of an individual reflex, the response tends to be evoked not only by exact repetition of the particular stimulus but also by other stimuli broadly resembling it though not necessarily very closely. The individual reflex is said then to be in the generalized stage. Further training brings greater precision, in the sense that the response occurs only to more precise repetitions of the specific stimulus. This process is differentiation. By this means it has been ascertained that the brain of the dog can discriminate between notes only one-eighth of a tone apart and can hear notes of much higher pitch than the highest audible to man. It exhibits discrimination between figure patterns of relatively slight difference; *e.g.*, a thicker and a thinner capital T. It fails, however, to discriminate colours, although well discriminating different luminosities.

The individually acquired reflex is termed a deferred reflex when the beginning of the conditioned stimulus considerably precedes that of the ground response, although continued until that of the ground response has begun. The individual reflex so acquired brings its effect, *e.g.*, salivation, only after the conditioned stimulus has endured for a time practically corresponding with that employed in the repetitions giving the training. The name trace reflex is given to individual reflexes in which the conditioned stimulus is allowed to lapse before the stimulus for the ground response begins. The trace reflex differentiates its stimulus relatively slowly and poorly; it is also less durable. It is noteworthy that although pain stimuli have inborn defensive reflexes at command, such stimuli are difficult for induction of individual acquired reflexes—the training is long and uncertain, although sometimes successful. This suggests paucity of pain-receiving afferent connections with the cortex in spite of probable wealth of connections with the thalamus.

If some unusual stimulus is employed concurrently with an established conditioned stimulus and in face of this concurrence the ground stimulus is omitted, the individual acquired reflex oc-

curs only weakly or not at all. The stronger this foreign stimulus, the greater its inhibitory effect. This inhibitory result wears off under repetition of the same foreign stimulus. It was shown in Pavlov's laboratory that the degree of inhibition exerted by the foreign stimulus is directly proportional to the intensity of the investigatory reflex that it excites. By investigatory reflex (Beritoff's orientation reflex—the reaction agrees with Head's "vigilance") is denoted an attitudinizing of the head, which is excited by all sorts of stimuli but on repetition of the same stimulus rapidly tends to die out. It may accompany various individual reflexes. It is destroyed by destruction of the pallium. It has been noted that incidental activity of a natural innate skin reflex (*e.g.*, the scratch reflex) may suffice to inhibit an acquired reflex belonging to quite another distant skin region (*e.g.*, of forefoot).

3. The Cerebral Cortex.—The effect of variously situated partial destructions of the cerebral cortex upon acquired reflexes was studied by Pavlov. The destruction of no one single even large field of cortex precludes totally or permanently all acquisition of individual reflexes. Pavlov regarded this as conclusive against the teaching that one special field for association exists in the cortex. The extirpation of a part of the cortex of whatever region temporarily upsets the conditioned reflexes, and with selective disturbance of them. After bilateral removal of the occipital region (visual) the dog never again directs its movements by sight and fails to distinguish size and distance of objects. Full and bilateral destruction of this region in man and monkey causes total blindness; but the dog after removal of even greater portions of both occipital regions still discriminates light from dark, and good conditioned reflexes are acquired with light difference as a stimulus. Bilateral removal of the temporal lobes (acoustic) precludes acquired reflexes to sounds, but only for a time; conditioned reflexes to single sounds, and even with some discrimination of tone sequences, can later be established. Yet after loss of the temporal lobes dogs cease permanently to respond to their names. Bilateral destruction of the parietal and motor area regions is found to especially impair acquired reflexes trained on touch and proprioception, respectively, and especially those in the limbs. After bilateral removal of the frontal lobes, formerly acquired visual and auditory conditioned reflexes return, and new ones can be established soon after the operation. There ensues a persistent supersensitivity of the skin.

In sum, localized damage to cortical areas affects acquired reflexes selectively according to the species of receptor of their stimulus (psychologically, their sense modality) and to the topographical seat of the lesion in the field of the cortex. Pavlov concluded that the motor area of the cortex is merely the area of proprioceptive receptors. He denied to the cortex any special association area. "The cerebral cortex should be regarded as the essential organ for the maintenance and establishment of conditioned reflexes." It may be added, on the basis of older experiments, that total destruction of the pallium of only one hemisphere in the dog impairs its behaviour relatively little.

Instinctive behaviour was defined by Lloyd-Morgan as "that which is, on its first occurrence (in the individual) independent of prior experience; which tends to the well-being of the individual and the preservation of the race; which is similarly performed by all the members of the same more or less restricted group of animals, and which may be subject to subsequent modification under guidance of experience." It is an innate behaviour trend which a certain more or less complex group of stimuli of external and internal origin can call forth.

The experiments of Ceni showed that in the hen the train of behaviour corresponding with incubatory and maternal rearing of the young is not obviously disturbed by destruction of the whole pallium. In the bitch, on the contrary, not only does complete destruction of the pallium cause all maternal instinctive behaviour to disappear but also bilateral destruction, even when confined to the frontal region, does so. Inherited behaviour, as well as individual acquired behaviour, is therefore laid up in the cerebral cortex of the dog.

The observations on the dog may be compared with those on the rat by Lashley in regard to ability to learn and retention of learned

behaviour, *e.g.*, for a maze or the entrance fastening to a food box, and the effect upon them of pallial destructions. With learning of a simple maze, acquisition occurs at normal rate after bilateral destruction of any one-third of the cortex, and similarly is retained. With a test in which two alleys to food are offered, one lighted, the other dark, the food being attainable always by the lighted and never by the dark one, bilateral destruction of the occipital third (visual) of the pallium abrogates totally the successful behaviour already learned but offers no impediment to acquiring it as quickly as in the original training. With a more complex test for entrance to a food box the learned solution of it and its reacquisition are disturbed, but not completely abolished, by bilateral destruction of either the frontal or occipital regions.

Turning from mammals lower than the dog to others higher, the older experiments on the monkey, while showing greater impairment of motor behaviour than in the dog, gave evidence of considerable powers of recuperation. In monkeys the destruction of the precentral gyrus, the motor area of both hemispheres, the animals having previously been trained in habits of manipulation, revealed, on subsidence of the temporary paralysis, perfect retention of these habits, as demonstrated by Lashley. Nor did even the paralysis recur on destruction of the corpus striatum subsequent to recovery from the diplegia. Even in the manlike apes the temporary arm paralysis caused by destruction of the cortical excitable area for the arm produces no permanent impairment of individually acquired motor habits executable by that arm. The peeling and other manipulations in eating a banana, the taking and holding of a cup of water to drink from and the learned handshake with a visitor are all recovered. Further, the recovery is not frustrated by additional removal of the arm area of the opposite hemisphere or of the postcentral gyrus of the same side.

But these are relatively restricted lesions, and in the manlike apes, as in man, objective study solely by means of motor behaviour apart from speech of the effects of damage to this or that field of the neopallium (cerebral cortex) becomes less and less adequate to the complexity of the phenomena if all reference to psychical accompaniment is omitted. The fully developed pallium is mainly so to say a mental organ. To a spectator otherwise unacquainted with the play, Hamlet in dumb show would convey but meagrely that play's contents. The experiments of Thorndike and others showed that lower mammals give little evidence for their possession of images in the form of ideas; or in their learning of mazes, door fastenings, etc., of doing so even by imitation. There is, it is found, some power of imitation, though not so much as has been generally supposed, in monkeys, and a questionable existence of image ideas. A situation before which a cat is helpless will be grasped by a monkey. A chimpanzee will solve a situation by making use of some object present at hand as an implement; will recall the position of an object it has seen placed in hiding a day previously; will in some cases fetch an object, remembered though out of sight, to serve as an implement suitable for solving a newly arisen situation; and has been observed to pause in a waiting attitude, trying, as it were, to "see" how to attain indirectly an objective unattainable directly, somewhat as a man stops to think. It is inferred that the manlike apes form and retain memory images not essentially dissimilar from man's memory images.

It would seem that no gross lesion of the neopallium occurs without inflicting a certain degree of lasting disturbance upon mental reactions. It may be that that impairment will, by improved analysis of the conditions, be found to be essentially of the same kind for all regions of the pallium. Be that as it may, it is already certain that disturbances predominantly in this or that sphere of sense are related regularly to spatially separate areas of the human cortex and that impairment of the performance of willed movements by the muscles, especially of limbs and face, in the opposite side, results from damage of a particular pallial region, the precentral gyrus in man just as in the ape, and more severely. Speech per se, without any paralysis of the motor mechanisms of its production, is affected very commonly by injury of the cerebral cortex. The manner and degree of the disturbance of speech so produced differ greatly in differently placed structural lesions. The study of these lesions, although difficult, affords perhaps the best opportu-

nity for analytic examination of the mental functions attaching to the neopallium in man. They form a theme too large and also too special to be entered upon adequately here.

4. The "Motor" Cortex.—Electrical stimulation, so useful a physiological agent in the case of nerve trunks and many of the nerve centres, fails in its application to most parts of the surface of the pallium, especially in the higher animal forms. From certain of the areas of the cortex, however, it does, and especially in the highest forms, evoke motor responses with regularity. The main such area occupies in ape and man the "precentral convolution" and is called the motor area. The movements evoked occur in the crossed half of the body. The particular muscular field yielding the motor response differs for different parts of this area, and for each such part is fairly constant. Thus flexion of the arm will be excitable from one set of points; the extension of the arm from another set; opening of the jaw from one set; movement of the tongue from another; and so on.

One characteristic of these movements is that they tend to spread. Thus when the point for the thumb is stimulated, the movement will begin in the thumb, then under continuance of the stimulus may spread to the fingers, then to the wrist, the elbow and shoulder, and even to the face and leg as well, so that the musculature of one entire side of the body may thus be simultaneously convulsed. This spread is called the march, because it resembles a feature, termed, by Hughlings Jackson, the march, in the epileptic seizure. Strong and prolonged stimulation of a motor cortical point is apt to be followed by a clonic (convulsive) spasm resembling that of the true epileptic seizure. The representation of certain fields of the musculature of the body is more liberal than that of others. Variety of movement rather than power of movement seems to determine the extent of the cortex. The cortical area for the thumb (gorilla and chimpanzee) is larger than those for the whole of the abdomen and chest combined. The cortical area for the tongue (anthropoids) is larger than that for the whole of the neck. Only in very few cases is the movement bilateral, *i.e.*, both right and left, from unilateral cortical stimulation. One of these rare instances is that of the vocal cords, which bilaterally adduct (phonation). Another is that of the eyelids, which blink for both eyes. A condition for obtaining the motor responses from this motor field of the pallium is that the narcosis under which the animal is necessarily placed at the time of experimenting must not be too deep. It is known from observations in man by surgeons (Harvey Cushing and others) that no pain or indeed other sensation attaches to electric stimulation of the motor cortex. All that is felt, even in the fully conscious person, is some perception of the movement which is evoked. If the narcosis goes beyond inducing sleep of a natural depth, no visible response to stimulation, however strong, is obtainable from the pallium, although spinal reflexes, *e.g.*, the knee jerk, are still readily elicitable by their appropriate stimuli.

It was at one time thought that the response on application of electrical currents to this cerebral surface was due to stimulation, not of the cortex itself, but of bundles of nerve fibres under the cortex. The distinction if existent would not be of much significance, because such fibres must issue from the cortex; that it is, however, some element in the cortex itself which is excited may be regarded as established. Probably the element in question is a large nerve cell, a number of which are scattered throughout this excitable field. Each such large cell sends a long threadlike fibre down far beyond the confines of the forebrain itself. These cells get severally into touch with the primary motor nerve cells in the various segments of the head and body. They form together a direct path, the pyramidal tract, from the motor cortex to the spinal cord, etc.

When this excitable field of the cortex was first investigated, it was thought by some that it might prove to be as the immediate starting place of willed movement. The immediate and severe paralysis of willed movement, which, in man and the monkey, results from destruction of this excitable field of the cortex, supported such a view. But there follows in short time a remarkable restitution of the willed movements, even in the manlike apes. And this is not due to vicarious functions on the part of the corresponding area of the opposite half of the pallium or of the un-

derlying corpus striatum. The inference is that fields of the cortex other than the so-called motor ones, and routes other than the pyramidal tract, are capable of carrying out willed acts.

That the movements excited from the motor cortex are produced via the fibres of the pyramidal tract seems clear; they are precluded by severance of that tract below the cortex. But that they resemble truly closely willed acts of movement is unlikely on several grounds:

1. Severance of the afferent spinal roots supplying a limb, although it does not impair the motor supply of the muscles, etc., in the least, disturbs the willed movements of the limb very greatly indeed, rendering them so inaccurate and wild as to be worse than useless. The animal, *e.g.*, monkey, soon relinquishes use of the "deafferented" limb altogether. Electrical stimulation of the field of the motor cortex corresponding with the "deafferented" limb nevertheless evokes in it all the movements normally so elicitable, and with no detected departure from the normal. The willed movements are grossly disturbed; yet the motor responses of the motor cortex remain practically unaffected.

2. Degeneration experiments show that the spinal terminals of the fibres (pyramidal tract) from the motor cortex are actually scattered among the ultimate motor cells themselves. The motor cortex presumably, therefore, makes direct synaptic junction with the final motor cell that directly innervates the muscle. This simplicity of connection of the motor cortex with the muscle could hardly provide for the complexity of a willed movement. But it accords with the further fact that under stimulation of the motor cortex the rate of rhythm of response of the muscle follows the rhythmic stimulation of the cortex even up to 180 per second. Also the time interval between delivery of the electrical stimulus to the motor cortex and the response by the muscle is much less than the latent period for many spinal reflexes.

3. Recent observations indicate that the electrical and myographic behaviour of the muscles under motor cortex stimulation denotes conflict of excitatory with inhibitory influence, simultaneously exerted on the same muscle. The clonic afteraction so characteristic of motor cortex excitation seems traceable to alternating excitation and inhibition. All this renders it unlikely that the motor cortex and the pyramidal tract descending from it to play upon the motor nerve cells yield of themselves, at least when excited artificially, *i.e.*, electrically in experiment, movements truly resembling willed movements.

Two patients of Cushing offered opportunity while in a fully conscious state for elicitation of movements of the right hand by electrical stimulation of the motor cortex. As reported from their own introspection, the reaction was attended by no sensation other than a secondary awareness of changed position of hand and fingers. With the anthropoid ape an impressive observation repeatedly noted is the seeming entire ignorance on the part of the animal, on its awakening from a motor cortex ablation experiment, of any disability precluding its performance of its willed acts as usual. Surprise at the failure of the limb to execute what is intended seems indubitably the animal's mental attitude, and not merely for the first few minutes but for many hours. The animal is slow to realize the limb's inability. It is often many hours before repeated and various failures to execute ordinary acts for climbing, feeding, satisfying its curiosity, etc., gradually impress upon the animal that the usual services are no longer to be expected from the limb. Even after this lesson seems to have been learned, an emergency will call forth a new attempt and surprise at failure as though the former experience has been for the moment again forgotten. The impression conveyed is that the forerunning idea of the act intended is present and as definitely and promptly developed as usual. The surprise seems to argue unfulfilled expectation and defect in the motor execution rather than in the mental execution of the act.

C. THE BRAIN STEM

In the developing body of man the embryonic central nervous system, coursing the length of the back, undergoes differentiation at its anterior end into the brain, in relation to which the head is formed, while the remainder becomes the spinal cord, associated with the trunk and its contained viscera and the extremities. The original part of this differentiating brain becomes the brain stem, and, as the term stem suggests, it bears two blossoms which, budding from its lateral and dorsal aspects, flower into the cerebral hemispheres and cerebellum. These so overgrow and cover their stalk that, when the adult brain is removed from the cranium, nothing of its initial component is seen until, viewed from the under side, a lumpy column about as large as a man's thumb from tip to wrist, and not greatly different in shape, can be distinguished as the brain stem.

The brain stem is thus interposed between and interconnected with the more differentiated parts of the brain on the one hand and the spinal cord on the other, and it bears certain similarities to each of these structures. By means of its entering and exiting nerves, the spinal cord is concerned very largely with gathering sensory impressions from and effecting motor behaviour in what were originally serially arranged segments of skin or muscles of the body. The skin of the head and the muscles of the eyeball and tongue are likewise supplied with nerves from the brain stem. In addition, sensory endings and muscles developed around the nasal, oral and pharyngeal cavities and their derivatives are also supplied by brain stem nerves. Lastly, the specialized sense organs, the ear, eye and olfactory receptors, which develop in the head, are innervated by nerves connecting with the brain stem. These nerves of the head are collectively designated as cranial.

Next, when, by a development called encephalization, the two great superstructures of the brain, the cerebral hemispheres and cerebellum, gained dominance over the performance of most of the remainder of the nervous system, it became necessary to provide these ascendant structures with knowledge of what was transpiring in the body below them and to develop channels over which their influences might reach lower outflows. As a consequence, ascending pathways from the cord continue upward through the brain stem and are joined there by others, conveying afferent messages from the head, to pass or be relayed to the cerebellum or cerebral hemispheres. Similarly, pathways from these latter structures descend into the brain stem, in part to terminate in relation to its motor outflows, in part to continue uninterruptedly through it toward motor outflows from the cord and in part to reach these cranial or spinal outflows indirectly after relay by collections of brain stem neurons. The brain stem therefore resembles the spinal cord, of which it is the rostral continuation, both in supplying nerves to the periphery and in accommodating ascending pathways to and exiting connections from the cerebral hemispheres and cerebellum.

The development called encephalization, which carried the cerebellum and, to a greater degree, the cerebral hemispheres to such heights of structural complexity and functional achievement, led the brain stem also to assume a dominating and integrating role over lower-lying outflows from the nervous system—in general, those innervating the viscera, or skeletal structures related to viscera—which preserve the internal environment of the body in a state of optimum activity; in addition, and less clearly perceived, this development also led the brain stem to assume the role of

maintaining a state of optimum activity within the interior of the central nervous system itself, both in the spinal cord below it and in the cerebral hemispheres above.

The account below concerns itself with each of these aspects of the brain stem and will consider: (1) the commoner reflexes mediated by the cranial nerves; (2) features of sensory conduction to and motor outflow from the cerebral hemispheres and cerebellum, of particular relation to the brain stem; (3) the role of the brain stem in regulating the internal environment of the body; and (4) a most important function of the brain stem (and the least understood), its capacity for maintaining the activity of the remainder of the central nervous system at an optimum level.

1. Brain Stem Reflexes.—A reflex is a relatively invariable and stereotyped response to a specific stimulus, the subservient neural connections of which appear to have become built into the nervous system for the beneficial result which their activity contributes to the organism's well-being. Those reflexes mediated by the brain stem and its cranial nerves are concerned with adjusting the related musculature for optimum performance of the body's distance receptors, the eye and the ear, with orienting parts of the body in spatial relation to the head and with managing the complicated acts involved in ingesting food. They may be considered in that order.

Eye and Ear.—Of the reflexes related to the eye, conjugate deviation of the eyeballs, often combined with turning of the head, better to perceive some interesting aspect in the field of vision, is in progress almost constantly during our waking moments. Alterations for near vision are also frequent and involve contraction both of muscles converging the eyeballs and of intraocular muscles which render the central part of the lens more convex; the latter maneuver, called accommodation, serves to focus light rays on the retina. Associated with it is a constriction of the pupil cutting off light from the periphery of the lens, whose shape is not changed so greatly. The light reflex is a constriction of the pupillary aperture also evoked, as the term implies, by visual stimulation. It is obviously purposeful in reducing excessive illumination of the retina, just as is stopping down the aperture of a camera in photographing a brilliantly lighted scene. An Argyll-Robertson pupil (extremely contracted and fixed to light but constricting in accommodation to various distances) is a frequently encountered sign in neural syphilis, for the brain stem path of the light reflex is unusually susceptible to injury by the spirochete of this disease.

More intense light evokes a reflex blinking of the lids, but the corneal reflex, a blink caused by stimulation of the cornea by touch or by drying, is more important both for protection and because loss of lachrymal secretion by frequent wiping of this structure leads to its injury, the cornea being the last portion of the body surface of terrestrial animals still to require a watery environment.

Two reflexes related to the ear are evoked by auditory stimulation. One directs the pinna concavity or, in man, the entire head toward the source of a sound and appears designed to capture the maximal intensity of sound stimuli. The other, the auditory reflex, involves the two smallest muscles of the body, buried in the middle ear, the tensor tympani and stapedius, whose contraction reduces undue movement of the ossicular chain to loud sounds. In its damping action to loud sound, the auditory reflex is analogous to the pupillo-constrictor reflex of the eye to bright light.

Also located in the ear is the vestibular organ (of whose very existence many are unaware because its afferent impulses are consciously perceived only when excessive, and then but vaguely, as vertigo), initiates reflexes involving: (1) the muscles which orient the eyeballs in effective positions for vision when the head is moved; and (2) muscles of the trunk and extremities which hold the body in a definite spatial relationship to the force of gravity, which we call being right side up in the world. The most easily examined of these vestibular reflexes is nystagmus, a repetitive deviation of the eyeballs designed to keep them abreast of the rotating head. It may be evoked by spinning in a chair or by irrigating the external ear with hot or cold water, thus creating

convection currents in the fluid-filled canals of the vestibular organ, simulating those induced by rotation. Prolonged repetitive stimulation of the balancing part of the vestibular organ, as by the pitching of a ship at sea, evokes a battery of visceral alterations not normally induced by vestibular nerve impulses, accompanied by sensations of nausea and distress—an incapacitating syndrome described as motion sickness.

Food Ingestion.—Reflexes associated with the nasal and oral cavities are broadly concerned with conveying solid and liquid food into the gastrointestinal tract and with expelling these or other foreign objects from the closely adjacent air passages, into which they sometimes inadvertently become directed. The first of these objectives is accomplished by the swallowing reflex, in which stimulation of the back of the mouth cavity evokes sequential contractions of the muscles of the lips, jaw, tongue, pharynx and part of the neck, propelling food or liquid into the esophagus. Ingested material is prevented from regurgitating into the nose, during swallowing, by a tensing of the soft palate and from entering the larynx, by a drawing up of this latter structure beneath the back of the tongue, so that the swallowed material cascades past it. Impairment or absence of swallowing from injury to its reflex arc, called dysphagia, is a frequent symptom of poliomyelitic involvement of the brain stem, its danger lying in the tendency to aspirate both ingested fluids and salivary and mucosal secretions, with the consequent development of pulmonary edema or pneumonia.

Reflexes expelling material from the nasopharynx are of two sorts—those in which the local musculature tries to accomplish this act unaided, as in gagging or choking, and those in which the respiratory musculature is also invoked to contribute a blast of expired air to the process, as in sneezing or coughing. Swelling of the mucosa in allergies or infections of the nasopharynx causes persistent stimulation of its receptor endings, which makes recurrent sneezing or coughing—actually perfectly normal reflexes—associated in many persons' minds with processes of disease.

Related to these last reflexes are vomiting and hiccoughing, the latter appearing to be a repeated but halfhearted and ineffective effort to vomit; both reflexes involve cramplike contractions of the abdominal and thoracic respiratory musculature—in particular, the diaphragm—designed to empty the stomach by regurgitation. Because hiccoughing is personally annoying and publicly ludicrous, the attempt is usually made to stop it by various maneuvers, many with a sound physiological basis, designed to augment the activity of the brain stem respiratory centre, with the hope that it will regain normal control of the diaphragm. In cases of prolonged and intractable hiccoughing, surgical crushing of the phrenic nerve, innervating the diaphragm, has sometimes been necessary to relieve an exhausted patient.

All these various stereotyped acts are managed by neural connections within the brain stem which underlie some of the reflex functions of this part of the nervous system—the management of the distance receptors located in the head, the most important being the eye, the maintenance of equilibrium, the ingestion of nutriment and the protection of the respiratory and alimentary passages from harmful agents.

2. Sensory Conduction Through the Brain Stem.—This account is limited to brief mention of three general aspects of sensation of particular relation to the brain stem.

First, afferent nerve impulses gathered from all parts of the body and conducted to the cerebral hemispheres are somehow transmuted there into consciously perceived sensations, in which the intermittent features of nerve conduction fuse into the familiar picture of the world we see, hear and feel about us. Though the nature of this transmutation is not understood, it is clear that the delivery of afferent impulses to the hemispheres is prerequisite to it; for, if a receiving area of the hemisphere is destroyed, or if the afferent pathway to it is interrupted at some lower level, the modality of sensation it subserves becomes lost to consciousness. Because paths conducting afferent messages toward the hemispheres are topographically distinct from one another, sensations can be lost singly. It has proved possible in patients with intractable pain, who can no longer be relieved with drugs, for the surgeon, by an

appropriately placed incision either in the spinal cord or in the brain stem, to interrupt that pathway mediating impulses from pain receptors and thus eliminate pain sensations from consciousness, while preserving other afferent pathways and leaving unaffected the sensations which they mediate.

Next, if the central course of any single sensory pathway is examined, it will be found that its component nerve fibres, mediating impulses from different portions of the receptor field, whether for vision, hearing, pain or touch, possess a definite spatial relationship to one another. This relationship is preserved in the relay of these impulses from the anterior end of the brain stem to the various sensory areas of the cerebral hemispheres. This orderly arrangement of conducting elements, an obtrusive structural feature of afferent pathways at each level of the central nervous system, may be without functional significance. It seems likely, however, that it underlies the orientation which objects are seen to bear to one another in the field of vision, or the orderly relation which sounds of different pitch hold to one another in audition or the sense of localization which normally is attached to painful or tactile impressions.

Lastly, another general feature of afferent conduction through the brain stem is the feeling quality which sensations often possess. Except in poetic persons, many sensations are perceived with no reaction but indifference, but the most phlegmatic can recall some dramatic instance when perception was accompanied by a warm suffusion of pleasure or by a shuddering chill of unpleasantness. Because lesions in or near the anterior end of the brain stem are sometimes followed by states collectively called the thalamic syndrome, in which the most prosaic sensations are accompanied by intense and unmerited feelings of pleasure or unpleasantness, it has been suggested that this region is particularly concerned with endowing sensation with these qualities.

Afferent conduction through the brain stem has thus been considered from the points of view of the conscious perception of sensation, the orientation of perceived objects in sensory fields and the feeling which may be attached to sensation. The importance of side branches or collaterals, which turn from the long sensory paths as they ascend through the brain stem into the central reticular formation of this structure, is considered below.

3. Motor Conduction Through the Brain Stem.—The activity of skeletal musculature, whose contraction holds body parts in position or moves them about, is integrated at both upper and lower levels of the nervous system, and the stereotyped contraction of some of the head muscles in cranial reflexes has already been considered. The finer, more labile and adaptive contractions of skeletal muscle, particularly in voluntary movement, are managed by a motor area in the cerebral hemispheres from which the pyramidal tract descends on each side through the brain stem to pass, with crossing, directly to the levels of motor outflow whose discharge it initiates.

A part of this pyramidal projection, concerned with voluntary contraction of the head musculature, terminates in relation to the brain stem cells of origin of the cranial motor nerves and is designated as the corticobulbar system. Though corticobulbar connections subservise a number of functions, the most important of which is speech, relatively little is known of their neural organization. After corticobulbar fibres are given off, the remainder of the pyramidal projection descends into the cord for voluntary contraction of the muscles of the body, in particular those manipulating the distal portions of the extremities. Injury to the motor area of the hemispheres or to its descending pyramidal tract, as frequently occurs at the junction of the brain stem and hemispheres in a stroke or apoplectic attack, is followed by a paralysis of voluntary movement.

Not all of the cerebral influence upon movement is exerted directly, viz., over the pyramidal tract, however. A significant part reaches lower outflows over a series of shorter paths, some of the constituent relays of which are provided by collections of brain stem neurons. Because this group of motor connections lies outside the pyramidal projection, it is termed the extrapyramidal system. This latter system is able to initiate contraction of a postural nature, involving chiefly muscles of the trunk or proximal

parts of the extremities. It serves also in managing grosser types of movements, such as those of progression. One of the major functions of the extrapyramidal system is, however, that of modifying activity initiated from other neural sources and already in progress. Because different components of this system respectively augment or reduce motion, their injury is followed either by depression or exaggeration of motor activity. Other symptoms that may follow injury to the extrapyramidal system are those of involuntary movement, as tremor, the basis of which is also little understood.

Important modulating influences on motion are also exerted by the cerebellum and are mediated by connections passing either upward, via the brain stem, to the cerebral hemispheres or downward, over brain stem relays which are apparently identical with those of the extrapyramidal system, to lower motor outflows. The brain stem thus plays an important part in motor conduction both from the cerebral hemispheres and from the cerebellum. Its role in this regard is discussed in more detail below.

4. Regulation of the Internal Environment.—In serving local reflexes and providing relays for pathways to and from other levels, the brain stem is analogous to the spinal cord. In exerting a dominating and regulating influence over collections of lower outflows concerned with certain general functions of the body, it resembles the cerebral hemispheres. The hemispheres are broadly involved with preserving optimum relations of the body with the external world, and, to a degree, the brain stem is comparably concerned with managing a number of the processes which maintain the internal environment of the body in an optimum condition. Parts of the brain stem so concerned are its anterior and posterior extremities, the first of which may now be considered.

Anterior Portion.—The anterior portion of the brain stem, overlying the pituitary or master gland of the endocrine system, sends connections to this gland which control the liberation of pituitary hormones and so exert widespread influences throughout the body. A second group of efferent connections from the anterior brain stem descends, with relays, to the spinal cord to terminate in relation both to outflows for skeletal muscle and, in larger part, to outflows of the autonomic nervous system, innervating smooth muscle and exocrine glands throughout the body. By exciting parts of the autonomic system in varying combinations, or throwing the whole system into activity at once, this second outflow from the anterior part of the brain stem may likewise alter body states profoundly.

Variations in the osmotic tension of blood circulating through the rostral brain stem cause its neurons to discharge, innervating the neurohypophysis and stimulating secretion of that gland's hormones. One of these, antidiuretic in action, passes in the blood stream to the kidney, where it facilitates the reabsorption of water from the kidney tubules. About 170 l. of water filter from man's blood every 24 hours and start down the kidney tubules toward the bladder. With the aid of a normal complement of an antidiuretic hormone from the neurohypophysis, about 169 l. of this water are, fortunately, reabsorbed into the blood stream before leaving the kidney, and only the remaining litre, conveying waste materials in solution, continues to the bladder and is thence voided as urine.

If the anterior end of the brain stem is injured, or if its path to the pituitary is interrupted, the neurohypophysis becomes paralyzed and atrophic, so that the secretion of its antidiuretic hormone fails. Reabsorption of body water from the kidney is then incomplete, and in record cases as many as 40 l. may be lost daily and passed as urine, so that were not a compensating quantity of water drunk, the body would rapidly become dehydrated. This disturbing syndrome is called diabetes insipidus, for its excess urine is not sweet as it is in the commoner diabetes mellitus. Administration of an extracted antidiuretic hormone, called *pituitrin*, constitutes as specific a therapy for diabetes insipidus as does that of insulin for diabetes mellitus.

Although the secretion of the anterior lobe of the pituitary appears to be somewhat more autonomous, appropriate injury to the anterior brain stem causes deficiency in production of gonadotropic hormones, with consequent atrophy of the sex glands, regression of secondary sexual characteristics and loss of potency.

Brain stem injuries causing deficiencies in the sexual sphere are often associated with the development of pronounced obesity, the etiology of which is unsettled. The combined disorder is referred to clinically as adiposogenital dystrophy, or Fröhlich's syndrome, after the person who first recognized its pathological basis and so inaugurated a long series of studies of this part of the nervous system. A contrasting disturbance, the precocious onset of puberty, which may result from involvement of the anterior brain stem, depends either upon overactivity of the mechanism just considered or upon malfunction of the pineal gland, connected with the dorsal, rather than the ventral, aspect of this level of the neuraxis.

Research has indicated that the anterior brain stem is involved in the increased secretion of the adrenocorticotrophic hormone (ACTH) from the anterior lobe of the pituitary in response to stress stimulation. Regulation of the adrenal cortex thus appears to be under the control of the brain. Stress stimuli have been found to cause increased discharge of the anterior brain stem, and direct stimulation of this structure has been shown to increase ACTH secretion. Conversely, after injury to the anterior brain stem, stress is no longer capable of leading to increased pituitary-adrenal activity. Because of the scarcity of the neural innervation of the anterior lobe, it was suggested that a humoral substance is elaborated in the anterior brain stem and conducted to the gland by way of vascular channels surrounding the infundibular stalk.

By way of its connections with autonomic outflows, the anterior brain stem is similarly able to regulate or widely alter conditions in the interior of the body. Excitation of this neural part evokes a mass discharge of the sympathetic portion of the autonomic system, with rise in blood pressure, increase in heart rate, cessation of gastrointestinal peristalsis, erection of hair, sweating, etc. A discerning person will recognize that these alterations constitute some of the objective changes of emotional excitement, known to be executed by this and other parts of the brain stem with the purpose of mobilizing the body's energies for dealing with an existing or anticipated emergency.

Many of the changes just mentioned are also those which are employed in preserving a relatively stable internal body temperature in the face of wide variations in environmental conditions. Heat, produced in the body, as in a stove, by oxidative reactions, is conserved by peripheral vasoconstriction and erection of the hair (particularly in fur-bearing animals), reducing the body's irradiation; when necessary, heat conservation is also augmented by shivering. It is dispelled by increased irradiation, consequent to peripheral vasodilation, and by the evaporation of an augmented sweat secretion. These opposing processes (heat retention and heat release) are regulated by two antagonistic thermal mechanisms in the anterior part of the brain stem, influenced by alterations in the temperature of the blood circulating through the brain stem.

These neural systems by which the brain stem preserves a constant body temperature normally exhibit the precision and efficiency of the operation of a thermostat, but, like their mechanical counterpart, they may sometimes undergo derangement. Circulating toxins or breakdown products, incident to infection, paralyze that neural mechanism dispelling body heat and periodically excite the other, initiating heat production and conservation. The patient then shivers and exhibits peripheral vasoconstriction, and although he subjectively experiences a chill, his internal temperature rises to fever height. Elevated body temperature together with increase in the count of white blood cells, enemies of foreign agents in the body, thus constitute the two most reliable diagnostic signs of infection.

The role of the rostral brain stem in the regulation of internal body processes is, then, attested by its control of the endocrine factors involved in water metabolism, reproductive function and adrenocortical activity, and by its management, exerted over neural channels, particularly those of the autonomic system, of the activities concerned in emotional excitement and in the preservation of a constant body temperature.

Posterior Portion.—Somewhat similarly, the caudal (tailward) part of the brain stem is concerned with managing internal processes, even more vital in nature, which clear the blood of carbon

dioxide, provide it with a fresh supply of oxygen and circulate it throughout the body. These respiratory and cardiovascular mechanisms of the caudal brain stem may next be considered.

The thoracic and abdominal musculature whose contraction expands the chest cavity, permitting air to flow into the lungs to carry oxygen to and carbon dioxide from the blood flowing through the exposed pulmonary capillaries, is initiated by lower brain stem neurons, the efferent fibres of which descend to the spinal outflows of the inspiratory muscles. These brain stem neurons are constantly being excited by a multiplicity of factors, associated with oxygen deficiency in their circulation. The rhythmicity of respiration is affected by the periodic prevention of inspiration, both by inhibitory afferent impulses initiated by lung stretch during inspiration and conveyed to the lower brain stem by cranial afferent nerves, and by central inspiratory-inhibitory or expiratory connections. In respiration more forceful than that of ordinary quiet breathing, the active contraction of expiratory muscles is added to the relaxation of inspiratory ones in expelling air.

Though the motor nerve supply to the respiratory muscles proceeds entirely from the cord, spinal neural levels are, by themselves, incapable of maintaining respiration. Participation of the brain stem mechanisms mentioned is essential for this activity. In the execution of criminals by hanging, the brain stem in effect is severed from the cord, and death is thus caused by asphyxia. In cases of poliomyelitic injury to the neurons either in the cord or brain stem, with consequent respiratory paralysis, life may sometimes be preserved by artificial respiration in an iron lung.

The lower brain stem also contains regulating collections of neurons whose efferent fibres influence autonomic outflows, from both the brain stem and cord, concerned with the rate of beat of the heart, and those autonomic outflows from the cord which innervate smooth muscle in the walls of arterial blood vessels, the contraction of which constricts their lumina and so maintains an optimum pressure in the circulatory system, enabling blood, pumped from the heart, to be conveyed to all parts of the body.

Two receptor organs, informing the lower brain stem of both the pressure and the chemical composition of circulating blood, by way of cranial afferent nerves, play an important part in the regulation of cardiovascular activity by this brain stem mechanism. The first of these is strategically located in the arch of the aorta, where it can test the blood just leaving the heart and starting on its way to all parts of the body. Because the body is apparently so particularly concerned in maintaining an optimum circulation through the cerebral hemispheres of the brain, another, similar receptor is found in the wall of the internal carotid arteries, supplying blood to these structures. Injury to the brain stem cardiovascular mechanism, or interruption of its connections to autonomic outflows, is followed by vasomotor collapse and fall of blood pressure. Resultant circulatory disturbances, if unrelieved, are fatal.

5. Regulation of the Central Nervous System.—Somewhat analogous to the role of the brain stem in managing the functions of other organs within the body is its role in maintaining an optimum state of activity within the interior of the central nervous system. Injury to the rostral brain stem is followed by deterioration of function of the cerebral hemispheres, and injury to more caudal parts results in impairment of activity within the spinal cord.

It is perfectly clear that the conscious perception of sensation, the voluntary control of motion, and other features which characterize the activity of the cerebral hemispheres in what is called the waking state are somehow dependent in an essential manner upon the functional integrity of the anterior brain stem. Injury to this region in man is followed by states varying in intensity from degrees of somnolence to coma. In the most severe states, though the patient's respiration and circulation are preserved and he may be nourished and kept free of infection for years, he has no more rapport with the external world than is exhibited by a vegetable. Developments in electroencephalography have revealed pronounced differences in the spontaneous electrical activity of the cerebral cortex in wakefulness and sleep. In the latter state the electrical record is composed largely of high, slow waves and is described as being synchronized. During wakefulness, in contrast, the electroencephalogram (EEG) is made up of low-voltage, fast activity.

Direct stimulation of the central core of the brain stem will reproduce the normal waking record. Injury to the cephalic part of the brain stem in experimental animals is followed by chronic somnolence and a synchronized EEG. After such injury, afferent stimulation is no longer capable of arousing the subject to wakefulness. Many side connections or collateral branches from ascending sensory paths have been shown to turn into the central core of the brain stem and to exert their arousing influences indirectly by modifying its activity. Structurally, the portion of the brain stem involved is a reticular formation, and research has identified the existence of an ascending reticular activating system concerned with regulation of the background activity of the cerebral cortex.

Though the lower brain stem's influence upon the spinal cord is not so specific and is abetted by both the cerebral hemispheres and the cerebellum, it is important in preserving the normal function of this part of the nervous system. Transection of the cord from the brain, even at thoracic levels, leaving respiratory and vasomotor activity unimpaired, is followed, in the isolated cord segments, by a specifically neural depression called spinal shock. In this condition, spinal reflexes for a period can no longer be evoked by afferent stimulation and, even when recovered, may exhibit abnormality. Though other factors may be concerned, spinal shock depends in part upon loss of excitatory influences descending to the cord over pyramidal and extrapyramidal connections, to the latter of which the brain stem makes contributions.

In addition to exerting ascending influences upon the cerebral cortex, the central reticular formation of the brain stem has been shown to give rise to descending connections to motor outflows from the spinal cord. The more cephalic of these augment or facilitate spinal motor discharge, while the more caudal region exerts an inhibitory or reducing action. An imbalance in these extrapyramidal motor connections is thought to be responsible for spasticity, in which condition inhibitory influences are no longer active, while facilitatory ones are preserved and exert an augmented effect since they are no longer opposed. The involuntary movements of other types of extrapyramidal disease may also have their basis in malfunction of these descending connections from the brain stem.

In addition to serving cranial reflexes, participating in sensory and motor conduction and managing a number of internal body processes, the brain stem is concerned also with maintaining an optimum state of activity within the remainder of the central nervous system. (H. W. M.)

D. NUTRITION OF THE BRAIN

A basic principle was stated by Joseph Barcroft as follows: "There is no instance in which it can be proved that an organ increases its activity, under physiological conditions, without also increasing its demand for oxygen." (Joseph Barcroft, *The Respiratory Function of the Blood*, The Macmillan Company, 1914.) Although this principle was formulated long before Barcroft's time, he was the first to demonstrate its general validity by direct measurements of the amounts of oxygen consumed by different organs (leg, muscle, heart, kidney, salivary gland, pancreas, liver) under different conditions of activity. Subsequent work abundantly confirmed his findings. Its validity as far as the brain is concerned, strongly suggested by evidence accumulated between World Wars I and II, was finally proved in 1944-45. Representative values for various organs are shown in Table I.

The oxygen requirement of the brain even at rest is high. Man's brain comprises only about 2% of his body weight, yet it uses

TABLE I.—Oxygen Consumption
(c.c. per 100 g. of tissue per minute)

Organ	At rest	Stimulated	Stimulus
Leg muscle (cat)	0.3	8.0	Nerve (electric)
Kidney (dog)	0.9	11.0	Caffeine (diuresis)
Salivary gland (cat)	3.0	10.0	Nerve (electric)
Pancreas (dog)	3.0	10.0	Secretin
Brain (monkey)	3.7	6.5	Picrotoxin (convulsion)
Brain (man)	3.3	?	—
Heart (dog)	8.0	16.0	Epinephrine

approximately 25% of all the oxygen taken up by his body under conditions of complete mental and physical rest. The purpose underlying the oxygen consumption by the brain undoubtedly is the same as in any other living system, viz., to provide energy to be used in doing work (see DIET AND DIETETICS). Yet, as Otto Warburg, a pioneer in studies of brain metabolism, pointed out in 1912, nerve cells do no work that is measurable in mechanical or chemical units, since they do not contract, move, divide or grow, nor do they secrete substances. Nevertheless, the brain obviously needs oxygen, as indicated by: (1) its extraordinarily high oxygen consumption; (2) its vulnerability to deprivation of oxygen; (3) the fact that functional activity of the brain runs parallel to its oxygen consumption, exhibiting cerebral depression from anaesthesia, diabetic coma, insulin shock, brain tumours, etc.

The foodstuffs and oxygen necessary to meet the requirements of the brain can reach it only by way of the blood. There are no important exceptions to the rule that an increase in the functional activity of any organ entails a simultaneous increase in the amount of blood which it receives. It is noteworthy, however, that the way in which this compensation is brought about differs markedly from organ to organ. In the case of the skeletal muscles, increased activity is associated with both an increase in the amount of blood expelled by the heart and a widening of the blood vessels supplying the exercising muscles, brought about largely by reflexes acting through regulating centres in the brain stem. In the case of the salivary glands, increased secretion of saliva is elicited by nerve impulses carried by special nerves, and these impulses also cause dilation of the blood vessels supplying the gland. In the brain, however, although nerves are known to be able to mediate either constriction or dilation of blood vessels, these effects are much weaker than those seen in other tissues, and there is general agreement that nerve control plays no important part in the normal regulation of the cerebral circulation. The most plausible idea is that the blood vessels of the brain possess the unusual property of tending to constrict if left to themselves and that this tendency is constantly opposed by the dilating action of the products of cell metabolism either arising in the brain itself or carried to it in the blood from other tissues. Any increase or decrease in the oxygen consumption of the brain would then be associated with a corresponding change in the calibre of its blood vessels (therefore in the volume of blood flowing through them) because the amount of vessel-dilating material had changed. Increase or decrease in the concentration of such material in the blood reaching the brain would have similar effects on cerebral blood flow.

The evidence in favour of this conception is of two main types: (1) All the characteristic products of nerve metabolism tested (increased carbon dioxide, decreased oxygen, acids, potassium salts, acetylcholine, phosphates, heat) have been found to dilate cerebral blood vessels. (2) Increase in the carbon dioxide or decrease in the oxygen content of the blood reaching the brain (by inhalation of appropriate gas mixtures) causes dilation of cerebral blood vessels and increase in cerebral blood flow, while decrease in carbon dioxide (by overbreathing) or increase in oxygen has the opposite effect. Table II shows representative effects of this type in normal young men at physical and mental rest.

The figures listed in the first column are probably fairly accurate approximations of the amounts of blood that flow through the brain of a normal young adult male at physical and mental rest and under normal environmental conditions. They represent about 20% of the total output of the heart. This confirms the conclusion—already derived from the fact that the brain, comprising only 2% of the body weight, accounts for approximately

25% of all the body's oxygen consumption even at rest—that the cerebral circulation occupies a very special place in human physiology. The changes in cerebral blood flow indicated in the table were brought about without any significant changes in blood pressure or cardiac output, and it is probable that the ordinary adjustments of the cerebral circulation to the changing requirements of the brain do not necessitate corresponding changes in the general circulation. When the latter is depressed by such influences as hemorrhage, shock or drugs, cerebral blood flow will follow this change apparently quite passively. When the general circulation is stimulated (as by blood transfusions or drugs), cerebral blood flow will be increased. No drugs have been shown to be able to produce a change in cerebral blood flow opposite to a change in general blood pressure, and in this respect the cerebral circulation is unique. Even the coronary vessels in the heart, which resemble the cerebrals in being obedient to changes in general blood pressure and in lacking important control by vasoconstrictor or vasodilator nerves, can be strongly constricted by extract of the posterior lobe of the pituitary gland, but this has no direct effect on the cerebral circulation. Spasm of cerebral vessels has long been suspected to be the cause of certain conditions, such as convulsions, temporary depression or loss of consciousness, memory or speech, transitory disturbances of vision, etc., but the cause of the spasm, or indeed the fact of its occurrence, has not been clearly shown. The only agency shown to be capable of causing an important degree of constriction of cerebral vessels is hyperventilation, which can produce mental confusion or even complete unconsciousness in normal persons and can elicit a typical convulsion in persons with latent epilepsy. Diminution in cerebral blood flow produced by constriction of cerebral vessels is probably a partial cause of these conditions.

The commonest and most important derangements of the cerebral circulation are produced by either a decrease in the arterial blood pressure or an impediment to flow in the cerebral vessels themselves. The former can be caused by an appropriate decrease in any of the three main factors concerned in the regulation of blood pressure; namely, efficiency of the heart, resistance of the blood vessels and volume or viscosity of the circulating blood. The latter may be caused by obstruction (embolism) of cerebral arteries by a clot carried by the blood from another part of the body (usually the heart), by formation of a clot in a cerebral artery or vein (thrombosis) or by actual rupture, with hemorrhage into the brain substance. In all such cases the part of the brain supplied by the involved vessel or vessels loses its functions, and from the consequent symptoms it is usually possible to locate the lesion with considerable precision. The loss of function is a result of the fact that the distribution of the arteries in the brain does not overlap significantly. Therefore there is no alternative source of supply of blood when one terminal artery is occluded, and the tissue supplied not only loses its function but also undergoes disintegration.

Another source of interference with the cerebral circulation lies in the peculiar location of the brain inside a rigid container, the skull. Since the contents of the container are incompressible and the container is practically indistensible, it follows that an increase in the volume of any of the cranial contents will lead to an increase in pressure involving all of them and will be reflected in an increase in pressure of the cerebrospinal fluid. This pressure operates on the blood vessels, as well as on other cranial contents, and when it rises to a level higher than the pressure inside the vessels, the latter collapse and flow of blood through them ceases. A change of this type in the vessels supplying the vasomotor centre in the brain stem causes increased activity there and thus brings about a rise in blood pressure. When the rise is sufficient to overcome the abnormal pressure on the outside of the vessels, flow of blood through them is restored. Thus the arterial blood pressure characteristically rises in cases of high intracranial pressure whether the latter depends on an intracranial hemorrhage or a tumour, on interference with drainage of the cerebrospinal fluid, on swelling of the brain itself (as in uremia or eclampsia) or on inflammatory disease (encephalitis, meningitis). If this rise in blood pressure did not occur,

TABLE II.—*Cerebral Blood Flow*
(c.c. per minute)

Cause of change	Before	During	Per cent change
Voluntary hyperventilation . . .	980	658	—32
Passive hyperventilation . . .	924	564	—36
Increased carbon dioxide . . .	966	1694	+75
Decreased oxygen . . .	980	1330	+36
Increased oxygen . . .	938	826	—12

all functions of the brain would cease as soon as the cerebrospinal pressure exceeded the normal pressure in the cerebral veins and capillaries, and death would occur from failure of respiration and circulation at a much earlier stage of these diseases.

Among the unusual features of the cerebral circulation, the anatomical arrangements deserve emphasis. Instead of depending on a single artery to supply most of the blood and a single vein to bring it back to the heart, the brain gets its blood from four major arteries and is drained by three separate sets of veins. Any two of the arteries and any one of the veins could meet the needs of the brain if time were given for adjustment, and even one artery is enough to supply the vital centres of the brain stem and thus prevent failure of circulation and respiration. The arteries (the two internal carotids and the two vertebrals) join at the base of the brain to form a circle (the circle of Willis) from which arterial branches are given off to course either through the brain substance or over its surface in the pia mater. The carotid arteries run in the neck and can be occluded by deep pressure, but the vertebrals arise in the chest and soon enter the vertebral column, where they are protected from pressure or injury short of disruption of the spine itself. The cerebral veins follow the arteries but meet not in a circle but in a number of wide thin-walled sinuses, from which blood leaves by way of the two large internal jugular veins, a variable network of veins at the base of the skull, and large sinuses inside the vertebral canal. Even if the entire venous return from the upper part of the body is obstructed (as by thrombosis of the superior vena cava), there is no serious impediment to the drainage of the cerebral circulation.

No definite statement has been made about the exact relation between deficient blood supply and functional activity of brain cells. Both stimulation and depression have been described—stimulation in the case of the vasomotor centre responding to high intracranial tension, or an epileptic seizure precipitated by hyperventilation; depression in the case of mental confusion or unconsciousness from severe hyperventilation, or failure of all brain functions as the final effect of cerebral anemia. The last-named is the inevitable result if the diminution in blood supply is sufficiently severe and lasts a sufficient time, and there is no doubt whatever on this score. The possibility of stimulant effects preceding the depression depends on the part of the brain under consideration. The cortical cells concerned with consciousness, judgment, memory, etc., apparently are depressed only while the vasomotor centre is characteristically stimulated strongly. There probably are many variations between these extremes, but the information available at mid-20th century did not warrant definite statements.

BRAIN, SURGERY OF: see NERVOUS SYSTEM, SURGERY OF.

BRAINERD, DAVID (1718-1747), American Protestant missionary to the Indians in Connecticut, New York, Pennsylvania and New Jersey, was born April 20, 1718, at Haddam, Conn. His great-grandfather, a Puritan minister, had emigrated from England. Orphaned at 14, Brainerd studied under tutors and entered Yale college, New Haven, in Sept. 1739. He was expelled, for minor offenses) in his junior year. Brainerd was ordained as a Presbyterian minister on June 12, 1744, at Newark, N.J. As a missionary, he was employed by the Honourable Society in Scotland for Propagating Christian Knowledge. He preached through an interpreter, Moses Tinda Tautamy, working among the Delawares, the Six Nations, the Senakes (probably Senecas) and Tutelas. He rode horseback along the Susquehanna

and Delaware rivers, camping at night, his only home a cabin at the forks of the Delaware. He kept a journal for the Scottish society, and a diary. Brainerd spent much time at Crosswecksung (now Crosswicks), N.J.; and visited New Haven and Hartford, Conn.; New York; Elizabeth and Princeton, N.J.; and Juniata and Philadelphia, Pa. He contracted tuberculosis and was nursed for 19 weeks at the home of Jonathan Edwards at Northampton, Mass., by Edwards' daughter, Jerusha, to whom he was engaged to be married. He died Oct. 9, 1747, at the age of 29.

Brainerd is known both for his missionary work and his diary and journals: which have been widely read.

See Jonathan Edwards, *The Life and Diary of David Brainerd*, ed. by Philip E. Howard, Jr. (1955). (P. E. H.)

BRAIN-FEVER BIRD (*Cuculus varius*), an Asian hawk cuckoo superficially resembling the old world sparrow hawk (*Accipiter nisus*). It takes its name from the suggested effect of its repetitious cry. Like the European cuckoo (*q.v.*), it lays its eggs in the nests of other birds, the usual hosts being babblers (*q.v.*). (G. F. Ss.)

BRAINTREE AND BOCKING, an urban district (since 1934) of Essex, Eng., is 15 mi. W. of Colchester and 41 mi. S.E. of London by road. Pop. (1961) 20,553. Area 10.6 sq.mi. The town lies between the Brain and the Pant (or Blackwater) rivers, on the Roman highway, Stane street. Braintree is the market town for a large agricultural area, and Bocking has many 16th- to 18th-century houses. Both have 13th-century churches. The manufacture of crepe and silk, introduced by Huguenot refugees in the 17th century, gradually superseded the older wool cloth industry. Steel windows, tools, plastics and rayon are also manufactured.

BRAINWASHING, a colloquial term variously used to describe the systematic efforts of Communists to persuade non-believers to accept Communist allegiance, commands and/or doctrine; more generally applied to any technique designed to manipulate human thought or action against the desire, will or knowledge of the individual. Brainwashing (Hsi Nao) is most appropriately used in reference to Chinese Communist thought reform or ideological remolding (*Szu Hsing Kai Tsaoy*, a program of political indoctrination based on the conception that persons who have not been educated in a Communist society have incorrect "bourgeois" attitudes and beliefs, and must be "re-educated" before they can take their place in such a society.

History.—During the growth of Chinese Communism (1921-48) thought reform was used to integrate new members into the movement and to strengthen the commitment to the Communist cause of the old rank and file as well as the elite of the party. Following the conquest of the Chinese mainland (1949), the Communists attempted to reform Chinese intellectuals, peasants, soldiers and all others who, because of their class origins or past behaviour, were not considered politically reliable. This group included Europeans and Americans who were imprisoned by the Communists and whose confessions and apparent conversions to Communism first brought widespread attention to thought reform. During the Korean war (1950-53) United Nations prisoners of war were subjected to a less intensive program of reform, but greater emphasis was placed in this program on obtaining propaganda material than on political re-education.

Process.—The techniques of thought reform vary with the target group and the circumstances, but the basic approach is the same whether used in a prison, a revolutionary college, a factory or a Communist cell. By controlling the physical and social environment an attempt is made to destroy loyalties to any non-Communist groups or individuals, to demonstrate to the individual that his attitudes and patterns of thinking are incorrect and must be changed, and to develop loyalty and unquestioning obedience to the Communist party.

In the political prison, for example, the following techniques were used: (1) isolation from former associates, sources of information and daily routines; (2) an exacting prison regimen that required absolute obedience and humility (eating, sleeping, washing, eliminating, etc., according to strict schedule, doing nothing without permission of the guard, keeping head bowed and eyes downcast in the presence of the guard, etc.); (3) physical pres-

asures ranging from deprivation of food and sleep to manacling as punishment for nonco-operation; (4) creation of an atmosphere in which redemption and freedom were completely contingent on successful reform; (5) social pressures, such as prolonged interrogations and "struggle meetings," in which attempts were made by more advanced cell members to persuade the less reformed members by any means from cajoling and harassment to humiliation and revilement; and (6) daily study groups in which Communist doctrine was learned—basic conclusions were presented in lectures and readings and were followed by group discussions in which each member was required to show how these conclusions could be derived from Communist premises and how they applied to himself (mutual criticism and self-criticism were an essential part of such group discussion).

In this setting prison officials and cell mates exerted unremitting pressure on the prisoner to make him re-evaluate his past from the Communist point of view, to recognize his guilt and to confess his crimes. Crimes were defined as actions or thoughts which in any manner could harm the Communist cause. The confession had to be built around actual events, and the sincerity of it had to be demonstrated by willingness to include in it denunciations of parents, friends and other close associates. When, and if, the prisoner had recognized his guilt (*i.e.*, accepted the Communist interpretations of his actions), had made a satisfactory confession and had demonstrated his change in attitude and point of view, he was brought to trial, convicted of the crimes to which he had confessed and given a lenient sentence because he had reformed. This entire procedure took from one-half to four or more years.

Analysis. — On the psychological level this process involves the removal of social and perceptual supports; the weakening of the ego by physical pressures; the coercion of guilt-provoking behaviour that then requires rationalization; the destruction of the person's self-image by humiliation and revilement; the rebuilding of this self-image through the positive personal relationships that develop in the enforced intimacy of the cell despite the ever-present atmosphere of hostility; a shift in perceptual and semantic frame of reference resulting from the desire to identify with the point of view of the cell mates and the need to rationalize coerced behaviour; and the elaboration of this new frame of reference through the intensive group study program. The depth and permanence of these changes in attitude and point of view depend on the personality of the individual, his degree of motivation to be reformed and the degree to which the environment continues to coerce his behaviour and support his new frame of reference. In persons who were expelled or escaped from the Chinese mainland the effects were transitory; in those who took their place in Chinese Communist society the effects were probably more permanent.

Thought reform contains elements which are evident in Chinese culture (emphasis on interpersonal sensitivity, learning by rote and self-cultivation); in methods of extracting confessions well known in the Papal Inquisition (13th century) and elaborated through the centuries, especially by the Russian secret police; in methods of organizing corrective prisons, mental hospitals and other institutions for producing value change; in methods used by religious sects, fraternal orders, political elites or primitive societies for converting or initiating new members. Thought reform techniques are consistent with psychological principles but were not explicitly derived from such principles.

(E. H. SN.)

BRAKE. A means for controlling the speed of a movement or of totally arresting it. Most brakes utilize friction, although braking may be obtained by compressing a gas in a cylinder or by using an electric motor as a generator where the energy generated may be returned as electricity to a distributing system or dissi-

pated as heat from resistors. Most friction brakes act on revolving elements, as wheels or drums, but slipper brakes pressing on flat surfaces are applied as for rail cars, mechanically or magnetically operated, and a pincer of caliper type grips each flank of a rack in some of the mountain railways and in elevators (lifts). A rope also serves for the application of a brake device in a few cases. The various arrangements used for clutches (see CLUTCH) are also usable for brakes when one member, having been made stationary, is engaged by the other. The eddy current coupling readily serves as a brake.

Band Brakes.—A highly effective braking action can be obtained by the coiling of a rope around a drum, as may be seen at any docks, a man holding the free end of the rope, and allowing it to slip gradually. The sustaining friction developed between rope and drum follows the law of belting so that a large arc of contact results in a high ratio of tension on the load end of the rope to the sustaining end. The more convenient application of this idea, a flexible steel band, is employed on winches, hoists, haulage and winding engines, cranes and motor vehicles. In order to increase the frictional effort and reduce heating, some kind of lining has to be fitted, such as wood, leather, asbestos or one of the special compositions. The band fits externally in all ordinary examples, but when access of dirt, moisture and grit must be prevented, an internal expanding type has the preference, the band being made of an expandable ring, with a pivotal freedom. By the multiplication of force with a lever, plus the frictional effect of the band embracing a large diameter, a man by exercising moderate force at a handle or treadle can hold a load of several tons and pay it out slowly or quickly by regulating his pressure. Fig. 1 may be noted

FIG. 1.—SIMPLE BAND OR STRAP BRAKE

to explain the essential features, the lever having its eye pivoted on a short shaft around which one end of the band is looped, while the other end is pinned a little way along the lever, being consequently pulled taut as the pedal is depressed. A balance weight at the tail end frees the band when the foot releases the lever. The band brake gives a large braking torque for the actuating force applied and in this respect is one of the most efficient brakes available. For rotation in one direction, greatest effectiveness is obtained when the tight side of the band is anchored at the lever pivot; effectiveness is not so great for operation of the drum in the opposite direction. By proper selection of the pivot point a band brake may be made self-locking for one direction of rotation and free running in the opposite direction. Such brakes are known as differential band brakes and are used on hand-operated hoists to prevent unintentional lowering of the load.

Although of high mechanical effectiveness, the band brake requires careful adjustment and has poor heat dissipating capacity, hence is not suitable for continuous operation.

Block Brakes.—A simple type of braking is obtained by pressing a block against the periphery of a rotating drum. To increase the braking capacity and at the same time greatly reduce the forces on the drum bearings, two diametrically opposed blocks are frequently used. The blocks are attached to posts pivoted to the frame and are forced against the drum as the posts are pulled together through a multiplying leverage. Such a brake used in a crane is shown in fig. 2. The blocks are held against the drum by the force from the spring multiplied through the linkage. Current supplied to the operating motor connected to the drum shaft flows through the coils of the solenoid, thus producing a flux to pull the solenoid plunger down and compress the spring, thereby releasing the brake to allow the motor to turn the drum. If the current fails, the spring applies the brake and prevents the load from being lowered. Block brakes with drums 12 or more feet in diameter are in use on mine hoists.

Motorcar Brakes.—Shoe brakes are commonly used. In them rigid shoes are pressed outward against the inside of a drum by a

BY COURTESY OF THE CLEVELAND CRANE AND ENGINEERING CO

FIG. 2.—CRANE BLOCK BRAKE ACTUATED BY SOLENOID

linkage and cam or by a hydraulic cylinder acting directly on the ends of the shoes. In fig. 3 for clockwise rotation the friction on the shoe surface helps to engage the right shoe more tightly, so that it is self-energizing, whereas the friction tends to lessen the pressure on the left shoe. The self-energized shoe is called the leading shoe; and the shoe with diminished energy, the trailing shoe. The trailing shoe requires about three times the tip operating force of the leading shoe. To give this greater force, some actuating cylinders have the piston for the trailing shoe larger than for the leading shoe. Temperatures caused by high energy generation in vehicles at high speed cause fade, or loss of braking power due to temperature expansion. Trailing shoes are less affected by fade than leading shoes. In order to obtain the desired ratio of front to rear wheel braking, some European designs use two trailing shoes with a servo unit or power assistance to increase the actuating force. United States practice sometimes uses two leading shoes to take full advantage of their self-energizing characteristic. English practice is to use two leading shoes on the front wheels and a trailing and leading shoe on the rear wheels, or leading and trailing on both front and rear.

Disk brakes of the caliper type operate in the open in small and sport cars. A small friction area is applied through a pincer linkage to each face of a rotating disk. As the exposed surface is large and plane heat dissipation is good, no temperature expansion problems exist.

Enclosed disk brakes utilize friction contact around the outer surface of two faces of a disk squeezed between pressure plates or single surfaces of two disks separated so as to bear on the inside end surfaces of a drum. The arc of friction material contact may be 360° or less. Smaller contact area results in greater energy per unit of contact area but also greater free disk area to dissipate heat. A proper balance is necessary. Thermal and mechanical distortions are less than in the drum of a shoe brake. Disk brakes may be made self-energizing. The Lambert hydraulically operated tractor brake shown in fig. 4 is automatically self-energizing. Hydraulic fluid from the master cylinder acting on two cylinders (one shown) forces the primary disk against the rotating, friction-lined middle ring, which then contacts the secondary disk. The rotating disk imparts a slight rotary motion to the primary disk causing the power rollers to ride up the ramp of the power insert, thus increasing the pressure between the plates. A British-designed brake uses a vacuum booster instead of a self-energizing device. European use of self-energization is less than in the U.S. Automotive brakes may be actuated by rod, cable, hydraulic pressure, high-pressure air, vacuum or electrically energized magnets. Most used is the hydraulic system whereby force applied

BY COURTESY OF THE CHRYSLER CORP.

FIG. 3.—HYDRAULIC AUTOMOBILE BRAKE

Entrance under pressure of fluid into the cylinder forces pistons apart and rotating shoes around their lower pivots, bringing friction surfaces into contact with the brake drum. When fluid pressure is released, the long spring pulls shoes out of contact

to the brake pedal moves a piston in a master cylinder from which the pressure is transmitted by the fluid through tubes to one or two actuating cylinders in each wheel brake. The pedal force may be used to control a vacuum cylinder which applies the principal force to the master cylinder. (See *AUTOMOBILE: The Chassis: Brakes.*)

In regions with long, steep grades the main brakes are relieved by auxiliary brakes, such as drum or disk brakes, on the transmission shaft, hydraulic retarders, or by using the driving motor as a compressor. In European exhaust brakes a valve is used to close off the exhaust line so that the engine acts as a compressor on the exhaust as well as the compression stroke. Fuel is cut off and induction air enters freely.

Railroad Brakes.—Air brakes, commonly used on railroads and required by law in the United States, consist of a compressor, pneumatic valves and regulators with the necessary pipes, reservoirs and accessories, with levers, rods and other rigging to transmit the forces to the brake shoes, which bear directly on the rim of the wheels. The simple air brake was superseded by automatic action so that the brakes would be applied upon release of air from the system—either when intentionally released by a control valve or accidentally by a broken pipe or burst hose. This automatic action is obtained by having in each car an auxiliary storage tank containing air of sufficient quantity and pressure to brake that car; and a triple valve to which are connected the brake pipe, auxiliary reservoir and brake cylinder. When pressure is reduced in the brake pipe by air escaping to atmosphere, the higher pressure from the auxiliary reservoir causes the triple valve on each car to admit air under pressure to the brake cylinder to apply the brake shoes. The brake is released by admitting high-pressure air from the main reservoir on the locomotive to the brake pipe until pressure is above that maintained in the auxiliary tanks. The triple valve parts are returned to their original positions and a release spring returns the piston (or diaphragm) to its original position, releasing the brakes.

The quick action automatic brake (AB), invented by George Westinghouse (*q.v.*), is the minimum standard required on freight cars introduced on United States roads from 1945. The triple valve is modified so that a quick reduction in pressure in the brake pipe establishes direct communication to the brake cylinder. The brake pipe is vented at each car and the pressure increased on each brake cylinder giving increased braking effort. The brake

BY COURTESY OF AUTO SPECIALTIES MANUFACTURING COMPANY

FIG. 4.—HYDRAULIC TRACTOR BRAKE WITH SELF-ENERGIZING DISK

force that can be applied to the wheels without locking them decreases as the speed decreases. In order to stop from high speed in the shortest time it is desirable to reduce the braking force when stopping rather than to keep it constant, as in the AB system. This effect is achieved in the high speed control (HSC) system, which is in effect an electropneumatic brake superimposed on an automatic brake so that the cars are braked quickly and smoothly by either system.

HSC uses a modified triple valve with a governor and electro-pneumatic control to reduce the braking force in three stages, at 60, 40 and 25 m.p.h., thus giving four speed zones with ratios of braking force to weight of wheel on the rail of 250%, 200%, 150% and 100%, respectively. At a ratio of 150% the wheels would lock and slide on the rails at low speed. The electro-pneumatic device consists of an equalizing portion for controlling the pneumatic service, the release and the automatic charging of the reservoirs; a portion for quick supply of high pressure for transmitting quick action to successive cars; and an electric system for operating switches, magnets, etc. A Decelostat is used to reduce automatically the braking force on any wheels which tend to lock and slide.

Vacuum brakes are used in some countries. The vacuum automatic brake is dependent on atmospheric pressure for its action, the brakes being normally kept off by the state of vacuum existing in the train pipe and cylinders. A steam ejector on the engine produces the vacuum and maintains it constantly. As there is vacuum both above and below the pistons in the brake cylinders, the pistons fall by gravity and the shoes remain off. But when atmospheric air is admitted to the train pipe, by the driver or guard, or through a breakaway, it closes a ball valve in the piston so as to seal the upper side of the cylinder and exerts pressure on the lower side of the piston, forcing it upward and actuating the brake rods. The two conditions appear in fig. j.

The object of the "rolling ring" of rubber is to make a perfect joint or packing without friction, and the release valve serves to enable the brake to be released by hand.

Streetcar (Tramcar) Brakes. — The hand brake which applies shoes to the wheels of a streetcar or tramcar suffers from limitations in regard to power; hence other systems must be utilized in conjunction with it. The regenerative method (causing the motors to act as generators) imposes a powerful braking effect. Or this may be combined with the operation of slippers magnetically clinging to the rails (an alternative to mechanically applied slippers), thus affording axle braking combined with the powerful slipper drag. And sometimes the mechanism includes wheel shoe attachments, the drag of the magnets causing an application of the wheel brake blocks.

The magnet coil is usually a large wire coil having a small number of turns, whereas for certain conditions a supplementary shunt or fine wire coil is added, energized by current from the line. With shunt winding the car can be brought completely to rest without having to apply the hand brake.

Brake Materials. — Brake drums of cast iron are most successful but are rather heavy and require too much machining for automotive use. Composite drums of pressed steel lined with centrifugally cast iron liners are successfully used. Aluminum brake housings, frequently ribbed, are used to aid in heat dissipation.

Railroads use cast-iron shoes bearing directly on the chilled rim of the cast wheels. Hard abrasive particles can be cast into the shoes so that the wheels are kept true without affecting the

braking efficiency. Automotive and industrial brakes use a lining made in either woven or molded form of asbestos fibres, mixed with fillers and bonding material, and some cotton or copper wire or other metals. The cotton and wire give increased strength to the short-fibre asbestos. Materials used to bind and saturate the linings to make them impervious to oil and moisture are asphalts, natural gums and oils, and synthetic resins.

There are two types of metal-bonded linings—powdered metals or ceramic-metallic. Applications of the ceramic-metallic linings to aircraft brakes result in life about four times that obtained with organic linings. Ceramic-metallic brakes are brittle and expensive, however, and offer little improvement for automotive use. Coefficient of friction obtainable with the usual linings is from 0.3 to 0.4 for temperatures up to 500° F. Friction linings may be attached to the brake shoes or plates by riveting or cementing.

(F. H.; E. S. A.)

BRAKPAN, a town of the Republic of South Africa, lies 5,400 ft above sea level and 23 mi. E. of Johannesburg, at the centre of the Far East Rand and of the mining and industrial complex of that area. Pop. (1960) 78,778, of whom 29,209 were of European descent. The municipal area is 93.5 sq.mi., the largest on the Witwatersrand. The climate is mild, and the average annual rainfall is 27.7 in. The town grew rapidly after it became an independent municipality in 1919. It is attractively laid out, with wide tree-lined streets and residential suburbs separated from its industrial quarters. There are 15 schools and colleges, and municipal grants and bursaries are provided to enable students to attend various universities. The town is known for its parks and sports grounds and has a swimming pool and golf courses. It is served by main rail and road services. Brakpan is 13 mi from Jan Smuts international airport and has a flying club. The municipality has encouraged industrial activity in the district and especially in its industrial township of Vulcania. (W P Do)

BRAMAH, JOSEPH (1749–1814), English engineer and inventor of the hydraulic press and other machinery, was the son of a farmer and was born at Stainborough, Yorkshire, on April 13, 1749. He worked as a cabinetmaker in London, where he subsequently started his own business.

His first patent, for some improvements in the mechanism of water closets, was taken out in 1778. In 1784 he patented the lock known by his name; and in 1795, his hydraulic press. For an important part of the press, the collar which secured watertightness between the plunger and the cylinder in which it worked, he was indebted to Henry Maudslay, one of his workmen, who also helped him in designing machines for the manufacture of his locks. In 1806 he devised for the Bank of England a printing machine for numbering bank notes.

Other inventions of his included the beer engine for drawing beer, machinery for aerating water, planing machines and improvements in steam engines and boilers and in papermaking machinery. In 1785 he suggested the possibility of screw propulsion for ships; and in 1802, the hydraulic transmission of power. He constructed waterworks at Norwich between 1793 and 1798. He died in London on Dec. 9, 1814.

See H. W. Dickinson, "Joseph Bramah and His Inventions," *Trans. Newcomen Soc.*, 22:169–186 (194142).

BRAMANTE (DONATO D'AGNOLO or D'ANGELO, incorrectly called BRAMANTE LAZZARI) (1444–1514), Italian architect, who represents, with Raphael (probably a younger relation of his) and Michelangelo, the full flowering of the Italian Renaissance. He was born at Monte Asdrualdo (now Fermignano), near Urbino, one of the great centres of the period. At Urbino he came under the influence of L. B. Alberti and Piero della Francesca. Bramante's architectural career, which followed his brief activity as a painter, falls into two periods, that in Milan, c. 1480–99; and that in Rome, c. 1500–14, which includes the planning of St. Peter's.

In Milan he was largely preoccupied with central planning, i.e., the design of buildings with plans of regular shape, such as the square or circle, related to one or more crowning domes. This re-

FIG. 5.—VACUUM AUTOMATIC BRAKE

flected contemporary Lombard practice, especially the architectural ideas of Leonardo da Vinci, and was based on Milanese buildings, such as S. Lorenzo, which were thought to be antique. He studied such models closely and used classical forms derived from them and also from the classical elements of Filippo Brunelleschi's style. His principal Milanese buildings are Sta. Maria presso S. Satiro and the domed crossing, transepts and choir which he added to Sta. Maria delle Grazie.

As a result of the French invasion (1499) Bramante left Milan for Rome, where contact with far more important remains of ancient architecture led to increased classicism and gravity in his style. From about 1503 Bramante was engaged in the rebuilding of St. Peter's for Pope Julius II, and the foundation medal of 1506 gives some idea of his project. When Bramante died on March 11, 1514, little was actually built, but he had established the idea of a huge domed church, roughly square in plan and strongly classical in feeling. His ideas were later radically altered, especially by Michelangelo and Carlo Maderna. His major surviving works in Rome are the Tempietto at S. Pietro in Montorio (1502), a tiny church which is a microcosm of the main ideas behind St. Peter's, and the Belvedere court and other works in the Vatican, later much altered. The "House of Raphael," now known only from engravings, strongly influenced the design of Italian palaces from the 16th century onward. The principles of symmetry and classical repose informing all these works were imitated and then rebelled against by later architects, many of whom were trained under Bramante at St. Peter's, but the brief moment of harmony and equilibrium called the High Renaissance was, in architecture, Bramante's creation.

See also Index references under "Bramante" in the Index volume. (P. J. MY.)

BRAMANTINO (d. 1530), Italian painter and architect; properly BARTOLOMMEO SUARDI but called Bramantino because of his association with the architect Bramante. Probably born about 1465 and a pupil of Bernardino Butinone, Bramantino seems to have been employed in the Milanese studio of Bramante, whose secular frescoes exercised strong influence on his style. Bramantino is mentioned in documents after 1490 and in 1508 was employed in Rome. In 1511 he designed the sepulchral chapel of the Trivulzio family in S. Nazzaro, Milan. Bramantino's principal extended works are 12 tapestries of "The Months," now in the Museo Civico, Milan. These were executed in 1509 and show him to have been the most gifted and original Milanese painter of his time. After his return from Rome his style suffered marked deterioration. Among Bramantino's followers were the painters Bernardino Luini and Gaudenzio Ferrari.

See W. Suida, *Branzante pittore e il Bramantino* (1953).

(J. W. P.-H.)

BRAMBLE: see BLACKBERRY.

BRAMBLING (*Fringilla montifringilla*), a handsomely coloured finch allied to the chaffinch (*q.v.*) but slightly larger and with a conspicuous white rump and a more forked tail. The brambling has a wide range in Europe and Asia; in spring it breeds in high northern latitudes, and in winter it migrates south, favouring thickets and wooded areas. The male has an orange breast, orange shoulder patches and a brownish (winter) or blackish (spring) head and back; the female is drabber. Both have the characteristic white markings on the wing and rump. (G. F. Ss.; X.)

BRAMWELL, GEORGE WILLIAM WILSHERE
BRAMWELL, BARON (1808-1892), English judge, as a result of whose suggestion the Companies act of 1862 required the word "Limited" to be added, for the protection of those trading with them, to the names of companies that sought to limit their liability. He was born in London on June 12, 1808, being the eldest son of a banker. He was educated privately and, after two years in a bank, was admitted as a student at Lincoln's Inn in 1830 and at the Inner Temple in 1836. At first he practised as a special pleader, but was called to the bar at both inns in 1838.

In 1850 Bramwell was appointed a member of the Common Law Procedure commission, which resulted in the Common Law Procedure act of 1852. This act he drafted jointly with James (after-

ward Mr. Justice) Willes, thus beginning the abolition of the system of special pleading. In 1851 Lord Cranworth made Bramwell a queen's counsel, and the Inner Temple elected him a bencher. In 1853 he served on the royal commission to inquire into the assimilation of the mercantile laws of Scotland and England and the law of partnership, which had as its result the Companies act of 1862. In 18j6 Bramwell was raised to the bench as a baron of the exchequer.

In 1867, with Mr. Justice Blackburn and Sir John Coleridge, he was made a member of the judicature commission. In 1871 he refused a seat on the judicial committee of the privy council. In 1876 he was raised to the court of appeal. On his retirement in 1881 he was raised to the peerage and he afterward sat in appeals to the house of lords.

Bramwell died at his home near Edenbridge, Kent, on May 9, 1892.

BRAN, in Celtic legend, the name of (1) the hero of the Welsh prose tale *Mabinogi* of *Branwen*, who dies in the attempt to avenge his sister's wrongs; he is the son of Llyr (= the Irish sea-god Lir), identified with the Irish Bran mac Allait, Allait being a synonym for Lir; (2) the son of Febal, known only through the 8th-century Irish epic *The Voyage of Bran* (to the world below); (3) the dog of Ossian's Fingal.

BRAN, the material obtained from the outer coat of cereals; the ground husk of grain. It is used largely as a feeding stuff for horses, cattle and poultry and for packing and in cleaning and polishing goods. It is used also as a human food, especially as an aid to digestion, either alone or with flour to make muffins and brown bread. The digestible matter in 1,000 lb. of wheat bran includes 585 lb. of organic matter, as follows: nitrogenous substances 110 lb.; fat 27 lb.; soluble carbohydrates 426 lb.; and fibre 22 lb. The nitrogenous content is approximately that of wheat or oats.

BRANCHIOPODA, one of the subclasses of the Crustacea (*q.v.*), comprising some of the most primitive existing forms of the class, distinguished by the flattened, leaflike form of the limbs. Although, like most Crustacea, they cannot be said to have any popular English names, various members of the group have been distinguished by writers on natural history as fairy shrimps, tadpole shrimps, clam shrimps and water fleas. Nearly all of them are inhabitants of fresh water, and they are remarkable for the prevalence of parthenogenesis (reproduction by unfertilized eggs) and for the fact that the eggs resist desiccation and can survive for long periods in the dry state. Because of this they often make their appearance in great numbers in rain pools, even in dry countries where for long periods no aquatic life is possible.

The members of the five orders named below differ much in structure. Those of the first four orders are characterized by the large number of somites, the general uniformity of the trunk

FIG. 1.—MALE OF ONE OF THE FAIRY SHRIMPS (*BRANCHINECTA PALUDOSA*), A MEMBER OF THE ORDER ANOSTRACA (THIS MALE IS OF MAXIMUM SIZE. X 3)

It has a circumpolar distribution and occurs in stagnant, shallow pools. The claspers of the male are formed from the second pair of antennae

limbs and, in the living species, by the tubular form of the heart and the ladderlike arrangement of the central nervous system. These characters are very primitive, but on the other hand the palpless mandibles and the reduced maxillulae and maxillae are more specialized than those of some other Crustacea.

Anostraca.—The Anostraca have no carapace (hard dorsal shield), and the fully segmented body is almost wormlike. The males are distinguished by the modification of the antennae into large and complicated claspers which are used for holding the females. The eyespots are set on movable stalks. Most Anostraca, such as the fairy shrimp (*Branchinecta*), inhabit rain pools and

FIG. 2.—DEVONIAN FOSSIL (LEPIDOCARIS RHYNIENSIS). A MINUTE CRUSTACEAN KNOWN ONLY FROM FOSSIL REMAINS IN THE OLD RED SANDSTONE OF SCOTLAND BELONGING TO THE ORDER LIPOSTRACA. Female enlarged about x 20

other temporary accumulations of fresh water, but the brine shrimp (*Artemia*) is found in the brine of salt pans in which sea water is exposed to evaporation for the manufacture of salt, and in salt lakes in which the brine is so concentrated that few other animals can live in it, such as Great Salt Lake, Utah. Brine shrimps are found throughout the world wherever conditions are suitable. Specimens from different localities differ considerably, but it has been shown that many of their variations are directly correlated with the degree of salinity of the water and probably many of the forms described are variants of a single cosmopolitan species. Brine shrimps are the only Anostraca known to be parthenogenetic, some colonies consisting entirely of females. Brine shrimp eggs are often gathered and sold in pet shops to fish hobbyists. When the eggs are placed in salt water, the young hatch and may be fed to aquarium fish.

Most Anostraca are of small or moderate size; giant among them are *Branchinecta gigas*, from Grand Coulee, Ore., a full two and three-quarters of an inch long, and *B. paludosa*, almost one inch long.

Lipostraca.—Related to the Anostraca is the order Lipostraca based upon the remarkable fossil *Lepidocaris* discovered in the Old Red Sandstone of Scotland. The fragmentary remains of this minute Crustacean are so perfectly preserved that its structure is known in greater detail than that of any other fossil Crustacean. Resembling the Anostraca in general form, it differs from them

FIG. 3.—A CLAM SHRIMP (LIMNADIA LENTICULARIS) MEMBER OF THE ORDER CONCHOSTRACA. ENLARGED ABOUT X 3

The lower figure represents the entire animal. In the upper figure the left valve of the shell has been removed to show the body and limbs

in the structure of the limbs, of which the posterior pairs are two-branched; in the absence of paired eyespots; and, most remarkably, in the claspers of the male which are formed, not by the antennae but by the maxillulae.

Notostraca.—The Kotostraca have a broad, oval carapace covering the fore part of the body and giving the animals, at first sight, some resemblance to the Arachnidan horseshoe crabs, with which, however, they have no near relationship. The somites and appendages are more numerous than in any other living Crustacea. The eyespots are sessile on the upper surface of the head, and the antennules and antennae are much reduced, their place as "feelers" being perhaps taken by the filamentous terminal processes of the first pair of abdominal appendages. The principal genus is *Apus* (*Triops*), the species of which may be two or even three inches long. Reproduction is largely parthenogenetic and males are rare.

Conchostraca.—The Conchostraca have the carapace in the form of a bivalve shell enclosing the body and limbs and marked with concentric lines of growth, so that it resembles very closely the shell of a lamellibranch mollusk. The large two-branched antennae are used in swimming. The paired eyespots are sessile

and are more or less coalesced into one. *Esteria* and *Limnadia* are well represented in Europe and America, but no Conchostraca have ever been found in the British Isles.

Cladocera.—The Cladocera are closely related to the Conchostraca, from which they should not, perhaps, be separated as a distinct order, and from which they differ chiefly in the great reduction in the number of body somites and of limbs. They are the water fleas, everywhere abundant in ponds and lakes. Nearly all are of small size, some species which do not exceed one hundredth of an inch in length are among the smallest of living Crustacea; the largest Cladoceran is *Leptodora kindtii*, from one-half to three-fourths inch long, found in larger fresh-water lakes of the northern hemisphere; and the only member of the order having a nauplius-like larval stage (characteristic of many Crustacea). The transparency of Cladocera allows the internal structure to be studied in the living animal, making them interesting objects for microscopic examination. The Cladocera reproduce largely by parthenogenesis; the developing eggs are carried within the shell of the female. In addition to the parthenogenetic eggs, which hatch while still within the brood chamber, the Cladocera produce, at certain seasons, another kind of eggs which require fertilization. These thick-shelled "resting" eggs do not hatch at once but are cast off when the female molts. These eggs can survive drying or freezing without injury. They are often produced in autumn and do not hatch until the following spring; in species that live in small pools, they may be produced in spring, insuring survival in the event that the pool should dry up in summer. The only branchiopods occurring in the sea are a few species belonging to three genera of Cladocera, *Evadne*, *Penilia* and *Podon*.

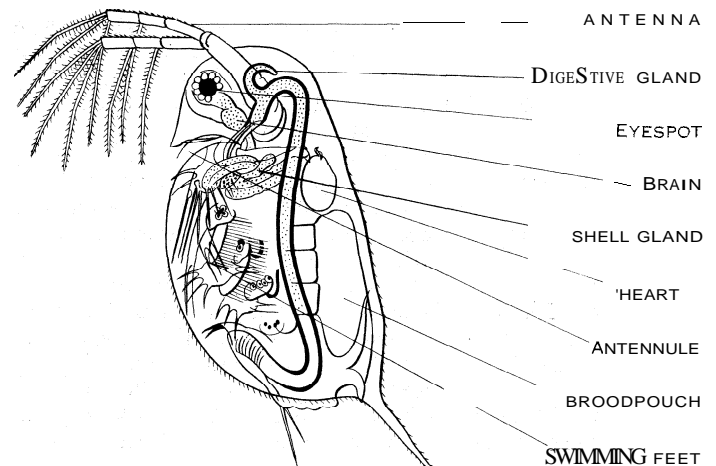

In converting the smallest aquatic and marine organisms into food material for animals higher in the scale of life, the Cladocera rank next to the Copepoda (*q.v.*) in importance.

The beating motion of the paired limbs in the Branchiopoda sets up a current of water along the midventral line of the body (food groove), from which particulate food is strained by bristles or feathered setae. Many have special provision for filtering off the fine particles of organic matter, chiefly microscopic algae, as well as coarser material and detritus, which some species may scrape or stir up from the bottom. The Kotostraca and Conchostraca are primarily bottom feeders, the Anostraca and Cladocera pelagic foragers, but in many cases they derive some food also from the bottom. The Notostraca are not above scavenging and eating small living or-

BRANCOVAN (properly BRÎNCOVEANU), a noble family prominent in Rumanian history, deriving its name from the estate of Brîncoveni, in Walachia. From the great Mateiu Basarab (see BASARAB), who died leaving no son in 1654, the Brîncoveni estate passed to a collateral line of his family. From this emerged CONSTANTIN BRANCOVAN, ruler of Walachia from 1688 to 1714. A vassal of the Turks, to whom he had to pay heavy tribute, he refused to subjugate himself entirely to the Austrians (whom he defeated at Zărnești in 1690 but from whom he received the title of prince in 1695) and negotiated with the third rival power, Russia. His promise to help Russia against Turkey in 1711 came to nothing. The Turks learned of it, and in 1714 he and his four sons were executed in Istanbul. Constantin built churches and palaces and founded printing works to produce books not only in Rumanian but also in other languages of the Orthodox Church.

The family was continued through Constantin's nephew. Its last direct descendant in the male line was the Greek scholar GRIGORE BRANCOVAN (d. 1833), whose adoptive daughter married Gheorghe D. Bibescu. The latter's son GRIGORE (1827-1886) took the name and title of Brancovan. His daughter Anna (1876-1933), comtesse de Noailles by marriage! was a distinguished French poet.

BRANCUSI, CONSTANTIN (1876-1957), Rumanian sculptor, a pioneer of abstract sculpture whose work exerted a tremendous influence on the art of the 20th century, was born in Pestisani, Rum., on Feb. 21, 1876. He studied at a local art school and then at the Art academy in Bucharest where he won a prize for a realistic statue. In 1904 he went to Paris where he studied at the École des Beaux Arts with M. J. A. Mercié and came under the influence of Auguste Rodin. Gradually he abandoned naturalistic sculpture, and, influenced by primitive carving and the modern art movement, devoted himself to works in a highly original abstract style. In these works he tried to bring out the essential form rather than the surface appearance and to utilize to the full the beauty of the material itself. Brancusi achieved prominence in connection with a lawsuit (1927) against the U.S. customs service which had refused to admit his "Bird in Space" duty free as a work of art. The ensuing argument between conservative and modern critics ended in a victory for Brancusi and modern art. His fame grew steadily, and at the time of his death, in Paris on March 16, 1957, he was universally regarded as the grand old man of modern abstract sculpture.

The most important collection of his work is in the Museum of Modern Art, New York city, including such masterpieces as "Bird in Space," "Fish," "Adam and Eve" and "Mlle Pogany." A large retrospective exhibit was held at the Solomon R. Guggenheim museum, New York city, in 1956.

BRAND, SIR JOHANNES HENRICUS (JAN HENDRIK) (1823-1888), South African statesman, who, as president of the Orange Free State from 1864 to 1888, sought to promote harmony between the Boer republics and the British colonies in South Africa. was born in Cape Town on Dec. 6, 1823. A son of Sir Christoffel Brand, speaker of the Cape Colony house of assembly, he was educated at the South African college, Cape Town, and at the University of Leiden, Neth. He was called to the English bar by the Inner Temple in June 1849 and thereafter practised as an advocate in the Cape supreme court (1849-63). He was appointed professor of law in the South African college in 1858.

Brand was elected president of the Orange Free State in Nov. 1863. He held office continuously from Feb. 2, 1864, until his death in 1888, being four times re-elected (see ORANGE FREE STATE: *History*). He conducted his presidential office with dignity and moderation, defending his authority against periodic attacks in the *volksraad* (parliament) and following a peaceful line under difficult conditions in his relations with the British government. He fought successfully against the Basuto from 1865 to 1868 and

then imposed such severe terms on them that Great Britain decided to annex Basutoland (1868). The resultant controversy with the British authorities was barely settled, by the treaty of Aliwal North (1869), when another arose in 1871 over the control of the Griqualand West diamond fields. Defeated by Great Britain's decision to annex the territory, Brand nevertheless obtained £90,000 compensation for his government when he visited London in 1876. Brand later mediated between the British government and the Transvaal leaders after the war of 1881 and was knighted (1882) for his services. Brand laid the basis for the customs and railway agreement between the Free State and Cape Colony which was signed soon after his death. He died at Bloemfontein on July 14, 1888. (T. R. H. D.)

BRAND, JOHN (1744-1806), English antiquary and topographer, who was historian of Newcastle upon Tyne and the resident secretary to the Society of Antiquaries, 1784-1806, was born on Aug. 19, 1744, at Washington, Durham. He was educated at Newcastle grammar school and Lincoln college, Oxford. Ordained in 1773, he occupied positions as a teacher and curate in and near Newcastle until 1784, when he received the livings of St. Mary-at-Hill and St. Mary Hubbard, London, from the duke of Northumberland, to whom he became a personal chaplain in 1786. He died in London on Sept. 11, 1806.

His most important works are *Observations on Popular Antiquities: Including the Whole of Mr. Bourne's Antiquitates Vulgares* (1777) and *The History and Antiquities of the Town and County of Newcastle upon Tyne*, two volumes (1789). Brand also published a poem entitled *On Illicit Love. Written Among the Ruins of Godstow Nunnery, Near Oxford* (1775) and numerous papers in *Archaeologia*. (J. M. WI.)

BRAND, SIR (CHRISTOPHER JOSEPH) QUINTIN (1893-), South African pioneer aviator and an air vice-marshal in the Royal Air Force (R.A.F.), was born at Beaconsfield, near Kimberley, Cape Province, on May 25, 1893, and was educated at the Marist Brothers' school in Johannesburg. He served with distinction in the Royal Flying Corps and R.A.F. in World War I and destroyed a German Gotha bomber in the last air raid carried out on the United Kingdom in that war.

In 1920, in company with Sir Pierre van Ryneveld, he made the first flight from London to Cape Town, via Cairo, in a Vickers Vimy aircraft. For this pioneer achievement both men were knighted. Brand qualified in engineering at Cambridge university in 1922 and, after various R.A.F. appointments, became director general of civil aviation in Egypt from 1932 to 1936. During World War II, he commanded no. 10 fighter group, which played a distinguished part in the battle of Britain. Brand retired from the R.A.F. in 1943 and returned to live in South Africa. (D. CR.)

BRANDEIS, LOUIS DEMBITZ (1856-1941), U.S. jurist and public advocate of the interests of consumers: labour unions and investors, was born in Louisville, Ky., on Nov. 13, 1856. His parents, members of cultivated Bohemian Jewish families, had emigrated from Prague, Czech., to the United States in 1849. Brandeis attended the public schools of Louisville and the Annen Realschule in Dresden, Ger., before entering the Harvard law school, from which he was graduated at the head of his class in 1877. After less than a year of practice in St. Louis, Mo., he returned to Boston, Mass., where he maintained an active and prosperous practice until his appointment to the supreme court of the U.S. in 1916.

Career as Counsel.—At the bar Brandeis came to be known as the people's attorney, by virtue of his representation of interests that had not commonly enjoyed such formidable advocacy. For the most part he took these responsibilities on condition that he receive no compensation; in this way he was able as a private citizen to indulge his passion for public service and, more important, to devise constructive solutions that would transcend the narrow concerns of client and class. When the affairs of the Equitable Life Assurance society of New York precipitated widespread alarm in 1905, Brandeis became unpaid counsel for the New England Policy-Holders' Protective committee. His investigations and reports anticipated in some respects the findings and recommenda-

tions of the legislative committee appointed in New York under state Sen. William W. Armstrong, whose counsel was Charles Evans Hughes (*q.v.*). Characteristically, Brandeis, his mind challenged by the issues of insurance-company abuses (*see* LIFE INSURANCE: *United States*), reached beyond the immediacies to create a remedy that would be easily administered, self-motivating and enduring and that would above all enlist the participation of ordinary men. Such a measure he constructed in the system of savings-bank life insurance, whereby insurance for workmen was offered by savings banks over the counter at economical rates. This plan, steered through the Massachusetts legislature in 1907 after a vigorous educational campaign, Brandeis regarded as his greatest achievement.

As counsel for shippers opposing a rate increase before the Interstate Commerce commission in 1911, he probed the economic position of the railroads. Out of this study came his dramatic challenge that the railroads could save \$1,000,000 a day through the adoption of the principles of scientific management. Labour relations came under his scrutiny in a similarly pragmatic way. Called on to settle a strike of New York garment workers, he put into effect a plan for a preferential union shop and continuing consultation between management and labour in the affairs of the industry.

During 1907-14 he served as counsel for a number of states in defending against the charge of unconstitutionality various state laws prescribing maximum hours of labour and minimum wages. For this purpose he devised what came to be known and emulated as the "Brandeis brief," in which the legal propositions are set forth simply and summarily and the bulk of the argument is given over to a massive assemblage of economic facts, historical experience and expert opinion in support of the reasonableness of the legislation being defended.

Brandeis' volume of essays, *Other People's Money and How the Bankers Use It* (1914), was a study of the power exercised by investment bankers over C.S. industry. Documented from his own intensive analysis of the financial condition of the New Haven railroad, as well as from the hearings of the Pujo committee of the U.S. house of representatives (1912-13), the book was a frontal assault on monopoly and interlocking directorates. The book was influential, as was Brandeis himself, in the enactment in 1914 of the Clayton act and the Federal Trade Commission act, strengthening the antitrust laws.

In politics, as in his law practice, Brandeis preserved his independence. Until his appointment to the supreme court in 1916 he had never held public office. Although he made a series of public speeches early in 1912 on behalf of Sen. Robert M. La Follette's nomination as Republican candidate for the presidency, the failure of this movement left Brandeis a choice between Theodore Roosevelt as the Progressive and Woodrow Wilson as the Democratic candidate. Without hesitation Brandeis gave his support to Wilson, whose antitrust philosophy of enforced competition was far more congenial to him than was Roosevelt's proposal of regulated monopoly. The first meeting between Brandeis and Wilson, in Aug. 1912, provided Wilson with an underpinning of facts and a framework of reform that stiffened his policy toward big business, and it laid the basis of an enduring friendship between the two men.

Supreme Court Justice.—On Jan. 28, 1916, President Wilson nominated Brandeis an associate justice of the supreme court. Over bitter opposition, which encompassed seven former presidents of the American Bar association, the senate by a vote of 47 to 22 confirmed the nomination. He was the first Jew to sit on the supreme court.

Brandeis' judicial opinions reflected his distinctive methods and the singularly coherent body of his beliefs. His major opinions are massive and close-textured, grounded in mastery of the facts, and conveying with a prophetic and didactic note. His fundamental beliefs were simple: that the limits of man's capacity for understanding are soon reached; that responsibility in the performance of manageable tasks is the great developer of men; that the widespread sharing of responsibility is both a moral duty and a practical necessity. In constitutional law, accordingly, he was solicitous of a viable federal system, with due scope to the states for legislative experiment. But by the same token he was ready

to declare out of bounds the suppression of radical or unpopular sentiments, except where the propagation of these views created a proximate danger of unlawful action. His sense of the fallibility of judgment extended to the judicial office itself; no one was more insistent that procedural and jurisdictional limits on the court's authority be scrupulously observed. Thus in the case of Charlotte Anita Whitney (*Whitney v. California*, 274 U.S. 357, 372 [1927]), convicted under a California criminal syndicalism statute, Brandeis delivered a deeply felt opinion urging that penalties on speech could be justified only by a "clear and present danger" as applied earlier by Justice Oliver Wendell Holmes (*q.v.*); paraphrasing Pericles' funeral oration he declared that the founders of the U.S. constitution "believed liberty to be the secret of happiness and courage to be the secret of liberty," and yet agreed that the conviction must be affirmed because the defendant's counsel had not properly raised the constitutional issue in the trial court.

On most important issues Brandeis was aligned, often in the minority, with his colleague Justice Holmes, although their outlook was by no means identical. Holmes was content to support legislative experiments because of a pervading skepticism in judging measures of social reform; Brandeis strove to understand and to explicate sympathetically the needs and aspirations embodied in such measures. During the period of the New Deal many of the dissenting positions of Holmes and Brandeis came to be accepted by the court. While Brandeis supported the constitutional validity of most New Deal legislation, he did not do so indiscriminately; he joined, for example, in the decision holding the National Industrial Recovery act to be unconstitutional.

As a judge Brandeis austere withdrew from extrajudicial activities, even declining to accept honorary degrees. The one public interest with which he allowed himself to be identified was the Zionist cause. When Senator La Follette indicated in 1924 his desire that Brandeis become the vice-presidential candidate of the Progressive party, it was a foregone conclusion that the justice would be impassive. Brandeis retired from the court on Feb. 13, 1939, and died in Washington, D.C., on Oct. 5, 1941.

BRANDENBURG, a margraviate or mark, then an electorate of the Holy Roman empire, in northeastern Germany, the nucleus of the dynastic power on which the kingdom of Prussia was founded. As a province of the Land Prussia in Germany after World War I, Brandenburg was bounded on the north by Mecklenburg and by the province Pomorze, on the east by the Polish province of Poznan, on the southeast by Silesia and on the south and west by parts of Prussian Saxony or by Anhalt (Berlin being a self-governing city from 1920). In 1945, at the end of World War II, under the Soviet occupation of eastern Germany, Brandenburg west of the Oder was constituted as a separate Land on the dissolution of Prussia, but in 1952 its old administrative identity was lost when the East German Lander were dissolved into new *Bezirke* ("districts").

The district was inhabited in ancient times by the Semnones and afterward by various Slav tribes, which were partially subdued by Charlemagne but soon regained their independence. In the 10th century, however, the emperor Henry I the Fowler defeated the Havelli (Havelane or Stodorane) and in 928, took their capital, Branibor, from which the name "Brandenburg" is derived. Subsequently, Gero (*q.v.*), margrave of the Saxon East Mark (Ostmark), pressed the campaign against the Slavs with vigour, while the emperor Otto I founded bishoprics at Havelberg and Brandenburg (938). After Otto's death (973), the Slavs regained much of their territory, including Brandenburg; conquest was not yet sufficiently backed by the settlement of German peasants, and the new ruling class, both in church and castle, was still too weak. A succession of feeble margraves ruled only the district west of the Elbe together with a small district east of that river.

Albert the Bear and the **Ascanians**.—A new era began in 1106 when Lothair, count of Supplinburg, became duke of Saxony.

Aided by Albert I (*q.v.*) the Bear, count of Ballenstadt, he renewed the attack on the Slavs and, having become emperor in 1133, appointed Albert margrave of the North Mark (Nordmark) in 1134. About 1140 Albert made a treaty with Pribislav, the childless ruler of the Havelland, by which he was recognized as that prince's heir, taking the title margrave of Brandenburg. The pressure of population, which was rising everywhere in western and central Europe, brought special opportunities to the margrave of a territory with a frontier opening on a sparsely populated and economically backward country. Albert knew how to make use of such a chance and so became the real founder of Brandenburg. Under his rule Christianity and civilization were extended, bishoprics were restored and monasteries founded. The country was colonized with settlers from the lower Rhineland.

The process was continued for the next 100 years under the rule of the Ascanians, as Albert's descendants were called (see ASCANIAN DYNASTIES). Under Albert's great-grandsons, the margraves John I and Otto III, prosperity was maintained, and new districts were conquered or purchased from the surrounding princes. By 1240 a broad front had been established along the Oder river, and Frankfurt an der Oder was founded in 1253 at a focus of communications. Moreover, Otto III's marriage (1253) with Beatrice, daughter of Wenceslas of Bohemia, added upper Lusatia to the margrave's possessions. Berlin (*q.v.*) was one of the many new towns founded. Of the numerous monastic foundations, which were richly endowed, the most notable were those of the Premonstratensians and Cistercians, whose eremitical ideal of a self-supporting community with its own disciplined labour force made them model landowners well-suited to the pioneer work of colonization. Entrepreneurs, or locatores, men not necessarily of noble birth, also brought German settlers from the west and, as the margrave's agents, founded villages, the inhabitants of which lived on the produce of the land that they cleared and drained. The Slav population between the Elbe and the Oder was, on the whole, not displaced but gradually became assimilated in language and in way of life to the economically and politically superior newcomers. Brandenburg's prosperity in the 13th century formed a marked contrast with the political disintegration that prevailed in western Germany.

Brandenburg appears, about this time, to have fallen into three divisions: the Old Mark (Altmark), lying west of the Elbe; the Middle Mark (Mittelmark), between the Elbe and the Oder; and the New Mark (Neumark), as the newly conquered lands beyond the Oder began to be called. When Otto III died in 1267, the area of the mark had been almost doubled, and the margraves had attained to an influential position in the empire. The *Sachsenspiegel*, a private but influential codification of custom law written before 1235, mentions the margrave as one of the electors (*q.v.*), by virtue of the ceremonial office of chamberlain, which had probably been conferred on Albert the Bear by the German king Conrad III; and when the list of electors was definitely established in the second half of the 13th century, the Brandenburger was one of the secular electors. On Otto III's death, however, the margravial territory was divided between his family and his brother's.

There was a permanent rivalry between the margraves and the archbishops of Magdeburg, whose territory, on colonial soil, penetrated like a wedge into the southwestern corner of the margravial lands. The conflict was most acute in the last quarter of the 13th century, under John I's son Otto IV (d. 1308 or 1309). Otto IV's nephew and successor Woldemar conquered Pomerellen (eastern Pomorze), on the western bank of the Vistula, which he partitioned with the Teutonic Order in 1310. He also held his own in a struggle with the kings of Poland, Sweden and Denmark and others over the possession of Stralsund. By marriage, purchase or inheritance, Woldemar finally came to rule over the whole mark, upper and lower Lusatia and various outlying districts. He died childless in 1319. Next year the Brandenburg male line of the Ascanians became extinct.

Wittelsbach and Luxembourg Dynasties.—Brandenburg now seemed to lose its territorial unity; portions were seized by neighbouring princes, and various claimants disputed for the mark itself. In 1323 the German king Louis IV, the first medieval king

from the house of Wittelsbach, took advantage of this condition to bestow the mark upon his young son Louis and so to obtain in Brandenburg a position in the colonial lands of eastern Germany; but Louis did not receive the whole succession of the Ascanian margraves. The king was forced to acknowledge competing claims, especially in the borderlands. During the struggle for power in Germany between the families of Wittelsbach and Luxembourg, which began in 1342, there appeared in Brandenburg an old man who claimed to be the margrave Woldemar. He was gladly received by Casimir III of Poland and other neighbouring princes, welcomed by a large number of the people and, in 1348, invested with the margraviate by Charles IV, the successful Luxembourg candidate for the German crown. This step compelled the Wittelsbach margrave Louis to make peace with Charles, who abandoned the false Woldemar, invested Louis and his half brothers Louis the Roman and Otto with Brandenburg and in return was recognized as king. Louis made peace with his neighbours, finally defeated the false Woldemar and was recognized by the Golden Bull of 1356 as one of the seven electors. After Louis' death in 1361 Charles IV took advantage of a family quarrel to obtain a promise from Louis' two half brothers and successors that the margraviate should come to his own son, Wenceslas, in case the electors died childless. Louis the Roman died in 1365, and when his brother Otto, who had married Catherine, daughter of Charles IV, wished to leave Brandenburg to his own family, Charles began hostilities; but in 1373 an arrangement was made, and Otto, by the treaty of Fiirstenualde, abandoned the margraviate for a sum of 500,000 gold gulden.

Charles invested Wenceslas with the margraviate in 1373 but undertook its administration himself and passed much of his time at a castle which he built at Tangermünde. He diminished the burden of taxation, suppressed the violence of the nobles, improved navigation on the Elbe and Oder and encouraged commerce by alliances with the Hanse towns and in other ways. He caused a *Landbuch* to be drawn up in 1375, in which are recorded all the castles, towns and villages of the land with their estates and incomes. When Charles died in 1378, and Wenceslas became German and Bohemian king, Brandenburg passed to the new king's half-brother Sigismund, then a minor, and a period of disorder ensued. Soon after Sigismund came of age he pledged a part of Brandenburg to his cousin Jobst, margrave of Moravia, to whom in 1388 he pledged the remainder of the electorate in return for a large sum of money, which he needed to build up his position as king of Hungary. As this money was not repaid, Jobst obtained the investiture in 1397 from King Wenceslas. In 1411 Jobst died and Brandenburg reverted to Sigismund, no German king, who appointed Frederick of Hohenzollern, imperial burgrave of Nürnberg, as his representative to govern the margraviate. A further step was taken when, on April 30, 1415, the king invested Frederick and his heirs with Brandenburg, together with the electoral privilege and the office of chamberlain in return for a payment of 400,000 gold gulden; the formal ceremony of investiture was delayed until April 18, 1417, when it took place at Constance. (See FREDERICK I, elector of Brandenburg; HOHENZOLLERN.)

Before the advent of the Hohenzollerns in Brandenburg its internal condition had become gradually worse and worse. The margraves, though according to constitutional law they were only the representatives of the German king, had always had a more or less free hand as leaders of colonization and territorial organization; and this independence had become almost complete in consequence of the emperor Frederick II's preoccupation with Italy and the downfall of his dynasty after 1250. Moreover, in contrast to the German southwest, feudal relationships did not complicate political geography to any great extent. The towns, the peasants in the villages, the prelates and the knights held their lands and derived their rights directly from the margraves. The locatores were installed as hereditary chief magistrates of the communities and received numerous encouragements to reclaim wastelands. The dues paid by these locatores in return for the concessions and the tax assessed on the peasants formed the main source of the revenue of the margraves. Gradually, however, the expenses of politics and warfare and the maintenance of numerous and ex-

pensive households (in consequence of the division of the country among several branches of the ruling dynasty) compelled them to pledge these dues for sums of ready money. The movement of population toward the east had been favourable both to the peasants, whose diligence and initiative had to be stimulated, and to the margraves, who exercised central control.

The 14th century saw both the petering out of colonization and the rise of the local nobility to political power. During the colonization period knights had been settled on lands about five times the size of a farmer's holding; but in most parts of the margraviate they were merely the peasants' important neighbours, not their lords. By the 14th century, however, the village authorities, formerly the margrave's servants, had become the local nobleman's agents, and the peasants sank into a condition of dependence and lost their right of direct appeal to the margrave. Many of the towns were forced into the same position. Others were able to maintain their independence and to make use of the pecuniary needs of the margraves to become practically municipal republics.

In the embarrassments of the margraves originated the power of the *Stände*, or estates, the nobles, the prelates and the towns. In 1280 the Ascanian margraves Otto V, Albert III and Otto VI had solemnly bound themselves not to raise a special *Bede* or extraordinary contribution without the consent of the estates except in cases of genuine emergency. Anarchy had reigned for a century before the Hohenzollern rule began; upper and lower Lusatia, the New Mark of Brandenburg and other outlying districts had been shorn away; and the electorate now consisted of the Old Mark and the Middle Mark with Priegnitz, Uckermark and Sternberg, a total area of not more than 10,000 sq.mi.

The First **Hohenzollerns**.—Such was the condition and extent of Brandenburg in 1411 when Frederick of Hohenzollern became margrave. He entered the electorate with a strong force in June 1412, but it was not until 1417 that his authority over it was undisputed. His intention to renew all territorial rights of his Ascanian predecessors provoked an invasion of the mark by an army of Pomeranians with their allies in 1420, when Frederick inflicted a severe defeat upon them at Angermünde; but in 1424 a temporary coolness between the elector and the emperor Sigismund led to a renewal of the attack in 1425, which Frederick was unable to repulse. This reverse induced him to leave Brandenburg in Jan. 1426 after handing over its government to his eldest son, John the Alchemist, and to spend the rest of his life engaged with the military and political problems arising from the Hussite Wars.

On Frederick's death on Sept. 21, 1440, he was succeeded in the electorate by his son Frederick II, surnamed "Iron" from the rigour of his government. Suppressing the rebellious nobles with ease, he found it less easy to deal with the towns. Three strong leagues had been formed among them about 1431, and the spirit of municipal independence was most prominently represented by the neighbouring towns of Berlin and Kölln, which had united in 1432. In his conflict with the towns, the elector's task was lightened by a quarrel between the ruling aristocracy and the trade guilds of Berlin, which he was called in to decide in 1442. He deposed the governing oligarchy and forbade the union of Berlin and Kölln (the two towns were to be kept separate in the future by the elector's castle on the Spree river); indeed all associations of towns, including membership in the Hanseatic league, were declared illegal throughout the elector's territory. The inhabitants soon chafed under these restrictions. A revolt broke out in 1447, but the power of the elector overawed the people, and after arbitration the arrangement of 1442 was re-established. In 1447 Frederick was compelled to cede the Old Mark and Priegnitz to his younger brother Frederick, under whose feeble rule they quickly fell into disorder. In 1463, however, when the younger Frederick died childless, the elector united them again with his own possessions and took measures to suppress the prevailing anarchy. In his dealings with neighbouring rulers Frederick pursued a peaceful and conciliatory policy. An attempt, however, to secure the duchy of Stettin (now Szczecin) failed, and the concluding years of his reign were troubled by warfare with the Pomeranians. As did other contemporary princes, he obtained important concessions from Pope Nicholas V on the appointment of bishops and on other

ecclesiastical matters in 1447, and in general he maintained cordial relations with the papacy. About 1467 his only son, John, died, and increasing infirmity led him to contemplate abdication. An arrangement was made with his brother Albert Achilles, to whom early in 1470 the mark was handed over, and Frederick retired to Plassenburg in Franconia, where he died on Feb. 10, 1471.

Albert Achilles (1470-86).—Albert III (*q.v.*) took up the struggle with the Pomeranians, which he soon brought to a satisfactory conclusion; for in May 1472 he not only obtained the cession of several districts but was recognized as the suzerain of their country and as its future ruler. The expenses of this war and heavy debts left by his predecessor led to a long-lasting dispute with the estates. Albert tried to introduce a system of excise in Brandenburg and finally succeeded in increasing his annual income from 17,000 to 23,000 gulden, mainly by carefully controlling his officials. But this amount was still only half that of his revenue from Franconia. Accordingly his political testament of 1473, the famous *Dispositio Achillea*, left Brandenburg undivided to his eldest son, John, while Franconia went to his second and third sons and thus remained separated from Brandenburg until 300 years after Albert's death.

The 16th Century.—Albert's son and successor, John Cicero (1486-99), was mainly interested in administration and brought a certain degree of order into the finances, but his poverty and the constant inroads of external enemies prevented him from seriously improving the condition of the country. He welcomed Italian scholars to the electorate and strove to improve the education of his people. When Joachim I (*q.v.*), his son and heir, undertook the government of Brandenburg, he found that highway robbery kept the lives and property of traders in continual jeopardy, but in a few years stern measures restored some degree of order.

By this time most of the nobility in Joachim's territories were adapting themselves to the fact that changes in military technique and the declaration of the Eternal Peace within the empire (1495) had restricted the possibilities of profitable war service, while the export of grain from the Baltic countries to western Europe made agriculture on a big scale a lucrative venture. The nobles used their political power in order to establish a firm hold over the land and over the persons of the peasants living in the neighbourhood of their seats. By depressing the status of the peasantry and by either enlarging its existing obligation to unpaid work or establishing such an obligation when it had not existed, they obtained the labour required for the considerably increased arable land under their direct control. By this process they came to form the Junker class of grain-exporting landowners whose existence was based on a combination of businesslike husbandry with the exercise of local administrative power, whereas the nobility of western Germany lived on rents collected from various sources.

The elector meanwhile gave a new organization to the highest court of justice, the *Kammergericht* for his territories, secured for himself an important voice in the choice of its members and ordered that the local law should be supplemented by the law of Rome. He founded the University of Frankfurt an der Oder in 1506. Joachim's attitude toward the teaching of Martin Luther, which had already won many adherents in the electorate, was one of unrelenting hostility. The Jews also felt the weight of his displeasure and were banished in 1510.

Joachim I bequeathed Brandenburg to his two sons. When he died on July 11, 1535, the elder, Joachim II (*q.v.*), became elector and obtained the Old and Middle Marks, while the younger, John (*q.v.*), or Hans of Brandenburg-Ciistrin, received the New. John went definitely over to the side of the Lutherans in 1538 and Joachim allowed the Reformed doctrines free entrance into his dominions in 1539. It was not the elector's intention to surrender completely to the "Church of Wittenberg," and he tried to steer a middle course by combining traditional ceremonies with the new doctrine; he obtained the approval not only of Luther but also of the emperor Charles V and was very careful not to make common cause with the Protestant group of princes organized in the League of Schmalkalden. Territorial policy was an important factor in Joachim's ecclesiastical decision, in view of the possibility of using secularized bishoprics as endowments for members of his dynasty.

In 1537 Joachim had concluded a treaty with Frederick II, duke of Liegnitz, which guaranteed to the Hohenzollerns the succession to the Silesian duchies of Liegnitz, Brieg and Wohlau (Legnica, Brzeg and Wolow) in the event of the ducal family's becoming extinct; this arrangement is important as the basis of the claim made by Frederick the Great on Silesia in 1740. The treaty was declared invalid in 1546 by the German king Ferdinand I, who as king of Bohemia was suzerain of the Silesian principalities; but the elector insisted on its legality. Of more immediate consequence was an arrangement made in 1569 with the representatives of Joachim's kinsman Albert Frederick, son of Albert (*q.v.*), duke of Prussia, after which the elector obtained the joint investiture of the duchy of Prussia from Sigismund II of Poland and was assured of the succession if the duke's family became extinct.

Joachim II's extravagance compelled him in 1540 to appeal for help to the estates. The estates voted him a sum of money as the price of valuable concessions, the most important of which was that the elector should make no alliance without their consent. Fresh liabilities were soon incurred! and in spite of frequent contributions from the estates of Joachim left at his death on Jan. 3, 1571, a heavy burden of debt to his son and successor, John George.

Joachim II's death was followed ten days later by that of his brother John, and as John left no sons the whole of Brandenburg was united under John George. The rule of John George was popular with the nobles and, to some extent, with the towns because his thrifty methods of government eased their financial position. Although by faith and in his ecclesiastical administration a Lutheran, he did not allow his religious tenets to involve his state in military adventures in defense of the Protestant cause. He died on Jan. 8, 1598. By his will his dominions were to be divided, as he left the New Mark to a younger son, Christian.

Joachim Frederick, the eldest son of John George, now became elector. He had been administrator of Magdeburg since 1566 and was also in control of the secularized Brandenburg bishoprics. Resigning these dignities in 1598, he contested his father's will and was successful in preventing a division of the electorate. Moreover, by a family agreement, known as the Gera bond, he definitely established the rule of primogeniture in Brandenburg for his dynasty. In Brandenburg he made concessions to the nobles at the expense of the peasantry and admitted the right of the estates to control taxation. In religious matters he was convinced of the necessity of a union between Lutherans and Calvinists and took steps to bring this about. Public opinion in Brandenburg, however, was too strong for him, and he was compelled to fall back upon the Lutheran *Formula Concordiæ* and the religious policy of his father. Joachim Frederick seems to have been a wise ruler, who improved the condition of the mark in various ways. When he died, on July 18, 1608, he was succeeded by his eldest son, John Sigismund.

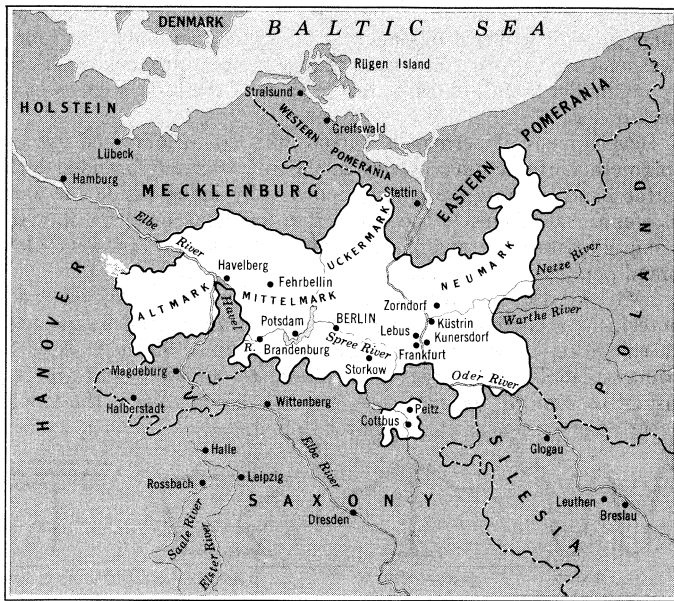

The most important facts in the internal history of Brandenburg during the 16th century were the growth of the power of the estates and the lapse of the peasantry into serfdom. A characteristic feature was the gradual decline of the towns in economic vigour and political importance, whereas in western Europe the rise of the commercial and industrial classes had already begun. The main trade routes to Leipzig and to Hamburg passed south and west of Brandenburg, and the change in the character of the landowning class, who had taken the export of grain into their own hands, considerably narrowed down the economic activities of the townspeople. These developments increased the power of the nobles, but circumstances were preparing for a great increase in the elector's authority. In the first place, the Reformation settlement had made him head of the church in his own territories; secondly, the introduction of Roman law served to strengthen the central authority and the central administration; thirdly, the tendencies to partition the electorate had been overcome; fourthly, the separate sections of the estates were inclined to act independently of one another rather than in unison; and, fifthly and most significantly, the Hohenzollern dynasty was becoming a power in international politics because of its possessions both in the east and in the west of Germany.

John Sigismund and **Cleve-Jülich-Berg**.—John Sigismund

had married in 1594 Anna, daughter of Albert Frederick of Prussia and Maria Eleonora of Jillich, a union which not only strengthened the pretensions of the electors of Brandenburg to the succession in Ducal Prussia but also gave to John Sigismund a claim on the duchies of Cleve, Jillich and Berg and other Rhenish lands should the ruling family become extinct. In March 1609 the death of Duke John William, Maria Eleonora's brother, left these duchies without a ruler; and by arrangement they were occupied jointly by the elector and by his principal rival, the Catholic Wolfgang William, son of Philip Louis, count palatine of Neuburg. This proceeding was complicated by religious considerations and by the importance of these Rhenish lands for the Spanish line of communications between troops in the Netherlands and elsewhere on France's eastern frontier. However, on Nov. 12, 1614, the dispute was temporarily settled by the treaty of Xanten. Brandenburg obtained the duchy of Cleve with the counties of Mark and Ravensburg, but as the Dutch and Spanish garrisons were not withdrawn these lands were only nominally under the elector's rule. In 1613 John Sigismund had publicly professed himself a Calvinist, thus joining the group of princes of the Reformed religion already politically active in western Germany. In view, however, of the discontent that this step aroused in the electorate, he quickly abandoned his attempts to proselytize and practically conceded religious liberty to his subjects. Over the Cleve-Jillich succession John Sigismund had incurred heavy expenses, and the public debt had again mounted up. He was thus obliged to seek aid from the estates and, in return for grants, to make concessions to the nobles. The elector spent much of his time in Ducal Prussia striving to assert his authority there. At last, with Albert Frederick's death (Aug. 26, 1618), he became duke according to the arrangement of 1569. He died, however, on Dec. 23, 1619, and was succeeded by his eldest son, George William.

The Thirty Years' War.—George William, who in 1616 had married Elizabeth Charlotte, sister of Frederick V, elector palatine of the Rhine (afterward king of Bohemia), had before his accession acted as his father's representative in Cleve. Although a Protestant, he was under the influence of Adam von Schwarzenberg, a Roman Catholic whose sympathies lay with the house of Austria. As a result the elector remained neutral during the early years of the Thirty Years' War (*q.v.*) in spite of his father-in-law's predicament and the obvious danger to his Rhenish lands. This attitude was not successful. Brandenburg was ravaged impartially by both parties, and in 1627 George William attacked his brother-in-law, Gustavus II Adolphus of Sweden, who was using Prussia as a base of operations for his war against Poland. This campaign was short and inglorious for Brandenburg, and the elector was soon compelled to make peace. Although alarmed by the Edict of Restitution of 1629, which ordered the restitution by Protestant princes of those ecclesiastical lands which they had taken over, George William took no steps to help the Protestants. In 1631, however, Gustavus Adolphus, at the beginning of his great expedition against the emperor Ferdinand II, marched on Berlin and compelled the elector to cede the fortress of Spandau and to aid him with men and money. Brandenburg troops then assisted the Swedes until the Swedish defeat at Nordlingen in 1634, after which the elector assented to the peace of Prague, made in May 1635 between the emperor Ferdinand II and John George I, elector of Saxony. The imperial armies did nothing, however, to drive the Swedes from Brandenburg. This was the principal reason why the elector was unable to annex Pomorze when its last duke, Boguslaw XIV, died in 1637. In 1638 George William transferred his residence to Königsberg, in Ducal Prussia, leaving Schwarzenberg to administer the electorate. Although his harsh measures aroused some irritation, Schwarzenberg did something to rid the land of the Swedes and to mitigate its many evils: but its condition was still deplorable when George William died at Königsberg on Dec. 1, 1640, leaving an only son, Frederick William (*q.v.*).

Frederick William, "the Great Elector" (1640–88).—Frederick William's first task was to restore order and in this he was eminently successful. He freed Brandenburg of the Swedes and, in 1647, accepted the *status quo* of provisional possession in Cleve, Mark and Ravensberg (this was made definite in 1666).

FROM SIDNEY B. FAY "THE RISE OF BRANDENBURG—PRUSSIA TO 1786," HENRY HOLT AND COMPANY (1937)

THE CENTRAL PROVINCES OF BRANDENBURG IN 1640

The terms of the peace of Westphalia in 1648 are the best commentary on the general success of the elector's policy. Although he was obliged to give up his claim to the western part of Pomorze in favour of Sweden, he secured the eastern part of that duchy, together with the secularized bishoprics of Halberstadt, Minden, Kammin and other lands, the whole forming a welcome addition to the area of Brandenburg. He was also promised the archbishopric of Magdeburg when its administrator, Augustus, duke of Saxe-Weissenfels, should die (the duke died in 1680).

The struggle between Sweden and Poland for the control of the Baltic coast on both sides of the Vistula estuary gave the elector the opportunity to obtain general recognition as sovereign in the duchy of Prussia, which his ancestor had taken over as a Polish fief. Military actions, political negotiation and changes of front brought about this important improvement in the European position of Brandenburg in 1660: under the terms of the peace of Oliva, which confirmed the Brandenburg-Polish treaty of Wehlau (1657), Frederick William's policy in the great conflict between Louis XIV and the Habsburgs was determined by his territorial interest in the Rhenish war zone, but still more by his great plan to obtain European backing for the conquest of the Oder estuary around Stettin from the Swedes. In this project he was finally frustrated, but his political and military activities increased the prestige of Brandenburg considerably. At his death on May 9, 1688, the state of Brandenburg, with Prussia behind it, was inferior to Austria alone among the principalities of the empire. The elector was regarded as the head of German Protestantism, his lands now covered more than 40,000 sq. mi. and his revenue had multiplied (though even so his policy remained dependent on subsidies from foreign powers). His army, still small but unsurpassed for its effective training, gave him the place formerly held by Sweden in the political and military combinations of the period.

The permanent financial needs of the army, his main instrument of power, proved the strongest motive in the Great Elector's internal policy, by which he initiated the age of absolutism for his territories. He fought successfully for a regular income no longer dependent on the votes of the various estates, which represented the local interest of the ruling classes in the widely dispersed territories under his rule. While his predecessor had been forced to leave the most important sources of income under the control of the estates, Frederick William was able to establish a loyal bureaucracy, well organized for the supervision of his domains and for the administration of the land tax in the rural districts and of the new system of excise in the towns. But the nobility were compensated at the expense of the peasantry: the Junker class yielded political power but completed its economic and social domination.

of the countryside. The land tax was paid by the peasants alone (the nobility's exemption having been confirmed in 1653), the peasants' legal status deteriorated, and villenage was more firmly established than ever.

In religious matters Calvinists and Lutherans were placed upon an equality, but the elector was unable to impress his own spirit of tolerance upon the clergy, who were occupied with ecclesiastical squabbles. The state of education and of public morals left much to be desired.

The Kingdom of Prussia.—The new elector, Frederick III (see FREDERICK I, king of Prussia), reaped the results of his father's policy under more favourable conditions. He assisted William of Orange to make his descent on England in 1688, allied himself with other German princes against Louis XIV and afterward fought on the side of the empire against both France and Turkey. Frederick's chief adviser about this time was Eberhard Danckelmann (1643-1722), whose services in continuing the reforming work of the Great Elector were very valuable; but having made many enemies, the electress Sophie Charlotte among them, he fell from power in Nov. 1697 and was imprisoned for several years. The most important work of the elector was to crown the labours of his father by securing the kingly title for himself and his descendants. Broached in 1692, this matter was brought up again in 1698 when the emperor Leopold I and his ministers, faced with the prospect of a fight over the Spanish succession, were anxious to conciliate Brandenburg. It was at length decided that the title should be taken from Prussia rather than from Brandenburg as the former country lay outside the empire, and in return Frederick promised to assist Leopold with 8,000 men. The coronation ceremony when Frederick made himself "king in Prussia" took place at Königsberg on Jan. 18, 1701. In his later years Frederick was largely preoccupied with participation in the War of the Spanish Succession and with watching his country's interests in the vicissitudes of the great Northern War. The territorial additions to Brandenburg during this reign were few and unimportant, but the state's comparative wealth and prosperity enabled the elector to do a good deal for education and to spend some money on buildings. In 1694 the University of Halle was founded; academies for arts and sciences were established; and Berlin was greatly improved.

Frederick died on Feb. 25, 1713. The subsequent history of Brandenburg is merged in that of Prussia (*q.v.*).

BRANDENBURG (BRANDENBURG AN DER HAVEL), a city of Germany, lies on both banks of the Havel river, 61 km. (38 mi.) W.S.W. of Berlin. Pop. (1959) 86,862. Among the town's historic buildings are the cathedral on an island in the river, originally (1170) a Romanesque basilica but rebuilt in the Gothic style in the 14th century, and the 14th-century Gothic Katharinenkirche, built of brick. Brandenburg was much damaged in World War II and was largely rebuilt thereafter. Its industries include steel-works and the manufacture of tractors, machinery, textiles and leather; on the Plauer lake, west of the town are rolling mills, railway repair shops and an inland-water shipyard. Brandenburg is on the railway between Magdeburg and Berlin and is a busy inland-water port.

Slavs settled in the district by 512, and Brandenburg was founded as Brennabor or Brennaburg by the west Slavonic Hevelli tribe. The Hevelli were defeated in 928 by the German king Henry I ("the Fowler"), under whose son Otto I the town became a bishopric in 948. Fighting persisted between the Slavs and Germans until Albert I ("the Bear") subdued the Hevelli and in 1153 rebuilt the town. The Slav settlement on the south bank became

the Altstadt ("old town"); the German village on the north bank became the Neustadt ("new town") and the seat of the margraves of Brandenburg (*q.v.*). The two parts were not united under one municipality until 1715. In 1544 the bishop became Lutheran, and in 1598 the see was incorporated in the electoral domains.

After the dissolution of Prussia in 1947, Brandenburg became a regional capital in the district of Potsdam, German Democratic Republic.

BRANDES, GEORG MORRIS COHEN (1842-1927), Danish critic and scholar, who had an unrivaled influence on Scandinavian literature after 1870, was born at Copenhagen, Feb. 4, 1842, of a Jewish family. In his youth he was influenced by Kierkegaard, Taine, Sainte-Beuve and John Stuart Mill. Feeling it his mission to bring Denmark out of cultural isolation, he became a friend of Ibsen, who charged him to lead the revolution of the spirit for which he himself was fighting. In 1871 Brandes began a series of lectures at Copenhagen university, published as *Hovedstrømninger i det 19de Aarhundredes Litteratur* (1871-87; Eng. trans., *Main Currents in 19th-Century Literature*, 1901-05), describing the growth and defeat of reaction. He succeeded in creating a following among the Copenhagen intelligentsia, although attacked as an "atheist Jew" by conservative opinion. Having been refused the professorship of aesthetics at Copenhagen and victimized in other ways, he settled in Berlin from 1877 to 1883.

During the 1870s and 1880s Brandes wrote many scholarly studies, illustrating his radical ideas. These include monographs on Kierkegaard, Ferdinand Lassalle, Lord Beaconsfield and Ludvig Holberg, and *Det moderne Gjenembruds Mænd* (1883; "The Men of the Modern Break-Through"; *i.e.*, his own followers). His *Dnnske Digtere* (1877; "Danish Poets") shows his penetrating critical gifts. In the late 1880s, influenced by Nietzsche, Brandes developed a philosophy of aristocratic radicalism, expressed in various essays, 1889-1905 (collected in Eng. trans. as *Friedrich Nietzsche*, 1909), and in his later biographies of Shakespeare, Goethe, Voltaire, Julius Caesar and Michelangelo. In other writings he discussed contemporary problems and gave an account of his travels, especially in Russia and Poland. He never lacked courage in denouncing tyranny and violence, and throughout his life remained a controversial figure. Such works as *Sagnet om Jesus* (1925; Eng. trans., *Jesus, a Myth*, 1926) made him many enemies, but his influence spread far beyond his native country. He died at Copenhagen, where he had become a professor of aesthetics in 1902, on Feb. 19, 1927.

(1939-42); *Correspondance de Georg Brandes* (1952-). Brandes' autobiography was published in 3 vol. (1905-08). Between 1878 and 1930 most of Brandes' works were translated into English. There are authoritative Danish studies by A. Ipsen (1902-03); O. Hansen (1918); H. Nathanson (1929); P. V. Rubow (1927-32); G. Rung (1930); H. Fenger (1955-57); and English studies by E. Gosse, *Two Visits to Denmark* (1911); W. Archer, *Shirking the Issue: a Letter to G. Brandes* (1917); and J. Moritzen, *G. Brandes in Life and Letters* (1922). (E. L. Br.)

BRANDING. A brand is a distinctive design made by hot iron, chemical, tattoo or paint for purposes of identification of livestock or goods; in agricultural usage it may also include tagging and notching. Brands are applied to animals principally to establish ownership, but are also used widely for keeping records of purebred lines and for identification in disease control and age differentiation. Professional breeders sometimes adopt brands as trade-marks to indicate high standards of quality.

Historical evidence indicates that hot-iron branding of livestock was practised in Egypt as early as 2000 B.C. In the 16th century Hernando Cortes introduced branding to North America, using three Christian crosses to mark his cattle and horses. As ranching spread across the open ranges, brands to show ownership developed into a heraldry as colourful as the armorial bearings of knighthood.

Branding of beef cattle and horses continued in general use in parts of North and South America and Australia. To prevent duplication of brands and to give legal protection to livestock owners, national and state governments passed brands acts requiring registration of all brands and making it an offense to alter registered brands. In the range country of western United States:

laws require branding of cattle that run on public lands, and in some states it is illegal to slaughter unbranded animals. As hides became more valuable, laws were changed to permit stockowners to apply smaller brands to less valuable parts of the hide, such as jaw, neck or legs

Development of permanent tattoo inks led to increased use of this method of branding. Dairy cattle are commonly branded with tattoo hand pincers, the application usually being inside the ear. Horses are sometimes tattoo branded in the upper or lower lip with clamp devices. Commercial poultrymen and fur farmers also brand poultry and fur-bearing animals with tattoo marks.

Swine breeders identify their animals with ear markings and notchings, a method occasionally applied to cattle, goats and sheep. Sheep most usually, however, are branded on the back with paint or lanolin-based dyes that adhere to the wool and are resistant to sun, air and moisture, but are dissolvable in the wool-scouring process used in commercial plants.

In lumbering areas where logs are transported mainly by floating down rivers to sawmills, identification marks are applied to logs with branding axes. In the 19th century American loggers devised thousands of ingenious brands, many of them reflecting the lusty humour of the woodsmen. Sorters in the collecting booms were able to determine ownership by brands and thus route logs to the proper mills. Each end of a log was marked, and in areas where organized thieves "rustled" river timber by cutting off the ends, owners adopted the practice of stamping brands into the middle of the log for additional protection. (D. A. B.)

Human Branding.—The Greeks branded their slaves with a delta, Δ , for *doulos*, "slave." Robbers and runaway slaves were marked by the Romans with the letter "F" (*fur*, "thief"; *fugitivus*, "fugitive"); and the toilers in the mines and convicts condemned to figure in gladiatorial shows were branded on the forehead for identification. Under Constantine the face was not permitted to be so disfigured, the branding being on the hand, arm or calf. The canon law sanctioned the punishment, and in France galley slaves could be branded "TF" (*travaux force's*) until 1832. In Germany branding was illegal. The punishment was adopted by the Anglo-Saxons, and the ancient law of England authorized the penalty. By the Statute of Vagabonds (1537) vagabonds, gypsies and brawlers were to be branded, the first two with a large "V" on the breast, the last with "F" for "fray maker." Slaves who ran away were branded with "S" on cheek or forehead. This law was repealed in 1636. In the 18th century coinage offenses were punished by branding the right cheek with the letter "R" for "rogue." From the time of Henry VII, branding was inflicted for all offenses which received benefit of clergy, but it was abolished for such in 1822 (*see* CLERGY, BENEFIT OF). In 1698 it was enacted that those convicted of petty theft or larceny, who were entitled to benefit of clergy, should be "burnt in the most visible part of the left cheek, nearest the nose." This special ordinance was repealed in 1707.

Cold branding or branding with cold irons became in the 18th century the mode of nominally inflicting the punishment on prisoners of higher rank. Such cases led to branding becoming obsolete, and it was abolished in 1829 except for deserters from the army. These were marked with the letter "D" by tattooing with ink or gunpowder. Notoriously bad soldiers were also branded with "BC" ("bad character"). By the British Mutiny act of 1858

it was enacted that the court-martial, in addition to any other penalty, might order deserters to be marked on the left side, two inches below the armpit, with the letter "D," such letter to be not less than one inch long. In 1879 this was abolished.

In the colonies in America the branding of runaway slaves and petty criminals was fairly common but was abolished before the American Revolution.

BRANDON, a city in Manitoba, Can., on the Assiniboine river, 133 mi. W. of Winnipeg. Pop. (1961) 27,787. Brandon house, a Hudson's Bay Company post, was established there in 1793, but the present city dates from the coming of the railway (1881). It is an important road and rail centre, with an airport served by some transcontinental flights, and the market for a rich wheat-growing region. Industries include flour milling, meat packing, tanning, oil refining and light engineering. Brandon college is affiliated with the University of Manitoba, Winnipeg. Brandon also has a teachers' college and a government experimental farm and is the site of the annual provincial exhibition. (W. H. PR.)

BRANDY is an alcoholic liquor distilled from the fermented juice of grapes or other fruits and used as an after-dinner drink, as a flavouring in coffee and other foods and in mixed drinks. Brandy is usually aged for some time in wood. The word "brandy" came into the English language originally as *brandywine*, *brandewine* or *brandwine* from the Dutch *brandewijn*, from *branden*, "to burn," "distill," plus *wijn*, "wine." The art of distillation was known to the east long before it was introduced into the west. It was introduced to the Italians to produce *acqua di vite* or *arzenite* in the 13th century or earlier, and from there the art traveled to France, where it produced *eau-de-vie*. The Moors introduced the process into Spain. The production of brandy became much more widespread in Europe in the middle of the 17th century.

The processing and the distillation of brandy are governed by laws or regulations of the country in which the brandy is produced. France and the United States are the chief producers; others are Greece, Spain, Portugal, South Africa, Italy and Peru.

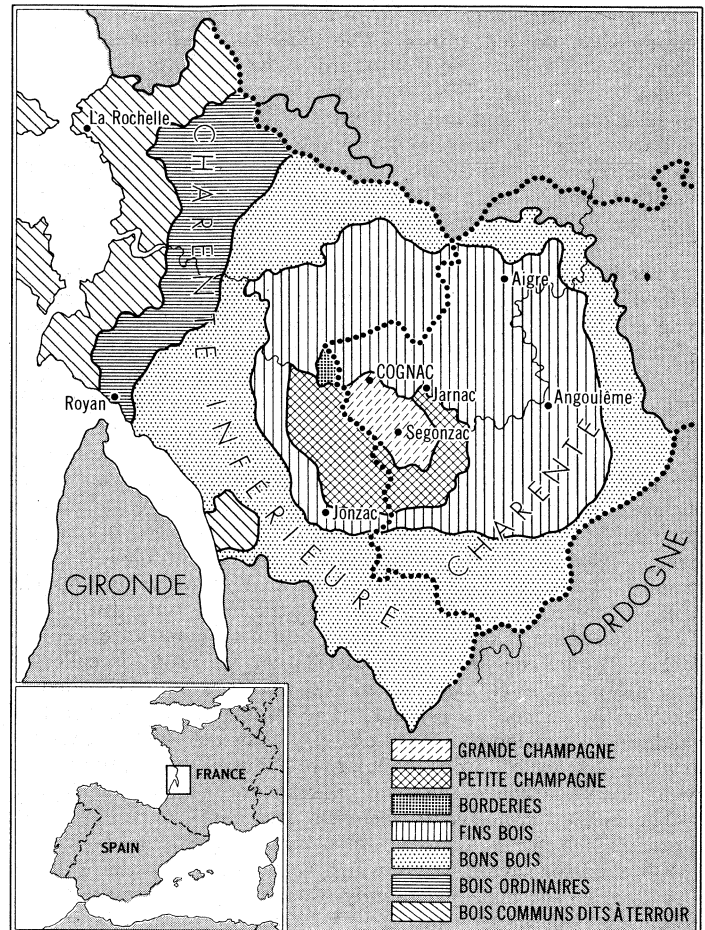

In the United States, under the Internal Revenue Code of federal regulations 1954, brandy is spirits distilled solely from the fermented juice, mash or wine of fruit, or from the residue thereof, and distilled at less than 190 proof (95% alcohol by volume) in such a manner that the distillate possesses the taste, aroma and characteristics generally attributed to brandy.

The regulations further state that brandy to be used as a beverage cannot be distilled over 170 proof (85% alcohol) and must be distilled from the juice or mash of whole, sound, ripe fruit or from natural wine, specially sweetened natural wine or standard agricultural wine made from dried fruit, having a volatile acidity calculated as acetic acid and exclusive of sulfur dioxide not in excess of .20 g. per 100 millilitres with or without the addition (to juice or wine only) of not more than 20% by weight of the pomace of such juice or wine, or 30% by volume of the lees of such wine, or both, and this is classed as fruit brandy. Pomace is the pulpy mass remaining after the wine or juice is drawn off the fruit. The lees are sediment, or dregs.

Grape brandy is derived exclusively from grapes and is labeled as grape brandy. Fruit brandy, other than grape brandy, derived exclusively from one variety of fruit, must be designated by the word "brandy," qualified by the name of such fruit; e.g., apricot brandy, cherry brandy, plum brandy, blackberry brandy, peach brandy, orange brandy, apple brandy, except that apple brandy may be designated as applejack.

Proof is an old English term for the strength or quality of spirits. In England 100 proof spirit contains 57.10% by volume of alcohol. In the U.S. proof spirit or 100 proof spirit contains 50% by volume of alcohol.

In the U.S. beverage brandies are distilled at not over 170 proof, while what is known as high-proof brandy can be distilled up to

COPYRIGHT 1940 BY HAROLD J. GROSSMAN. REPRODUCED FROM "GROSSMAN'S GUIDE TO WINES, SPIRITS AND BEERS" BY HAROLD J. GROSSMAN (REV. ED. 1955, CHARLES SCRIBNER'S SONS, NEW YORK). USED BY PERMISSION OF THE PUBLISHERS

MAP OF THE COGNAC DISTRICT OF FRANCE SHOWING THE SEVEN SUB-DIVISIONS WHERE WINES ARE MADE FROM GRAPES FOR DISTILLATION OF COGNAC

The lime content of the soil is greatest in the Grande Champagne and Petite Champagne areas where the finest wines are produced. The soil is less limy in the Borderies, Fins Bois, Bons Bois, Bois Ordinaires and Bois Communs Dits à Terroir areas. These five areas distill a cognac of varying quality

190 proof. The high-proof brandies are used almost exclusively in fortifying dessert wines. The annual production of beverage brandy in the U.S. in the early 1960s was approximately 3,000,000 proof gallons (one proof gallon = one gallon of 100 proof spirits), while the production of high-proof brandies (those between 170 proof and 190 proof) was approximately 27,000,000 proof gallons. High-proof brandy and neutral spirits are produced in Italy almost wholly for use in making sweet or fortified (dessert) wines.

The Cognac Region of France.—The most famous beverage brandies are produced in or near the town of Cognac, in the Charente *département* of southwestern France. For labeling purposes the Cognac brandy region was officially defined by decree on May 1, 1909, as including all of the Charente *département* except for a few northern communes and extending beyond the Charente boundaries on the north into parts of Deux-Sèvres *département* and on the southeast into Dordogne. Only those brandies produced in the officially defined Cognac region can bear the word "Cognac" on their labels. Much brandy, however, is produced in other regions of France, and in other parts of the world.

The Cognac region is divided into seven subregions according to the quality of brandy produced. The best quality brandy comes from grapes produced in the Grande Champagne subregion, followed by that made from grapes grown in the Petite Champagne. Cognac distilled from wines of the Borderies, Fins Bois, Bons Bois, Bois Ordinaires and Bois à Terroir subregions are of varying quality. The best brandies are distilled from grapes grown on soil with a high limestone content.

White varieties of grapes, for reasons not known, produce better brandy than do red grapes. The varieties used are the Folle-Blanche, St. Émilion and Colombard. The St. Émilion grape was used almost exclusively in the early 1960s because of its superior ripening qualities and ability to resist mildew and other causes of spoilage. The soil and climatic conditions make the grapes of the Cognac region highly acidic, and when the juice is fermented, the resulting wine has an alcoholic content of from 7% to 10%. The high-acid content contributes to the quality of the resulting brandies.

Processing Cognac Brandy.—In making the wine that is later to be distilled into cognac brandy the grapes are crushed in a roller-type crusher and pressed in a basket-type press. The white juice is allowed to ferment naturally without the addition of sugar or sulfur dioxide. The high acidity of this juice favours a clean fermentation with no deleterious flavours. It also seems to inhibit oxidation of the wine, which would adversely affect the flavour of the brandy. The wine is distilled during the winter months in the traditional pot stills of the region by the method known as the *méthode charentaise*. The still holds about 250 gal. and is enclosed in a brick firebox; either wood or coal is used to heat the wine. The first distillation, which is about 25% alcohol, is called *brouillis*. There are generally three charges of wine, and the *brouillis* collected is returned to the still for a final distillation. This distillation is done very slowly and with much care. About 1% to 2% of the first of the distillation, or heads, is collected separately and eventually mixed with the tails and redistilled to recover their alcoholic content. The middle cut or the heart of the brandy is called the *bonne chauffe*. This cut, which starts out at about 150 proof; drops gradually to about 68 to 70 proof, after which the remainder is run to tails to recover the remaining alcohol.

The cognac collected is then run into casks of Limousin or Tronçais oak for aging. Before being coopered into casks, the oak is aged for several years, which helps in imparting a desirable character to the brandy. Brandy when it comes from the still is colourless, but under aging in oak barrels or casks, it gradually becomes yellowish brown in colour; caramel colouring often is added to meet commercial standards. Before new casks are filled: they are often washed with steam under pressure and then soaked for some time with a solution of alcohol. Cognacs are sweetened with sugar sirup in order to soften the blend. The amount added is generally about ½% to 1% by volume. The particular flavour of cognac brandy is due, among other things, to an oily substance produced by yeast cells in the distilling substance, to certain qualities of the grape attributable to their variety as well as the soil and climate, to the variety of oak in which the brandy is aged, to long aging and to blending with older brandies. Most cognacs are from 5 to 10 years old but have some aged stock blended in them, which may be 25 or 30 years old.

Other Brandies.—Armagnac is a brandy produced in the *département* of Gers, and the best armagnac is produced in the Bas Armagnac. The white wine made for distilling is a wine made essentially from the same variety of grapes as those used in the Cognac region. However, the armagnac brandy is distilled in a type of still called the *alambic du Gers Systkme Verdier*. The wine is fed into this still continuously, but the spent wine is drawn off intermittently. The brandy flows from the still at about 52% to 54% alcohol and is run into casks of about 100-gal. capacity. Only one distillation of the brandy is made. These casks are made from Gascony black oak, which is given a great deal of credit for the distinctive flavour of armagnac brandy. Armagnac is recognized as an outstanding brandy. Here again proper maturation in the wood is as necessary to produce a good armagnac as a cognac.

Stars on brandy labels have no standardized meanings. Neither do such symbols as "V.S.O.P.," which once meant "very superior old pale" brandy. The so-called Napoléon brandies 80 to 104 years old are a bit of romantic nonsense aimed at promoting sales. Whereas cognac will age in the wood with improvement for from 50 to 55 years, the cost of aging brandy this long would be extremely excessive. Brandy ages either very slowly or not at all in the bottle.

Some brandy is made by distilling the pomace, or marc. In France this brandy is known as *eau-de-vie de marc* and is akin to the top brandy of South Africa and the *grappa* brandy in the United States.

In the U.S. most of the grape beverage brandy is produced in California by the use of continuous or column stills. Not much attention is paid to the grape varieties used. The use of a column still with its accompanying high rectification (purification) apparently eliminates certain of the congeners responsible for the distinguishing character and flavour of the cognac brandies. There also is a tendency to make the California brandy more neutral. The California brandy is generally a straight brandy barreled at 102 proof in either new or used white oak cooperage of about 50-gal. capacity. Rectification of beverage brandy is allowable upon payment of an excise tax and provided that not more than 2½% by volume of approved ingredients are added. These added ingredients are generally sugar, sirup and wine, which tend to give body and smoothness to the final product. Brandy is generally aged about four to six years in California. No old stocks of brandy are kept for blending purposes as in France. The quality of California brandy is generally improving. Most of the aldehydes and a large percentage of the fusel oils are now being removed.

Composition.—A chemical analysis of five different types of brandies gives the following results:

Contents (in mg. per 100 ml., proof and pH)	Types of brandies				
	8-year-old California brandy, new white- oak barrels	1-year-old California brandy, re-used barrels	California rectified brandy	French cognac, age unknown Sample A	French cognac, age unknown Sample B
Proof	84.0	84.0	84.0	84.0	84.6
pH	3.99	4.48	4.5	4.12	4.14
Total acid	72.3	14.3	11.4	44.3	5.15
Aldehydes	16.3	5.9	1.76	8.1	8.6
Ester:	42.0	1.6	15.8	36.0	4.43
Fusel oil	114.0	45.5	42.8	132.0	—
Furfural	2.2	0.18	—	1.4	0.13
Tannin	42.0	11.6	—	29.0	—
Copper	—	0.46	0.03	7.2	—
Reducing sugar Extract	54.0 160.0	23.4 78.9	—	—	—
Volatile acid	—	—	—	—	3.42
Higher alcohols	—	—	—	—	13.38
Methyl alcohol	—	—	—	—	0.0017
Solids	—	—	—	—	97.5

The congeners in brandy are responsible for its taste and character, but it is recognized that the amounts necessary are quite small in comparison to the volume of the spirits. In France the brandies are required to have a minimum "coefficient of non-alcohol," obtained by totaling the contents of these substances and expressed as milligrams per 100 millilitres of absolute alcohol. The lowest coefficient permitted is 280, but, generally, French brandies average 400 or 500 or more.

See ALCOHOLIC BEVERAGES, DISTILLED: *Brandy; Modern Types of Stills.* (E. M. BN.)

BRANDYWINE, BATTLE OF, an engagement of the American Revolution (*q.v.*) fought Sept. 11, 1777, in which Sir William Howe's British army of about 15,000 defeated George Washington's American army of about 11,000. The battle took place in the vicinity of what is now Chadds Ford, on Brandywine creek in southeastern Pennsylvania, about 25 mi. S.W. of Philadelphia. The area is now maintained as a battlefield park by the commonwealth of Pennsylvania.

Howe's Philadelphia campaign is among the most controversial of the Revolution, for it was conducted simultaneously with Gen. John Burgoyne's invasion of New York. Howe's absence from the New York area was an important factor in Burgoyne's disaster at Saratoga (*see SARATOGA, BATTLES OF*). Apparently, Howe was lured to Philadelphia by a belief that its large Tory element would rise up when joined by a British army and virtually remove Pennsylvania from the war. Leaving Burgoyne to fend for himself, therefore, Howe embarked his army at New York city early in July 1777 and proceeded, by way of Chesapeake bay, to approach Philadelphia from the south and west. Landing at the

head of the Elk river, Howe's troops marched toward Philadelphia but found Washington's army barring their crossing of the Brandywine. Rather than attempt to force the sometimes steep banks of the creek, Howe merely feinted against Washington's front with one wing of his army, while he marched northward with a somewhat stronger wing to cross the Brandywine and fall upon the American right and rear. At best he hoped this envelopment might destroy the American army; short of that, the enveloping column might interpose itself between Washington and Philadelphia and, thus, open the city. During the morning and early afternoon of Sept. 11. Washington unaccountably ignored evidence that Howe was turning his right. Thus, the turning column was across the Brandywine before Washington reacted to it, and the troops he dispatched to oppose it had little time to form a defensive line. Hastily assembled, both flanks of the new American line quickly collapsed. The centre fought valiantly, however, and held long enough to permit the army reserve to form a second line, which: in turn, held stubbornly to protect the road toward Philadelphia so that Washington might withdraw safely those troops who had remained in the original position along the Brandywine. In the end, the British troops occupied the battlefield, but they neither destroyed Washington's army nor cut it off from the American capital at Philadelphia. Washington still stood before the city, and it required a skilful campaign of maneuver before Home could find his way into it. Even then, the bravery of many of the American troops kept Washington's army intact and, thus, the Revolution alive. (R. F. WE.)

BRANGWYN, SIR FRANK (1867-1956), English decorative painter, was born May 13, 1867, at Bruges, Belg. When he was 15 he began designing textiles for William Morris, and a large collection of his work is at the William Morris museum; Walthamstow, Essex. After selling his first picture at the Royal Academy exhibition of 1885, he went to sea, visiting Africa and the east, where he acquired a great love of oriental art. Elected to the Royal Academy in 1919, he was knighted in 1941 and in 1952 became the first living artist to be honoured with a retrospective exhibition at the academy. Brangwyn showed his mastery of design in richly if somewhat floridly coloured, dramatic, large compositions, such as those in Skinner's hall and the Royal exchange. London, Christ's hospital. Horsham, Sussex, the Canadian house of parliament, Ottawa and Radio city, New York. His work on the royal gallery in the house of lords, begun in 1925, was rejected when partly finished, and in 1933 he presented it to the town of Swansea, Wales. Brangwyn also worked as architect, book illustrator, and pottery and stained glass designer. He died at Ditchling, Sussex, on June 11, 1956.

BRANKS (SCOLDING BRIDLE), a contrivance formerly in use throughout England and Scotland for the punishment of scolding women. It seems never to have been a legalized form of punishment, but corporations and lords of manors in England, town councils, kirk sessions and barony courts in Scotland assumed a right to inflict it. While specially known as the "gossip's or scold's bridle," the branks was also used for women convicted of petty offenses, breaches of the peace, street brawling and abusive language. Apparently, it was not used in America, where, instead, the tongue of the scold was sometimes put into a cleft stick.

In its earliest form it consisted of a hoop headpiece of iron, opening by hinges at the side so as to enclose the head, with a flat piece of iron projecting inward so as to fit into the mouth and press the tongue down. Later it was made, by a multiplication of hoops, more like a cage, the front forming a mask of iron with holes for mouth, nose and eyes. Sometimes the mouth plate was armed with a short spike. With this on her head the offending woman was marched through the streets by the beadle or chained to the market cross to be gibed at by passers. The date of origin is doubtful. It was used at Edinburgh in 1567, at Glasgow in 1574, but not before the 17th century in any English town. A branks in the church of Nalton-on-Thames, Surrey, bears

the date 1633, and as late as 1856 another was in use at Bolton-le-Moors, Lancashire.

See W. Andrews, *Old Time Punishments* (1890); A. M. Earle, *Curious Punishments of Bygone Days* (1896).

BRANSFIELD, EDWARD (c. 1795-1852), English naval officer who was the first man to chart a portion of the antarctic mainland and holds the honour of having discovered that continent. The South Shetland Islands were discovered in Feb. 1819 by W. Smith, during a voyage to Valparaiso, Chile, in the brig "Williams." On arrival, he reported to Capt. W. H. Shirreff of H.M.S. "Andromache," who subsequently chartered and dispatched the "Williams" to survey the newly discovered lands. Shirreff appointed Bransfield, master of the "Andromache," to command this voyage, Smith remaining aboard as pilot. The "Williams" arrived at the South Shetlands in Jan. 1820. Bransfield repeated Smith's examination of the islands, landed on King George Island to take formal possession and coasted to Deception Island. He then turned southward, charted Tower and Ohlin islands and skirted the northern coast of Trinity peninsula, sighting and charting "high mountains, covered with snow" (Mts. Bransfield and Jacquinet). This discovery was made on Jan. 30, 1820. He then followed the ice edge to Elephant and Clarence islands, where he repeated the ceremony of taking possession.

On his return to Valparaiso, Bransfield delivered his charts and journals to the senior naval officer, who forwarded them to the admiralty. The original charts survive in the hydrographic department, but his journal has been lost. No official account of the voyage was issued, but two private versions are extant, in the *Edinburgh Philosophical Journal* (April 1821) and in the *London Literary Gazette* (Nov. 1821).

See *Geographical Journal* (Oct. 1939) and *Mariner's Mirror* (July 1941). (B. B. RS.)

BRANT, JOSEPH (1742-1807), American Indian chief of the Mohawk tribe, known also by his Indian name, THAYENDANE-GEA, was born on the banks of the Ohio river in 1742. He was educated at Lebanon, Conn., in Moor's Indian Charity school, in which Dartmouth college had its origin. He took part, on the side of the English, in the French and Indian War and in 1763 fought with the Iroquois against Pontiac. He later devoted himself to missionary work and translated the Prayer Book and St. Mark's Gospel into the Mohawk tongue (1787). When Guy Johnson (1740-88) was named superintendent of Indian affairs in 1774, Brant became his secretary. At the outbreak of the American Revolution, he remained pro-British and organized and led the Mohawks and other Indians allied to the British against the settlements on the New York frontier. After the war he discouraged the continuance of Indian warfare on the frontier and aided the commissioners of the United States in securing treaties of peace with the Miamis and other western tribes. Settling in Upper Canada, he again devoted himself to missionary work and in 1786 visited England, where he raised funds to erect the first Episcopal Church in Upper Canada. His character was a peculiar compound of the traits of an Indian warrior—with few rivals for daring leadership—and of a civilized politician and diplomat of the more conservative type. He died on an estate granted him by the British government on the banks of Lake Ontario on Nov. 24, 1807.

BRANT, SEBASTIAN (1458?-1521), German humanist and poet, best known as the author of *The Ship of Fools*, was born at Strasbourg. He studied in Basel, where he was made doctor of laws (1489) and taught in the law faculty. When Basel joined the Swiss confederation (1499), Brant returned to Strasbourg; in 1503 he became city clerk. Maximilian I appointed him imperial councillor and count palatine. His writings are varied: legal; religious (hymns to the Virgin and the saints); political (in support of Maximilian, against the French and Turks); and, especially, moral (adaptations of medieval didactic works: *Facetus*, 1496; *Disticha Catonis*, 1498; *Freidank*, 1508). His chief work, however, is *Das Narrenschiff* (*The Ship of Fools*, 1494), which tells of a shipload of fools setting sail for Narragonia, the fools' paradise. The ship allegory, probably familiar to readers from Shrovetide customs, is not sustained; instead, Brant presents satirically over 100 fools representing every contemporary short-

coming, serious and trivial. His aims are the improvement of his fellows and the regeneration of church and empire. The language is popular, the verse rough but vigorous, and each chapter is accompanied by a woodcut, probably by Albrecht Dürer, beautifully executed but often only loosely connected with the text. Its success was immediate. Numerous editions and adaptations appeared, as well as translations into Latin (the first by Jakob Locher, 1497), Low German, Dutch, French and English (the first by Alexander Barclay, 1509). A whole "fool literature"—by Erasmus, Thomas Murner, Hans Sachs, Johann Fischart—followed. Yet Brant essentially looks backward. He is not a forerunner of the Reformation nor even a true humanist, but rather a last embodiment of medieval thought and ideals.

BIBLIOGRAPHY.—The best edition of *Narrenschiff*, by F. Zarncke (1854), contains most of the other works; there is a facsimile ed. by F. Schultz (1913); and a modern Eng. trans. by E. H. Zeydel (1944). See also A. Pompen, *The English Versions of the Ship of Fools* (1925); *Die deutsche Literatur des Mittelalters. Verfasserlexikon*, ed. by W. Stammler, vol. 1 and 5 (1933 and 1955). (J. R. WE.)

BRANTAS, a river in east Java, Indon. In its almost circular course of 120 mi., it drains a watershed of about 4,400 sq.mi. The Brantas has its source 5,500 ft. up on the south side of the saddle between the volcanic Andjasmoro and Ardjuno peaks and flows south across the Malang plateau. The river then turns west through a ravine where Mt. Kawi abuts on the southern limestone range (Gunung Kidul), and turning north enters the wide Kediri plain, a region which grows rice and sugar. From Kediri city downstream the river is diked. On the border of Surabaya district the Brantas is joined by the Widas from the left and the Konto from the right. The central limestone range (Gunung Kendeng) forces the Brantas eastward toward the Madura strait. Below Modjokerto it divides into several delta arms; the northernmost is the Surabaya river, on which lies the city of that name; the southernmost branch is the Porong. This carries the largest volume of water. In the dry season the flow is only 2.825 cu.ft. per second, but in the wet season maximums of 60,035 cu.ft. have occurred (at Kediri). Large amounts of sand, particularly from the Kelut volcano, have raised the river bed, impeding the drainage of adjoining areas. Several engineering works have been carried out in the last century to protect the sea approach to Surabaya from silting and to improve irrigation and drainage in the delta. (J. O. M. B.)

BRANTFORD, the county seat of Brant county, Ontario, Can., is located 21 mi. W. of Hamilton on the Grand river, which was formerly commercially navigated between Brantford and Lake Erie. First named Brant's Ford after Joseph Brant (*q.v.*), the Mohawk chief who was granted the site in 1784 for settlement of the Six Nations Indians, after the American Revolution. Brantford was incorporated as a town in 1847 and became a city in 1877. Agricultural implements, motor coaches, truck bodies, refrigerators, stoves, garments and clocks are among the products of more than 150 factories. The city has a statue and a monument commemorating Alexander Graham Bell's first successful experiment with the telephone carried out at nearby Tutela Heights where the Bell homestead is now a museum. Pop. (1961) 54,458. (G. FN.)

BRANTING, KARL HJALMAR (1860–1925), Swedish statesman, a pioneer of social democracy in his country and the winner of the Nobel peace prize in 1921, was born in Stockholm on Nov. 23, 1860. After studying science at Stockholm and at Uppsala, he began work for the Radical newspaper *Tiden* in 1883 and became its editor shortly afterward. From 1886, however, he was editor of the *Socialdemokraten*, and when the Social Democratic Labour party was formed in Sweden in 1889, he was prominent among its founders. Elected to the lower chamber of the *riksdag* for the first time in 1896, he was until 1902 the only Social Democrat in it. His advocacy did much to ensure that the separation of Norway from Sweden came about peacefully in 1905. In 1907 he became the leader of his party.

Branting had been energetic in his party's mobilizing of the working classes in support of the demand for adult, equal and direct suffrage (see SWEDEN: *History*); but he also took care to make co-operation possible between his party and the progressive

middle class. From this resulted the Liberal-Socialist coalition government of 1917 (in which he was minister of finance) and the constitutional reform of 1918, which facilitated the spread of social democracy throughout Sweden.

Throughout World War I, Branting insisted that Sweden should be strictly neutral. He was appointed delegate to the Paris peace conference in the spring of 1919 and to the London discussions on the Aland Islands in 1920. He was also the first Swedish representative in the assemblies of the League of Nations, becoming a member of its council in 1923. He was chairman of the Berne conference of the Second (Socialist) International in 1919 and became a member of the permanent international commission for reconstruction within the International.

In March 1920 Branting formed Sweden's first Social Democratic government, but the elections of the following September went against him. The elections of Sept. 1921, however, enabled him to form another government, which remained in power till April 1923. In Oct. 1924 he formed a third government, but ill-health made him resign the leadership to Rickard Sandler on Jan. 25, 1925. He died in Stockholm on Feb. 24, 1925.

BRANTÔME, PIERRE DE BOURDEILLES, ABBÉ AND SEIGNEUR DE (*c.* 1540–1614), French soldier and chronicler, and author of a valuable and informative account of his life and times. He was born in Périgord, third son of the baron of Bourdeilles, at some date between 1539 and 1542. After spending his early childhood at the court of Marguerite de Valois, where his mother and maternal grandmother were ladies of the royal household, he went to Paris to continue his education, which was finished at the university at Poitiers in 1555. He then visited the court of Henry II, by whom he was given the abbey of Brantôme, but, although he also held several other benefices, his contact with religious life was limited to the enjoyment of ecclesiastical revenues.

Adventurous and brave by nature, though without any real military talent, he passed most of his life in the combined roles of courtier and soldier. Between 1557 and 1569, wars and fighting took him to Italy, Spain, Portugal, Malta and north Africa, while in 1561, when he was part of the retinue of the widowed Mary Stuart, he visited Scotland and England. Intermittent fever forced him to retire to his abbey from 1569 to 1571. Thereafter during the reigns of Charles IX and Henry III he was rarely absent from court until he incurred royal disfavour. In the wars of religion he fought against the Huguenots and took part in the siege of La Rochelle, but he was influenced by the ideas of the reformers. In later years, severe incapacity resulting from a fall while riding provided him with the opportunity to write. He died on July 5, 1614.

His works, characterized by frankness and naïveté, consist mainly of accounts of battles or tales of chivalry. Though not a great or reliable historian, his bold, capricious and amoral character well equipped him to be a chronicler of the 16th century. The first edition of his works was published posthumously in 1665 and 1666 as *Mémoires de Messire Pierre de Bourdeilles*. It comprises *Les vies des dames illustres*, *Les vies des dames galantes*, *Les vies des hommes illustres et grands capitaines français* and *Les vies des hommes illustres et grands capitaines étrangers*. There were many later editions, most of which have also included *Discours sur les duels*; the edition produced by Ludovic Lalanne for the Société de l'Histoire de France (11 vol., 1864–82) is definitive.

BRAQUE, GEORGES (1882–), one of the most distinguished modern French painters. was born at Argenteuil on May 13, 1882. His youth was passed at Le Havre where he became an apprentice house painter and attended night classes in drawing; he then moved to Paris. His early paintings (1906–07) were in the Fauve style but soon he came under the influence of Cézanne. This led to a close friendship with Picasso and subsequently to the development of Cubism. The paintings of the two artists for the next years (1910–14) were often quite similar: still lifes of bottle.

glass and tobacco. or a seated figure severely broken into angular planes in colours of tan and gray with occasional insertion of block letters. Braque seems to have originated the collage (*papier collé*), a Cubist picture, composed mainly of cutout strips of newsprint or wallpapers pasted on canvas. After serving in World War I, he returned to a less austere kind of Cubism: still lifes of musical instruments on a table with textural variations of marbleizing, wood graining or sand-roughened surfaces. Toward 1920 the lingering geometric traits of Braque's Cubism began to be softened by elaborations of brushwork and looser drawing, particularly in his large paintings of fruit, flowers, pitchers or guitars, magnificently composed on low-keyed harmonies of gray-green, black and oyster white. Though he occasionally did figure paintings, especially of ancient Greek subjects, and a few small landscapes of the Norman coast, his best work was in still life, particularly his paintings of the 1920s and 1930s. During World War II his health suffered but he managed to paint many large canvasses, somewhat looser in execution than his previous work. Braque also made prints, colour lithographs, plaster reliefs and a few small sculptures. In the 1950s he worked with the theme of birds in flight. After World War II his painting became more colourful and impressionistic but did not lose its former subtle beauty. His later painting is the epitome of French taste and elegance.

BRAS D'OR LAKE, a complex lake system occupying 360 sq.mi. in the heart of Cape Breton Island, Nova Scotia. The water is saline but tideless. Two channels, the Great Bras d'Or and Little Bras d'Or, join the lake to the Atlantic ocean at the north end, while St. Peter's canal (less than one mile in length) connects it with the ocean at the south. The lake system has many channels and bays and is surrounded by high hills and deep glens. At Baddeck, pop. (1956) 772, Alexander Graham Bell and others founded the Aerial Experiment association in 1907, and his friend J. A. D. McCurdy made the first public airplane flight in the British empire two years later. See also CAPE BRETON ISLAND. (C. W. RD.)

BRASIDAS (d. 422 B.C.), a Spartan officer and the only commander of genius whom the Spartans produced during the Archidamian War, the first decade of the Peloponnesian War (q.v.). He won his first laurels by the relief of Methone, which was besieged by the Athenians (431). During the following year he seems to have been eponymous ephor, and in 429 he was sent out as one of the three commissioners to advise the admiral Cnemus. As trierarch he was wounded in the assault on the Athenian position at Pylos in 425.

In the next year, while Brasidas mustered a force at Corinth for a campaign in Thrace, he frustrated an Athenian attack on

Megara. Immediately afterward he marched through Thessaly with a force of helots and mercenaries and, refusing to join the Macedonian king Perdiccas in a private war, set about breaking up the Athenian empire in the north. During the winter he won over to alliance with Sparta the cities of Acanthus and Stagirus, and, most important of all, the Athenian colony of Amphipolis.

An attack on Eion was foiled by the arrival of Thucydides, the historian, at the head of an Athenian squadron. In the spring of 423 a truce was concluded between Athens and Sparta, but Brasidas refused to give up Scione, which, the Athenians declared, revolted two days after the truce began, and he occupied Mende shortly afterward. Thus, fighting still continued in Thrace. An Athenian fleet recovered Mende and blockaded Scione, which fell two years later (421).

In April 422 the truce with Sparta expired, and the Athenians sent Cleon to recover Thrace. By the skilful generalship of Brasidas the Athenian army was routed at Amphipolis and Cleon was slain, but the Spartan general also fell. He was buried at Amphipolis, and the sacrifices which had formerly been offered to the Athenian founder Hagnon were transferred to him. Brasidas and Cleon had been leaders of the war party, and their deaths enabled Athens and Sparta to conclude the peace of Nicias (421).

Brasidas possessed charm and eloquence, qualities unusual in a Spartan, and his diplomatic treatment of the cities caused the allies of Athens to regard Sparta more favourably and paved the way for revolt against Athens after the disaster in Sicily.

BRASÍLIA, the federal capital of Brazil, is in the west central state of Goiás (q.v.) at the headwaters of the Tocantins, Paraná, São Francisco and Corumbá rivers. The serenely rolling federal district of 2,245 sq.mi. is 550 mi. N. of São Paulo, 580 mi. N.W. of beautiful but overpopulated Rio de Janeiro and 640 mi. S.W. of São Salvador from whence the capital had been moved to Rio de Janeiro in 1763.

The site selection completed a search which began in 1789 with the first recorded mention by the Inconfidentes hfineros who started the first movement toward independence from Portuguese domination. In 1822 José Bonifácio de Andrada e Silva, the "Patriarch of Independence," proposed the movement of the capital to the interior. With the founding of the republic in 1889, the projected movement to the central plateau was set down in the constitution. In 1894, a commission under Luiz Cruls recommended a general area in the sparsely populated temperate central plateau at an elevation of 3,500 ft. A 1948 commission under Gen. Polli Coelho made no progress toward defining a site and it was not until 1956 that a definitive site was chosen by a commission under Marechal José Pessoa. The technical work was a joint Brazilian

"THE WARRIORS." A MONUMENT TO THE CITY BUILDERS BY BRUNO GIORGI. STANDING BEFORE THE PALACE OF JUSTICE, BRASÍLIA

and United States enterprise under the direction of Donald J. Belcher, Thomas W. Mackesey and Hollister Kent from the United States and Edson de Alencar Cabral and Placidino Machado Fagundes from Brazil. No site for a city has been so carefully chosen. Consideration was given to topography, climate, drainage, water supply, geology, soils, land use, engineering, power, transportation, recreation, building materials, public administration, scenery and the general relation of man to his surroundings.

A combination of aerial photoanalysis, photogrammetry and ground surveys was used on the study area of 20,000 sq. mi. In the process, topographic maps were produced for the entire study area, for five city sites in particular and for the federal district to surround the site finally selected. Thus, not only was information prepared for the capital site, but also a large amount of data was made available for the future development of many urban areas and vast regions to support them.

The project was conceived with the dual object of serving the administrative needs of a fast-growing nation and providing a nucleus for the development of the vast expanses of the Brazilian back country and at the same time removing the centre of political life from Rio de Janeiro, a city which in many ways was unsuited to serve as an efficient capital. In essence, the main object was to speed up national development.

As soon as the site was selected in 1956, a new federal commission was formed to finance, construct and move the capital. Its first act in March 1957 was to conduct a capital design competition limited to Brazilians. The winning design for Brasília, the world's first air-age capital, resembled a huge airplane or a cross which its designer, Lúcio Costa, described as the primary gesture of one who marks or takes possession of a place.

The seat of the federal government was moved in April 1960, as Pres. Juscelino Kubitschek had designated. The Brazilian architect Oscar Niemeyer was commissioned to prepare designs for the first major governmental buildings.

Brasília had an estimated population (1960) of 120,000; the projected population is 500,000. (H. KT.)

BRAȘOV (formerly **STALIN**; Ger. **KRONSTADT**; Hung. **BRASSÓ**), a town in central Rumania, headquarters of the Brasov *regiune* (administrative and economic region) and centre of the old German district of the Burzenland, lies on the northern slope of the Transylvanian Alps at an elevation of 1,900 ft., 75 mi. N.N.W. of Bucharest. Pop. (1960 est.) 128,882. In a valley opening northeast toward the plain, the inner town with its old walls is dominated by the Tâmpa mountain (3,140 ft.); it contains the town hall (1420, restored 1777); the Gothic Protestant church (1425), called the Black church because of its smoke-stained walls caused by the fire of 1689; the Orthodox St. Nicholas church (1392, restored 1751); the ruined citadel (1553) on a steep hill; and the 13th-century St. Bartholomew's church. In the town are the polytechnic, a state theatre and a regional museum and library. "The apostle of Transylvania," Johannes Honterus (1498-1549), who led the Reformation in the area, was born and died in Kronstadt, and established there the first printing press in Transylvania. There also was published in mid-16th century the first book printed in Rumanian, by the deacon Coresi.

Adjoining the chief passes from Transylvania into Moldavia and Walachia, Brasov is an important rail and road junction and is linked by air services with Bucharest, Cluj and Tîrgu Mures. Industrial development, initially stimulated by neighbouring deposits of lignite, was expanded by the Communist regime, and production included tractors, trucks, electrotechnical equipment, chemicals and textiles.

Brasov was founded by the Teutonic Order in 1211 and settled by Germans, becoming one of the chief centres of expatriate Germans in Transylvania (*q.v.*). Under Habsburg rule they enjoyed a substantial autonomy that was ended in 1876 by the abolition of their separate national status. Following World War I Brașov with Transylvania was ceded by Hungary to Rumania, but in 1922 more than 30% of its inhabitants described themselves as Germans. Between 1950 and 1960 it was named Stalin or Orasul Stalin ("Stalin city"), after which it reverted to its former name of Brasov.

BRAȘOV ADMINISTRATIVE AND ECONOMIC REGION had a population (1960 est.) of 1,034,021 and an area of 5,826 sq. mi. In the south the Transylvanian Alps reach 8,343 ft. (Mt. Moldoveanu). The climate is colder than that of the rest of Rumania, with a mean temperature of 47° F. and about 31½ in. annual precipitation. The chief towns are Brasov, Sibiu (*q.v.*), Medias, Sighișoara and Săcele, a new industrial centre near Brasov. Forest covers about 30% of the region and agricultural land 60%; wheat, maize (corn), sugar beets and potatoes are the chief crops, and livestock is raised. Industrial development was encouraged by rich supplies of natural gas (methane) at Bazna, Copșa Mică and Saraș amounting to nearly three-quarters of Rumanian output, by lignite deposits and by the hydroelectric power station on the Sadu river. Industrial products include machinery, ball bearings, machine tools, timber, pulp and paper, cement, glass and food products.

BRASS, an alloy consisting mainly if not exclusively of copper and zinc; in its older use the term was applied rather to alloys of copper and tin, now known as bronze (*q.v.*).

The brass of the Bible was probably bronze, and so also was much of the brass of later times, until the distinction between zinc and tin became clearly recognized. It is quite likely that from very early times brass was made accidentally, owing to the admixture of zinc ores with those of copper, but was not recognized as distinct from bronze. The Latin word *aes* signifies either pure copper or bronze, not brass, but the Romans comprehended a brass compound of copper and zinc under the name of *orichalcum* or *aurichalcum*, into which, according to Pliny, copper was converted by the aid of cadmia (a mineral of zinc). One of the earliest examples of Roman brass is a coin of date 20 B.C. containing 17.3% zinc. There was considerable production of brass in the Low Countries commencing about A.D. 300, and it became an important article of commerce. Monumental brasses, memorials of hammered sheet brass, or latten, may still be seen in many churches, particularly in East Anglia. The word latten is a corruption of the French word *laiton*; and until about 1550 latten was always imported from Flanders and Germany. One of the earliest lattens in England is at Stoke d'Abernon (c. 1277). The composition of these lattens is approximately 66% copper, 1%-3% tin, up to 7% lead and the remainder zinc. (See also METALWORK, DECORATIVE.)

There is good evidence of the manufacture of brass in England in the 16th century, for Queen Elizabeth I by patent granted to William Humfrey and Christopher Schutz the exclusive right of working calamine (zinc ores) and making brass. This right subsequently devolved upon a body called "The Governors, Assistants and Societies of the City of London of and for the Mineral and Battery Works," which continued to exercise its functions down to the year 1710. The word battery refers to the process of hammering brass into sheets, which was the normal method in England for some 200 years; but by the latter half of the 18th century this method began to be superseded by the rolling mill, and became obsolete. Until 1850 brass was still being made by the process in which copper shot were heated with zinc ores and charcoal. The resulting partially-brassed shot were then melted, mixed and cast. This process, however, had been going out of favour since 1781, when James Emerson patented the production of brass from copper and zinc metals, which replaced the older method.

Copper and zinc mill alloy in all proportions, but there are several distinct series, known technically as solid solutions, which are distinguished by the letters of the Greek alphabet, the alpha brass having the greatest percentage of copper and being the sole constituent of all wrought brasses containing over 63% copper. It is to this constituent that brass owes its malleability and general usefulness. (See also Brass Manufactures, below.) The beta constituent contains less copper and is of a much harder nature. As it increases, the brass (37%-45% zinc) becomes less amenable to cold-work, but well adapted to hot-work. The other solid solutions contain less and less copper. (For further information on solid solutions see ALLOYS.)

Malleable and Nonmalleable Brass.—The brasses may be conveniently divided into two groups by the test of malleability,

the dividing line being about the composition of 55% copper and 45% zinc. All the higher copper alloys are workable either hot or cold and in some cases both hot and cold, while the remainder are not malleable at all.

The unworkable brasses are known as the white brasses and are not of great industrial importance. The 50% mixture is much used in a crushed or granulated form for purposes of brazing, and those with lower percentages of copper can be cast and used for sliding parts, since though brittle they offer considerable resistance to frictional abrasion. They also form the basis of certain alloys used for die casting (*q.v.*), a form of casting which came into much prominence after World War II.

The malleable brasses may be further divided into the cold-working and the hot-working alloys. The dividing line is not precisely drawn but commercially it is not usual to cold-work alloys of less than 62% copper on account of increasing hardness and brittleness. Hot-working of the high copper alloys is feasible only with brass practically free from lead, which usually is added to facilitate machining; hot-working does not give the smooth surface, the dimensional accuracy or the hardening which is obtained with cold-work. Hot-worked brass is often finished cold.

The most widely used of the brasses are those around 70% copper, or cartridge brass, and from 62% to 67% copper. The former is the most suitable for extreme amounts of cold-work and the latter, with lead from $\frac{1}{2}$ % to 3%, for combined cold-work and machining operations. Cartridge brass, cold-worked, has a tensile strength of 30 to 45 tons per square inch and 10% elongation or less; when soft annealed, of some 22 tons and up to 70% elongation. The general mechanical properties of brass vary widely; indeed it is this wide range which makes brass such an important alloy. By variation of the composition, or by the amount of cold-work put upon the metal, or by the degree of annealing, a tensile strength of from 15 to 45 tons per square inch, an elongation of from 3% to 70% and a hardness of from 60 to 150 Brinell can be obtained with all the intermediate degrees. It is readily drawn into fine wire, rolled into strips as thin as .001 in., drawn into tubes and extruded as rods or sections.

Colours of Brass.—The alloys of copper and zinc give a remarkable series of colours, of which the most notable are those with about 80% of copper, since they simulate gold, and have names which were once familiar, such as Dutch metal, Mannheim gold, pinchbeck (invented by Christopher Pinchbeck, a London clockmaker, in 1732), and others too numerous to mention. The colours due to composition vary from that of pure copper through yellow to dull white. Brass is susceptible of a fine polish, but tarnishes on exposure to the air; the brilliancy of the surface can however be preserved if the metal is thoroughly cleansed and lacquered. The brasses also lend themselves to a variety of chemical and heat colour finishes which are quite different from the natural colours of the alloy. There is also the possibility of producing a thin almost invisible oxide film by heat treatment at about 100° C. as a protection against tarnish.

There is a series of alloys which are commonly classed as brasses since brass is their foundation, but they contain other metals also. (See also ALLOYS; COPPER; ZINC.) (S. P.; C. H. MN.)

BRASS MANUFACTURE

The manufacture of brass is usually, although not always, associated with the fabrication of copper and copper-base alloys in general.

The manufacture of copper and its alloys, including brass, is essentially a heavy industry and the normal products of copper and brass mills are the basic forms of the metal industry, namely, sheet, strip, rod, tube, bars and plates.

Brass is a generic term applied to the most widely used and industrially important copper-base alloys. There is a large number of commercial brass alloys but in general the brasses can be classified in three broad groups.

Group I comprises the binary alloys of copper and zinc containing more than approximately 63% copper. Alloys in this group, where the range of copper content is 63%–95%, are, structurally, single-phase solid solutions of zinc in copper. Brasses in this

group known as alpha brasses are characterized by excellent cold-working properties and are widely used in applications requiring extreme ductility and ease of forming and drawing.

Group II comprises those alloys of copper and zinc in which the copper range is about 55%–63%. Structurally, these alloys exhibit the two constituents, or phases, previously mentioned: an alpha phase, which is typical of the alloys of Group I, in combination with a beta phase richer in zinc.

The alpha-beta brasses are excellent hot-working metals and in general are characterized by higher strengths and lower ductilities than the alpha brasses. They find their principal applications in engineering fields as structural materials and are seldom used for spinning, stamping or drawing, or other fabrication requiring cold-working or deformation substantially beyond the point of original manufacture.

Group III may be considered as including a large range of special or modified brasses in which third and fourth constituents have been added to the basic copper-zinc alloys for the purpose of usefully modifying their properties.

The added elements may serve to improve physical properties, such as tensile strength, increase corrosion resistance, render the material more readily machinable or in some instances to modify the colour of the basic alloy.

Typical of these special brasses are the aluminum brasses, in which aluminum has been added to increase the corrosion resistance and strength of the brass; the leaded brasses, where lead has been added to improve machining properties, as in certain alpha-beta brasses for free cutting on high-speed automatic screw machines; the admiralty and naval brasses in both of which 1% tin has been added to improve resistance to corrosion by sea water; the manganese bronzes, where manganese and iron have been added to increase the tensile strength of alpha-beta brass; and nickel silver, in which nickel has been added to brass in order to obtain a desirable white colour in base material for subsequent nickel or silver plating. Following is an outline of certain basic operations, namely casting, annealing and pickling, employed in the fabrication of brass. Other basic operations such as hot- and cold-rolling, cold-drawing, extrusion and piercing will be discussed in connection with types of finished products, such as sheet and strip, rod and bar, and tubes.

Castings.—It has often been said that the heart of the brass industry is its casting shop. Here are produced from basic raw material the specially shaped castings required in the production of its many manufactures. The most rigid control must be exercised along all fronts to secure the quality necessary to the production of brass products.

Raw material used consists of cathode copper, *i.e.*, copper refined electrolytically, scrap copper from its own mills or purchased on the market, zinc, pure aluminum, lead and other virgin metals. In addition to pure metals large quantities of both processing and purchased scrap brass are used.

Regardless of the source of the scrap, precautions are taken to keep it segregated according to its composition. Scrap which is secured from without is carefully analyzed and then placed in special bins to be utilized later for the casting of alloys whose composition it most closely approximates. Purchased scrap is usually passed over a magnetic separator so that all iron and steel which may be present are removed. The presence of iron in most brass alloys is not desired in amounts above 0.10%.

Depending upon the type of equipment used for melting furnaces, charges will vary from 100 to 10,000 lb. The composition of the alloy is determined to a large extent by the care with which these charges are weighed. Usually separate departments are set up within the casting shop under the direct supervision of a chemical control department. For any given composition the necessary amounts of copper, zinc and scrap are carefully weighed. Usually an excess of 0.5% of zinc is added as this much is lost due to volatilization during the melting period. Every effort is made to keep the scrap as free as possible from oil, dirt and grease, which on burning produce gas which may be trapped when the metal is solidifying.

The furnaces used for melting vary from the pit-crucible type

used for small-sized castings and for sand castings to electric furnaces of the induction type which usually hold between 1,000 and 2,500 lb., to the reverberatory furnace which holds up to 10,000 lb. and which is extensively used for making large castings for the production of heavy sheet and plate. Large-size oil- and gas-fired, tilting crucible furnaces are also used extensively. These are particularly useful because of their flexibility, it being possible to change from one alloy composition to another at a minimum cost.

Electric furnaces are lined with special refractories depending on the composition to be melted. Such linings are quite expensive and usually separate furnaces are set aside for casting special mixtures. Electric furnaces are highly adapted to big production runs of a particular alloy or alloys within a narrow composition range.

During melting of the metal considerable care is taken to protect the molten metal from the atmosphere and a cover of charcoal is used. The cover produces a reducing atmosphere at the surface and prevents undesirable oxidation of the molten metal. (See also FURNACE, METALLURGICAL.)

Molds used for the making of castings for the production of wrought brass products are usually cast iron. Their shape is determined by the shape of casting required. For the manufacture of tubing or rod, castings may vary from 2 in. to 30 in. in diameter and from 12 in. to 96 in. in length.

Molds may be of the air-cooled type or the water-cooled type. The latter represents common practice in the production of large-sized castings. Cooling is effected by circulating water through a chamber between the outer casing of the mold and an inner plate usually made of copper or bronze.

Molds are dressed with mixtures of oil and rosin, graphite or black lead. These dressings serve to produce cleaner surfaces on casting and to protect the casting surfaces of the mold.

In the best practice, the temperature at which the molten metal is poured is carefully controlled by means of thermocouples immersed in the liquid and either read visually or arranged for continuous recording.

To standardize the rate at which the metal is poured, special pouring boxes, cups or funnels are used. These serve two purposes: to regulate the rate of rise of the molten metal in the mold and to prevent the molten metal from splashing on the mold wall and forming bad spots on the casting.

When brass changes from the liquid to the solid condition shrinkage takes place. In order to compensate for this shrinkage the casting is fed by adding liquid metal during the entire period of solidification. Sometimes mold extensions called hot tops or dozzles are employed. Before any processing of the castings, their top ends containing the pipe or the gate are sawed or sheared off. Continuous casting of slabs or billets is becoming well established in the brass industry. Molten brass is poured continuously into a shallow, water-cooled mold. At the start of the process the bottom of the mold is closed by means of a piston but, as the solidification of the brass proceeds, the piston is lowered at a controlled rate so that the solidified brass emerges from the bottom of the mold. The process can be continuous, appropriate lengths of the brass casting being cut as it is withdrawn from the bottom of the mold, or semicontinuous, the length of the brass casting being limited by the depth to which the piston can be lowered. (See also FOUNDRY.)

Annealing.—Annealing consists of heating a metal that has become hardened by cold-work to a temperature which renders it soft and suitable for further cold-work. Annealing operations are usually conducted in furnaces of the muffle, or oven, type but of many forms of construction. Many designs of furnace incorporate a control of the furnace atmosphere for the purpose of preventing the excessive oxidation or tarnishing of metal during the annealing operation. The term open-fire annealing is frequently used to designate annealing operations in which no effort is made to prevent oxidation of the metal. Controlled-atmosphere annealing ordinarily designates an operation in which excessive oxidation or scaling is prevented by suitable control of the furnace atmosphere, and bright annealing is a term descriptive of those

annealing operations which are conducted under conditions so controlled as to prevent tarnishing of the metal.

The design of annealing furnaces for brass varies from a mechanical point of view with the particular type of product being handled. There are continuous- and batch-type furnaces, strip-annealing furnaces, roller-hearth furnaces, salt-bath furnaces for special work such as end-section annealing of brass tubing or partial annealing of artillery cases and many others to meet specific needs.

In the United States there is a wide use of electrically heated annealing muffles. Gas- and oil-fired furnaces are also widely used. (See also ANNEALING.)

Pickling.—Pickling is a term applied in the brass industry to the cleaning of annealed metal by acid solutions. Ordinary pickling practice on copper and brass products consists in immersing the annealed metal in a sulfuric acid solution, usually containing about 10% by weight of sulfuric acid. The function of the acid is to combine chemically with the metallic oxides formed in annealing operations and to remove dirt, combustion products and other impurities from the surface of the metal.

Such a cleaning operation is essential before cold-working operations can continue, as otherwise subsequent cold-working would result in the imbedding of oxides and other impurities in the surface of the metal, rendering it unsuitable for most commercial applications.

While sulfuric acid is the chemical used for ordinary pickling operations, there are several pickling or finishing solutions commonly used in the brass industry. A solution of sodium or potassium bichromate in a water solution of sulfuric acid is frequently employed as a bright dip. Such a bright dip is used, not essentially as a pickle, but rather to give a lustrous, clean finish to metal or metal parts after they have been subjected to their final processing operation. Nitric acid solutions are also frequently used for the same purpose and other chemicals appropriate to the composition of special alloys are sometimes used when the constituents of such special alloys necessitate such treatment.

Sheet, Strip and Plate.—Brass sheet, strip and plate are manufactured by either hot-rolling or cold-rolling or combinations of these two forms of working. As a general rule the dimensions of the finished product will to a large extent influence the manner in which it is produced, e.g., thick, wide and long plates are usually produced by hot-rolling only, while thin sheet and strip are produced by a combination of the two forms or by cold-rolling alone.

While no clear-cut line of demarcation between sheet and strip exists, generally thin brass over 22 in. wide furnished in flat lengths is considered sheet, and brass under this width furnished in flat lengths or coils, considered strip.

Each of the brass alloys possesses a temperature range in which it is most plastic. Some brasses, as mentioned above, hot-work much easier than others. These compositions are usually hot-rolled with just enough cold-rolling to secure close dimensions and the desired properties. The castings, or cakes as they are called, are first heated to the optimum hot-rolling temperature and held at this temperature for several hours to insure uniformity of heating. They are then fed to a pair of driven rolls which exert pressure on the plastic cake, causing it to be elongated and thinned. This rolling operation takes place so rapidly that it is possible to reduce a four inch or five inch thick casting to $\frac{3}{16}$ in. with only one heating. In hot-rolling, no hardening of the metal takes place so it is not necessary to anneal.

In cold-rolling much the same operations take place with the exceptions that the castings or bars are narrower, not as thick, and the operation is performed at room temperature.

When a metal is cold-rolled the crystals or grains of which it is composed are elongated in the direction of the working; as working increases these crystals become fragmented. The combination of fragmentation and elongation of the grains results in the metal becoming very hard. When this condition is reached, it becomes necessary to anneal the bar before further cold-work can be done.

Annealing temperatures of from 800°–1,350° F. and exposure

BRASS

times of from 30 minutes to 2 or 3 hours are standard practice. The temperature and time utilized depend upon the amount of metal being annealed and the degree of softness required. The hardness of annealed brass is proportionate to its grain size, *i.e.*, small grain size brass is harder than large grain size material. After annealing the brass is pickled and is then ready for further cold-rolling.

Usually in the production of brass sheet, strip and plate, it is necessary to remove the surface, as by milling, at some intermediate point to insure a finish surface, free of imperfections. This surface removal is called overhauling or scalping.

Brass sheet or strip is furnished to the trade in both hard and soft conditions. If furnished hard its final operation consists of a definite amount of cold-rolling, *e.g.*, quarter-hard brass is brass cold-rolled to give a reduction in thickness of about 10%; half-hard, about 20%; hard, about 35% and extra hard, about 50%. Soft brass sheet or strip is annealed to various degrees of softness, *i.e.*, different grain sizes. If the brass is going to be further worked and is subsequently going to be polished and plated, a grain size of 0.03 mm or even less average diameter will likely be specified. If surface characteristics of the finished article are of no importance, a larger grain size will be selected.

Rods, Bars and Shapes.—Brass rod, bar or shapes may be produced by hot-rolling, hot-rolling and cold-drawing, cold-rolling, cold-rolling and cold-drawing, extrusion, extrusion and cold-drawing, or even continuous casting and hot or cold processing.

The hot-rolling process for the manufacture of rods, bars and shapes of brass is similar in principle to that employed in the production of sheet and plate with the exceptions that castings of 4 in. or 5 in. round or square cross sections and up to 60 in. long are used and the rolls used are grooved to produce the cross-sectional shape desired. Roll stands for rods, etc., as for sheet and plate, are so made that the direction of the rolls can be reversed quickly, thus allowing rolling to proceed from either side. In the manufacture of brass wire and small diameter rods, it is possible to hot roll in one preheating from a 4 in. square or round to $\frac{1}{4}$ in. round. This operation is performed at high speed. As a general rule only alpha-beta and lead-free alpha brasses are manufactured by the hot rolling process and this process is used only when the cross section of the shape desired is relatively simple. For complicated cross sections, such as hexagons, triangles, T-shape and others, the hot extrusion method is utilized. This method of working is very flexible and adapted to the production of extremely complicated shapes of all types. Castings used are cylindrical and dimensions vary depending upon the capacity of the extrusion equipment. The extrusion operation consists essentially of pushing a casting, which has been heated to its most plastic range, through an alloy steel die.

Both the hot-rolling and extrusion methods are used as intermediate steps for the production of rods and bars. It is impossible to produce materials to very close gauge tolerance with either of these processes; in addition strengths are low. In order to secure both close dimensions and higher strengths the material is finally cold-drawn.

In the cold-drawing operation a piece of equipment known as a draw-bench is used. Fixed at one end of the bench is a holder which contains the die. The remainder of the bench, which may be 50 ft. or 60 ft. long, contains an endless chain operating similarly to a conveyor belt. Fixed to one point on this endless chain is a pair of viselike jaws. First, the rod or bar to be drawn has one end swaged, or forged, to a smaller diameter than the size to which it is to be drawn. This reduced end is then inserted through the die and clamped or engaged with the jaws. Power is then applied and the rod, etc., are drawn through the die assuming the cross-sectional shape of the die. This operation is then repeated using smaller dies until the required cross section is secured. Usual reductions of area are of the order of 25% for each operation. Very often such large reductions are required that it becomes necessary to anneal frequently as cold-drawing, like cold-rolling, hardens the brass rapidly. Brass rods, etc., are furnished in both hard and soft conditions. Brass rods of less than 80% copper content, etc., are even more sensitive to season cracking (failure

of highly stressed brass under mildly corrosive conditions of storage or service) than brass sheet so it is necessary to relieve strains as soon after the cold-working operation as possible. This is done by low-temperature annealing and by springing or straightening operations. Both of these latter operations consist essentially of whipping the product by fixing one end and flexing the other. This operation readjusts the strains sufficiently to eliminate danger of cracking in storage or in service.

Cold-rolling is used when the composition of the material is such that it is not economical to extrude or it cannot be hot-rolled. Alpha brasses containing lead as a free-cutting constituent (that is, to improve machinability) cannot be hot-rolled. While they can be extruded in the larger sizes and less complicated sections, the process is slow and expensive. Accordingly, it is usual practice to cold-roll to some intermediate size and then cold-draw to the finish size.

The cold-rolling of rod is similar to the hot-rolling process except that working speeds are slower and cross sections of castings are smaller. As in any cold-working operation the metal becomes hard and it is necessary to anneal frequently to soften it.

Tubes.—In the manufacture of brass tube there are several methods by which intermediate sizes of tube can be secured. The method which is utilized for the production of the tube is determined by the nature of the brass alloy and the use for which the tube is intended. These processes are: (1) extrusion; (2) piercing—Mannesmann process; (3) hollow shell castings; (4) cup drawing; (5) brazing; and (6) lock-seam construction. With the exception of the lock-seam method these are all preliminary methods and in order to produce commercial size tube to close dimensions it is necessary to cold-draw or cold-reduce.

Extrusion.—The extrusion of tube is similar to the extrusion of rod, etc., with the exception that prior to any extrusion a mandrel is forced through the hot casting forming thereby a cylindrical hole whose diameter conforms to the inside diameter of the extruded tube. The mandrel remains in this hole and simultaneously with the completion of this piercing operation the casting is pushed through the die and over the mandrel. The outside diameter of the tube or shell is controlled by the die and the inside diameter by the mandrel. (See also METALLURGY: Mechanical Working: *Extrusion*.)

Piercing.—In the piercing operation, castings are used which vary from 2 in. to 6 in. or larger in diameter and up to 50 in. long. These castings are placed in a furnace and heated uniformly to the optimum hot-working temperature of the alloy, and then are placed between two revolving rolls which are so constructed as to present to the surface of the castings or billets inverted broad vee surfaces. These rolls are so adjusted that rolling of the billet occurs and elongation results. Due to the shape of the rolls a small opening is made at the centre of the billet during the rolling operation. This opening is further enlarged and controlled roughly as to tolerances by entrance therein of a pointed steel mandrel which is rotating at high speed counterclockwise to the revolving billet. The beginning of rolling of the billet and the entrance therein of the mandrel point are coincidental.

This operation is very rapid and is extensively used for the production of intermediate tube sizes of red brass, 85% copper, 15% zinc; Muntz metal, 60% copper, 40% zinc; and others.

Hollow Shell.—The hollow-shell method involves the use of special castings which are secured by pouring molten metal into a cylindrical mold with a removable core through its middle. The core controls the inside diameter of the casting. The shell or hollow casting is reduced to smaller sizes by suitable cold-drawing operations.

Cup Drawing.—The cup-drawn shell or tube is produced by deep-drawing, *i.e.*, pushing a flat piece of metal through a die by means of a round-nosed punch. One of the disadvantages of this method is that there is a definite weight limitation to the tube that can be produced. It is practically impossible to produce a tube of 1 in. diameter much more than 15 to 20 ft. long. Any of the other methods mentioned above can produce tubes of this size up to 60 ft. long.

Brazing.—At one time all of the brass tubes supplied were made

by the brazing method, which has become practically obsolete. This method consisted essentially of taking flat strip of the proper gauge and drawing it through a forming die of the desired shape and then brazing the contiguous edges with a solder consisting of 50% copper and 50% zinc.

Lock Seam.—The lock-seam method is similar to the brazing method with the exception that the contiguous edges are lock seamed, or clamped. Soft solder, *i.e.*, lead-tin alloy, may or may not be applied to the joint depending upon the ultimate use of the tube.

Cold-Drawn Tube.—The cold-drawing of extruded and pierced shells, hollow-shell castings, cup-drawn and brazed tubes is performed on equipment identical to that used in the cold-drawing of rod, etc. The operation in the main is similar except to control the inside diameter of the tube there is introduced into the tube at the moment of drawing either a polished steel plug attached to a rod of smaller diameter than the plug or a polished steel mandrel of uniform cross section. The mandrel method of maintaining inside diameters is most widely used in England while the plug method is used in the United States. The outside diameter of the tube is controlled by the die. As in other cold-working operations it is necessary to anneal the tubes as they become hard so that further cold-drawing operations can be performed.

Tube Reducing.—This method for cold-working extruded shell to smaller sizes, developed in the 1930s, consists essentially of swaging or forging a tube over a tapered mandrel. Simultaneously with the swaging the tube is automatically rotated slowly. Very large reductions can be effected in single operations due to the uniform working of the metal that occurs.

Forgings.—Brass alloys containing from 55% to 62% copper can be readily hot-forged into very intricate shapes of close dimension limits thus eliminating the necessity for very much machining as is the case with sand castings. Such articles as faucet handles, sprinkler heads, window and door fittings and many others are produced in this manner.

Brass containing in excess of 64% copper can be cold-forged very easily into many shapes and articles. This method is used in the manufacture of pins, bolts, screws, and the like. Most often automatic equipment is used. Wire of the proper diameter is fed into the special machines and upsetting, cold-heading and threading operations are performed.

Other Forms of Fabrication.—Large castings in alpha-beta brass or manganese bronze are manufactured by sand casting methods for uses such as marine propellers and the bodies of large pumps. Brass die castings are readily made in cold-chamber machines but owing to their relatively high melting points and consequent adverse effect on the life of the dies have not reached large production. Similarly, centrifugal, precision investment and plaster-mold brass castings are produced in limited amounts where specially applicable. Sintered brass powder compacts, made principally from atomized 80% (leaded) copper alloy, are rapidly increasing in importance, both as to variety of products and range of proven alloys.

BRASSEUR DE BOURBOURG, CHARLES ÉTIENNE (1814–1874), French missionary and ethnographer, who specialized in the prehistory of Central America, was born at Bourbourg, near Dunkirk. From 1848 to 1864 he traveled as a missionary, chiefly in Mexico and Central America. He published in 1857–59 a history of Aztec civilization and from 1861–64 edited a collection of documents in the indigenous languages. In 1864 he was archaeologist to the French military expedition in

Mexico, and his *Monuments anciens du Mexique* was published by the French government in 1866. He translated into French the *Popol Vuh*, a sacred book of the Quiché Indians, and wrote a Quiché grammar. In 1871 he brought out his *Bibliothèque Mexico-Guatemalaienne*, and in 1869–70 gave the principles of his decipherment, much disputed, of Indian picture writing in his *Manuscrit Troano, études sur le système graphique et la langue des Mayas*. See also QUICHÉ.

BRASSEY, THOMAS (1805–1870), notable English railway contractor, was born at Buerton, near Chester, on Nov. 7, 1805. At 16 he was apprenticed to a surveyor, afterward becoming a partner and finally sole manager of the business. Invited by Joseph Locke, in 1835 he constructed a section of the Grand Junction railway and later was responsible for completion of the London and Southampton line, contracts for which totaled some £4,000,000, requiring the use of about 3,000 men. Other lines were his responsibility in northern England and Scotland. In 1841–43, with W. Mackenzie, he built the Paris-Rouen railway, Locke being engineer, followed by other lines in France, the Netherlands, Italy, Prussia and Spain. The Grand Trunk railway in Canada, 1,100 mi. long, including a lengthy bridge over the St. Lawrence, was constructed by Brassey in association with Sir M. Peto and E. L. Betts and, at one period, he had work in hand in Europe, India, Australia and South America, with a labour force estimated at 75,000. Coal, ironworks and dockyards were among his other interests. He died at St. Leonards, Sussex, on Dec. 8, 1870.

The eldest of his three sons, THOMAS (1836–1918), educated at Rugby and Oxford, became a baron in 1886 and an earl in 1911. Elected member of parliament for Hastings in 1868, he concentrated on naval matters, becoming civil lord of the admiralty (1880–83) and then parliamentary secretary to it (1884–85). President of the Institution of Naval Architects (1893–95), he became governor of Victoria, Austr. (1895–1900) and warden of the Cinque Ports (1908). Lord Brassey founded the *Naval Annual* (1886) and wrote *The British Navy* (1882–83), a monumental work. Dying in London on Feb. 23, 1918 he was succeeded by his son Thomas Allnutt Brassey, who died in 1919.

See Sir Arthur Helps, *Life and Labours of Mr. Brassey* (1872).
(C. E. R. S.)

BRASSICA, a plant genus of the family Cruciferae (*q.v.*), including the cabbage, mustard (*qq.v.*) and other well-known plants.

BRATHWAIT, RICHARD (1588–1673), English poet best known for the lively *Barnabees Journall*, was born in 1588 near Kendal, Westmorland. Educated at Oxford and Cambridge, he went to London to practise law but instead wrote plays and pastoral poetry of little merit. Upon his father's death he retired to Westmorland, where his life as a country gentleman enabled him to write *The English Gentleman* (1630) and *The English Gentlewoman* (1631), courtesy books of interest to the social historian. *Barnabees Journall* was first written in Latin rhymed verse (1636) under the pseudonym "Corymbaeus," and later published with an English translation (1638); the title page says it is to be chanted to the old tune of "Barnabe." It contains much amusing topographical information and its gaiety is unflagging. At Banbury, Oxfordshire, the author saw the Puritan who has become proverbial,

Hanging of his cat on Monday,
For killing of a Mouse on Sunday.

Brathwait's identity with "Corymbaeus" was established by J. Haslewood, who edited the *Journall* in 1805, 1818 and 1820. Brathwait died at Catterick, Yorkshire, on May 4, 1673.

Brathwait's many works are listed in Haslewood's edition of *Barnabees Journall*, ed. by W. C. Hazlitt (1876).

See M. W. Black, *Richard Brathwait* (1928).

BRĂȚIANU, the name of a prominent Rumanian family of statesmen and financiers.

ION C. (CONSTANTIN) BRĂȚIANU (1821–91) was born at Pitești, in Walachia, on June 2, 1821. After studies in Paris, where he imbibed revolutionary ideas, he returned to Walachia to take a prominent part in the uprising of 1848. The restoration of

Turkish authority drove him back to Paris, where he worked for the union and autonomy of Moldavia and Walachia, gaining the attention of Napoleon III. He and his brother DUMITRU BRĂȚIANU (1818–92) returned home in 1856; after the union of the principalities (1859) under Alexandru Cuza (*q.v.*) they founded the Rumanian Liberal party and assisted, in 1866, in the deposition of Cuza and the election, with the approval of Napoleon III, of Prince Charles of Hohenzollern-Sigmaringen. later King Carol I (*q.v.*), under whom Ion Brătianu held several ministerial posts in the next four years. Accused of complicity in the abortive plot of 1870 against the king, Brătianu was temporarily arrested. Restored to favour, he became prime minister in 1876, remaining in office for 12 years—with a short break in the spring of 1881, when he resigned in favour of his brother. Ion Brătianu was thus in office when Rumania signed the secret treaty of 1883 with Germany and Austria-Hungary. From 1883 onward he was sole leader of the Liberal party, his old political associate C. A. Rosetti and his brother Dumitru having broken away. There was an inevitable clash between their doctrinaire views and Brătianu's realism. His long tenure of office and autocratic methods made him very unpopular, and the Conservative government which succeeded him in 1888 actually demanded an impeachment of him, but this was rejected by a substantial majority in the chamber of deputies. Ion Brătianu died on May 16, 1891, Dumitru on June 21, 1892. Ion stands second only to King Carol I as the maker of modern Rumania. (For his policy in internal and foreign affairs, see RUMANIA: History.)

ION I. C. OF IONEL BRĂȚIANU (1864–1927), eldest son of Ion C. Brătianu, was born at Florica, near Cîmpulung, on Aug. 20, 1864. He and his two brothers Vintila and Dinu (see below), who all received a technical education in Paris, carried on their father's work for Rumania as leaders of the Liberal party and as financiers. They pursued their party's traditional policy in favouring the growth of a prosperous urban middle class and in opposing the admission of foreign capital. Ionel Brătianu served as an engineer on the state railways. Elected deputy in 1895, he was appointed minister of the interior in Dimitrie Sturdza's cabinet, formed in 1907 after the outbreak of the peasant revolt. Taking over the party leadership and premiership from Sturdza in 1909, he remained in power until Jan. 1911. Out of office during the Balkan Wars, he was in power again in 1914. Loyal to the secret treaty that his father had signed in 1883, Ionel Brătianu hoped to avoid conflict with Germany, but agreed to Rumania's entry into World War I on the Allied side in Aug. 1916. He resigned in Feb. 1918, before Rumania signed the separate peace with Germany, but became prime minister again in Dec. 1918. He put Rumania's case brilliantly at the Paris peace conference, but resigned in Dec. 1919 rather than accept the minority clauses of the treaty of Trianon and the division with Yugoslavia of the Banat, which had been promised to Rumania by the Allies in 1916. Prime minister again from Jan. 1922 to March 1926, he was responsible for the passing of a new constitution (which included universal suffrage) and for the confirmation of the agrarian reform. In June 1927 he again formed a government. After King Ferdinand's death on July 20, Brătianu supported the regency and maintained a stout opposition to the return of Prince Carol, who had been excluded from the succession in Jan. 1926 (see CAROL II). Ionel Brătianu died in Bucharest on Nov. 24, 1927.

Ionel was succeeded as prime minister by the younger of his two brothers, VINTILA BRĂȚIANU (1867–1930), who had been minister of finance in his cabinets of 1922 and 1927. Lacking Ionel's prestige and incurring unpopularity by continuing to block the admission of foreign capital at a time of growing economic crisis, he had to resign in Nov. 1928. He died suddenly on Dec. 22, 1930.

Although a year older than his brother Vintila, CONSTANTIN OR DINU BRĂȚIANU (1866–1952?) appeared later on the political stage, having confined himself at first to the family's business and banking interests. A deputy since 1895, his first government post was that of minister of finance, held for a few months in 1933–34. After the assassination in Dec. 1933 of Ion Duca, who had succeeded Ionel Brătianu as leader of the Liberal party, Dinu in

turn became leader of the party. He kept its organization intact against Gheorghe Tătărescu's splitting tactics (instigated by Carol II) and from 1953 onward co-operated increasingly with the National Peasant leader Iuliu Maniu (*q.v.*) in opposing the king's dictatorial methods. He refused to join the king's National Renaissance front in 1938. During World War II, Dinu Brătianu joined Maniu in protesting against Marshal Ion Antonescu's policies and the continuance of the war into Soviet territory and worked with Maniu in preparing King Michael's *coup d'état* of Aug. 23, 1944. He was minister without portfolio in the two post-war non-Communist governments, but refused to participate in the Soviet-imposed government of Petru Groza in 1945. With Maniu he protested against that government's refusal to implement the Moscow agreement and to allow free elections. Dinu Brătianu was arrested without trial, probably in 1950, and died in prison.

CONSTANTIN BRĂȚIANU, called "BÉBÉ" (1887–1955?), son of Dumitru, worked with his cousin Dinu in keeping the Liberal party together and helped in the coup d'état of 1944, serving also in the non-Communist postwar governments. He also died during imprisonment.

The only prominent member of the third generation of the family, Ionel's son GHEORGHE BRĂȚIANU (1898–1955?) was, unlike his uncles, a supporter of King Carol and formed for a time a dissident Liberal group. A scholar and dean of the faculty of letters at Bucharest university, he also died in prison. (B. BR.)

BRATISLAVA (Ger. PRESSBURG; Magyar, POZSONY), the third city in population of Czechoslovakia and the capital of historic Slovakia, is situated near the meeting place of the frontiers of Czechoslovakia, Austria and Hungary. It stands on the left bank of the Danube at the exit of the gorge which the river has cut through the Little Carpathians and just upstream from the branching of the river to embrace the Vel'ky Zitny Ostrov ("the Great Rye island"). Pop. (1957) 236,523. Flanked by hills and surrounded by parklands, the city bears the stamp of its frontier history, particularly in its architecture and in the mixture of its population. On the plateau 270 ft. above the Danube stand the ruins of the former castle and royal palace, destroyed by fire in 1811. Between the castle and the river lie the former ghetto and the 13th-century churches and old town hall (now a museum) flanked by the old river port. On the flat land of the north bank is the main producing and trading centre of Slovakia, with commerce in grain, timber, wine, meat and petroleum, and developing industries, including oil refining, textiles, timber and other products. On the opposite side of the river is the bridge-head settlement of Petrazalka. The systematic application of capital to Slovak resources in the third Czechoslovak republic suggests that the growth of its principal city will continue. Bratislava is an important centre of both railways and roads, with connections with other parts of Czechoslovakia and with Austria and Hungary.

The most ancient settlement in this region is Devin, upstream on the western side of the Danube gorge, near its confluence with the March (Morava), where a mass of ruined fortifications crowns the cliff about 240 ft. above the river. Bratislava itself dates back to the 10th century and has seen some spectacular changes of population. Up to the 19th century it was largely a community of German traders and its university (with a broken history) dates from 1467. The city became the capital of Hungary between 1541 and 1784, when most of the middle Danube basin was in the hands of the Turks, and the coronation of the Habsburg rulers as kings of Hungary took place in its Gothic cathedral. The Hungarian parliament continued to meet at Bratislava until 1848, and in the 19th century it was a Magyar rather than a German city; but in the 20th century it became the Slovak capital. With the formation of the first Czechoslovak republic after World War I its function as regional capital began, and in spite of fluctuations in development because of political upheaval, Bratislava has grown markedly since 1918, as revealed by the statistics of its population (1931, 140,000; 1937, 246,523).

BRATTAIN, WALTER HOUSER (1902–), U.S. physicist, who with John Bardeen and William Shockley was awarded the 1956 Nobel prize in physics for their investigations

on semiconductors and the development of the transistor. He was born in Amoy, China, Feb. 10, 1902. He spent his youth in the state of Washington and graduated from Whitman college, Walla Walla, Wash., in 1924. After receiving the M.A. degree from the University of Oregon in 1926 he attended the University of Minnesota and was awarded the Ph.D. degree in 1929. In that same year he joined the technical staff of Bell Telephone laboratories as a research physicist. His chief field of research is the surface properties of solids. His early work was concerned with thermionic emission and adsorbed layers on tungsten. He continued with research on rectification and photo effects at semiconductor surfaces, beginning with a study of rectification at the surface of cuprous oxide. Similar studies of silicon followed. After World War II he pursued the same line of research with both silicon and germanium. His chief contributions to solid state physics have been the discovery of the photo effect at the free surface of a semiconductor; the invention of the point-contact transistor, jointly with Bardeen; and work leading to a better understanding of the surface properties of germanium. Jointly with Bardeen he received the Stuart Ballantine medal of the Franklin Institute in 1952 and the John Scott medal in 1955, for their invention of the point-contact transistor. He has been granted a number of patents and has written extensively on solid state physics. See TRANSISTOR.

BRATTLE, THOMAS (1658–1713), American colonial merchant and official of Harvard college, was born into a wealthy Boston family on June 20, 1658. He amassed a considerable fortune and made substantial contributions to the finances of Harvard as a personal benefactor and by good management as treasurer from 1693 until his death. He had a marked influence on the intellectual life of New England largely because of his liberalism in politics and religion and his breadth of intellectual interests. The liberal Brattle Street church was organized under his direction. It violated Puritan orthodoxy by dispensing with the "relation of experiences" as a qualification for membership and by other unorthodox practices such as the use of the Lord's Prayer and Bible reading without comment as a part of the services. The witchcraft proceedings he condemned as "ignorance and folly" and he circulated a pamphlet "giving a full and candid account of the delusion." Brattle was an accomplished amateur mathematician and astronomer whose observations of Newton's comet, 1680, based on fixed stars helped Newton test Kepler's laws. He continued to make observations until his death on May 18, 1713.

His brother **WILLIAM BRATTLE** (1662–1717) was for many years pastor of the First Church of Cambridge and tutor in Harvard college. He has the distinction of being the author of America's first textbook in logic. Urbane, tolerant and scholarly, he contributed to the softening of Puritan orthodoxy, as did his brother. (RA. MU.)

BRAUCHITSCH, WALTHER VON (1881–1948), German field marshal, was commander in chief of the army at the outbreak of World War II. He was born in Berlin on Oct. 4, 1881, the son of a cavalry officer. Brauchitsch was educated at a military academy and commissioned to the Prussian guard in 1900. In World War I he was employed on the general staff.

A contemporary described him as a very able man, with charm and breadth of vision to a degree not always found in the German officer class. He was appointed inspector of artillery in 1932 and, with the expansion of the German army under Hitler, became an army group commander in 1937. In Feb. 1938 he succeeded Werner von Fritsch as commander in chief. In that capacity, when World War II broke out, he directed operations against Poland (1939), Norway, Denmark, the Netherlands, Belgium and France (1940) and the early part of the campaign against the U.S.S.R. He was dismissed by Hitler after the failure of the last assault against Moscow in 1941. He died on Oct. 18, 1948, while awaiting trial by the Allies as a war criminal.

See W. Gorlitz, *History of the German General Staff*, Eng. trans. (1953); Telford Taylor, *The March of Conquest* (1959). (C. N. B.)

BRAUN, ALEXANDER (1807–1877), German botanist best known for his speculations on the theory of the arrangement of leaves (phyllotaxis), was born at Regensburg on May 10, 1805,

and graduated in medicine from the University of Munich in 1827. He continued his study of medicine and natural history in Munich and later in Paris (1832). He was appointed professor of botany and zoology in the polytechnic school of Karlsruhe in 1833 and in Freiburg im Breisgau in 1846; he was transferred to Giessen in 1850 but the next year went to Berlin as professor of botany and director of the botanical garden. Braun made numerous contributions to the study of fresh-water algae and microscopic fungi. He described swarm spores in algae and fungi and noted two kinds of spores in many algae. By his studies he contributed materially to the development of the cell theory and to the idea of the cell. Braun died in Berlin on March 29, 1877.

Although he worked in almost all branches of botanical science, Braun's greatest achievement was in plant morphology. He laid the basis for modern knowledge of phyllotaxis in his *Untersuchung über die Ordnung der Schuppen an den Tannenzapfen* (1831) and demonstrated his ability for philosophical treatment of vegetable morphology by publishing his *Betrachtungen über die Erscheinung der Verjüngung in der Natur* (1849–50, Eng. trans. 1853) and *Das Individuum der Pflanze in seinem Verhältniss zur Species* (1853, Eng. trans. 1855). His other works include *Fragmente einer Monographie der Characeen* (1883); *Ueber die Richtungsverhältnisse der Saftströme in den Zellen der Characeen* (1852–53); and some other papers mostly on higher and lower cryptogams, as *Marsilia*, *Pilularia*, *Isoetes*, *Cizara*, etc.

BRAUN, EVA (1912–1945), mistress and later wife of Adolf Hitler, was born on Feb. 6, 1912, into a lower middle-class Bavarian family. She was educated at the Catholic Young Women's institute in Simbach-am-Inn and in 1930 was employed as saleswoman in the shop of Heinrich Hoffman, Hitler's photographer. In this way she met Hitler. She became his mistress and lived in a house that he provided in Munich; in 1936 she went to live at the Berghof.

There is no evidence that the relationship between Hitler and Eva Braun was other than a normal one, except that the pleasures which she provided him were those of domesticity and relaxation rather than eroticism. She was an accomplished swimmer and skier, but her interests were generally frivolous. Hitler never allowed her to be seen in public with him or to accompany him to Berlin, and she had no influence on his political life.

In April 1945 she joined Hitler in Berlin, against his orders, determined to stay with him until the end. In recognition of her loyalty he decided to marry her, and the civil ceremony was carried out in a bunker on April 29. The next day Eva Hitler ended her life by taking poison; her husband is believed to have shot himself at her side. (W. KP.)

BRAUN, KARL FERDINAND (1850–1918), German physicist whose pioneer work in wireless telegraphy won him, jointly with Guglielmo Marconi, the Nobel prize for physics in 1909. He was born at Fulda, Hesse-Nassau, Ger., on June 6, 1850, and was educated at the universities of Marburg and Berlin. After appointments at Würzburg, Leipzig, Marburg and Strasbourg, he was in 1883 elected to the chair of physics in the Karlsruhe polytechnic school, and in 1885 became professor of physics in the University of Tübingen, where he did much to establish the new physical institute. In 1895 he returned to Strasbourg to the chair of physics and the directorship of the institute of physics. Braun's first notable contribution to wireless telegraphy was the discovery of crystal rectifiers, and his invention of the "coupled" system greatly improved wireless transmission. He contributed to the early study of cathode rays and in 1897 devised the Braun tube, which represented an important improvement in the cathode-ray oscilloscope. He died in New York on April 20, 1918. (D. McK.)

BRAUN, LILY (1865–1916), leading German feminist and socialist writer, was born at Halberstadt on July 2, 1865, the daughter of a Prussian infantry officer, Hans von Kretschman. Passionate and enthusiastic, she was converted to atheism, pacifism and feminism by Georg von Gizycki, whom she married in 1893. After Gizycki's death (1895) she joined the Social Democratic party and, in 1896, married a member of it, Heinrich Braun (1854–1927). With Minna Cauer, she founded the feminist newspaper *Die Frauenbewegung*. In her important book, *Die Frauenfrage*,

ihre geschichtliche Entwicklung und wirtschaftliche Seite (1901), she sought to show how capitalism, by employing women in industry, destroyed the family and thus made socialism inevitable. Never a conformist, she collaborated with her husband in publishing their own weekly *Die Neue Gesellschaft* (1905-07). Attacked by orthodox Social Democrats, she finally left the party.

Lily Braun's successful books were two large-scale period studies in novel form: *Im Schatten der Titanen* (1908), based on her grandmother's recollections of the era of Napoleon and Goethe; and *Memoiren einer Sozialistin*, two volumes (1909-11), mainly autobiographical. She died in Berlin-Zehlendorf on Aug. 8, 1916. Her collected works were published in five volumes in 1922.

Her son, OTTO BRAUN (1897-1918), who was killed in World War I, also showed precocious talent as a writer (*Aus nachgelassenen Schriften eines Frühvollendeteten*, ed. by Julie Vogelstein, 1919).

See J. Vogelstein, *Lily Braun, ein Lebensbild* (1922). (O.K.F.)

BRAUN-BLANQUET (originally BRAUN), **JOSIAS** (1884-), Swiss-French botanist and pioneer in the study of plants as units in a plant community, was born at Chur, Smitz., on Aug. 3, 1884, and educated at Ziirich and at Montpellier, France. After serving for some years as *privatdocent* of botany at the Polytechnical school in Zurich, he went in 1926 to France as docent of the Cabinet de Géobotanique Méditerranéene et Alpine at Montpellier, becoming eventually director of the Station Internationale de Géobotanique Méditerranéene et Alpine at the same city. He made several exploring trips to Morocco, Spain, Portugal and Scandinavia.

He was one of the founders of the new science of phytosociology, which was formerly regarded as an offshoot of ecology and plant geography. He introduced a concept of plant community as a social unit upon which rests the whole structure of plant sociology. He helped to develop the methods of study of plant associations, their classification and nomenclature.

His ideas of plant sociology and its ultimate objects are most fully represented in his *Pflanzensoziologie* (1928), which was revised, enlarged and translated into English in 1932 by H. S. Conard and G. D. Fuller.

BRAUNSCHWEIG: see BRUNSWICK.

BRAVO, NICOLÁS (c. 1786-1854), Mexican general and political leader, was born at Chilpancingo of lower-class parents. In 1811 he joined José Maria Morelos y Pavón in his fight for independence against Spain, and upon the death of Morelos he became a guerrilla leader in southwest Mexico. After independence and adoption of a constitution Bravo served as vice-president of Mexico from 1824 to 1827. He led an unsuccessful revolution against the president, Guadalupe Victoria, in 1827. At various times Bravo was acting president, the last occasion during the war with the United States. He was taken prisoner by the U.S. forces in Mexico City in 1847. After the war Bravo retired to private life on his hacienda at Chichihualco, where he died on April 22, 1854. (R. E. Q.)

BRAXTON, CARTER (1736-1797), American colonial leader and signer of the Declaration of Independence, was born in Newington, Va., Sept. 10, 1736. He graduated from William and Mary college, and in 1761 became a member of the Virginia house of burgesses, where he served for more than a dozen years. He was active in the earliest step of protest against British taxation, serving as a member of the committee of safety preceding the establishment of a state government. He was chosen a delegate of Virginia to the continental congress. He expressed conservative political views in an "Address to the Convention of Virginia on the Subject of Government," published in Philadelphia in 1716. He continued to serve his state in the assembly and the privy council until his death in Richmond, Va., on Oct. 10, 1797. (E. E. R.)

BRAY, THOMAS (1658-1730). English clergyman and a founder of the Society for Promoting Christian Knowledge (1698) and of the Society for the Propagation of the Gospel (1701), was born at Marton, Shropshire, and educated at All Souls college, Oxford. After ordination he held a number of appointments, and in 1695 Bishop Henry Compton made him his commissary for

Maryland. To assist poor clergy Bray established parochial libraries, first in America and then in England. Out of this grew the S.P.C.K. and later the S.P.G., for encouraging educational and missionary activity. From 1706 until his death in London on Feb. 15, 1730, he was rector of St. Botolph Without, Aldgate, London. His writings include the *Catechetical Lectures* (1696).

See H. P. Thompson, *Thomas Bray* (1954). (G. HU.)

BRAY, a village in Berkshire, Eng., on the right bank of the Thames between Maidenhead (2 mi.) and Windsor (5 mi.). Pop. (1951) 4,272. The name is celebrated in a well-known ballad, "The Vicar of Bray," of unknown authorship, which tells how a vicar held his position by changing his creed according to necessity, from the days of Charles II until the accession of George I. Tradition ascribes the song to the reign of George I, but the story is usually supposed to have originated around Simon Aleyn, who remained vicar from 1540 to 1588. The church, dating from the 13th century, is partly Early English and decorated with a Perpendicular tower. Bray is residential, with interesting early 17th-century red brick almshouses (Jesus hospital).

BRAY (BRI CHUALANN, "the hill of Cuala"), an urban district in County Wicklow, Republic of Ireland, 13 mi. S.S.E. of Dublin by road. Pop. (1961) 11,680. Its proximity to Dublin and the Wicklow hills made it very popular as a seaside resort. In 1215 the abbot of the monastery of St. Thomas obtained a lease of the lands. The coming of the railway in 1851 began the process of changing a small residential township into a large holiday place. The esplanade was granted for public use in the 19th century by the earl of Meath. The town has a number of light industries, including electric bulbs, glassware, gloves, inks, polishes, wallpaper, toothpaste and leatherwork. Bray Head (653 ft.) lies to the south and Carrickgollogan hill (900 ft.) to the northwest.

BRAYLEY, EDWARD WEDLAKE (1773-1854), English antiquary and topographer, coauthor and coeditor of a popular topographical work, *The Beauties of England and Wales*, was born in London in 1773. He was apprenticed to the enameling trade but early developed an interest in literature. He became a close friend of John Britton (1771-1857), a young man of similar interests, and together they wrote some popular songs and plays. Brayley assisted Britton with his *Beauties of Wiltshire*, three volumes (1801-25), and they then began *The Beauties of England and Wales*, 18 volumes in 25 (1801-15). They toured every county in north Wales, and several western and midland counties in England, on foot, and descriptions of these counties appeared in alphabetical order, illustrated with copperplate engravings. The first six volumes ended with Herefordshire, at which point disagreements between the authors and their publishers caused Brayley and Britton to dissociate themselves gradually from the work, which was completed by others. Of indefatigable industry, Brayley continued his enamel work long after he had become famous as a topographer, and also published many other historical and antiquarian works. He died in London on Sept. 23, 1854.

BRAZIL (ESTADOS UNIDOS DO BRASIL), a republic occupying nearly half the continent of South America. It is exceeded in size only by the Soviet Union, China, Canada and the United States. It has an area of 3,287,195 sq.mi., extending 2,683 mi. from north to south and 2,689 mi. from east to west. Its territory touches on that of all the other South American countries, including the three Guianas, except Chile and Ecuador. Brazil is made up of the former colonies of Portugal; unlike the Spanish colonies, which became separate countries, the Portuguese colonies were united in one huge country. The language of Brazil is Portuguese. Beginning on April 21, 1960, its federal capital was Brasilia, replacing Rio de Janeiro (*qq.v.*). In many fundamental ways Brazil stands in strong contrast to the other countries of the western hemisphere.

There are separate articles on all the Brazilian states and territories and more important towns.

I. PHYSICAL GEOGRAPHY

1. Geology and Surface Features.—The greater part of the area of Brazil consists of hilly uplands, plateaus and low mountains. Very little of the national territory can be described as a plain. The largest area of plain is in the upper Amazon basin, and Brazil shares with Bolivia a part of the upper Paraguay plain. There is no coastal plain. The Guiana highlands north of the Amazon and the Brazilian highlands south of the Amazon are both similar in geology and surface features. Underlying them are some of the oldest geological formations on earth. The ancient igneous and metamorphic rocks of Archean age were described by John Casper Branner as the Brazilian complex. The rocks are granites, gneisses and metamorphic schists, folded and faulted, and cut in many places by pegmatite veins in which are found gold, diamonds and a variety of semiprecious stones. The ancient crystalline rocks weather rapidly under the rainy conditions of the tropics, forming convex slopes, rounded hilltops and narrow valleys.

More resistant than the Archean rocks are the Algonkian (Proterozoic) beds, consisting of phyllites, quartzites and limestones. Where these beds occur they hold massive rounded low mountains that stand above the general level of the Archean rocks. The Serra do Espinhaço and Serra Geral running northward from central Minas Gerais into Bahia are made up of Algonkian rocks, as is also the Pico da Bandeira. Brazil's highest peak 19,495 ft., located near the border of Minas Gerais and Espírito Santo. In the Algonkian rocks are found the chief occurrences of iron ore, gold and manganese.

A large part of the Brazilian and Guiana highlands consists of tabular land forms. Here the Brazilian complex is covered by Paleozoic sedimentary rocks consisting of sandstones, shales and limestones, and ranging mostly from Silurian to Permian in age. The Permian beds of southern Brazil contain seams of low-grade coal and the remains of plants, some of which belong to the *Glossopteris* flora. In some of the Permian formations, also, there are traces of ancient glaciation, including erratic boulders, striations and glacial till. Where the limestones are exposed, as in the middle Sdo Francisco valley, karst land forms are developed.

Overlying the Paleozoic rocks, especially in Sdo Paulo and the southern states, there are soft, reddish sandstones of Triassic age, interbedded with sheets and flows of diabase lava. The diabase is very resistant and wherever it occurs holds up prominent cuestas and mesas, and the rivers are frequently interrupted by falls and rapids.

The great waterfalls of the Rio Parana (Salto das Sete Quedas) and the Iguassu falls on the Iguassu river are formed where the rivers pour over the edge of the diabase. One of the world's largest lava plateaus, the Paraná plateau, is in southern Brazil. Diabase formations appear also in Paraguay, Argentina and Uruguay. Where the diabase is exposed at the surface it weathers into the dark purple-coloured soil known as *terra roxa*, famous as a producer of coffee.

Still more recent rocks of Cretaceous and Tertiary age occur along parts of the Brazilian coast, especially in the northeast. These sedimentary strata form the mesalike *tabuleiros* along the coast. From the vicinity of Salvador a sedimentary basin filled with Tertiary strata extends northward across the lower São Francisco. Oil has been found in these shallow formations near Salvador (*q.v.*).

The Brazilian and Guiana highlands are made up of an intricate pattern of hilly upland, low mountain and tabular plateau. Each surface form reflects the underlying geological formation. The hilly upland, associated with Archean rocks, stands at a general elevation of about 2,600 ft. above sea level. The low mountains on Algonkian formations stand about 1,000 ft. higher, with a few peaks that are just under 10,000 ft. The highest tabular uplands, such as Mt. Roraima are also just under 10,000 ft. (9,094 ft.), but the general elevation of the plateaus is between 3,000 and 4,000 ft.

2. Physiography.—The geomorphologist L. C. King has pointed out the remarkable similarity of the land forms of South Africa and Brazil. The various levels, such as the conspicuous summit level at about 2,600 ft., are the result of successive cycles of erosion. The oldest cycle, now preserved on a few of the highest summits, was probably developed in the Cretaceous—so that these highest surfaces have been exposed to erosion for a very long period of time. As the rock material was stripped off during each cycle of erosion: the land rose higher above sea level because of isostatic readjustment. Each rise of the land initiated a new cycle, which cut back into the older and higher lands, thus creating a landscape that looks much like a relief model when the layers have been put together but before the edges have been smoothed over.

The Great Escarpment.—The eastern margin of the Brazilian highland descends abruptly to the sea. In some places the descent is over a series of steps; but in back of Rio de Janeiro, Santos and Paranagua, there are places where the descent from about 2,600 ft. to sea level is accomplished in one steep slope. Whether there is one slope, or a series of steps, the eastern edge of the highland is sharply marked all the way from Salvador to Pôrto Alegre. This feature is called the Great Escarpment. In back of Santos it was

given the name Serra do Mar (*q.v.*), although incorrectly described as a mountain (Serra). According to King and others, the Great Escarpment is not a fault scarp, but rather a monoclinical flexure. The same erosion levels that stand at different elevations in the interior are warped down below sea level along the eastern margin of the highlands. From Cabo Frio southward the Great Escarpment is unbroken by rivers; but north of Cabo Frio a succession of rivers have cut back across the Escarpment, from the Rio Paraíba in the south to the Rio Paraguaçu in the north, west of Salvador. The Rio Doce, which reaches the sea north of Vitória, provides a relatively easy route back into the highlands from the sea.

The Coast.—Although there is no true coastal plain along the Brazilian coast, there is a zone of varying width in which there are sand bars and lagoons. There are many miles of white, sandy beaches, and many places where there are sand dunes. The largest zone of sand bars and lagoons is in the south, where two large lakes are separated from the ocean by bars—the Lagôa dos Patos and Lake Mirim. But the bar and lagoon coast is interrupted in a few places where the rocky slopes of the Great Escarpment plunge directly into the ocean, as they do east of Santos. The coast, 4,603 mi. in length, has several very fine, deep harbours. Most famous are Guanabara bay, on which Rio de Janeiro and Niterói are situated, and All Saints bay (*q.v.*; Baía de Todos os Santos) on which Salvador is situated. But there are also many smaller harbours from São Francisco in the south, to São Luis in the north. Especially important among these smaller harbours are Paranaguá, Vitória, Ilhéus and Recife. The Amazon itself is drowned at its mouth, providing deep water for ocean-going ships as far inland as Manaus, and for ships drawing 14 ft. of water as far as Iquitos in eastern Peru.

The Rivers.—The Brazilian highlands are drained by three major river systems. In the north is the great Amazon river, with its succession of great tributaries such as the Tocantins-Araguaia, the Xingú, the Tapajós and the Madeira on the southern side, and the Rio Negro on the northern side. The headwaters of the Amazon collect the water from the Andes all the way from Bolivia to Colombia. The Amazon lowland has the peculiarity of being widest along the eastern base of the Andes. It becomes narrower toward the east, until, east of Manaus, only a narrow ribbon of flood plain separates the Guiana highlands to the north from the Brazilian highlands to the south. At Óbidos the flood plain is less than a mile wide. The flood plain opens up again as it approaches the Atlantic. The main river, as noted above, is navigable all the way into eastern Peru. But the tributaries are all interrupted by falls and rapids where they descend from the Brazilian highlands. See AMAZON; TOCANTINS; ARAGUAIA.

The second of the great river systems of Brazil is that of the Paraguay-Paraná-Plata. From southwestern Minas Gerais southward, the highlands are drained into the Paraná. The water that falls at the crest of the Great Escarpment overlooking the Atlantic ocean in back of Santos, flows westward and then southward, eventually reaching the sea through the Rio de la Plata, near Buenos Aires. The two southernmost states are drained through the Rio Uruguai (Spanish, Rio Uruguay) also to the Plata. None of these rivers in Brazil is navigable except for short stretches. (See PLATA, RÍO DE LA.)

The third of Brazil's great river systems is that of the Rio São Francisco, the largest river wholly within Brazil, and a river for which many Brazilians have an almost mystical feeling. The São Francisco, like the Parana and the Tocantins, rises in the Planalto Central in western Minas Gerais and southern Goiás, inland from Rio de Janeiro. A place on the high country, about 4,000 ft. above sea level, where the three great rivers have their origin, was selected as the site for Brasília, the new capital. The São Francisco flows for over 1,000 mi. northward into the state of Bahia and the border of Pernambuco before it turns eastward to the ocean. The great river is navigable for shallow-draft river boats between Pirapora in Minas Gerais north of Belo Horizonte and Juazeiro in Bahia. Below Juazeiro the river current becomes swifter as it approaches the Paulo Afonso falls, 279 ft. high, where the water plunges into a deep trench. Only the last 148 mi. of the lower river

are navigable for ocean ships. The Brazilian government has built a hydroelectric plant at the Paulo Afonso falls. (See SÃO FRANCISCO.)

There are also a number of smaller rivers that drain more directly to the Atlantic, and because they pass through the most densely populated part of Brazil they are of great importance. In the state of Piauí, the Rio Paraíba flows northward to the ocean, and is navigable for hundreds of miles for river barges. South of the Rio Paraguaçu, which drains into All Saints bay, there are several short streams descending from the Serra do Espinhaço across the Great Escarpment to the coast. Among these are the Rio de Contas, the Rio Jequitinhonha and the Rio Doce—the latter by far the most important. The Rio Paraíba rises in São Paulo state and starts flowing toward the west. A little east of São Paulo city the river turns completely around and flows eastward parallel to the coast. In its middle course it meanders across a wide flood plain used now for the production of rice. It then plunges on eastward through a narrow gorge, finally to emerge on its delta near Campos. The headwaters of the Rio Paraíba, which flow toward the west, were formerly a part of the Rio Tietê, a tributary of the Paraná, but were captured by the Paraíba. In the far south, in the state of Rio Grande do Sul, the Rio Jacuí drains eastward past Pôrto Alegre into the LagBa dos Patos. The water of both LagBa Mirim and LagBa dos Patos enters the sea through an opening in the bar near the port of Rio Grande do Sul. The Jacuí together with Lagôa dos Patos is the inland river system of Brazil that carries the largest tonnage of goods, partly because of coal shipments to Pôrto Alegre.

3. Climate.—The climates of Brazil contain no extremes of temperature or rainfall. Contrary to popular opinion, the temperatures of the equatorial regions are not excessively high. The average annual temperatures in the Amazon basin are between 78° and 79° F., with ranges between warmest and coldest months of about 4°. Temperatures as high as 100° have never been experienced in the Amazon, nor are there temperatures below 50°. In the northeast of Brazil temperatures of over 100° do occur during the dry season each year, but this is the hottest part of the country. At Rio de Janeiro the average temperature of the warmest month is 79°. The average of the coldest month in Rio de Janeiro is 68.7°. The temperatures on the highlands are several degrees lower than those of the coast with frosts occurring every winter as far as the southern border of São Paulo state. Frosts also occur at sea level in southern Rio Grande do Sul.

Most of Brazil receives moderate rainfall. Very heavy rains are received in the upper Amazon and near its mouth; and along the sea-facing slope of the Great Escarpment in São Paulo state. Moisture deficiency is encountered in the northeast, and in this region there is a record of recurring droughts that cause great distress for the inhabitants. Over most of Brazil the rainfall is between 40 and 60 in. In the Amazon the rainy season is from

TABLE I Average Temperatures (Fahrenheit) and Annual Rainfall

Locality	Average temperature		Annual rainfall (in.)
	Warmest month	Coldest month	
Amazon basin			
Manaus	82.8	79.7	69.7
Belém	79.9	77.4	86.0
Atlantic coast			
Recife	82.2	77.0	64.9
Ilhéus	79.3	71.4	88.0
Rio de Janeiro	79.0	68.7	43.3
Santos	77.9	66.0	78.5
Pôrto Alegre	76.5	56.3	50.0
Highlands			
Belo Horizonte	72.1	62.2	59.3
São Paulo	69.1	57.9	56.2
Curitiba	70.0	54.0	55.0
Goiás	78.1	72.3	66.8

January to June, but the rest of the year is only a season of less rain. In most of the country the rains come in summer (*verão*) from December to April and the winters (*inverno*) are dry.

4. Vegetation.—The various conditions of the climate together with those of soil and drainage are reflected in the cover of vegetation. Seven major kinds of vegetation are found in Brazil. In the Amazon basin, and in those places along the Atlantic coast where the rainfall is very heavy, there is a tropical rain forest or selva,

composed of broadleaf evergreen trees growing luxuriantly. The selva is made up of a great many different species—as many as 3,000 in a square mile. The trees have tall, straight trunks, and the branches are interlaced overhead, with foliage so thick that little light reaches the ground below. The soil under the selva is deeply leached, and when the forest is cleared the land quickly loses its capacity to produce shallow-rooted crops.

Where the rainfall is slightly less and the dry season is really dry, there is a semideciduous forest, composed of broadleaf trees most of which are evergreen, but a few of which lose their leaves in the dry season. The trees are smaller than in the selva, and the land is easier to clear. This type of forest extends in a narrow band from near Natal southward to Pôrto Alegre. It covers a wide area in southern Minas Gerais and in São Paulo state. This kind of land supported Brazilian agriculture during the 400 years of Portuguese settlement, but due to lack of soil conservation techniques it is now largely destroyed.

In the dry area of the northeast, inland from the semideciduous forest, there is a scrubby thorn woodland or caatinga, consisting of gnarled low broadleaf trees that lose their leaves in the dry periods. The land is of little value except for the grazing of goats.

The greater part of the interior of Brazil, south of the forest of the Amazon basin and west of the semideciduous forest, is covered with a woodland savanna known as *campo cerrado*. This is a mixture of scrubby deciduous woodland and savanna. There are patches of pure savanna (*campo limpo*), probably produced by repeated burning of the grass, and patches of uninterrupted woodland (*cerradão*). Where rivers have cut back into the upland surface, the valleys are often covered with semideciduous forest. With some exceptions, attempts to use the *campo cerrado* for the growing of crops have not been successful, nor is this vegetation good for cattle grazing. The soils are very poor and the grass is lacking in essential minerals.

In the flood plain of the upper Rio Paraguai (Spanish, Rio Paraguay) the area that is covered annually with flood waters is covered with a mixture of wet savanna and palms—known as *pantanal*. In the dry season the savanna can be used for the grazing of cattle.

In the southern part of Brazil two vegetation types reflect the recurrence of frosts. Where the land is covered with grass, the *campo cerrado* gives way to a tall-grass prairie with little clumps of trees on the hillsides where water emerges in springs at the valley heads. These open prairies extend southward from the vicinity of Sorocaba in São Paulo state through Rio Grande do Sul into Uruguay. These prairies have long been used by the Portuguese for pasture land. There has been some effort to use these lands for wheat, but with uncertain results.

Where the land is covered with forest recurring frosts limit the southward extension of the semideciduous forest. This tropical type of forest is replaced by an *Araucaria* or Paraná pine forest, consisting of an upper story of evergreen needle-leaved trees, and a lower story of broadleaf deciduous trees, among which is the tree that is used to produce Paraguay tea (*Ilex paraguayensis*). The Paraguay pine is not a producer of high-grade lumber, but the better stands are used for this purpose. A paper mill makes use of this pine in the state of Santa Catarina.

The part of Brazil that has been used most completely for agriculture is the semideciduous forest, and this forest, also, has furnished most of the cabinet woods for which Brazil is famous. A serious problem has arisen as this forest has been largely destroyed, partly through burning to clear the land, and partly through charring wood for charcoal which is used both for cooking throughout Brazil and in some of the steel plants for fuel. The question is can any of the other kinds of land in Brazil be developed for agriculture? Many Brazilian political leaders are urging the advance of farmers onto the *campo cerrado*.

5. Animal Life.—Brazil has no large game animals, such as are found in the savannas and forests of Africa. There are many kinds of birds, insects and reptiles. There are also several species of animals of the cat family, known generally as *onças* (although they are not bears). The largest land animal of the selva is the tapir, and the rivers of this tropical rain forest abound with fish and turtles.

In a country like Brazil, where the climatic data are not very reliable and where only a few localities have been studied by the methods of modern soil science, the vegetation is the best indicator of the potential utility of the land.

II. GEOGRAPHICAL REGIONS

The vast national territory of Brazil, 3,287,195 sq.mi. in area, can be divided into six major geographic regions. These are: (1) north; (2) northeast; (3) east; (4) São Paulo; (5) south; and (6) central-west. These regions are shown on the map as states or groups of states. In most cases the more accurate construction of regional boundaries would cut across state territories, but for census purposes whole states are placed in one or another region. The Conselho Nacional de Geografia, an official Brazilian government agency charged among other things with the mapping of enumeration areas for the census, uses essentially these same geographical regions, excepting that it includes the southern part of the northeast with the east, and it includes São Paulo with the south.

1. North.—The largest of Brazil's regions includes the world's most extensive area of tropical rain forest, or selva, and the central part of the Amazon basin. There are low-lying alluvial lands around the embayed mouth of the great river and in a narrow ribbon along the flood plain. But most of the surface of the north consists of low plateaus, or low, rolling hills. Very little of the area is subject to floods, for the flood plain of the Amazon in the vicinity of Óbidos is scarcely a mile wide, and the tributary rivers occupy narrow valleys and descend to the main stream over falls and rapids. The rain forest, consisting of enormous trees with boughs interlaced overhead and with little undergrowth, covers most of the north. The dense tangle of vegetation which the popular books describe as "steaming jungle" exists only in old clearings or along the river banks. The soil, excepting on the flood plains, has been so deeply leached during long exposure to heavy rainfall that it has little sustained fertility for shallow-rooted crops.

The main problem in the economic development of the north is the lack of inhabitants. A million rice-growing orientals working the flood plain might make this region highly productive; but the few thousand Brazilians and foreign immigrants, limiting their agriculture to the high ground away from the river where soils are poor, are lost in the great forest. At one time this was the world's only source of natural rubber. Rubberworkers went along the rivers and into the forest to look for rubber trees growing wild. The rubber boom ended in 1910, when rubber was produced more cheaply on plantations in southeast Asia. Attempts by the Ford industries to plant rubber in the Amazon failed, not because of climate, or health, or agronomical problems, but because there were not enough workers in the whole basin to clear land sufficiently to plant the trees. In the late 1950s there was a new speculative boom of planting along the lower Amazon where Japanese settlers were raising jute and black pepper. The manganese deposits in Amapá were being rapidly developed. But most of the region remained decadent. There are still great possibilities for economic development when enough capital and enough labour can be brought together; but lacking these things the north remains one of the world's great empty areas.

2. Northeast.—There are two contrasted parts of the northeast. Along the east coast there is a belt of dependable rainfall, supporting a strip of forest running northward from Bahia as far as Natal. The rest of the region is one of recurring calamities of flood or drought, which, in this densely populated area, cause widespread suffering. The rainy belt was originally occupied by a semideciduous tropical forest, not so dense as the selva. Most of this forest has been cleared away for crops or pastures. The other part of the region is covered with a thorny deciduous scrub woodland known as caatinga. The western part of Maranhão is covered with selva and resembles the north; and the southern part of Bahia, south of Salvador, resembles the east. Bahia and Sergipe have been included in the northeast being typical of this region; only the southern part of Bahia really fits the geographical characteristics of the east.

The northeast was the first part of Brazil to achieve great wealth. In the 16th century the Portuguese established the world's first large-scale sugar-cane plantations with Negro slave labour in the forested areas of Pernambuco and Bahia. This part of the northeast still produces sugar, although it no longer competes in the world market with producers such as Cuba. In Rio Grande do Norte large areas are used to grow cotton. The chief profits are made from the sale of cottonseed cake to the cattlemen. In the state of Paraíba there is a boom area of sisal planting; and in Pernambuco there are coffee plantations. In the state of Bahia, west of the sugar-cane plantations, there is a tobacco-growing area. The greater part of the northeast, however, is used for a shifting cultivation of food crops and for the pasture of animals. Cattle can only be raised where the rainfall is adequate; the dry interior is mostly used for goats. In Maranhão there is an area where the babassu palm (a source of oil) grows wild; and Ceará is the world's chief source of carnauba wax, derived from the leaves of a palm.

Politically, the states of the northeast often co-operate to decide national issues in their favour. The region has a sense of unity, based on long history and cultural tradition, that is far stronger than that found in any other Brazilian region.

3. East.—This is a region of complex terrain. Immediately in back of the swampy lowlands along the coast the Great Escarpment rises like a wall, breached in only a few places by rivers. From the top of the Great Escarpment, 2,600 to 2,800 ft. above sea level, the land rises in a series of steps to the top of the Serra do Espinhaço between 6,000 and 6,500 ft. above sea level. Most of the east receives abundant rainfall, but toward the interior the rains are concentrated in a rainy season from October to April. The slopes of the Great Escarpment and the uplands to the east of the Serra do Espinhaço were originally covered with a tropical semideciduous forest, most of which has now been cleared. The western part of Minas Gerais is within the area of the *campo cerrado*, the woodland savanna, which is characteristic of the central-west.

The settlement of the east took place largely between 1700 and 1800. Gold was discovered in the stream gravels in 1698, and soon after diamonds. Rio de Janeiro was selected as the outlet of the mining region, and made its start as a great city when a road was built to Ouro Preto in 1701. But gold mining declined about 1800, and the 19th century was one of decadence. Sugar cane and coffee were planted and remained productive for a time. But the major use of the land in this region remains the grazing of cattle on planted pastures. The shifting cultivation of food crops (maize, rice, beans) has resulted in the widespread destruction of the forest. But in the 20th century the east has again become an important mining region. Now it is the iron and manganese that are of major significance. Iron ore is mined at Lafaiete for use in the new steel plant at Volta Redonda (*q.v.*) in the Paraíba valley. Other ore bodies are used to supply the large charcoal-burning steel plants in and around the Serra do Espinhaço. Manganese and limestone are also supplied from this region; and other minerals include semiprecious stones, industrial diamonds and quartz crystals. Rio de Janeiro is second only to São Paulo in manufacturing industry, and throughout southern Minas Gerais and Rio de Janeiro states there are numerous industrial towns, such as Juiz de Fora.

4. **São Paulo.**—São Paulo is identified as a separate region because of its outstanding economic development. Immediately in back of Santos the Great Escarpment stands like a wall, rising to 2,600 ft. Transportation up or down this steep slope has always been a problem. In 1867 a British company completed a cable railroad to connect São Paulo with its port, and until 1946 this railroad had a monopoly of all shipments in or out. In the 1950s a four-lane highway was built for motor vehicles. The Escarpment, too, is used for Latin America's largest single hydroelectric installation at Cubatão. The greater part of the interior of the state is a hilly upland, covered with semideciduous forest, or woodland savanna.

During the gold period of the 18th century, São Paulo was a frontier. Sorocaba and Campinas were on the margin between settled country and the wilderness. São Paulo as a geographical

region was created during the coffee period from 1850 to 1930. The rise of São Paulo city as an industrial centre came after 1930, and only in 1954, at its 400th anniversary, did São Paulo declare itself larger than Rio de Janeiro. Coffee is produced in the interior, and also sugar cane, cotton, oranges and cattle. São Paulo leads Brazil in the production of almost everything except cacao (from Bahia), tobacco (from Bahia and Rio Grande do Sul) and minerals.

5. South.—The surface features of this region in many ways resemble those of São Paulo. The Great Escarpment continues southward as far as Pôrto Alegre. But along the southern border of São Paulo is the northern limit of occasional winter frosts, marking the southern limit of such tropical products as coffee. The forest in the south consists of a mixture of pine and deciduous broadleaf trees; but a large part of the area, especially of Rio Grande do Sul, is a tall-grass prairie.

The Portuguese gave scant attention to this part of Brazil. Finding no source of wealth in the forested areas they left this part of the south to the Indians. They settled on the prairies and raised cattle and mules to supply the miners of the east. Starting in 1822 in Rio Grande do Sul, and in 1850 in Santa Catarina, German colonists were settled in the previously unoccupied forests. Later came colonists from Italy, Poland and other European countries. The south is today very largely populated by the descendants of these European colonists. Lacking the speculative profits from sugar cane or coffee, the south has developed a less spectacular kind of agricultural economy, producing pork and lard, rice, cattle and sheep, and manufactured products based on these raw materials. Rio Grande do Sul supplies a quarter of the rice needed in São Paulo and the east, and a large part of the carne seca, or dried beef. From the Parana pine forests come timber, charcoal and yerba maté (or Paraguay tea). From the Italian settlements in Rio Grande do Sul come most of Brazil's wines. And in both Santa Catarina and Rio Grande do Sul there are coal mines. Pôrto Alegre is a rapidly growing commercial and industrial city.

6. Central-West.—This region includes a vast area of the Planalto Central, or Central plateau, an old erosion surface standing now some 3,300 ft. above sea level. Into this old erosion surface the numerous streams are in the process of extending their valleys. Where the valleys have been cut into the high surface the land is hilly and the streams torrential; but the high country along the drainage divides is conspicuously level. The old erosion surface has probably been exposed to the work of the weather since the Cretaceous period, during which time the soils have been deeply leached. The undissected part of this surface is covered with a woodland savanna, or *campo cerrado*; but where the stream valleys have been cut below this surface the valleys are filled with semideciduous forest. The annual rainfall is around 40 in., but concentrated in the rainy season from October to April. In the dry season the woodlands lose most of their leaves, and the savanna grasses turn brown.

Although the central-west has been tramped over in search for gold or other sources of wealth, it has been settled only in a few places, these mostly in the patches of forest. The *campo cerrado* has never been easily occupied by farmers or cattlemen.

(P. E. J.)

III. THE PEOPLE

1. Ethnic Composition.—The population of Brazil has been formed of three racial stocks, namely the Indians of Mongolian derivation, the African Negroes and the Europeans from Portugal. When the Portuguese arrived in the 16th century, they found the huge area which is today Brazil inhabited by only about 1,000,000 Indians. These were divided into numerous warlike tribes speaking a variety of native tongues. Their technology was simple, although the majority of these tribes practised agriculture; yet their way of life was well adapted to the tropical forest and the open savanna uplands. In a relatively brief period, most of the Indians along the coast had died off from disease acquired from the Europeans, from slavery or from war; others fled deep into the interior. During this short period, however, Portuguese men formed

unions with Indian women, and their offspring, called *mamelucos*, became an important element in the early colonial population.

About the middle of the 16th century, the Africans began to arrive in Brazil in large numbers. Neither the remaining Indians nor the *mamelucos* were numerous enough to supply the necessary labour for the very prosperous sugar-cane plantations along the northeastern coast. The planters turned to Africa, where the Portuguese were already established in the slave trade. No one knows with any exactness just how many Negro slaves came to Brazil; but during the 17th, 18th and 19th centuries at least 3,500,000, probably many more, were imported, mainly from West Africa. For a time there were more Negroes in the colony than either Portuguese colonists or Indians. The total population of the colony in 1817 has been estimated at 3,617,000, of whom 2,887,500 were Negroes, 628,000 *mestizos* (mixtures of Indians, Negroes and whites), 843,000 whites and 258,000 Indians. During the 19th century, however, the flood of Africans came to a halt with the suppression of the slave trade after 1850, and slavery was abolished in 1888. The Portuguese had little prejudice against people of dark skin colour and they mixed rather freely with Negro slaves as well as with the remaining Indians. For a time, the most numerous elements in the population were people of mixed ancestry—mulattoes and *mestizos* (*mamelucos*) descended from all three racial stocks.

During the second half of the 19th century and the early decades of this century, Brazil received a large number of immigrants from Italy, Portugal, Spain, Germany and other countries of central Europe and from the middle east. Between 1874 and 1949, 4,546,560 immigrants entered Brazil, the great majority of whom were Europeans. This increased the proportion of Caucasoids in the population; but immigration alone cannot be held accountable for the fact that after the turn of the century the preponderance of the population of Brazil has been white. It has been explained that, in addition to the wave of immigrants of European origin, the whites in Brazil, both the older Portuguese stock and the newcomers, have reproduced faster than the Negroes, Indians and people of mixed ancestry. The higher rate of reproduction of the whites was possible because of their higher standard of living, resulting in lower indices of infant mortality and a lower death rate in general. This progressive increase of the proportion of people of light skin colour in the population has been called, in Brazil, the "bleaching process." Whatever the explanation, by 1950 the official census showed 61.66% of the population to be white, 10.96% to be Negroes, 26.54% to be "brown" or *pardo* (*i.e.*, people of mixed ancestry) and the remainder to be either "yellow" or of undeclared colour. Those classed as "yellow" are of Japanese and Okinawan origin or Indians. Between 1925 and 1940, about 200,000 Japanese and Okinawans immigrated to Brazil, settling in São Paulo state and in the Amazon valley. By 1950 there were perhaps no more than 150,000 tribal Indians left in Brazil, but since the remaining tribes live deep in the interior they were often not counted in the official census.

The population of Brazil continues to be a highly mixed one in racial composition but the relative importance of each racial stock in the make-up of the population varies from one part of the country to another. Whites predominate in the southern states, which received the largest number of European immigrants. Indian elements are of greatest importance in the population of the Amazon basin, where the so-called *caboclo*, or backwoodsman, often is the descendant of both Portuguese and Indian ancestors. The Negroes and mulattoes are most numerous in the northeast coastal and the central states, the region which had a large slave population.

Brazilians are generally proud of their racially mixed population and racial equality is a point of national pride. Although there is undoubtedly some degree of prejudice toward people of dark skin colour, Brazilians point out the relative lack of discrimination and segregation on the basis of race as part of their highly valued national heritage.

2. Cultural Heritage.—Just as three main racial stocks contributed physically to the Brazilian population, the cultures of the American Indian, the African Negroes and the Portuguese have

together formed the modern Brazilian way of life. By far the most important of these three elements, however, is the cultural contribution of Portugal. Brazilians acquired their language, their religion and most of their traditional customs from the Portuguese. Throughout the vast area of Brazil, the Portuguese were able to establish a remarkably homogeneous way of life. Except for a few colonies of German, Italian and Japanese immigrants, and except for the few remaining Indian tribes, all Brazilians speak Portuguese with relatively little dialectical variation from one region to another. Analogous to the English spoken in the United States, Brazilian Portuguese has its own accent and vocabulary which sets it off from the same language as spoken in the mother country. Also derived from their Portuguese heritage is Roman Catholicism, which has deeply influenced Brazilian culture. Church and state are entirely separated and religious tolerance prevails. By far the great majority of Brazilians are by tradition Roman Catholics although church writers indicate that a large proportion of them are not practising Catholics. Protestants of various denominations are numerous, especially in the southern portion of the country, and there are significant numbers of Spiritualists, Jews, Eastern Orthodox Catholics, Buddhists, Maronites and Moslems in the population. Very numerous, although their exact number has never been determined, and of great influence among the lower classes are the devotees in various Afro-Brazilian fetish cults which flourish in the poorer residential districts of Bahia, Rio de Janeiro, Recife, São Luis and other important cities, as well as in numerous rural communities throughout the nation.

From one end of the country to another, Brazilians share a set of traditions inherited from Portugal or formed in the new world during their own history as a nation. Among the important popular festivals is Saint John's Eve (June 23rd) on which families and friends gather around bonfires to roast yams, set off fireworks and paper balloons, and sing. This is a Catholic festival celebrated also in Portugal. Brazilians also celebrate their Independence day (September 7th) in memory of their separation from Portugal and other patriotic holidays.

Although the Portuguese were able so successfully to transmit their way of life to the Indians, Negroes and the mixed population, the influence of the aborigines and of Africa can be felt in the way of life of the Brazilian countryman. From the Indians, Brazilians learned much about their environment. Throughout the country, Brazilian farmers still use a rather wasteful type of aboriginal fire agriculture and they plant manioc (cassava) and other crops which were cultivated by the Indians. Tupi, the language which was spoken by most of the Indians along the coast, was adapted as early as the 16th century by missionaries for catechism and came to be called *lingua geral*, the general language. For a time, this language was spoken widely throughout the interior of northern Brazil by Indians, *mestizos*, Portuguese and Negroes. From this language come many of the names of plants, animals and places in Brazilian Portuguese. Some of these terms of Tupi origin have come to be used in English, such as tapioca (a by-product of the manioc tuber) and cashew (*acajú* in Tupi). The Indian contribution to Brazilian culture is most apparent in the Amazon valley, where many Indian customs and beliefs have been retained by the rubber collectors and isolated farmers.

African influence on the Brazilian way of life is strongest in the old plantation region north along the coast from Rio de Janeiro. Particularly in Salvador, the capital of Bahia state, one encounters a series of traditional dishes of African origin, such as *vatapá*, made of rice flour, coconut oil, fish and shrimps, red peppers and many condiments, and *acarajé*, a beancake fried in coconut oil. In most northern coastal cities, there are religious cults of African origin called *macumba* in Rio de Janeiro and *candomblé* in Bahia which are analogous to the voodoo, or *vodum* of Haiti. These cults worship West African deities as well as Catholic saints. Throughout Brazil, people tell folktales similar to the Uncle Remus stories told in southern United States. African influence is clearly apparent in Brazilian popular music, especially in the highly rhythmic sambas.

Because of the great environmental variation over this large country, there are also marked regional differences in Brazilian

culture. The extreme southern state of Rio Grande do Sul is known for the gauchos, the cowboys of the pampas. The southern states of Rio Grande do Sul, Paraná and Santa Catarina are known for their colonies of European farmers. The people of the progressive city of São Paulo have the reputation of being the energetic yankees of Brazil. Rio de Janeiro is known for the cosmopolitan charm of its people, spoken of as *cariocas*; for the gaiety of its pre-Lenten carnival; and, of course, for the beauty of the city and its setting at the feet of green mountains on Guanabara bay. The northeastern semidesert is characterized by another type of cowboy, the *vaqueiro*, who dresses entirely in leather for protection against the thorny bushes of the region. The Amazon valley has the lonely *seringueiro*, the gatherer of wild rubber from the tropical forest. The coffee plantations of São Paulo and Paraná states, the cocoa plantations in southern Bahia state and the sugar plantations of the northeast coast have also provided distinctive settings for typical regional variations in the Brazilian way of life.

3. Arts.—This varied racial and cultural past of Brazil and the striking regional differences are reflected in Brazilian art, literature and music. Without doubt the outstanding artist of the colonial period was the crippled mulatto architect and sculptor, Antônio Francisco Lisboa (1730–1814) who was known simply as Aleijadinho ("the little crippled one"). His famous carvings in soapstone may be seen in the 18th-century churches of Minas Gerais state. Brazil's most famous modern artist, Cândido Portinari (1903–1962), was the son of Italian immigrants and he made regional scenes the subject of many of his paintings. The internationally famous composer, Heitor Villa-Lobos (1887–1959), has incorporated folk music from the Negroes and Indians into his compositions, as in his *Bachianas Brasileiras* and *Chôros*. Likewise, contemporary Brazilian architecture, stressing open terraces and large windows shuttered against the sun, has become famous throughout the world as a new school of architecture adapted to the tropical and semitropical climate.

Literature.—In the field of literature, the mixed racial and cultural heritage of Brazil is also felt strongly. Joaquim Maria Machado de Assis (1839–1908), perhaps Brazil's greatest novelist, was himself of mixed ancestry. In a series of brilliant novels: including *Memórias póstumas de Braz Cubas*, published in 1881 (translated with the title *The Epitaph of a Small Winner*), he describes the Brazilian scene at the end of the century with an acute irony and depth of psychological observation. Another novelist, José Pereira da Graça Aranha (1868–1931), in his *Canaan* told of the German colonists in Espírito Santo state and of the conflicts of the Brazilian melting pot. Perhaps the most influential book on Brazilian literature was *Os sertões* (translated as *Rebellion in the Backlands*) by Euclides da Cunha (1866–1909), originally published in 1902. It is both an historical account of the uprising of a group of religious fanatics against the newly formed republic and a brilliant study of the arid hinterland of the northeast. These three authors, writing around the turn of the century, mark the beginning of a vigorous literary movement concerned with the reality of the Brazilian scene.

A series of outstanding writers have appeared in the 20th century to continue this movement, which focuses upon regional subjects. José Bento Monteiro Lobato (1883–1948) wrote children's books, literary essays, political tracts and short stories. One of his principal characters was *Jeca Tatú*, the country hick of his native state of São Paulo. Through this character he called attention to the real capacities and problems of such simple Brazilians. A modern Brazilian classic is *Casa grande e senzala* (translated into English as *The Masters and the Slaves*) by Gilberto Freyre; it is a masterly social history of the Brazilian slave system of the northeast and the fusion of Indian, Negro and Portuguese social patterns into the national culture. It is in the modern novel that this literary movement, however, has been most active. Jorge Amado (1912–) writes in *Terras do sem fim* (translated as *The Violent Land*) of the frontier days of the early 20th century in the cocoa growing region of Bahia; and, in *Jubiabá*, of a heroic Negro character from the slums of Bahia. José Lins do Rêgo (1901–1957), in five novels called collectively

The Sugar Cane Cycle, describes the whole range of life revolving about the sugar-cane industry in the northeast. Other novelists, such as Rachel de Queiroz (1910–), José Américo de Almeida (1887–), Erico Veríssimo (1905–), Graciliano Ramos (1892–1953) and J. Guimarães Rosa have written novels focusing upon regional Brazilian subjects.

4. Modern Achievements.—Out of its varied past and mixed population Brazil has built a dynamic and distinctive civilization. In the 20th century, its older cities have become great metropolitan centres, and Brazil has built cities where none existed before, such as Belo Horizonte with more than 476,000 people in 1956 and Goiânia in Goiás state which was completed in 1940 and had almost 40,000 inhabitants by 1950. Modern universities and scientific institutions have been developed, such as the Butantan institute in São Paulo, where important work on snake serum has been done, and the Institute Oswaldo Cruz in Rio de Janeiro, famous for its scientific work in tropical disease. Efficient and technically proficient public-health services have successfully combated yellow fever, malaria and other diseases. Among Brazilian scientists may be noted the geographers Homem de Mello, Belfort Mattos and Carlos Delgado de Carvalho, and the botanist João Barbosa Rodrigues. Scientific explorations of great value have been performed by Gen. Mariano da Silva Roudon.

Modern communications and systems of transportation and communications such as the press, radio, television, commercial airlines, and motor roads have been expanded rapidly. Brazilians have become a more sports loving people. Thousands crowd the beautiful beaches; and literally hundreds of thousands attend soccer matches for which a stadium seating 200,000 was constructed in Rio de Janeiro. (C. W. WY.; T. L. SH.)

IV. HISTORY

A. EARLY PERIOD

1. Discovery and Settlement.—The discovery and early settlement of Brazil appear in the larger perspective of history as episodes in the great movement of Portuguese colonial expansion to the east. Vasco da Gama's discovery of an all-water route to the Indies and Spice Islands by the Cape of Good Hope in 1498 led the Portuguese crown to dispatch to India an imposing armada under Pedro Álvares Cabral, whose sailing directions had been drawn up by the great Vasco himself. To avoid the calms off the Gulf of Guinea, Cabral bore so far to the west that on April 22, 1500, the mainland of South America was sighted and the region was promptly claimed by Portugal, as it lay well within the zone assigned to Portugal by the treaty of Tordesillas (1494). The coast of Brazil had been touched early in the year 1500 by the Spanish navigator Vicente Yañez Pinzón but the Spanish crown made no effort to follow up the discovery. Portugal's new possession was at first called Vera Cruz or the True Cross, a name soon abandoned in favour of Brazil after the valuable red dyewood (*pau-brasil*) in which the country abounded. The tidings of Cabral's discovery aroused great enthusiasm and further explorations were undertaken. According to the generally accepted account the first of these expeditions, which set sail from Lisbon on May 13, 1501, had as its pilot Amerigo Vespucci (*q.v.*), who had already been once and possibly twice to the new world. As the little fleet sailed along the coast of Brazil—whose immense extent was for the first time realized—Vespucci, calendar in hand: baptized the different points on the coast with the names of the saints on whose days they were discovered. A majority of these names (*e.g.*, Cape Santo Agostinho, São Francisco river) have remained. It is probable that the spacious bay of Guanabara was entered Jan. 1, 1502, and named Rio de Janeiro ("River of January").

For over a quarter of a century following Vespucci's voyage, interest in Brazil all but ceased. No precious metals were discovered, and the energies of the Portuguese were increasingly absorbed by the establishment of a great empire in the east. Portugal's enemies and rivals, especially the French, were quick to take advantage of this neglect. Swift corsairs from Honfleur and Dieppe loaded their ships with the valuable brazilwood and even attacked Portuguese vessels returning from the Indies. Brazil became a sort of no man's land over which the Portuguese crown

wielded only a shadowy control. This apathy ended, however, with the accession of John III (1521-57) and the centre of gravity in colonial affairs gradually shifted from Asia to America.

The first systematic effort to establish an organized government in Brazil was made in 1532. Brazil was divided into 15 hereditary captaincies or fiefs, extending 50 leagues along the coast and an indefinite distance inland. These grants were distributed to favoured persons, chiefly courtiers, who took the names of *donatarios*. Their rights and privileges were extensive. They were authorized to found cities, issue land grants, levy internal taxes and appoint municipal officers. To the crown was reserved the right to impose export taxes and the monopoly of brazilwood and spices. The captaincy system failed to realize the hopes of the crown. Only ten of the fiefs were occupied by their owners and of these only two were really successful. The most flourishing of the settlements was that of São Vicente, south of the present city of Santos. This had been granted to Martim Afonso de Sousa, who in 1530 had explored the coast as far south as the La Plata estuary and had penetrated for some distance into the interior. By the middle of the 16th century the captaincy had a population of about 5,000, including the growing port of Santos and the town of São Paulo, over the edge of the Serra do Mar, on the fertile plateau of Piratinga. In northern Brazil, Duarte Coelho had converted the captaincy of Pernambuco into a great sugar-producing region. But the remaining captaincies were for the most part tragic failures. The *donatarios* were generally incompetent and tyrannical, and the struggling settlements were powerless against attacks of hostile Indians or the depredations of French corsairs.

2. Royal Control. — At length, fully alive to these perils, King John determined to substitute for the inefficient rule of the *donatarios* a unified, centralized administration. Brazil was brought directly under royal control through the appointment of a governor general. The first to hold this office was Tomé de Sousa, a Portuguese noble who had gained wide experience in India. In 1549 he took up his new duties at Bahia (São Salvador) which remained the capital of Brazil for the next 214 years. The governor general was granted wide powers in civil and criminal affairs. The *donatarios* were obliged to surrender their political and judicial rights, though they were allowed to keep possession of their fiefs until they were acquired by the crown. Local officials, responsible to the governor general, were placed over the captaincies, and strategic points along the coast were fortified. In the cities municipal organizations, similar to those in Portugal, were established. Brazil then began to attract settlers in increasing numbers. By 1600 Bahia and Pernambuco (Recife) each had a population of 2,000 whites, with more than twice as many Negro slaves and converted Indians.

A factor of great importance in the progress of the colony was the labour of the Jesuits. At the instance of John III several fathers accompanied Tomé de Sousa to Bahia. Among them was Manuel da Nóbrega, the first of a long line of missionaries who devoted their lives to the protection and conversion of the Indians and to the raising of the moral level of the colonists. At the site of the present city of São Paulo, Nóbrega established a school for the training of missionaries. There he was joined by José de Anchieta, whose heroic labours among the Indians won for him the title of the "Apostle of Brazil." As rapidly as the Indians were converted, they were settled in villages or *aldeias*, similar to the missions in Spanish America. The activities of the Jesuits soon aroused the antagonism of the colonists, particularly the Paulistas, the name given to the hardy and tough-fibred settlers of São Paulo. The colonists demanded an abundant labour supply, and as white labourers were lacking they proceeded to enslave the Indians and to force them to work on their plantations. Both the Jesuits and colonists appealed to the crown; the former won a partial victory by the decree of 1574, which granted to the Jesuits full control over the Indians in the *aldeias* while permitting the colonists to enslave Indians captured in legitimate warfare. In the north, the storm centre of a somewhat similar conflict was Father Antônio Vieira, who in the 17th century established a chain of missions in the Amazon valley. Naturally the restrictions on Indian labour stimulated the introduction of Negro slaves, a movement which

steadily gathered momentum after the middle of the 16th century.

3. Dutch and French Incursion. — Brazil had hardly been brought under royal authority before a determined effort was made by the French to establish a permanent colony. The prime mover in this enterprise was a French adventurer and soldier of fortune named Nicolas de Villegagnon, who contrived to enlist the support of Admiral Gaspard de Coligny and even John Calvin by the assurance that the future colony would be an asylum for Huguenots and other Protestants. King Henry II lent his sanction and in 1555 the French took possession of the beautiful harbour of Rio de Janeiro, which the Portuguese had strangely neglected to occupy. But Villegagnon failed to rise to his opportunities. He showed little skill as a colonist. His promise of religious toleration was broken. Attempts at forceful conversion to Roman Catholicism alienated the support of the Protestants. Rumours of these dissensions reached Europe and checked what might have become a great migration from France and Switzerland. Meanwhile the Portuguese had come to realize the extent of the French menace. A large force under Mem de Sá, the governor general, blockaded the entrance to the harbour and forced the French garrison to surrender. To ward off future attacks Mem de Sa in 1567 founded the city of Rio de Janeiro. Although subsequent attempts were made by the French to gain a foothold in Brazil—notably by Jean François Duclerc and Adm. René Duguay-Trouin in 1710 and 1711—the hope of establishing "France-Antarctique" as a pendant to the French colonies in North America was never realized.

From 1580 to 1640 Portugal was united to Spain, and as a part of the Spanish colonial empire Brazil was naturally exposed to attacks by Spain's enemies. Among these were the Dutch, who had just succeeded in establishing their independence. Bahia was seized and held briefly in 1624-25, and in 1630 a fleet sent out by the Dutch West India company captured Pernambuco, the metropolis of the rich sugar-growing district in the north. As governor of its new possession the company chose Count Maurice of Nassau-Siegen, a prince of the house of Orange, and perhaps the ablest man in the Netherlands. His statesmanlike program included the creation of a great colonial empire, reconciliation between Dutch and Portuguese, the grant of religious toleration and the limited participation of the colonists in the government. Imposing public works were erected in the capital, renamed Mauritzstadt. Distinguished artists and scientists were invited to make known to Europe the resources and beauties of Brazil. But the directors of the company, intent on a policy of greed and gain, refused to support their enlightened governor and he resigned in 1644. A rebellion launched by a wealthy plantation owner, João Fernandes Vieira, proved beyond the power of Maurice's incompetent successors to crush. The Dutch, who were expelled in 1654, renounced all claim to Brazil in 1661.

4. Expansion and Unity of Brazil. — Perhaps the most striking development of the colonial period was the vast expansion of Brazil beyond the line of Tordesillas (a vertical line drawn 370 leagues west of Cape Verde Islands) westward to the slopes of the Andes and north and south to the Amazon and the Rio de la Plata. In the north the movement was led by missionaries, seeking to convert the Indians to Christianity, who established missions along the Amazon in the 17th century. In the northeast cattlemen from the sugar zones of Pernambuco and Bahia pushed inland into the present area of Piauí, Maranhão and Goiás in search of new pastures. However, the brunt of the "march to the west" was borne by the Paulistas. With the purpose of capturing Indian slaves and of finding gold and precious stones, they organized great expeditions into the interior, known as *bandeiras*. At times these expeditions, involving entire families, were veritable treks or migrations which lasted for a period of years. Some of the more spectacular *bandeiras* took the Paulistas as far as the silver-mining region of Peru and even to the area of Bogotá in Colombia. In the 17th century they explored the area of Mato Grosso and attacked the Indian *reducciones* (Indian converts) of Misiones and southern Brazil. For the most part they met with resistance from the Indians and their Jesuit protectors; only along the Rio de la Plata, in modern Uruguay, did the Spanish settlers resist the invaders, and there eventually the Paulistas were pushed back.

The war against the Dutch, which involved not only the people of northeastern Brazil but also drew upon the manpower and resources of São Paulo, was said to mark the emergence of a Brazilian consciousness. Probably for the first time the people of Brazil collaborated in a major effort as Brazilians rather than as colonists of Portugal, for the imperial government had been willing to recognize Dutch control of Pernambuco. The movement to expel the Dutch was launched in Brazil despite initial objections by the crown. During the colonial period most of the other factors which tended to unite the people of Brazil became evident. Among the most important of these was the heritage of Portugal. The Portuguese language formed a common bond between plantation residents, cattlemen, miners, slaves (both Indian and Negro), slave hunters and city dwellers from the Amazon to the Rio de la Plata and distinguished them from their Spanish-speaking counterparts elsewhere in South America. Although Tupi-Guarani served as a sort of lingua franca throughout much of the interior of the colony, Portuguese remained the official and the common language of Brazil. The expanded, patriarchal family structure, also derived from Portugal, was nearly uniform throughout Brazil, and power was exercised in all regions by the heads of those families which controlled the land, slaves, cattle and later mines, that produced the wealth of the colony. Despite regional differences, Brazilian society and economy were rural based. This pattern persisted for a century after the colonial period. The population was divided unevenly between those who possessed landed wealth and prestige and those who were dependent upon them. No great cities such as those of Spanish America grew up in Brazil during the colonial period. Moreover, contact with Portugal, although at times intermittent, was maintained with all parts of Brazil, and little trade or other regular contact existed between Brazil and neighbouring Spanish colonies. These common factors proved far stronger than regional variants when Brazilian unity was under severe stress in the second quarter of the 19th century.

The colonial economy of Brazil was marked by two major cycles, that of sugar and that of gold. As mentioned above, the sugar industry, confined primarily to the northeast, was introduced into Brazil early in the 16th century, and it was the principal basis for the wealth of the colony for over 200 years. Throughout the entire period of Portuguese control in Brazil, sugar produced substantially more revenue for the crown than any other export product, including gold. A plantation product, sugar called for a large capital investment in land, slaves and machinery, and consequently was concentrated in the hands of a relatively small number of wealthy families. Tobacco and cattle raising, conducted chiefly by independent freemen around the periphery of the sugar plantations, contributed to the wealth of the sugar zones and became important industries before the end of the colonial period. In the 18th century cotton and coffee, originally produced by small landholders, were also becoming significant export products of the coastal area.

Gold, which was sought by colonists in Brazil from the period of first settlement, was not found until 1693 in what is now the state of Minas Gerais. The deposits were the wealthiest that had been discovered to that date, and their discovery set off a gold rush which anticipated in many ways the days of 1849 in California and those of 1851 in Australia. Gold seekers followed the São Francisco river upstream from Pernambuco (Recife) and Bahia (São Salvador) and surged northward from São Paulo. In the hitherto unbroken wilderness towns sprang up as if by magic, while large sections of the littoral or coastal region were virtually denuded of their inhabitants. African slaves from the sugar plantations and directly from the gold-working regions of Africa introduced many of the techniques employed by Brazilian miners. The yield of the mines during the 18th century has been variously estimated between £50,000,000 and £200,000,000. The impact of the gold mines upon the Brazilian economy was largely responsible for the transfer of the capital of the colony from Salvador to Rio de Janeiro in 1763. The search for gold led to the discovery of diamonds in the early 18th century in Minas Gerais, Bahia and Mato Grosso. Diamonds became a royal monopoly, and although many famous stones were found no figures for the total diamond

output are available. While most of the gold mines were exhausted within a century, diamond production is still significant in Brazil.

5. **Colonial Reforms.** — The treaties of Madrid (1750), Pardo (1761) and Ildefonso (1777) with Spain gave some legality to Portuguese claims including the conquests of the *bandeiras*. During this period Sebastião José de Carvalho e Mello, marquis of Pombal, the famous prime minister of King Joseph I, introduced into Brazil a number of reforms which profoundly affected the social, administrative and religious life of the colony. The last rights of the *donatarios* were absorbed by the crown, the capital was transferred from Bahia to Rio de Janeiro, the Indians were placed on a legal equality with the whites, immigration from the Azores and Madeira was encouraged, two privileged companies were created and a monopoly of the diamond fields was established. The act for which Pombal is best known was the expulsion of the Jesuits from Brazil in 1759. Through their protection of the Indians and their various commercial ventures they had stirred up widespread resentment, and when they attempted to thwart some of Pombal's reforms the all-powerful minister banished them from both Portugal and Brazil with brutal thoroughness. The value of many of Pombal's reforms is more than questionable but it can hardly be denied that they tended on the whole toward the development of the capabilities and resources of Brazil.

B. THE INDEPENDENCE OF BRAZIL

In 1789 the first rebellion against Portuguese authority was instigated by Joaquim José da Silva Xavier, known as Tiradentes (tooth puller) because of his occasional practice of extracting teeth. The uprising was put down and Tiradentes, later to become a national hero, was executed.

Despite its isolation Brazil could not escape the effects of the revolutionary and Napoleonic epoch in Europe. Brazil is the only instance of a colony becoming the seat of government of its own mother country. In 1807 Napoleon resolved upon the invasion and conquest of Portugal, a traditional British ally, largely in order to tighten the European blockade of Great Britain. The Portuguese prince regent Dom John, afterward King John VI, realized the futility of resistance and decided to take refuge in Brazil. After creating a regency, he sailed from the Tagus on Nov. 29, 1807, under the protection of the British fleet. He was accompanied by the royal family and a horde of nobles and functionaries. After a short sojourn at Bahia the court arrived safely at Rio de Janeiro on March 7, 1808. The colonists, convinced that a new era had dawned for Brazil, welcomed their sovereign with tremendous enthusiasm. Their expectations were in a measure realized, for the prince regent promptly decreed a number of reforms which radically altered the status of the colony. Some of these amounted to practical recognition of Brazil's position as seat of the Portuguese empire and its new requirements in view of the war in Europe. Both are evident in the abolishment of the old Portuguese commercial monopoly and the opening of Brazilian harbours to the commerce of all friendly nations. British trade with Brazil immediately took on important proportions and a number of British trading companies established offices in the colony. To accommodate the imperial administration, and in response to local demands, a ministry with four portfolios and a council of state were installed in Rio de Janeiro, and a supreme court of justice, a court of exchequer and royal treasury, the royal mint, the Bank of Brazil and the royal printing office were established. A royal library, a military academy and medical and law schools were founded. Industries were encouraged for the first time, foreign scholars and artists were welcomed and immigrants from northern Europe were brought in at government expense. The changed status of Brazil was reflected in the decree of Dec. 16, 1815, by which the Portuguese dominions were designated the United Kingdom of Portugal, Brazil, and the Algarves, thus making Brazil coequal with Portugal. In the following year, the insane queen, Maria I, died, and the prince regent became king.

Although Dom John enjoyed a certain degree of personal popularity his government, corrupt and extravagant, aroused much opposition, which was still further increased by the fermentation

of liberal ideas produced by the French revolution. In Pernambuco a revolt broke out in 1817, and was put down with difficulty after a republic had been formed which lasted for 90 days. Still more critical was the situation in Lisbon, Port. After the departure of the French, Portugal had been governed by an arbitrary and tyrannical regency. The growing discontent found vent in the revolution of 1820. The regency was swept aside and the Cortes, which had not met for over a century, was summoned for the purpose of drawing up a constitution. The presence of Dorn John in Portugal was imperative if the revolutionary movement was to be kept in hand. On April 22, 1821, he appointed his son Dorn Pedro regent and two days later set sail for Lisbon. The tasks confronting the young prince were truly formidable. Antagonisms between the Portuguese and Brazilians were becoming increasingly bitter, republican propaganda was active, and, worst of all, Dorn Pedro had to face the responsibility of a separation of Brazil from Portugal as a result of the shortsighted policy of the Cortes at Lisbon. The majority of this assembly were in favour of restoring Brazil to its former status of colonial dependence. Without waiting for the Brazilian deputies they proceeded to undo most of the reforms introduced into Brazil by Dorn John. Fearful that Dorn Pedro might head a movement for independence, the prince was ordered to return to Europe "in order to complete his political education."

These acts aroused great indignation in Brazil. Supported by the majority of the Brazilians, Dorn Pedro openly defied the Cortes by his refusal to return to Lisbon. In Jan. 1822 he formed a ministry in which the chief portfolio was held by the distinguished Paulista, José Bonifácio de Andrada e Silva (*q.v.*). Known as the "Patriarch of Independence," he was a scholar of European reputation and proved at this critical juncture a tower of strength to the young regent. Events followed rapidly. On June 3 Dorn Pedro convoked a legislative and constituent assembly. On Sept. 7, on the plain of Ipiranga, near the city of São Paulo, he solemnly proclaimed the independence of Brazil, and on Dec. 1, 1822, was crowned emperor. With the co-operation of Lord Dundonald (Thomas Cochrane), an able British naval officer who had entered Brazilian service, the strong Portuguese garrisons were forced to return to Europe. Before the end of 1823 independence had become an accomplished fact. The United States was first to recognize the new government, on May 26, 1824. Portuguese recognition was secured in 1825. The early resumption of formal relations between Portugal and its former colony was due in large part to the influence and good offices of the British government.

C. THE BRAZILIAN EMPIRE (1822-1889)

The first years of Brazilian independence were difficult. The nation was without experience in self-government and the emperor, though able and patriotic, was inclined to be despotic and arbitrary. When the constituent assembly, on which the nation had pinned such high hopes, proved unmanageable Dorn Pedro dissolved it in 1823 and sent the radical José Bonifácio de Andrada e Silva and his two brothers Antonio and Martim into exile. Fortunately he realized that the days of absolutism were passed; a new and liberal constitution, drawn up by the council of state, was submitted to the municipal councils of the provinces and sworn to with great solemnity by the emperor on March 25, 1824. By this stroke of policy he saved himself and Brazil. The remaining years of Dorn Pedro's reign witnessed a growing estrangement between the monarch and his subjects. Parliamentary government was little to the emperor's liking, and the opposition generally commanded a majority in the chamber of deputies. Brazil became involved in a disastrous war with Argentina resulting in the loss of the Provincia Cisplatina (the present republic of Uruguay). Finally, worn out and disheartened by attacks from both within and without parliament, Dorn Pedro formally abdicated on April 7, 1831. In favour of the heir apparent, Dorn Pedro II, then only five years of age.

1. The Regency (1831-1840).—The next decade proved the most agitated period in Brazilian history. From 1831 to 1835 a triple regency laboured in vain to put down the civil war in the provinces and check the lawlessness and insubordination in the

army. In 1834 an important amendment (the so-called *Acto Adicional*) was made to the constitution. A measure of decentralization was granted the provinces through the creation of provincial assemblies with considerable local power. Provision was made for a sole regent to be elected for four years. For this office in 1835 an able and energetic priest by the name of Diogo Antônio Feijó was chosen. For two years the regent struggled heroically against the force of disintegration, but he was forced to resign in 1837 and was succeeded by Pedro de Araújo Lima. As the end of the decade approached, sentiment began to crystallize in favour of a declaration of majority of the young Dorn Pedro. The Brazilians as a whole, impatient with the regency, hoped to find in the person of the emperor a symbol to which the entire nation might rally. On July 23, 1840, both houses of parliament passed a declaration that Pedro de Alcantara had attained his majority.

2. Dorn Pedro II.—The reign of Dorn Pedro II, with its duration of practically a half century, constitutes perhaps the most interesting and fruitful epoch in Brazilian history. To an extent true of few monarchies in the 19th century the prestige and progress of the nation were due to the enlightened statesmanship of its ruler. Yet Dorn Pedro cared little for the trappings of royalty. Though not without personal distinction he was always simple, modest and democratic. He possessed an insatiable intellectual curiosity and was never more happy than when conversing with scholars. He was generous and magnanimous to a fault. One of his favourite occupations was inspecting schools. He was wont to declare, "If I were not emperor I should like to be a school teacher." Yet this kindly, genial and scholarly ruler took his prerogatives and duties as sovereign with great seriousness and in all matters of first importance he was the final arbiter. According to the "moderative power" granted to the executive under the constitution of 1824 the emperor had the right to dissolve the chamber of deputies, to select the members of the life senate from triple lists submitted by the province and to appoint and dismiss ministers of state. That parliamentary life in Brazil was pitched upon such a high plane, that the highest officials in the state generally left office poorer than when they entered it, that the machinery of government functioned smoothly year after year was due in large measure to the tireless vigilance of the emperor.

Dorn Pedro's government maintained an active interest in the affairs of the Plata republics, especially of Uruguay, which it sought to control through indirect measures. Opposed in this by the Argentine dictator Juan Manuel de Rosas (*q.v.*), Brazil aided in his overthrow in 1852. In 1864 Brazil intervened in Uruguayan internal affairs and, in so doing, brought about war with Paraguay. In alliance with Argentina and Uruguay, Brazil successfully waged the costly and bloody Paraguayan war of 1864-70 (*see PARAGUAY*), eventually overthrowing the famed Paraguayan dictator Francisco Solano Lopez. With occasional lapses the empire's relations with the United States and with Europe were exceedingly cordial. Pedro personally did much to cement these international friendships, visiting Europe in 1876 and 1888 and the United States in 1876.

The outstanding social and economic problems with which the empire had to grapple were intimately associated with slave-based plantation agriculture. Real political power rested, as in the colonial period, with large rural landholders who formed the core of the social and economic elite of Brazil. Industrialization, introduced in the 19th century, was still economically insignificant and, with the decline of gold mining early in the century, agriculture again was unrivaled as the source of Brazil's wealth. Cotton, and increasingly coffee, cultivated by slave labour, competed with sugar as the leading export crop. While a few large cities with European-influenced populations developed along the seaboard, the rural landholders were largely insulated from the anti-slavery current of the times. Although manumission was common and the number of freedmen and their descendants far surpassed the number of slaves in Brazil, the slaveowners as a group resisted pressures for the complete abolition of human servitude upon which their economy was based. Partly as a result of pressure from Great Britain, Brazil had agreed to abolish the slave trade in 1831, but it was not until 1853 that slave traffic completely ceased. In the 1860s agitation began in favour of the

abolition of slavery as such. Dom Pedro was opposed to slavery but he had to reckon with the determined resistance of the slave-owners. Finally in 1871 a bill for gradual emancipation, sponsored by the viscount of Rio Branco, was passed by parliament. The importance of this act lay in the provision that henceforth all children born of slave mothers should be free. But this concession did not satisfy many of the abolitionists, who, led by a brilliant young lawyer and writer, Joaquim Nabuco, demanded that abolition be immediate and complete. In 1883 Nabuco wrote a remarkable book, *O Abolicionismo*, in which he endeavoured to prove that slavery was poisoning the very life of the nation. The propaganda began to bear fruit. In 1884 Ceará and Amazonas freed their slaves; in 1885 all slaves over 60 years of age were liberated. Finally, complete emancipation without compensation to the owners was decreed by the princess regent in the absence of the emperor on May 13, 1888. About 700,000 slaves were freed.

3. The Collapse of the Empire.—At first sight the overthrow of Dom Pedro II seems inexplicable. Under his wise guidance Brazil had made very real progress. His half century of rule had witnessed a growth in population from 4,000,000 to 14,000,000, a fourteenfold increase in public revenues and a tenfold increase in the value of the products of the empire. Railroad mileage in 1889 exceeded 5,000; the same year more than 100,000 immigrants came to Brazil. But despite this impressive economic progress there were grave causes of dissatisfaction. Propaganda in favour of a republic, launched in 1871, had gained many recruits. The great landowners, who had lost their slaves without compensation, withdrew their support from the monarchy. The clergy, another prop of the throne, had been antagonized by the punishment of several recalcitrant bishops. Isabel, the heiress to the throne, and her husband, the comte d'Eu, were unpopular. Most serious of all, important elements in the army, which had become a political force after 1870, turned against the emperor, largely because Dom Pedro insisted that they stay out of politics. A conspiracy was hatched by these disgruntled military elements and on Nov. 15, 1889, a revolt of part of the army was the signal for the collapse of the empire. Dom Pedro formally abdicated and with his family was banished to Europe.

D. THE REPUBLICAN PERIOD

During the next few years Brazil passed through a difficult period of adjustment. The leader of the revolt against Dom Pedro II was a prominent military figure Gen. Manuel Deodoro da Fonseca (*q.v.*). For the next 14 months Brazil was ruled by a military autocracy in which Deodoro, now chief of the provisional government, was virtually supreme. Decisions of great importance were reached. Church and state were separated, civil marriage was introduced and a constituent assembly was summoned which adopted in 1891 a constitution modeled closely on that of the United States.

1. The Presidencies.—As president, Deodoro employed the same dictatorial methods that he had followed as head of the provisional regime. He kept in power an unpopular ministry and was constantly at loggerheads with congress. On Nov. 3, 1891, he forcibly dissolved this body and proclaimed himself dictator. But opposition was so widespread that on Nov. 23, 1891, he resigned in favour of the vice-president, Gen. Floriano Peixoto. But Floriano, also one of the conspirators against Dom Pedro, differed little in his methods from his predecessor. Of the meaning of constitutionalism in the strict sense he had scant understanding. The growing opposition to Floriano finally culminated in 1893 in a naval revolt and military uprising that aere put down the following year only with the greatest difficulty.

The advent of a civilian as president was hailed with undisguised relief. Prudente de Moraes Barros, who assumed office in 1894, was a distinguished lawyer of São Paulo and a republican of long standing. Though his intentions were excellent and his ability and honesty unquestioned, his administration was rendered largely sterile through the opposition of the disgruntled military elements and the necessity of putting down a rebellion of the ignorant and fanatical population in the hinterland of Bahia. His successor, Manuel Ferraz de Campos Salles (1898–1902), former

president of the state of São Paulo, is chiefly remembered for his striking success in saving Brazil from the financial collapse threatened by the orgy of extravagance, inflated currency and speculation which had followed the overthrow of the monarchy. While still president-elect, Campos Salles in 1898 negotiated through the Rothschilds a funding loan of £10,000,000, interest on which was to be suspended for three years and amortization payments for ten. Because of the able and economical administration of Campos Salles and the marvelous recuperative power of the country, the credit and finances of Brazil were again placed on a sound foundation. Francisco de Paula Rodrigues Alves (1902–06), likewise a Paulista, is generally regarded as Brazil's ablest civilian president. During his term of office the capital was transformed into one of the world's most beautiful cities. Under the direction of the distinguished physician and scientist, Oswaldo Cruz, Rio de Janeiro was completely freed from yellow fever. Some of Brazil's most thorny boundary controversies were settled during the presidencies of Campos Salles and Rodrigues Alves by the able minister of foreign affairs, the baron of Rio Branco, son of the viscount of the same name.

Pres. Affonso Augusto Moreira Penna (1906–09) took an important step toward the stabilization of the exchange through the creation of the so-called Caixa de Conversão, or Bank of Conversion, whose function was to redeem inconvertible paper currency through the issue of convertible notes secured through the deposit of gold. Unfortunately this project had to be abandoned on the outbreak of World War I. Penna died in 1909 and was succeeded by the vice-president, Nilo Peçanha. The campaign of 1910 was fought with great bitterness. The official candidate, Gen. Hermes da Fonseca, the nephew of Deodoro da Fonseca, was opposed by a civilian, Ruy Barbosa, a noted lawyer and publicist. Though the conviction was general that Barbosa had received a majority of the votes cast, the official machine easily secured the election of Hermes da Fonseca. The administration of the new president (1910–14) represented a step backward. The high standards set by the first three civilian executives were largely abandoned.

2. World War I and After.—A change for the better came with the election of Wenceslau Braz (1914–18), a former governor of Minas Gerais. His administration was closely associated with Brazil's reaction to and participation in World War I. From the outset the sympathies of most Brazilians inclined toward the Allies. On April 11, 1917, Brazil broke off relations with Germany following the torpedoing of the steamer "Parana" off France. On June 1 Brazil revoked its decree of neutrality in the war between Germany and the United States as a mark of continental solidarity and friendship with the United States. Following the sinking of more Brazilian ships, war was declared on Oct. 26. Brazil's participation in the war was confined to the dispatch of a part of its fleet to European waters and the sending of a medical mission and a number of aviators to the western front. Its chief contribution was the placing of its food supplies and other resources unreservedly at the disposal of the Allies. Brazil participated in the peace conference and was given a temporary seat on the council of the League of Nations.

In the election of 1918 a new precedent was established in Brazilian political life by the re-election of Rodrigues Alves. The new executive was too ill to accept office, however, and died on Jan. 16, 1919. In the new election, in April, the successful candidate was Epitácio da Silva Pessôa, a lawyer of note and head of the Brazilian delegation at the Versailles conference. His presidency, coinciding with the wave of postwar prosperity, was an era of reckless expenditures accompanied by an immense increase in both the internal and foreign debt. Large sums were absorbed by the Brazilian Centenary exposition, which was celebrated with great brilliance in 1922. The presidency of Arthur da Silva Bernardes (1922–26) was beset with difficulties. The collapse of the boom found Brazil in financial extremities. The new executive endeavoured to carry out a policy of strict economy. Governmental expenses were cut down, the prosecution of costly public works was postponed and new sources of revenue, such as the income tax, were created. The success of this program of retrenchment and reform was compromised by a dangerous flare-up

of militarism. In the closing weeks of Pessôa's administration a military group made a desperate but fruitless attempt to prevent Bernardes' inauguration. Another revolt was launched in July 1924 at São Paulo city. This, too, was suppressed, but only after heavy loss of life and much property damage. In 1926 Washington Luis Pereira de Souza, minister of justice in the two preceding administrations, was elected president without a contest.

In retrospect it is apparent that the shift from empire to republic produced little immediate change in Brazil's basic political or social institutions. Under the constitution of 1891 state and municipal governments were granted somewhat greater freedom from central control than had been the case under the empire, with a consequent increase in the power of local bosses. However, no significant new elements were added to the political spectrum and the bulk of the population remained outside the political process. Rural landholders, particularly in the states of São Paulo and Minas Gerais, adjusted to the loss of slave labour and retained their pre-eminence under the republic. In São Paulo state massive immigration from the Mediterranean area in the years before World War I provided a new source of rural labour for the expanding coffee industry. Coffee became the outstanding export crop and source of government revenue early in the 20th century. Diversification of agriculture, and expansion and diversification of the mining industry provided economic stimulus in Minas Gerais. The problems of rapid urban growth and industrialization, as well as the cultural assimilation of the immigrants, did not become acute until about 1930. The old areas of Bahia and Pernambuco gradually declined in political significance and were eventually replaced by the increasingly important state of Rio Grande do Sul. However, the latter did not successfully challenge the political hegemony of the central states until 1930. Thus, economic and political power was effectively concentrated in São Paulo and Minas Gerais during the first four decades of the republic, and national policies usually reflected the interests of those states. The principal new factor introduced with the republic was the politically active role of the military. After 1889 the armed forces asserted their claim as guarantors of the constitutional process, and served usually as a check upon the civilian administrations. The military also provided the leadership of occasional protest movements. As indicated above, the first stirrings of social unrest and vaguely expressed demands for a modification of the institutional patterns of the republic were voiced by young military officers: the *tenentes*, in the mid-1920s. The movement which they headed culminated in the revolution of 1930 which marked the end of the so-called "old republic."

3. The Vargas Era.—Following the election of 1930, when the administration-sponsored presidential candidate was officially declared winner, a revolt broke out. This successful rebellion was led by Getulio Vargas, a figure who was to remain central in Brazilian national life until his suicide in 1954.

Vargas held offices as chief executive on two occasions—1930–45 and 1951–54. Early in the first of these periods! the country's difficulties were essentially economic, accentuated by a policy of subsidizing coffee production. The tremendous powers which the states possessed also served as steady irritants to the country as a whole. In 1934 a new constitution, which gave the central government greater powers, was promulgated. Three years later, as the country prepared for new presidential elections; President Vargas suddenly seized practically absolute power and set up still another constitution, under which he continued as president. The new administration was known as the *Estado Novo* ("new state"). This so concentrated power in Vargas' hands that he was able to suppress not only disorders but all manifestations of popular will as well. Brazil had never been truly a democracy, but Vargas stripped it of most of the trappings through which it might eventually hope to become one. Press and mail censorship was imposed, and many regarded Brazil as on the threshold of totalitarianism. On the other hand, considerable social legislation was enacted, with positive benefits to the labouring man.

Vargas' policy, from his accession to power, was one of increasing curtailment of states' rights, of emphasis on nationalism and, in effect, the transfer of the locus of power from the country to

the city. More and more the states were subordinated to the central government, politically, economically and socially. The ruinous coffee policies of the past were done away with; manufacturing was encouraged, as was diversification of agriculture.

After the outbreak of World War II in 1939, Vargas' government supported inter-American solidarity; in Jan. 1942 it broke relations with the Axis powers, and on Aug. 22, 1942, declared war against Germany and Italy. Besides participating in the defense of the South Atlantic against Axis submarines. Brazil sent an expeditionary force to Italy in July 1944 under the command of Gen. Mascarenhas de Noraes. The Brazilian troops distinguished themselves in several battles, especially that of Monte Castello. Brazil also granted the United States the right to use certain Brazilian naval and air bases during the war. A number of agreements were signed between the two governments for the economic development and production of raw materials.

On Oct. 29, 1945, President Vargas was overthrown in a bloodless revolution. For some time there had been unrest and dissatisfaction with his regime, and when it appeared that the president intended to continue indefinitely in power, a group of high army officers forced him to resign, transferring the government to Chief Justice José Linhares on an interim basis.

4. Politico-Social Changes Since 1945.—On Dec. 2, 1945, Gen. Eurico Gaspar Dutra, long a loyal friend of Vargas, was elected president by a large majority of the popular vote. He was inaugurated Jan. 31, 1946. The following month a constituent assembly met at Rio de Janeiro and adopted a new constitution which was promulgated on Sept. 18, 1946. In general, it was more liberal and democratic than the 1937 charter (see below). Dutra's administration was characterized by a sincere determination to govern the country in harmony with the constitution. He endeavoured to halt inflation, although without much apparent success.

For the general elections of Oct. 3, 1950, former President Vargas emerged as the chief candidate to succeed Dutra. The result was a resounding triumph for Vargas—he received more votes than did both of the two rival candidates. Accordingly he was installed in the presidency once more on Jan. 31, 1951. Vargas' second period in power contrasted sharply with his first. During the first three years of his second administration, he endeavoured to abide by the constitution of 1946; he was even criticized in some quarters for exercising weak leadership. Early in 1954, however, some tension and instability accompanied rumours that Vargas might again attempt to prolong his period in power. A decree providing for a general wage rise—supported by Vargas and viewed by some as his bid for labour backing for a possibly unconstitutional move on his part—produced a series of crises which reached a climax in Aug. 1954. At that time, a group of army officers presented Vargas with a demand for his resignation. Vargas' answer was suicide on Aug. 24, 1954.

Vice-Pres. JoCo Café Filho served out the unexpired portion of Vargas' term. Much of the Café administration was occupied by preparations for the presidential election which was to be held on Oct. 3, 1955. Three major candidates for the presidency emerged: former Minas Gerais state governor Juscelino Kubitschek, popularly regarded as Vargas' political heir; former São Paulo state governor Adhemar de Barros, generally backed by financial and commercial groups; and Gen. Juárez Távora, regarded as representing the military and conservative civilian groups. The election was a close contest. Kubitschek emerged as victor, with Távora running a close second and Barros a somewhat more distant third. The election of Kubitschek was widely interpreted as a popular vindication of the Vargas position. After a brief military intervention Kubitschek took office on Jan. 31, 1956.

In Oct. 1960 another election was held amid great excitement but in an orderly atmosphere. Jânio Quadros, who advocated re-establishment of diplomatic relations with the U.S.S.R., won a substantial plurality of the votes. He was the candidate of the National Democratic Union (U.D.N.), the major opposition party.

After only seven months in office, during which his foreign and domestic policies made him a centre of controversy, Quadros resigned. His successor, Vice-Pres. JoCo Goulart, was out of the

country at the time and there was an attempt by Brazilian military forces to prevent him from taking office. As a compromise measure, congress amended the constitution to transfer most of the presidential powers to a newly created post of prime minister. The compromise was accepted by the opposing factions and Goulart was inaugurated. The first prime minister under the new system was Tancredo Neves.

In many respects the period beginning with the 1945 election marked the beginning of a new phase in the political history of the country with the overthrow of the *Estado Novo* and the election of a president and congress responsible to the electorate. Yet, the economic and social trends encouraged by the preceding regime were only slightly modified by the revival of representative government. The fact that the political forces which had just regained freedom of expression were unanimously agreed upon the need for a new national political charter, dramatically illustrated their recognition that return to pre-1930 *status quo* was impossible. While the constitution of 1946 borrowed heavily from that of 1891 in certain exterior forms, a cursory comparison of the two charters reveals the nature and extent of the socio-economic transformation that Brazil had experienced after 1930. The 1946 constitution largely confirmed the concentration of power in the central government which Vargas had accomplished at the expense of the states, and acknowledged the responsibility the federal government had assumed to maintain and foster economic development and social welfare programs beyond the restricted capabilities of the various state administrations. The constitution of 1891, despite its positivist trappings, was essentially a 19th-century liberal document that stressed the rights of the individual and of state governments as opposed to the national administration. The 1946 constitution, in contrast, emphasized the obligations of the state to society, particularly to the urban working class which had emerged as a vocal element on the Brazilian political scene. The experience of 15 years of paternalistic rule, sanctioned in the 1946 constitution, encouraged economic and social groups to political action in order to guarantee the favours of the central government to satisfy their demands and aspirations. The period since its promulgation has witnessed no discernible weakening of the political philosophy it mirrors.

Perhaps the most striking development revealed by the elections of 1945 and since has been the extent of the politically active population in Brazil. In 1930 scarcely 1,500,000 voters, out of a total population of approximately 30,000,000, had cast ballots for the two presidential candidates. By 1945 the electorate had increased fourfold, and General Dutra alone received more than 3,000,000 votes. The number of registered voters rose to nearly 12,000,000 by 1950, and by 1955 the figure was more than 15,000,000, of whom more than 8,000,000 actually went to the polls. Thus, while the Brazilian population roughly doubled in the quarter century following 1930, the effective voting population showed a sixfold increase and the number of eligible voters had multiplied ten times over. Natural population growth and the enfranchisement of women provided for much of the increase, but even when these factors are taken into account it is apparent that important new groups, whose voices had been dimly heard at best before 1930, had come of age and were in a position to influence the course and policies of government in Brazil. As yet there has been no thorough analysis of the Brazilian electorate according to economic or social status. However, it appears certain that the bulk of the voters enfranchised since 1930 belong to the urban working class and government bureaucracy, which under the *Estado Novo* had been encouraged to develop a sense of political awareness.

The rise of a politically conscious urban proletariat has not signified the emergence of a true labour-based political movement. Leadership of this new political force has been contested by the traditional civilian elite—principally landowners and large-scale merchants—and by a new middle class composed of industrial, commercial and professional elements who, in an environment of sustained industrialization and urban growth, have gained elite status.

The new middle sectors have yet to acquire a strong sense of

class consciousness which would permit them to regard themselves as distinct elements in Brazilian society. Thus, it is not surprising that they have not sought political expression in a party oriented solely or principally to a single social or economic group. Rather, they have vied with the traditional ruling groups for leadership of the existing political organizations. Members of both groups are found in the leadership of virtually every party on the Brazilian scene. Since 1945, however, urban-oriented parties have grown at the expense of more traditional, rural-based parties, as indicated in the elections of 1950 and 1955. These two contests reveal clearly that the urban vote, relatively unimportant before 1945, is now essential to the election of a presidential candidate.

V. POPULATION

1. Number and Distribution.— Carefully planned and well-executed modern censuses showed the population of Brazil to be 41,236,315 in 1940, and 51,976,357 in 1950. The 1960 population was estimated at 66,302,271. The manner in which the inhabitants were distributed among the various states and territories is shown in Table II. Except in São Paulo and Rio Grande do Sul the population has remained concentrated to a large extent in the zone lying within about 200 mi. of the coast. Since 1950 the population has continued to increase by an average of approximately 1,400,000 annually.

2. Composition.— The white elements predominate in the racial composition of Brazil's population; other groups are Negroes and the mixed (*pardos* or "brown" category). South American Indians were not classified separately, so undoubtedly the mixed group includes millions of persons who are largely of Indian stock, as well as the crosses of both white and Indian and white and Negro. The Japanese, immigrants and their children, constitute almost 1% of Brazil's people. Whites predominate to the greatest extent in the southern states of São Paulo, Paraná, Santa Catarina and Rio Grande do Sul where the people are largely descendants of Portuguese, Italian, Spanish, German and Polish immigrants. Negroes and mulattoes are found in the highest proportions in all of the old sugar-plantation districts, and especially those in the states of Bahia, Rio de Janeiro, Pernambuco and Paraíba. They

§Area in litigation between the states of Minas Gerais and Espírito Santo.

also make up high percentages of the populations of such cities as Salvador (or Bahia), Rio de Janeiro, Recife and Sio Luis. Indians and mestizos are relatively numerous throughout the Amazon basin and in the states of Maranhão, Goiás and Mato Grosso. The Japanese are located mostly in the state of São Paulo, in northern Paraná and along the railroad which crosses southern Mato Grosso. See *The People: Ethnic Composition*, above.

As a result of the high birth rate and the high death rate which have prevailed in Brazil, the nation's population is highly concentrated in the younger ages. Thus, according to the 1950 census, the proportions in the three large age groups were as follows: under 15, 41.9%; 15-64 55.7%; and 65 and over, 2.4%. The sexes, though, are approximately equal in number, the ratio in 1950 being 99.3 males per 100 females.

Brazil ranks high among the nations in the extent to which persons born and reared elsewhere have been incorporated into its population. During the period 1874 to 1957 approximately 5,000,000 immigrants were admitted, of whom about one-half settled in the state of São Paulo. More than 4,000,000 immigrants arrived prior to 1930 and about 500,000 after 1945, mostly from Portugal, Italy, Spain, Japan, Germany, Syria and Poland.

3. Growth of Population.— Throughout the 20th century the population of Brazil has increased rapidly. In 1900 the rate of increase was approximately 2% per annum, but by 1950 it had risen to about 2.5%. A large excess of births over deaths undoubtedly has been responsible for this rapid growth of population. The death rate appears to have fallen sharply, or from about 30 deaths per 1,000 population in 1900 to less than 20 per 1,000 for 1950 and subsequent years. Since 1930, immigration has had no appreciable effect upon the rate of population increase.

(T. L. SH.)

VI. ADMINISTRATION AND SOCIAL CONDITIONS

1. **Constitution.**—The regimes which have governed Brazil have been of four kinds: colonial, imperial: republican and dictatorial. When World War II and the dictatorship of Getúlio Vargas ended, the Brazilians in 1946 adopted a new constitution, their fifth since they achieved independence. These facts both contain a pattern and present a problem. The country's form of government exhibits an evolutionary development, but the impermanence of the forms suggests an underlying instability. What is the explanation of the changes, and why so many?

4 clue is provided in the two key words of Brazil's national motto "Order and Progress." "Order" has meant the preservation of established tradition; "Progress," the departure from it. The politics of modern Brazil have been marked by conflict between these tendencies. In the colonial period which lasted until 1822, the social order, and therewith the system of government, was cast in a definite mold whose effects continued after the causes had disappeared. Brazil had a stratified society composed of three ethnic groups and their intermixtures. At the top, the great clans of the plantation owners made up an oligarchy of privilege. At the bottom were the slaves imported from Africa for their labour. The harshnesses of social distance were somewhat mitigated, however, by a tolerance for colour, by the practice of miscegenation, and frequently by parental education and support for illegitimate half-caste children. Thus the Portuguese legacy in government was the paternalism of a dominant elite, benevolent at its best, selfish and soft at its worst.

Such was the "Order" which "Progress" has sought to challenge. Each of the constitutions inaugurated from 1824 to 1946 met this problem differently, though in one respect they were all alike. The inspiration for reform was drawn from outside; the models were foreign. This was as true of the British-inspired empire of Dom Pedro Segundo, as of the republican constitution which Rui Barbosa in 1891 modeled upon the United States, and the *Estado Novo* of the 1930s which Vargas patterned upon Mussolini's corporativism. In this respect, the constitution of 1946 resembles its predecessors. It was Brazil's second try to govern itself after the fashion of the United States, but with safeguards against a *golpe* by a second Vargas. The constitutional amendment

of 1961, which transferred many of the presidential powers to a prime minister or to congress, was a movement away from a presidential type of government toward a parliamentary system. Under this new system executive functions were vested in the president and council of ministers, with the latter responsible for administration and government policy. The major powers left to the president included that of the veto, which could be overridden by a two-thirds vote of congress, and the power to dissolve congress after successive no-confidence votes. In the latter case, however, new elections must be called within 90 days, the old congress sitting until these elections are held.

2. The Electorate.— Because reform in Brazil has had to overcome a tenacious tradition, the constitution of 1946 must be interpreted with caution. To take everything at its face value could be misleading. Much of what the document prescribes is excellent intention, rather than accomplished fact. For example, the constitution not only establishes a republic, but incorporates the political principles of liberal democracy. Thus art. 1 affirms that "all power emanates from the people and shall be exercised in its name." But who are the people? For all effective purposes, the people in a democracy are those who at election time can vote for their political representatives. Hence the qualifications for the franchise are a crucial index to the degree of democracy. The constitution provides for universal! direct suffrage with a secret ballot (art. 134) and confers voting rights on all citizens of both sexes at the low age of 18 (art. 131). However, it denies the vote to the illiterates (art. 132), so that popular participation in elections is tied to the spread of education.

The fact that the number of qualified voters doubled in those ten years is a welcome sign. But the figure must be considered in relation to the total population, which amounted to nearly 52,000,000 at the census of 1950 and was estimated at 58,633,000 in 1955. Since illiterates in 1950 numbered approximately one-half of those aged over ten, the denial of voting rights to illiterates undoubtedly had the effect of reducing the potential electorate by at least half. As for those who actually voted in the federal elections, the table shows that, while their total has increased, when expressed as a percentage of the registered voters it dropped in ten years from 83.8% to 59.7%.

3. Political Parties.— The difficulty of converting a dominant oligarchy to the forms and spirit of a representative democracy can also be seen in the party system. When political freedom was regained in 1945, many parties were quickly organized. Only five, however, have had any national significance. The Social Democrats (P.S.D.) were the official party of Pres. Eurico Gaspar Dutra's period and include many adherents who gained preferment at that time. In 1950, and again in 1956, they won approximately one-third of the seats in the house of deputies. The National Democratic Union (U.D.N.), which mobilized opposition to Vargas at the end of the dictatorship, has continued since then to organize the right of centre. Besides wealth, it contains members who are leaders in the professions and highly educated. Less than a quarter of the deputies belonged to it in 1956. The Brazilian Labour party (P.T.B.) was created by Vargas to represent the urban and industrial workers and to be a spokesman for nationalism. It filled 56 out of 326 house seats in 1956. The Social Progressives (P.S.P.) were founded by Adhemar de Barros and have been strongest in the state of Sio Paulo, of which he was governor. The Communist party made some striking electoral gains between 1945 and 1947, but then, with the development of the cold war, followed the Stalinist line. It was therefore outlawed under an article of the constitution (141, sec. 13) which prohibits any totalitarian party or movement. In general, the Brazilian parties have been amorphous, and the whole system has remained fluid. *Personalismo*, or the cult of personality, has often been more important than a program, and the parties have had less influence on policy than such pressure groups as the industrial workers, the *fazendeiros*, the importers, the army and the church.

4. The Presidency.— It was in this political context that the institutions of government functioned. These consisted of a federal union, a chief executive who was outside the legislature and a judicial review of legislation. Among the institutions of the

union, the presidency supplied the natural link between traditional Brazil and the principles of republicanism. The president, while embodying the appeals of *personalismo*, also continued the symbolism of emperorship which Brazil did not abandon until 1889. The candidate with a national plurality was elected for a term of five years by direct popular vote. In 1955 Juscelino Kubitschek won over three rivals, receiving 35.7% of the votes cast. The president could serve more than one term, but not successively. The vice-president was elected simultaneously with the president, but on a separate ballot, and the voting for the two offices was far from identical. The executive departments were headed by ministers who could be members of the legislative branch and could be required to appear before it. With the constitutional amendment of 1961, the president remained as chief of state, but most of the powers of government were turned over to a prime minister. The amendment further changed the method of choosing the president, giving the power of selection to congress. This provision, however, did not affect Goulart who took office as the constitutional successor to Quadros.

5. Congress.—The national congress is bicameral, the house of deputies being more potent than the senate. The former, was composed in 1956 of 326 members who are elected simultaneously by proportional representation for a term of four years. Although seats in the house are distributed among the states and territories according to population, the apportionment is so weighted as to favour the areas that have few inhabitants. In the senate, three seats are assigned to each of the states and to the federal district. They are elected for eight years, their terms being staggered. Because of the number of parties and the lack of strong discipline, the congress is hard to organize. Leadership is subject to challenge, and the outcome of proposed legislation is often in doubt.

6. Federalism.—The choice of a federal structure contrasts strongly with the centralization that prevailed under the colonial and imperial regimes and the dictatorship of Vargas. Although the institutions of federalism have been imported from the north, they do conform to some basic conditions of Brazilian society. Because of Brazil's size, historical evolution, race mixture and economic diversity, the regional differences are profoundly marked. In literature and art, in politics and the idioms of daily speech, these facts and feelings are expressed by such terms as *cariocas*, *Paulistas*, *sertanejos*, *gauchos*, *mineiros*, etc. The country is, therefore, naturally fitted to a federal form of government. But, to operate these institutions has not been easy because Brazil's various regions are so dissimilar in resources and in cultural and economic development.

The union (Estados Unidos do Brasil) is composed of 21 states, five federal territories, and the federal district containing the capital, which has the constitutional position of a state. When the constitution of 1946 was drafted, elaborate care was taken to prevent undue centralization. Modernization had proceeded in Brazil most unevenly. Glaring contrasts existed between the advanced states of the south and those of the northeast and west, and also between Rio de Janeiro and the state capitals, on the one hand, and the smaller towns and rural areas, on the other. Hence the intention of the new constitution was to ensure that, as the nation progressed, the benefits would be more uniformly spread. Thus, the union is required to transfer fixed percentages of the yield of designated taxes on a proportional basis to state and local treasuries (art. 15, sec. 2 & 4). The states likewise are obligated to distribute a share of certain of their revenues to the local units and especially to those other than the state capital (art. 20, 21). The constitution also recognized a national interest in two regional problems which transcend the resources of the states directly concerned, namely the economic development of the Amazon valley and the periodic droughts in the *sertão* of the northeast. All in all, however, so great is the constitutional authority of the union, and so disparate are the states, that the federal government cannot fail to be predominant—especially at a time of rapid industrial expansion and monetary inflation.

7. Taxation.—Besides the problem of geographical allocation, the equities of taxation are further complicated by the inequalities

in the economy. Not only is a large share of the national revenue collected in the state of São Paulo and the city of Rio de Janeiro, but the burdens of taxation were by no means fairly distributed in the past. Traditionally, the richer individuals were favoured, as well as the richer regions, and too much of the revenue was derived by indirect taxes which fell heavily on consumers with modest means. In the 1950s some attempt was made to correct this situation by increasing the yield from the graduated income tax. More may be expected from this source in the future, as industrialization fosters the growth of cities and the urban middle class increases. But so far, this emerging class has been too hard hit by price inflation to make long-range plans or to feel any security.

8. Living Conditions.—As may be expected in a country where economic inequality is still the rule, living standards vary so widely that national statistics must be used with caution. In the federal capital, São Paulo and the three southern states, the standard of living approximates that of eastern Europe. In the northeast and the sparsely-settled areas of Mato Grosso and the Amazon, the conditions are closer to those of Asia. Even within the more advanced centres, squalor and luxury are but a stone's throw apart. In Rio de Janeiro, the beaches are fringed with massive new apartments that exude an ostentatious wealth. But overlooking them, atop the rocky hills, are the festering *favelas*.

In general, though, the prospects for the individual are best in the cities, next best in the suburban areas and worst in the rural districts. Indeed, there are parts of Brazil where to go inland 100 mi. is to go back in time 100 years. Since the mid-1930s, the occupational group who have advanced most rapidly are the industrial workers. Vargas' lasting achievement, and the source of his political strength, was to care for their welfare, which had been neglected by his more conservative predecessors. The social gains of the dictatorship were not abandoned under the subsequent republic. Working conditions are controlled in detail by law and by the bureaucracy of the ministry of labour, so that an extensive code embraces hours and wages, the settlement of grievances, job security, pensions and health and welfare benefits. The system is well-intentioned, but suffers from two defects. The workers are protected too much by the state, and too little by their unions, which are mostly the creatures of the state. Also, the chronic inflation, to which the policies of successive governments have contributed, has made it impossible to stabilize wages and has caused many strikes.

9. Health and Education.—The same may be said of health and education as of other social conditions. There have been tremendous obstacles to overcome. Considerable headway has been made. But the progress has been uneven, and much remains to be done. In both fields, the greatest advances have occurred in the south and the principal cities. Notable achievements were the work of Oswaldo Cruz in eradicating yellow fever from Rio de Janeiro, and of the National Malaria service which between 1945 and 1951 drastically reduced the number of deaths from malaria by spraying with DDT. But in rural Brazil, and in the north, northeast and west, the expectancy of life is still short. Resistance to disease is lowered by malnutrition, the diet of most Brazilians being seriously deficient in vitamins and low in calories.

In education, the results look good or bad depending on which statistics one takes and how they are interpreted. In absolute numbers, more primary and secondary schools have been built every year and the pupils in attendance have steadily increased. Also in the universities, more students have been enrolled both in general courses and professional schools. By the early 1960s more Brazilians were literate, and more have received higher degrees, than ever before in the country's history. But the rate of development in education did not match the rapidity of industrial expansion. In fact, the conquest of illiteracy barely kept pace with the growth of population. Shortages of trained teachers, of buildings, books and equipment have detracted from the quality of much of the education that is given. At the highest level, however, individual Brazilians have continued in the present, as in the past to attain international eminence in various fields—for instance, Heitor Villa-Lobos in music. Cândido Portinari in

painting. Oscar Niemeyer in architecture and Gilberto Freyre in sociological scholarship. (See *The People: Arts*, above.)

10. Military and Police.—Except for the period of the Vargas dictatorship. Brazil has not been governed as a police state. Its politics have been less affected by violence and coups *d'état* than in neighbouring countries. Independence, emancipation and republicanism were peacefully accomplished. Even the dictatorship of 1930-45 was moderated by the national flair for effective ridicule. The armed forces have not lacked influence in civic affairs, but their actions have generally been restrained and have often assisted the constitutional regime. The army helped to stabilize the infant republic in the 1890s and was instrumental in procuring Vargas' resignation in 1945. Along with the air force, it contributed to the events that led to his downfall and suicide in 1954 and ensured that President Kubitschek would take office in 1956 after the interregnum. For the most part, the generals have stayed in the background, buttressing the civilian authorities as occasion required. The military threat to bar Vice-Pres. João Goulart from the presidency after the resignation of President Quadros in 1961, however, led to the constitutional amendment of that year which created the post of prime minister.

11. Order and Progress.—The problems of Brazilian government since 1945 have been related to the fact that the various sectors of national life are changing at different speeds. Economic change is the fastest. Social change—in the family system, church and education—is the slowest. Politics move in between, dragged onward by economics, but held back by social rigidities. The institutions of government have had the task of bridging the gap. (L. LIP.)

VII. THE ECONOMY

Brazil is still overwhelmingly an agricultural country with approximately 60% of the labour force in agriculture and related employments. The percentage of the population engaged in agriculture has steadily declined since 1940, indicating increasing urbanization and industrialization. Rapid economic development is a feature characteristic especially of the south of Brazil where the state of São Paulo produces approximately one-third of the national income and as much as one-half of the exports of Brazil. São Paulo stands out both as an agricultural centre, producing about 50% of Brazil's coffee, as well as an industrial region of rapidly growing importance.

Great economic advances have been made in spite of many obstacles. Out of the low per capita income only a fraction can be saved and invested in capital. The mere maintenance of the average capital equipment of a rapidly increasing population places a formidable strain on Brazil's available resources. Economic development is further hampered by the inadequate transportation system and by the tight power supply.

The government is an active promoter of accelerated economic development. It has formulated a number of development plans, of which the Salte plan of 1948 is best known. The name of this plan is derived from the fields in which development is considered most urgent: health (*saúde*), food (alimentos), transportation (transporte) and energy resources (energia).

As diversified economic activities come to the fore, Brazil is gradually reducing the dependence of her economy upon a single commodity, be it coffee as in the most recent phase of her economic history, or such other products as brazilwood, livestock, sugar, gold and rubber, which have been of similar importance in different periods of the past. (See *History*, above.)

A. PRODUCTION

1. Agriculture.—Only a small proportion of the large area of Brazil is under permanent cultivation. Much larger regions consist of pastures and forests. Of the cultivated area, approximately 15% is used for coffee, 12% each for cotton and rice, 10% for beans, 6% for wheat, and 5% each for manioc (cassava) and sugar cane. Coffee contributes about a quarter of the value of crop production, followed by rice and corn. Together these three represent well over half the total value of crops. The most significant expansion of crop production is in wheat, the output of

which more than doubled in the 1950s.

Brazil is by far the largest producer of coffee in the world. Next to Ghana, it is the world's largest producer of cacao and is second to the United States as the largest producer of corn. In the Americas, it is the largest producer of rice, and as a producer of cotton is outranked only by the United States and Mexico. Because of its rapidly growing population, Brazil needs to expand food production.

In many ways, methods of farm production have changed little over the years. Total consumption of industrial fertilizers although on the increase, is only 1%–2% of that used in the United States. In 1948 there were less than 100 000 plows and 6 000 tractors in the whole of Brazil. Since then, tractors and other farm machinery have been imported in substantial volume.

Throughout Brazil the rural economy rests on a foundation of cattle raising. More than 60,000,000 cattle are raised, mostly in the agricultural zone of the semideciduous forests.

2. Forestry.—Brazil has huge forest resources, but those which are readily accessible have been badly depleted because of charcoal production and the widespread use of wood as fuel. In terms of solid volume of roundwood (without bark), the annual production exceeds 100,000,000 cu.m., that is, about 10% of the world's total. Of the thousands of different species of trees, the Paraná pine is commercially the most important.

3. Mining.—Brazil is endowed with an abundance of minerals including manganese and iron ore, bauxite, magnesite, beryllium, bismuth, lead, cobalt, copper, chrome, tin, molybdenum, nickel, rutile, wolframite, scheelite, corundum and carbonado. In the ancient crystalline rocks of the Brazilian highlands there are gold, gem stones and industrial metals—concentrated in the state of Minas Gerais (which means "general mines"). Gold was discovered in 1698, and for a century thereafter Minas Gerais was one of the world's major sources of gold, providing great wealth for the Portuguese crown. By the end of the 18th century the richest placer deposits had been worked over. One vein mine, the deepest in the world, has been operated by a British company for more than a century at Morro Velho. In 1729 diamonds were discovered, also in Minas Gerais. Although Brazil is not so well known for gem diamonds as is South Africa, it remains a major source of industrial diamonds. Gem stones also include aquamarine, topaz and many others. Brazil is the world's chief source of quartz crystals for use in radios, and a leading producer of tantalite, thorium and mica.

Brazil's endowment of industrial metals is one of the world's richest. In Minas Gerais is one of the world's major sources of high-grade iron ore, some 13,000,000,000 tons of highest quality ore. The largest manganese deposits in the western hemisphere are in Brazil. A large manganese mining development has taken place in the territory of Amapá, near the mouth of the Amazon. Another source is near Corumbá on the upper Paraguay river.

4. Fisheries.—Brazil's fish catch, the largest in South America, comes close to 200,000 short tons per year. There are thousands of different species of fish, almost 2,000 in the Amazon river system. Commercial exploitation is hampered by primitive equipment and lack of seagoing craft.

5. Power.—The inadequacy of power resources is one of the principal problems of the Brazilian economy. Domestic coal is of inferior quality and contains so much sulfur that special grates are required to burn it; the deposits are scarce and not easily accessible. There is active prospecting for petroleum, but the known reserves are small. At mid-20th century, the only oil field actually in operation was located in the Recôncavo lowland of Bahia. The exploitation of petroleum resources is by law reserved for Petrobras (Petróleo Brasileiro), a mixed corporation which excludes foreign equity participation.

In recent years, increasing reliance has been placed on hydroelectric power, of which the potential is large, being estimated at 15,000,000 kw. Approximately one-half of the electric power is produced by the Brazilian Traction, Light and Power company, a Canadian concern with significant American and British participation.

6. Industries.—A rapid rate of growth of many lines of manu-

facturing production is the most impressive symptom of economic progress in Brazil. The census of 1950 listed 89,000 industrial establishments, most of them small, with 1,300,000 employees. One out of three establishments was in food processing. The textile industry, with improved equipment, is becoming more important. In 1936 there were 74,000 hand cotton looms and only 7,000 automatic ones; 20 years later, there were 72,000 hand looms and 40,000 automatic looms. Other impressive advances have occurred in the pulp and paper, cement and steel industries.

The carnauba palm tree is the basis of an important wax industry in the northern states of Ceara and Piauí. The high-grade wax is exported and used in the manufacture of polishes, carbon paper, explosives and phonograph records.

The production of crude steel, 101,000 short tons in 1938, had increased over eight times by 1950 and almost 18 times by 1960, when it satisfied the bulk of domestic requirements. Much of the steel is produced in the modern Volta Redonda mill, in the Paraíba valley, which was constructed with the help of credit from the Export-Import Bank of Washington.

B. TRADE AND FINANCE

1. Foreign Trade.—Generally imports as well as exports stand in a proportion of 1:10 to the Brazilian national income. Foreign trade thus is of considerable importance. Of the imports, 32% are raw materials, 27% machines and vehicles, 15% chemical and pharmaceutical products, 14% manufactures not otherwise classified and 12% foodstuffs (1956). The two largest single import items are wheat and petroleum (crude and derivatives), which together constitute about one-fourth of the value of all imports.

Of the exports, three-fourths are foodstuffs and one-fourth raw materials. Over 60% of the value of all exports is coffee, with cotton holding second rank, contributing about 10%. More than half of the coffee is exported to the United States, and about a quarter of the cotton by Japan.

Among the trading partners of Brazil, the United States holds first rank, followed, though at a considerable distance, by Germany, Argentina, France, Great Britain and the Netherlands. Ordinarily Brazil has export surpluses with all of these countries except Argentina. The proceeds earned therefrom are used for debt service, other invisible imports and the payment of commodity import surpluses incurred in the trade with Argentina (wheat) and the Netherlands Antilles (petroleum).

2. Foreign Debts and Investments.—While the external debt owed to private creditors has declined, there has been considerable lending in Brazil by such public credit institutions as the International Bank for Reconstruction and Development and the Export-Import Bank of Washington, mostly for economic development or the liquidation of commercial debts. Although a number of restrictions are placed on the operations of foreign business firms in Brazil, there are important foreign business investments. These were until the late 1920s predominantly British. In later years, United States business investments came to exceed all others.

3. Banking and Currency.—In the early 1960s more than 360 banking firms were engaged in business in Brazil, with about 3,500 offices and branches. In addition, there are hundreds of branches of savings banks and credit co-operatives. The largest bank is the Banco do Brasil, whose loans and discounts are a multiple of those of all other banks together. This bank, controlled and partly owned by the government, is the official bank, and acts as a lender of last resort, fulfilling some other central-banking functions. There is no full-fledged central bank. Other monetary authorities include the superintendency of money and credit and the treasury, which issues the currency and holds the gold reserve.

Besides bills of exchange and promissory notes, Brazil has another credit instrument, the *duplicata*, a copy of the invoice which the law considers as a bill of exchange.

The Brazilian monetary unit reflects the chronic inflation which for long has been in existence in Brazil. The monetary unit of colonial times, the real, which in 1822 bought the equivalent of one-tenth of a United States cent, was gradually replaced by the milreis, which was equivalent to 1,000 units of the former currency.

Since 1942 the unit of money has been the cruzeiro, which is equal in value to the milreis. One milreis (or cruzeiro), worth about \$1 in the 1820s, was worth about 5 cents in the early 1960s at the official rate. The free rate dropped to about 10% of the official rate. A complicated system of foreign exchange control has for long been in force.

The fall of the value of Brazilian money in terms of foreign exchange is paralleled by the decline in its domestic purchasing power. Prices are on the rise virtually at all times. They increased about 13 times from 1840 to 1940. Between 1940 and 1945 they doubled, to double again by 1952 and again by 1956. Inflation in the late 1950s was in part attributed to government expenditures in the construction of Brasília, the new federal capital.

4. National Finance.—The 1960 budget called for expenditure of 194,300,000,000 cruzeiros. There is usually a government deficit, facilitated by the federal treasury's monopoly of note issue. The federal government's share in total revenues, less than half of the total, is on a decline relative to that of the states. Local revenues, less than 10% of the total, are heavily concentrated among the state capitals, which receive over 40% of local government revenue although their population is only about one-tenth of the national total.

Among the federal taxes, excise and income taxes are the most important, each contributing about one-third of the total federal tax revenue. Import duties have lost much of their former significance as sources of revenue. The most important state tax is a transaction tax, which falls due whenever goods change hands.

C. TRANSPORT AND COMMUNICATIONS

1. Roads.—One of Brazil's major problems of economic development is its inadequate transportation. Part of the lack of good inland transportation can be laid to the difficulty of climbing the Great Escarpment; but a part also is the result of a scarcity of domestic capital. The deficiency of other means of transportation has given considerable stimulation to highway construction. This development was accompanied by a substantial increase in the number of motor vehicles in use. Highway construction is financed with the help of a gasoline (petrol) tax. •

The great bulk of the roads are unpaved, and many in disrepair. Because of these conditions, the operating costs of the trucking (road haulage) industry are very high. This is important also from the viewpoint of Brazil's international financial position, because an estimated 70% of the operating costs of the trucking industry requires foreign exchange to pay for gasoline, lubricating oil, spare parts, etc.

Inadequate railroad service has been responsible for the use of trucks for purposes which could more economically be served by railroad transportation, such as the movement of timber, cereals and sugar, which not infrequently are shipped by truck over highways that run parallel with railroads, at double the expense.

2. Railways.—The large area of Brazil is served by a railroad network of only 23,577 mi. This is distributed among some 40 lines, many of which are inadequately interconnected. There are more than three gauges. With only a few exceptions the lines are poorly built, badly maintained and inefficiently operated. Routes often are tortuous, with many curves and steep grades. The equipment is old and poorly maintained, and over 50% of the locomotives are more than 30 years old. Many freight cars are of all-wooden construction.

Traffic density, while light in the northeast, is very high in the south of Brazil. The failure of the railroad system to expand with the growth of the Brazilian economy places it under a considerable strain. Approximately one-half of the railroads, with about 80% of the mileage, are owned by the federal government. The states, private companies and mixed state and private organizations account for the rest.

3. Shipping.—Coastwise shipping is of great importance in Brazil, since it is the only means of communication for many regions. The total volume of freight thus carried is over 5,000,000 tons per year. In terms of ton-miles of cargo, the Brazilian coastal fleet carries about as much as the railroads. There are two government-owned shipping companies, Lloyd Brasileiro and Companhia

Nacional de Navegação Costeira, which together handle about 50% of all shipping operations. The remainder is distributed among one well-sized and a host of smaller companies. The government-owned concerns operate 86 ships of a total of 328, which includes many small vessels.

The hub of the coastwise shipping is Rio de Janeiro. Except for the Amazon, which is open to ships of all nations. Brazilian coastal commerce is restricted to Brazilian-owned ships, but numerous foreign shipping lines connect Brazil with the rest of the world.

The extensive Brazilian river system has a total navigability of about 27,000 mi. The inland waterways, especially the Amazon, São Francisco and Jacuí rivers, provide important communication and shipping routes.

4. Air Transport.—Commercial aviation came to the fore during the 1940s and 1950s. During the same period, air freight, though still less than 1% of the ton-miles handled by the railroads, also increased. The lack of alternative facilities has led to the use of airplanes as carriers of some bulk commodities, including certain minerals. There are about 500 airports in Brazil, but only a small number have paved runways or are large enough for four-engine planes.

5. Telecommunications.—There are radio-telephone connections between Rio de Janeiro, São Paulo and Brasília and the major cities of North and South America and Europe. Submarine cables also link Brazil with countries of the northern hemisphere.

Television was introduced in 1950 in São Paulo and there soon were four television stations in the largest cities, with an estimated 150,000 television receiving sets.

BIBLIOGRAPHY.—For a comprehensive bibliography of writings about Brazil see R. Borba de Moraes and W. Berrien, *Manual bibliográfico de Estudos Brasileiros* (1949). Annually since 1935 by the Library of Congress, see the Brazil sections of the *Handbook of Latin American Studies*.

General Works: Among the 19th-century travelers in Brazil there were many who wrote important accounts of what they saw, such as: A. R. Wallace, *A Narrative of Travels on the Amazon and Rio Negro* (1853); T. Ewbank, *Life in Brazil* (1856); H. W. Bates, *The Naturalist on the River Anzons* (1864); L. and E. C. Agassiz, *Journey in Brazil* (1868); D. P. Kidder and J. C. Fletcher, *Brazil and the Brazilians* (1857; 6th ed., 1866). General works in the 20th century include: P. Denis, *Brazil in the XXth Century* (1911); R. Nash, *The Conquest of Brazil* (1926); H. Tavares de Sá, *Brazilians, People of Tomorrow* (1947); Charles Wagley, "Brazil" in Ralph Linton (ed.), *Most of the World* (1949); F. de Azevedo, trans. by W. R. Crawford, *Brazilian Culture* (1950); T. L. Smith and A. Marchant (eds.), *Brazil: Portrait of Half a Continent* (1951); G. Freyre, *New World in the Tropics* (1959).

Geography: For general treatment of the geography of Brazil, including earth resources and human use, see the chapters on Brazil in P. Denis, "Amérique du sud," in *Géographie universelle* (1927); P. E. James, *Latin America* (1942; rev. ed., 1950); R. S. Platt, *Latin America, Countrysides and United Regions* (1942). See also geographic studies of specific areas and problems, such as J. Zarur, *A Bacia do Médio Sítio Francisco* (1946); S. Faissol, *O "Mão Grosso de Goids"* (1952); P. Monbeig, *Pionniers et Planteurs de São Paulo* (1952).

The People: For studies of the racial and cultural elements in the Brazilian population see Francisco J. de Oliveira Viana, *Populações meridionais do Brasil* (1920); D. Pierson, *Negroes in Brazil* (1942); and the description of each of the Indian tribes of aboriginal Brazil contained in the several volumes of J. H. Steward (ed.), *Handbook of South American Indians*, 6 vol. (1946-50). There are also several studies of the social institutions and patterns of life in small communities, such as D. Pierson, *Cruz das Almas* (1951); C. Wagley, *Anzons Town* (1953); and M. Harris, *Town and Country in Brazil* (1956). General surveys include T. Lynn Smith, *Brazil: People and Institutions* (1954); Giorgio Mortara, "The Brazilian Birthrate: Its Economic and Social Factors," in Frank Lorimer, et al., *Culture and Human Fertility* (1954).

History: There are many valuable works on various aspects of the history of Brazil, many of the best in Portuguese. A selection of historical works includes: R. Southey, *History of Brazil*, 3 vol. (1810-19); J. Armitage, *Historia do Brasil* (1914); J. M. Pereira da Silva, *Historia da Fundação do Império Brasileiro*, 6 vol. (1864-68); F. A. de Varnhagen, *Historia geral do Brasil* (1877); F. da Rocha Pombo, *Histria do Brasil*, 10 vol. (1905); A. de Escagnolle Taunay, *Historia geral das bandeiras paulistas*, 6 vol. (1924-30); P. Calmón, *Historia da civilização brasileira* (1933); P. A. Martin, "Brazil," in A. C. Wilgus (ed.), *Argentina, Brazil and Chile Since Independence* (1933); R. Simonsen, *Histria econômica do Brasil*, 2 vol. (1937); A. C. Wilgus

(ed.), *Colonial Hispanic America* (1936); M. W. Williams, *Dom Pedro the Magnanimous, Second Emperor of Brazil* (1937); J. P. Calógeras, *Formação histórica do Brasil*, trans. by P. A. Martin, *History of Brazil* (1939); R. Simonsen, *Brazil's Industrial Evolution* (1939); C. R. Boxer, *Salvador de Sá and the Struggle for Brazil and Angola, 1602-1686* (1952); H. G. James, *Constitutional System of Brazil* (1923); L. F. Hill, *Diplomatic Relations Between the United States and Brazil* (1932); E. Hambloch, *His Majesty, the President of Brazil* (1936); C. R. Boxer, *Dutch in Brazil, 1624-1654* (1957); C. H. Haring, *Empire in Brazil* (1958).

The Economy: In addition to the economic history of Simonsen, cited above, see J. F. Normano, *Brazil: a Study of Economic Types* (1935); J. Jobim, *Brazil in the Making* (1943); G. Wythe, et al., *Brazil: an Expanding Economy* (1949); H. W. Spiegel, *Brazilian Economy* (1949); U.S. Foreign Operations Administration, *The Development of Brazil* (1954); F. B. de Avila, *Economic Impacts of Immigration* (1954); and S. H. Robock, *Nuclear Power and Economic Development of Brazil* (1957).

Literature: For a general view of Brazilian literature see E. Verissimo, *Brazilian Literature* (1945); S. Putnam, *Marvelous Journey* (1948); F. P. Ellison, *Brazil's New Novel* (1954). Three books on Brazil written in English are S. Leão, *White Shore of Olinda* (1943); H. Chamberlain, *Where the Sabiá Sings* (1947); V. Prewett, *Beyond the Great Forest* (1953). A number of books by Brazilian authors have been translated, notably: J. Amado, *The Violent Land*, trans. by S. Putnam (1945); A. Azevedo, *A Brazilian Tenement*, trans. by H. W. Brown (1928); E. da Cunha, *Rebellion in the Backlands*, trans. by S. Putnam of *Os Sertões* (1944); G. Freyre, *The Masters and the Slaves*, trans. by S. Putnam of *Casa grande e senzala* (1946); A. de Escagnolle Taunay, *Inocência*, trans. by H. Chamberlain (1945); E. Verissimo, *Crossroads*, trans. by L. C. Kaplan (1943), *The Rest is Silence*, trans. by L. C. Kaplan (1946), *Tinza and the Wind*, trans. by L. L. Barrett (1951).

Current history and statistics are summarized annually in *Britannica Book of the Year*.

(P. E. J.; X.)

BRAZIL (BRASIL), a legendary island in the Atlantic ocean. The name refers to the red dyewood called brazilwood (*q.v.*), used in the middle ages, in which the island supposedly abounded. It first appears as the I. de Brazi, one of the larger islands of the Azores, in the Venetian map of Andrea Bianco (1436). When this group became better known and was colonized, this island was renamed Terceira. Probably the familiar existence of "Brazil" as a geographical name led to its bestowal upon the vast region of South America, which was found to supply dyewoods. But the Island of Brazil retained its place in midocean, to the west of Ireland, both in the traditions of the forecastle and in charts. In J. Purdy's *General Chart of the Atlantic* "corrected to 1830" the "Brazil Rock (high)" is marked with no indication of doubt, in 51° 10' N. and 15° 50' W. In a chart of currents, dated 1853, A. G. Findlay gives the name, but in his 12th edition of Purdy's *Memoir Descriptive and Explanatory of the N. Atlantic Ocean* (1865), the existence of Brazil and some other legendary islands is discussed and rejected. See also ATLANTIS.

BRAZIL NUT, the pleasing, edible seed of a large South American tree, *Bertholletia excelsa*, useful also for valuable timber. The fruit is globular, four to six inches in diameter, hard-walled, and contains 8-24 nuts or seeds, arranged like sections of an orange. The harvest is from January to June. The tree is not hardy where frosts occur, and although once established in Florida, it failed to survive.

Under test in several tropical areas of the British Commonwealth, it offers small inducement to commercial planters, because of its habits of tardy and light bearing. It is also called Paranot, niggertoe, butternut, creamnut and castanea.

BRAZILWOOD, a dyewood obtained largely from the shrub or small tree *Haematoxylon brasiletto* of the family Leguminosae. Most of the commercial dyewood comes from Nicaragua, but the plant ranges from Mexico to Colombia and Venezuela. There are other less important woods, commercially distinguished as brazilwood, belonging to other groups of the Leguminosae and yielding the same dyeing element. Brazilwood is imported for the use of dyes in billets of large size, and is a dense compact wood, red-brown in colour, bright when cut, but becoming dull on exposure. The colouring matter of brazilwood, brazilin, is soluble in water; it is extracted for use by infusion or decoction of the coarsely powdered wood.

When freshly prepared the extract is yellowish; but by contact with the air, or the addition of an alkaline solution, it develops a

brick-red colour. This is due to the formation of brazilein, the colouring matter used by the dyer.

BRAZING, the process of joining pieces of metal together by the fusion of alloys that have lower melting points than the pieces being joined. The brazing alloys, also known as hard solders, include various copper-base alloys and the silver solders. Copper-zinc brazing alloys sometimes are known as spelter solder. Brazing requires more intense heat than soldering, but makes a more intimate union with the metal and hence a stronger joint; welding, which provides even more intimate union, involves the fusion of the metal itself. For discussion of processes and techniques of brazing and the compositions, uses, etc., of brazing alloys, see **SOLDERING**. See also **WELDING**.

BRAZZA, PIERRE PAUL FRANÇOIS CAMILLE SAVORGNAN DE (originally **BRAZZA SAVORGNANI**) (1852–1905), French explorer and administrator and founder of the French Congo, was born near Rome, Jan. 26, 1852. He was educated in Paris, naturalized French (1874) and subsequently joined the French navy. When his ship was serving off the Gabon he was attracted to the possibility of exploring the Ogooué or Ogowé river which he thought might be the lower course of the Lualaba, recently discovered by David Livingstone. This expedition began from the Gabon, Oct. 1875, and Brazza was accompanied by a naval doctor, Noel Ballay. They penetrated beyond the Ogooué basin and discovered the Alima and Likona rivers, which Brazza realized were tributaries of the Congo, after the navigation of that river by H. M. Stanley. The expedition returned to the coast, Nov. 1878.

Brazza's intention was to obtain some of the Congo territory for France, but the French government decided that his activities should be directed to the Niger basin to compete with British interests which were then being forwarded by Sir George Goldie (then Goldie-Taubman). The expedition left for west Africa in late 1879, but at Lisbon was given instructions to proceed to the Congo instead. French interests thereby came into competition with those of the International African association (later the Congo Free State) and left a virtually free field for British interests in those parts of the Niger basin which were later to be included in Nigeria. Brazza reached the Gabon in early 1880, traveled up the Ogooué, founding Franceville, and reached the Congo at Stanley pool, where Brazzaville was later founded. Treaties were made with the chiefs placing the country under French protection and Brazza then returned down the Congo meeting Stanley, who was traveling upstream making similar treaties. After further exploration in the hinterland of the Gabon he returned to France in June 1882 and in November his treaties were ratified. In 1883 he returned to the Congo with official financial backing to open up the colony and in 1886 was made commissioner general. He remained in this post until recalled in 1897, directing and carrying out systematic exploration. His administration was severely criticized, but any lack of success was due largely to lack of support from the authorities in France.

His record in respect to his dealings with Africans both as an explorer and administrator was excellent. He fully realized the importance of the development of communications in the opening up of Africa and pressed for the construction of a railway through French territory to link the upper Congo with the Atlantic. After seven years of retirement in France Brazza accepted, in 1905, a mission to investigate charges of cruelty to natives brought against officials in the Congo. He concluded his inquiry and sailed for France but died at Dakar, Senegal, on Sept. 14, 1905.

See M. de Crisenoy, *Les Héros du Congo: Pierre Savorgnan de Brazza (1938)*; F. Savorgnan di Brazza, *L'Uomo che dono un impero (1945)*. (R. M. P.)

BRAZZAVILLE, the principal town and capital of the Republic of Congo and former capital of French Equatorial Africa, is situated on the right bank of the Congo below Stanley pool. Pop. (1959 est.) 96,000, including about 6,000 Europeans. The town grew without any plan; under French administration the African quarters were Potopoto on the east and Bacongo on the west; the European quarters comprised the Plateau, Chad, the Plain on

marshy ground to the east and Aiglon, the most modern quarter, on the road to Maya-Maya airport. Brazzaville was founded in 1883 on the site of Ntamo, a village bought by France. The village was replaced by the Plateau, where the governor's palace, administrative offices and colonial-style residential quarters mingle with modern buildings of concrete mixed with the local violet-coloured sand; many shops replaced the former factories. Chad is a military quarter adjoining the Plateau. The Plain is the commercial quarter, and along the river extends the industrial area of M'Pila, with its machine shops, tanneries; and factories for building materials and matches. Xiglon, originally the home of the missions, has become a residential quarter and includes the new hospital. Bacongo and Potopoto contain the former African "concessions," in regular squares of 20 sq.m., separated by hedges and shaded by palm trees or multicoloured cassias; the huts are usually of mud or mud brick. Bacongo is the smaller and houses mainly the Balali (about 25,000), the aboriginals, who keep much to themselves. Potopoto contains groups of Africans of varied origin. The women cultivate the market gardens and the little fields of manioc, and the men travel by truck to the workshops. The river port forms the terminus of the Congo-Océan service (517 km. or 321½ mi.). A motorboat service links it with Léopoldville in the former Belgian Congo across the pool. (J. D.)

BREACH OF THE PEACE: see **DISTURBING THE PEACE**.
BREAD. Bread is a baked product made of dough that has been raised by yeast or other gas-forming agents. Some of the gases are trapped in the dough, which is set by heat. Many different kinds of breads are made in various countries; these breads differ as to contents as well as to methods of preparation.

Early Origins.—Why or when man first ate the seeds of grasses, learned to grind them into flour, mix the flour with water and bake it into bread is not known. Remains of the Swiss lake dwellers, who lived about 10,000 years ago, show that even then man had developed a baking art. Tomb paintings of ancient Egypt portray not only the planting and harvesting of wheat but grinding, bread mixing and baking as well. Around 100 B.C. there were 258 bakeshops in Rome, and about A.D. 100 Emperor Trajan established a school for bakers. Parts of western Europe had developed a wheat agriculture and a bread food before the Roman invasions.

Bread has been made from acorns and the inner layers of pine bark; but it has been and still is made chiefly from cereal grains—wheat, rye, maize (corn), barley, millet and oats.

The acts of 1822 and 1836 in England defined what may and may not be sold as bread in that country. It is stated that "it shall and may be lawful . . . to make and sell . . . bread made of flour or meal of wheat, barley: rye, oats, buckwheat, Indian corn, peas, beans, rice or potatoes, or any of them, and with any (common) salt, pure water, eggs, milk, barm, leaven, potato or other yeast, and mixed in such proportions as they shall think fit, and with no other ingredients or matter whatsoever." Of these only wheat and rye, because of their gluten content, make the raised loaf commonly called "bread" today.

Perhaps the earliest form of bread was made from crushed acorns and beechnuts. To this day an acorn cake is eaten by the Indians of the Pacific slopes. The flour extracted from acorns is bitter and unfit to eat till it has been thoroughly soaked in boiling water. The saturated flour is squeezed into a cake and dried in the sun.

Pliny speaks of a similar crude process in connection with wheat; the grain was evidently pounded and the crushed remnant soaked into a pulp, then made into a cake and dried in the sun. Virgil (*Georgics*, i. 267) refers to the husbandman first toasting and then crushing his grain between stones.

The first bread was very different from the light, white loaf of today. The "flour" was coarsely crushed grain, mixed only with water. Probably the dough was laid on a flat or convex-shaped stone, which was heated, while the cake was covered with hot ashes. Stones that were apparently used for this purpose have been found among prehistoric remains.

In primitive times milling and baking were twin arts. The housewife crushed or ground the grain and prepared the bread or cakes. An oven for baking bread was to be found in the courtyard of every house in Chaldea; close by were kept the grinding stones.

The White Bread of Egypt.—In the valley of the Nile the Egyptians raised barley and wheat. For thousands of years the flat barley cake probably furnished the strength of many peoples. In the Book of Judges an Israelite dreams of a cake of barley bread tumbling into the Midianites' camp and destroying Israel's enemies. Some students maintain, however, that barley could not have been used as a major human food because of its high fibre content.

Eventually the Egyptians discovered that letting the dough of wheat ferment to form gases would make a light loaf. This was the first real bread, and the Egyptians also learned to build ovens to bake it properly. Long ago western man learned to prefer raised bread instead of cooked grains and flat breads, but until the last two centuries white bread was a luxury that only the nobility could afford. At the time of William and Mary (late 17th century) wheat was sent to the towns, while the peasants ate rye and barley bread and oat cakes.

Early Greece and Rome.—The history of baking in classical Greece and Italy can be clearly traced. Xthenaeus in his *Deipnosophists* minutely describes many different kinds of bread, which may be assumed to have been currently used in Greece. According to Pliny (*Nat. Hist.* xviii, ii, s. 28) Rome had no public bakers till after the war with Perseus (171–168 B.C.). It is certain that the Romans continued to make a great deal of bread at home long after public bakehouses came into use. In Pompeii several private houses had their own mill and bakehouse. That city must also have possessed bakers by trade because loaves of bread have been found, round in form and stamped with the maker's name, possibly to fix responsibility for weight and purity. In the time of the republic, public bakehouses were under the control of the *nediles*. The bakers were known as *pistores* or "pounders," recalling the primitive time when grain was pounded by a pestle in a mortar. Juvenal, in his famous satire, said that the Romans required only two things, *panem et circenses*, bread and circuses.

The Middle Ages and Later.—Oldest of the town guilds of the middle ages were the bakers' guilds, which had begun in the Roman empire. Laws protected the baker from unfair competition and the people from dishonest bakers.

Use of Yeast.—The progress of breadmaking as an art and industry has been tied closely with the development of the use of yeast. In the early years of breadmaking, spontaneous fermentations were used; an advance was made with the introduction of yeasts grown on the fermented mashes used in brewing beer. The first compressed yeast of this type was made in England about 1792; by 1800 it was being used throughout England and northern Europe. Large-scale commercial production of bread became possible when Charles Fleischmann of the U.S. in 1868 introduced an improved type of distiller's compressed yeast in which the yeast cells were separated from the liquid medium and compressed into cakes.

Use of single yeast cultures became possible about 1883 when bacteriologists learned how to isolate single cells and from them to develop yeast strains of great stability, rapid fermentation capacity and the ability to withstand the high salt and sugar concentrations and the high temperatures used in dough fermentation and proofing (allowing dough to stand to prove quality). Pure cultures of yeast make possible a uniform product and uniform procedures in commercial bakeries.

The advances in yeast production were accompanied by improvements in temperature control, product handling, oven fuels and refrigeration, so that by 1915 the modern methods of commercial bread production were well established.

See YEAST; FERMENTATION.

TYPES OF BREAD

Flour.—Improvements in milling methods have been largely responsible for the fine white bread of today. As long as the housewife had to grind her own grain in a hand mortar, the flour was coarse and the loaf dark and rough. Early stone mills powered by donkey or water often produced a gritty flour as the stones themselves wore away. In Switzerland in 1830 a large mill was built that crushed the wheat between steel rollers, thus eliminating stone dust and producing a finer flour. Jacob Sulzberger improved this mill and set up several in the wheat regions of Hungary, which for a time became the flour centre of the world. Soon, however, the vast wheat fields of America superseded Hungary. In practice, wheat is ground gradually, by stages. After each grinding the flour particles are separated from the bran by sifting and air currents. In a modern mill as many as 50 different "streams" of flour and feed are produced.

A flour made from all the flour streams is a "straight grade flour" that represents about 74% of the wheat, the remaining 26% being used as animal feed.

Depending on the baking use intended and characteristics desired, the many streams that enter into straight grade flour can, by combination or omission, provide special flours. The main differences in the streams are in mineral matter (ash) and protein (or gluten); in general, streams of lowest ash are highest in quality. (For further details about flour and milling see the article FLOUR.)

Kinds of Bread.—Over the world, bread is known by many names and is made from many grains. Scotland has its oatcakes and bannock, the latter made either from oats or barley.

In Germany, the U.S.S.R. and Scandinavia the common bread is a "black" bread made mostly from rye, sometimes with barley or potato flour added. India makes millet cakes and chapatties (unleavened) from wheat.

The far eastern peoples prefer rice, which they use as a grain, to the western bread, but in the orient bread forms an increasingly large part of the diet. The baking industry in Japan grew rapidly after World War II as Japanese bakers adopted U.S. breadmaking processes and bread types. People of Mexico and much of Latin America eat *tortillas*, little flat cakes made chiefly from corn. In Brazil, little cakes are made from cassava or manioc root.

Wheat breads take many forms. The choice among most people, if they can afford it, is raised white bread made from finely sifted wheat flour. Whole-wheat bread is made from unsifted flour; *i.e.*, it contains much if not all of the outer brown coat as well as the white inner part of the wheat grain. Gluten bread is made from flour with much of the starch removed so that it yields little sugar when digested. Vienna and French breads are long, narrow, crusty loaves not shaped in a pan. Lighter rye loaves are made by using part wheat flour, as in the United States. (See Table.) Pumpnickel is a dark, whole rye.

Corn (maize) also takes many forms and may be used as finely ground flour or as coarser meal. The simplest are corn pone, made without eggs or milk and baked in flat cakes, and hoecake, originally baked on the blade of a hoe. Spoon bread is soft and served with a spoon. Johnnycake contains more seasonings—milk, eggs, shortening, honey or sugar.

BY COURTESY OF BOND BREAD BAKERS

PRELIMINARY STEPS IN BAKING OF BREAD

1. Mixing machines, each of which mixes enough dough in one operation for approximately 1,000 loaves
2. A divider, which cuts the dough into exact sizes for the loaves
3. The rounder, which shapes the loaf-size pieces of dough into flour-sprinkled balls
4. After a "quick" rising in an overhead proofer, the dough enters the moulding machine, where each piece is kneaded and shaped into loaves
5. Feed end of a travelling oven, where the pans of dough are placed after a controlled second rising

61 COURTESY OF BOND BREAD BAKERS

FINAL STEPS IN BREAD MANUFACTURE

1. Delivery end of a travelling oven, which bakes approximately 3,600 loaves an hour
2. Cooling racks for the freshly baked bread
3. After cooling for two hours, the loaves pass on conveyors to the slicing and wrapping machines
4. Automatic slicer

The amount of bread consumed in the world is known only in a very general way. About half the world's farmlands planted in cereals are devoted to wheat and rye. Yearly crops of those two bread grains total more than 8,500,000,000bu. Seed for the next crop must be deducted; some is fed to cattle or used in industry for distilling, etc.; flour milling residues are used for livestock feeds. In the United States about 20% of the flour is used in products other than bread.

If only one-half of the wheat and rye produced eventually becomes bread, the result is at least 100 one-pound loaves per year for each of the world's inhabitants. Wheat contributes less than 5% of total food calories in several countries, mostly tropical or oriental, and as much as 50% in some others. Climate, food preference and income status appear to explain the major differences. In the U.S., about one-third of each year's wheat crop is milled into flour, from which about 15,500,000,000 lb. of bread are produced, 90% of it white enriched bread.

The first form of bread—flat bread—was still being eaten in much of the world in the latter half of the 20th century, notably in Asia and Africa. Corn, barley, millet and buckwheat, from which raised bread cannot be made, are the principal grains used for flat bread, although large amounts of wheat and rye are also used. In India, Iran and Armenia, flat bread of wheat is widely eaten. Flat and sometimes raised bread is included in various religious services and ceremonies. In Europe and America the Jewish Passover bread matzoth is perhaps the best-known uheat flat bread. Swedish or Scandinavian knackebrod, a hard, round sheet made of whole rye that will keep for months, is still of some importance as a supplement to raised bread.

Bread in America differs from that in the old world because it includes sweetening, shortening and milk in addition to flour, water, leavening and salt.

Other forms of bread in the U.S. include rolls and buns, which may be made from a sweeter dough than regular bread; quick breads, made with some ingredient other than yeast to produce carbon dioxide gas; biscuits, made with a dough containing high levels of shortening and leavened with baking powder; and sweet goods, made of yeast-raised doughs richer in shortening and sugar than bread and sometimes containing eggs.

BREAD MANUFACTURE

Fundamentally breadmaking has changed little since the Egyptians discovered that fermentation would make a lighter loaf. The grain is ground, the dough is mixed and allowed to rise (ferment), and the loaf is baked in an oven.

Early ovens were dome shaped, built of adobe or brick and located out-of-doors. The fire was built inside and raked out when the oven was hot enough; then the bread was slid in with a long-handled shovel. Later, men learned to build the fire under the oven. Early commercial bakers used this kind of oven, and housewives would bring their home-mixed dough to bake in the village oven. In some rural areas in many parts of the world this type of oven was still in use in the second half of the 20th century. But in other areas each housewife had her own oven, heated by wood, coal, gas or electricity, in which she baked sometimes all the bread eaten by the family.

The making of bread requires ingredients of flour, liquid, salt and yeast, the maintenance of an even temperature during the rising process, skilful kneading and proper baking. In North America fat and sugar are usually added in the dough-mixing stage.

Different kinds of wheat flour vary in breadmaking value according to the gluten that can be developed in them. Gluten makes the bread dough elastic so that it can expand and hold the bubbles of carbon dioxide gas formed by the yeast. Yeast, which serves as the leavening agent, may be used in the commercially prepared dry or compressed form or, as it is made in the home, in the liquid form. Liquids used in breadmaking are milk, water and potato water. Shortening, consisting of animal fat or vegetable oil, is used in breadmaking to produce a soft crumb.

(J. A. To.; J. K. R.)

Commercial Baking.—The commercial baker uses the same ingredients and fundamentally the same methods as the housewife

but, because he is producing for sale, his doughs are enormous in size and careful controls must be employed throughout the process to assure uniformity of product. Ingredients must be checked for quality. This is especially true of flour because baking characteristics of flour depend upon the variety of wheat milled, the area where the wheat was grown, and the skill of the miller. Small variations in flour quality produce substantial variations in bread quality.

In the development of the industry, bakeries have grown from hand operations to highly mechanized factories. The extent to which mechanization has replaced hand operations varies widely in different countries and within a country. The process itself will also vary in detail according to the type of bread required (e.g., French bread, crusty bread, pan bread) and according to the breadmaking quality of the flour. The following description is of a typical large U.S. installation for pan bread.

Incoming ingredients are palletized and handled with lift trucks or are transferred from unloading docks to storage areas by conveyors. Flour is purchased in carload quantities and generally is delivered in bulk in specially designed railroad cars or trucks. Flour is transferred by air movement from these cars or trucks to storage bins from which it may be withdrawn on demand to be transported again by air-flow to sifters and automatic scales before being transferred to the mixers. The millers' use of oxidizing agents, such as chlorine dioxide and potassium bromate, has eliminated the need for the lengthy storage of flour once used by bakers to "mature" the flour to improve its baking quality. Millers also now use benzoyl peroxide as a bleach to destroy the yellow pigments in the milled flour to produce a snow-white product.

Sugar and shortening may be purchased in bulk also. Sugar sirups delivered in tank cars are transferred by pumps to holding tanks and subsequently pumped directly to the mixers. Shortening must first be melted and then kept in a liquid state for transfer from tank cars to storage tanks and then to the mixing area. Water at the desired temperature is metered directly into the mixers in the exact quantities required to give doughs of proper consistency. The quantity of water employed depends upon the characteristics of the flour and the water demand of the other ingredients in the bread formula. The amount of water required generally ranges from about 60%–65% of the flour weight.

White Bread Formula.—An average bakery formula for white enriched bread requires for 100 lb. of flour about 60–65 lb. of water, 2 $\frac{3}{4}$ lb. of yeast, 2 lb. of salt, 6–7 lb. of sugar, 1 lb. of malt sirup, 4 lb. of nonfat dry milk, 3 lb. of shortening, 1 enrichment wafer, and 6 oz. of yeast food. The yeast food is a mixture that includes a calcium salt to make the water hard, an ammonium salt to serve as a ready source of nitrogen for the yeast, and an oxidizing agent such as potassium bromate to improve the baking quality of the flour proteins. Doughs weighing as much as 1,600 lb. can be handled in a modern mixer.

Mixing Methods.—The dough made from these ingredients is mixed by one of two methods—straight dough or sponge dough. In the straight dough method, all ingredients are mixed at one time. This method is favoured in small bakeries.

In the sponge dough method, a "sponge" containing only part of the ingredients is mixed. After it has fermented, it is mixed with the remaining ingredients to form the dough. In this method 60%–70% of the flour and 60%–70% of the water are fed into the mixer. The yeast, malt enzymes, yeast food, and enrichment ingredients suspended in water are manually added to the flour-water mass. These ingredients are mixed into a sponge that is ejected into a large trough and allowed to ferment for a definite time (generally four to five hours) in a fermentation room, the temperature and humidity of which is carefully controlled. When the sponge is properly fermented it is returned to the mixer along with the remaining flour and water, the salt, nonfat dry milk, sugar, and shortening, and is mixed into a dough. Because heat is generated by the mixing, mixers are jacketed so that the dough may be kept at a temperature of 80° F. either by circulating ice water through the jacket or by mechanical refrigeration coils within the jacket. The dough is then returned to the trough and permitted to stand for 20 to 30 minutes before it is sent

to the divider, which mechanically divides the large dough mass into the carefully scaled (weighed) pieces required for each loaf.

Final Steps.—The dough pieces are rounded into balls mechanically and conveyed through a temperature-controlled cabinet called the overhead proofer to the moulder, where the dough balls are passed between rollers to form flat sheets, which are then curled up into cylinders and automatically deposited in the pans.

The panned dough is conveyed through a chamber whose temperature and humidity are controlled so that the dough pieces may rise in the pans before they go to the oven. This chamber is called a proofer and the process of proofing requires approximately one hour.

From the proofer the pans are conveyed and loaded automatically into a traveling tray oven. Such an oven has a series of trays that travel from one end of the oven to the opposite end. In a single passage through the oven the baking process is completed so that by the time pans reach the opposite end the bread is baked.

The bread is removed from the pans automatically and after being conveyed by belts through a cooling tunnel is sliced and wrapped. The individual loaves are packed in paper board cartons or wood or metal trays so that they may be loaded on the trucks for distribution.

Continuous Mixing.—Despite this high degree of mechanization and automation, the baking industry in the early 1960s was going through a production revolution caused by the introduction of continuous mixing operations. These operations eliminate the scaling of ingredients for individual batches, the fermentation of the sponge, the double-mixing process required by the batch system, as well as the divider, rounder, overhead proofer, and moulder.

The continuous-mix operations employ liquid ferments consisting of the water, yeast, yeast food, part of the sugar and generally some nonfat dry milk. This fermented broth, flour, melted shortening, and an oxidizing agent are fed continuously to a premixer, which roughly forms a dough. This is pumped to a dough developer, which rapidly kneads the dough into its final consistency. The dough is extruded from this developer as a ribbon and is cut automatically into pieces that fall directly into pans. The panned dough is conveyed to the proofer to be made ready for the oven. The flow of the individual ingredients is automatically controlled so that uniform doughs are mixed continuously during the entire work day.

By the early 1960s equipment of this design was being manufactured in the United States and was in operation in many bakeries in the United States and a few in Canada, Australia, England, and Japan.

(W. B. BR.)

Regulations and Standards.—The regulations of the middle ages to protect bread consumers have a modern counterpart in such requirements as those that loaves carry an indication of net weight and ingredients used. Sanitation has received much attention since the first Bakehouse Regulation act of 1863 in the United Kingdom.

In the United States a large part of the regulations and inspection is in the hands of local authorities. Nevertheless, the Federal Food, Drug and Cosmetic act of 1938 provided that foods shipped across state lines must be free from filth and must not be prepared, packed or held under unsanitary conditions that cause them to become contaminated.

The 1938 act also provided for the issuance of standards for food products, including bread. Enrichment of white flour began on a voluntary basis in 1941 and was made mandatory for all bakery white bread and rolls in 1943–46. When the war measure was rescinded in Oct. 1946, more than half the states continued to require enrichment and some processors and bakers continued to enrich their products on a voluntary basis. By the early 1960s 27 states had passed enrichment legislation and about 85% of all white bread consumed in the U.S. was enriched.

Standards for bread and flour shipped in interstate commerce and labeled as enriched became effective Aug. 13, 1952. Bread or flour identified as enriched must contain the following amounts of the four required enrichment ingredients in each pound of bread or flour:

White flour	thiamine 2.0–2.5 mg.	riboflavin 1.2–1.5 mg.	niacin 16–20 mg.	iron 13–16.5 mg.
Bread	1.1–1.8 mg.	0.7–1.6 mg.	10–15 mg.	8–12.5 mg.

During baking, about 15% of the thiamine and a small percentage of niacin and riboflavin are destroyed. Consequently, slight excesses of the minimum requirements are added to flour so that the finished bread will meet the minimum requirements.

Besides the four required enrichment ingredients, enriched flour and bread may contain two optional ingredients in the following amounts:

White flour	calcium 500–1,500 mg.	vitamin D 250–1,000 U.S.P. units
Bread	300– 800 mg.	150– 750 U.S.P. units

Nutrition.—Enriched bread is easily digested and supplies energy as well as protein, calcium and essential vitamins. Wheat offers a well-balanced mixture of protein, with the exception of the amino acid lysine. The addition of a quarter pound of lysine to 100 pounds of flour corrects this deficiency. The quality of bread protein is greatly improved by adding nonfat milk solids in an amount equal to 4% of the weight of the flour.

Eight ounces of enriched bread supplies 55% of the thiamine, 30% of the riboflavin, 50% of the niacin and 40% of the iron required daily by an adult (minimum amounts that will provide good health). Nonfat milk solids also supply calcium, as do calcium-containing compounds, such as calcium propionate, added as dough conditioners and mold inhibitors. Eight ounces of bread supplies 25% or more of the daily calcium requirements.

In the United Kingdom, the government has laid down a minimum standard of nutrition for all flour sold. This means that all flour must contain specified minimum quantities of iron, vitamin B, and niacin, whether these are present naturally in the flour or whether they are added during the milling process. In addition, calcium must also be added to all flour other than whole wheat flour. This regulation has been made to ensure that even those on the poorest diets receive sufficient amounts of these nutrients.

Some Economic Aspects.—The commercial baking industry of the United States was producing and selling about 40,000,000 loaves of bread daily in the early 1960s. More than half of the total was bought through grocery stores and constituted more than 8% of the total trade of such stores. The value of all bread and other goods produced by bakeries was estimated in excess of \$4,500,000,000, and the number of bakeries in the U.S. was placed at 19,000. The baking industry ranked second among U.S. food industries and seventh among all manufacturing industries.

BREADALBANE, JOHN CAMPBELL, 1ST EARL OF (c. 1635–1717), Scottish politician, chiefly remembered for his alleged complicity in the "massacre of Glencoe." was the son of Sir John Campbell of Glenorchy, Bart. (d. 1686). and of Mary Graham, daughter of William, earl of Airth and Menteith. He took part in the royalist rising under the earl of Glencairn in 1654, and was one of those who urged George Monck to declare a free parliament to facilitate the Restoration. As principal creditor of the 6th earl of Caithness (d. 1676), he obtained a conveyance of that earl's dignities, lands and heritable jurisdictions in Oct. 1672; he was created earl of Caithness and viscount of Breadalbane on June 28, 1677. He had married in 1657 the daughter of the 1st earl of Holland, Mary Rich, with a dowry of £10,000. She died in 1666, and by marrying in 1678 Mary, widow of the earl of Caithness, he saved the alimentary provision which he had undertaken to pay. He invaded Caithness in 1680 and dispossessed the earl's male heir, but the latter was later confirmed in his lands

and titles. whereupon Campbell obtained a new patent (Aug. 13, 1681) as earl of Breadalbane and Holland, viscount of Tay and Paintland, Lord Glenorchy, Benederaloch, Ormelie and Weick, with special power to nominate his successor from among the sons of his first wife.

Breadalbane, who had sat in the Scottish parliament under Charles II and had supported the administration of the duke of Lauderdale by sending 1,700 Highlanders to overawe the disaffected southwest in 1678, became a member of the Scottish privy council in 1685. He was described as having "neither honour nor religion but where they are mixed with interest" and as of "the gravity of a Spaniard, cunning as a fox, wise as a serpent but as slippery as an eel." To gain the support in the Highlands of a man of such qualities, possessed of wide estates and related by marriage to several leading families, was of high moment to William III. Breadalbane did not commit himself to Lord Dundee, or join his rising, and after the battle of Killiecrankie (July 1689) he was entrusted by the government to offer a large sum of money to secure the submission of the clans. On June 30, 1691, he met the Jacobite chiefs and prevailed on them to agree to an armistice until October: not, however (so it was alleged), by expending the money but by holding out the hope that he might later join them. When asked to render an account, he is said to have replied, "The money is spent, the Highlands are quiet, and this is the only way of accounting between friends." On Aug. 27, 1691, indemnity was offered to all taking the oath of allegiance before Jan. 1, 1692, while all refusing were threatened with the penalties of treason. MacLan, the chief of the MacDonalds of Glencoe, postponed his submission till Dec. 31 and was prevented from taking the oath till Jan. 6, 1692, through the absence of a magistrate at Fort Rilliam. Subsequently, in the "massacre of Glencoe" (Feb. 13, 1692), a number of the MacDonalds were butchered in cold blood by troops to whom they had given hospitality. Opinion was strong against Breadalbane, who may well have welcomed the opportunity of destroying a clan which had for generations lived by plundering his lands and those of his neighbours, but although he was aware that violent action was planned it is less likely that he was personally involved in organizing the massacre. No real evidence against him was disclosed, and his imprisonment (Sept. 1695) was on the ground of his earlier dealings with the Jacobite chiefs. He was released when William III announced that he had acted with royal approval.

Breadalbane did not vote for the union of England and Scotland in 1707, but was a representative peer in the parliament of Great Britain (1713-15). He maintained his contacts with the Jacobites, whom he encouraged in 1708, without, however, committing himself on paper. At the time of the Jacobite rising in 1715 he excused himself (Sept. 19) from obeying a summons to Edinburgh on the ground of his age and infirmities; but the next day he visited the earl of Mar's camp at Logierait and afterward the camp at Perth, his real business being, according to the master of Sinclair, "to trick others, not to be trickt," and to obtain a share of French subsidies. He is said to have promised and taken money for 1,200 men in the Jacobite cause, but he sent only 300 or 400, who acquitted themselves well at Sheriffmuir (1715) but were withdrawn after that battle. Breadalbane's son was imprisoned, but he himself escaped any punishment for his part in the rising because of his age. He died on March 19, 1717.

See William A. Gillies, *In Famed Breadalbane* (1938). (Gr. D.)

BREADALBANE, a district of Perthshire, Scot., bordered on the north by Loch Rannoch, east by Strathtay, south by Strathearn and west by the districts of Argyll and Lorne, and occupying about 1,020 sq. mi. The Grampians (*q.v.*) are the chief mountain range; Ben Lawers (3,984 ft.), Ben More (3,843 ft.) and Ben Lui (3,708 ft.) the principal peaks. Loch Tay is the chief lake, and the rivers are the Orchy, Dochart, Lochay, Lyon, Almond and upper Tay. The population of Breadalbane centres in Aberfeldy, Fortingall, Kenmore and Killin (*q.v.*). It is a land of deer forests, shooting and fishing; only a little soil in glens and straths (broad river valleys) is cultivable. The famous Breadalbane vine is at Kinnell house, Killin.

BREADFRUIT. The staple food of the South Pacific, culti-

vated less commonly in other parts of the tropics, is the fruit of *Artocarpus altilis*, a tree of the family Moraceae (*q.v.*).

The tree is extremely handsome. It reaches a height of 40 to 60 ft. and has large, oval, glossy green leaves entire toward the base and three- to nine-lobed toward the apex. Male and female flowers are borne in separate inflorescences on the same tree: the staminate or male ones appear in dense, club-shaped catkins; the female or pistillate, which are very numerous, are grouped together and form a large prickly head upon a spongy receptacle. The ripe fruit, which is composed of the matured ovaries of these pistillate flowers, is roundish, commonly four to eight inches in diameter, greenish to brownish-green externally, with white and somewhat fibrous pulp.

There are two distinct forms of breadfruit, one seedless, the other (sometimes known as breadnut) containing many seeds resembling chestnuts.

The seedless form is the most valuable and the one usually grown. It has been cultivated in the Malay archipelago (where the species is held to be indigenous) since remote antiquity. From this region it spread throughout the tropical South Pacific region in prehistoric times. Its introduction into the new world is connected with the memorable voyage of Capt. William Bligh in H.M.S. "Bounty," a voyage recommended by Capt. James Cook, who had seen the breadfruit in the Pacific islands and considered that it would prove highly useful as a foodstuff for Negro slaves in the West Indies.

After the failure of this voyage, a second was carried out which resulted in the successful establishment of the tree in Jamaica, where, however, it failed to live up to expectations, because the Negroes preferred bananas and plantains.

The breadfruit is not a fruit in the popular sense of the term, but a product containing considerable amounts of starch, not to be eaten uncooked. Regarding methods of preparing it for the table, W. E. Safford writes (*Useful Plants of Guam*):

It is eaten before it becomes ripe, while the pulp is still mealy, and of a consistency between bread and sweet potatoes. In Guam it was formerly cooked after the manner of most Pacific island aborigines, by means of heated stones in a hole in the earth—layers of stones, breadfruit and green leaves alternating. It is still sometimes cooked in this manner on ranches but the usual way of cooking it is to boil it or bake it in ovens; or it is cut in slices and fried like potatoes. The last method is the one usually preferred by foreigners. The fruit boiled or baked is rather tasteless by itself, but with salt and butter or gravy it is a palatable as well as nutritious article of diet.

In the West Indies and on the American mainland from Mexico to Brazil the breadfruit tree is grown in dooryards and the fruit appears upon the market. Propagation of the seedless forms is by means of root suckers or root cuttings.

Numerous varieties are cultivated in the Pacific islands, but these are not known in tropical America. The tree withstands no frost and has not been successful even in the southernmost parts of Florida.

In the South seas, cloth is made from its fibrous inner bark; the wood is used for canoes and furniture; and a glue and calking material are obtained from the viscid milky juice which exudes from incisions in the trunk.

BREADNER, LLOYD SAMUEL (1894-1952), Canadian air force officer and, during World War II, air officer commanding the Royal Canadian Air Force (R.C.X.F.) overseas, was born on

BY COURTESY OF CHICAGO NATURAL HISTORY MUSEUM
BREADFRUIT (ARTOCARPUS ALTILIS)

July 14, 1894, at Carleton Place, Ont., and was educated at the Collegiate institute in Ottawa. He had a distinguished record in World War I, becoming a flight sublieutenant in the royal naval air service in 1915. He later transferred to the royal naval air force, and by Nov. 1918 had attained the rank of major (equivalent to the later rank of squadron leader). From 1920 Breadner was associated with the R.C.A.F. In 1922 he became director of civil aviation and had much to do with shaping civilian and commercial flying in Canada between World Wars I and II. From 1928 onward Breadner was drawn into military aviation, serving as acting director of the R.C.A.F. until 1932. In 1936 he became air staff officer at National Defense headquarters and in 1940 was made air vice-marshal and chief of air staff. He became air marshal in 1941 and on Nov. 11, 1943, was named air officer commanding the R.C.A.F. overseas. He was created a companion of the Order of the Bath in 1943. In 1945 Breadner retired as air officer commander in chief of the R.C.A.F. and was advanced to air chief marshal, the first to hold that rank in the R.C.A.F. He died in Boston, Mass., on March 14, 1952. (J. I. C.)

BREAKWATER, a barrier constructed for the purpose of providing protection from waves. Breakwaters are used to create harbours on open coasts, to provide supplementary protection for natural harbour areas, to reduce wave action and sedimentation at inlets to navigable waterways and to prevent shore erosion. The term breakwater is usually reserved for off-shore structures which may or may not be connected to the shore line at one end. Breakwaters built perpendicular to the shore line for the purpose of protecting an inlet are called jetties. Shorter structures of the same type, often used to prevent shore erosion, are known as groins. Barriers built parallel to the shore line and in contact with it are called sea walls or bulkheads. The size, shape and method of construction of a breakwater depend upon the depth of the water, the severity of the local wave forces, the availability of the various types of construction materials, the use for which it is being constructed and the nature of the foundation conditions. The presence of a breakwater affects the shore processes, and care must be exercised in planning its size, location and orientation. The most effective location and orientation of a breakwater at any site is determined by means of an engineering analysis of the physiographic features and the characteristics of the waves and currents at the proposed location. In most cases the best solution can be determined only by the construction and study of a model. The various factors that must be considered in planning and designing breakwaters are presented under the following topics: *Waves; Shore Processes; Types of Breakwaters; Harbours; and Wave Forces.*

Waves.—By far the major portion of the water waves which attack shore and harbour areas are those generated by the wind. Wind-generated waves may continue their violent, periodic pounding for hours or even days. As the waves approach the shore their energy must be reflected or dissipated or the resultant powerful forces and high water velocities may seriously damage unprotected vessels or shore structures. Breakwaters are designed to withstand such violent conditions.

Waves may also be generated by a sudden change in barometric pressure over a limited area of water surface or by an underwater seismic or volcanic disturbance. The latter are called seismic waves or tsunamis and are often mistakenly referred to as tidal waves. Barometric pressure changes or seismic disturbances usually create only a small number of relatively low waves. Damage resulting from such waves is primarily due to the fact that they often arrive without warning and quickly inundate low-lying coastal areas.

The distinguishing characteristics of a wave are its height (the vertical distance from a trough to a crest), its length (the horizontal distance between successive crests) and its period (the time between the arrival of successive crests at a fixed point). These characteristics are determined by the velocity of the wind, the length of time that the wind continues at this velocity (duration of the wind) and the distance over which the wind is in contact with the water (fetch). In general, the greater the velocity and duration of the wind and the larger the fetch, the greater will

be the height and period of the waves. Wind-generated waves are called oscillatory waves because the water particles oscillate in nearly circular or elliptical paths, only the wave form moving forward. This motion of the water is similar to the wave motion produced in a rope when one end is fastened and the other end is moved rapidly up and down. The wave velocity is the rate at which the wave form moves forward and may be found by dividing the wave length by the wave period. The actual velocity at which particles of water move in their circular or elliptical orbits is much less than the wave velocity.

As waves enter shallow water the wave length decreases while the wave height first decreases and later increases. The relative decrease in wave length is greater than the change in height, with the result that the water surfaces on either side of the crests become much steeper as the waves approach the shore. This change begins when waves reach depths less than half the wave length and culminates in a breaking wave at the location where the depth is approximately equal to the wave height. Upon breaking, the waves lose their oscillatory characteristics and become waves of translation or surges. In surge-type waves, the volume of water in the wave moves forward at the wave velocity, which may be very high. Breakwaters located at the point of breaking are subject to the full impact of this uprushing mass of water.

In addition to the change in shape undergone by waves as they enter shallow water, previously described, waves approaching the shore at an angle have their crests bent into a curve which tends to make the waves more nearly parallel to the bottom contours and shore line when they enter the breaker zone. This effect, called refraction, is caused by the fact that the wave velocity is smaller in shallow water. Therefore, that portion of a wave which reaches shallow water first slows down and permits the portion still in deeper water to catch up to some extent. This is illustrated by the refraction diagram shown in fig. 1. The orthogonal lines, shown in the figure, are lines which are perpendicular to wave crests. When waves approach a bay formed by two points of land, refraction causes the waves to turn toward the two points and away from the centre of the bay. As a result wave heights and wave energy are high at the points and low in the bay area. Thus currents are generated which flow along the shore (littoral currents) from each point toward the centre of the bay and thence outward toward deep water. Such outward currents are called rip currents and in many cases are the ones commonly referred to as undertow. When waves encounter a breakwater or headland, that portion of the wave which passes the end of the breakwater or headland bends and directs some of its energy into the quiet water in the sheltered area. This effect is called diffraction. Waves entering a harbour entrance diffract some energy into the lee of both of the breakwaters forming the harbour.

Waves generated in storm areas may travel thousands of miles across the oceans, gaining energy from favourable secondary fetches or losing energy in regions of calm or opposing winds. An expanse of relatively calm water through which waves pass is known as a region of decay. In general, an important characteristic of wave decay is an increase in wave period, hence in length. The wind-generated waves in the ocean are divided for convenience

BY COURTESY OF UNIVERSITY OF MICHIGAN RESEARCH INSTITUTE

FIG. 1.— REFRACTION DIAGRAM SHOWING CHANGES IN WAVE CRESTS APPROACHING SHORE

into three categories: sea, swell and surf. The term sea refers to waves under the direct influence of generating winds; swell, to waves which have left the generating area and are subject to decay in regions of weak winds or calms; the breakers which result from waves moving into shallow water comprise surf.

Waves have been found to obtain a maximum height measured from trough to crest of about 20 ft. in the Mediterranean and in the Great Lakes of North America, 25 ft. in the Bay of Biscay and 40 ft. in the Atlantic ocean; waves of 50 to 60 ft. in height are said to have been observed in the South Atlantic ocean off the Cape of Good Hope where the expanse of sea reaches a maximum. The length of large waves bears no definite relation to their height. The length of storm waves in the Atlantic seldom exceeds 600 ft., while waves from 600 to 1,000 ft. long are regarded as of common occurrence in the Pacific ocean during storms. The large waves observed in mid-ocean do not, however, reach the coast, because their progress is checked and their height and length are reduced by encountering the shelving sea bottom on approaching the shore. Where outlying sandbanks stretch in front of a coast, large waves cannot approach the land, for they break on the sandbanks outside. Waves always break when, on running up a shoaling beach, they reach a depth of water approximately equal to their height; and the largest waves which can reach a shore protected by intervening sandbanks are those which are low enough to pass over the banks without breaking. Waves often break in depths of water greater than their own height, and any sudden change in the level of the sea bed over which a wave is traveling may bring about its disruption even in water of considerable depth. The height and consequently the destructive force of waves are increased on running up a funnel-shaped bay by the increasing concentration of the waves in the narrowing width. This effect is intensified when the bay faces the direction of the strongest winds.

The velocity of wave travel depends upon the wave length. For waves of 600-ft. length the wave velocity in deep water is about 33 knots, and for a 1,000-ft. wave the velocity is about 43 knots. Waves generated by earthquakes (tsunamis), have been recorded as traveling at the rate of 430 knots. (See also WAVES OF THE SEA.)

Shore Processes.—The action of waves and longshore currents causes a nearly continuous movement of bottom and beach material. The wave motion creates turbulence which places material in suspension and the currents carry the suspended material and roll the heavier bottom material from place to place. During severe storms the violent action of the waves and currents may displace vast quantities of material, often much more than the quantity moved by months of more normal wave motion. The direction of longshore movement of beach material (littoral drift) varies with the direction of the wind. However, on most coasts there is a prevailing direction which can be determined from typical formations of the coast. At any particular location this movement of the beach material may not be obvious because the material carried away is replaced by similar material from the updrift direction. However, there must be a source of supply somewhere in the updrift region. This could be an eroding headland, sediment deposits from rivers or material carried shoreward from deep water. In general, erosion is most severe when large waves occur during high water levels while similar wave action during low water may build beach. On inland lakes, high water levels may be caused by excessive rain or by the drag of the wind. On

the oceans, high levels result from a combination of lunar tides and wind. Storm waves are more likely to cause erosion than long-period swell, which may carry material shoreward.

When the natural drift of shore material is intercepted by a deep-water inlet or by a breakwater, the region on the downdrift side of the obstruction is deprived of its natural replenishment, with the result that an erosion area may be created. Many of the most serious shore erosion problems occur on the downdrift side of breakwaters or jetties protecting inlets. When breakwaters are built to create harbours on open coasts, they are often kept disconnected from the shore in order to permit beach material to pass and prevent erosion.

The best protection against wave action is the presence of a beach upon which the waves break and dissipate their energy before attacking the higher inland areas. Short jetties or groins are often used to intercept and hold shore material and thus create stable beaches at erosion sites. At locations where no littoral drift is present the beach material must be supplied by filling artificially. Where severe erosion threatens high-value locations, offshore breakwaters parallel to the coast may be used to prevent the erosion and build beach. The presence of the breakwater not only prevents the larger waves from reaching the shore, but also creates a quiet area in which littoral drift is deposited in the same manner as in the case of a deep inlet. In fact, care must be exercised in planning a breakwater for this purpose to avoid such a large deposition as to cause complete interception of all littoral drift and thus create another erosion area.

The construction of protective structures at the shore line (sea walls and bulkheads) is usually less expensive than the construction of offshore breakwaters. Such structures may be used in areas where property very near the water front requires protection. However, the presence of sea walls and bulkheads tends to increase the turbulence and currents generated by the wind with the result that beach erosion may be accelerated.

Types of Breakwaters.—Breakwaters may be divided into three general types: rubble-mound, composite and vertical-face. The rubble-mound type, illustrated in fig. 2, consists of a pile of natural or artificial stone protected with an armour of larger stones. The composite type of breakwater (fig. 3) consists of a rubble base and a suitable superstructure. There are two classes of composite breakwaters, those whose superstructures are founded near or above low water and those whose superstructures extend sufficiently far below low water to reduce disturbances of the rubble base. Vertical-face breakwaters (fig. 7) present a vertical face on the sea side extending to a sufficient depth to prevent the breaking of maximum-height waves.

BY COURTESY OF U. S. NAVY

FIG. 2.— RUBBLE-MOUND BREAKWATER

Rubble-Mound Breakwaters.—The rubble-mound type is indicated where there is an abundant supply of rock. It is particularly adapted for locations with small tidal range and depths of water up to perhaps 60 ft. It has the advantage that storm damage or vertical settlement caused by a poor foundation site may be repaired by renewing or replacing the dislocated stone. The earliest breakwaters were unformed piles of stone of a size that could be handled with the limited equipment available at the time. It soon became evident that the sea slopes were not adequate nor the stones of sufficient size to resist the forces delivered by storm waves. Heavy wave action lowered the top of the mound and flattened the seaward slope. It was necessary to replenish the mound constantly until an equilibrium slope was reached. This slope was often found to vary from 1 to 5 to 1 to 10 on the seaward side within the range of the worst storm attack. Below this level the slope to the bottom was often as steep as 1 to 1. The portion of the mound above low water is extremely vulnerable to injury by storm waves in either one or both of two different actions. The first is the raising and forward transport of the stone by the incoming waves; the second is the withdrawal and lowering of the stone during the backwash or recoil.

Mounds have been fashioned in an almost endless variety of cross section. In nearly every case, the original shape has been altered by heavy storms after which reshaping and replenishment of stone has been necessary. The large mass of stone is so arranged that the smaller sizes, forming the lower central portion of the core, are protected by the larger stones forming the exterior slopes and the upper portion, the latter being most severely exposed to direct wave action. The stone is classified by size into three categories, conventionally designated A for cap rock and heavy armour rock, B for intermediate-size rock and C for the smaller size forming the lower core. The relatively large volume of class B stone is to provide adequate stability during construction.

Soft deposits of deep mud do not have the necessary supporting power to hold the large weight of a breakwater. When the foundation is of soft and compressible material, the stone rubble sinks into the sea bed as a result of the weight of the superimposed materials. In some instances, the rubble at the base has been known to sink as much as 20 to 30 ft. below the original bed.

A reduction in the amount of stone may be accomplished by removing the soft material with an ocean-going hopper dredge and replacing it with a sand blanket, or a sand blanket of extra

width and thickness may be deposited on the bottom without dredging. A protective blanket of clay or quarry waste chips and fines may also be deposited to prevent leaching of the sand core. Where the bottom is firm but susceptible to erosion, a blanket of quarry-run rock may be deposited to protect the natural bottom.

The larger stones forming the exterior slopes in the upper portion may be of natural stone or of concrete formed into blocks, prisms or other special shapes. The tetrapod (see fig. 2) is a cast concrete form with four symmetrically spaced legs, each shaped like a truncated cone, radiating from a central body. Tetrapods, deposited by random dumping, are self-interlocking, add hydraulic roughness to the breakwater facing without losing porosity, and develop a progressive wedging action under wave pressure. The heaviest armour is placed on the top of the mound and down the seaward face to a plane 10 to perhaps 30 ft. below the low-water level, depending on the intensity of wave attack. The heaviest natural stone armour weighs from 10 to 20 tons, and concrete blocks have been cast in sizes up to 40 tons. The general range of weight for the class B material is from 1 to 10 tons and that for the class C material from $\frac{1}{4}$ lb. to 1 ton, with the greater portion less than 100 lb. Class C and class B material is always dumped at random. The class A rock and cap rock may be placed pell-mell, semiset or accurately set in neat lines to form a dense facing.

Rubble-mound breakwaters are constructed by means of pile-supported trestles for support of railroad tracks, by the use of a floating plant or by the truck-and-crane method, employing the top of the breakwater as a roadway. Trestles are generally used at sites subject to frequent heavy sea action, where the use of floating equipment is impracticable. A single-track trestle will ordinarily suffice for the construction of moderately sized breakwaters, but two parallel trestles may be necessary for the portions of major breakwaters in deeper water. At locations where the wave action is not too severe, a floating plant may be used to advantage. The smaller material is moved to the site in bottom dump barges, and the larger material is handled by floating derrick equipment. The truck-and-crane method is best suited to small-and moderate-size breakwater projects. It consists essentially of building the structure outward from the shore with material dumped from trucks, the larger pieces being placed in final position by means of a crane. Modern heavy-duty truck-and-crane equipment materially increases the usefulness of this method.

Composite Breakwaters.—Full-height rubble mounds are not feasible at deep-water sites or at locations having large tidal variations. The composite type of breakwater, consisting of a rubble base and suitable superstructure, has found extensive application in such areas. The rubble mound provides a base, accommodates itself to irregularities in the bottom and may be deposited in deep water and allowed to stand, thus obtaining a large part of the total settlement before the superstructure is placed.

The solid superstructure reduces the amount of material required, according to the depth at which it is founded, and the solid capping also serves to protect the top of the mound from the action of the waves. In the case of a mound breakwater, portions of the highest waves generally pass over the top of the mound, and their force is also to some extent expended in passing through the interstices between the blocks or stones, whereas a superstructure presents a solid face to the impact of the waves. A superstructure, accordingly, must be strongly built in proportion to the exposure and to the size of the waves liable to reach it. Special care has to be taken to prevent the superstructure from being undermined, because storm waves dash up against this nearly vertical solid obstacle and recoil down the face, scouring and displacing the materials at the superstructure's outer toe. This risk is especially great when the superstructure is founded on the mound near low-water level (see fig. 3[A]), and there is no adequate cushion of water above the mound to withstand the recoil. Because of this danger and the growing need for breakwaters in great depths of water, it has become more usual to carry superstructures down well below low water.

In view of the increased depths at which superstructures are now founded upon rubble mounds, causing the breakwaters to approximate more and more to the vertical-wall type, it may seem at first

FIG. 3. — COMPOSITE BREAKWATER

FIG. 4.— SECTION OF CONCRETE-CAPPED JETTY

that the rubble base could be dispensed with and the superstructure founded directly on the sea bed. Two factors, however, still render the composite form of breakwater indispensable in certain cases: (1) the great depths to which breakwaters sometimes extend, reaching 60 ft. below low water at Peterhead, Scot., 117 ft. below mean sea level at Naples, Italy, and 180 ft. at Valparaiso, Chile; and (2) the necessity, where the sea bottom is soft or liable to be eroded by scour, for a wide base between it and the upright superstructure.

The injuries to which composite breakwaters appear to have been especially subject must be attributed primarily to the greater exposure and depth of the sites on which they have been frequently constructed as compared with rubble mounds or upright walls; but the direct cause of damage and even destruction has in many cases been the insufficient depth at which superstructures have been founded.

The superstructures of composite breakwaters may consist of a solid concrete cap (see fig. 4), formed concrete blocks (fig. 3[A]), concrete caissons filled with stone or concrete (fig. 3[B] and 6), rock-filled timber cribs (fig. 5), or an asphaltic concrete cap. The selection of the type best suited to any location depends upon such factors as the relative costs at that location, the severity of the wave conditions, the depth of the water and the speed with which completion of construction is desired.

In most locations, the rubble-mound foundation will continue to settle for several years after being placed, and there may be additional settlement when the weight of the superstructure is added. Where such settlement is severe, a solid concrete superstructure or a superstructure consisting of horizontal layers of blocks may be impractical unless the foundation is allowed to settle for several years before adding the superstructure. Although from the point of view of resisting wave forces it is desirable to use massive units or blocks in forming such structures, the problem of transporting and placing very heavy blocks somewhat limits their size. This problem is solved to some extent by using hollow concrete blocks or caissons. The most extreme example of a hollow block would be a relatively thin-walled, reinforced concrete box with no bottom. When either a temporary or permanent bottom is placed on such a box, it is called a caisson. Caissons may be floated into place and then lowered by filling them with water or stone. Single units of caisson superstructures can be made much larger than any that

FROM "SHORE PROTECTION PLANNING AND DESIGN," TECHNICAL REPORT NO. 4 (1954); REPRODUCED BY PERMISSION OF BEACH EROSION BOARD, U.S. ARMY CORPS OF ENGINEERS

FIG. 5.— ROCK-FILLED TIMBER CRIB BREAKWATER

could be handled by mechanical equipment. Concrete blocks or caissons are sometimes supported on piling (fig. 6) to avoid damage due to settlement.

During World War II, caissons of 204-ft. length, 60-ft. width and 60-ft. height were towed across the English channel and sunk in rapid succession to form the artificial harbour at Arromanches-les-Bains for the invasion of northern France.

The composite breakwater at Bilbao harbour, Spain, probably was one of the most difficult to construct because of its great exposure to the Atlantic waves. The original design consisted of a wide rubble mound up to about 16 ft. below low water, a mound of concrete blocks up to low water and a solid masonry superstructure. The repeated damage to this wall by successive winter storms led to the abandonment of the original design and the construction, on a widened rubble base, of a superstructure protected to some extent by the outlying concrete-block mound. The modified superstructure was formed of iron caissons partially filled with concrete which were floated out, sunk in position and filled with concrete blocks and mass concrete. The caissons measured about 43 ft. in width across the breakwater, 23 ft. in length and 23 ft. in height and weighed about 1,400 tons when filled. They form the base of a concrete wall founded at half-tide level and carried up to 8 ft. above high water. Although some difficulties were brought about by the settlement of the rubble foundation, they were overcome, and the breakwater successfully resisted the attacks of the heavy Atlantic rollers. A modern concept of this type of construction is shown in fig. 3(B) in which the caisson is of reinforced concrete.

Rock-filled timber cribs are suitable for use as superstructures

FIG. 6.— COMPOSITE BREAKWATER WITH CONCRETE CAISSONS

on rubble-mound foundations in fresh water. In salt water the activity of marine borers makes the life of a timber structure too short to be economically feasible. The portion of the timber near the water surface which is subjected to alternate wetting and drying may rot in time, but that portion which is continuously submerged may be expected to last for many years. Timber structures have the advantage of being somewhat flexible and thus able to adjust themselves to a settlement of the foundation. A common procedure is to place a concrete cap on the timber cribs after all settlement has ceased. An example of timber-crib breakwater is shown in fig. 5.

Vertical-Face Breakwaters.— This type of breakwater is placed directly on or embedded into the sea or lake bottom without the use of a rubble-mound foundation. This type includes structures varying in their nature from single walls of wood or steel sheeting to massive concrete gravity-type structures (fig. 7). As the name implies, gravity-type structures depend upon their own weight to resist both overturning and sliding. Such structures must be built in locations where the bottom consists of sufficiently solid rock to support the weight of the structure and to resist erosion at the base of the structure. In order to avoid the excessive forces and erosive action of breaking waves, such structures are usually placed outside the breaker zone. This means that they must be built in water depths no smaller than about 1.3 times the height of the maximum waves to be expected at that location. Any of the types of construction described previously for the superstructures of composite breakwaters might be used for the gravity type of vertical-face breakwaters.

The Admiralty pier at Dover, Eng., which was begun about the middle of the 19th century, is an early and notable example of a vertical-face breakwater resting upon a hard chalk bottom. It

FIG. 7. — VERTICAL-FACE BREAKWATER

was subsequently extended in connection with the works for forming a closed naval harbour at Dover, which included the construction of an eastern breakwater and a detached south breakwater. They are founded on the hard chalk underlying the surface layer of the sea bed, leveled by men in diving bells. The breakwaters were built of concrete blocks in bonded courses, the outer blocks above low water being faced with granite masonry (fig. 8). The face blocks were joggled together, and above low water the block work was set in cement mortar and the vertical-face joints grouted. The blocks were laid by goliath traveling cranes running on temporary staging supported by clusters of timber piles driven into the chalk bottom. Four goliaths on each staging were used for excavating, for preparing foundations with diving bells and for block setting. The deepest foundation is 53 ft. below low-water springs. The rise of the spring tide being $18\frac{3}{4}$ ft., the average depth is approximately 66 ft. at high tide, necessitating a pressure of about 30 lb. per square inch which is near the limit at which men in diving bells could work continuously without injurious effects. All the breakwaters are protected from scour along the outer toe by an apron of concrete blocks.

The stability of breakwaters made of single rows of sheet piling depends primarily upon the resistance of the soil into which the piling is driven. Although such walls must be designed for the wave and foundation conditions at each location: for average conditions it is usually found necessary for the piling to be embedded approximately twice as far as it projects above the bottom. Such walls may be strengthened by buttresses or, in the case of steel piling, by arranging the piles in a manner which provides some additional stability. Walls of single sheet piling are suitable only for shallow water depths and for locations where soil conditions permit piles to be driven. Where the soil is heavy clay or rock,

FIG. 8 — CROSS SECTION OF SOUTH BREAKWATER, DOVER HARBOUR ENGLAND, ILLUSTRATING THE METHOD EMPLOYED IN THE CONSTRUCTION OF THE THREE BREAKWATERS AT DOVER HARBOUR

or contains large stones, it is usually necessary to use a gravity-type structure.

One of the most commonly used forms of vertical-face breakwaters, the cellular type, combines the gravity and sheet-piling types described above. In its simplest form this type consists of two parallel sheet-pile walls filled with stones as shown in fig. 9. The walls are usually tied together and the space between may be divided into cells by cross walls. Concrete caps or parapets may be placed on top of the walls. A more elaborate type of cellular wall is made by forming circular or elliptical cells of sheet piling. These are connected by curved or straight segments of wall and all the cells are filled with stone or gravel.

Harbours.—One of the most important functions of breakwaters is in the development of quiet water for the mooring or loading of ships. This is accomplished either by supplementing natural protective features of a coast line or by the creation of a completely artificial harbour. In either case, the breakwater arrangement must be such as to provide the maximum amount of quiet area together with easy-entrance conditions, at a minimum cost. The intensity of wave conditions inside a harbour depends on the direction and size of the waves approaching the entrance, the size and location of the entrance and the orientation, height and shape of the breakwaters. The nature of the waves at a harbour location must be determined from wind records because virtually no long-term wave records are available. The sizes and periods of waves computed from wind records are for deep-water conditions.

FROM "SHORE PROTECTION PLANNING AND DESIGN," TECHNICAL REPORT NO. 4 (1954); REPRODUCED BY PERMISSION OF BEACH EROSION BOARD, U.S. ARMY CORPS OF ENGINEERS

FIG. 9. — CELLULAR TYPE, VERTICAL-FACE BREAKWATER

described earlier. Refraction diagrams must, therefore, be drawn to determine the modified form of the wave at the harbour entrance. Although methods of computing the diffraction of waves as they pass through a harbour entrance have been developed, these are applicable only to the most simplified cases. As a result, the design of the harbour entrance and the arrangement of the breakwaters are nearly always determined by means of hydraulic model studies. Models are built at scale ratios varying from 1:50 to 1:125. In general, the larger the model the more accurate will be the results obtained. This is because viscosity and surface tension influence the results obtained from very small models. The size of the model is usually limited by cost and the amount of space available. The natural refraction outside the harbour is reproduced in the model by constructing the bottom topography to scale. Waves of selected sizes and orientations are generated by means of a wave machine and projected toward the harbour. Many different breakwater arrangements can thus be studied and the most effective arrangement can be selected.

One of the problems which model studies help to solve is the reflection of waves within the harbour. Often a slight rearrangement of breakwaters or docks will completely change the reflection pattern. Waves reflect from vertical walls with virtually no loss of energy; therefore, rubble-mound breakwaters are far more desirable than vertical-faced ones.

The harbour entrance is usually arranged in such a manner as to prevent the entrance of waves generated by the prevailing winds. However, other wind directions will always project some waves into the harbour. Wave absorbers consisting of beaches or baffle walls must be arranged to dampen such waves and prevent harbour surging. (See also HARBOURS.)

Wave Forces.—In addition to determining the best location of breakwaters from a functional point of view, the civil engineer must design the structures to withstand the wave forces to which they are subjected. The size of the waves to be expected at the location of the breakwater is determined from wind records and

refraction diagrams as described in the sections on Waves and Harbours. The manner in which wave forces attack breakwaters depends on the shape and location of the structure. In the case of rubble-mound breakwaters, the waves usually break at or near the face of the structure and any damage suffered results from the uprushing water which may displace stones from the face of the breakwater. Usually the top layers of stones are heavier than those forming the core (see fig. 2), and once these are displaced the breakwater may be quickly breached. Extensive model tests, conducted by the U.S. army corps of engineers, relate the size of stone required to the height of the waves and the slope of the face of the breakwater. Similar relationships have also been determined for the height of wave run-up and the quantity of water overtopping the structure. Using such relationships the engineer can design a rubble-mound structure which will resist the wave forces at any location as economically as possible.

Vertical-faced breakwaters and the superstructures of composite breakwaters must be designed to resist overturning and sliding as the result of forces produced by the waves. When vertical-faced breakwaters are located in water deeper than about 1.3 times the wave height, there is little danger that the waves will break. Under such conditions the oscillatory waves are reflected from the breakwater and a standing wave (also called clapotis) is formed at the face of the wall. This standing wave is approximately twice as high as the approaching waves. Thus the height of wall necessary to prevent overtopping can be determined. The characteristics of such standing waves and the pressures resulting from them are sufficiently well known to permit the satisfactory design of a stable wall.

When vertical-faced or composite structures are located in the breaker zone, they are subjected to dynamic forces resulting from the impinging mass of high-velocity water. Violent scouring action at the toe of the structures is also associated with these conditions. The violent action of the water is accentuated by the entrapment of air pockets in the waves which burst upward at the face of the wall, carrying spray many feet into the air. Analytical methods are of little help in predicting the forces resulting from breaking waves. However, laboratory and field tests with pressure cells have provided some data. Perhaps of even greater value for this purpose are computations of wave force based on observations, made during storms, in which breaking waves have displaced known amounts of concrete or rock.

BREAM (*Abramis brama*), a carplike fish of some value as food, having a deep, compressed body and a long anal fin. It is found in the rivers of Europe and northern Asia, in lakes and sluggish streams; a related species, the white bream (*A. blicca*), is much smaller. The name is also given to the sea breams (*Sparidae*) and in the United States to the golden shiner (*A. chrysoleucus*) and others of the carp family.

BREAST, in mammals, the anterior part of the chest or thorax that contains the milk or mammary gland of the mammals. See **MAMMARY GLAND**

BREASTED, JAMES HENRY (1865–1935), U.S. orientalist and historian, was born in Rockford, Ill., on Aug. 27, 1865. After graduate studies at Yale university and the University of Berlin, he began his teaching of Egyptology at The University of Chicago in 1894. At the beginning of the century the royal academies of Germany commissioned him to copy inscriptions in the museums of Europe for a comprehensive dictionary of ancient Egyptian. On an expedition to Egypt and the Sudan in 1905–07 he copied inscriptions from monuments which previously had been inaccessible or were perishing. In a five-volume work, *Ancient Records of Egypt* (1906), he published translations of all the old historical texts. His *History of Egypt* (1905) and his high school textbook, *Ancient Times* (1916), both lucidly written, enjoyed extraordinary success. A pioneer work in a specialized field was

Development of Religion and Thought in Ancient Egypt (1912). In 1919, with funds first supplied by John D. Rockefeller, Jr., and later by Rockefeller boards, Breasted organized at The University of Chicago the Oriental Institute, for research on ancient civilization. During the next 40 years the institute sent more than 20 archaeological expeditions to the near east and issued more than 125 scholarly publications. Breasted was president of the American Oriental Society (1918), of the History of Science Society (1926), and of the American Historical Association (1928). His influence as translator, historian and promoter of research on the ancient orient was powerful, and he did more than any other scholar of his generation to make his countrymen aware of a long cultural tradition. He died in New York, N.Y., on Dec. 2, 1935.

See Charles Breasted, *Pioneer to the Past; the Story of James Henry Breasted, Archaeologist* (1943). (J. A. W1.)

BRÉAUTÉ, FALKES DE (d. 1226), a Norman adventurer and professional soldier, probably taking his name from Bréauté (Seine-Inférieure), who gave loyal military and administrative service to King John of England but was hated by contemporaries who attacked him as an upstart and self-seeking governor. He was given command in Glamorgan in 1207, and led expeditions against the Welsh; he conducted embassies in Flanders in 1213, and by 1215 was a seneschal of the king's household. In the war between King John and his barons (1215–16), Falkes was one of the chief royal commanders, and was made sheriff of Northamptonshire, Huntingdonshire, Cambridgeshire, Bedfordshire, Buckinghamshire and Oxfordshire, and custodian of the castles of Oxford, Northampton and Bedford. Although already rewarded with extensive estates in the honour of Gloucester, he received in marriage (1216) Margery, widow of Baldwin de Redvers, earl of Devon, and by 1221 he had acquired custody of the lands of his stepson.

After King John's death (1216), Falkes gave less steady allegiance to the regents of the young Henry III and in 1223–24 had to surrender his midland counties and castles (except Bedford) as part of a redistribution of office aimed against the aliens and their supporters. Complaints against his conduct of local government were made as early as 1220. His brother William ambushed a royal justice and imprisoned him at Bedford in 1224. The castle was besieged, taken and the garrison hanged. Falkes was held responsible, and had to submit to the king and go into exile. He appealed to the pope with no success, and died in 1226, according to the chronicler Roger Wendover at Sanctum Cyriacum (probably either the modern St. Ciriè, near Turin, Italy, or St. Cyriac, Var, France). (J. C. Ho.)

BRÉBEUF, SAINT JEAN DE (1593–1649), French Jesuit and patron saint of Canada, was born at Condé-sur-Vire, Normandy, on March 25, 1593. He entered the Society of Jesus in 1617, was ordained priest in 1623 and arrived in New France in 1625. Assigned to Christianize the Huron Indians between Georgian Bay and Lake Huron, he lived in danger of death until forced by the British to return to France in 1629. Back again in "Huronion" in 1634, Brébeuf laboured for 15 years in bestial surroundings trying to civilize the savages, his trust in God keeping him serene in all hardships and suffering. He was the veteran of 18 missions in 1647 when the French-Iroquois peace was made. The Iroquois, however, continued their fierce war against the Hurons and destroyed all villages and missions in 1648. They seized Brébeuf and his fellow Jesuit, Gabriel Lalemant, and tortured them to death near the French Fort St. Ignace, March 16, 1649. Brébeuf endured stoning, slashes of knives, a collar of red-hot tomahawks, a "baptism" of scalding water and burning at the stake. Because he showed no sign of pain, his heart was eaten by the Iroquois. He was canonized with other Jesuit martyrs in 1930, and their feast day in the Roman Catholic Church is Sept. 26.

St. Jean de Brébeuf's writings are source materials for historians and ethnologists. He composed a grammar and catechism in Huron, and his annual narratives, which were published and avidly read in France, are translated in R. G. Thwaites' *The Jesuit Relations and Allied Documents*, 73 volumes (1896–1901). (J. V. J.)

BRECCIA is a rock made of coarse, sharp, angular fragments embedded in a matrix. The matrix may be similar in origin to the fragments and differ only in size of grain, or it may be an

infiltration product—a precipitate of mineral matter from solution. Breccias differ from conglomerates in the angularity of their fragments and in a greater diversity of origin (see CONGLOMERATE). The sedimentary breccias have been designated sharpstone conglomerates.

Because of their polygenetic nature, breccias are a diverse group of rocks. Volcanic breccias include those rocks composed of lava fragments imbedded in lava and also those composed of poorly sorted blocks in a tuffaceous (formed from volcanic ash or dust) matrix. The first type is the product of the break-up of a solidified lava crust by further movement of the flow (fluxion breccia); the second is a product of explosive volcanic action (see also AGGLOMERATE).

Sedimentary breccias form in several ways. Common are the intraformational breccias formed by the fragmentation of a sediment that has been partly lithified and the incorporation of these materials, unmodified by transport, in a similar or related sedimentary matrix. Fragmentation is due mainly to desiccation on mud flats, either tidal or floodplain. Reef breccias composed of blocks of reef rock in finer debris form on the seaward side of coral reefs. Breccias also form by travertine (calcium carbonate) cementation of talus or rock debris and by dripstone—cementation of rock falls in caves.

Tectonic or structural (crush) breccias form by earth movements along fissures or faults or by folding. Fault breccias are commonly cemented with vein calcite and quartz or less commonly with the sulfides and other vein minerals. The folding of thin beds of mixed character and unlike competency or strength produces a fold breccia (reibungsbreccia).

See W. H. Norton, "A Classification of Breccias," *Jour. Geol.*, 25:160-194 (1917). (F. J. P.)

BRECHIN, a royal and parliamentary burgh and market town of Forfarshire (Angus), Scot., on the left bank of the South Esk, 42½ mi. S.S.W. of Aberdeen by road. Pop. (1961) 7,114. About 5 mi. N.W. of the town are hill forts on the twin hills of White and Brown Catterthun, the summits ringed by concentric circles of gray stones and by earthworks. The district contains stone circles, standing stones, cists and other antiquities; it is also richly agricultural. Brechin was probably a pre-Christian religious centre long before a monastic settlement was made by Celtic Culdees (*q.v.*) on the knoll where the cathedral now stands. At the end of the 10th century King Kenneth II MacMalcolm is recorded as having "dedicated to the lord" the "civitas" or religious settlement of Brechin; in 1012 it was burned by the Danes. The Cathedral Church of the Holy Trinity was erected in the 13th century after David I had made Brechin a diocese before his death in 1153. It was restored in 1900-02 to remedy the reconstructions of 1806 and is now the Presbyterian parish church. Adjoining it is a slim round tower, dating from about 1050, which is 25 ft. in diameter at the base and 12½ ft. at the top, 87 ft. high and capped by a 15th-century hexagonal spire. This type of structure is common in Ireland, but the only other Scottish examples are at Abernethy and Egilsay. Brechin is also a see of the Episcopal Church in Scotland.

Both town and castle saw fighting across the centuries, and no trace remains of the old castle or of the town walls or gates. The present castle is the seat of the earl of Dalhousie. Its library contains Robert Burns's correspondence with George Thomson. The ancient bridge was for centuries the only one over the South Esk. The grammar school, founded in the 15th century, is now Brechin high school. Sir Robert Watson-Watt, the pioneer of radar, was born in Brechin. Industries include agriculture, light and precision engineering, linen, jute and rayon weaving and whisky distilling. The north and south branches of the Esk offer salmon and sea trout fishing.

BRECHT, BERTOLT (1898-1956), German dramatist and poet, one of the most controversial figures in the modern European theatre, was born at Augsburg, Bavaria, on Feb. 10, 1898. After World War I, he gave up his medical studies to devote himself to literature and the theatre. His early plays, *Baal*, *Trommeln in der Nacht* (both 1922) and *Im Dickicht der Städte* (1924), bore the stamp of Expressionism but were distinguished by stark realism and simplicity of style, as were his early lyrics and ballads,

collected under the ironical title *Die Hauspostille* ("Book of Family Devotions"; 1927). In a comedy *Mann ist Mann* (1927), he first used song as a means of dramatic emphasis. His greatest theatrical success was *Die Dreigroschenoper* (*The Threepenny Opera*; 1928), with music by Kurt Weill. This and another, less successful, opera marked Brecht's conversion from nihilism to Marxism, which he propagated in a series of *Lehrstücke* (1929-34), short didactic pieces for amateur actors.

In 1933 Brecht went into exile, first to Denmark and Finland, then to the United States. During these years, he wrote a number of plays inspired by the struggle against Fascism. His main claim to fame is based on plays dealing with wider human issues: *Mutter Courage und ihre Kinder* (1941), a chronicle of the Thirty Years' War; *Leben des Galilei* (1943); *Herr Puntila und sein Knecht* (1948); and the dramatic parables *Der gute Mensch von Sezuan* (1943) and *Der kaukasische Kreidekreis* (1948).

In 1948, Brecht returned to Germany and settled in east Berlin where with his wife, the actress Helene Weigel, he founded the Berliner Ensemble. Here he realized his theory of epic theatre in productions mainly of his own plays. Though politically provocative, these productions, based on meticulous teamwork, gained him international fame. He died in Berlin on Aug. 14, 1956.

BRECKINRIDGE, JOHN CABELL (1821-1875), U.S. lawyer, soldier and political leader, was born near Lexington, Ky., on Jan. 21, 1821. He graduated from Centre college, Danville, Ky., in the class of 1839, continued his education at the College of New Jersey (now Princeton university) and studied law at Transylvania university, Lexington, Ky. After practising law in Frankfort, Ky., Burlington, Ia., and Lexington, Ky., Breckinridge served in the Mexican War with the rank of major in a volunteer regiment. He began his political career in 1849 as a member of the Kentucky legislature and in 1851 was elected to the U.S. house of representatives. In 1856 Breckinridge was elected vice-president of the United States on the ticket with James Buchanan and served as presiding officer of the U.S. senate in the difficult years preceding the American Civil War. When internal dissensions brought about a split within the Democratic party in 1860, Breckinridge was nominated for the presidency by the southern proslavery Democrats who refused to accept Stephen A. Douglas as their nominee. Though defeated in the election, Breckinridge received 72 electoral votes from the 11 states comprising the lower south. He succeeded John J. Crittenden as U.S. senator from Kentucky in March 1861. Later in the year he made a speech in Kentucky, resigning from the senate, and in December was formally expelled from that body.

Meanwhile he had accepted a commission as brigadier general in the Confederate army. Following the battle of Shiloh, in which he commanded the reserve, Breckinridge was promoted to the rank of major general and thereafter took part in many campaigns. He defeated Gen. Franz Sigel at Newmarket, Va., served with Lee's army in the Wilderness and was second in command to Gen. Jubal Early in the Shenandoah campaign. In the final months of the war Breckinridge served as Confederate secretary of war, and at the close of hostilities he fled to England via Florida and Cuba. After a self-imposed exile of three years, Breckinridge returned to the United States and resumed his law practice in Lexington, Ky., where he remained until his death on May 17, 1875.

BRECKNOCKSHIRE (BRECONSHIRE; Welsh, SIR FRY-CHEINIÖG), an inland county in south Wales, the third largest administrative and fourth largest geographical county in Wales, bounded on the northwest by Cardiganshire, on the north and northeast by Radnorshire, on the east by Herefordshire, on the southeast by Monmouthshire, on the south by Glamorgan and on the west by Carmarthenshire. Area 733.5 sq.mi.

Physical Geography. — The greater part of the county is composed of Old Red Sandstone of the Devonian period. On the southern boundary this is overlain successively by Carboniferous limestone, Millstone Grit and, in the southwest and southeast, by the lower coal measures of the south Wales basin. In the north the Old Red Sandstone has been eroded to expose older Silurian and Ordovician rocks which appear in bands running approximately northeastward, the widest being the shales, sandstones and conglomerates of the Llandeilo and Llandovery beds, while to the southeast of these are narrow outcrops of the Wenlock and Ludlow sandstones and mudstones. Intrusions of igneous rocks produce sulfur and saline springs at Builth Wells, Llangamarch Wells and Llanwrtyd Wells, the last-named having the highest sulfur content of any mineral springs in Great Britain.

The oldest rocks in the northwest of the county form a barren upland rising to more than 2,000 ft. and are part of the central Wales massif. This is separated from Mynydd Epynt by the valley of the Irfon, a tributary of the Wye which latter forms the boundary with Radnorshire for about 30 mi. Mynydd Epynt, stretching northeastward across the county and rising to 1,560 ft., is the most northerly outcrop of the Old Red Sandstone. Another tributary of the Wye, the Llynfi, flowing northward through Llangorse lake, separates Mynydd Epynt from the deeply channeled, high plateau of the Black mountains in the east. Except for one isolated cap of Carboniferous limestone, Pen Cerrig-calch, near Crickhowell, these hills are composed of rocks of the Old Red Sandstone series, the highest point, Waun Fach, rising to 2,260 ft. Near Abergavenny, the Sugar Loaf (1,955 ft.) is a conspicuous landmark on the county boundary. Running from west to east across the south of the county are the upland masses of Fforest Fawr and the Brecon Beacons, with their main crests frequently rising to summits over 2,000 ft., which are regarded as remnants of the much-dissected high plateau of Wales. At the highest point of the Brecon Beacons (Pen-y-Fan, 2,906 ft.) are residual summits regarded as ancient monadnocks rising well above the high plateau surface and which form the highest hills in south Wales. These hills are separated from Mynydd Epynt and the Black mountains by the valley of the Usk (Wysg) which rises on the western borders of the county at Carmarthen Van (Fan Foel, 2,632 ft.) and flows eastward and southeastward across the county.

The dip slope of each of these upland masses is south or southeast giving fairly steep and well-defined escarpments on the northern sides of Mynydd Epynt, the Brecon Beacons and the Black mountains. The more gentle southerly slopes are channeled by roughly parallel streams. The Tawe, Neath (Nedd) and Taff (Taf) all flow southward from the Brecon Beacons range, and the Towy (Tywi), also flowing southward, forms the county boundary on the northwest. All the rivers eventually flow southward into the Bristol channel thereby cutting across the geological structure of the Paleozoic rocks of the south Wales coal basin. This discordant drainage pattern is regarded as having been superimposed from a now vanished cover of Mesozoic rocks. There is evidence that the region was heavily glaciated. The northern flanks of the higher hills have the steep cwm (dingle) formations associated with ice erosion, while much boulder clay or till is found in the lower valley lands. Striated pebbles and boulders occur at a great height on the Black mountains, where several ice streams converging on their northern escarpment forced the ice up over the ridge southward into the valley of the Honddu. The county is one of the best water-producing areas in Wales, and Birmingham, Swansea, Cardiff, Newport and other towns are supplied from its reservoirs.

History. — Barrows, implements and standing stones give evidence of occupation of the county in the Stone Age and Bronze Age. Traces of prehistoric lake dwellings were found at Llangorse lake (Llyn Safaddan) in 1869. There are many hill camp sites of the Early Iron Age. The conquest of the district by the Romans from the Silures was effected about A.D. 75–80, and the most important remains of this occupation, at Y Gaer near Brecon, were excavated by Sir R. E. Mortimer Wheeler in 1925–26. Five Roman roads radiated from this camp.

On the departure of the Romans about A.D. 400 the land, excepting the lordship of Buellt (Builth), came under the domination

of Brychan Brycheiniog, a native prince, after whom the county is named. Many of the older churches were founded by or dedicated to his descendants during the age of the Celtic saints and monastic missionaries. St. Illtud, who greatly influenced the foundation of early scholarship in south Wales, is supposed to have been buried about 480 near one of the churches in the county dedicated to him. Subsequently Bernard de Newmarch conquered the area for the Normans. He built a castle at Talgarth, Brychan's ancient capital on the Llynfi. After advancing westward and fighting a battle at Y Gaer about 1091, in which Bleddyn ap Maenarch, the king of Brycheiniog, was slain, he founded the castle and town of Brecon (Aberhonddu). A number of other castles were erected, some of them on the sites of older defense points established against Mercian attacks. Brycheiniog afterward became a marcher lordship and suffered in the strife which follo ed. In 1282, Llewelyn, the last native prince of Wales, fell in a skirmish with the English near Builth. Later, Owain Glyndwr (see GLENDOWER, OWEN) carried out raids in the area. Warfare was almost continuous until the dissolution of the marcher lordships in 1536 by the Act of Union, when the present county was formed.

In the 17th and 18th centuries the market towns became centres of thriving wool and leather industries, and iron was smelted at various points before the large iron-working communities, on the southern borders of the county, sprang up with the development of the south Wales coal field during the Industrial Revolution. John Penry (1563–93), whose birthplace is preserved at Llangamarch, typified the spirit of Puritanism in this region. Howell Harris (1714–73), a leader of the Methodist revival, was another native of the county.

The most important medieval remains at Brecon are the castle and the cathedral (see below), both of Norman foundation, and Christ college, a public school which was founded by charter from Henry VIII in the 13th-century Dominican friary on the site of the present school. Tretower court near Crickhowell, parts of which date back to c. 1400, is one of the finest examples extant of a lightly fortified dwelling of the period. It was especially associated with the Vaughan family which included Sir Roger Vaughan, the Yorkist, and the metaphysical poet, Henry Vaughan (1622–95), who was a native of the county. Some of the Norman castles remain. Of the many old churches in the county, Llanfilo and Partrishow are of particular interest. The county museum contains collections representative of all periods of Brecknockshire's history.

Population and Administration. — In 1961 the census showed a population of 55,544, including an appreciable number in the various military establishments in the county. The county figure rose from 54,213 in 1901 to 61,069 in 1921 but fell to 52,540 (est.) in 1939. The fluctuation in the total conceals a tendency to a steady decline throughout the 20th century in most of the rural areas. The only municipal borough is Brecon (*q.v.*), the county town. There are four urban districts: Brynmawr, Builth Wells, Hay (*qq.v.*) and Llanwrtyd Wells.

The county forms part of the south Wales circuit, and the assizes are held at Brecon. It has one court of quarter sessions and is divided into ten petty sessional divisions. The county is not divided for parliamentary purposes and until 1918 returned one member to parliament; after that time its representation was joined with that of the county of Radnor. There are 89 civil parishes. Ecclesiastically the county is part of the diocese of Swansea and Brecon, which was formed in 1923 out of the ancient dioceses of St. David's and Llandaff. The fine old Benedictine priory of St. John at Brecon became the cathedral of the new diocese.

Industries and Communications. — Agriculture is the county's chief occupation. Nearly 50% of its area is rough grazing and, the average rainfall varying from about 30 in. per annum at Hay to nearly 100 in., on the Brecon Beacons, the emphasis is on beef cattle and sheep rearing, though arable farming is undertaken on the lower valley lands, especially the fertile alluvial soils of the Usk and Llynfi valley regions. The Brecknockshire Agricultural society is one of the oldest in Great Britain, dating from 1755. Extensive afforestation has also been undertaken. The mining of anthracite coal is an important industry in the Ystradgynlais district in the southwest of the county, and the quarrying of limestone

and silica rock is undertaken near the southern boundary. A small part of the southern region of the county was included in the south Wales and Monmouthshire development area defined after World War II, and a few new industries, including one employing disabled persons at Ystradgynlais, were introduced. Its scenic beauty makes Brecknockshire a tourist county; more than half its area was designated in 1955 as part of the Brecon Beacons National park.

Single-track railways radiate from Brecon in the centre of the county to Builth Wells and Moat Lane, Hereford, Newport, Merthyr Tydfil and Neath. The Craven Arms-Swansea line runs through the north of the county. The pattern of main roads is similar, trunk or class I roads running from Brecon to Builth Wells and north Wales, Hereford, Newport, Cardiff, Swansea and Carmarthen. The Swansea-Manchester trunk road runs through the Irfon valley and the Neath-Abergavenny trunk road passes along the southern edge of the county. The Brecon-Newport canal, opened in 1800 but, like the Ystradgynlais-Swansea canal, disused for many years, is being repaired for pleasure boats on the length between Brecon and Pontypool.

Whyte (1943).

BRECON (BRECKNOCK; Welsh, ABERHONDDU), a cathedral town, municipal borough and county town of Brecknockshire, Wales, is 42 mi. N.N.W. of Cardiff. Pop. (1961) 5,797. It lies where the Honddu from the north and the Tarell from the south enter the Usk, near the centre of the county. Its site commands routes from Builth Wells in the north, Llandovery in the west, Merthyr Tydfil in the south, Crickhowell in the southeast and Hay in the northeast. About 3 mi. W. of the town is the Roman fort known as Y Gaer, garrisoned during the 2nd century by a squadron of Spanish cavalry. Brecon maintained the importance of its nodal site selected by the Romans. Bernard de Newmarch conquered the district known as Brycheiniog (named for Brychan, son of a 5th-century Welsh chieftain) and probably built the original Norman castle in 1092. Bernard de Newmarch subsequently founded, near the castle, the Benedictine priory of St. John. Nothing remains of the original church except portions of the nave, but it was entirely rebuilt in the first half of the 13th century and the 14th century with Early English and Decorated additions. In 1923 it was made the cathedral of the newly constituted diocese of Swansea and Brecon.

The town, picturesquely situated, is remarkable for its medieval plan and for its Georgian buildings. Around the original castle and priory a small medieval town grew up. It received a series of charters from the de Bohuns, into which family the castle and lordship passed, the earliest recorded charter being granted by Humphrey, 3rd earl of Hereford. A Dominican friary (now Christ college) was established southwest of the town and was refounded by Henry VIII in 1542 as a collegiate church and school. The position of the town offered special facilities during Tudor economic developments for the establishment of trade guilds as well as a guildhall. There were formerly five guilds, the main industries being cloth and leather manufacture. Brecon destroyed its castle to preserve its neutrality during the Civil War, and in 1645 Charles I, while staying at Brecon priory, wrote the famous letter to his son in which he tells him to "prepare for the worst." Thomas Coke, founder of the American Methodist Episcopal Church, the actress Mrs. Sarah Siddons and her brother Charles Kemble were all born in the town. There are two ancient pleasure fairs, and stock fairs are held monthly.

BREDA, the name of two Italian industrialists, cousins, who did much to develop Italy's railway and heavy engineering industries during the 19th and early 20th centuries.

VINCENZO STEFANO BREDA (1825–1903) was born at Limena (Padua) on April 30, 1825, and became a railway engineer. In 1854 he founded a society for the development of railways in cen-

tral Italy, in 1872 the Società Veneta for public engineering projects, and is best remembered for his foundation of the Terni steelworks (see TERNI). He also took an interest in agriculture and promoted horse racing. He died at Padua on Jan. 4, 1903.

ERNESTO BREDA (1852–1918), born at Campo San Martino (Padua), worked first under Vincenzo Stefano Breda, his cousin, at the Terni plant. In 1886 he founded the heavy engineering firm known from 1900 onward as the Società Italiana Ernesto Breda, with works at Sesto San Giovanni near Milan. By the outbreak of World War I this firm was producing numerous locomotives for the Italian state railways, besides agricultural machinery. Ernesto Breda rapidly put the works on a wartime production footing, created a steel plant and exploited hydroelectric power. At this period also the firm began to produce airplanes and aircraft engines, as well as electric locomotives. At the same time Breda planned postwar reconversion and a scientific metallurgical research institute. He died in Milan on Nov. 6, 1918.

(S. Lo.)

BREDA, town, province of North Brabant, Neth., at the confluence of the Merk (Mark) and Aa rivers. Pop. (1960) 107,843. Breda was in the 12th century a direct fief of the duchy of Brabant, its earliest known lord being Godfrey I (1152–1170), in whose family it continued, until 1327, when Gerard of Rassoghem sold his rights to Brabant. It passed ultimately to William I of Orange (1533–84). Breda obtained municipal rights in 1252. It was fortified 1531–36 by Count Henry of Nassau: who restored the old castle built by John of Polanen in 1350. It remained until the 19th century an important fortress on the Mark. Captured by the Spaniards in 1581, it fell again into the hands of Maurice of Nassau in 1590. Its surrender to the Spaniards (1625) is the subject of the famous picture by Velázquez in the Museo del Prado in Madrid. In 1637 Breda was recaptured by Frederick Henry of Orange, and in 1648 was finally ceded to the Netherlands by the treaty of Westphalia. It was the residence during exile of Charles II of England. In 1696 William of Orange, King of England, completed the castle (now the Royal Military academy). During the French Revolution it was taken by (Charles François) Dumouriez in 1793, evacuated soon after and retaken by Charles Pichegru in 1795. In 1813 the citizens of Breda again made themselves masters of the town. In 1575 a conference was held there between the ambassadors of Spain and the United Provinces; in 1667 a peace was signed by England, the Netherlands, France and Denmark. The town has a fine quay, town hall and park. The principal Protestant church (Grote Kerk) is a Gothic building (15th century), with a fine tower, and a choir (of 1410). The population of Breda was evacuated in May 1940 and the town was liberated from the Germans in Oct. 1944.

The seat of a Roman Catholic bishop, the town's manufactures include the making of machinery, artificial silk, matches and chocolate.

BREDERO, GERBRAND ADRIAENSZON (1585–1618), Dutch poet and playwright, the rugged epitome of an age of change and conflict. Born in Amsterdam, March 16, 1585, he was of humble origins and little learning, yet he had artistic leanings and poetic genius; and his erotic temperament warred with his stern Protestant convictions. The irreconcilable conflict between his birthright—the medieval, full-blooded life of the back streets of Amsterdam—and the sophistication of the Renaissance intelligentsia is most evident in his earliest poetry, contained in *Groot Liedt-Boeck* (1622). Here, the humorous poems reveal a power of observation rivaling that of the painters Jan Steen and Xdriaen van Ostade (*qq.v.*), while the sensuality of the amorous songs and sonnets strikes a wild contrast to the sincerity and often the remorse of the devotional poetry.

His dramatized versions of Spanish romances show his true talent only in the comic intermezzos and indeed his farces, the best of which is *Klucht van de Koe* (1612), with their trenchant caricature and brisk Terentian dialogue, provide the best and the last of this medieval genre. But his comedy *De Spaanschen Brabander* (1617) makes Bredero unique in Dutch letters. This play, inspired by the Spanish picaresque novel *Laazarillo de Tormes*, is truly great, like the medieval poem *Vanden Vos Reinaerde*, be-

cause of its humanity and wit. While championing the quick-witted underdog at the expense of the pompous hidalgo, it also provides a salutary corrective to the romantic notion that the Golden Age was a period of universal prosperity and culture. Bredero died, Aug. 23, 1618, in Amsterdam.

See his *Werken*, ed. by J. A. N. Knuttel, 3 vol. (1918-29); G. A. Bredero *Toneelwerk*, ed. by A. A. van Rhijnbach (1942). (P. K. K.)

BREDERODE, HENDRIK, LORD OF (1531-1568), the popular resistance leader during the first phase of the revolt of the Netherlands, was born in Brussels on Dec. 20, 1531, of a family whose genealogy reaches back to 1205 and who from 1418 had also held the lordship of Vianen, south of Utrecht. A soldier, hard-drinking, reckless and jovial, Hendrik seems to have been moved above all by hatred of popery and (true to his family traditions) by resentment against the encroaching monarchical power. Succeeding to the family titles in 1556, he joined the league of great nobles who succeeded in 1564 in getting rid of Cardinal Granvelle, his relative by marriage (see NETHERLANDS: *Philip II*). Sharing the more radical sentiments of the gentry, he became in Dec. 1565 one of the leading men of the newly founded confederacy of the lesser nobility, which had a markedly Protestant tinge. On April 5, 1566, it was he who, at the head of approximately 300 gentlemen, presented to the regent Margaret of Parma, at Brussels, the petition known as the "Compromise of the Nobility" asking for a new religious policy. He continued to press for freedom of conscience. During the reaction following the excesses of the iconoclasts in 1566, he refused to take the oath of unconditional loyalty demanded by the regent. Resorting to force, he made military preparations at Vianen, raised troops at Antwerp and elsewhere and took a prominent part in an abortive Calvinist rising. Having vainly tried to win over Amsterdam, he fled to Emden on April 27, 1567. He died at Harenburg castle near Recklinghausen on Feb. 15, 1568. (A. G. J.)

BREEZE. A current of air less than a wind, which in turn is less than a gale. (See BEAUFORT SCALE.) The term is qualified in many different ways; e.g., glacial breeze—a cold breeze blowing down the course of a glacier; lake breeze—light wind blowing on to the coast of a lake in sunny weather during the middle of the day; mountain breeze—a mass of air flowing down into the valley during the night; valley breeze—a day breeze blowing up the valleys. The unqualified term is usually applied to the light wind blowing landwards by day, sea breeze, and the counter wind blowing offshore at night, land breeze.

BRÉGUET, LOUIS CHARLES (1880-1955), French aviation pioneer and founder of Air France, was born Jan. 2, 1880, in Paris, a descendant of the famous watchmaker, Abraham Louis Bréguet. Educated at the Lycées Condorcet and Carnot and at the École Supérieure d'Electricité, he joined the family engineering firm, Maison Bréguet, becoming head engineer of its electric service. He published reports on aerodynamics, and in 1917 built and flew a "gyroplane," the forerunner of the helicopter. He built his first airplane in 1909, set a speed record for 10 km. in 1911, and in that year founded the Société des Ateliers d'Aviation Louis Bréguet. In 1912 he built his first hydroplane. He built military planes in World Wars I and II, and in 1919 founded the Compagnie des Messageries Aériennes, which ultimately became Air France. He died at St. Germain-en-Laye, Paris, May 4, 1955.

BREHON LAWS, more properly called *Feinechus*, were the ancient laws of Ireland. Brehon (*Breitheamh*) is the Irish word for judge. Regular courts and judges existed in Ireland from prehistoric times.

The extant remains of these laws are manuscript transcripts from earlier copies made on vellum from the 8th to the 13th century, now preserved with other Gaelic manuscripts in Trinity college and the Royal Irish academy, Dublin, the British museum, Oxford university, some private collections and several libraries on the continent of Europe. The largest and most important of these documents is the *Senchus Mdr*, or "Great Old Law Book." No copy of it now existing is complete. What remains of it occupies the first, second and a portion of the third of the volumes produced by the Brehon Law commission appointed in 1852.

In the Annals of the Four Masters it is said: "The age of Christ

438, the tenth year of King Laeghaire (Lairy), the *Senchus Mór* and *Feinechus* of Ireland were purified and written." This entry has some historical corroboration.

The text and earlier commentaries are in the *Bearla Feini*—the most archaic form of the Gaelic language. Many words, phrases and idioms are now obsolete and so difficult to translate that the official translations are to some extent confessedly conjectural. Frequently only the opening words of the original text remain. Wherever the text is whole, it is curt, elliptical and yet rhythmical. The rigorously authentic character of these laws, relating to, and dealing with, the actual realities of life, and with institutions and a state of society nowhere else revealed to the same extent, the extreme antiquity both of the provisions and of the language, and the meagreness of continental material illustrative of the same things endow them with exceptional archaic, archaeological and philological interest. No man was allowed to act as judge until he had studied the full law course, which occupied 20 years, and had passed a rigorous public examination. The course of study for judge and law agent, respectively, is carefully laid down. The Brehon was an arbitrator, umpire and expounder of the law rather than a judge in the modern acceptance. It appears, without being expressly stated, that the facts of a case were investigated and ascertained by laymen before submission to a Brehon for legal decision. The complainant could select any Brehon he pleased, if there were more than one in his district. Every king or chief of sufficient territory retained an official Brehon, who was provided with free land for his maintenance and acted as registrar or assessor in the king's court. In ordinary cases the Brehon's fee was said to have been one-twelfth of the amount at stake.

Assemblies, national, provincial and local, were a marked characteristic of ancient Irish life. They all, without exception, discharged legal, legislative or administrative functions. Most of the assemblies were annual, some triennial, some lasted only a day or two, others a week and occasionally longer. All originated in pagan funeral or commemorative rites and continued to be held, even in Christian times, in very ancient cemeteries. They were called by different names—Feis, Aenach, *Dál*, etc. At one assembly held at Uisneach about a century before Christ a uniform law of distraint for the whole of Ireland was adopted. Each provincial kingdom and each tuath had assemblies of its own. Very careful provision is made for the preparation of the sites of great assemblies, and the preservation of peace and order at them is sanctioned by the severest penalties of the law.

The Clan System.—Tuath, *Cinel* and *Clann* were synonyms meaning a small tribe or nation descended from a common ancestor. The theory of common origin was not rigidly adhered to, a king and clan being able, subject to certain limitations, to adopt new members or families, or amalgamate with another clan. Kinship with the clan was an essential qualification for holding any office or property. The rules of kinship largely determined status with its correlative rights and obligations, supplied the place of contract and of laws affecting the ownership, disposition and devolution of property, constituting the clan an organic, self-contained entity, a political, social and mutual insurance copartnership. The solidarity of the clan was its most important and all-pervading characteristic. According to the traditional view the entire territory occupied by a clan was the common and absolute property of that clan, a portion being set apart for the maintenance of the king. Warriors, statesmen, Brehons, Ollamhs, physicians, poets and even eminent workers in the more important arts were also rewarded with free lands. Rank, with the accompanying privileges, jurisdiction and responsibility, was based upon a qualification of kinship and of property, held by a family for a specified number of generations, together with certain concurrent conditions; and it could be lost by loss of property, crime, cowardice or other disgraceful conduct. A portion of land called the *Cumhal* Senorba was devoted to the support of widows, orphans and old childless people. According to the later and now very generally accepted view of John (Eoin) MacNeill there was no communal holding of land by the clan. Clan itself meant little more than a princely family,

like, say, the Hohenzollerns in Germany. There was no land, blood or personal name common to the people subject to such a family. Anything in the nature of common holding or redistribution of land was confined to the joint families next to be described.

Fine (*finē*), originally meaning family, came in course of time to be applied to a group of kindred families or a joint family group of four generations. Even those who adhere to the traditional view of the clan will admit that in course of time a large and increasing proportion of the good land became limited private property. The area of arable land available for the common use of the clansmen was gradually diminished by these encroachments. The land belonging to the joint family (*find*) was at intervals liable to redistribution when the joint family broke up. In this distribution men might or might not receive again their former portions. In the latter case compensation was made for unexhausted improvements. This land could not be sold, nor even let except for a season in case of domestic necessity. The holders had no landlord and no rent to pay for this land and could not be deprived of it except for a crime. They were subject only to public tributes and the ordinary obligations of free men. The unfenced and unappropriated common lands—waste, bog, forest and mountain—all clansmen were free to use promiscuously at will.

Tenure of Land.—There was hardly any selling and little letting of land in ancient times. Nobles and other persons holding large areas let to clansmen not the land but rather the grazing of a number of cattle specified by agreement. They also let cattle to a clansman who had none or not enough, and this was the most prevalent practice. There were two distinct methods of letting and hiring—*saer* ("free") and *daer* ("unfree"), the conditions being fundamentally different. The conditions of *saer*-tenure were largely settled by the law, mere comparatively easy, did not require any security to be given, left the clansman free within the limits of justice to end the connection, left him competent in case of dispute to give evidence against that of the noble and did not impose any liability on the joint family of the clansman. By continued use of the same land for some years and discharge of the public obligations in respect of it in addition to the *ciss* or payment as tenant, a clansman became a subowner or permanent tenant and could not be evicted. There is no provision in these laws for evicting anyone. For the hire of cattle a usual payment was one beast in seven per annum for seven years, after which the cattle that remained became the property of the hirer. *Daer*-tenure, whether of cattle or of the right to graze cattle upon land, was subject to a *ciss-ninisciss* ("wearisome tribute"), for the payment of which security had to be given. A man not in the enjoyment of full civil rights, if able to find security, could become an unfree clansman. A free clansman by becoming an unfree clansman lowered his own status and that of his joint family, became incompetent to give evidence against that of a noble, and could not end the connection until the end of the term except by a large payment. The members of his joint family were liable, in the degree of their relationship, to make good out of their own property any default in the payments. Hence this tenure could not be legally entered into by a free clansman without the permission of his joint family. Unfree clansmen were also exposed to casual burdens, like that of lodging and feeding soldiers when in their district. All payments were made in kind. When the particular kind was not specified by the law or by agreement, the payments were made according to convenience in horses, cattle, sheep, pigs, wool, butter, bacon, corn, vegetables, yarn, dye plants, leather, cloth, articles of use or ornament, etc.

People who did not belong to the clan and were not citizens were in a base condition and incompetent to appear in court in suit or defense except through a freeman. The *Bothach* ("cot-tier") and the *Sen-cléithe* ("old dependent") were people who, though living for successive generations attached to the families of nobles, did not belong to the clan and had no rights of citizenship. *Fuidhirs*, or manual labourers without property, were the lowest section of the population. Some were born in this condi-

tion, some clansmen were depressed into it by crime, consequences of war or other misfortune; and strangers of a low class coming into the territory found their level in it. The *fuidhirs* also were divided into free and unfree, the former being free by industry and thrift to acquire some property, after which five of them could club together to acquire rights corresponding to those of one freeman. The unfree *fuidhirs* were tramps, fugitives, captives, etc.

Fosterage, the custom of sending children to be reared and educated in the families of fellow clansmen, was prevalent among the wealthy classes. A child in fosterage was reared and educated suitably for the position it was destined to fill in life. There was fosterage for affection, for payment and for a literary education. Fosterage began when the child was a year old and ended when the marriageable age was reached, unless previously terminated by death or crime. Every fostered person was under an obligation to provide, if necessary, for the old age of foster parents. The affection arising from this relationship was usually greater, and was regarded as more sacred, than that of blood relationship.

Law of Contract.—The solidarity of clan and joint family in their respective spheres, the provisions of the system, the simple rural life and the prevalence of barter and payments in kind left comparatively little occasion for contracts between individuals, consequently the rules relating to contract are not very numerous. They are, however, sufficiently solemn. No contract affecting land was valid unless made with the consent of the joint family. Contracts relating to other kinds of property are more numerous. When important or involving a considerable amount, they had to be made in the presence of a noble or magistrate. The parties to a contract should be free citizens, of full age, sound mind, free to contract and under no legal disability. "The world would be in a state of confusion if express contracts were not binding." From the repeated correlative dicta that "nothing is due without deserving," and that a thing done "for God's sake," *i.e.*, gratis, imposed little obligation, it is clear that the importance of valuable consideration was fully recognized. So also was the importance of time. "To be asleep avails no one"; "Sloth takes away a man's welfare." Contracts made by the following persons were invalid: (1) a servant without his master's authority; (2) a monk without authority from his abbot or manager of temporalities; (3) a son subject to his father without the father's authority; (4) an infant, lunatic or "one who had not the full vigilance of reason"; (5) a wife in relation to her husband's property without his authority. She was free to hold and deal with property of her own and bind it by contract. If a son living with his father entered into a contract with his father's knowledge, the father was held to have ratified the contract unless he promptly repudiated it. "One is held to adopt what he does not repudiate after knowledge, having the power." Contract of sale or barter with warranty could be dissolved for fraud, provided action was taken within a limited time after the fraud had become known. Treaties and occasional very important contracts were made "blood covenants" and inviolable by drawing a drop of blood from the little finger of each of the contracting parties, blending this with water, and both drinking the mixture out of the same cup. The forms of legal evidence were pledges, documents, witnesses and oaths. In cases of special importance the pledges were human beings, "hostage sureties." These were treated as in their own homes according to the rank to which they belonged and were discharged on the performance of the contract. If the contract was broken they became prisoners and might be fettered or made to work as slaves until the obligation was satisfied. Authentic documents were considered good evidence. A witness was in all cases important and, in some, essential to the validity of a contract. His status affected the force of the contract as well as the value of his evidence; and the laws appear to imply that by becoming a witness a man incurred liabilities as a surety. The pre-Christian oath might be by one or more of the elements, powers or phenomena of nature, as the sun, moon, water, night, day, sea, land. The Christian oath might be on a copy of the Gospels, a saint's crozier, relic or other holy thing.

Criminal Laws.—These laws recognized crime, but in the same calm and deliberate way in which they recognized contract and other things seriously affecting the people. Although we find in the poems of Dubhthach, written in the 5th century and prefixed to the *Senchus Mor*, the sentences "Let every one die who kills a human being," and "Every living person that inflicts death shall suffer death," capital punishment did not prevail in Ireland before or after. The laws uniformly discountenanced revenge, retaliation, the punishment of one crime by another, and permitted capital punishment only in the last resort and in ultimate default of every other form of redress. They contain elaborate provision for dealing with crime, but the standpoint from which it is regarded and treated is essentially different from ours. The state, for all its elaborate structure, did not assume jurisdiction in relation to any crimes except political ones, such as treason or the disturbance of a large assembly. For these it inflicted the severest penalties known to the law—banishment, confiscation of property, death or putting out of eyes. A crime against the person, character or property of an individual or family was regarded as a thing for which reparation should be made, but the individual or family had to seek the reparation by a personal action. This differed from a civil action only in the terms employed and the elements used in calculating the amount of the reparation. The function of a judge in a criminal as in a civil action was to see that the facts, with modifying circumstances, were fully and truly submitted to him, and then by applying the law to these facts to ascertain and declare the amount of compensation that would make a legal adjustment. For this amount the guilty person, and in his default his kindred, became legally debtor, and the injured person or family became entitled to recover the amount like a civil debt by distraint. There were no police, sheriffs or public prisons. The decisions of the law were executed by the persons concerned, supported by a highly organized and disciplined public opinion springing from honour and interest and inherent in the solidarity of the clan. Mac-Neill, however, contends that the state took a far more active part in enforcing Brehon decisions than that herein described, the king in general acting as judge, subject to professional advice. There is good reason to believe that the system was as effectual in the prevention and punishment of crime and in the redress of wrongs as any other human contrivance has ever seen.

In calculating the amount of compensation the most characteristic and important element was *Enechlann* ("honour-price," "honour-value"), a value attached to every free person, varying in amount from one cow to 30 cows according to rank. It was the assessed value of *status* or *caput*. It was frequently of consequence in relation to contracts and other clan affairs; but it emerges most clearly in connection with crime. By the commission of crime, breach of contract or other disgraceful or injurious conduct, *Enechlann* was diminished or destroyed, a *capitis diminutio* occurred, apart from any other punishment. Though existing apart from fine, *Enechlann* was the first element in almost every fine. *Dive* was the commonest word for fine, whether great or small. *Eric* ("reparation," "redemption") was the fine for "separating body from soul"; but the term was used in lighter cases also. In capital cases the word sometimes meant *Enechlann*, sometimes *coirp-dire* ("body-fine"), but most correctly the sum of these two. It may be taken that, subject to modifying circumstances, a person guilty of homicide had to pay (1) *coirp-dire* for the destruction of life, irrespective of rank; (2) the honour-value of the victim; (3) his own honour-value if the deed was unintentional; and (4) double his own honour-value if committed with malice aforethought. The sum of these was in all cases heavy; heaviest when the parties were wealthy. The amount was recoverable as a debt from the criminal to the extent of his property, and, in his default, from the members of his joint family in sums determined by the degree of relationship; and it was distributable among the members of the joint family of a murdered person in the same proportions, like a distribution among the next of kin. The joint family of a murderer could free themselves from liability by giving up the murderer and his goods,

or, if he escaped, by giving up any goods he had left, depriving him of clanship and lodging a pledge against his future misdeeds. In these circumstances the law held the criminal's life forfeit, and he might be slain or taken as a prisoner or slave. He could escape only by becoming an unfree labourer in some distant territory. When the effect of a crime did not go beyond an individual, if that individual's joint family did not make good their claim while the criminal lived, it lapsed on his death. "The crime dies with the criminal." If an unknown stranger or person without property caught red-handed in the commission of a crime refused to submit to arrest, it was lawful to maim or slay him according to the magnitude of the attempted crime. "A person who came to inflict a wound on the body may be safely killed when unknown and without a name, and when there is no power to arrest him at the time of committing the trespass." For crimes against property the usual penalty, as in breach of contract, was generic restitution, the quantity, subject to modifying circumstances, being twice the amount taken or destroyed.

Law of Distress.—Distress or seizure of property being the universal mode of obtaining satisfaction, whether for crime, breach of contract, nonpayment of debt or any other cause, the law of distress came into operation as the solvent of almost every dispute. Hence it is the most extensive and important branch, if not more than a branch, of these ancient laws. There was no sale, because sale for money was little known. The property in the thing seized, to the amount of the debt and expenses, became legally transferred from the debtor to the creditor, not all at once but in stages fixed by law. A creditor was not at liberty to seize household goods, farming utensils or any goods the loss of which would prevent the debtor recovering from embarrassment, so long as there was other property which could be seized. A seizure could be made only between sunrise and sunset. "If a man who is sued evades justice: knowing the debt to be due of him, double the debt is payable by him and a fine of five *seds*." When a large debt was clearly due and there was no property to seize, the debtor himself could be seized and compelled to work as a prisoner or slave until the debt was paid.

When a defendant was of superior rank to that of the plaintiff, distress had to be preceded by *troscad* ("fasting"). This is a legal process unknown elsewhere except in parts of India. The plaintiff, having made his demand and having waited a certain time without result, went and sat without food before the door of the defendant. To refuse to submit to fasting was considered indelibly disgraceful and was one of the things which legally degraded a man by reducing or destroying his honour-value. The law said, "he who does not give a pledge to fasting is an evader of all; he who disregards all things shall not be paid by God or man." If a plaintiff having duly fasted did not receive within a certain time the satisfaction of his claim: he was entitled to distraint as in the case of an ordinary defendant, and to seize double the amount that would have satisfied him in the first instance. If a person fasting in accordance with law died during or in consequence of the fast, the person fasted upon was held guilty of murder. Fasting could be stopped by paying the debt, giving a pledge or submitting to the decision of a Brehon. A creditor fasting after a reasonable offer of settlement had been made to him forfeited his claim. "He who fasts notwithstanding the offer of what should be accorded to him, forfeits his legal right."

BIBLIOGRAPHY.—Pending the work of a second Brehon Law commission, the laws are best studied in the six imperfect volumes (*Ancient Laws of Ireland, 1865-1901*) produced by the first commission (ignoring their long and worthless introductions), together with Whitley Stokes's *Criticism* (1903) or Atkinson's *Glossary* (1901). The following are important references (kindly supplied by Stokes) for detailed research:—R. Dareste, *Études d'histoire de droit*, pp. 356-381 (1889); Arbois de Jubainville and Paul Collinet, *Études sur le droit celtique*, 2 vol., (1895); Patrick W. Joyce, *Social History of Ancient Ireland*, vol. i., pp. 168-214 (1903); *Zeitschrift für celtische Philologie*, vol. 4, p. 221 (see also vol. 14, p. 1 and vol. 15); the Copenhagen fragments of the laws (1903); important letters in *The Academy*, nos. 699, 500, 701, 502, 703, 704, 706, 707 (substantially covered by Stokes's *Criticism*); *Revue Celtique*, vol. xxv, p. 344; *Eriu*, vol. i, pp. 209-315 (collation by Kuno Meyer of the lam tract Crith Gablach). Maine's *Early History of Institutions* (1875) and *Early Law and Custom*, pp. 162, 180 (1883); William E. Hearn's *Aryan Household* (1879) and MacLennan's *Studies*

in *Ancient History*, pp. 453–507 (1876), contain interesting general references, but the writers were not themselves original students of the laws. L. Ginnell's *Brehon Laws* (1894) may also be consulted. See also A. Ua Clerigh, *History of Ireland to the Coming of Henry II*, ch. 14 and 15 (1908); J. MacNeill, *Phases of Irish History*, ch. 10 and 12 (1919); S. Bryant, *Liberty, Order and Law Under Native Irish Rule* (1923); R. Thurneysen, *Cóic Conara Fugill (Die fünf Wege zum Urteil)* (1926).

BREISACH, a town of Germany, stands on a basalt rock 250 ft. above the Rhine, 16 km. (10 mi.) W. of Freiburg. Pop. (1959 est.) 4,778. Breisach has a fine minster, partly Romanesque, partly Gothic, dating from the 10th to the 15th centuries. The interior is remarkable for the wood carving of the high altar, and for tombs and pictures. Although most of the town was destroyed in World War II, it has been rebuilt in the original style. On the opposite bank of the Rhine, connected by a road bridge, lies the little town of Neubreisach, built as a fortress by Louis XIV. Railways run to Freiburg and Riegel. Breisach trades in textiles and electrical goods and also in wines and other agricultural produce. Breisach (ancient Brisiacum) was a stronghold of the Sequani (*q.v.*). It was captured in the time of Julius Caesar by Xriovistus and became known as the Mons Brisiacus. Fortified by the emperor Valentinian in 369 to defend the Rhine against the Germans, it remained throughout the middle ages as one of the chief bulwarks of Germany and was called the "cushion and key" (*Kissen und Schlüssel*) of the German empire." It gave its name to the district Breisgau. In 939 it was taken by the German King Otto I. In 1254 and 1262 the bishops of Basel obtained full control over it, but in 1275 it was made an imperial city by King Rudolf I, and the Habsburgs possessed it from the 14th century. In the Thirty Years' War Breisach successfully resisted the Swedes, but it was forced to capitulate to the Protestants after a memorable siege in 1638. The French held it from 1648, and it was several times besieged by them after its restoration to Austria in 1697. By the peace of Pressburg (1805) it was finally incorporated into Baden, and the fortifications were razed. Two medieval gates, however, remain. After the merger of Baden *Land* in 1952, Breisach became a town of Baden-Württemberg, Federal Republic of Germany.

BREISGAU, the most southwesterly district of Germany, and originally an Alamannic province, lies in the upper Rhine plain between Kenzingen and Lorrach and is bounded by the Black Forest. In the early middle ages the Zähringen counts ruled Breisgau, founding the town of Freiburg in 1120. The Zähringen counts died out in 1218 and the countship was partitioned between the line of Zähringen margraves and the counts of Freiburg. From the 14th century the Habsburgs began to extend their influence east of the Rhine and by the end of this century Breisgau, except for the so-called margrave lands and the lordship of Hachberg, formed with the lordships of Hauenstein and Triberg a constituent part of the Austrian lands. In 1457 Albert VI of Austria founded the university at Freiburg. Breisgau suffered heavily during the Peasants' War and the Thirty Years' War, Freiburg undergoing many sieges and falling for a while into Swedish hands. In 1665 the Austrian *Vorlande* reverted to the senior Habsburg line, but in Feb. 1679, when the emperor Leopold I accepted the treaty of Nijmegen, Freiburg passed under French rule, only being returned to Austria, together with Breisach, by the treaty of Rijswijk in 1697. By the peace of Lunéville in 1801 Breisgau was given to the duke of Modena to compensate for the surrender of his duchy to Napoleon, and at the peace of Pressburg in 1805 the countship was divided between Baden and Württemberg. The latter ceded its portion to Baden in 1806. (M. KR.)

BREITENFELD, BATTLES OF, two engagements in the Thirty Years' War (*q.v.*), fought near the village of Breitenfeld (now a suburb of Leipzig) in Saxony.

The First Battle. — On Sept. 17 (new style: Sept. 7, old style), 1631, the army of the Catholic league under Tilly was decisively defeated by Gustavus Adolphus of Sweden. Tilly's invasion of Saxony at the end of August, intended to force the elector to abandon his neutrality, had led instead to a Swedish-Saxon alliance. Confronted by the Swedish army of 16,000 foot, 10,000 horse and 50 guns as well as by the Saxon army, under Hans von Arnim, of

14,000 foot (mostly untrained militia), 6,000 horse and 20 guns, Tilly, who had only about 21,000 foot (13,000 veterans of the league and 8,000 imperial troops), 15,000 horse (8,000 veterans! 7,000 imperial) and 27 guns, wanted at first to effect a junction with strong detachments of imperial troops in Thuringia and Hesse, but was persuaded by his cavalry commander, Gottfried von Pappenheim, to accept battle. He arrayed his army, in accordance with the classical Spanish tactics, in 13 unwieldy squares composed equally of musketeers and of pikemen, with the imperial cavalry on the right and the league horse under Pappenheim on the left. Gustavus Adolphus, on the other hand, interspersed his flexible infantry units (with two musketeers to one pikeman) with cavalry shock squadrons. The Saxon army on the Swedish left was quickly overrun by the Bavarians and pursued by Johann Isolani's cavalry, and Tilly then tried to outflank the Swedes. Meanwhile, however, the Swedish right had, by its well-drilled combination of infantry and artillery fire, completely routed Pappenheim's cuirassiers. Thus, while Gustaf Horn on the Swedish left built up a new front, Gustavus Adolphus, supported by Lennart Torstensson's artillery, could wheel his right and centre against Tilly's exposed left, capturing the guns and mowing down the now defenseless squares. Tilly, seriously wounded, escaped with a few thousand men, having lost more than 12,000 men on the field. The Swedish losses amounted to about 1,500, the Saxon to 2,000. The victory opened central and southern Germany to the Swedes. The age of the Spanish infantry was over; the military future lay with the shock attack of heavy cavalry preceded by the disciplined fire-power of guns.

The Second Battle. — On Nov. 2 (N.S., Oct. 23. O.S.), 1642, a Swedish-French army under Torstensson and the comte de Guébriant (J. B. de Budes) defeated an imperial army under Ottavio Piccolomini. Four days later, Leipzig surrendered to the Swedes. (S. H. S.)

BREITINGER, JOHANN JAKOB (1701–1776). Swiss writer, like his friend J. J. Bodmer (*q.v.*), one of the most influential 18th-century literary critics in Germany, was born in Zürich, March 15, 1701. He studied theology and became professor at the Collegium Carolinum. He lectured on Hebrew, Greek, Latin, logic and rhetoric, showed his excellence as a philologist in many editions, and advocated education on humanist lines (Zürich school reform, 1765–75).

Inspired by the *Spectator* papers of Joseph Addison and Richard Steele, Breitinger founded the weekly *Discourse* (1721–23) for which he wrote essays on morals and aesthetics. The most important of his many publications; however, was the *Critische Dichtkunst* (1740): in which he attacked the narrowly rationalist *Dichtkunst* of the Leipzig "literary pope" J. C. Gottsched (*q.v.*) (1730), which was chained to Latin and French patterns. Breitinger stressed the place of the imagination and the wonderful in poetry; fired the German public with enthusiasm for Homer; and spread the ideas of John Locke, Lord Shaftesbury and Alexander Pope. He was visited by Goethe and others, and his pupils included J. K. Lavater and J. H. Pestalozzi. He died in Zürich, Dec. 14, 1776.

BREMEN, a city and the largest port, after Hamburg, of Germany, the capital of the *Land* of Bremen and one of the old free Hanseatic towns. It extends 27 mi. along the Weser, covering 125 sq. mi., and is 46 mi. from the North sea. Pop. (1959 est.), 552,025. The old town (*Altstadt*) occupies a sandy slope on the right bank of the river. In the 17th century the new town (*Neustadt*) on the left bank was added to it. Suburban expansion was rapid after the late 19th century and there were large-scale incorporations of rural communities in 1902, 1921, 1939 (when some former Prussian boroughs to the north and southeast were also added) and 1945. Other satellite towns have risen in the east and south: Neue Vahr, Huchting and others. In Bremen city the Weser is spanned by five bridges (the Grosse Weser bridge mentioned as early as 1250, was reconstructed a little farther up-

stream). At the beginning of the 19th century the town's ramparts were made into promenades.

The old town was severely damaged in World War II, but the Gothic town hall (Rathaus) was spared. Dating from the early 15th century, it has a three-gabled Renaissance façade (early 17th century). Before it stands the statue of Roland (1404), the emblem of ancient legal privileges and imperial freedom. These rights are also embodied in the Gothic sculptures on the Rathaus front, which depict the emperor and the seven electors. Within the hall is particularly noteworthy for its murals (including "The Judgment of Solomon," painted in 1532 by Bartholomaeus Bruyn) and for its Golden Chamber (Guldenkammer) with rich baroque wood carvings and its 16th- to 18th-century ship models. In 1909–13 a new wing (Neues Rathaus) was built on the site of the former Stadthaus, which in turn stood on the foundations of the archbishop's palace. The Schiitting on the opposite side of the market square was the guildhall of the merchant aldermen and dates from the 16th century. It houses the chamber of commerce. Though damaged in World War II, it was restored in its original form. On the site where a wooden church once marked the institution of the bishopric by Charlemagne rises St. Peter's cathedral, an 11th-century structure crowned by two tall spires facing west. At the end of the 19th century restoration was completed and a third spire added. Of the four parish churches, dating mainly from the 13th century, the Church of Our Lady was repaired after World War II, except for its spire; St. Martin's and St. Stephen's were also restored. St. Ansgarius', with its celebrated 310-ft. "helmet" spire, was completely demolished. The old blinorite church of St. John's is used by the Catholic community. Among the notable public buildings the Gewerbehaus (originally the guildhall of the cloth traders, later of the retail traders' guild) and the Essighaus (an example of an old Bremen merchant's house) were restored, while in the early 1960s the Stadtwaage was restored, as were the old houses to the west of the market place and the oldest quarter of the town (the Schnoor and adjoining streets). An important development was the one-family house unit peculiar to Bremen. There are several parks, of which the most beautiful, the Bürgerpark, was founded and is maintained by private gifts.

Industry.—Bremen's economy has always depended greatly on trade and shipping, particularly after the close of the 18th century. A world market for tobacco and the foremost cotton centre on the European continent, Bremen led for a time in the rice trade and in crude oil transactions; then it developed its trade in wool and coffee. Transit and forwarding business also developed. The Norddeutsche Lloyd is the most prominent shipping company, followed by the Hansa, with a network of regular services to India and the middle east. During 1883–94 the Weser was transformed into a waterway capable of carrying ocean-going shipping. Bremen has 9.6 mi. of quays and Bremerhaven 9.1. The main imports are cotton, wool, tobacco, coffee, timber (notably Scandinavian sawn wood), cellulose, grain, citrus fruits, wine, cork, iron and manganese ores, gasoline, oilseed, crude oil and anthracite coal.

Most of the products of Bremen's own industry are exported. Industrial undertakings were originally closely affiliated with commerce and navigation: the main industries were shipbuilding and associated industries and the processing of colonial goods—tobacco, rice, coffee, cocoa, wool, jute and, to some extent, grain. After 1900 large-scale machine production and related industries, automobile manufacturing, electrical industries and smelting of imported ores grew up. Heavy industry (iron and steel production) gained a foothold with the acquisition of the Norddeutsche Hutte by the Klockner group, and big steel-works were erected.

History.—In 787 St. Willehad, whom Charlemagne had established as missionary bishop of the lower Weser, chose Bremen as his see. When the destruction of Hamburg by the Normans in 845 led to the succession of St. Ansgarius, the archiepiscopal title and the office of a north European mission were transferred from Hamburg to Bremen. In 965 the right to establish a market "in the place called Bremun" was conferred on Archbishop Adaldag. Under Archbishop Adalbert (*q.v.*) (*c.* 1043–72), who planned a north European patriarchate, Bremen was a centre for north Europe and experienced its first, though short, period of prosperity.

After the close of the 12th century the gradual consolidation of legislation led to the adoption of an independent policy under the leadership of the town council whose main concern was the securing of trade routes by sea and land, priority being given to the defense of the *Dominium Visurgis*, or free access to the sea. The council strove to achieve its purpose by founding on the banks of the lower Weser a coastal state over which it exercised absolute control, while, as early as 1400 efforts were made to attain the freedom of the empire. This was not finally secured until 1646. Bremen entered the Hanseatic league (*q.v.*) in 1358, but often steered its own course. Upon the dissolution of the league (the last meeting took place in 1669) Bremen, with Hamburg and Lübeck, was entrusted with guarding the privileges of the German merchant class.

Bremen was inclined toward the Reformation as early as 1522, but about 1600 it turned away from orthodox Lutheranism and toward Calvinism, establishing a close relationship with its sympathizers in faith, particularly Holland. This had political, economic and cultural consequences. After the Thirty Years' War, Bremen had to defend its status as a free city in two wars against the Swedes, who occupied the ancient diocese of Bremen, and subsequently against the claims of the electors of Hanover, the legal successors to the Swedes in the diocese. However, the new era heralded by the proclamation of the United States of America and by the French Revolution brought with it a notable resurgence which gained momentum when the damage caused by the French occupation (Bremen formed part of the Napoleonic empire in 1810–13) had been overcome. Efficient statesmen, notably Bürgermeister Johann Smidt, secured its independence; Smidt also established its importance as a seaport by the foundation (1827) of Bremerhaven (*q.v.*). Until 1866 Bremen was one of the member states of the German confederation, then of the North German confederation and after 1871 of the reconstituted German empire, in which Bremen and Hamburg held unique positions as a result of their leadership in international trade and world shipping and their port facilities. After the abolition of the monarchy, in 1918, the federal state was transformed into a *land* and new democratic institutions were adopted, while an earlier constitution of 1854 providing for a senate and parliament (*Bürgerschaft*) was repealed. A system of "deputations" permitted citizens to participate in the administration. Later constitutional amendments did not touch these basic functions, and they were incorporated in the constitution of 1920–47. After 1945, Bremen and Bremerhaven together comprised the *land* of Bremen, German Federal Republic.

BREMEN (officially FREIE HANSESTADT BREMEN), the smallest of the nine *Länder* of the German Federal Republic. The population, mostly Protestant, was 683,600 (1959 est.); area, 404 sq.km. (156 sq.mi.). In 1945 the last of the localities in the former rural areas were incorporated in Bremen municipality, and the *land* now consists of two cities, Bremen and Bremerhaven (*q.v.*). Bremen is the oldest German republic and is governed by a senate elected by the *Bürgerschaft* ("parliament"), with one representative from Bremerhaven for every four from Bremen city.

BREMER, FREDRIKA (1801–1865), Swedish novelist and champion of women's rights, was born at Åbo, Fin., on Aug. 17, 1801. When she was three her father, a wealthy merchant, settled on his own estate at Årsta, near Stockholm, and there she was carefully educated. Her reading included Schiller, as well as the contemporary English novelists, by whom she was deeply impressed. Later she studied Jeremy Bentham, John Stuart Mill and Plato, but above all she read the Bible; her greatest ambition was to prepare for a Christian millennium. Her *Teckningar utur hvardagslifvet*, begun in 1828, introduced the domestic English novel into Swedish literature and was followed by *Familjen H.*

(1831). a great success. Her best novels are *Grannarne* (1837), *Hemmet* (1839) and *En dagbok* (1843). Her works were admirably translated by the poet and writer Mary Howitt (11 vol., 1844-45) and became well known in the United States, where she was warmly welcomed (1849-51). She gave an account of her experiences there in *Hemmen i denna världen*, three volumes (1853-54), one of the most interesting of Swedish travel books. Her novels *Hertha* (1856) and *Fader och dotter* (1858) deal with the social effects of assertion of women's rights. From 1856 to 1861 she traveled widely. Her journals. *Lifvet i gamla världen*, were published during 1860-62. She died at Årsta on Dec. 31, 1865.

See also G. Axberger, *Jaget och skuggorna, Fredrika-Bremer-studier* (1951); G. Fredén, *Arvet från Fredrika Bremer* (1951). (G. F.)

BREMERHAVEN, a port of Germany, situated on the east of the Weser estuary on both banks of the Geeste river at its confluence with the Weser. 61 km. (38 mi.) N. of Bremen. Pop. (1959 est.) 139,611. Bremerhaven became a single municipality by the amalgamation of three separate towns: (1) Bremerhaven, founded as a port on the north bank of the Geeste in 1827 by Bremen's burgomaster Johann Smidt on a strip of territory ceded by Hanover; (2) Geestemunde, founded in competition on the south bank of the Geeste in 1845; and (3) Lehe, a borough dating from medieval times which attained town status in 1920 and was united with Geestemünde four years later to become the town of Wesermünde. In 1939 Bremerhaven was incorporated in Wesermünde and put under Prussian rule. This unified city was restored to the Land of Bremen, Federal Republic of Germany, in 1947 and thereafter known as Bremerhaven.

After 1830, when the "Old Harbour" was opened, the docks were expanded by repeated cessions of Prussian territory. They include the Columbus quay and Columbus station which deal with transatlantic passenger traffic. After improvements to the Weser channel freight traffic was increasingly diverted to Bremen. On the Geestemunde (south) bank is the fishery port, the home of much of the German trawler fleet. Shipbuilding flourishes. During World War II Bremerhaven suffered heavy damage, particularly on Sept. 18, 1941, when the central town area was demolished, although the docks were substantially unimpaired. There are museums and 17th-century peasant houses (open-air museum).

See G. Bessell et al., *Heimatchronik der Stadt Brenzerhaven* (1955). (F. J. D. P.)

BREMERTON, a city of Kitsap county, Wash., U.S., 15 mi. W.S.W. across Puget sound from Seattle. It is located on an arm of Kitsap peninsula and is surrounded on three sides by water. It is the site of Olympic college, a two-year college established in 1946, which has an extensive adult education program.

Bremerton was named after William Bremer, German-born real-estate promoter, who platted the town in 1891. Bremer sold land to the federal government at a low price in his successful effort to secure the navy yard for the new town. The Puget sound naval shipyard became the chief economic feature of the city and the second largest industry in the Pacific northwest. Employing about 10,000 men and covering more than 300 ac. of land, it is a vast concentration of piers, dry docks, shops, cranes, railroads (more than 35 mi. of track) and buildings.

Bremerton was incorporated as a city in 1901. For comparative population figures see table in WASHINGTON: *Population*.

(R. E. BU.)

BRENDAN, SAINT (BRANDON or BRANDAN, correctly BRÉNAIND) (c. 484-c. 578). Irish saint and hero of legendary voyages in the Atlantic, was born at Tralee in Kerry. He founded his chief monastery, Cluain Ferta Brénaind (anglicized Clonfert), in County Galway some 20 years before his death, and is known as Brendan of Clonfert to distinguish him from several namesakes, the chief being his contemporary St. Brendan of Birr. It seems reasonably certain that St. Brendan himself made a voyage to the Scottish isles, and perhaps to the Clyde valley and Wales—nothing unusual for a Celtic abbot in the 6th century. At a later period, possibly as early as the 8th century, he was made the hero of a Christian tale of sea adventure similar to the *Imrama* (see IRISH

LITERATURE). The legend, a narrative masterpiece, known as the *Navigatio Brendani* ("Voyage of St. Brendan"), was put down in Latin prose early in the 9th century. Nearly every detail, though set forth in the vague way of an epic narration and hardly ever localized, is clearly based on authentic seamen's reports. Either as ascetics in search of an island abode or more prosaically as explorers, the Irish had thus first-hand accounts to give, not only of islands lying north and northwest, but also of the continent of America, before the Scandinavians settled on Iceland. St. Brendan's ultimate goal was the "Promised Land of the Saints"; after a prolonged search he reaches it, but is sent back to Ireland and tells his tale. Over 100 manuscripts of the *Navigatio Brendani* are extant, besides translations and adaptations in prose or verse, with many variations, into Norman French, French, Italian, Provençal, English, Dutch, Flemish, German, Irish, Welsh, Breton and Scottish Gaelic. St. Brendan's Island! somewhere in the Atlantic ocean, long sought by sailors, was sometimes believed to have been sighted, probably an effect of mirage. His feast day is May 16.

See F. Nansen, *In Northern Mists*, 2 vol. (1911); J. F. Kenney, *The Sources for the Early History of Ireland*, vol. i (1929).

(PL. GN.)

BRENNAN, CHRISTOPHER JOHN (1870-1932), Australian poet and scholar whose awareness of French and German literary movements influenced his own work and brought Australian literature into closer touch with European culture, was born at Sydney, on Nov. 1, 1870. He was educated at Riverview college, Sydney university and Berlin university. He returned to Sydney in 1894 and in 1895 became assistant librarian, at the public library. In 1908 he became a lecturer in French and German at Sydney university and in 1920 an associate professor, but resigned in 1925 when his wife divorced him. He died on Oct. 7, 1932.

Brennan has been described as the "arthritic giant" of Australian literature. A huge, heavy, amiable man, with a talent for conversation and a taste for good food, he impressed those who knew him by his personality. His poetry, despite some obscurity, shows maturity of outlook and technical skill.

BIBLIOGRAPHY.—Brennan's chief works were *XXI Poems 1893-1897: Towards the Source* (1897); *Poems* (1914); *A Chant of Doom and Other Verses* (1918). See also A. R. Chisholm, *Christopher Brennan: The Man and His Poetry* (1946). (C. M. H. C.)

BRENNER PASS (Ital. PASSO DEL BRENNERO; Ger. BRENNER SATTEL), the lowest and one of the most important passes through the main chain of the Alps. It divides the Rhaetian and Noric alps, and the highest point of the pass (4,501 ft.) is a continental divide between the Adriatic and Black seas. The Brenner pass has been one of the main entrances to Italy from the north and since Roman times the principal road between the eastern Alps, Germany and the Po valley. There was a Roman road across the pass, and since the 14th century it has been one of Europe's great trade routes. A carriage road was built across the pass in 1772 and the railroad was completed in 1867, linking Innsbruck in Austria with Verona in Italy. The road and railway climb rather steeply from Innsbruck to the Brenner pass and then descend into the valley of the Isarco past Bressanone to Bolzano, where the Isarco joins the Adige river. From Bolzano past Trento to its terminal at Verona, the railway and road follow the Adige valley, a distance of 175 mi. by rail from Innsbruck to Verona. The village and customs station of Brennero, scene of the meetings between Hitler and Mussolini (1940-41), is near the head of the pass in Italy. (G. KH.)

BRENNUS, the name of two leaders of the Gauls in the 4th and 3rd centuries B.C. The first invaded Italy in 390 or 387 B.C. His name, which first appears in the works of Livy, is not mentioned by Polybius or Diodorus Siculus. It is difficult to disentangle the fact of his capture of Rome from the legends. It is clear that Brennus crossed the Apennines, advanced on Rome down the Via Salaria, and defeated the Roman army at the Allia river, about 12 mi. from Rome. He then appears to have delayed a day or two on the field, giving time to fortify the Capitol; he sacked Rome, besieged the Capitol for seven months, accepted the offer of the defenders to ransom themselves, and then departed safely with his booty. Details are less credible: the massacre of the

patricians in their chairs; the night attack on the Capitol; the sacred geese and the exploits of Marcus Manlius; the false weights at the paying of the ransom; and the hurling by Brennus of his sword into the scales, with the famous words *vae victis* ("woe to the vanquished"). The ending given by Livy, wherein Marcus Furius Camillus arrived at the moment of payment and wiped out Brennus and his forces, cannot be accepted.

In 279 another Brennus at the head of a band of Gauls invaded Greece. Earlier in the year Gallic invaders had defeated and killed Ptolemy Ceraunus in Macedonia. Brennus then advanced through Macedonia toward Greece proper, and was first held up at Thermopylae with great loss. Later, as had happened to Leonidas, the mountain pass was betrayed, but the Greek army was taken off by the Athenian fleet. Brennus, with the advance guard that had gone over the upper pass, pushed on for Delphi with its vast treasure. He was wounded, and in the subsequent general retreat northward few Gauls escaped. Brennus committed suicide.

BRENT, MARGARET (c. 1600—c. 1671), American colonial landowner and administrator, was born at Gloucester, Eng., the daughter of Richard Brent, Lord of Stoke and Admington. Little is known about the first 35 years of Margaret Brent's life or her later private life, except that she never married.

In 1638, Margaret and her sister Mary, accompanied by two brothers and a number of indentured men and women, landed at the town of St. Mary's, Md. The patent for the town land which Margaret and Mary were granted was recorded in 1639 as the "Sisters' Freehold." The two sisters thereafter paid for the transportation of additional indentured men and women from England, and by 1650 had patented many thousands of acres in Maryland and Virginia. Through land deeded to her by members of her family and through business transactions, Margaret Brent in 1657 had become one of the largest landowners in the colony, exercising her rights as a manorial lord granted under her contract with Lord Baltimore.

In 1642 she began her public career as an attorney and administrator for other colonists. The death of the governor of Maryland, Leonard Calvert, in 1647 opened the period of her most active service to the colony. He appointed her his sole executrix and from that time she appeared again and again to defend the rights of the deceased governor. Her position was complicated by claims against the estate by Virginia soldiers, who had fought for Calvert in the dispute with William Claiborne over the possession of Kent Island. Their wages, long overdue, had been promised by the governor out of his own estate and that of the lord proprietor. Margaret was unable to raise enough cash from the estate to discharge the debt, and in 1648 she obtained an order from the council making her attorney for Lord Baltimore's estate. Thus empowered, she sold enough of the proprietor's cattle to pay the soldiers, quelled a mutiny, and was credited with having saved the province from civil war. Convinced that she needed a voice in the assembly to discharge her obligations, and having the stipulated property qualifications, she went to that body on Jan. 21, 1648, to request one vote for herself and another as Calvert's administrator and Baltimore's attorney. The votes were denied her, whereupon she protested against all proceedings of the assembly.

Lord Baltimore, who remained in England, condemned her actions, however, and his displeasure continued to be expressed as late as 1653 in various exceptions and land actions against Margaret. She moved to her estate in Westmoreland county, Va., and died between May 1669 and May 1671.

BRENTANO, CLEMENS (1778—1842), German poet and novelist, a leader of the second movement in German romanticism, was born at Ehrenbreitstein on Sept. 9, 1778. His sister was Bettina von Arnim, the correspondent of Goethe; his mother, Maximiliane Brentano. Goethe's friend of 1772—74. He studied at Halle and Jena, where he made the acquaintance of the Schlegels, Hardenberg (Novalis) and J. L. Tieck, and afterward lived at Heidelberg, Vienna and Berlin, in close touch with writers of the patriotic revival of 1813. Emotionally unstable, he reflected in his troubled life the atmosphere popularly associated with the romantic poets. In 1817 he became a fervent Roman Catholic and spent the years 1819—24 at the monastery of Dülmen, taking down the

revelations of a stigmatized nun Anna Katharina Emmerich. He died at Aschaffenburg on July 28, 1842.

Brentano belonged to the Heidelberg group of romantic writers, and his works are marked by fantastic imagery and by abrupt, bizarre modes of expression. His cultivation of the poetry of the Rheinland and of the medieval and student atmosphere are important in the history of German romanticism. A born poet, he created some of the best-known German lyrics. The publication of *Des Knaben Wunderhorn* (1805—08), which he edited with Achim von Arnim, showed the new character of the romantic movement. Instead of the vague profundity typical of the first romantics, there is here the simplicity of the *Volkslied*, a form of lyric which Brentano could imitate and reconstruct most skilfully. Some of his prose works show a satirical vein. Among his first publications were *Satiren und poetische Spiele* (1800) and a fantastic romance *Godwi* (1801—02); of his dramas the best are *Ponce de Léon* (1804) and *Die Gründung Prags* (1811). On the whole his finest work is the collection of *Romanzen vom Rosenkranz* (1852); his short stories, and especially the charming *Geschichte vom braven Casperl und dem schönen Annerl* (1817; Eng. trans., *The Story of the Just Casper and Fair Annie*, 1927), imbue the folk stories on which they are based with a delicate romanticism.

BIBLIOGRAPHY.—*Gesammelte Schriften*, ed. by Christian Brentano, 9 vol. (1852—55); the best modern edition is *Sämtliche Werke*, ed. by C. Schüddekopf (incomplete; 1909—17). Pfeiffer-Belli, *C. Brentano* (1947).

BRENTANO, FRANZ (1838—1917). German philosopher, one of the most influential teachers of his period, was born at Rlarienburg, near Boppard on the Rhine, on Jan. 16, 1838. His uncle was the poet Clemens Brentano, his father a well-known Catholic writer. Ordained as a Catholic priest in 1864, he was appointed *Privatdocent* in philosophy at Würzburg in 1866 and professor there in 1872. Religious doubts, exacerbated by the dogma of papal infallibility (1870), led to his resigning this post and seceding from the church in 1873. In 1874 he became professor of philosophy at Vienna. He resigned this post in 1880, thereafter teaching in Vienna till 1895. From 1896 to 1915 he lived in retirement in Florence. He died in Zurich on March 17, 1917.

Unlike most German philosophers of his day, Brentano's guiding principle was "back to Aristotle" rather than "back to Kant." His earliest publications were Aristotelian studies, and his last important book, *Aristoteles und seine Weltanschauung* (1911), was an attempt to reassess the essential features of Aristotle's thought in the light of modern knowledge.

In metaphysics Brentano's own views inclined toward realism rather than toward idealism; but he insisted throughout on the existence of a personal and immaterial soul. Psychology he defined as the science of the soul; but the special object of its study was, he held, not psychical states but psychical processes or acts. His most original contribution was a revival and modernization of the scholastic theory of "intentional inexistence," or, as he sometimes called it, "immanent objectivity." His restatement of the doctrine is set forth most clearly in his most important book, *Psychologie vom empirischen Standpunkte* (1874), in a paragraph (ii, 1. 5) that became the credo of his followers and formed the starting point of their later work. Psychical phenomena, he declares, are distinguished from all other types of phenomena by a property "which the schoolmen called the intentional or mental inexistence of an object, and which we should rather describe as *the direction of the mind to an object*, by which we need not understand a reality." The task of the psychologist is therefore to investigate the various ways in which a mind can refer to an object. Three, Brentano maintains, are fundamental: (1) perception (the placing of the object or idea before the mind), a process which is logically prior to the rest; (2) judgment or belief; and (3) approval and disapproval, which he preferred to call love and hate. The doctrine of love and hate he subsequently treated

as the key to an analytic theory of value.

Brentano's influence on the later development of philosophic thought has been exerted largely through the work of his two most famous pupils. Edmund Husserl and Alexius Meinong (*qq.v.*). Critics have contended that the reference of the mind to an object is not so fundamental as Brentano supposed; in experiences of sheer pain or pleasure there is little extrinsic reference. Nevertheless, the property is one which no nonmental thing could possess; and the priority given by Brentano to the psychic act as distinct from the psychic state has gained wide acceptance.

See *F. Brentano: Gesammelte philosophische Schriften*, ed. by O. Kraus and A. Kastil, 10 vol. (1922-30). (Cv. B.)

BRENTANO, LUJO (LUDWIG JOSEPH) (1844-1931), German economist. was born at Aschaffenburg on Dec. 18, 1844. He received some of his academic education in Dublin and was professor of political theory in Breslau (1872) and later in Strashourg, Vienna, Leipzig and Munich. He retired in 1914.

In 1868 Brentano made a thorough study of trade unionism in England, which resulted in his principal work, *Die Arbeitergilden der Gegenwart* (1871-72). The book was attacked by some economists but was important not only as an authority on modern associations of workmen but also for the impetus it gave to the study of guilds of the middle ages. His other works, of a more theoretical nature, relate chiefly to political economy. He advocated free trade, and in industrial questions combated the wages fund theory. Brentano received the Nobel peace prize in 1927; he was a leading opponent of German militarism.

BRENTFORD AND CHISWICK, a municipal and parliamentary borough of Middlesex, Eng., is a western suburb of London on the north bank of the Thames near its confluence with the Brent (now canalized) opposite Kew gardens. Pop. (1961) 54,832. In 1927 the urban districts of Brentford and Chiswick were united and in 1932 they were incorporated. The borough includes Turnham Green, where the municipal offices are located, and Bedford Park, one of the earliest ventures in town planning. Brentford, once the centre of Saxon government, was granted a toll bridge and a market by Edward I. The ancient street market, which was at Kew bridge and was moved to its present site in 1893, now covers several acres and is open daily. During the 16th and 17th centuries Brentford was a favourite resort of London citizens. Boston manor, with its house dating from 1622, was bought by the council in 1923 for a public park.

Chiswick preserves more of its old appearance than Brentford. The church of St. Nicholas has ancient portions; in the churchyard on the south side is the tomb of William Hogarth and in the new cemetery James Abbott McNeill Whistler is buried. Other famous names connected with the area are W. M. Thackeray, Alexander Pope, J. J. Rousseau, P. B. Shelley, J. M. W. Turner and William Morris. At Strand-on-the-Green, Kew bridge and Chiswick Mall, cottages and Georgian houses flank the river. Chiswick house, with 66 ac. of wooded grounds (now public property), was designed by the 3rd earl of Burlington with William Kent (1727-36), largely modeled on Andrea Palladio's Villa Rotunda or Capra near Vicenza, Italy. The wings added by James Wyatt, removed in 1928, were acquired by the Middlesex County council for the nation. Toward Isleworth is Syon house founded by the lord protector Somerset in 1547 and enlarged by Robert Adam.

The united borough has more than 320 ac. of open spaces, excluding Gunnersbury park, originally laid out by Kent, which is administered jointly with Acton and Ealing boroughs. The district is largely residential, but underground railway rolling stock is repaired. Other industries include soapmaking and, since the 17th century, brewing. There are docks at Brentford where the Grand Junction canal joins the Brent.

BRENTWOOD, an urban district, Essex, Eng., is 18 mi. N.E. of London by rail. Pop. (1961) 51,959; area 28.5 sq.mi.; altitude 400 ft. Surrounded by pleasant undulating country, now including Royles Court, Thorndon and Weald parks, Brentwood (*i.e.*, "burned wood," its site being originally that of a forest fire) was on the route followed by pilgrims from East Anglia to Canterbury. It was an assize town when judges first went on circuit and the Elizabethan assize house remains. The grammar school was

founded by Sir Anthony Browne in 1558. Warley barracks were erected in 1805. Brentwood is the seat of a Roman Catholic bishop and the site of a county mental hospital.

The district is predominantly residential. Industrial products include photographic films! agricultural machinery, steel equipment and prefabricated concrete.

BENZ, JOHANN (1499-1570), German reformer, a leader of the Reformation in Württemberg, was born at Weil, Württemberg, on June 24, 1499, and studied at Heidelberg under John Oecolampadius. Ordained priest in 1520, he ceased to celebrate mass in 1523. Benz was a strong advocate of Lutheran doctrine, and author of *Syngramma Suevicum* (Oct. 21, 1525), which set forth Luther's doctrine of the Eucharist. Protected by his patron Duke Ulrich of Württemberg, he was appointed (Jan. 1533) provost of the collegiate church of Stuttgart. He opposed applying the death penalty to Anabaptists or other heretics in the *De Haereticis, an sint persequendi* (1554). An incomplete edition of his works appeared in 1576-90, and T. Pressel edited *dnccdota Brentiana* in 1868. Benz died on Sept. 11, 1570.

See J. Hartmann and C. Jager, *Johann Benz*, 2 vol. (1840-42).

BREQUIGNY, LOUIS GEORGES OUDARD FEUDRIX DE (1714-1794), French scholar who investigated the annals of French history in England. He was probably born at Gainneville near Le Havre on Feb. 24, 1714. After the Seven Years' War he was sent to search in the archives of England for documents bearing upon the history of France, particularly upon that of the French provinces which once belonged to England. From this mission Bréquigny brought back copies of 70,000 documents, which form 109 vol. in the Bibliothèque Nationale. A selection was published by Jean Jacques Champollion-Figeac in *Documents inédits relatifs à l'histoire de France*, 2 vol. (1839-47). Bréquigny was a member of the Académie des Inscriptions and in 1753 was elected to the Académie Française. The Revolution interrupted him in his collection of *Mémoires concernant l'histoire, les sciences, les lettres, et les arts des Chinois*, begun in 1776, when 14 volumes had appeared. He died in Paris, July 2, 1794.

See the article on Bréquigny by E. Dumont in *Assises de Caumont* (1896), including a bibliography; L. P. de Bachaumont, *Mémoires secrets* (1777-89).

BRERETON, LEWIS HYDE (1890-), U.S. air force officer who commanded the 9th air force in European operations during World War II, was born on June 21, 1890, at Pittsburgh, Pa. He was graduated from the U.S. naval academy in 1911, but became an army pilot and served as combat commander during World War I. He was promoted to the grade of major general in 1941. Commander of the U.S. far east air force which was almost destroyed in the Philippines in 1941, Brereton thereafter commanded the 10th air force in India (1942); the 9th air force based in the middle east (1942-43) and England and France (1943-44); and the 1st allied airborne army (1944-45). Beginning with a small nucleus in Oct. 1943, he built the 9th air force into the world's most powerful tactical air unit which, together with the Royal Air Force, defeated the *Luftwaffe* in western France and supported U.S. armies in their sweep across France and Belgium in the summer of 1914. He published his war memoirs under the title of *The Brereton Diaries* (1946). (A. Gg.)

BRESCIA, capital of the province of Brescia, Lombardia, northern Italy, lies at the foot of the Alps, 91 km. (52 mi.) E. of Milan by road. Pop. (1957 est.) 154,424. The plan is rectangular, with streets at right angles, a Roman peculiarity, though the Roman town occupied only the eastern portion of the later one. The Piazza del Foro marks the site of the forum, and the museum on its north side is in a Corinthian temple with three cellae, probably the Capitolium of the city, erected by Vespasian in A.D. 73. It contains numerous tombstones, objects in bronze (one of which is the famous "Statue of Victory" found in 1826) and glass, as well as ceramics, mosaics and coins. Near it are the remains of the ancient theatre. The castle, at the northeast angle, commands a fine view. The old cathedral (11th-12th century) is a round domed building over a 6th-century church, and the Broletto, adjoining the new cathedral (1604) on the north, is a massive building of the 12th and 13th centuries (the original town hall, now the

prefecture and law courts), with a lofty tower. The convent of S. Salvatore! founded by Desiderius, king of Lombardy, has three churches, two of which have been occupied since 1882 by the fine medieval museum, in which can be seen the "Dittici consolari" (5th century), the "Lipsanoteca" (4th century), the "Croce di Desiderio" (8th century), sculpture, objects in bronze, glass and majolica, enamels and medallions. The church of S. Francesco has a Gothic façade and cloisters. The Palazzo del Comune, begun in 1492 and completed by Ludovico Beretta in 1554-74, is a magnificent structure, with fine ornamentation. The church of Sta. Maria dei Miracoli (1488-1523) has rich details, especially of the reliefs on the façade. Many other churches, and the picture gallery (Galleria Tosio-Martinengo), contain works of the painters of the Brescian school, Vincenzo Foppa, Girolamo Savoldo. Alessandro Bonvicino (Moretto), Girolamo Romano and Rloretto's pupil, Giambattista Moroni. The city has no less than 72 public fountains. Brescia is on the main line from Milan to C'erona; other lines run to Trento, Cremona and Parma. It makes ironware, particularly firearms, also machinery, woollens, linens and silks, matches and candles. It is the chief centre of the stocking factories of Italy. Mazzano, 13 km. (8 mi.) E. of Brescia, has stone quarries.

The Celtic Brixia of the Cenomani submitted to Rome in 225 B.C. Xugustus founded a civil colony there in 27 B.C. In 452 it was plundered by Attila, but was the seat of a duchy in the Lombard period; from 1167 it was an active member of the Lombard league. In 1258 it fell to Ezzelino da Romano, and belonged to the Scaligers (della Scala) until 1421, when it came under the Visconti of Milan, and in 1426 under Venice. Early in the 16th century it was one of the wealthiest cities of Lombardy, but never recovered from its sack by the French under Gaston de Foix in 1512. It belonged to Venice until 1797, then to Austria; it revolted in 1848, and in 1849 was the only Lombard town to rally to Charles Albert, but it was taken by the Austrians and lost again in 1859. In World War II it was captured by the Allies on April 27, 1945.

BRESCIA PROVINCE (area 4.749 sq.km.; pop. 877,241) is situated between lakes Garda and Iseo. The mountainous northern region gives way to a fertile irrigated plain (agricultural and cattle raising) in the south. The province is drained by the Oglio, Mella and Chiese rivers. (G. Pa.)

BRESLAU: see WROCLAW.

BRESSANONE (Ger. BRIXEN), a town in the Bolzano province of the Trentino-Alto Adige region, lies in the extreme north of Italy at a height of 559 m. (1,834 ft.) in a fertile Alpine valley at the confluence of the Rienza and Isarco rivers, 41 km. (25 mi.) N.N.E. of Bolzano by road. Pop. (1957 est.) 13,468. It has an 18th-century baroque cathedral, a bishop's palace, 12 churches including the round church of St. Michael (12th and 16th centuries) and five monasteries. Bressanone is on the main railway crossing the Brenner pass. Wool and hydroelectric power are produced, orchards and vineyards are cultivated and there is a large tourist trade. The episcopal see was transferred to Bressanone from Sabiona in 992. (M. T. A. N.)

BRESSE, a natural region of eastern France, embracing parts of the *départements* of Ain and Saône-et-Loire, and extending for 60 mi. from the Dombes region in the south to the Doubs river in the north and for 20 mi. from the Jura in the east to the Saône river in the west, toward which it gradually slopes. A fairly prosperous agricultural area: it has long been renowned for its poultry.

In the northern part the lords of the Vienne, Antigny, Sainte-Croix and Coligny families were powerful landowners for many years, beside the dukes of Burgundy, who from the 14th century were continually increasing their possessions in Bresse until the death of Charles the Bold (1477), after which most of northern Bresse was annexed, together with Burgundy, to the crown of France. The southern part was at first also under the rule of various lords! the most powerful being the lords of Bâgé. They were, however, superseded in 1272 by the house of Savoy, which in the 15th century organized the province of Bresse! with Bourg as its capital. This province was ceded to France in 1601 by the treaty of Lyons. Soon afterward the whole of Bresse was in-

corporated into the royal *gouvernement* of Burgundy.

(M. PAC.)

BREST, a naval station and port in the *département* of Finistère, Brittany, western France, lies on the northern shore of the magnificent landlocked Rade de Brest and on the slopes of two hills divided by the Penfeld river. It is 255 km. (158 mi.) W.N.W. of Rennes. Pop. (1954) 110,713. Eighty per cent of the town was destroyed during the siege of 1944 in World War II, but by 1960 rebuilding was almost complete and the tourist trade increased. The chief streets are the rue de Siam, rue Jean Jaurès and rue de Lyon; the first two meet in the Place de la Liberté, the centre of the new town. Along the shore south of the town is the Cours Dajot promenade. At the western end stands the castle with its keep and seven towers commanding the entrance to the Penfeld. Its first walls were built at the end of the 3rd century.

The roadstead consists of a deep indentation formed by coastal subsidence, about 23 km. (14 mi.) long and of the same average width, barred by the peninsula of Quétern, leaving the Goulet passage 2-3 km. (1-2 mi.) wide. The outline of the bay is broken by numerous submerged tributary valleys. The naval port, much of it excavated out of the rock, extends along both banks of the Penfeld. Large areas have been reclaimed from the sea, and the principal dry docks and workshops are now situated along the roadstead on both sides of the mouth of the river. The commercial port, separated from the town by the Cours Dajot, comprises a tidal port with docks and an outer harbour.

Brest is the terminus of the main railway line from Paris through Chartres, Le Mans and Rennes. Another line runs southeastward through Nantes to Bordeaux. There is a daily air link with Rennes and Paris. Many industries from the Paris district are moving to Brest. The principal industries are brewing: ship repairing, the manufacture of chemicals and superphosphate, and the cleaning of oil tankers. Wine, coal, timber, gasoline, iron and steel, fertilizers and paper pulp are imported, while fruit (strawberries from Plougastel), seed potatoes, and cattle are exported.

Brest was ceded about 1240 by Count Hervé V of Léon to John I, duke of Brittany. From 1342 to 1397 it was in English hands, and the saying was current that "he is not duke of Brittany who is not lord of Brest." By the marriage of Charles VIII, king of France, with Duchess Anne of Brittany in 1491 Brest passed to the French crown with the rest of Brittany. Richelieu decided in 1631 to create the port of Brest, and it became a station for the French navy. Colbert improved the port: Vauban's fortifications followed in 1680-94. The fortifications and the naval importance of Brest continued to develop. During World War I it was the port of disembarkation for the U.S. army fighting in France. After 1918 it became increasingly important as a port of call for transatlantic liners and a leading naval centre. In World War II Brest was occupied by the Germans in June 1940. The town was besieged by U.S. forces from Aug. 15 to Sept. 18, 1944, when it was captured; by 1960 the destroyed docks had been rebuilt with the most modern equipment. (A. J. MI.)

BREST (BREST LITOVSK), an *oblast* of the Belorussian Soviet Socialist Republic, was formed in 1939 following the Soviet occupation of east Poland from part of the territory held by Poland from 1921 to 1939. Its area of 12,973 sq.mi. lies almost wholly in the basin of the Pripyet (Pripyat) and its tributaries, notably the Yaselda. Most of the *oblast* is very level and covered by the great swamps and forests, known as Polesye (Polesie, *q.v.*). Extensive spring floods occur. Only in the north, around Pruzhany and Baranovich, where the land rises to the morainic hills of the White Russian ridge, is it drier, and there most of the forest has been cleared. After 1873 drainage was accomplished in various areas. Agriculture is chiefly flax, hemp, potato and sugar beet growing, with cattle raising and dairying on the abundant pastures. Forestry is important. The main industries are the processing of agricultural products and timber. Peat is widely used for power. The population (1959) is 1,205,000, of whom 283,000 (23%) are urban. The largest towns are Brest (73,000), Baranovich (58,000), Pinsk (*q.v.*) and Kobrin. The main Moscow-Warsaw railway and highway traverse the *oblast*, together with the Brest-Gomel and Vilnius (Vilna)-Rovno railways. The Dnieper

(Dnepr)—Bug canal, linking the Pripiet to the Bug, takes small craft, chiefly with iron ore westward and coal eastward.

The town and administrative centre of the *oblast*, formerly Brest-Litovsk, stands on the right bank of the Western Bug at the Mukhavets outfall. First mentioned in 1017, Brest has a long and stormy history, and has frequently been destroyed. The council of 1596 established the Uniate Church there. The fortress, built in the 1830s, was ruined in its prolonged resistance to the Germans in 1941. There are food processing, textile, furniture and light engineering industries. Brest is a river port and rail centre and the chief transit point for traffic between the U.S.S.R. and Poland.

(R. A. F.)

BREST-LITOVSK, TREATIES OF. The short-lived peace treaties signed at Brest-Litovsk during World War I by the Central powers with the Ukrainian republic (Feb. 9, 1918) and with Soviet Russia (March 3) disclosed what sort of peate victorious Germany had in mind for eastern Europe.

On Nov. 8, 1917, the day after it had assumed power in Petrograd, the Soviet Russian government published a declaration proposing an immediate opening of negotiations for a "just and democratic peace, without annexations or indemnities." On Nov. 26, Russian truce-bearers crossed the front and started discussion with the representatives of the German high command in the east, who agreed to come to terms. On Nov. 30 the Soviet government sent notes to the Entente powers suggesting peace negotiations, but they did not reply.

On Dec. 3, at Brest-Litovsk, preliminary negotiations started between the Soviet government and the Central powers. On Dec. 5 a truce was arranged for a week, and on Dec. 15 an armistice was signed to last until Jan. 14, 1918, with automatic prolongation unless seven-day notice of rupture was given by either party.

Peace negotiations began on Dec. 22. The Soviet delegation was headed by Adolf A. Ioffe, the German by Richard von Kiihlmann (*q.v.*), the Austro-Hungarian by Ottokar Graf Czernin (*q.v.*); Bulgaria and Turkey were also represented. Ioffe at once laid down as a *sine qua non* the principle of "peace without annexations and indemnities, and the recognition of the right of self-determination for all nations." Kiihlmann and Czernin accepted this with the proviso, supplied by Gen. Max Hoffmann, chief of staff of the German armies in the east and second German delegate, that Poland, Lithuania and Courland had already exercised their right of self-determination when they opted "either for an independent existence or a protected status within the German empire." On Dec. 28 the conference was suspended on the pretext that the Soviet government wanted to secure the inclusion of Entente powers in the negotiations. Actually the Russians were delaying in the hope of arousing the workers not only of Germany and Austria-Hungary, but also of the Entente countries.

When the conference reopened on Jan. 9, 1918, Lev D. Trotski (*q.v.*) was the head of the Soviet delegation. A new situation was created by the arrival at Brest-Litovsk, on Jan. 7, of a delegation claiming to represent the independent Ukrainian republic and insisting on concluding a separate peace treaty with the Central powers. Ignoring its presence, Trotski insisted on the withdrawal of German and Austro-Hungarian troops from the territories of the former Russian empire and demanded that the non-Russian peoples should determine their future through plebiscites. Hoffmann refused to evacuate the occupied territories, and on Jan. 18 the negotiations were again adjourned.

Trotski left for Petrograd and at a meeting of the Soviet government recommended a policy which he summarized as follows: "We shall stop the war but should not sign the peace treaty." Lenin had his doubts. Speaking on Jan. 22 as the central committee of the Communist party, he said: "We cannot afford Trotski's formula. If the Germans advance we will have to conclude peace in any case, but the terms will be worse if we do not sign now."

Trotski, however, who returned to Brest-Litovsk on Jan. 30, was in no mood of compromise. Thus deadlock was complete and in these circumstances the Central powers decided to sign, on Feb. 9, the peace treaty with the Ukraine against the will of Russia. A considerable area of Russian Poland—the so-called Chelm dis-

trict—was ceded to the Ukraine, and Austria-Hungary undertook to erect the Ukrainian parts of Galicia and Bukovina into an autonomous crownland—all of which was a deadly offense to the Poles. In return the Ukrainian delegation, headed by Vsevolod Holubovych, the prime minister, undertook to supply the central powers with 1,000,000 tons of breadstuffs annually.

Trotski announced that the treaty with the Ukraine was an unfriendly act. On Feb. 10, he left Brest-Litovsk after announcing that Russia would cease hostilities but not conclude a peace. On Feb. 16 Hoffmann denounced the armistice, and on Feb. 18 the German and Austro-Hungarian armies advanced to occupy the rest of Latvia, Estonia, almost all of Belorussia and the Ukraine.

In Petrograd stormy meetings of the central committee of the party as well as of the All-Russian Central Executive committee took place. Lenin declared that Trotski's experiment had failed, that there seemed no hope of immediate revolution in Germany and that therefore peace must be signed at once. Trotski now sided with Lenin, and on Feb. 19, by seven votes to six, the central committee decided to sign the peace treaty. Germany, however, replied by an ultimatum embodying fresh demands: all the occupied lands were no longer to be subject to Russian sovereignty. On Feb. 24, after a dramatic debate, the All-Russian committee, by 116 votes against 85, with 26 abstentions, accepted the ultimatum.

On Feb. 26 the Russian delegation, G. Ya. Sokolnikov, A. A. Ioffe, L. M. Karakhan, G. V. Chicherin and G. I. Petrovski, once more appeared at Brest-Litovsk. The peace treaty was signed on March 3. Russia renounced control over Estonia, Latvia, Lithuania, Russian Poland and a major part of Belorussia and also ceded to Turkey the districts of Kars, Ardahan and Batum. The independence of Finland and of the Ukraine was recognized. In all, Russia lost about 386,000 sq. mi., with about 46,000,000 inhabitants. On March 15 the All-Russian committee ratified the peace treaty.

Both peace treaties, the Russian and the Ukrainian, were annulled by the armistice of Nov. 11, 1918, which marked the final defeat of Germany. Two days later the Soviet government declared the Brest-Litovsk treaty null and void.

See US, Department of State, *Proceedings of the Brest-Litovsk Peace Conference, Nov. 21, 1917–March 3, 1918* (1918); J. W. Wheeler-Bennett, *Brest-Litovsk, The Forgotten Peace* (1938). (K. SM.)

BRETHREN, CHURCH OF THE, the parent and largest of several bodies of Brethren (variously known also as GERMAN BAPTIST BRETHREN, DUNKARDS, DUNKERS, TUNKERS, TAUFERS or DONKELAARS) who took their theology largely from the Lutheran Pietists of the 17th century (see PIETISM). They are now found in the United States, West Germany and Denmark. (1) The parent body, the Church of the Brethren (headquarters Elgin, Ill.), numbers about 1,000 churches with a membership of about 200,000. (2) The Brethren Church (Progressive Dunkers), which separated from the main body in 1882 because of differences over church polity (headquarters Ashland, O.), claims about 18,000 members. (3) The Old German Baptist Brethren (Old Order Dunkers), separated from the main body in 1881 in protest against liberalizing tendencies (headquarters North Manchester, Ind.), number around 4,000. (4) The Church of God (New Dunkers), which separated in 1848 (headquarters Anderson, Ind.), numbers fewer than 700 members. (5) The Grace Brethren Church (1939; headquarters Rinona Lake, Ind.) has about 25,000 members.

Origins.—By 1708 a large number of Pietists and evangelicals had found refuge at Schwarzenau, in U'ttgenstein. A group of eight persons, who with Alexander Mack as their leader had been meeting there for Bible study and prayer, determined to covenant with God to forsake the world and to follow Christ in all the commandments and ordinances of the New Testament. This led them to accept baptism by trine immersion (a figure of death, burial and resurrection). Mack was baptized by one of the eight, chosen by lot after which he baptized the other seven. Devotions and confirmation followed the baptism. An intense missionary enthusiasm was manifested by the group and their fervour was so contagious that other persons rapidly united with them in Witt-

genstein, Marienborn and other parts of the Palatinate. Because of the persecution that followed in some of these communities (as a result chiefly of their social views, one of which was pacifism), many of the believers finally went to Krefeld in Prussia, where they found safety.

Move to America.—The Brethren began their emigration to America in 1719, joining the 15,000 Palatine Germans who settled in Pennsylvania between 1683 and 1730. Peter Becker and Brethren from the Marienborn district were among the first, and after three years' residence in Pennsylvania, Becker became pastor of the first organized Brethren church, in Germantown (1723). In 1729 Mack and his three sons arrived. The first withdrawals from the church took place as a result of Conrad Beissel's establishment, beginning in 1732, of the Ephrata colony, a semimonastic communal group of celibate men and women who observed the seventh day as the Sabbath. The group was never large; at Beissel's death in 1768 the community numbered 135 members. The town of Ephrata (12 mi. N.E. of Lancaster) remains, and the cloister there is maintained by the state as a historical shrine.

The Church of God group separated from the parent body in 1848; it is strongly conservative in belief and strictly congregational in government. The Old Order Dunkards, who withdrew in 1881, stand for the literal interpretation of the Scriptures in regard to the Lord's Supper, and practice close communion; they have no Sunday schools, educational work or missions.

The worst split occurred in 1882 when a group withdrew to form the Brethren Church. This now centres in Ashland, O., where Ashland college, a seminary, a publishing company and mission board offices are located. The *Brethren Evangelist* is the church weekly. Its mission fields are in Nigeria and Argentina. The Grace Brethren Church withdrew from the Brethren Church in 1939 over points of church polity and theological emphasis. Its centre is at Winona Lake, Ind., where Grace college and seminary are located. The church carries on mission work in the region formerly known as French Equatorial Africa and in Argentina.

The parent Church of the Brethren operates nine colleges and Bethany seminary, Chicago, Ill., and carries on mission work in Europe, Asia and Africa.

Polity.—The Brethren's rejection of every form of mingling of church and state, in opposition to the ideas prevalent during the period of their emergence in Germany, caused them to emphasize individual freedom of belief and a congregational form of church government, with each member of the congregation having a vote in church affairs. Since 1742, however, the Standing Committee of the Annual Meeting has taken an increasingly active part in the over-all supervision of the individual congregations. The Standing Committee, the "upper house" of the Annual Meeting, is made up of delegates elected from the member churches. Local congregations are headed by moderators (lay or clerical, men or women), and ministers are chosen by congregational vote.

Doctrine and Worship.—The Brethren recognize only believer's baptism, by trine immersion (see BAPTISM, CHRISTIAN). They model their communion service after what they believe to have been the experiences of Jesus and his disciples at the Last Supper. Thus they perform the rite of footwashing, and follow it by partaking of the love feast, after which the communion of the bread and the cup (as symbols of the broken body and shed blood of Christ) is taken (see AGAPE).

The Brethren use the kiss of charity; they anoint the sick with oil in the name of the Lord for healing; and they refuse to take oaths. They endeavour to settle matters of difference with each other without appeal to law or the courts. They hold to the position of nonresistance. They believe in total abstinence from alcohol and tobacco and in the avoidance of places of amusement.

BRETHREN IN CHRIST (RIVER BRETHREN), a religious body of the United States and Canada, incorporated in 1904 and numbering about 6,500 members. Its headquarters is at Lancaster, Pa.

The Brethren in Christ, who derive from the general background of European Pietists, Anabaptists and Waldensians, came to America about 1750 and settled in Pennsylvania along the Susquehanna river; hence the name River Brethren, by which they were known for many years.

The church was not officially organized under the name Brethren in Christ until 1863, when the drafting of young men into the Union army made necessary its formal organization as a body of conscientious objectors.

The church stands for equality of all communicants, though the ultimate authority in policy and doctrine is vested in a General Conference held annually. There are six regional conferences, five in the United States and one in Canada, by which petitions and business reach the General Conference.

The revised constitution of the church (1959) sets forth its theological position: its object is "to promote worship of Almighty God and to disseminate His gospel." The confession of faith states that God is eternal, omnipotent and triune, the Creator, sustainer, provider of redemption through faith in Christ. The work of the Holy Spirit is stressed, and the Bible is the inspired Word of God and final authority for faith and practice. The confession teaches believer's baptism by trine immersion (see BAPTISM, CHRISTIAN), washing of the saints' feet, partaking of the Lord's Supper, the holy kiss, nonconformity to the world, nonresistance in war, the imminence of the second coming of Christ, and general resurrection of the dead. The Brethren frown on worldly amusements.

The denomination supports three colleges, home missions and foreign missions in Rhodesia, India, Japan and Cuba.

In 1843 a small group of members, feeling that the River Brethren were becoming lax, seceded and formed the Old Order or Yorker Brethren; they number only a few hundred members in Pennsylvania. In doctrine they are identical to the other River Brethren, but they refuse to build or meet in churches. Another branch, the United Zion Church, was formed in 1855 when Bishop Matthias Brinser was expelled from the River Brethren for holding services in a meetinghouse; the body was incorporated in 1954. It has fewer than 1,000 members, nearly all in three Pennsylvania counties.

See Frank S. Mead, *Handbook of Denominations in the United States*, pp. 52–53 (1956). (E. Bo.)

BRETHREN OF THE COMMON LIFE, living a form of Christian communal life, were established by Gerhard Groote (1340–84) at Deventer in the Netherlands. Groote, originally a worldly cleric, was converted by the Carthusians, with whom he lived for several years, and was influenced by the mystic Jan van Ruysbroeck; he subsequently became a well-known preacher of penance. From among his friends and disciples, among whom was Florentius Radewyns (d. 1400), he formed about 1380 a community devoted to education and the care of the poor; similar groups of women were established practising weaving and spinning. After Groote's death, and at his express wish, many of the brotherhood became Austin canons (1337) at Zwolle; henceforth the movement had two forms, the one of regulars, the other in the world. The institute spread throughout the Low Countries, the Rhineland and north Germany. It displayed, and by means of its teaching fostered, all the most characteristic features of north European piety in the century before the Reformation: the concept of a Christian life, social and self-supporting, based on that of the first disciples (Acts iv, 32–35); a simple regime in common, an absence of ceremonial, complicated ordinances, penances and severe fasting, and little of the rich liturgical life of medieval monasticism. The Brethren were among the principal exponents of the *devotio moderna*, which received its fullest and most permanent expression in the *Imitation of Christ*, usually ascribed to their friend and sometime associate Thomas à Kempis. Among the chief aims of the Brethren were the education of a Christian élite, and the furtherance of the reading of devout literature by the production of finely written manuscripts and later by the printing press. They kept large schools, in which the scholarship though not the spirit of the Italian Renaissance found a home; Erasmus as a boy was deeply influenced by them, both in this and

in many features of his religious outlook. Gerhard Groote also founded at Deventer in 1379 the first house of Sisters of the Common Life, devoted to education, the copying of books and weaving. The whole movement! eminently characteristic of its epoch and region, which was a principal theatre of activity of the early reformers, was seriously affected by the religious upheaval, and passed out of existence early in the 17th century.

See M. Heimbucher, *Orden und Kongregationen*, vol. 1, pp. 532-560 (1933-34); A. Hyma, *The Brethren of the Common Life* (1950).

BRÉTIGNY, TREATY OF, an unratified treaty between Edward III of England and John II of France, signed on May 8, 1360, at Brétigny, near Chartres. It ended the first phase of the Hundred Years' War (*q.v.*), after the French defeats at Sluis (1340), Crécy (1346) and Poitiers (1356), where John was captured. The valid treaty of Calais, ratified on Oct. 24, 1360, which replaced that of Brétigny, differed from it in that the English agreed to defer the signing of a clause whereby Edward renounced the French throne and John any suzerainty over territories that he ceded. Such an agreement was to be concluded after the agreed exchanges of territories between the contracting parties should have been effected.

Otherwise the treaties were virtually identical. John agreed to pay a ransom of 3,000,000 gold crowns and to surrender, in west-central and southwestern France, all Aquitaine (including Guienne, Gascony, Bigorre, Béarn, Poitou, Aunis, Saintonge, Limousin, Périgord, Angoumois, Gaure, Rouergue and Quercy) and, in the north, the counties of Ponthieu (including Montreuil) and of Guînes, together with Calais, Sangatte and Ham. All adjacent islands to these territories and all other islands then in Edward's possession (hence the Channel islands) became English. In his turn Edward relinquished Normandy and Touraine and renounced suzerainty of Brittany and Flanders.
(J. D. L.)

BRETON, NICHOLAS (1555?-1625?), indefatigable English writer of religious and pastoral poems, satires: dialogues, essays, etc. His father, a wealthy London merchant, died when his children were minors, and his mother subsequently married George Gascoigne, who squandered his stepson's patrimony and influenced his early poetry. There is no official record of Breton's residence at the university, although a contemporary described him as "once of Oriel College." His life was spent mainly in London; he was presumably still alive when the burial of Matilda, daughter of "Nicholas Breton, gent.," was recorded on July 27, 1625. He dedicated his works to many patrons, including James I; his chief early patron was the Countess of Pembroke, whose favour he temporarily lost in the 1590s.

In 1598 Breton was accounted one of the best lyrical poets but he outwrote himself and outlived his reputation. His satires are rather mild and general; more successful are the descriptions of simple country pleasures, whether in the pastoral poetry of *The Passionate Shepherd* or in the prose descriptions of the months and the hours in his *Fantastics* (1604?) which in some respects anticipates the fashion for character books. Breton himself wrote two character books later (*The Good and the Bad* and *Characters Upon Essays*—the latter containing essays as well). His prose works also include stories, dialogues and letter writers: his *A Post With a Packet of Mad Letters* was many times reprinted in the 17th century. His carefully balanced quadrapartite sentences become rather monotonous, as also do the fervent stanzas of the long devotional poems he wrote under titles such as "A Solemn Passion of the Soul's Love."

BIBLIOGRAPHY.—Most of Breton's works were collected by A. B. Grosart in 1879: some of the volumes which he could not obtain (all Breton's works are bibliographical rarities) will be found, with a biography and canon, in *Poems by Nicholas Breton Not Hitherto Reprinted*, ed. by J. Robertson (1952).
(J. R. N.)

BRETÓN DE LOS HERREROS, MANUEL (1796-1873), Spanish poet and dramatist who was one of the most important and prolific writers in Spain during the 19th century. Born at Quel, Logroño, on Dec. 19, 1796, he was educated at Madrid where his family had settled in 1806. Six years later he enlisted, fought against the French in Valencia and Catalonia and served in the army until 1822. His first play, *A la vejez viruelas*,

was produced in 1824 with some success, and thereafter he managed to combine writing with his duties in a number of minor posts in government service. In 1837 he was elected to the Spanish Academy and ten years later became director of the Biblioteca Nacional. He died in Madrid on Nov. 8, 1873. His total of 177 plays, most of which portray the everyday life of middle-class society and lack the profundity of earlier Spanish dramatists, exhibit a great wealth of verse-forms and an astonishing degree of metrical dexterity. Among his best works are *Marcela* (1831), *Muñete y verás* (1837) and *El pelo de la dehesa* (1840).

BRETON LANGUAGES: see INDO-EUROPEANS; CELTIC LANGUAGES.

BRETON LITERATURE, like the language, divides into three periods—old, middle and modern. Old Breton written remains (8th to 11th centuries) consist entirely of names and glosses in documents, the chief collections of which were all published by Joseph Loth in *Vocabulaire vieux-breton* (1884). Breton names occur in Latin books and charters written between the 9th and 11th centuries. Lists appear in Loth's *Chrestomathie bretonne* (1890).

No Breton literature has survived from the beginning of the Middle Breton period (11th to 17th centuries), though it certainly existed, since Breton harpists were well known; but they were content to sing their compositions and we can learn nothing about their poetry except from the many works their songs inspired in the better-known languages. Until the 15th century only names are found, in such documents as charters, apart from a few scraps of verse discovered in a 14th-century manuscript in Paris (*Revue celtique*, vol. xxxiv, pp. 241-248 [1913]), which constitute the earliest known connected text in Breton. Written Breton literature did not really begin until the late 15th century, when there appeared the *Catholicon* of Jean Lagadeuc—a Breton-Latin-French dictionary dated 1464 and printed in 1499 (probably the first printed Breton book)—and Quiquer de Roscoff's French-Breton dictionary and conversations, printed in 1616 and often reprinted, an edition appearing in 1915. A collection entitled *Cantiques bretons* (1642) names several Breton airs. All the remaining works of the period are religious and most are in verse. *Buez santez Nonn* ("Life of St. Nonn," late 15th-century, reprinted, 1835) paraphrases and dramatizes the Latin life, attempting to localize some events in Brittany. *Burzud bvas Jezuz* ("The Great Mystery of Jesus," 1530, reprinted 1865) follows Arnoul Gresban and Jean Michel's French play. *Buhez santes Barba* ("Life of St. Barbara," 1557, reprinted 1885) also derives from a French play. These three mystery plays were probably the most significant products of the middle period. Three long poems belonging to the 1530s, reprinted in *Poèmes bretons du moyen âge* (1879), "Tremenvan an itron gwerches Maria" ("The Passing of the Virgin Mary"), "Pemzec levez Maria" ("The Fifteen Joys of Mary") and "Buhez mabden" ("The Life of Man") were all probably based on French versions. *Mellezour an Maru* ("The Mirror of Death"), a long, somewhat lugubrious poem composed in 1519 and printed in 1575, is based ultimately on a Latin work of which versions exist in French. A book of hours in verse reprinted as *Middle Breton Hours*, ed by W. Stokes (1876), a prose extract from the Léon missal and a prose catechism also belong to the 16th century as does the prose *Buhez and itron sanctes Cathell* ("Life of St. Catherine," 1576), a translation of the Golden Legend version. *An Mirouer an Confession* ("The Mirror of Confession," 1621) is translated from French and so is *Doctrin an Christenien* ("Christian's Doctrine," 1622). A collection of carols. *An Nouelou ancient ha devot*, appeared in 1650, and a book of metrical meditations in 1651. Middle Breton literature obviously lacks originality and does not reflect Breton life of the period. The indigenous culture of Brittany seems to have been entirely neglected by the educated classes, who introduced an enormous number of French words into the preponderantly religious works published.

17th- and 18th-Century Mystery Plays.—Linguistically, Modern Breton is said to begin in 1659, when Julien Maunoir substituted a more phonetic orthography for the traditional system in his grammar *Le Sacrk Collège de Jésus*. However, this is of little literary significance since works of the Middle Breton type con-

tinued to appear up to the 19th century. Much religious prose and verse was published, but the bulk of Breton literature in this period consisted of mystery and miracle plays treating subjects taken from the Old and New Testaments, saints' lives and stories of chivalry, generally derived from French or Latin sources. Even Breton saints are treated in the invariable traditional style and though there is occasional local colouring, the plays evince little originality. Old Testament plays include *Creation ar bed* ("Creation of the World"), *Bue Jacob* ("Life of Jacob"), *Trajedî Moyses* ("The Mystery of Moses"), and *Bue Devy* ("Life of David"); New Testament plays *Bue santes Anna* ("Life of St. Anne"), *Sant Ian Baptist*, *An Passion* and *Buez Antekrist* ("Life of Antichrist"), which treats of the Last Judgment. There are, naturally, several Breton plays about saints—*Buez an abad Goenole* ("Life of Abbot Gwenolê"), *Bue an otro Sant Garan* ("Life of St. Garan"), a play about St. Patrick, etc. Dramas on chivalric themes are *Vie des quatre fils Aymon* and *Bue Huon a Yourdel* ("Huon of Bordeaux"). Other plays included *Buhez Louis Eunius* ("Life of Louis Eunius"), *Bue Robard an Diaoul* ("Robert the Devil") and three farces *Ar Farvel goapaer* ("The Mocking Fool"), *Ian Mêlarge* ("Shrove Tuesday") and *Bue en tad Mallarge a Tristemina e vroec hac e vugale* ("The Life of Mallargé, Tristemin His Wife and His Children"). These plays were always acted by peasants and incurred the displeasure of the clergy, with the result that at the time when the old religious drama was struggling to survive, the revival of Breton literature began. In the 18th century, many Breton dictionaries were published but little of literary significance was produced. However, one name survives: Claude-Marie Le Lae (1745–91) who wrote satirical poems—*Ar C'hy* ("The Dog") and the sermon of *Mikel Morin*.

The Revival of Breton Literature.—The "Celtomanes"—*e.g.*, Le Brigant and La Tour d'Auvergne—became enthusiasts for the Breton language; Le Gonidec (1775–1838) codified modern Breton, wrote a Celto-Breton grammar (1807) and dictionary (1821) and edited a Breton translation of the New Testament (1827). Interest in Breton revived at the time when the central government was trying to impose French on the area and destroy the regional language: however, the Bretons endeavoured to create a national literature, particularly after the publication of the celebrated *Barzas Breiz* (1839; after 3rd ed., 1845. *Barzas Breiz*—"Breton Bardic Poems"), a collection made in the villages by Théodore Hersart de La Villemarqué (1815–95) who edited, translated and commented on each song, declaring that internal evidence showed they were composed in the remote past and had survived unchanged as part of Breton folklore.

The collection acquired considerable renown: George Sand called it "finer and more perfect poetry than any masterpiece the human mind has yet conceived" and such historians as Augustin Thierry thought the poems precious documents. However, Breton-speaking scholars were surprised at its strange vocabulary, which included Welsh words and incorrect expressions. Critics who doubted its authenticity soon began to speak of "the Breton Macpherson." Attacks on the book reached their height about 1870, when La Villemarqué, who had published several learned works in the interim, had been elected a member of the *Institut*. R. F. Le Men, in his reprinting of *Catholicicon* (1867), and François-Marie Luzel, in a paper delivered in 1872, showed that *Barzas Breiz* was not an anthology of Breton folk poetry. They divided its contents into three classes: (1) old poems rearranged by the editor or others, chiefly love songs and ballads, (2) modern poems made to look medieval and (3) spurious poems on such personages as Merlin and Nomenoë. But neither this nor even the publication of a 600-page thesis by Francis Gourvil in 1960 abated the controversy. The fact remains that *Barzas Breiz* was very important: the historical poems (which exalt the Breton's traditional struggle against oppression) had an especially strong influence. Although they were often read only in French translation, the poems made Bretons proud of their own language and continue to be admired (the 1959 edition almost sold out in a year). *Barzas Breiz* led to the reawakening of Breton writers and stimulated Luzel himself to collect authentic folksongs and publish *Gwerziou Breiz-Izel* ("Ballads of Lower Brittany," two volumes, 1868, 1874) and in collabora-

tion with Anatole Le Braz. *Soniou Breiz-Izel* ("Folksongs of Lower Brittany," two volumes, 1890–91).

19th- and 20th-Century Prose.—Luzel also collected folk tales and legends, publishing many in Breton as well as in French translation, including *Contes bretons* (1870), *Veillées bretonnes* (1879) and *Les Légendes chrétiennes de la Basse-Bretagne* (1881). His collaborator, Le Braz, investigated Breton stories concerning an *Ankou* ("Death"), which he published as *La Légende de la Mort* (1893; Eng. trans. *Dealings With the Dead*, 1898). Many books of stories appeared in Breton between the 1800s and the 1960s in which it is hard to distinguish between traditional and literary elements, as in Gabriel Milin's *Marvailhou Grac'h koz* ("Old Wives' Tales," 1867), Lan Inisan's *Emgann Kergidu* ("The Battle of Kergidu," 1877) and many others. When Breton writers do not depend on folk legends for material, they like to fictionalize their own life stories; *e.g.*, Faïch Al Lay, who transposes his own youth into the 18th century in *Bilzig* (1925). Many books of war memoirs and mixtures of autobiography and imaginative writing were published in Breton in the early and mid-20th century. Other prose works include the novels of Berthou-Kerverziou, Faïch Elis-Abezen, J. M. Kerwerchez, Roparz Hémon and the painter Xavier de Langlais. The few published works of Jakez Riou (1899–1937) show what a loss Breton literature sustained when he died in his prime: the short stories in *Goetenn ar Werc'hez* ("The Virgin's Herb," 1934) are remarkably concise and unexpectedly combine sensitivity with profound skepticism. His friend Youenn Drezen wrote the best Modern Breton novel, *Itron Varia Garmez* ("Our Lady of the Carmelites," 1942). The many improving religious works published are not at all original; yet many Bretons who have read only one book in their own language have read *Buez ar Zent* ("Lives of the Saints").

19th- and 20th-Century Drama.—Most playwrights were concerned to teach moral and religious lessons—*e.g.*, Toussaint Le Garrec (1866–1939) and Abbé J. Le Bayon (1876–1935), who revived the tradition of the mystery plays, inspired by the Oberammergau passion play (*q.v.*), and at his theatre at Sainte Anne d'Auray produced four great mysteries—*Nicolazig*, *Boeh er Goed* ("The Voice of the Blood"), *Ar hent en Hadour* ("In the Steps of the Sower") and *Ar en lzent de Vethleem* ("On the Way to Bethlehem"). Since 1900 more than 100 plays have been written in Breton by writers of great talent such as Le Braz, Eliès, Hémon, de Langlais, Riou and Drezen. The work of Tanguy Malmanche (1875–1953) dominates the first half of the 20th century, it was compared with that of Paul Claudel and J. M. Synge. Several of his plays were performed in French translation. His work was carried on by Pierre Hélias, a talented younger writer who has written 300 radio plays and had many stage plays produced. His writing was both popular and extremely polished.

19th- and 20th-Century Poetry.—;lost novelists and playwrights wrote poetry as well as prose. For 200 years Bretons expressed their feelings in poems published as pamphlets—either as *soniou* (love songs, satires, carols, marriage lays) or *gwerziou* (ballads or broadsides describing recent events in Brittany and elsewhere). Their authors were people of every social class, very few of whom read *Barzas Breiz*, and the poems were hawked around from fair to fair. A catalogue of the 2,000 of these pamphlets that remain was made by Joseph Ollivier (1942). Prosper Proux (1812–73) had his *soniou* printed in book form, as *Bombard Kerne* ("The Hautboy of Cornouailles," 1866), and dozens of poets published collections after the appearance of *Barzas Breiz*; well known are those by Jaffrennou-Taldir, Loeiz Herrieu, Roperh Er Mason, Joseph Cuillandre, Paotr Tréouré; but the outstanding figure was undoubtedly Jean-Pierre Calloc'h, killed in action in 1917, whose poems were published with a French translation in 1921 as *Ar en Deulin* ("Kneeling").

Reviews and Movements.—Literary reviews abounded in the early 20th century and published much valuable work. The most influential leader of any of the literary schools publishing a magazine was Roparz Hémon, whose *Gwalarn* ("North-West") was founded in 1925. He published work of enormous diversity, including many fine poems and stories and other pieces—*g.*, translations from W. B. Yeats, Synge and Aeschylus—intended chiefly to

further the literary development of the Breton language and increase its range and power. René le Roux, author of the "archaeological romance" *Skella Segobrani* (1923–25), and the lexicographer François Vallée were similarly preoccupied with the struggle to resist the encroachment of French words and to make Breton self-sufficient. The new standardized spelling system introduced in 1941 was adopted only by some writers, so that in the mid-20th century there were two literatures differing in spelling, vocabulary and outlook: one, as represented by the review *Al Liamm* ("The Link"), aimed at only a small number of initiates (its best writers were Ronan Huon and the poet Maodez Glanndour); the other school, which published the review *Brud* ("Fame"), was led by Pierre Hélias: it did not wish to be cut off from ordinary Breton readers, whom it tried to attract little by little toward literary works of an increasingly high standard. A law passed in 1951, which gave Breton a place in the state schools as well as in the *baccalaureat* syllabus, might well make this task easier, for if instruction is given in Breton, writers might increase in numbers and quality. Until 1951, however, though all Bretons could read books written in their own language, the only people who could write in it were educated French-speakers who had come to Breton late in life (hence the ease with which certain writers forget the realities of the language) and a very small proportion of the 900,000 native Breton-speakers who had been taught to use their own language in a few church schools and seminaries (this, rather than the Bretons' traditional piety, probably accounts for the abundance of Breton literature inspired by religion).

BRETONNEAU, PIERRE (1778–1862), French physician, one of the greatest epidemiologists of his time, was born on April 3, 1778, at St. Georges-sur-Cher. His fame rests on the first performance (1825) of the operation of tracheotomy for croup; on the clinical distinction of diphtheria, so-named by him in his *Des inflammations spéciales du tissu muqueux et en particulier de la diphthérie* (1826); and on his work on typhoid, which, he foresaw, would be differentiated from typhus. In 1814 he passed the examination for doctor of medicine in Paris and in 1815 became *médecin en chef* of the hospital at Tours. There he studied epidemic typhoid. His contribution to the knowledge of this disease is second in historical importance only to that of his work on diphtheria. The doctrine of specificity was his third most important contribution to medicine. By this doctrine he foreshadowed the germ theory of disease. Bretonneau died on Feb. 18, 1862.

See P. Triaire, *Bretonneau et ses correspondants* (1892); *Proceedings of the Royal Society of Medicine*, vol. 18, page 1 (1924).

BRETSCHNEIDER, KARL GOTTLIEB (1776–1848), German theologian, was born at Gersdorf, Saxony, on Feb. 11, 1776. He lectured on philosophy and theology at Wittenberg (1804–06); was pastor of Schneeberg, Saxony (1806–08); superintendent at Annaberg, Saxony (1808–16); and then moved to Gotha, where he was general superintendent until his death on Jan. 22, 1848. The best part of his life's work was done at Gotha. In 1820 appeared his most notable work, a treatise on the Gospel of St. John, which discussed with moderation the arguments against Johannine authorship. His greatest contribution to exegesis was his *Lexicon Manuale Graeco-Latinum in libros Novi Testamenti* (1824), valuable for its use of the Greek of the Septuagint, of the Old and New Testament Apocrypha, of Josephus and of the apostolic fathers, in illustration of the language of the New Testament. In 1826 he published *Apologie der neuern Theologie des evangelischen Deutschlands*. An English translation of his *Manual of the Religion and History of the Christian Church* appeared in 1857. Recognizing a supernatural element in the Bible,

Bretschneider nevertheless allowed a full critical exercise of reason in the interpretation of its dogmas.

BRETT, GEORGE HOWARD (1886–), U.S. air commander in World War II, was born in Cleveland, O., Feb. 7, 1886. He served with the C.S. air service in France in 1917–18 and after extensive experience, especially in the matériel field, became chief of the U.S. army air corps in 1940. When World War II began, Brett was on an official tour of India and China, from which he was diverted to Australia to take command of U.S. troops there. After Gen. Douglas MacArthur's arrival in Australia in March 1942, Brett became chief of the Allied air forces in the Southwest Pacific, directing the defense of Australia and New Guinea until he was succeeded by Maj. Gen. George C. Kenney in Aug. 1942. Operating with air forces described as "pitiable" in strength, Brett had not been able to stop the Japanese advance along the island chain toward Australia. From Nov. 1942 he headed the Caribbean defense command in the war against German submarines in that area. He retired in 1945, with rank of major general. (A. Gg.)

BREUER, JOSEF (1842–1925), Austrian physician and physiologist and the principal forerunner of psychoanalysis, was born in Vienna on Jan. 15, 1842.

In 1868 he studied the respiratory cycle and discovered the Hering-Breuer reflex, which is the foundation for the understanding of the nervous control of respiration. In 1873 he discovered the sensory function of the semicircular canals and their relation to positional sense. He practised medicine and was physician to many members of the Viennese medical faculty.

In 1880 he used hypnosis in treating a hysterical patient, "Anna O." (Bertha Pappenheim). Breuer found that she improved when she remembered unpleasant past experiences. He concluded that neurotic symptoms result from unconscious processes and disappear when the unconscious processes become conscious. Breuer treated no other patients by psychotherapy, but he described his methods and results to Freud and referred several patients to him. Breuer and Freud published *Studien über Hysterie* in 1895 but Freud soon after broke off his relations with Breuer. Freud rightly stated that Breuer's contributions were an integral part of the foundations of psychoanalysis. Breuer was elected to the Viennese Academy of Science in 1894. He died in Vienna on June 20, 1925.

(P. F. C.)

BREUER, MARCEL LAJOS (1902–), Hungarian-U.S. architect, one of the most influential representatives of the international style of modern architecture in the U.S., was born in Pécs, Hungary, on May 21, 1902. He studied and later taught (1920–28) at the Bauhaus in Weimar and then in Dessau, Ger., pioneering in the design of tubular steel furniture. From 1935 to 1937 he practised architecture in London. Then his former associate at the Bauhaus, Walter Gropius, invited him to teach architecture at Harvard university, and Gropius and Breuer became architectural partners (1937–42). Among Breuer's many notable works are his own home in Lincoln, Mass. (1939), the UNESCO building in Paris (with Zehruss and Nervi, 1953–58), St. John's abbey, Collegeville, Minn. (1954), and the Bijenkorf department store in Rotterdam (1955–57). Breuer was the author of *Sun and Shadow, the Philosophy of an Architect* (1955).

BREUGHEL: see BRUEGHEL, PIETER.

BREUIL, HENRI EDOUARD PROSPER (1877–1961), French archaeologist, an authority on prehistoric archaeology especially associated with the evaluation of the cave paintings of Europe and Africa, was born in Mortain, Manche, on Feb. 28, 1877. His science professor at the Seminary of Issy les Moulineaux encouraged him to take up a scientific career. After first studying the Bronze Age of the Paris basin, he became one of the pioneers in the field of Paleolithic art. Among his many books, illustrated by his copies of paintings and engravings: are those on *La Caverne de Font-de-Gaume* (1910), *Les Combarelles* (1924) and *Les Trois*

Frères (1958) in France, *La Caverne d'Altamira* (1906) and *Les cavernes de la région cantabrique* (1911) and other regions in Spain. *Quatre cents siècles d'aut pariétal* (1952) reveals the great scope of his activities in this field. During and after World War II he spent about six years in South and South-West Africa and Rhodesia, copying many of the painted rock shelters. His archaeological publications include *Les Subdivisions du Paléolithique supérieur et leur signification* (1912), which added the Aurignacian period to the existing classification; *Les Industries à éclats du paléolithique ancien. 1. Le Clactonien* (1932). On his 80th birthday his bibliography listed more than 600 items. He was professor at the Institut de Paléontologie Humaine (Paris) from 1910 and at the Collège de France from 1929 to 1947. He became a member of the Institut de France in 1938. Breuil died in L'Isle-Adam, Seine-et-Oise, on Aug. 14, 1961. (H. K.E.)

BREVE: see MUSICAL NOTATION.

BREVET: see OFFICERS.

BREVIARY, the book that contains the daily service for the divine office (canonical hours) in the Roman Catholic Church (Lat. *brevarium*, "abridgment," "epitome"), and including the complete psalter, lessons, antiphons, etc., for every day in the year. It may be considered in close connection with the missal (containing the eucharistic office); the *Rituale Romanum* (the official service book for administration of the sacraments such as baptism, marriage, etc.): and the Pontifical (containing prayers, etc., for rites restricted to the bishop). The service of the divine office, which is distinct from but auxiliary to the mass, is recited daily by all priests and certain other clerics and said or sung by monks, friars, many nuns and some other religious.

History. — In the early days of Christian worship the Bible furnished almost all that was required, containing as it did the books from which the lessons were read and the psalms recited. The first step in the evolution of the breviary may have been the separation of the psalter into a choir book. The monks originally recited the 150 psalms every day, but this took so much time that eventually the recitation was spread over a week, each day being divided into seven or eight "hours" with allotted psalms for each hour. St. Benedict in the 6th century drew up such an arrangement, and the Roman division of the psalter, which remained practically unchanged until 1912, is perhaps even older. To the psalter were added, in course of time, other service books, containing prayers, antiphons, etc. There was originally a service corresponding to and resembling the synagogue services, consisting of scripture reading, singing of psalms, homiletic explanation and prayer formulas. By the 2nd century A.D. the synagogal service was connected with the Eucharist. The Easter vigil with its lessons influenced the other vigil services, especially Saturday of Ember days, and these became the model of the nocturnal service performed by monks. John Belet, a 12th-century liturgical author, gives a list of books needful, besides the psalter and Old and New Testaments, for right conduct of the canonical office: antiphonary; passionary; and collectar, containing antiphons, the four versions of the Passion and the prayers (collects) sung by the presiding officiant.

The inconvenience of using a whole library of books for these services naturally led to the idea of substituting one compendious volume. Attempts in this direction were made as early as the 8th century by Alcuin, and a little later by Galindo Prudentius (d. 861), bishop of Troyes; Gregory VII (pope 1073–85) completely reformed the liturgy used at the Roman curia, and accepted for his abridgment the name of breviary. But the earliest extant manuscript containing the whole canonical office in one book is of the year 1099 (from Monte Cassino, now in the Clazarin library at Paris). A few 12th-century breviaries are extant, all Benedictine. Under Innocent III (pope 1198–1216) their use began to be more general.

The first attempts to enforce a daily pensum of organized prayer with the secular clergy (the original impetus to the divine office came from the monasteries) were made in the 6th century in Italy. St. Ambrose in A.D. 397 mentions the use in Milan of the *lucernarium* (vespers) and lauds or matins, and the daily night vigil. These were read in the cathedral churches. The little day hours

DETAIL OF A PAGE FROM SALISBURY BREVIARY. 15TH CENTURY. FRENCH

(prime, terce, sext and none) were said privately at home, a practice that has survived to this day with the Carthusian monks. The breviary of the Roman curia was adopted (with some modifications; e.g., the substitution of the Gallican for the Roman version of the psalms) by the newly founded order of Franciscan friars, with the authorization of Gregory IX, and through the Franciscans' wide-ranging activity it became known all over Europe, supplanting the older partial books. Nicholas III (1277–80) introduced the Franciscan breviary for the Roman churches, and thus made its position secure. It did not supersede the various local diocesan breviaries, however, until 1568, when Pius V issued it in a revised form, as the *Breviarium Romanum*, and made it obligatory in every diocese where the local use could not show at least 200 years of undisturbed and unchallenged existence. Since then it has gradually become universal except in the Benedictine, Cistercian, Carmelite, Carthusian and some other religious orders, in the diocese of Milan (where the Ambrosian rite persists) and in a chapel of the cathedral of Toledo (where the Mozarabic rite, once universal throughout Spain, is still followed). Of the many attempts to make the breviary more suitable for private use the most remarkable is that by Cardinal Francisco de Quiñones (1535), which, undertaken by order of Clement VII, passed through many editions before its suppression in 1558 and was largely used by the compilers of the English Prayer Book of 1549. The breviary of Pius V was altered by Clement VIII in 1602 (through Caesar Baronius and St. Robert Bellarmine), especially as concerns the rubrics; and in 1632 by Urban VIII, a classical purist who unfortunately tampered with the text of the hymns, injuring both their literary charm and their religious content.

In the 17th and 18th centuries a movement of revision, largely under Gallican and Jansenist influences but also in the interest of sound critical scholarship, took place in France, and affected about half the breviaries of that country. These reformed French breviaries (e.g., the Paris breviary of 1680 by Archbishop François de Harlay and that of 1736 by Archbishop Charles Gaspard Guillaume de Vintimille) show a profound knowledge of Holy Scripture and much careful editing of different texts. During the pontificate of Pius IX, however, an uncompromising Ultramontane movement arose against them, its chief advocate being Dom P. L.

P. Guéranger, a zealous conservative Benedictine monk, abbot of Solesmes, helped by the radical Ultramontane Louis Veuillot; the movement succeeded in suppressing them everywhere, the last diocese to surrender being Orléans in 1875. The Jansenist and Gallican influence, not to speak of the 18th-century Enlightenment and rationalism, also was strongly felt in Italy and in Germany, where breviaries based on the French models were published at Cologne, Münster, Mainz and other dioceses.

Under the direction of Benedict XIV (pope 1740–58), a special commission of cardinals collected many materials for an authoritative revision, but nothing was published. Pius X, by the apostolic constitution "Divino Afflatu" (Nov. 1, 1911), ordained the use of a newly arranged psalter, as well as the observance of certain new regulations in the manner and order of reciting the office—the main object of the changes being to restore the weekly recitation of the entire psalter and the reinstatement of the Temporale as opposed to the Sanctorale (see below). Pius XII, acceding to the wishes of many of the bishops, reduced both the breviary and the missal to a simpler form (decree of the Sacred Congregation of Rites of March 23, 1955). In the following year he surveyed the opinions of the bishops on the matter of liturgical improvement of the breviary, and on the basis of their answers decided that it was time to attempt a general and systematic revision of the breviary and missal. The question was referred to a special committee of experts who had been appointed to study the general liturgical reform.

A new code of rubrics of the Roman breviary and missal was announced by Pope John XXIII in an apostolic letter of July 25, 1960, and went into effect on Jan. 1, 1961. Pope John wrote:

The fact is that this new arrangement of the rubrics has two effects. On the one hand, the whole structure of the rubrics of the Roman Breviary and Missal is reduced to a better form, distributed in a clearer order and brought together into a single text. On the other hand, some special modifications have also been introduced, by which the Divine Office is somewhat shortened.

Contents.—Until 1961 the breviary usually was published in four volumes (for the winter, spring, summer and autumn portions of the ecclesiastical year), but the reform of John XXIII produced a two-volume breviary. After the calendar, tables for finding Easter, general rubrics and other prefatory matter, each volume contains: (1) psalter; (2) *Proprium de Tempore*; (3) *Proprium Sanctorum*; (4) *Commune Sanctorum*; (5) extra services.

Psalter.—This contains the psalms arranged in sections, with prayers, hymns, antiphons, etc., for the several hours throughout the week. The psalms are arranged so that the whole psalter may be recited each week and (by dividing some of the longer psalms) so that the portions allotted to each day's office are of approximately the same length. Ps. cxlviii to cl are always used at lauds, and give that office its name (each of them begins with *laudate*, "praise ye"). The text of the psalms is that commonly known as the Gallican; *i.e.*, St. Jerome's second revision from the Greek Septuagint into Latin. This was adopted at Rome in the 13th century (having long been accepted elsewhere) instead of his first translation, the so-called Roman version, which is still used in St. Peter's and the Lateran. The reform started by Pius XII, built on a revised psalm text of the 1946 version (after the Hebrew version), was marred by the use of classical Latin instead of the Latin created by Christian writers.

The tradition of reciting the whole psalter every week so far has prevailed, with a few exceptions, over the desire to recite the psalms meaningful for the occasion; the exceptions are Sunday, compline and special feast psalters, whose psalms are easily recognized as having been selected *ad hoc*.

The psalter of the breviary also includes Old Testament canticles—*i.e.*, songs or prayers, other than psalms, derived from the Bible—for use at lauds in place of the fourth psalm (*e.g.*, the Song of the Three Children, Dan. iii, 57–88, on Sunday; the canticle of David, I Paralipomenon xxix, 10–12, on Monday; etc.); and three New Testament canticles from St. Luke (*viz.*, the *Benedictus*, Luke i. 68–79, at lauds; *Magnificat*, i, 46–55, at vespers; and *Nunc dimittis*, ii. 29–32, at compline). The monastic breviary has six more canticles from various old Testament sources.

Proprium de Tempore—The "Proper of the Season," or Temporale, contains the antiphons, hymns, responsories, readings and little chapters of the feasts and seasons built around the great mysteries of redemption, the Easter and Advent cycles; in other words, it is "Christ-centred." The sum of these days, the intervening Sundays and ferias (weekdays without a saint's feast) and the Ember days form the backbone of the ecclesiastical year. (See CHURCH YEAR.)

Proprium Sanctorum.—The "Proper of the Saints," or Sanctorale, contains those parts of the office that are strictly proper to the individual saint (a special selection of psalms, antiphons, biography, proper orations, hymns, responsories, etc.). Some of these proper are of sublime beauty, some are undistinguished.

Canonization of new saints and the press of popular devotions tend to crowd out the Proper of the Season. Practically all reforms have had to deal with this problem: after an undisturbed growth of saints' feasts an energetic pope restores the temporal office. Pius X started to do this, but his successor quickly gave way to conservative pressure and reintroduced feasts of some saints just abolished.

While the liturgical veneration of saints is sober and truly Christ-centred, the general effect of this influx from the Sanctorale is to destroy the subtle beauty of the two major cycles of the season.

Commune Sanctorum.—The Common of the Saints contains all those parts of the services for the saints where proper are lacking—that is, offices that are common to saints, grouped as Apostles, martyrs, confessors, holy women, etc. These offices usually are of very ancient date, and most of them actually are former proper of one particular saint, now made common.

Extra Services.—These include the Little Office of the Blessed Virgin Mary, the Office of the Dead, and office peculiar to each diocese.

Terms Common to All Roman Breviaries.—Not only each day, but each part of the day, has its own office, the day being divided into liturgical hours. (See HOURS, CANONICAL.) Each of the hours of the office is composed of the same elements, psalms (including canticles), antiphons, responsories, hymns, lessons, little chapters, versicles and collects. The psalms and canticles have been discussed above.

Antiphon.—The antiphons are sentences of biblical or patristic origin, recited before and after the psalms and canticles. They bestow a certain flavour on the otherwise neutral psalms. The term originally signified a chant by alternate choirs, but has quite lost this meaning in the breviary.

Responsory.—The responsories are meditative Bible verses read following the lessons and even little chapters; their purpose is to enlarge the significance of the lesson in a quiet and contemplative mood. The most famous one is the first responsory on first Advent Sunday (matins).

Versicle.—The versicle is a short call stirring the attention of the listeners to inaugurate a different mood.

Hymn.—The hymns are rhythmic poems going back in part to Prudentius (d. c. 410) and Ambrose. Together they make a fine collection, despite Urban VIII's attempts to improve them. The original version can be found with all the older religious orders and may be used by all clerics. (See also HYMNS.)

Lesson.—The lessons are drawn from the Bible! woven around the acts of the saints and patristic homilies. In the lessons, as in the psalms, the order for special days frequently breaks in upon the normal order of ferial offices and dislocates the scheme for consecutive reading. At matins, on simple feasts and ferias, three lessons are read; on the occasions when matins is divided into three nocturns ("nine-lesson feasts"), three lessons are read at each nocturn.

Little Chapters.—These are in fact very short lessons (see above) read at the hours other than matins (but also in the second nocturn of matins in the monastic breviaries). They usually are taken from the epistle (the first of the two scriptural lessons of the mass).

Collect.—The collects are short prayers said near the close of the office. They are always taken from the mass of the day, ex-

cept in the case of prime and compline, which use the same collect all the year round.

Meaning of the **Breviary**.—By its close connection with the eucharistic service the breviary in its ideal form is an instrument to carry the main thoughts of this service over the whole day. The collect at the hour prayer is from the mass of the day; the day's Gospel dominates the nocturns and the choice of the antiphons; the little chapter is usually part of the epistle read at mass; on major hours the hymn, too, is a reminder of the day's feast or feria. All this is meant to cause the rhythm of the natural day to conform with that of the superimposed spiritual day. The scripture texts provide more than a simple quotation; if understood correctly, they keep alive the *mysterium* of the day in the church and in the individual. This is a fact not only for the individual day but also for the major seasons of the year. The spacing of the hours at about three-hour intervals is, so to speak, a grid to which the day's work is attached to make the ordinary as well as the extraordinary day a spiritual day, a thing sacramental, for the Christian.

BREVIAIRY OF ALARIC (*Breviarium Alaricianum*), also called **LEX ROMANA**, **CORPUS THEODOSII** or, most usually, **LEX ROMANA VISIGOTHORUM**, a collection of Roman law, compiled by order of Alaric II, king of the Visigoths, and promulgated at Toulouse in A.D. 506 for the use of his Roman subjects. The task was entrusted to a committee of lawyers, but the final work was submitted for approval to an assembly of Roman bishops and elected provincials. The breviary contains about one-ninth of the constitutions of the Theodosian code (see **ROMAN LAW: Sources of Law**) and one-third of the post-Theodosian *Novels*; a few extracts from the Gregorian and Hermogenian codes; an epitome of Gaius' *Institutes* (see **GAIUS**); about 600 of the *Sententiae Pauli*; one *responsum* of Papinian. An *Interpretatio* accompanies all the breviary except the epitome of Gaius.

In 654 the Visigothic king Recceswinth promulgated a uniform law for Goths and Romans and repealed the breviary, except for a few decrees (called *Antiqua*). The breviary, however, continued to be used for legal study in several countries (particularly in France, where it had considerable persuasive authority); indeed it was almost the only source of Roman law in western Europe down to the 11th century. Abridgments were made between the 6th and the 9th centuries. An imperfect abstract of it formed the basis of the *Lex Romana Curiensis*, probably written in Graubiinden in the 8th century. A 9th-century recast made for the use of Lombardy was preserved in a manuscript called *Codex Utinensis*.

There is considerable dispute concerning the *Interpretatio*. For example, F. Wieacker held that it was not original work by the Visigothic lawyers but was based on 5th-century commentaries. W. W. Buckland found features that distinguish the *Interpretatio* for the *Sententiae Pauli* from the *Interpretatio* for the extracts from the Theodosian code. E. F. Bruck stressed the haste with which the breviary was compiled (to appease Alaric's Roman subjects) as a reason for the absence of an *Interpretatio* for the epitome of Gaius, while admitting that the *Interpretatio* for the *Sententiae Pauli* probably existed before the compilation.

BREWING. Brewing is the preparation of beer from carbohydrate material, chiefly malted barley, by means of the action of yeast and usually with the addition of hops. For a description of beer; including types of beer, see **BEER**.

HISTORY

The Middle East and Europe.—Since many fermentative yeasts occur naturally on vegetable matter and in soil, alcohol no doubt originated accidentally but man must soon have learned to carry over some of the active agent from one brew to the next. The nature of the earliest fermented beverages is uncertain; they may have been derived from barley, dates, grapes or honey. Brewing seems to have originated in Babylon where, as in Egypt, barley grew wild, and there is some evidence that beer made from malted grain was being brewed in Mesopotamia by 6000 B.C. By the fourth or fifth millennium B.C. brewing was well established and evidence exists of the various types of beer extant in Babylon about 1800 B.C. Brewing in Egypt began at a later date than in Babylon but probably developed independently. It was said to have been a gift of the god Osiris, or his wife Isis, about 2000 B.C. although it seems that several different types of beer were brewed in Egypt a thousand years before then, and there is a reference to its use as a mortuary offering in the 5th dynasty, about 2800 B.C. In later times beer drinking is well documented and illustrated, and beer appears to have been the national beverage. It played an important part in religious worship, and some of the festival offerings were dispensed among the populace. During his reign Rameses III (about 1225 B.C.) is claimed to have distributed the equivalent of more than 500,000 gal. Beer was also used extensively in medicine.

Since the raw materials are grain and yeast, brewing was usually carried out by bakers. The barley was soaked until it germinated and then was roughly ground. Yeast was added to this malted material and molded into cakes, which were partially baked. These were then crumbled, put in a jar of water and left to ferment. This method is similar to that still used in Egypt in the making of "bouza." The end product has the consistency of soup and is sometimes strained through a cloth.

The origin of the use of hops is unknown. Some authorities think herbs and other flavourings were widely used in these ancient brews but the evidence, particularly with regard to hops, is slender. The modern "bouza" has no flavouring added although the Abyssinian add the bitter leaves of a shrub called "ghesh." One suggestion is that the Hebrews learned the use of hops during the Babylonian captivity in the 8th and 9th centuries B.C.

The Greeks learned brewing from the Egyptians and also grew hops, although they do not appear to have used them particularly in brewing. The Romans learned about beer from the Greeks, and it became known also in Gaul and Spain, but references to the use of hops do not reappear till the 8th century.

The northern European races probably discovered the technique of brewing long before the Christian era, the earliest Teutonic and Celtic beverages being made from a mixture of corn and honey and hence approximating mead. Beer has always been drunk most extensively in lands where soil and climate are inhospitable to the vine.

There is no direct evidence of beer brewing in Britain prior to the Roman occupation but by Anglo-Saxon times, probably as the result of invasion, beer or ale was well established. In the early middle ages brewing was carried on in most large households and was largely the duty of the women folk, hence the terms "maltster" and "brewster," which are the feminine forms of "malter" and "brewer." The growth of the monasteries resulted in the development of larger brewing units: the monks became excellent brewers. There was a great variety of brews, and the strength of the best beers was considerable. Weaker brews were drunk in great quantity since the water in many areas was unwholesome. The use of hops was introduced from northern Europe in the 16th century; thereafter the hopped beverage became commonly known as "beer"

whereas "ale" indicated the unhopped drink. Nowadays in Britain the term "ale" has no special significance but it is used in America to distinguish top-fermented or British beers (see *The Brewing Process* below) from the more widespread lager beers.

North America.—Various alcoholic beverages were made by the Indians long before the advent of Europeans but the history of American brewing really begins in 1584 when the British brewed beer from corn (maize) during their first attempt to colonize Virginia. Later, in 1612, Dutch colonists are said to have set up a brew house on the most southerly point of Manhattan Island. In Massachusetts the price of beer was carefully controlled and in 1657 regulations were also laid down about the ingredients of the different varieties. Fines were imposed on maltsters whose product contained too many impurities. Although the quantity and quality of the home-grown barley soon became inadequate, the import of European grain, malt and flour was prohibited in order to encourage home production. In 1660 this law, in regard to malt, was repealed because it encouraged the people to drink poor spirits instead of beer. This legislation is an early example of attempts to discourage heavy spirit drinking by encouraging the consumption of beer. Similarly, when Jean Talon, *intendant* of New France, was faced with a high degree of alcoholism among the colonists he established a brewery in Quebec city on the shore of the St. Charles river. This was the first brewery in Canada.

In 1683 William Penn erected the first brewery in Pennsylvania and in the following century many other famous men were concerned with brewing. Samuel Adams, "Father of the Revolution," was a brewer, as was his father before him. Thomas Chittenden, first governor of Vermont, was a brewer and innkeeper, and others who fostered the industry included Thomas Jefferson, Patrick Henry, Israel Putnam, Benjamin Rush and James Madison. George Washington himself had a small brewery at Mount Vernon.

Until the mid-19th century only "British" types of beer were brewed in North America but about 1840 German brewers introduced the newer methods of making lager beer, thus laying the foundations of the vast modern American industry, which produces 87,000,000 U.S. barrels a year. Between 1870 and 1960 the quantity brewed in the U.S. increased tenfold but since the industry became concentrated in the hands of a few large firms the number of breweries: and hence the variety of beers available, decreased considerably.

Measurement.—The units of measurement used in America differ from those used in Britain. 1 U.S. gal. = 0.8327 British gal.; 1 standard U.S. barrel contains 31.5 U.S. gal.; 1 U.S. beer barrel contains 31 U.S. gal.; 1 British barrel contains 36 British gal. Unless otherwise designated, measurements referring exclusively to British beers will be given in British units and all other measurements will be given in American units.

BREWING MATERIALS

The principal materials employed are malted barley, hops, water and yeast. In certain countries, *e.g.*, Germany, the use of other materials is forbidden by law (except for export beers), but in most places other materials are employed to give colour and flavour and are known as "adjuncts."

Malt.—Barley malt is far and away the most important raw material. Not all barleys are suitable for malting but there is a great variety among those that are. In North America six-rowed barleys are by far the most widely used but in Europe the two-rowed varieties are grown for brewing (see *BARLEY: Uses*).

After harvesting, barley passes through a dormant phase; the length of this phase depends not only on the variety of barley but also on climatic conditions at harvest. For this reason, malting used to start several months after harvesting, but dormancy can now be overcome in various ways so that malting takes place all the year round. During malting, profound changes occur in the barley (barley grain), the most important being the development of certain enzymes. The two most important groups are the amylolytic enzymes, which can convert starch to carbohydrates of lower molecular weight, and the proteolytic types, which can break down the protein constituents of the barley to simpler nitrogenous compounds. These processes are actually initiated during the

malting, together with a partial breakdown of the cell walls, and the extent to which they are allowed to proceed is known as the degree of modification of the resulting malt.

Malting is carried out at some breweries and also as a separate industry. The skill of the maltster lies in achieving the desired modification from variable raw materials. Before malting, the barley is steeped in water to soften the grains and initiate germination. Steeping also removes undesirable materials! such as tannin complexes (mostly from the husks)! which are thought to inhibit the subsequent fermentation. Steeping takes place at 55°–60° F. and lasts up to 48 hr. in the case of the barley used in British beers and up to 70 hr. for the harder and more nitrogenous barley used in lager beers. Steeped barley is known as "green malt."

There are three principal methods of malting: (1) In floor malting, which is the oldest method, the green malt is spread thinly over a heated floor, sprinkled with water and turned over from time to time in order to air it. In these favourable conditions germination takes place, the rate of growth of the acrospire (germinating shoot) increasing as the rootlets begin to wither about the eighth day. (2) In box malting (also called the Saladin process after its inventor) the steeped barley is put into a long rectangular box, to a depth of about two feet, and moist air is blown into the grain through vents in the sides of the box. Vertical helical screws move slowly back and forth through the barley, turning it twice or thrice a day. (3) Drum malting is another form of pneumatic malting, in which the steeped barley is put into large cylindrical drums that are rotated horizontally while water-saturated air is driven through the grain.

After germination the malt is dried in a kiln until the moisture content is between 1.5% and 2%. The shriveled rootlets drop off and are collected and sold as animal feed. The temperature at which each operation takes place, and the time taken, varies with the type of beer being made. Generally British malt is allowed to germinate for 11 days and is dried by direct heat for 3 to 4 days at temperatures up to 225° F. Lager malt is allowed to germinate for only 7 or 8 days and is consequently less highly modified. It is dried with hot air at about 130° F. Malt in Britain is measured in quarters that weigh 336 lb. as opposed to quarters of barley, which weigh 448 lb.

Since the composition of the malt is of paramount importance each batch is analyzed for moisture content, extract (a measure of the soluble matter extracted from the malt), tint, diastatic activity and cold water extract (the proportion of water-soluble materials), total nitrogen and permanently soluble nitrogen. (See also *MALT*.)

Adjuncts.—These are carbohydrate materials that provide additional fermentable material. They are used to reduce costs, to give flavour and to correct the balance in the composition of the extract; for example, with a malt made from a high-nitrogen barley. They are added during mashing, when the excess amylolytic enzymes in the malt break them down to fermentable sugars (see *The Brewing Process* below). In Europe they usually account for 10%–25% of the total weight while in the U.S. they may reach 40%.

The principal adjuncts are corn (maize); rice! unmalted barley and tapioca. Corn is the commonest; while rice is used particularly for the palest beers. Brewing sugars and sirups are also used and, since they need no further conversion, are added during boiling (see below). These sugars may be in the form of glucose, made by the acid hydrolysis of starch; invert sugar (equal parts of glucose and fructose), made by the dilute acid inversion of sucrose; or sucrose itself. The yeast that is added at a later stage secretes an enzyme, invertase, that inverts the sucrose to glucose and fructose so it can be fermented. Glucose made from starch contains unfermentable dextrins that act as mellowing agents in the finished beer.

HOPS.—Hops are not an essential constituent of beer and have not always been employed in brewing (see *History*). Nowadays their use is almost universal, but the types and quantities employed vary widely and greatly influence the character of the resulting beers. The hop plant (see *HOP*) is dioecious; *i.e.*, the male and female flowers are borne on separate plants. The flowers of the fe-

male plants are grouped in cones and contain a resinous material, lupulin. It is these cones that are used in brewing. If fertilized with pollen from a male hop flower, they develop seeds with an unpleasantly bitter taste, and for this reason the male plant is banned in most European countries. The female plant is propagated exclusively by cuttings. The finest hops are those from the Saaz district of Czechoslovakia, such Bavarian types as Hallertau and the Styrian hops from Yugoslavia. Britain produces rich aromatic hops for her "top fermentation" beers (see *Yeast* and also *The Brewing Process* below); other small producers are France: Poland, Russia and Belgium. Outside Europe, the U.S. is the only large hop grower, hops being grown chiefly in Oregon, California, Idaho and New York state. They tend to have a strong flavour that restricts their use for British and European beers, although when used with brewing waters containing calcium sulfate the undesirable part of the flavour is suppressed.

Hops are added to the wort, or mashed malt solution, during boiling (see *The Brewing Process* below). They have several functions. Their resins and oils impart the desired bitter flavour and aroma, and the derived constituents act as a preservative. Also, the tannin they contain assists the "break," or precipitation of protein material, which might later cause haze in the beer. The quantity of hops added during brewing varies with the type of beer being brewed and with the species of hops. The amount may be less than $\frac{1}{3}$ of a pound per barrel of light lager and over 29 pounds per barrel of strong British beer.

Water.—The chemical composition of brewing water has a profound effect on the character of the beer being brewed. In the past the suitability of the certain waters has decided the locality of the breweries, for instance those at Burton upon Trent, Dortmund, Dublin, Pilsen and Munich. Nowadays the composition can be adjusted.

The hydrogen ion concentration of the water is of extreme importance. If the water is alkaline, large amounts of unwanted matter will be dissolved from the husks of the malt and, since an acid solution is needed for the maximum activity of amylolytic and proteolytic enzymes, enzymic activity will be somewhat diminished. The commonest cause of alkalinity is the presence of magnesium and calcium bicarbonates in solution. These bicarbonates produce what is known as temporary hardness and can be removed by boiling since the bicarbonates decompose and precipitate as the insoluble carbonates. Permanent hardness, which gives a faintly acid solution, is caused by the presence of calcium and magnesium in the form of sulfates and chlorides and is usually an advantage to the brewer.

Broadly speaking: waters containing calcium sulfate (gypsum) are the best for pale ale brewing, as at Burton and Dortmund. Dark lagers are brewed at Munich with a type of water very similar to that of Dublin. A very small amount of gypsum is necessary for the best bitter beers, such as those brewed in London. However, the question of brewing waters can be oversimplified, and many other factors have to be considered, such as the other materials present and the methods of brewing involved.

The waters must also be free of bacterial contamination; iron and of any malodorous content. Since the quantity of water used for washing bottles and casks is 8–20 times the amount used in brewing, the supply must also be a plentiful one. Nowadays most brewers use their local town supply, which should ensure its good quality.

In Britain, brewing water is generally referred to in the trade as "liquor," a term likely to be misunderstood elsewhere.

Yeast.—Yeast (*q.v.*) is used to convert the fermentable sugars in the wort, which consists mainly of the sugar maltose, into ethyl alcohol and carbon dioxide. The original Gay-Lussac formula for this reaction:

is actually only 95% correct and is the oversimplification of a complex series of intermediate steps, as indicated by the Embden-Meyerhof-Parnas scheme (see FERMENTATION: *The Modern Position*). Yeasts are microscopic vegetable organisms belong-

ing to the fungi family. There are many thousands of species and strains but those used in brewing all belong to the species *Saccharomyces cerevisiae*. Although there are a great many types within this single species, from the brewer's point of view they can all be placed in one of two categories, "bottom" and "top," depending on whether the cells sink or rise during fermentation. In the brewing process it is the manner of fermentation that is responsible for the basic difference between British beers, which are "top fermented," and lager beers, which are "bottom fermented." Bottom fermentation takes place at lower temperatures.

THE BREWING PROCESS

The three main stages of the brewing process are: mashing, boiling and fermentation.

Prior to mashing the malt is crushed between rollers so that the resulting flour is well separated from the husk, though not too finely ground. The husk should remain as unfragmented as possible because it is used later as a filter bed.

Mashing.—The procedure after the grist (flour and husk) leaves the mill depends on whether British or lager beer is being produced.

Infusion Mashing.—This is the top-fermentation, or British, system. The grist is passed through a Steel's masher, a machine with a revolving worm screw, which mixes the grist with incoming water to make a porridgelike mixture. This then enters the mash tun, a circular vessel having a domed cover fitted with sliding doors or hinged segments that can be raised individually. The diameter is about twice the height from base to the edge of the dome, and the vessel has a false bottom to permit drainage. The "striking heat" of the water as it meets the grist is about 150° F. and the principal reaction is the breakdown of the insoluble starch in the endosperm of the malted barley. It is converted into soluble maltose and other sugars and dextrins by the amylolytic enzymes, α - and β -amylase, which are present in the malt (see *Malt* above). The mash is kept moving by rakes and the "wort," as the solution of converted carbohydrate is called, filters out of the bottom of the mash tun, leaving the malt husks behind. The mash is left to stand for about two hours and then the husks are sparged (sprinkled) with hot water to complete the extraction of the sugars and dextrins. The proportion of maltose and dextrins obtained in the mash can be controlled by varying the acidity and temperature. α -amylase converts the starch into dextrins and is most active between 150° and 168° F.; β -amylase breaks down starch and dextrins into maltose, but above 140° F. its power is diminished. A higher temperature therefore yields a more dextrinous and less fermentable wort and will tend to give a less alcoholic though more fully flavoured beer. In infusion mashing the breakdown of the nitrogenous material is restricted since proteolytic enzymes react best at temperatures from 122°–130° F., which are well below those for amylolytic enzymes.

Decoction Mashing.—This process is used for all but British beers and has many variations. Because the malts to be mashed are usually less modified than British malts, they have to be more finely mashed. The most common variation is the three-mash system in which, after a preliminary mashing at 100° F., the temperature of the mash is raised in three stages: first to the optimum temperature for the activity of the proteolytic enzymes (122°–130° F.), second to 150° F. and lastly to 168° F. The first of these stages lasts two hours and is known as the "protein rest." The temperature rises at each stage are achieved by withdrawing about one-third of the mash, boiling it and returning it to the rest of the mixture. Though the enzymes in the portion that is boiled are destroyed, the body of the mash retains a sufficient quantity to convert the whole. In a two-mash process the preliminary mash is omitted, the temperature being taken straight up to 122–130° F. There are many variations to this and other mashing systems; for instance, the Pilsen system, a decoction using only two vessels. In a one-mash system about 5% of the total is taken off, the bulk is raised by stages to boiling and then cooled and mixed with the withdrawn 5%, which still has its enzymes intact and can convert the whole mash. The quick-mashing system: which is used in America, employs two mashes at temperatures of about 145° and 172° F.

When rice and corn are to be added they are mashed separately with a little malt to provide the necessary enzymes. They are then added to the main mash in quantities calculated to give the requisite rises in temperature.

Decoction mashing is suitable for malts that are not highly modified and have a high nitrogen content, because the "protein rest" permits the breaking down of the nitrogenous material into soluble nitrogen compounds, and the various subsequent boilings encourage protein coagulation and precipitation.

Boiling.—After mashing, and sometimes after filtering, the wort is boiled in a copper tank or kettle. This prevents any further enzyme action and coagulates a great deal of the protein material, which is known as the "hot break" or "trub." The boiling also sterilizes the wort, makes it more concentrated and provides an opportunity for the hops to be added.

The length of boil depends upon the type of beer to be brewed but it is usually about two hours. Some of the hops may be added when the boiling is half completed and more towards the end. If sugar adjuncts are used, they too can be added during the latter half of the boil.

Kettles once were fired directly, but nowadays heating coils, steam jackets or a percolating system in the kettle are more usual, particularly in America. Pressure boiling is sometimes used; it tends to affect the colour and flavour of the beer.

After boiling, the wort is filtered quickly to remove the hops and also as much of the hot break as possible. The filter bed is formed of spent hops between 18 and 24 in. deep and after filtering is sprinkled with water to remove any residual wort.

From the hop strainer the hot wort passes either through a high-speed centrifuge to achieve greater clarity or directly to the cooler. In the cooler protein-resin-tannin complexes are precipitated, a reaction known as the "cold break." During this phase the wort is susceptible to infection by bacteria and wild yeasts, and great care must be taken to ensure sterility.

The simplest form of cooler is a large shallow vessel (cool ship) where the wort stands at a depth of about 6 in. until it is cool. A second type is the original "refrigerator," a vertical cooler in which the wort flows over flattened pipes containing cold brine. The third form of cooler, and one which is extensively used, is the closed plate cooler in which the wort passes between plates on the other sides of which cooling water flows. The advantage of this closed system is that there is less risk of infection.

Fermentation.—Fermentation begins when the yeast is "pitched" into the wort.

Bottom Fermentation.—This type of brewing was developed in Germany in the 15th century in order to produce a stable beer that could be stored satisfactorily.

The temperature of the wort at pitching is 43°–50° F. and the yeast is added in the form of a slurry, about 1 lb. of pressed yeast being allowed for each barrel of wort. A certain amount of aeration may be employed at the earliest stage to encourage yeast growth. The sooner the yeast begins to grow, the less danger there is from bacterial infection. Within a few hours a fine fluffy white head appears and the fermenting wort is often pumped or transferred to another, preferably closed, vessel, leaving behind much of the unwanted protein, hops and resins. Activity increases and the stage known as the "krausen," or "cauliflower," stage is reached after two days. After a further 24 hr. the most active stage, the "high krausen," is reached and continues for three days, during which the temperature must not be allowed to rise above 50° F. or the activity of the yeast is impaired. The head then starts to collapse and the temperature is allowed to fall gradually to about 39° F. After about eight days' fermentation in all, most of the fermentable material will have been converted to alcohol and the "green" beer is then removed to the storage cellar (for the "Ruh," or resting stage) at just over 32° F.

During the lagering period which follows, a slow secondary fermentation takes place. Carbon dioxide is evolved, suspended protein matter and yeast settle out and a polyphenolic protein complex, which tends to cloud chilled beer, is also partly precipitated. During this stage the beer improves in flavour so long as oxygen is excluded. Lagering may be continued for three months but much

shorter periods are common, particularly in America. Nowadays, in order to save lagering time, the beer is often filtered and carbonated soon after fermentation.

Pure strains of yeast have been used in bottom fermentations since this practice was introduced in 1883 by E. C. Hansen, first director of the Carlsberg laboratory in Copenhagen. Later pure strains with different characteristics were mixed together; e.g., a yeast that starts fermenting quickly is used in conjunction with one that is a good attenuator, (converter of sugar to alcohol) but a slow starter. Now the pure-culture yeasts are worked up by stages from a laboratory stock culture or taken from a previous uninfected brew.

The strength of the beer is sometimes referred to in terms of the specific gravity of the wort from which it was made. The original gravity (O.G.) of the wort is high when its content of fermentable sugars is high. The higher the O.G., the higher the alcohol content after fermentation and specific gravity of the resultant beer.

Top Fermentation.—About 98% of British beer is still brewed by this method. The wort is at 60° F. when fermentation begins and is allowed to rise about 10° F. during five- to seven-day fermentation period. A light froth appears in the first few hours, giving place to small "cauliflowers" and then to "rocky heads" that contain a considerable amount of protein and resinous matter that is skimmed off. On the second day a high rocky head develops, fermentation is vigorous and heat generation is at its greatest. On the third day the head gradually collapses and the blanket of yeast is skimmed off, except for the bottom inch, and used for a subsequent brew. The head then forms pleats or folds as the beer is cooled for a second skimming.

Two other famous systems of top fermentation need special mention: the Burton union and the Yorkshire stone square. In the first: fermentation takes place in large casks, or unions, and the beer and yeast work up through swan necks into a trough and are fed back into the unions. For this a nonflocculating yeast must be used. The resulting beer is of good character and stability but the system is susceptible to infection and much labour is expended on cleaning. In the Yorkshire stone square, a system still used in the north of England, a highly flocculant type of yeast is used in conjunction with characteristically small fermentation vessels. The mixture is kept moving from one vessel to the other and a full-flavoured beer is obtained although, with so much unfermented material present, stability is not high.

In top fermentation brewing pure-culture yeasts are not generally employed; several strains are usually present. The use of pure yeast cultures is, however, increasing and should continuous fermentation (see *Research and Consumption* below) come, it may be essential.

Flocculence.—Some brewing yeasts form clumps or flocs during fermentation whereas others do not. Both top and bottom yeasts exhibit this phenomenon, which has nothing to do with whether they rise or sink during fermentation. A yeast that flocculates is removed from the sphere of action, leaving a great deal of sugar unfermented. On the other hand, an entirely nonflocculating or powdery yeast may convert too much of the sugar into alcohol and leave large amounts of yeast still in suspension at the end of fermentation. The degree of conversion is known as the "attenuation" of the brew. Numerous theories of the cause of flocculence exist and none, by itself, is completely satisfactory. The most important factors appear to be genetics, electrical charge and the nature of the cell wall.

Kegging, Bottling and Canning.—When fermentation is complete the beer is run off into tanks for racking (casking). Some beers are "conditioned" in tank and cask for several days before leaving the cellars, and special beers may be retained for many months, thereby acquiring excellent character, though this practice is less common than it used to be. When mild beers are casked, or racked (placed in kegs or barrels), they are sometimes primed with sugar to give condition and flavour, while bitter beers are often dry hopped; i.e., a few ounces of hops are added to each barrel. A colloid such as isinglass is also added to precipitate particles of protein material and yeast cells and to give a bright beer.

Except for dark and conditioned beers, beer for bottling and canning is filtered through pulp, sheet or diatomaceous earth and carbonation is carried out at the same time. The "polished" beer goes to bright beer tanks, where it is fed to filling machines. Most bottled and canned beers are pasteurized nowadays in their containers but a recent system of "hot bottling" is arousing interest. Pasteurization destroys wild yeasts and bacteria whose action might make the beer turbid or unpalatable, and is usually effected by holding at a temperature of 140° F. for about 20 min.

The can is becoming increasingly*popular as a container, particularly since the development of linings that do not alter the taste of the beer. In a flat-topped can the air content is very low and the beer keeps well. In America far more beer is consumed from bottle and can than from keg: in Britain the trend is in the same direction though in 1960 the consumption of bottled and canned beer was roughly equal to that from the keg.

By-Products.—The chief by-products are carbon dioxide, yeast and the spent grains from the mash tun.

After the first few hours of fermentation the carbon dioxide evolved reaches a high degree of purity and can be recovered for use in carbonation.

Far more yeast is produced during fermentation than is needed for subsequent brews and it has a high nutritive value, containing 50% protein and 2% fat by dry weight, a good content of the B vitamins and minerals such as calcium and iron. It is very bitter on account of the hop resins so that for some purposes a debittering process is necessary. It is in good demand for livestock feeding stuff, yeast extract manufacture and for various pharmaceutical purposes.

Like the rootlets from the malt (see *Malt* above), brewer's spent grains are used for animal feeding since they contain about 20% protein and 8% fat by dry weight. The spent hops are dried and sold as hop manure.

RESEARCH AND CONSUMPTION

Scientific research in brewing has been going on for over a century but has intensified since World War II. This applies to North America, western Europe and particularly to the Brewing Industry Research Foundation in Britain. The larger brewing organizations also have research staffs. Work on raw materials is mainly carried out by agricultural institutes in close collaboration with the industry. In Britain, hop research is concerned with breeding palatable types of hops that are resistant to disease and with the chemistry of hop resins and oils. Barley research is directed to the production of barleys that malt well and can stand up to the vagaries of climate. Improved malting methods are being investigated and systems of continuous brewing are being developed that will have a substantial effect on capital outlay as regards plant, space and labour. Already the fermentation stage is being operated commercially and the ultimate aim is to streamline the whole process into one continuous operation. Other topics always under investigation are head retention, haze prevention and yeast behaviour, while such bodies as the European Brewery convention and the American Society of Brewing Chemists are working together to reach agreement on analytical methods.

Annual world consumption of beer is estimated to be about 8,500,000,000 U.S. gallons. In the United States beer is estimated to account for approximately 49% of the total alcohol consumed; in the United Kingdom this figure is 84.3% and in Canada 64.5%. On a per capita basis the greatest consumers of beer are Belgium (34 U.S. gallons annually), Luxembourg (33), Australia and west Germany (27), United Kingdom (22), Denmark and Austria (19), Switzerland and Canada (16) and the United States (15).

BREWSTER, SIR DAVID (1781–1868), Scottish physicist, is notable for his experimental work in optics and polarized light. He was born at Jedburgh on Dec. 11, 1781, and died on Feb. 10, 1868, at Allerby, Melrose. At the age of 12 he was sent to the University of Edinburgh to study for the ministry. He finished his theological course but his interest in science prevented him from pursuing this profession.

In 1799 he was induced by a fellow student to begin the study of the diffraction of light. He made his name by a series of investigations on this subject, the results of which he contributed from time to time to *Philosophical Transactions* and other scientific journals.

Brewster's most important studies concerned polarization, metallic reflection and light absorption. He formulated the rule governing polarization by reflection which states that light reflected from a glass surface is completely polarized when the reflected and refracted rays are perpendicular to one another. He discovered biaxial crystals.

Brewster was elected a fellow of the Royal Society in 1811 and was awarded the Rumford gold and silver medal for his discoveries in connection with the polarization of light in 1818. In 1816 he invented the kaleidoscope (*q.v.*). He improved the stereoscope by suggesting the use of lenses to combine the dissimilar binocular pictures. More important was his work in persuading the British authorities to adopt the dioptric apparatus, perfected by Augustin Fresnel, in their lighthouses. He suggested its use for this purpose as early as 1820.

Brewster was one of the group of scientific men who assembled in the archiepiscopal palace at York and developed the idea of a British Association for the Advancement of Science, realized in 1831.

In 1838 Brewster became principal of the united colleges of St. Salvator and St. Leonard, St. Andrews, Scot., and from 1859 till a short time before his death was principal of Edinburgh University.

In spite of his activity in research and, in his later days, in university life, Brewster accomplished a mass of literary work. He edited the *Edinburgh Encyclopaedia* (1808–30), was one of the leading contributors to the 7th and 8th editions of the *Encyclopaedia Britannica*, joint editor (1819–24) of the *Edinburgh Philosophic Journal*, and then (1824–32) editor of the *Edinburgh Journal of Science*. Among his many separate publications may be mentioned his *Treatise on Optics* (1831) and his *Memoirs of the Life, Writings and Discoveries of Sir Isaac Newton* (1855).

BREWSTER, WILLIAM (1567–1644), leader of the Plymouth colony in America, was born in England in 1567 and spent his early life at Scrooby, Nottinghamshire. He acquired his first Separatist ideas while at Peterhouse, Cambridge, which he attended for a short time, beginning in December 1580. In 1583 he became the personal secretary of William Davison, an Elizabethan diplomat. Because of disillusionment with diplomatic and court life and because of his father's illness, he returned to Scrooby in 1589 to become his father's deputy (and successor the next year) as bailiff and postmaster. At Scrooby he became the leader of the Puritan congregation that separated from the Established Church in 1606.

He and John Robinson were the leaders in the migration to Amsterdam in 1608 and the move to Leiden in 1609. In Holland he made his living by printing Puritan books by English authors and exporting them to England until pressure applied by the British government on the Dutch government forced the abandonment of his enterprise. He accompanied the first group of settlers on the "Mayflower" in 1620 and remained until his death one of the most important members of the Plymouth colony. Brewster, the only university-trained Pilgrim, was the real leader of the church as its senior elder, and he dominated the formulation of its doctrines, worship and practices. He was not a magistrate, but the governor, William Bradford, was so dependent upon him and so attached to him that he played a major role in civil as well as religious affairs.

This "wise and discrete" man of "cherfull spirite, tender hart! peaceable disposition, inocent life," and "plaine and distinct" teaching left an indelible mark on the first successful colony in New England. He died at "New Plymouth" in April 1644.

(RA. MU.)

BRÉZÉ, the name of an Angevin noble family eminent in French history. PIERRE DE BREZE (1410?-1465) was one of the trusted soldiers and statesmen of Charles VII. He had made his name as a soldier in the English wars; and in the Pragerie (*q.v.*) he supported the royal cause against the dauphin Louis and the rebels, a service which was remembered against him after Louis's accession to the throne. He was made seneschal of Anjou in 1437 and of Poitou in 1441. He fought against the English in Normandy in 1440-41 and in Guienne in 1442. He became chamberlain to Charles VII and gained the chief power in the state through the influence of Agnès Sorel (*q.v.*). The six years of his ascendancy (1444-50) were the most prosperous period of Charles VII's reign. The dauphin Louis in 1448 brought against him accusations which led to a formal trial, resulting in a complete exoneration of Brézé and his restoration to favour. He played a large part in the reconquest of Normandy (1449-51), especially in the battle of Formigny, and became seneschal of the province in 1451, after Agnès Sorel's death and the consequent decline of his influence at court. He made an ineffective descent on the English coast at Sandwich in 1457 and was preparing an expedition in favour of Margaret of Anjou when the accession of Louis XI brought him disgrace and a short imprisonment. He accompanied Margaret to Scotland with a force of 2,000 men in 1462 and brought her back to Flanders on the collapse of her plans in 1463. He was reappointed seneschal of Normandy and fell in the battle of Montlhéry on July 16, 1465. He was succeeded as seneschal by his eldest son JACQUES DE BREZE (*c.* 1440-90), comte de Maulévrier; and by his grandson LOUIS DE BRÉZÉ (d. 1531), husband of the famous Diane de Poitiers. This branch of the family became extinct in the 16th century.

Bernus, *Le Rôle politique de Pierre de Brézé au cours des dix dernières années du règne de Charles VII* (1908), *Louis XI et Pierre de Brézé* (1912) and *Notes sur la famille de Brézé* (1912). See also the chronicles of Pierre's secretary, Georges Chastellain, ed. by Baron H. Kervyn de Lettenhove, 8 vol. (1863-68).

The lordship of Brézé itself had been from the 14th century in the hands of another branch, the house of Maillé-Brézé, whose most eminent members were URBAIN (1597-1650), marshal of France, and his son ARMAND (1619-46), grand admiral. At Armand's death the lordship passed to his sister, CLAIRE CLÉMENCE, wife of the great Condé. She sold it to Thomas Dreux, who took the name of Dreux-Brézé when it was erected into a marquisate (1685). HENRI ÉVRARD (1762-1829), marquis de Dreux-Brézé, became master of the ceremonies to Louis XVI in 1781. On the meeting of the estates-general in 1789 it fell to him to regulate the questions of etiquette and precedence among the three estates. His delay in notifying the third estate that Louis XVI was to hold a "royal session" was the cause of its famous meeting in the Jeu de Paume (tennis court) at Versailles on June 20, when it found the room that it usually occupied full of workmen preparing for the king's visit (see FRANCE: History). In 1792 Brézé emigrated to Italy for a short time. At the Restoration he was made a peer of France and resumed his functions as guardian of an antiquated ceremonial. He died on Jan. 17, 1829, when he was succeeded in the peerage and at court by his son SCIPION (1793-1845).

BREZINA, OTAKAR (pseudonym of VACLAV IGNAC JEBAVY) (1868-1929), one of the greatest of Czech poets, was born at Počátky, Bohemia, on Sept. 13, 1868. He spent most of his life as a schoolmaster in Moravia, isolated from the political and literary movements that influenced the work of many of his contemporaries. His lasting poetical achievement is contained in a lyrical cycle of five books: *Tajemné dalky* ("Secret Distances"; 1895), *Svitání na zapade* ("Dawn in the West"; 1896), *Vetry od polu* ("Polar Winds"; 1897), *Stavitelé chramu* ("Builders of the Temple"; 1899), *Ruce* ("Hands"; 1901). Earlier poems, written under the pseudonym "Vaclav Dansovsky," are of less account. After completing the cycle he wrote only 13 more poems and a few

essays. He died at Jaromerice, Moravia, on March 25, 1929.

Starting from a position of metaphysical pessimism reminiscent of Schopenhauer, Brezina advanced to a positive love of humanity and acceptance of life. Nietzschean concepts played some part in this development, but the final synthesis is by no means derivative. It represents an original poetic vision of great power, the product of a deeply religious but unorthodox mind. Further light is cast on his intellectual and spiritual development by his correspondence with the philosophical essayist Anna Pammrová. In form Brezina's verse moved from regular, largely trochaic stanza forms to free rhythms with a marked dactylic tendency. His influence on the formal development of later Czech poetry was considerable.

BRIALMONT, HENRI ALEXIS (1821-1903), Belgian soldier and military engineer, the leading European fortification engineer of the late 19th century, was the son of Gen. Laurent Mathieu Brialmont (d. 1885). He was born at Venlo, Limburg, on May 25, 1821. Educated at the Brussels military school, he entered the army as sublieutenant of engineers in 1843, becoming lieutenant in 1847. In 1853 he entered the staff corps, and became major general in 1874. He was then made director of fortifications in the Antwerp district, and in 1875 he became inspector general of fortifications and of the corps of engineers. He retired in 1886 and died on June 21, 1903.

At first Brialmont's plans followed with but slight modification the ideas of Sébastien de Vauban, and his original scheme for fortifying Antwerp provided for both *enceinte* and forts being on a bastioned trace. But in 1859, when the great entrenched camp at Antwerp was finally taken in hand, he had already gone over to the school of polygonal fortification and the ideas of Charles de Montalembert. About 20 years later Brialmont's own types and plans began to stand out amid the general confusion of ideas on fortification that naturally resulted from the introduction of long-range guns and from the events of 1870-71. The extreme detached forts of the Antwerp region and the fortifications on the Meuse at Liège and Namur were constructed in accordance with his principles, viz., lavish use of armour to protect the artillery inside the forts, suppression of all artillery positions open to overhead fire, and multiplication of intermediate batteries. See also FORTIFICATION: *Permanent Fortifications*.

BRIAN (941-1014), king of Ireland from 1002 to 1014, was known as Brian Boru from the ford, Béal Boruma, on the river Shannon near Killaloe, beside which he was born. He was a younger son of Cennedig (d. 951), ruler of a small state, later called Dal Chais, which grew strong during the 10th century through its persistent efforts to expel from its territory the Danes who had settled at Limerick (922). The vikings established on the river Suir (916) had been less successfully challenged by the Eoganachta rulers of Munster, who thus grew progressively weaker, and Brian's half brother, Mathgamain (d. 976), was able to occupy the rock of Cashel (964) and become king of Munster.

Brian became successor and avenger of Mathgamain, mysteriously murdered in 976 by the Eoganachta septs who resented his usurpation. Brian was a leader of high capacity, hardened by experience on the battlefield, and he destroyed first the Eoganachta and then the Northmen, constructing a fleet to drive them from the Shannon. He was also remarkable as a diplomat, and under his rule Munster became a unified and powerful state. Brian invaded Ossory (983) and thus began a duel lasting nearly 20 years with the high king Maelsechlainn II. He won control of the southern half of Ireland from Maelsechlainn (997), replaced him as high king (1002), and in due course received the submission of every lesser ruler. The men of Leinster and the Northmen of Dublin united against him in 1013, enlisting help from abroad, especially from the earldom of the Orkneys and from the Isle of Man. The decisive battle was fought at Clontarf, beside Dublin, on April 23, 1014; Brian was too old to take an active part, and his forces were commanded by his son, Murchad, who achieved victory after a 12-hour struggle. A little group of Northmen,

flying from the battlefield, stumbled on Brian's tent, overcame his bodyguard and hacked the aged high king to death. He was buried in the chief church of the nation, that of St. Patrick in Armagh. His fame as the victor of Clontarf and as a ruler of outstanding ability and energy was so great that the princes descended from him, the O'Briens, subsequently ranked as one of the chief dynastic families of the country.

BRIANCHON, CHARLES JULIEN (1783–1864), French mathematician who was born at Sèvres, France, on Dec. 19, 1783, and died at Versailles, France, on April 29, 1864. He was educated for a military career at the École Polytechnique, where he gained first place in his class (1804), and at Metz (1806). While still a student he published (1806) the theorem by which he is known in treatises on conics and in histories of mathematics: joins of pairs of opposite vertices of a hexagon circumscribed about a conic are concurrent. This is obtainable as the dual of Blaise Pascal's theorem, and Brianchon discovered it thus. As an artillery officer in Napoleon's armies, Brianchon was distinguished for courage and ability, particularly in the Peninsular campaign. The rigours of field service affected his health and in 1813 he sought a professorship in the artillery school, which he obtained in 1818. His principal works were a memoir on curves of the second order (1808) and one on transversals. (E. T. B.)

BRIAND, ARISTIDE (1862–1932), French statesman, 11 times premier of France and winner of the Nobel peace prize in 1926: was born at Nantes, March 28, 1862. As a law student he became associated with advanced movements in politics, writing articles for *Le Peuple* and for some time directing the *Lanterne*. From this he passed to the *Petite République*, leaving it to found, with Jean Jaurès, *L'Humanité*. At the congress of working men at Nantes in 1894 he secured the adoption of the general strike idea against the adherents of Jules Guesde, and became one of the leaders of the French Socialist party. In 1902 he was elected deputy and occupied himself with the question of the separation of church and state. He was appointed *rapporteur* of the commission charged with the preparation of the law and succeeded in carrying his project through with but slight modifications. He accepted the portfolio of education and religion in the Sarrien ministry (1906) so that he might apply the law for which he was largely responsible. Acceptance of a portfolio in a bourgeois ministry led to his exclusion from the Unified Socialist party (March 1906). As opposed to Jaurès, he contended that the Socialists should co-operate actively with the Radicals in all matters of reform. In Oct. 1906 Georges Clemenceau formed his first government, and in it Briand remained minister of education and religion. There were certain difficulties in the application of the Separation law due to the hostility of the Vatican. It was then that Briand gave proof of his essential liberalism. Though he held fast to the principle of the new legislation, he made possible the carrying on of the rites of the Roman Catholic Church under the laws as to associations and public meetings. In Jan. 1908 he was appointed to the ministry of justice.

When the government of Clemenceau fell in July 1909 Briand formed his first cabinet, himself taking the portfolio of home affairs and religion. He announced that he would adopt a policy of national understanding and tranquillity. In Oct. 1910 there was a threat of a general strike on the railways. Briand mobilized all the railwaymen who were still subject to military service, dismissed those who disobeyed and had the members of the strike committee arrested. A majority in the chamber approved his action, but it was bitterly condemned by the left wing, and the government resigned on Nov. 2, 1910. Briand immediately formed a new cabinet, of a more radical tendency than its predecessor. In Feb. 1911, when he was accused by the Radicals of failing in the strict application of the law with regard to religious houses, his majority fell to six and he resigned. After some months out of office, he became minister of justice in Raymond Poincaré's first cabinet on Jan. 13, 1912. When Poincaré was elected president

of the republic in Jan. 1913, Briand succeeded him as premier. His most important work was to lengthen the period of military service from two to three years as a rejoinder to the increase in German armaments. On March 18, 1913, on the question of proportional representation, which he supported, he was overthrown by the senate.

Briand remained in retirement until the outbreak of World War I. On Aug. 26, 1914, René Viviani offered Briand the portfolio of justice. On the fall of Viviani, Briand on Oct. 29, 1915, formed a government in which he himself took over the direction of foreign affairs in a national coalition. By the end of the autumn of 1916, the Rumanian disaster, and especially the situation in Greece, made him the object of attacks. The question of the higher command was also causing much anxiety. At this time Joseph Joffre, who had been made a marshal, was replaced by Gen. Robert Georges Nivelle. Briand thought it advisable for all these reasons to reform his cabinet. He appointed Gen. Hubert Lyautey minister for war, and called in experts who were not in parliament to take charge of the more technical offices. On March 14, 1917, Lyautey resigned, and after a vain attempt to reform his government, Briand decided to resign.

For three years Briand took scarcely any part in public affairs. In Jan. 1921, on the fall of the Georges Leygues ministry, he was called upon to form a government, and himself took charge of foreign affairs. He interested himself particularly in the application of the treaty of Versailles, especially with regard to reparations. In the autumn he went to Washington, D.C., as the French representative at the conference on naval disarmament. He was fiercely attacked by those who accused him of having failed to safeguard the interests of his own country. This campaign reached its height when, early in 1922, the Inter-Allied conference met at Cannes, France, and Briand discussed with David Lloyd George the question of an Anglo-French mutual defense treaty. A telegram which he received from Alexandre Millerand, then president of the Republic, decided Briand to return to Paris and confront his enemies. When he arrived he realized that his position had become untenable. He announced his resignation to the chamber on Jan. 12, 1922.

In April 1925 he was offered the portfolio of foreign affairs in Paul Painlevé's cabinet, and he remained in the same office in the second government formed by this leader in October. The Locarno agreement in Oct. 1925 enormously increased the influence of Briand, who had played an important part in the negotiations. When Painlevé resigned on Nov. 22, Briand led the government. On March 6, 1926, Briand's ministry fell, the chamber having thrown out a financial measure which he considered necessary. He accepted office again, but the situation became more and more difficult because of the financial crisis and the continued depreciation of the franc. The government fell on June 15. But, once again, Briand reconstructed the ministry and brought in Joseph Caillaux as finance minister. A month later, on July 17, the ministry was again defeated, the chamber refusing to grant the special powers demanded for dealing with the financial problem. Boudard Herriot's ministry, which succeeded it, lasted only a few days and fell on July 21, 1926. Poincaré formed a coalition government in which Briand again became minister for foreign affairs. In this position for the following five and a half years (until Jan. 12, 1932) he continued to direct the foreign policy of France on the basis of European consolidation and reconstruction and acquired great influence within the League of Nations. He received the Nobel peace prize, as did the two other principal signatories of the Locarno treaties, Austen Chamberlain and Gustav Stresemann. Among postwar statesmen he was the firmest supporter of the idea of bringing about the renunciation of war as an instrument of national policy, and the antiwar treaty signed in Paris on Aug. 27, 1928, known as the Kellogg, or Briand-Kellogg, pact (see WAR). From July 27 to Oct. 22, 1929, he presided over his last (11th) cabinet.

Briand died in Paris on March 7, 1932.

A great parliamentarian, although he broke with the extreme left wing in 1906, he retained his connection with many of the more advanced political thinkers. His liberal ideas and his con-

stant endeavours toward national unity gained him the sympathy of the moderate parties. His ease and animation as a speaker, his parliamentary experience and his well-known ability in the conduct of foreign affairs all contributed to that great influence which made him, up to that time, premier more often than any other politician in France.

BRIAREUS (AEGAEON), in Greek mythology, one of three 100-armed, 50-headed Hecatoncheires (name derived from the Greek words for "hundred," "hands" and "arms"), the sons of Uranus and Ge (Heaven and Earth). According to one legend, Briareus and his brothers were called by Zeus to his assistance, when Olympus was attacked by the Titans. The latter were defeated and thrown into Tartarus, the brothers being set to guard them. Other accounts make Briareus an opponent of Zeus and one of the assailants of Olympus, who, after his defeat, was buried under Mt. Etna. Another tradition makes him a giant of the sea, an enemy of Poseidon and the inventor of warships. The Hecatoncheires may represent the gigantic forces of nature which appear in earthquakes and other convulsions, or the multitudinous motion of the sea waves. While W. H. Roscher sees in them a reference to the polypus, which often attained a great size.

BRIBERY, a penal offense generally defined as the giving or receiving of consideration for official favour. Particular statutes vary regarding the kinds of officials covered, the kinds of consideration covered and the severity of the penalties authorized. The crime is typically punishable as a felony, and the offending official may be declared ineligible to hold office.

At an early stage of the law's development, only officials authorized to decide or to vote on matters pending before them were encompassed: other public servants, denominated "ministerial," were excluded on the theory that the evil to be dealt with was subversion of discretion, whereas ministerial employees have little or no discretion. The practical significance of this distinction was that one would not be guilty of bribery for giving tips, fees or presents to minor functionaries to induce them to perform their duties. Modern bribery legislation is usually drafted to cover all public employees. Sometimes this legislation, in its application to minor functionaries, is restricted to consideration given to induce the official to "violate his duty," thus also excluding the tipping situations referred to above. Special provisions have also been enacted to punish bribery of voters, jurors, witnesses and other lay participants in official and political proceedings. Finally, a number of codes penalize bribery in designated classes of private or commercial transactions; e.g., bribery of labour union officials by employers.

As to the nature of the consideration which it is criminal to give or receive, the main issue is whether to limit bribery to cases where money or property is the inducement or to extend the crime to cases where "any benefit or advantage" is conferred or promised. Most statutes are of the latter form. It has been observed that few legislative or executive compromises could stand if such a principle were applied. The California Penal code, among others, does not leave the matter in doubt: authorizing imprisonment up to 14 years, for example, for any legislator who gives his vote in consideration of a reciprocal commitment from a fellow legislator. Needless to say, criminal prosecutions of this character are virtually unheard of, but there are occasional reports of civil proceedings challenging an official's right to hold office on this ground.

The statutes defining bribery frequently include an element of "corrupt" purpose. This does not mean that a defendant can avoid conviction by proving that the decision which he sought to buy was a proper one that the official should have given in any event, since the gist of the offense is the exertion of improper influence on decision-making. On the other hand, giving a gift or tip to a civil servant out of general friendship or gratitude and without intent to influence his official behaviour is not punishable as bribery, although it may be prohibited under the corrupt practices legislation. (L. B. S.)

In English law, the legislation relevant to bribery is contained in three statutes, namely the Public Bodies Corrupt Practices act, 1889, the Prevention of Corruption act, 1906, and the Prevention of Corruption act, 1916, collectively known as the Prevention of Corruption acts, 1889-1916; and, as to bribery at elections (including paid entertainment and undue influence), in s. 99 of the Representation of the People act, 1949. Of the former group of statutes, the first deals with corruption in municipal affairs, the second with the bribery of agents and others in business affairs and the 1916 act increases the maximum penalty in certain cases and provides that corruption shall be presumed, unless the contrary be proved, where some consideration has been given to a person in public employment by a person holding or seeking to obtain a contract with the employing authorities.

BRICK, a small rectangular unit, usually of burnt clay. used in the construction of foundations, walls, piers, buttresses and arches of buildings and other structures, and of the ducts, flues, linings and chimneys of furnaces. (See BRICKWORK; FURNACE, METALLURGICAL.) By massing bricks in quantity, with mortar joints, in definite patterns or bonds, greatly varied forms of construction can be erected, having massive or delicate proportions as required, to carry loads, to provide screens or protection against the weather or to resist the action of heat.

Throughout their long history bricks have varied greatly in size. Although today the term brick is usually associated with a unit approximately 8-9 in. long by 3-4 in. wide by 2-3 in. deep, the larger hollow clay units, invented in the middle of the 19th century and quite widely used for building in Europe and the United States, can be considered to be a development of the brick. The raw material from which these larger units are made and the processes used for their manufacture are similar to those described for bricks below. Again, although some refractory bricks for special high-temperature furnaces are made from materials other than naturally occurring clay, all refractories are made by one or other of the processes described for building bricks, and they are burned in similar kilns. (See FIREBRICK.)

On the other hand, a few building bricks are made from a mixture of sand and hydrated lime pressed together in a high pressure press and subsequently autoclaved; sand-lime bricks and concrete bricks have not been considered in detail in this survey of bricks and brickmaking.

History.—The history of the brick goes back to the earliest days of civilized man. By some it is averred that bricks were made more than 10,000 years ago; and although such great antiquity cannot yet be proved, certainly archaeologists working at the site of Ur of the Chaldees, the city of Abraham in the valley of the Euphrates, have accurately determined that the burnt and unburnt bricks in the lower levels of the great ziggurat or moon temple were made more than 5,000 years ago. It is probable that the Tower of Babel (for which, in the words of the Old Testament, "And they had bricks for stone, and bitumen for mortar") was another of these great brick temples raised above the surface of the flat river valley. Successive civilizations in the Euphrates-Tigris delta used clay bricks for building their houses, palaces and temples; and many of the original bricks, such as those used in the 6th century B.C. to build Nebuchadrezzar's great city of Babylon were later taken from the ruins to build the modern towns of Ctesiphon and Baghdad.

From western Asia the art of brickmaking appears to have spread westward toward Egypt and the Mediterranean and eastward to India and China. Beautiful examples of ancient bricks are to be seen in the Paharpur temple in eastern Bengal (now in Pakistan). Built in the 8th and 9th centuries of small bricks set in mud mortar, the walls are decorated with rows of terra-cotta plaques of considerable artistic merit. This interesting 20th-century discovery shows that the art was not lost throughout the world while Europe was passing through the dark ages.

In Egypt there are many examples of bricks made in the earliest and subsequent dynasties. Often their surfaces were impressed by the seals of the kings for whom they were made, and by these

their date can be established. Although many of the tombs and temples of Egypt were built of stone, most houses and some palaces, temples and tombs, such as the stepped pyramid of Saq-para, were built with both sun-dried and kiln-burnt bricks.

From Egypt brickmaking spread throughout the eastern Mediterranean to Rome, whose legionaries carried the art throughout the Roman empire. It flourished in England in the 3rd and 4th centuries A.D. until with the descent of the dark ages it fell into disuse not only in England but throughout Europe. It was revived in the 12th century, first in Italy and a little later in France, Germany and Flanders. Some bricks began to come into England from Flanders (the word "brick" is of Flemish origin) in the latter half of the 14th century, and by the beginning of the 15th century brickmaking was once more a native industry. The brick castles of Hurstmonceaux in Sussex (c. 1450) and Tattershall in Lincolnshire (c. 1440) and the smaller manors of Shirburn lodge and Stonor park in Oxfordshire (both c. 1420) are among the earliest English medieval brick buildings. The Tudor, Jacobean and Queen Anne brickwork, which is so well suited to the countryside and climate of England, laid the foundations of a tradition for fine brickwork that has continued unbroken to the present day.

Bricks were first made in America in about the middle of the 17th century, but it was not until the latter half of the 19th century that the industry began to expand, when English machine makers went there to seek a market.

The Raw Material.—Most building bricks are made from clay, the product of the breakdown of rocks by weathering and other destructive agencies. Clays suitable for brickmaking are distributed very widely throughout the world. In Great Britain they are to be found in almost all the geological systems from the Devonian to the Pleistocene; in the U.S. clays suitable for brickmaking exist in 45 states. Most natural clays are complex mixtures of one or more of the clay minerals with salts of common elements such as iron and calcium: the proportions of the various clay minerals and presence of these impurities not only dictate the quality and appearance of the finished product but also the process involved in brickmaking and burning. (See also ADOBE.)

Brickmaking.—Until machinery was introduced in the mid-19th century, it was necessary to dig the clay in the early autumn and pile it in heaps so that the winter weather would render it fit for forming by hand-molding into brick shapes. In the spring the clay was dug down from the heaps, spread on the ground, watered and then tempered by being trodden by men's feet until a suitable consistency was reached. The soft plastic clay was then thrown into molds to form the shape of the brick.

Although the seasonal digging of the clay and its weathering in heaps is still practised in some small works where clays of recent geological ages are used, this old method was superseded in the 19th century by the pugmill. The original pugmill consisted of a large wooden tub without heads, set upright on the ground and furnished with an iron spindle at the axis, carrying

knives which cut and compressed the clay to force it through the tub and extrude it through a hole cut in the side or bottom.

From the latter half of the 18th century many attempts were made to mechanize the old manual process of filling molds but, although soft-mud machine-molded bricks were made in the United States as early as 1833, none of the earlier attempts to reproduce hand molding by machine appear to have been successful in England. There mechanization followed the development of the pugmill. By the middle of the 19th century a horizontal version of the pugmill was developed, and the plain rectangular opening from which the clay emerged from the crude pugmill was replaced by properly designed dies. The column of clay emerging from the die was then cut off to brick size by a wire in the manner of a grocer cutting cheese, and bricks so made became known as wire-cuts.

The Wire-Cut Process.—In the early days of brickmaking, surface clays only were used, but with the increase of population and industry following the Industrial Revolution, it became necessary, particularly in the north of England and the midlands, to work the harder clays of earlier geological age. In order to break down drier and harder clay it was crushed by passing it between pairs of heavy cast-iron rollers mounted above the hopper of the pugmill; and to make it plastic it was mixed with water in trough mixers having one or two long shafts fitted with knives to chop the clay and carry it along the mixer.

Another type of grinding machine, known as the wet pan, has been added to the train of grinding equipment in the 20th century. It consists of a large flat-bottomed cast-iron dish from 7 to 9 ft. in diameter, with sections of the bottom perforated with holes or slots. A vertical shaft in the centre carries heavy cast-iron rollers on the two ends of a horizontal cross shaft. These two heavy rollers, sometimes called edge runners, are carried rapidly round and round the pan, and crush the clay thrown into it, forcing it gradually through the perforations in the pan bottom.

A later development in the wire-cut process was that of de-airing the clay in the pugmill. Earlier it had been an approved practice to interrupt the flow of clay, to rest or "age" it just before it entered the pug machine. It is thought that this may have given time for the continued diffusion of water along the cleavage lines of the minute clay crystals, and that it allowed some bacterial action to assist in further wetting of the dry internal surfaces. In about 1930 it was found that removing the air under a vacuum of from 15 to 29 in. gives similar, or even better, results, and this at less cost and with less interference with production. De-airing reduces laminations in the brick, increases workability and plasticity and promotes greater strength in the green and fired products.

The cutting-off table has also been developed far beyond the original simple wire. Cutting off is now usually automatic, and often the bricks are taken off the table and loaded by machinery onto the pallets used to transport the comparatively soft green bricks to the drying plant.

About one-third of all the bricks made in Great Britain are wire-cuts; and the process is also very widely used in all European countries, in South Africa, in Australasia and in North America, where the stiff-mud process, as it is called, dominates the market.

The Semidry Process.—Toward the end of the 19th century the semidry process for making bricks from hard, almost dry, clays and shales was devised. The clay is ground without added water in a dry pan of construction similar to the wet pan described above, but in which the pan revolves, and the horizontal shaft carrying the two heavy grinding rollers is stationary; the inner ring of the pan base plate, on which the rollers revolve, consists of solid or "dead" plates, but the outer ring, annular in shape, consists of cast-iron plates perforated with fine holes. The dry clay is ground on the solid part of the pan bottom and is thrown by centrifugal force onto the outer perforated plates, so that the finely ground clay particles fall and are screened through the holes in the pan grids. After leaving the dry pan the powdered clay is again screened, and the finest portion is passed to the hopper of a powerful press. From the hopper an automatically measured portion

BY COURTESY OF STRUCTURAL CLAY PRODUCTS INSTITUTE

FIG. 1.—FORCED FROM THE PUGMILL THROUGH A DIE, A COLUMN OF CLAY PASSES ALONG THE CUTTING TABLE

is fed into strong steel molds with movable plungers operating from the bottom and the top of the mold. The plungers, actuated either by cam, lever or toggle motion, or in some cases by hydraulic power, press the clay particles together until they coalesce into the form of a brick. The bottom plunger then pushes the pressed brick upward out of the mold, and the hard green brick is ready for drying and firing in the kiln.

The Fletton Brick.—The semidry press method of manufacture has been used successfully for the treatment of a number of different types of clay and for different products, including building bricks, hard paving bricks, refractory bricks and floor tiles, but it is probably best known as the method used for the manufacture of fletton bricks. These were first made in about 1880 at the village of Fletton near Peterborough, Northamptonshire, from the lower Oxford clay, a material with a natural moisture content and a hard and shale-like consistency that are ideal for the semidry process. In addition to these useful properties, the lower zones of the Oxford clay contain carbonaceous material which under efficient firing control can supply most, if not all, the heat required to dry and fire the bricks. The clay in the neighbourhood of Peterborough and Bedford occurs as deep uniform deposits, and the fletton industry is today organized on a highly mechanized mass-production basis.

The common fletton brick was for many years the staple building brick of London, and many different types of face (or facing) bricks were introduced after about 1930. They were produced at such a low cost that they could compete with bricks made by the plastic processes in areas far from the centres of the fletton industry, and in the early 1960s more than 40% of all the bricks made in England were of the fletton type.

Stiff-Plastic Process.—The stiff-plastic process of brickmaking is intermediate in character between the plastic wire-cut and the semidry processes. The shale or clay is ground in a dry pan and moistened in a horizontal mixer until it contains about 12% of water. The moistened clay is fed into a short vertical pugmill from which it emerges as an immature clot. This clot drops into a finishing mold of a mechanical press where it is pressed into its final form ready for setting in the kiln.

Nearly one-third of all the bricks made in England are from stiff-plastic plants. The process is particularly popular in the north of England and in Scotland for the manufacture of hard, strong and dense common face bricks. It is also quite widely used for firebricks and high-quality engineering bricks requiring great strength.

Hand-Molding.—Some bricks are still hand-molded in the old manner. The clay, either weathered or broken down in a wet pan, is pugged as in the wire-cut process, but the soft plastic clot of clay is rolled by hand in sand and is then thrown into a sanded or natered wooden stock or mold. When turned out onto a pallet the brick shows richly sanded surfaces on all sides.

Although only about 5% of the bricks made in England in the early 1960s were hand-molded, the method is still used to make some face bricks found in the south and east of England; these are renowned for their variation and beauty and add delightfully to the appearance of English brick buildings of all ages. The wooden mold, or stock, lent its name to London stock bricks, with which so much of Regency and Victorian London was built. London stocks are made in Kent and Essex from a mixture of brick earth and washed chalk, and some are still hand-molded. Hand-molding is also still favoured by many manufacturers of firebricks, which are of such great importance to the manufacturing trades of all countries in which high-temperature furnaces are employed.

Full-Plastic Process.—The mechanical imitation of hand-molding was developed in the middle of the 19th century in the United States, where it is known as the soft-mud process. The brickmaking machine consists of a horizontal or vertical pugmill that extrudes very soft and plastic clay over a composite mold with compartments for 3–12 bricks which are located side by side in one frame. The washed and sanded wooden molds are fed in at the side of the machine, and a vertical plunger presses the clay into them. The set of molds is then automatically pushed forward, the surplus clay is struck off and the filled molds are jolted

to consolidate the clay. In some machines the bricks are automatically expelled onto pallets. Although the full-plastic process is employed at only a few works in England, it is quite widely used in the Hudson river valley in the United States, and in the Netherlands.

The Drying of Bricks.—Bricks molded by hand and those formed by the full-plastic and wire-cut processes are comparatively soft and weak when they are formed, so that it is necessary to dry them before they can be stacked in a kiln for firing. Even if, as in the case of stiff-plastic and semidry bricks, they are strong enough to be set directly in the kiln, it is still necessary to dry them at least partially to remove the shrinkage water before subjecting them to high temperature.

In the early days of brickmaking all bricks were dried naturally by the sun and air; open-air drying, or hack drying, as it is now called, is still employed in some seasonal works in England, on the continent of Europe and in tropical undeveloped countries. The molded bricks are set on edge in long single rows (or hacks) 8–10 bricks high; they are protected from rain and wind by pent-shaped covers and side boards.

Labour costs, loss by storms and damage by handling render this system more costly than it would seem, and since considerable space is also required, hack drying is being superseded by artificial drying in most industrial countries.

Hot-Floor Drying.—In the 19th century, when open-air drying was found to be too slow and too erratic for the rapidly growing brickmaking industry in the midlands and the north of England, hot-floor drying was developed. As its name implies, the dryer consists of a heated floor in which the green bricks are set. The floor is built inside a shed which protects the bricks from the weather, but which, at the same time, allows the evaporated water to escape. The floors, which are of steel, cast iron or concrete, may be heated by coal or coke fires, or by steam passing through pipes below the floor.

While this method of drying is more certain and less costly than hack drying, the hot floor is considered to be thermally inefficient. There are, however, many hot-floor dryers in use.

The Tunnel Dryer.—In order to speed up the drying still more, the tunnel dryer was developed both in the United States and in Europe in the late 19th century. The modern tunnel dryer consists of one or a series of tunnels, usually about 6 ft. square in cross section, and from 80 to 100 ft. long. Cars, carrying the green bricks either directly or on pallets, are pushed at regular intervals through the tunnel. The bricks are dried by hot air, which can either pass longitudinally through the tunnel from the exit end toward the entrance, or can be forced transversely from one side to the other. The use of saturated air to heat the wet bricks before removing any moisture, known as humidity drying, is essential for fast-drying practices. For this it is arranged that the air meeting the bricks at the entrance, where they are wet, is saturated with water; as a given brick proceeds along the tunnel it encounters progressively drier air.

Chamber Dryers.—Chamber dryers are also widely used throughout the world. They consist of a series of adjacent chambers, often about 9 ft. high by 5 ft. wide and up to 80–100 ft. long; on the continent of Europe they are often built above kilns to take advantage of waste heat. Whereas in tunnel dryers the bricks pass steadily through the dryer, in chamber dryers the bricks are left in the position in which they are set until they are dry. They are sometimes placed in the chamber on trucks, but more often special finger cars transfer loaded pallets of green bricks from the brickmaking machine to the dryer racks. The chambers are usually heated by hot air which has passed over steam pipes below the floor of the dryer, but sometimes hot air is taken from the cooling zone of a kiln associated with the dryer. Modern chamber dryers also adopt the principle of humidity drying; the humidity and temperature of the drying air and, therefore, the rate of drying being adjusted as drying proceeds.

The Burning of Bricks.—The resistance of building bricks to the action of weather, the resistance of refractories to heat, their strength, their colour and other essential properties are imparted to green clay by burning or firing the bricks in kilns to a tempera-

ture approaching the vitrification point of the clay of which they are composed.

There are many different types of kilns in use in the industry. In some the hot gases which burn the bricks flow upward; in others they are drawn downward. In some the bricks are stationary during firing; in others they pass through a fixed furnace or heating zone. It is convenient here to make a broad distinction between the types that are intermittent in operation and those that are continuous.

Intermittent Kilns.. Updraft Scotch Kilns.—From the earliest days brickmakers have used small brick-built ovens, in which the necessary heat is produced by burning wood or coal in furnaces below the bricks. Kilns of this type are now known as Scotch kilns, and a few are still in use. They consist of four permanent brick walls which are perforated at intervals with fire holes or grates from which hot gases pass into the kiln and flow upward through the bricks by buoyancy. The kiln is not roofed and as might be expected, the fuel consumption is high and control is difficult.

Downdraft Kilns.—The downdraft kiln is much more advanced and is very generally used in the United States and in Great Britain, particularly for the firing of face bricks, engineering bricks and refractories. Some are circular in plan with domed roofs, while others are rectangular, usually with arched roofs. The kilns are permanent brick structures, and the walls are pierced with a number of fire holes or furnaces, the gases from which, on entering the kiln, are forced to pass up over the bricks and then down through them to underground flues leading to a small chimney. Although, since there is no heat recovery the fuel efficiency is not high, the temperature distribution within the kiln chamber is very uniform, and the quality of materials produced in a downdraft kiln is high. It is comparatively easy to control the kiln atmosphere (and hence the colour of the fired bricks) by adjusting the air flow through the fire holes. In order to increase fuel efficiency a number of these kilns are sometimes linked together with flues so that waste heat from cooling kilns can be used to preheat air for drying or for combustion in other kilns that are being fired. Mechanical stokers also give improved fuel consumption.

Clamp Burning.—A method of burning bricks in what are called clamps in England and scove kilns in the U.S. was devised toward the beginning of the 19th century. Clamps are still used quite widely for burning London stock bricks and some face bricks in the south of England, and they are common in northern France

BY COURTESY OF STRUCTURAL CLAY PRODUCTS INSTITUTE

FIG. 2.— DOWNDRAFT OR BEEHIVE KILN

FIG. 3.— PLAN AND CROSS SECTION OF A HOFFMANN KILN

and Belgium. Clamps are large heaps of bricks stacked systematically as closely as possible. In England they are built of various sizes holding from 100,000 to 1,000,000 bricks and generally about 10–12 ft. high; on the continent of Europe they are much larger and higher, and may contain as many as 3,000,000 bricks. In the United States scove kilns are built inside a permanent shed, and the pattern of brick setting is somewhat different from that in Europe.

The fuel for burning is usually incorporated in the clay mix, with a certain variable amount sprinkled between the layers of bricks. Fires are started in small channels at the bottom and serve to ignite the fuel in and between the bricks. When once the fire has started in the bottom courses no more stoking is needed, and the heat spreads gradually throughout the mass. The fuel is economically applied but the results are uncertain and dependent on weather conditions; waste by over- and underburning is always considerable.

Continuous Kilns.—As the cost of fuel rises, so does it become more important to use kilns of high efficiency, and today most building bricks and many refractories are burnt in one or other of the two principal types of continuous kilns. These are described below.

The Hoffmann Kiln.—The Hoffmann ring kiln consists of a tunnel of brick construction (originally circular in plan but later distorted into an ellipse) built as a continuous ring with an arched brick roof. Openings or wickets pierce the outer walls to give access to the tunnel, and flues controlled by dampers lead the gases of combustion from the burning bricks to a tall chimney which provides the draft for operating the kiln. In its modern form as the transverse arch Hoffmann, the ring tunnel has been replaced by a series of separate, but side-by-side, chambers, each about 15 ft. wide and up to about 80 ft. in length. Each chamber is spanned by its individual brick arch. A single fire kiln usually has about 16 chambers, 8 on each side of a large flue or smoke chamber leading to the central chimney. Trace holes in the separating walls allow the gases to pass from one chamber to the next, the flow of the gases being determined by the opening or closing of dampers leading to the smoke chamber.

Once the kiln has been filled with green bricks and the fire started in one chamber, the fire front moves forward at the rate of about one chamber per day. When the burnt bricks have cooled they are drawn from the chamber, which is then reset with green bricks, so that in about 16 days the fire travels through the complete circuit of the kiln and continues to do so for as long as is required.

The air needed for combustion enters the kiln at or near the chamber that is being drawn and passes through several chambers of cooling bricks via the trace holes in the walls between chambers. In doing so the air picks up heat from the cooling bricks and so is preheated on its arrival at the firing zone. It is also possible to divert some of the preheated air through hot air flues above the

FIG. 4.— CARLOADS OF BRICKS BEING PLACED IN A TUNNEL KILN FOR BURNING

arches to aid drying in the forward chamber. This recovery of heat for both combustion and drying accounts for the high fuel efficiency of the Hoffmann-type kiln.

There are many variations of the original Hoffmann ring kiln, each having some special characteristic, but all based on the principles of F. Hoffmann. For example, since some firebricks may be damaged if they come into direct contact with fuel ash during firing, they are often burnt in Belgian kilns, in which the fuel is fed on grates external to the chambers. Again, the zigzag kiln, in which the path that the fire travels, instead of being circular or elliptical, has been compressed into a zigzag shape, is most popular on the continent of Europe because its shape gives economy of space, fast fire travel and good fuel efficiency. The chambers of the transverse arch Hoffmann, and those of the somewhat similar Staffordshire kiln, can be built as large as is required for the mass production of building bricks.

It is now common practice, both in England and in Europe, to use automatic stokers for firing continuous kilns. For top-fired kilns, batteries of stokers, each feeding one fire hole through the arch of the kiln, are moved forward day by day as the fire progresses. Oil-burning equipment was also developed after World War II.

Tunnel Kilns.—The tunnel type of continuous kiln differs from the Hoffmann type in that the bricks travel continuously through a tunnel, while the fire zone, located near the middle of the kiln, remains stationary. The principle of heat recovery is the same for the two types. The tunnel is usually about 300 ft. long and is rectangular in cross section. Kiln cars, each carrying about 1,200 bricks, travel on rails set on the tunnel floor; sand seals and the massive refractory decks of the cars protect the undercarriages and the rails from the heat of the kiln. The cars are pushed by hydraulic or gear-driven rams at the rate of about one 6-ft. car per hour, so that the bricks traverse the whole length of the tunnel in about 50 hours.

For refractory bricks and other expensive ware that must not come into direct contact with fuel ash, the kilns are fired from the sides into muffled combustion chambers. For building bricks the muffle is dispensed with, and the kiln can be fired either from the sides or from the top. Coal, oil, producer gas and (where available) natural gas are all used for firing bricks in tunnel kilns.

Modern Trends.—This survey of bricks and brickmaking would not be complete without some reference to a trend that has been gathering momentum in all industrialized countries since the beginning of the 20th century. As labour costs increase so does it become more necessary to mechanize the manufacture of bricks at every stage of production from clay winning to delivery of the product to the building site. For example, until 1907, when the first steam shovel was introduced into a clay pit in Peterborough; Eng., all clay for brickmaking was dug by hand, and it was usually transported to the brickworks either by handbarrow or by pony and tram. Today the clay is dug by one of the various

machines available to the brickmaker; it is only when great care is required in the selection of particular seams and in a few very small works that the clay is 'hand-dug'. Again, in place of the barrow or pony tram, 95% of all the clay dug for bricks is now transported mechanically from the clay pits to the works. Within the factory itself the raw material is moved from stage to stage either by conveyors or by automatic feeders, and many complex devices are used to handle the green bricks. After 1945 the use of fork-lift trucks revolutionized the heavy manual task of setting bricks in dryers and kilns and the still heavier labour of drawing the fired bricks.

Finally, in co-operation with the builders, brickmakers in all parts of the world are developing systems of brick distribution to meet the call for greater mechanization on building sites. In the United States, self-unloading trucks, sometimes equipped with cranes, are used; in England, brickmakers strap packages of bricks with steel bands to facilitate unloading by crane and by special barrows direct to the scaffold.

BRICKER, JOHN WILLIAM (1893–), U.S. senator, was born on Sept. 6, 1893, in Pleasant township in Madison county, Ohio. He received a law degree from Ohio State university in 1920. During World War I he served as a first lieutenant in the army. Bricker was assistant attorney general of Ohio, 1923–27, and attorney general, 1933–37. Elected governor of Ohio on the Republican ticket for the 1939–41 term, Bricker was re-elected twice. Bricker ran unsuccessfully as the Republican vice-presidential candidate in 1944. Two years later, he was elected senator from Ohio and re-elected in 1952; he was defeated in 1958.

In the senate he led in efforts to curb the powers of the president in international relations. He sponsored a proposed constitutional amendment that would have required congressional or at least senatorial approval of executive agreements. The Bricker amendment thus would have left to the congress or even to state legislatures the internal enforcement of international agreements made by the United States. Proposed in 1953, it was debated at length but did not come to a vote. The following year a modified version, the George resolution, was brought to a vote in the senate and failed by one vote to win the support of the necessary two-thirds majority.

BRICKWORK. Building construction in R'estern civilization has until very recently been almost wholly of masonry (*q.v.*). Although timber has played a prominent secondary role, important and lasting buildings have been built of inorganic material dug and fashioned from the earth: stone, clay, sand, lime and cement. Men have been building with brick for at least 5,000 years. The masonry tradition embraces two rival techniques, stone and brick. Brickwork is ordinarily considered a humble cousin of stone masonry; yet the vault was probably introduced in brick made of common clay, and brickwork remains a vital technique even in industrialized countries where the stone industry languishes.

In the beginning the choice between stone and brick was forced by local geographical circumstances. The cost of transportation still remains an important factor in the availability of these heavy materials. In cities built on the alluviums of broad valleys, far from limestone or sandstone deposits, the arts of brickmaking and bricklaying were developed. Abundant fuel was also needed for kiln-firing.

Stonemasonry involved the difficulty of handling large pieces of stone or the cost of cutting at the quarry. Bricks could be cast or extruded into whatever size and shape was best suited to transportation and construction. Some antique bricks weighed as much as 90 lb., but most bricks are small and light enough to be held in one hand. Moreover, standardization of size and shape brought uniformity of pattern and modularization of dimensions. Bricks

here the first prefabricated building elements; cutting and fitting on the site were minimized. In spite of the multiplicity of joints, a brick wall requires less labour than a stone wall of comparable workmanship. Yet brick is not inferior to stone in load-bearing capacity or in resistance to fire, decay and weather.

HISTORY

Brickwork is related in its origins to rammed earth (*q.v.*). Primitive bricks were always sun-dried; a major advance was the process of burning the bricks in a kiln. Sun-dried bricks can only be used in climates having low humidity and rainfall, and even then they require safeguards against dissolution. Adobe construction, used in Spanish colonial architecture, was introduced into Spain by the Saracens, but was originally developed in the Tigris-Euphrates valley.

The Etruscans are believed to have come from Asia Minor to colonize central Italy, and they may have brought with them a knowledge of the ancient brick construction of that region. The Romans acquired this knowledge and passed it on to the Byzantines who, in turn, influenced the Seljuk and Ottoman Turks. Byzantine brick buildings in Italy furnished prototypes for the great Lombard development of brick architecture beginning in the 11th century. Inspired by the Italian example (and perhaps also by the east through the crusades), brickwork then began to appear elsewhere and came to dominate the architecture of northern Germany, Denmark, the Low Countries and parts of England.

Egyptian and Mesopotamian. — The surviving monuments of Egyptian architecture were primarily built of the excellent limestone, sandstone and red granite which the Egyptians had at their disposal. However, the firm black mud of the Nile, mixed with sand or straw to reduce shrinkage cracking, made excellent brick; excavations reveal both sun-dried and kiln-burnt examples. As early as the 1st dynasty, Egyptians made their bricks only slightly larger than modern ones and gave them the same proportions. Mortar was composed of the same mud and sand as the brick material. Contrary to some accounts, the Egyptians also knew the vault: it appeared in utilitarian buildings; such as the laminated vault granaries of the Ramesseum at Thebes.

The most primitive construction is thought to have been mud reinforced by reeds, and brickmaking may have been developed from it, before the development of stonemasonry. The Egyptians used brickmasonry for houses and palaces and for mastaba tombs. Pyramids at Dahshur and Abu Roash were of brick in their main mass, faced with stone.

In Mesopotamia (modern Iraq) the Sumerians were perhaps the earliest to develop brick architecture. On the flood plain of the Tigris-Euphrates, enormous elevated platforms were required to protect important installations. These platforms were built of solid earth. Clay compressed in molds and dried in the sun was the most convenient form where everything depended upon unaided human labour. Abundant deposits in the region supplied bitumen for dampproofing the mortar; kiln-burnt bricks were used for facing.

The palace of Sargon at Khorsabad (713 B.c.) dates from late in the period of Assyrian supremacy. Its platform is cut by drains built in vault form, and the plan of its superstructure shows long narrow rooms defined by brick walls massive enough to have supported brick-vaulted roofs.

The Persians (538–333 B.c.) produced friezes of great beauty formed of colour-glazed bricks. Large-scale brick vaults are commonly supposed to have been in use at a very early date in Mesopotamia. The Sassanian dynasty palace at Ctesiphon near Baghdad (A.D. 550) contains the remains of an elliptical vault spanning 85 feet. This span compares favourably with the somewhat earlier Roman vaults.

The early origin of the arch, vault and dome in Mesopotamia seems probable in view of the shortage of stone or timber capable of spanning openings with one member. In brickwork a curved surface of large radius compared to the brick size can be constructed without special brick shapes simply by varying the joint thickness. Mesopotamian vaults were apparently made by first projecting courses into the opening (corbeling) to diminish the

DRAWN BY JOSEPH YOHANAN FOR "ENCYCLOPÆDIA BRITANNICÆ"

FIG. 1. — ROMAN BRICK CONSTRUCTION

(Left) Vault using brick ribs and (right) wall construction using brick and concrete

span before constructing on this haunch a wooden centring to support the remainder during the construction of the vault. The horizontal joint at the haunch was a statically imperfect but empirically workable solution.

The dome is a more complex form than the vault, but more stable and more amenable to construction, since in small sizes it can be built almost without centring. Concentric rings of masonry have an arch action in the horizontal plane which tends to prevent the elements of the incomplete dome from falling inward. Brickwork provides the ideal material for exploratory experiments in domical structures. (See also ARCH AND VAULT; DOME.)

Roman. — The Romans improved the durability of both brick and mortar, and throughout the regions of the ancient empire. Roman brickwork may still be seen thrusting up through fields or seeming to support buildings in the tons. Roman bricks were formed square and flat (about 18 in. square \times 1½ in. thick) and burned hard; thin bricks were less liable to fracture during drying and burning. Pozzuolana, a volcanic cement, gave strength as an ingredient of mortar and concrete. The irregularities inherent in the units required ¾-in. to 1-in. wide joints.

But Roman masonry was not pure brickwork. Brickwork defined wall faces and corners, and bonding bricks protruded into interior voids. The voids were then filled with concrete and small stones to form a homogeneous mass whose brick exterior was veneered with stone, marble or stucco. Bricks were not ordinarily meant to show, but the ravages of time have peeled off the finish leaving the blunted romantic remnants seen today.

For arches, vaults and domes the Romans also used a combination of brickwork and mass concrete. They first constructed ribs of brickwork with the aid of centring. After hardening, the ribs were capable of partly supporting the fluid concrete as it was placed to complete the vault. This method was preferred to the use of watertight wooden forms that would permit placing the entire vault in one continuous pour. Roman techniques were first systematically analyzed by the French engineer and historian Auguste Choisy, and described in his beautiful drawings published in *L'art de bâtir chez les Romains* in 1873.

The plasticity of concrete, stiffened in its lines by the brickwork skeleton, made it possible for the first time to organize curved structural surfaces with large dimensions. Roman architects designed spaces which are superb in their control of geometrical form. The baths of Caracalla, one of a number of great public *thermae*, had vaulted halls 108 ft. high spanning 79 ft.; the dome of the Pantheon (A.D. 120–124) spanning 142 ft. 6 in., is the only large vault surviving relatively undamaged. (See also ROMAN ARCHITECTURE; BATH.)

Byzantine. — Following the decline of Rome and the division of the empire, new sites of government and culture developed at Constantinople and Ravenna. In the 6th century A.D. the great monuments of the first fully mature Christian art appeared in these centres. The financial power and the slave-labour pool of the Romans had been swept away, but the emperor Justinian commanded adequate resources for a major building program. Byzantine architects and artisans called on their ingenuity to produce new solutions out of local materials. They used bricks propor-

tioned essentially like Roman bricks. Sometimes, as at S. Vitale, they built domes with hollow terra-cotta jars to save weight.

Their major architectural problem was that of the dome. In the Pantheon, the Romans had already used the dome as a way to enclose the top of a circular room, but the Byzantines developed organic structural solutions to the problem of supporting the dome on polygonally arranged piers. Spatially their crowning dome grew out of contributory domed spaces, enlarging and enriching the envelope as an architectural enclosure. Structural brickwork was left bare on the exterior, humble in appearance, but enlivened with a few patterns natural to the material. Interiors, on the other hand, were covered with marble and with breathtaking golden mosaics. Ravenna, on the edge of the alluvial plain of the Po, and once an Adriatic port, is a town still dominated by brick churches and church towers. The church of S. Vitale, consecrated by Justinian in 547, has a dome spanning 55 ft. The sides of its octagonal base, about 65 ft. high below the dome, are pierced by semicircular niches crowned with semidomes; the niches in turn are pierced by galleries, also vaulted. The transition from the octagon to the circular base of the main dome is made by squinch arches thrown across the interior angles.

One of the greatest buildings of all time is the Byzantine church of Hagia Sophia in Istanbul (532–537). No more daring piece of brickwork exists. The main dome (rebuilt following an earthquake in 558, and further damaged by earthquakes in the 10th and 14th centuries) covers a central space 107 ft. square, surrounded by four massive piers supporting four great arches. Nearly spherical triangles (pendentives) rest on the shoulders of the arches to produce a circular base at the level of the tops of the arches; this is the most satisfactory means by which a circular dome may be placed over a square structure. The arches to east and west open into great semidomes each of which is in turn cut by three smaller radiating semidomes. The tremendous unity of this great oval interior (107 ft. by 225 ft.) is due to the perfect spatial relationships of these spherical surfaces. (See also *BYZANTINE ARCHITECTURE*.)

Medieval. — Brickwork is a craft requiring economic stability and labour organization. Time is needed for digging the clay, curing, reworking, molding, drying and burning. During the unstable early middle ages, very little brick architecture was produced in Europe except by the Byzantines. Italy alone possesses a continuous tradition of brickmaking.

By about the year 1000, however, Romanesque church-building was flourishing. In the Po valley, where Roman and Byzantine traditions were strong and building stone scarce, a brick architecture called Lombard was produced. Magnificent examples remain in Parma, Pavia, Milan, Venice, Padua, Mantua, Modena, Cremona and Bologna. Best known is the basilica of S. Ambrogio at Milan, whose several parts date from the 9th, the 11th and the 12th centuries.

The plain extending along the North Sea and the Baltic from Flanders through southern Scandinavia and northern Germany was the next region to embrace brickwork. Here brick first appeared in Sjaelland about 1150 and rapidly became preferred for the enormous new building program of the church. The 12th century saw the construction of innumerable small country churches, often enlarged or added to in later periods, particularly in the late-Gothic 15th century. Larger churches include the cathedral at Roskilde in Denmark and the Marienkirche in Lubeck in north Germany. Flemish, Dutch, German and Danish churches were the counterparts, in brick, of the medieval stone architecture of northern France.

In southwestern France the medieval brickwork had a quite different regional character. The cathedral of Albi was begun in 1282 by a bishop who, anxious for the prestige of the church following the suppression of the Albigensian heresy, created a smooth-walled brick fortress with small high windows and a flat roof, in spirit totally unlike any of the other large churches of the time. Great silo-shaped buttresses show how the vibrant texture of brick delineates curved surfaces. Together with the adjoining archbishop's palace, the cathedral of Albi is outstanding in special character resulting from the use of brick. Spain also had its re-

vival of brick construction in medieval times; Moorish cultural dominance is evident, as in the tower (once a minaret) in Seville called the Giralda (1159?). From Moslem origins came the idea of the screen or grille, so easy to execute in brickwork, although the Moors also used several other materials for it. As for England, bricks were imported from Flanders in the latter part of the 14th century, and local manufacture soon developed.

The artistry shown in medieval European brick churches testifies to the high standards of the brickmasonry guilds. Lombard architects invented a great range of elements all based on the brick arch; their facades were rich with forms admirably suited to masonry in brick. North German brickwork successfully executed tracery, groin moldings and thin-shell vaults of Gothic architecture. In half-timber masonry (*q.v.*), structural carpentry was combined with brickmasonry in countless minor buildings of great charm.

Insofar as medieval architecture was concerned with craftsmanship, a sense of the fitness of materials, and spatial conceptions consistent with logical structural principles, brickwork was equal to the task. Only the fact that its grain was too coarse for carved sculptural detail kept it from full parity with limestone and marble.

Renaissance and Later. — Renaissance architects had different objectives from those of their predecessors; their preoccupation with visual harmony conflicted with interest in materials, workmanship and structural purity. Gothic architects had been master builders; Renaissance architects assumed greater prestige as creative personalities, but lost the close association with building craftsmen that had prevailed earlier. The apparent formal organization of a Renaissance building did not necessarily coincide with its hidden structural organization. Brickwork continued as a reliable and economical structural material. Brunelleschi's dome in the Duomo of Florence (1420–37), Michelangelo's in St Peter's in Rome (1546–90) and Wren's in St Paul's in London (1675–1710) all have structural shells of brick. However, it is difficult to find Renaissance buildings with a character peculiar to brick architecture.

Throughout northern Europe many brick castles, manor houses and chateaux were built during the early Renaissance. The early portion of Hampton Court palace has brickwork characteristic of the Tudor style in England, in the south and east of which, at this time, good-quality brickwork was characteristic. There are also many examples, particularly in French architecture, of happy combinations of stone and brick. Much of the minor secular architecture in European towns continued to be executed in brick, sometimes trimmed with carved features in stone, terra cotta, stucco or wood. Large cities were built almost wholly of brick; e.g., Amsterdam and Copenhagen. The Georgian period in England (1702–1830) produced many fine houses of classical proportions executed in brickwork of great refinement. There, and also in Maryland and Virginia, bricks were "rubbed and gauged" after burning, to obtain trapezoidal shapes for flat arches and accurate rectangular bricks that could be laid with very tight joints to form pilasters, quoins and belt courses. Philadelphia and Boston have fine brick structures from this period, but normally their decorative features are of wood.

20th Century. — Growing revulsion against aimless 19th-century eclecticism stimulated the use of materials in straightforward recognition of their properties. Traditional brickmaking countries produced restatements of the medieval principle of the maximum use of a single material. Grundtvig's Mindekirke in Copenhagen by P. V. J. Klint (1921–40) and the stock exchange in Amsterdam by Hendrik Berlage (1898–1903), though divergent in feeling, are two examples. But the role of brickwork was soon eclipsed by the entry of new technology. Steel inevitably became prominent. Embedded in concrete, it endowed this material with new properties. Great savings in bulk and weight made the building envelope independent of its structural armature.

In large buildings stone and brick began to lose their load-bearing function and were relegated to the role of enclosing space without supporting it. Brickwork could especially play such a role with great elegance, but it was soon apparent that industry, which had provided better support, would also improve on enclosure material. Brickwork is fireproof, resists weather, and should need little

maintenance, but it is heavy and it has to be laid by hand. Its future is therefore problematical.

Frank Lloyd Wright seemed to have captured the essence of north European brickwork tradition; he made use of the grain of a brick surface as well as its warm colour in the Johnson's Wax building at Racine, Wis. (1947), and in many of his houses. Ludwig Mies van der Rohe, on the other hand, made brickwork express the precision and modular clarity of the machine in spite of its patent handcraft origin. His Promontory apartments (1946) in Chicago are a pure example of the use of brickwork for nonbearing (or curtain) walls in a multistory skeleton-frame building. The separate roles of the skeleton and brick walls are satisfyingly apparent

TECHNIQUE

Brickwork Dimensions.— The height, width and length of modern bricks are given the approximate proportions $\frac{1}{2}:\frac{1}{2}:1$, including the presumed dimension of the mortar joint. In England and Scandinavia the usual module is 3 in., per brick course; this requires a brick whose actual dimension is about $2\frac{1}{2}$ in. \times $4\frac{1}{4}$ in. \times 9 in. In the United States the standard brick is more nearly $2\frac{1}{4}$ in. \times $3\frac{3}{4}$ in. \times 8 in., providing three horizontal joints for 8 in. of vertical measurement. The 4-in. horizontal increment of modular co-ordination requires a somewhat shorter brick.

Brickwork resists efforts at complete modularization. Joint thickness is necessarily variable according to the conditions encountered and the effect sought. Its variability is valuable to offset the variations and inaccuracies in the structural frame. For rough brick quite variable in size, a joint $\frac{3}{4}$ in. to $\frac{7}{8}$ in. may be appropriate for horizontal joints, but the vertical joints will probably be smaller. Machine-made brick, especially as interior finish, may approach jointing of $\frac{1}{4}$ in. or even $\frac{1}{8}$ in. The dimension of the joint should not be less than twice the variation expected in the bricks themselves. The architect anticipates these factors in determining the dimensions of openings and piers; the brickmason determines their feasibility in the light of the materials provided. Thick joints are likely to leak more than thin joints.

Brick-wall thicknesses are modular increments of brick width plus mortar. This thickness, in the U.S., is expressed in terms of *withes*, a *withe* being the width of a single brick. In England the term *withe* refers only to the thickness of brickwork separating two chimney flues, and walls are said to be a half-brick (single *withe*), one brick (two *withes*) or a brick-and-a-half thick. At the University of Virginia, Charlottesville, Thomas Jefferson demonstrated beautifully that a single *withe* of brick was adequate for stabilizing a garden wall of serpentine form. Double-thick walls are convenient where brickwork must be dressed on both sides, because the individual brick may be placed with regard for only one exposure. In all but the drier climates, three brick *withes* are necessary for exterior walling to provide watertightness. Such a wall, slightly over a foot thick, has great loadbearing capacity; greater thickness may be required to prevent overturning in the case of high walls without lateral support.

Bonding.— Stability in masonry walls requires that the separate units cling together so that the masonry will retain its character as one piece. Vertical loads that compress all parts are less

feared than are unequal settlement, movement due to changes in temperature, and stresses induced by the pulling or pushing of floors and roofs. Masonry is relatively inflexible; cracks weaken the wall, admit the weather and are unsightly.

Bonding is the staggering or overlapping of units to break the vertical joints according to a definite pattern. A sense of how bonding strengthens a wall may be obtained by laying up small sections of brickwork dry. Every vertical joint in masonry is a potential plane of cleavage; the more discontinuous these joints can be made, the stronger the wall becomes (assuming always that the mortar, or the bond between mortar and brick, is weaker than the brick itself). The incipient crack is thereby required to extend in a zigzag manner, overcoming the resistance offered by the interlocked units.

Considering a single *withe* of brickwork, bonding is a two-dimensional problem with one best solution, running bond with plumb alignment of alternate vertical joints. In walls composed of several *nithes* the vertical joints parallel to the wall face must be interrupted, and the problem is three-dimensional. There are several traditional solutions. English bond consists of courses of headers alternating with courses of stretchers—in a variant called English cross bond the vertical joints of each stretcher course break joint with the stretcher course below. In Flemish bond the bricks of each course are alternately header and stretcher, laid so that a header is always over a stretcher. Other bonds are variations

In English bond one-half of the surface has headers penetrating two *nithes* deep, in Flemish bond one-third of the surface is headers. Either bond provides a tremendous interlocking effect, which can be carried through the wall to interrupt every vertical mortar *withe*, no matter how many. The satisfying and subtle patterns of good bonding reflect a structural order within the wall

Such bonding is a disappearing craft. In most walls only the outer *withe* is of face brick, made to be seen and to withstand weather. The core is made of cheaper back-up brick. Bonding requires more face bricks, increasing the expense. Often back-up material is hollow concrete or burned clay-tile blocks much larger than bricks, and bonding would require special shapes for interlocking. A decline of handcrafts accompanies mechanization of production, and in brickwork there has been a tendency to eliminate complexities. Skeleton construction has diminished the need for high strength in brickwork, and has made interlocking of units less important.

Workmanship.— Traditional procedures in building were revolutionized by the industrialization, early in the 19th century, of the production of portland cement. Mortars for masonry were greatly strengthened by this new ingredient. Mortar usually makes up about one-third the volume of brickwork. Portland cement did not eliminate the need for lime, and except where high compressive strength or unusual resistance to moisture are required, the addition of lime putty or hydrated lime to the cement, sand and water is advantageous. Lime helps mortar to retain water, to flow easily and to have workability, a fatty consistency that both clings and spreads. Lime produces a low-modulus mortar which can absorb local strains without undue accumulation of movement. Workability enables the mortar to be forced into all the voids between the bricks. (See also MORTAR IN BUILDING)

Brickmasonry can therefore be primarily directed toward provision for watertightness and relief from the inevitable movement due to exposure, rather than loadbearing. A well-laid wall is permanent protection against rain, but poor brickwork is a liability difficult to correct. Brick and mortar are moderately porous; their slow absorption provides protection against exterior wetness. Brickwork must be protected at openings and at the intersections of roof planes with sheet-metal or waterproof-fabric flashings built in to form barriers. Water may penetrate wherever the bond between mortar and brick is imperfect, and it will collect and flow into any unfilled voids.

To obtain good bond and to fill the voids the brickmason uses techniques described by key words of the trade. When he "spreads" mortar horizontally to receive a row of bricks, he should

FIG. 2.—BRICK PROPORTIONS AND DEFINITIONS

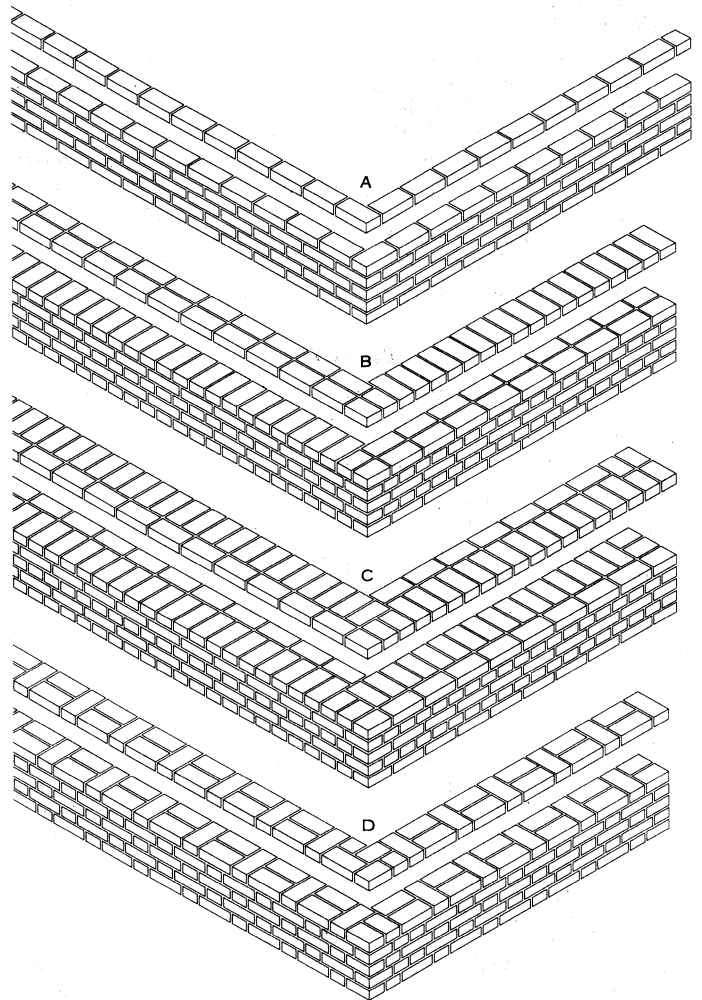

do so for only a few bricks at a time, so that the mortar will remain plastic until covered. While smoothing it to the proper thickness, he should avoid excessive "furrowing" with his trowel as this may leave a trough under the bricks. The end of each brick, as it is picked up, should be "battered" so that the mason may place it in its bed and shove it laterally against the next stretcher to assure full contact. After tapping for alignment he should not further disturb it. Laying against a back-up brick already in place, he may "pick-and-dip?" throwing mortar on the wall with one hand and immediately shoving a brick into it so that mortar squeezes out of all three joints. A way of assuring watertightness is to lay the back-up brick ahead and then to "parge" its surface by plastering on a coat of mortar $\frac{3}{8}$ in. thick before bringing the facing up to level. The reverse procedure, leading with the facing and parging its back surface, is less desirable because the lateral pressure may break the moist joints of the face brick. It is better to parge than to "slush"; slushing attempts to fill the vertical joint by throwing mortar into it after the units are placed. Where these vertical voids are too deep they cannot be adequately filled, and if pressure is used to ensure filling, the face brick may be forced out of line. The above method, known as "overhand work," is less commonly used in England than the alternative technique in which the bricklayer works away from himself, from left to right if he is right-handed. Similarly, details of good practice vary slightly in different countries.

Accuracy is assured by the use of long spirit levels to plumb the corners and by strings stretched horizontally as guides. The bricklayer or mason begins by laying out bricks from corner to corner to determine the thickness of heading joints and the necessity for cutting. It is customary to wet highly absorbent bricks with a hose to correct excessive suction on the water in the mortar. However, the methods commonly used do not produce the desired result, and the practice is questionable.

Exposed joints in brickwork are finished in a separate operation, pointing, that affects both its appearance and its weathering. It is best to wait until the mortar is partly hardened, so that substantial pressure is required to produce a smooth, dense finish, the mortar being forced into intimate contact with the brick. Exposed faces must not be stained with mortar; its removal may require the use of hydrochloric or muriatic acid, which also attacks the tooled mortar joint.

Efflorescence is a defect in brickwork caused by the presence of excess water in the wall. Whitish salts are deposited by the evaporation of water containing dissolved salts from the mortar and brick. Aside from avoiding ingredients containing soluble salts, the best defense is to design a watertight wall and to minimize the amount of entrapped water. Research suggests that headers employed for bonding may be disadvantageous for watertightness; they interrupt a continuously parged mortar with, which is an effective barrier to water penetration. Galvanized-steel wall ties laid in the bed joints are supplanting bonding for anchoring parallel brick withes together. In freezing weather, the materials and the finished work must be kept warm. Circumstances will determine whether the additional cost of cold weather operation can be justified.

Cavity Walls.—Since a solid wall only two brick withes thick is rarely leakproof, an alternate construction using no more material has been devised. In cavity walls two 4-in. or 44-in. withes are separated by a 2-in. air space so that the total thickness is 10–11 in. Additional back-up withes can be added if needed for load-bearing, or the back-up can be made of insulating blocks or other masonry material. The withes on either side of the continuous air space are connected only by galvanized metal ties. These are incapable of carrying water across the air space and provide some flexibility for difference in expansion and contraction between the inner and outer withe due to temperature differences. They also furnish valuable lateral stiffening so that the wall may bear loads. The air space must not become filled with mortar during construction, and if droppage cannot be prevented, strips of wood must be placed on the metal ties. Drawing these up to remove the mortar must be done carefully to avoid breaking the joints in the face bricks. Water coming through the outer withe will run down its

DRAWN BY JOSEPH YOCHANAN FOR "ENCYCLOPEDIA BRITANNICA"

FIG. 3.—TYPES OF BRICK BONDS

(A) Running bond; (B) English bond, 8 in. thickness; (C) English bond, 12 in. thickness; (D) Flemish bond, 8 in. thickness

inner face instead of penetrating; the bottom of the air space is protected by a stepped through-wall flashing, and in the lowest exterior brick course the heading joints are left open for drainage. The air space is not only a protection against rain penetration, but is fairly effective as thermal insulation, overcoming a weakness of solid brick walls. The air space may be filled with either loose- or rigid-board insulation, if materials that are completely durable and nonabsorbent are used. The effects of freezing and thawing on cavity walls should always be considered.

So-called brick veneer construction is often used in small houses in the U.S. A wood frame house is covered with rough wood sheathing and building paper; a parallel with of face brick is then laid with air space and anchorage as in a cavity wall. The flexibility of the metal ties overcomes incompatibility in the movements of the two materials, but the combination is architecturally unsatisfactory.

Reinforced Brick Masonry.—Masonry materials can carry heavy compressive stresses, but in shear or tension they are relatively weak. Gothic architects were ingenious in avoiding tensile stress. Renaissance architects were not above embedding iron chains or hoops in their domes and they sometimes used visible iron tie rods. In the 19th century, engineers in France and England realized that new structural forms could result from systematically combining steel with concrete or brickwork. Mathematicians developed theories to predict the distribution of stresses in structures. An unreinforced masonry beam may fail of its own weight, but can be made very strong by building steel bars lengthwise into its lower cross section. In any concrete or masonry

structure the correct positioning of steel reinforcement makes a combination utilizing the strongest qualities of both materials.

Reinforced brick masonry, called R-B-M, although now virtually unknown in England, was originated by an English engineer, Marc Isambard Brunel, who first used it in 1813 in chimney construction, then built reinforced brick caissons for the Thames tunnel in 1825, and in 1836 began to design and test reinforced brick beams. (Patents for reinforced concrete were first obtained in the 1850s.) The reinforcing bars are laid in the wet mortar. Formed systems of bars may be fastened together and positioned before brickwork is built up around them. Reinforcing bars must remain thin; when thicker bars are required, either the mortar joint must be thickened or special bricks employed. R-B-M utilizes the compressive strength of brickwork to a large degree, hence strong mortar is necessary. Often a fluid mortar (grout) is poured into the inner joints to assure filling all voids. The danger of grouting lies in excessive shrinkage which may cause interior strains to open up the face joints.

The advantages of R-B-M over reinforced concrete are similar to those that made the Romans use a brick framework for their concrete vaults. Vertical surfaces can be built without formwork, and forms for soffits need not be watertight. In spite of its advantages and its somewhat earlier development, R-B-M has proved less useful than reinforced concrete. Brick imposes limitations on shapes and dimensions, whereas, in concrete work, form building in lumber and plywood or steel is more flexible. Brickwork introduces incipient planes of cleavage; the bricks interfere with the most advantageous placement of reinforcing steel, especially when it must be bent or curved. Nevertheless if brickwork is the desired medium. R-B-M is acceptable because it is capable of withstanding complex loading, such as that encountered in earthquakes.

Appearance.—Whenever brickwork is used as an exposed structural system, as curtain walling or as walk pavement, its visual qualities are important and subject to the designer's control. The rhythm, colour and scale appeal to the senses, and its fabric has many possible variations. It may appear either rich or austere, hand- or machine-wrought, variegated or monotonous, glowing in colour or muddy, according to subtle differences in these variables. Clays burn to different colours, and the product of one kiln may have uniformity or be highly varied in colour, shape and size. The manner of stacking in the kiln and the time of burning are sources of variability—single bricks contain characteristic variations in colour. Bricks may be burned so as to be vitreous, or glazes may be applied by second burning. Bonding is quite important to the appearance of brickwork.

Both in structure and appearance, mortar joints play a disproportionate part. At a distance the mortar colour and brick colour tend to be mixed by the eye. Mortar colour contrasted to brick colour, e.g. cold versus warm, produces vibrancy. Colour is controlled by choice of ingredients, and further by the addition of pigments, of which red or black are the most used. Whiteness, formerly obtained through the addition of oyster shells, can now be obtained through the use of white cements. Joint thickness is important, as is the method of pointing it. Deeply raked, it will cast shadows to model the surface; in contrast is a technique in which mortar is rubbed into the joint with a piece of sacking or the face of a brick held in the hand so that low points in the wall are submerged in a flush mortar surface. In Virginia and Delaware, joints were accented by a narrow groove cut into the centre of a rather fat and variable joint, giving discipline and refinement; similar "tuck pointing" was frequently done in England during the Georgian period.

Qualities of brickwork that depend on the skill of the brick-mason have tended to disappear. However, sound and beautiful brickwork is still being produced, resulting from high standards of manufacture and selection, conscientious construction procedures, scientific controls and a full appreciation of the variables affecting the appearance of bricks and mortar.

BRIGONNET, GUILLAUME (c. 1472–1534), one of the most energetic personalities in the French church at the beginning of the Reformation, was the son of Charles VIII's counselor Guillaume Briçonnet (1445–1514), who after his wife's death took holy orders and became bishop of St. Malo, archbishop of Reims, archbishop of Narbonne and cardinal. The younger Guillaume was made bishop of Lodève (1489), abbot of St. Germain-des-Prés (1507) and bishop of Meaux (1516). He took part in the Council of Pisa in 1511 and was entrusted by Francis I of France in 1516 with the negotiations in Rome over the application of the Concordat of Bologna.

It is thought that the influence of some Italian bishops of the Oratory of the Divine Love—particularly Gian Matteo Giberti, bishop of Verona—prompted Briçonnet to begin reforms in his diocese of Meaux, where he made frequent visitations, encouraged devotion to the Blessed Sacrament and to the Virgin Mary and promoted a religious revival by means of sermons and tracts printed in his own palace. This activity won him such a reputation that he became the spiritual director of the king's sister Margaret.

Briçonnet moreover was the leader of the "Meaux group" of evangelicals. This group, which included Jacques Lefèvre d'Étaples, Gérard Roussel, Guillaume Farel, Jodocus Clichtove, François Vatable and Martial Mazurier, combined humanism with a return to the study of the Bible and, especially, of St. Paul's epistles as the primary source of Christian doctrine. Its members, however, differed in their attitude to Lutheranism, to which Farel adhered while Briçonnet condemned it (1523). Even so, Briçonnet had to appear twice before the Paris *parlement* on suspicion of heresy. The group was finally dispersed about 1525. Briçonnet, still a Catholic, died at St. Germain-des-Prés on Jan. 24, 1534.

BRIDE, the term used of a woman on her wedding day. It appears in many combinations, some of them obsolete; e.g., "bride bell" (wedding bells), "bride banquet" (wedding breakfast). The bridecake, or wedding cake, had its origin in the Roman *confarreatio*, a form of marriage, in which the couple ate a cake made of salt, water and flour, and the bride held three wheat ears, symbolical of plenty. In the middle ages the wheat ears were worn or carried by the bride. It became the custom for young girls to assemble outside the church and throw grains of wheat over the bride. Later wheat grains were cooked into thin dry biscuits, which were broken over the bride's head. In 16th-century England, these biscuits took the form of small rectangular cakes made of eggs, milk, sugar, currants and spices. Every wedding guest had at least one, and the cakes were thrown at the bride as she crossed the threshold.

In rural parishes of England, even into the 20th century, wheat was thrown over the bridal couple with the cry, "Bread for life and pudding for ever," expressive of a wish that the newly wed might be always affluent. The throwing of rice, a very ancient custom but later than the wheat, is symbolical of the wish that the bridal may be fruitful. The bridecup was the bowl or loving cup in which the bridegroom pledged the bride, and she him. The bridecup was also sometimes a bowl of spiced wine prepared at night for the bridal couple. Bride favours (or bride lace) were at first pieces of gold, silk or other lace, used to bind up the sprigs of rosemary worn at weddings. Later these took the form of bunches of ribbons. Bridegroom men, or groomsmen, represented a survival of the primitive days of marriage by capture, when a man called his friends to assist to "lift" the bride. Bridesmaids were usual in Saxon England. The senior of them attended the bride for some days before the wedding. The making of the bridal wreath, the decorations for the wedding feast, the dressing of the bride, were among her special tasks. The senior groomsmen (the best man) was the personal attendant of the husband. The bride-

wain, the wagon in which the bride was driven to her new home, gave its name to the weddings of any poor couple, who drove a "wain" round the village, collecting small sums of money or articles of furniture toward their housekeeping. These were called bidding weddings, or *bidales*. The bride's veil is the modern form of the *flammeum* or large yellow veil which completely enveloped Greek and Roman brides during the ceremony.

See also MARRIAGE.

BRIDEL, PHILIPPE SIRICE (1757–1845), Swiss man of letters, known as *le doyen* Bridel, whose work was aimed at arousing a national consciousness in Swiss thought and writing, was born at Begnins (Vaud), Nov. 20, 1757. After studying at Lausanne he became a pastor, first at the French church in Basel and later at Château-d'Oex and Montreux, occupying himself largely with literature, national history, linguistic questions and the natural sciences. His purpose was to endow his country with a literature completely native to it—a movement continued by the patriotic poet Juste Olivier. Of his own writings, *Poksies helvétiques* (1782) have only documentary value, but his *Glossaire du patois de la Suisse romande* (1866) and the series of *Étrennes helvétiques* (1783–87) and *Consevateur suisse* (1813–31) are a source of information, anecdote, legend and graphic description. Bridel's influence helped to bring together French- and German-speaking Swiss on the political as well as literary and scientific level. He died at Montreux, May 20, 1845.

BRIDEWEALTH is the payment made by the groom to ratify marriage in certain primitive societies. As it is not always a form of wife purchase, the older term "bride-price" has been replaced by "bridewealth." It can be found in all parts of the globe in one form or another but, as an instrument for the ratification of marriage, it is most highly developed in Africa, and in many African societies the husband may not assume his full marital status until a standard proportion of the bridewealth has been transferred; often, until this is done, he cannot affiliate his children to his own descent group or claim damages against an adulterer or receive bridewealth for his own daughter. The payment of bridewealth provides a criterion for distinguishing cohabitation, with no legal consequences, from marriage with all it implies for succession and the definition of incest categories. Consistently, a marriage is not reckoned to have ended until the return of bridewealth signifies divorce.

Often the bridewealth is part of a long series of exchanges between the two families. Those made by the bride's family are sometimes called dowry, misleadingly, since there is no clear analog, with the European dowry system.

Bridewealth also consolidates friendly relations between intermarrying families which are not already united by ties of kinship. It is a pledge that the bride will be well treated and is in some sense a compensation for her loss, and so is comparable to blood-compensation or "bloodwealth." In marriages between aristocrats and commoners, it may carry implications of tribute or of payment for social advantages.

The goods transferred as bridewealth vary considerably from specified amounts of livestock, spears or cowries to drink and food, money or even an exchange of women. Where bridewealth is not required the groom is often expected to serve his father-in-law for a set period.

BRIDEWELL, a district of London, Eng., between Fleet street and the Thames, so called from the well of St. Bride or St. Bridget. It was open ground until Cardinal Wolsey built Bridewell palace where in 1525 Henry VIII entertained the emperor Charles V. In 1553 Edward VI made it over to the City of London as a place of training and education for its homeless apprentices. Bridewell Royal hospital and Christ's hospital, founded at the same

time, worked closely together. Subsequently the cells, meant for recalcitrant apprentices, came to be used for political and religious prisoners, vagrants and prostitutes; this practice continued side by side with the teaching of apprentices until the mid-19th century when the prison was closed. By 1863 the palace was demolished. Bridewell Royal hospital, now a charity, maintains King Edward's school, Witley, Surrey, opened in 1867, which became coeducational in 1953. The name bridewell, in general usage, has come to mean prison or house of correction.

BRIDGE, FRANK (1879–1941), English composer and, in several fields, one of the most accomplished musicians of his day. Born at Brighton, Sussex, Feb. 26, 1879, he started to study the violin at the Royal College of Music, London, then changed to the viola, of which he became a virtuoso player. After a short time as deputy in the Joachim quartet (1906), he became a permanent member of the English String quartet until 1915, and this experience of chamber music was valuable to him as conductor and composer. As a symphonic and operatic conductor he was much respected, but was musically and personally perhaps too fastidious to attain wide recognition. As a composer, his activity was almost lifelong: he won a composition scholarship in 1899 and remained consistently productive until his death (at Eastbourne, Sussex, Jan. 10, 1941). Although he worked freely in all branches of composition, it was in the smaller forms, such as the Phantasie Quartet for piano and strings of 1910, and in numerous songs and piano pieces, that he was most successful. His music was widely performed and shows great technical skill and the effectiveness that comes from practical insight into problems of performance, although he seldom achieved a personal style. In a busy life he sometimes found time to teach, and among his pupils was the schoolboy Benjamin Britten. (Th. A.)

BRIDGE, a name applied to each of three card games, bridge whist, auction bridge and contract bridge, derived from whist (*q.v.*). The essential features of these games, as of whist, are: four persons play, two against two as partners; a full 52-card pack is dealt out one at a time clockwise around the table so that each player holds 13 cards; the object of play is to win tricks, each trick consisting of one card played by each player. Another feature is that one suit may be designated as the trump suit (*i.e.*, any card in that suit will take any card of the other suits), but the methods of designating the trump suit (or of determining that a hand will be played with no-trump suit) differ, as explained below.

Since about 1896 these games have successively been the principal intellectual card games of the English-speaking countries. The third game of the series, contract bridge, spread throughout the world and in some respects constituted a social phenomenon unparalleled in the history of games. By the second half of the 20th century there were an estimated 50,000,000 players of contract bridge in all civilized countries, constituting about equal numbers of men and women, at least half of them in the United States. The literature of the game comprised more than 9,000 volumes and at least 100 periodicals were published in 17 countries and 13 languages. There were at least 5,000 clubs devoted to the game. International bridge competitions were treated with as much gravity as that accorded the Olympic or other athletic games.

This article is divided into eight broad sections dealing with the principal aspects of bridge. A summary of bridge laws is presented below, and a table lists conventional contract bridge leads. Following are the main divisions of this article:

- I. The Bridge Games
 1. Bridge Whist
 2. Auction Bridge
 3. Contract Bridge
- II. How to Play Contract and Auction Bridge
 1. The Deal
 2. The Auction
 3. The Play

 - 2. Vienna Coup

I. THE BRIDGE GAMES

The first game of the series was originally called simply bridge, but is now called bridge whist to distinguish it from the two later games. Upon its introduction to New York in 1893 and to London in 1894 it almost immediately supplanted whist in the card rooms of men's clubs and before 1900 it was the favourite diversion of fashionable mixed gatherings. Bridge whist was itself supplanted with almost equal rapidity by auction bridge, which was introduced in England about 1904 and which became, from 1907 to 1928, the most universally popular card game theretofore known. Auction bridge had at least 15,000,000 adherents when in 1930 it became secondary to contract bridge.

Though contract bridge won and greatly extended the popularity of auction bridge, it did not entirely replace auction bridge. A survey in the 1950s indicated that there then remained about 5,000,000 auction-bridge players in the United States. Bridge whist, however, had been obsolete since 1910.

1. Bridge Whist.—In bridge as in whist there are four players in two partnerships, each player being dealt 13 cards. But in whist there is always a trump suit, determined by turning up the last card dealt to the dealer, and each player holds and plays his own hand. The principal innovations of bridge whist were: selection of the trump suit by the dealer or his partner, after they saw their hands; the option of playing at no-trump; the exposed dummy (the hand of dealer's partner), which was played by the dealer; a different method of scoring; and the right to double (the scoring values).

In bridge whist, after the cards were dealt, the dealer could make the declaration (name any suit as trump, or decide to play without any trump); or he could transfer this duty to his partner. Before leading the player on the dealer's left (eldest hand) could

double, or could pass that privilege to his partner; and if either doubled, dealer or his partner could redouble, and so the redoubling might continue indefinitely (except that many clubs placed a limit upon the number of doubles).

The player on the dealer's left then led. Dealer's partner, called the dummy, placed his entire hand face upward on the table in front of him and dealer played both his own cards and dummy's, from each hand in proper turn. Otherwise play was as at whist.

The side that won the majority of the tricks scored, for each odd trick (trick over six): if spades were trumps, 2 points; clubs, 4; diamonds, 6; hearts, 8; no-trump, 12; these values doubled and redoubled as previously determined. The first side thus to score 30 or more points won game, and a fresh game was begun. The first side to win two games won rubber and received a 100-point bonus. Other bonuses, which did not count toward game, were scored by a side holding three or more honours (ace, king, queen, knave (jack) and ten of the trump suit, or, at no-trump declarations, three or more aces; for making slams (12 or 13 tricks won); and for chicane (a player's holding no card of the trump suit).

2. Auction Bridge.—The essential feature added by auction bridge was that all four players bid for the right to name the trump suit and that the high bidder or his partner (not necessarily the dealer) became declarer and played the dummy's hand. In other respects the procedure at auction bridge underwent constant and frequent change (see *Laws of Bridge*, below).

3. Contract Bridge.—In its mechanics contract bridge differs from auction bridge only in the scoring. At auction bridge declarer's side scores toward game each odd trick that it wins, whether or not it contracted to win such a trick. At contract bridge, the odd tricks won by declarer cannot be scored toward game unless declarer's side previously contracted to win those tricks. Values of tricks, penalties and premiums are higher in contract than in auction bridge, and large bonuses are awarded for bidding and making slam contracts. See *Scoring*, below.

II. HOW TO PLAY CONTRACT AND AUCTION BRIDGE

The full pack of 52 cards is used, the suits ranking downward in order: spades, hearts, diamonds, clubs; and the cards ranking downward in order: ace (A), king (K), queen (Q), knave or jack (J), 10, 9, 8, 7, 6, 5, 4, 3, 2.

Four play, two against two as partners, who face each other across the table. To determine partners a pack may be spread face down and each player draws a card (not valid are one of the four cards at either end). The players drawing the two highest cards play as partners, the highest having choice of seats and cards (when two packs are used) and becoming the first dealer.

If five or six wish to play in the same game, the draw establishes precedence: A player lowest in order of precedence sits out until the end of the first rubber, when he replaces the next lowest in the order. If two players draw cards of the same rank, the card of the higher-ranking suit takes precedence over the other.

1. The Deal.—The player at dealer's left shuffles the cards. Preferably two packs are used so that one may be shuffled while the other is being dealt. Dealer transfers the shuffled pack to his right, where his opponent cuts it into two packets, each containing at least five cards. Dealer completes the cut.

The rotation in contract bridge is always from player to player to the left. Dealer deals the cards in rotation, one at a time face down, the first card to the player at his left and the last card to himself, so that each player's *hand* (cards received for one round) has 13 cards.

2. The Auction.—The deal completed, each player in rotation beginning with dealer has a chance to call. A call is a pass, a bid, a double or a redouble.

A pass signifies disinclination to contract to win any number of tricks.

A bid contracts to win a specified number of odd tricks with a specified trump or at no-trump. Thus, a bid of one heart assumes a contract to win seven tricks with hearts as trumps; a bid of one no-trump, seven tricks with no-trump suit. The highest possible bid is seven, a contract to win all 13 tricks.

Each successive bid must overcall, that is, be higher than, any preceding bid. It must name a greater number of odd tricks, or the same number of odd tricks in a higher-ranking suit. In the auction, no-trump is highest ranking. Thus, two no-trump will overcall a bid of two in any suit but may be overcalled by three clubs or any higher bid.

A player may double the last preceding bid if it was made by an opponent and has not previously been doubled. A player may redouble the last preceding bid if it was made by his own side, doubled by an opponent and not previously redoubled. A bid may be overcalled as usual whether or not it has been doubled or redoubled.

Each time a player's turn comes in rotation, he must make a call and he may not change that call once it is made. A call out of rotation, or a change of calls, is subject to penalty (see *Laws of Bridge*, below).

The auction continues until any call is followed by three consecutive passes. If there was no bid, the next player in rotation deals. If any bid was made, the highest bid becomes the contract. The suit (if any) named in the contract becomes trump. The contractor who first named that suit (or no-trump) becomes declarer. His opponents become defenders. The auction period is ended and the play period commences.

3. The Play.—The object of play is to win tricks. A trick consists of four cards, one played from the hand of each player in rotation. The first card played to a trick is the lead.

The defender at declarer's left leads to the first trick. Declarer's partner then spreads his hand face up before him on the table, grouped in suits with the trumps, if any, to his right; this player, and his hand, are dummy. Declarer plays both his own cards and dummy's; but each in proper turn.

Each player in rotation must follow suit to the card led (play a card of the same suit, if he has one). If unable to follow suit he may play any card, including a trump, if he wishes. A trick containing any trump is won by the highest trump; any other trick is won by the highest card of the suit led. One member of each side gathers in all tricks won by his side, turns them face down, and keeps them separated sufficiently to make their number and sequence apparent. The winner of each trick leads to the next.

When all 13 tricks have been played the result is scored. The next dealer in rotation deals a new hand.

III. SCORING

A. CONTRACT BRIDGE SCORING

Each player is entitled to keep a score; it is preferable for one member of each side to keep a score. Scores are entered on a score sheet (U.S.) or bridge block (British), which is ruled as in the illustration. Scores earned by the scorekeeper's side go to the left of the vertical line, scores earned by his opponents to the right. Below the horizontal line is the trick score, and above the line is the honour score.

Provided declarer's side has at least fulfilled its contract, it scores, for each trick over six:

If trumps were		no-trump
♠ or ♥	♦ or ♣	
30	20	for the first odd trick
30	20	for each subsequent odd trick

Such of these tricks as were included in the contract go in the trick score; the value of additional tricks (overtricks) goes in the honour score. If the contract was doubled, trick points scored below the line count twice their normal value, while overtricks count 100 each above the line if declarer's side was not vulnerable (a term explained below) and 200 points each if declarer's side was vulnerable. If the contract was redoubled, these values are again multiplied by two. A side fulfilling any doubled or redoubled contract receives also a bonus of 50 points on its honour score.

When either side has scored 100 or more trick points below the line (whether they were scored in one or more hands), it wins a game. Another horizontal line is drawn across the score sheet, below the trick score, to signify the end of the game, and a new game is begun. Only trick scores count toward game, all other points score above the line.

When either side has won two games, it wins the rubber and receives a bonus of 700 if its opponents have not won a game, or 500 if its opponents have won a game. All the trick and honour points of each side are totaled, and the side with the higher total wins the difference from its opponents' score. For purposes of settlement or of keeping a running score, this difference is usually reduced to the nearest 100, a difference of 50 or more counting as 100 and a smaller portion of 100 being disregarded. After each rubber there may be a new draw for partners, seats and deal.

1. Vulnerability.—When a side has won a game it is said to be vulnerable and is exposed to heavier undertrick penalties but receives larger bonuses for overtricks at doubled and redoubled contracts, and for slams. Vulnerability also may be determined by rotation (see *Kinds of Bridge*, below).

2. Undertrick Penalties.—If declarer fails to fulfill his contract, his opponents score for each trick by which he falls short ("goes down," or "is set"):

Ist undertrick Each subsequent undertrick	If declarer were:					
	Not vulnerable			Vulnerable		
	Undbld.	Dbld.	Redbld.	Undbld.	Dbld.	Redbld.
	50	100	200	100	200	400
	50	200	400	100	300	600

3. Honours.—The ace, king, queen, knave (jack) and ten of the trump suit are honours. If any player holds four trump honours in his hand, his side scores 100 above the line; if any player holds all five trump honours, or all four aces at a no-trump contract, his side scores 150.

4. Slams.—For bidding and making a contract of six (little slam or small slam) a bonus of 500 is scored if not vulnerable, 750 if vulnerable. For a grand slam (all seven odd tricks) bid and made, the bonus is 1,000 if not vulnerable, 1,500 if vulnerable. A side bidding six and making seven scores only the small-slam bonus plus one overtrick. A side bidding seven and making only six has not fulfilled its contract and its opponents score an undertrick penalty.

5. Unfinished Rubber.—If a player has to leave before the rubber is completed, and no satisfactory substitute is available, a siding having the only game scores 300 points; a side having the only part score (trick score of less than 100) in an unfinished game scores 50.

B. AUCTION BRIDGE SCORING

If declarer's side has won at least as many odd tricks as it bid for, it scores below the (horizontal) line for each odd trick won: if clubs were trumps, 6; diamonds, 7; hearts, 8; spades, 9; no-trump, 10. This trick score is multiplied by two if the contract was doubled, by four if it was redoubled.

A game ends when one side has scored 30 or more trick points. A rubber ends when one side has won two games, and that side receives a bonus of 250 points.

If declarer's side has not fulfilled its contract, its adversaries score 50 points for each undertrick (100 at a doubled contract, 200 at a redoubled one). These points go into the honour score and do not count toward game. Other entries in the honour score are:

For holding three of the honours (A, K, Q, J and 10 of the trump suit, or the aces at no-trump), 30 points; four honours, divided between the declarer's and his partner's hands, 40; five honours, divided, 50; four trump honours in one hand, 80, or 90 if partner holds the fifth; five trump honours in one hand or all four aces at no-trump, 100. For winning 12 tricks (little slam, or small slam), 50; for winning all 13 tricks (grand slam), 100. These scores are credited to the side earning them, regardless of who is declarer.

If declarer fulfills a doubled contract, he receives a bonus of 50 points plus 50 points for each odd trick he wins above his contract (100 points in each case at a redoubled contract). These go in the honour score.

The side that has scored the greater total of honour plus trick points wins the rubber, whichever side has won two games.

IV. THE DEVELOPMENT OF THE GAME

Bridge was probably born of three-hand whist games. In-

veterate whist players, unwilling to forego their game merely because there were only three available players, played a game called "dummy" (with one hand exposed) long before any bridge game was known or willingly played.

The origin of bridge whist is not definitely known, but a similar game appeared in Constantinople before 1870, under the name Khedive, and almost the same game had been played in Greece before that. Khedive, whose name had for some reason become Biritch, was played on the French Riviera in the 1870s. A pamphlet entitled *Biritch*, or *Russian Whist*, was issued in London in 1887 and very nearly described bridge whist. There is a story that Ludovic Halévy, in 1893, tried to persuade some whist-playing friends in Paris to play bridge with him, but they refused. In the same year, however, it was played at the Whist club of New York, and in 1894 Lord Brougham, penalized for failure to turn the last (trump) card in a whist game at the Portland club, apologized with the excuse that he forgot he was not playing bridge, "the finest card game ever introduced."

Whist players were prompt to deplore the arrival of bridge, almost unanimously asserting that whist, with all four hands hidden, was far more scientific than bridge. The fallacy of this soon became apparent, for exposure of the dummy provided clarity in thousands of situations in which the whist player had had to guess blindly. This provided new opportunities for analysis and greatly stimulated the study of skilful play. By 1897 almost all the leading whist players had succumbed to the attractions of the new game, and even "Cavendish" (Henry Jones, *q.v.*), who had refused for a period in 1897-98 to enter the Portland club because whist had been all but abandoned there, was converted to bridge before his death in 1899.

Bridge whist was the first game of the whist family to appeal to women as much as to men. It quickly became the favoured game of the fashionable world but did not supplant euchre and the other card games among the middle and lower classes, as auction bridge did later.

1. Development of Auction Bridge.—Several accounts of the origin of auction bridge have been advanced. It is probable that just as bridge whist developed from three-hand whist, auction bridge developed from three-hand bridge whist. A letter in the *Times* (London), Jan. 16, 1903, signed by Oswald Crawford, describes "auction bridge for three players." A book by "John Doe" (F. Roe), published in Allahabad, India, in 1904, presents three-hand auction bridge as an invention of Roe and two other members of the Indian civil service when, at an isolated post, they had no "fourth" for bridge whist. Experimental games in England and America apparently followed immediately on the publication of the Crawford letter, for by 1904 the best club players were turning to auction bridge. The Portland club adopted auction bridge in 1907, the Whist club and other American clubs in the two years following. By 1910 bridge whist was all but obsolete and auction bridge was virtually the only card game played by fashionable society and its emulators.

The widespread appeal of auction bridge is attributable partly to the character of the game, partly to the social conditions into which it was born. The science of auction bridge was more complex and more nearly inexhaustible than that of any previous game, creating a demand for large numbers of instructors in skilful play. The instructors, as a professional class, served as proselytizers. Concurrently, the rapid growth of the leisure class increased the demand for means for the entertainment of guests, and auction bridge was found to fill this need ideally. The gradual relaxation of church opposition to cardplaying, but not to gambling, stimulated acceptance of auction bridge, a game most often played without stakes and never for high stakes in the sense that gambling games are.

2. Development of Contract Bridge.—This game was developed almost concurrently with auction bridge but was slower to win popularity. At least as early as 1915, auction-bridge players tried a variant in which one could score toward game only the odd tricks he had bid for. The committee on laws of the Whist club considered incorporation of this principle into the auction-bridge laws in 1917 and again in 1920. They refrained in both

instances because they thought such a difficult game would compromise the popularity of auction bridge.

A French game called *plafond* (*q.v.*), embracing the same principle as contract bridge, was played in Paris in 1918. From about 1922 to 1931 it was more popular than auction or contract bridge in most of the French and Belgian clubs. It was barred from the New York clubs because of the opposition of the auction-bridge authorities.

In the middle 1920s there was a growing demand for faster and higher-scoring games that provided higher-stake gambling. This spirit was responsible for the introduction into auction bridge of the "goulash" or "mayonnaise" deal: when all four players passed, their hands, unshuffled, were stacked and dealt five and three cards at a time to produce more unusual hands and more daring bidding. The atmosphere was still more conducive to adoption of a higher-scoring game.

Harold S. Vanderbilt of New York was one of the expert auction-bridge players who had experimented with contract bridge. In the early winter of 1926, voyaging by sea from the Pacific coast to New York through the Panama canal, he played in *plafond* games on shipboard. In the course of these games he devised a new schedule of scoring values, multiplying auction-bridge values five times or more; large slam bonuses; and the factor of vulnerability. (With minor changes this became and remained the contract-bridge scoring schedule.) By 1927, this scoring schedule had made contract bridge popular; by 1928, contract bridge had all but supplanted auction bridge among the leading American players and was widely played in English clubs; by 1929 it had become the standard club game on both sides of the Atlantic, though in France it did not fully replace *plafond* until 1934.

Until 1931 most of the casual players, constituting a great majority, continued to play auction bridge. The publicity whereby contract bridge found its way to such players was supplied by another of the former auction-bridge experts, Ely Culbertson of New York. Culbertson established contract bridge as the leading card game and himself as its principal authority by a succession of tournament victories and by various maneuvers devised to publicize contract bridge and Culbertson personally. In 1930 Culbertson's teams won nearly every one of the principal American tournaments, then went to England and defeated three leading British teams, including one headed by Lieut. Col. Walter E. Buller, who was then and until his death in 1937 the most vociferous proponent of British bridge (permitting no conventional signals in bidding). In the winter of 1931-32 Culbertson and his wife, Josephine Culbertson, played and defeated in a 150-rubber match one of the most prominent players among the former auction-bridge authorities, Sidney S. Lenz. The progress of the match, called by American newspapers "the bridge battle of the century," was featured for more than a month on their front pages. The Culbertsons won by 8,980 points. The unprecedented publicity made contract bridge a fad not only in the U.S. but also in South American and European countries.

By 1935 the white heat of the fad had cooled. Nevertheless the sales of books and playing cards for contract bridge increased steadily. Periodicals devoted to contract bridge were still published throughout the world. The 800 bridge clubs that New York had known in 1932 had dropped to 400 in 1935 and to 200 in 1955, but nearly all were profitable enterprises whereas few of the larger numbers had been. The 4,000 or more professional teachers in the 1930s dropped to 1,000 by the 1950s, but almost all of the latter were successful professionally. When one young married couple went to have dinner with another young married couple, it was still probable that after dinner they would play bridge. Contract bridge had settled down to a quiet but substantial role in the lives of people throughout the world. By 1938 its function as such was acknowledged. By the second half of the 20th century it had become so commonplace that it was no longer a remarkable phenomenon. The number of bridge players continued to increase in almost direct proportion to the growth of population. Two-thirds of all U.S. and British newspapers carried regular articles of contract-bridge instruction. Throughout the 1950s and into the 1960s about 200 new books on bridge were published each

year, and of new and old books combined about 1,000,000 copies were sold each year in the U.S., about 150,000 in Great Britain.

V. PARTY, DUPLICATE AND TOURNAMENT BRIDGE

Contract bridge is the game most often used for the entertainment of guests and for card parties. Often the group merely forms separate tables of contract bridge, and the games progress independently without any attempt to make a tournament. Pivot bridge provides an arrangement whereby four or five players can be assured that each will play at least once as the partner of each other. Progressive bridge is the favoured American method for social gatherings of 16 to 40 players. More serious players play duplicate bridge.

A. PARTY BRIDGE

1. Pivot Bridge.—When there are four players, they cut as usual for partners and play three rubbers as follows:

Five players cut for precedence, no. 1 being highest and no. 5 lowest. They play five rubbers as follows:

These schedules cause each player to have each other player once as his partner, once as his right-hand opponent and once as his left-hand opponent, and each player sits out one round in turn. When time permits, the process may be repeated after a full round is completed.

2. Progressive Bridge.—This game is played with either contract or auction bridge scoring. There should preferably be equal numbers of ladies and gentlemen, and each pair should consist of one member of each sex; but this is not essential. The tables are numbered consecutively, table 1 being the head of the room. Prior to the game, the hostess or game director prepares tally cards in two contrasting colours, marking one tally of each colour with a table number and pair or couple number, there being two couples for each table.

As guests arrive, the gentlemen draw tallies of one colour, the ladies draw the other colour, and thus the original partnerships and seats are determined by lot.

A signal is given to commence play, and four deals are played at each table. Players deal in rotation, drawing for the first deal. If a deal is passed out it passes to the dealer on the left. On the first deal neither side is vulnerable; second and third deals, dealer's side only is vulnerable; last deal, both sides vulnerable. Each player enters his own and his opponents' totals for the round, in the places provided on his tally. The couple with the higher total for the round moves to the next lower-numbered table, and the other pair remains. Ladies and gentlemen exchange partners and a new round is begun. At table 1, the head table, the winning pair remains seated and the losing pair moves to the highest-numbered table.

3. Scoring.—In progressive contract bridge, for making game (100 or more trick points) in one hand, a bonus of 300 points is scored when not vulnerable, 500 when vulnerable. For making any contract of less than game, there is a bonus of 50 points. Rubber bonuses are not scored. Other scoring is as in regular contract bridge, but no score higher than 1,000 points may be counted in any one deal, except by bidding and making a slam.

In progressive auction bridge, there is a bonus of 125 for making game in one hand. Lower trick scores receive no bonus and do not carry over to the next deal.

4. Progressive Rubber Bridge.—This is the same game except that six deals are usually played in each round and rubbers are scored instead of bonuses for games and part scores. The game may be interrupted at the end of any round and the net scores of all players computed to determine the winner. The laws of the game require that each player subtract his opponent's points from his own to determine his net total, plus or minus. As most people play, however, the opponents' scores are disregarded and the highest-scoring player has won, no matter how many points have been scored against him.

B. DUPLICATE BRIDGE

The purpose of duplicate bridge is to eliminate, as nearly as possible, the element of luck from the game. After the usual deal and auction, the four players in playing their cards do not gather them up as tricks; instead, each shows the card he plays, then turns it down and keeps it on the table in front of him. After the result of the play has been ascertained and scored, the four hands in their original form are placed in a duplicate board, or tray, which is a rectangular container having four pockets, one for each hand. This board is then passed on to another table, where it is played by four other players. Thus it is possible to compare results made with identical cards, the conclusion being that the pair making the higher score must have been more skilful.

1. Scoring.—The result of each deal at duplicate contract bridge is first scored as in regular contract bridge, with these exceptions: there are no rubber bonuses; when declarer's side fulfills a game contract it receives 300 points if not vulnerable, and 500 points if vulnerable. For a trick score of less than 100 points the bonus is 50 points regardless of vulnerability. The bonuses for honours held in one hand are not scored in match point play (*see below*).

Dealer and vulnerability are assigned by the markings on the duplicate board. Sixteen such boards comprise a full set; and although approximately 30 boards are usually played in one session, the series from 17 . . . 32, 33 . . . 48, etc., are respectively identical to the series 1 . . . 16. North is dealer on board 1, east on board 2, and so on in rotation. Neither side is vulnerable on boards 1, 8, 11, 14; north-south only are vulnerable on boards 2, 5, 12, 15; east-west on boards 3, 6, 9, 16; and both sides on boards 4, 7, 10, 13.

Total point, or cumulative, scoring is used in matches between two teams of four and sometimes in pair contests. The team or pair scoring the greatest number of points, as described above, is the winner.

Match-point scoring is used in all individual contests, most pair contests, and most team-of-four contests in which more than two teams compete. Each pair's (or team's) score for a board is compared with the scores made on that board by all other pairs that played precisely the same hands. A pair receives 1 match point for every such comparison in which it has the higher score, $\frac{1}{2}$ match point for the same score. The pair or team amassing the most match points during the session is the winner.

The European system of match-point scoring in team matches combines the total-point and match-point ideas. This system has been widely adopted in the United States. A team scores international match-points (IMP), in proportion to its margin of victory on each board, thus:

International Match-Point Scale

The difference in scores on each deal is converted into match-points on the basis of the scale below:

0-10 = 0	220-340 = 4	1000-1240 = 8	2500-2990 = 12
20-60 = 1	350-490 = 5	1250-1490 = 9	3000-3490 = 13
70-130 = 2	500-740 = 6	1500-1990 = 10	3500-3990 = 14
140-210 = 3	750-990 = 7	2000-2490 = 11	4000 and plus = 15

2. Movements.—The first schedule for conducting pair contests at duplicate whist was devised by John T. Mitchell of Chicago, Ill., in 1892, and is still the most popular method of duplicate play for relatively small groups (8 to 40 pairs). The Mitchell movement requires half the pairs to be assigned to north-south seats and the other half to east-west seats. A set of boards is placed at each table, shuffled and played; thus, with 18 pairs at 9 tables playing 27 boards, boards 1, 2, 3, would start at table 1,

boards 4, 5, 6 at table 2, and so forth. When a round is completed, each east-west pair moves to the next higher-numbered table (and from the highest-numbered table to table 1) while each set of boards is moved to the next lower-numbered table. North-south pairs retain their seats. When all pairs have played all boards, the game ends. With an even number of tables, a relay stand must be used; it serves as a table in the rotation of the boards. Thus, with eight tables, boards 13, 14, 15 would be placed on the relay stand and not on table 5; no boards would be placed on table 8; and tables 8 and 1 would share the same boards in each round, one set always being out of play on the relay stand and, at the end of the round, moving to the next lower-numbered table.

When the Mitchell movement is used, there must be two independent winners, for the scores of the north-south pairs are compared only with the scores of other north-south pairs, and the same is true of the east-west pairs. Therefore Edwin C. Howell of Boston, Mass., devised, and published in 1897, a circulating movement for pair contests. This permits each pair to play against each other pair once during the session. The Howell schedules are good for as many as 16 pairs, but the use of printed guide cards is necessary to direct the movement of the pairs and boards.

In large tournaments, when more than 50 teams of four, or 150 pairs, often play through two, three or four sessions to determine the winner, far more complex schedules are required.

C. TOURNAMENT BRIDGE

The idea of duplicate play had occurred to whist players during the 19th century and achieved great popularity in the United States after Cassius M. Paine and J. L. Sebring patented the duplicate tray in 1891. Duplicate auction bridge became similarly popular in the 1920s, and championship tournaments were played regularly, but the game did not spread to Europe until contract bridge had arrived. The international matches between American and British teams in 1930 (see below) so stimulated interest that nearly all serious students of contract bridge took up duplicate play within the next two years. From 1934 until war and the threat of war interrupted them, national and European championships were held annually, the latter attracting teams from as many as seventeen different countries. In 1947, international play was resumed.

In the U.S., championship tournaments at auction bridge were conducted by the American Whist league, 1924–35, by the American Bridge league, 1927–37, and by the United States Bridge association, 1933–37. In addition there was an annual team-of-four tournament for the Harold S. Vanderbilt cup, the first trophy given (1928) for a national championship at contract bridge. In 1937 all these tournaments came into the control of a new, consolidated association, the American Contract Bridge league (A.C.B.L.). The membership of the A.C.B.L. grew from 9,000 in 1940 to more than 70,000 by the 1960s, and its principal tournaments attracted 4,000 or more players twice a year.

Similar contests were held annually in Great Britain by the British Bridge league, founded in 1932, and European championships were conducted by the European Bridge league, founded the same year. These tournaments continued through 1937 and were resumed in 1946.

International matches were played by an American team against three British teams in 1930; by American teams, against British teams in 1933 and 1934 for a trophy given by Charles M. Schwab of New York; and by an American champion team against a French team, European champions, in 1935. The American teams won all these matches. In 1937, two American teams competed in the last prewar tournament of the European Bridge league. Also entered were teams representing Austria, Belgium, Czechoslovakia, Denmark, Estonia, Finland, France, Great Britain, Hungary, the Netherlands, Norway, Romania, Sweden and Yugoslavia. Austria won, with America second. Other prewar European champions were: Austria, 1933; Hungary, 1934; France, 1935; Austria, 1936.

In 1950 the U.S. resumed international play in a match at Bermuda among champion teams of the United States, Great Britain and Europe (represented by Sweden). The U.S. won and the Bermuda bowl given as a trophy for victory remained the emblem of

the world championship. From 1952 through 1957, an annual match was played between the champion team of the American Contract Bridge league and the European Bridge league; in 1958 the champion team of the South American Bridge federation was admitted, to make a three-cornered match.

At the annual tournament of the European Bridge league held at Oslo in 1958 a World Bridge federation was formed, to control the world-championship matches as previously played and to conduct an olympiad world championship open to all continents and countries beginning in 1960 and renewable each four years thereafter and, in olympic years, replacing the international team matches for the Bermuda bowl. Twenty-nine nationals from all six continents took part in the first world bridge olympiad, at Turin, Italy. Six teams reached the finals which were won by the French team. The British team finished second, United States teams third, fourth and fifth, and the Italian team sixth. Fourteen countries were represented in the concurrent first world olympiad event for women's teams, won by the United Arab Republic. France finished second, Denmark third, Great Britain fourth and the United States fifth.

Teams in international competition have six players each, of whom four play at a time, plus a nonplaying captain. Scoring of matches is by international match points (see above). Finalists and winners since 1950 have included:

1950: United States, Great Britain and Sweden, at Bermuda. Won by United States.

1951: United States v. Italy, at Naples, Italy. Won by United States.

1952: Postponed.

1953: United States v. Sweden, at New York. Won by United States.

1954: United States v. France, at Monte Carlo. Won by United States.

1955: United States v. Great Britain, at New York. Won by Great Britain.

1956: United States v. France, at Paris. Won by France.

1957: United States v. Italy, at New York. Won by Italy.

1958: United States, Argentina and Italy, at Como, Italy. Won by Italy.

1959: United States, Argentina and Italy, at New York. Won by Italy.

1960: First World Bridge Olympiad. Finals: United States (three teams), Great Britain, France and Italy. Won by France.

VI. LAWS OF BRIDGE

As descendants of whist, the several bridge games have always had more detailed laws than those of any other nonathletic game except chess. The Portland club of London and the Whist club of New York became traditionally the lawmaking bodies for rubber auction bridge, the game played chiefly in clubs and private homes. With the rise of duplicate and tournament bridge in the 1930s and '40s, the A.C.B.L. and the European Bridge league became predominant in lawmaking.

The Portland club adopted a code of laws for bridge whist in 1895, the Whist club a different code in 1897. The Whist club's laws were revised in 1902, the Portland club's never. In 1909 the Portland club published the first code of laws for auction bridge (revised 1914, 1924, 1928), and in 1910 the Whist club published its first auction-bridge laws (revised 1912, 1913, 1915, 1917, 1920, 1926). After 1910 auction bridge was never officially played under identical laws in Great Britain and elsewhere. Under the American laws, a bid of (for example) three in any suit would overcall a bid of two in any suit. Under British laws, a bid of one no-trump, worth 12 points, would overcall a bid of five spades, worth $5 \times 2 = 10$ points. The American principle prevailed, and by 1930 had become universal.

The scoring values were changed several times in both countries. At first the scoring was as it had been in bridge whist. Then for a time the game was called royal auction because the spade suit had alternative values: a player might bid either spades, worth 2 points per trick, or royal spades (in the U.S. often called "lilies"), worth 9 points per trick. The same suit would be trumps in either case, but the declarer's profit or risk would depend on which scoring value he had established by his bid. The count for chicane was dropped after the first few years.

The first laws of contract bridge were published by the Knickerbocker Whist club of New York in 1927, but when later in the same

vear the Whist club issued a code the Knickerbocker laws were withdrawn. The Portland club issued a code in 1929. In 1932 representative: of the Portland and Whist clubs met and agreed on the first International code, to which the Commission Française du Bridge subscribed. Since then, except for a 1941 American code (published 1943) issued unilaterally because the European correspondents were at war when it was written, every code has been international, and the revisions of 1948 and 1949 were promulgated by the A.C.B.L. and the European Bridge league, to which the Whist club and Portland club had ceded their claims of prerogative.

Among all contract-bridge players and nearly all auction-bridge players, irregularities are rectified or penalized under the 1948-49 code, which is summarized below.

Summary of Bridge Laws

New Deal.—There must be a new deal if it is ascertained before the last card is dealt:

1. That the shuffle, cut or deal was irregular.
2. That a card was faced in the pack or elsewhere.
3. That the deal is out of turn (provided some player demands a new deal).
4. There must be a new deal if it is discovered before the first call is duly made, that one player has picked up and looked at the wrong hand.

5. There must be a new deal if it is discovered at any time before the cards are mixed together that one player has too many cards, another player too few; or that the pack is imperfect (contains the wrong number of cards, or a duplication of cards).

When there is a new deal, the same dealer deals again (unless he was dealing out of turn) with the same pack, and there is a new shuffle and cut.

Penalty Cards.—A card improperly exposed during the auction and play periods may become a penalty card. No card of declarer's or dummy's may become a penalty card. A defender's penalty card must be left face upward on the table and must be played at his first legal opportunity (subject to his duty to follow suit and to comply with any other penalty that declarer is permitted by the laws to impose.)

Card Exposed During the Auction.—One exposed card, if lower than a knave, may be picked up without penalty; but two low cards, or a knave or higher card, or any card prematurely led, becomes a penalty card.

Lead Penalties.—If declarer has led from the wrong hand, he may be required to lead a card of the same suit from the correct hand (if it has such a card). If a defender leads out of turn, the card so led may be treated as a penalty card or the offender's partner may be forbidden (by declarer) to lead a card of that suit.

Barred Player.—When during the auction a player makes an irregular call, his partner may in certain cases be barred. A player barred for one round must pass in his next turn; a player barred from the auction must pass at every turn thereafter.

Reviewing the Previous Calls.—In his turn to call, a player may ask to have all previous calls restated (preferably by an opponent).

Slip of the Tongue.—If corrected practically in the same breath, there is no penalty. This does not sanction a change of mind. If a player makes two separate calls in the same turn, and permits his first call to stand, his partner is barred for one round of bidding; but the offender may substitute another call if he wishes, in which case his partner is barred until the next hand is dealt.

Insufficient Bid.—Unless the authorized opponent condones it, expressly or by making any call over it, an insufficient bid must be replaced by a sufficient bid or a pass. If the offender chooses the lowest sufficient bid in the same denomination (suit or no-trump), there is no penalty. If the offender makes any other bid, his partner is barred throughout the auction. If the offender passes, his partner is barred throughout the auction and the declarer, if he is an opponent of the offender, may require or forbid the opening lead of a specified suit.

Call Out of Rotation.—The improper call is canceled and the offender's partner is barred from the auction; unless it was a pass made before the first bid, or any call made when it was the offender's right-hand opponent's turn, in which case the offender must pass at his next turn.

Bid After the Auction Closes.—The bid is canceled, and if it was made by a defender, declarer may require or forbid the lead of a specified suit from the offender's partner at his next turn to lead.

Played Card.—A defender's card is played when his partner sees its face. Declarer plays a card when it touches the table after he detaches it from his hand with apparent intent to play. Dummy plays a card when declarer touches it, except to arrange dummy's cards. Any player plays a card when he names it as his intended play. A played card may not be taken back except to correct a revoke.

Revoke.—Failure to follow suit when able, or to comply with a penalty in leading or playing, when able. A revoke becomes established when the offender or his partner leads or plays to the next trick. If it is corrected before that, the card played in error becomes a penalty card. A revoke by dummy, or by failure to play a faced

card, is not subject to penalty but must be corrected on demand before it becomes established.

A revoke on the 12th trick never becomes established but must be corrected without penalty before the cards are mixed for the next deal. For any other established revoke, the penalty is two tricks transferred to the nonoffending side and scored exactly as though won in play. The penalty tricks may be transferred only from tricks won by the offending side after the revoke occurred (including the revoke trick).

Lead Out of Turn.—If a defender leads out of turn, declarer may either: condone the lead; or forbid the lead of the same suit by the offender's partner (at his next turn, if it was not his lead at the time); or call the card led in error a penalty card. If declarer leads from the wrong hand, the authorized opponent may condone the lead or require him to lead a card of the same suit from the correct hand; declarer may then lead any card of the same suit from the correct hand and is not required to play from the other hand the card he led in error. If declarer has no card of the proper suit in the correct hand, he may lead any card from that hand.

Claim or Concession.—If declarer claims or concedes one or more tricks, he should make a statement of how he intends to play the remaining cards. If he fails to make such a statement, a defender may demand it. Declarer must play on if a defender so requires, and may not depart from his statement.

If a defender claims or concedes one or more tricks, he should show his hand to declarer only. His concession is not valid unless his partner also concedes.

A concession is void if the trick conceded could not be lost by any play of the cards.

Premature Lead or Play.—If a defender leads or plays out of rotation before his partner has played to the current trick, declarer may require the offender's partner to play his highest or lowest proper card, or to discard a specified suit.

Precedence of Obligations.—A player must follow suit if able; next, he must respond if able to a proper lead or play penalty; third, he must play a penalty card if able. If a player is unable to comply with a penalty in leading or playing, because of his duty to follow suit or because he has no card of the suit required, the penalty is deemed satisfied.

Proprieties.—"The Scope of the [Bridge] Laws" is stated, in part, as follows:

"The laws are designed to define correct procedure and to provide an adequate remedy in all cases where a player accidentally, carelessly or inadvertently disturbs the proper course of the game, or gains an unintentional but nevertheless unfair advantage . . . The laws are not designed to prevent dishonorable practice . . ."

Appended to the laws are statements of the proprieties, ethics and etiquette of the game. The principal points are covered in the following paragraphs.

The dealer should refrain from looking at the bottom card before completing the deal.

A player should refrain from varying the formula used in calling. The recommended phrases are: "Pass" (U.S.) or "No bid" (British); "One heart"; "One no-trump"; "Double"; "Redouble"; "Six spades"; etc.

Undue delay, emphasis, inflection or intonation in calling or playing should be avoided.

An intentional breach of law, even when the player is prepared to pay the penalty, is considered dishonourable conduct.

It is improper to use any method of calling whose significance is known to partner by prior agreement and which has not been fully explained to the opponents.

Partner's hesitation, remark or manner should not be permitted to influence a call or play.

A review of the previous calls or information as to the score should not be requested except for one's own information.

It is improper to watch the place in a player's hand from which he draws a card and to draw any inference therefrom.

It is proper to keep silent as to irregularities committed by one's side. It is not proper to commit a second offense (such as a revoke) to conceal a prior offense.

It is proper to draw conclusions from information gratuitously supplied by an opponent, but only at one's own risk.

It is proper to warn any player against infringing any law of the game.

It is not proper for a defender to play out of turn even if declarer has played from both hands.

VII. STRATEGY OF CONTRACT BRIDGE

The object in contract bridge is to score as many points as possible and to permit the opponents to score as few points as possible. The strategy employed by the best players in pursuit of this object embraces a technique that in complexity approaches the technique of chess; and, in addition, a scope for deductive analysis, psychology, alertness and mental ascendancy over one's opponents. Thus it is an art, which can hardly be taught or even described. The best players of the game (like the best players of bridge whist and auction bridge before them) combine unusual

aptitude, interest amounting virtually to obsession, and experience derived from constant play with and against their peers.

Nevertheless the general rules, called systems, enable the casual player to emulate the expert standard in most cases. In whist, the progenitive game, the science was meagre; in bridge whist it improved; in auction bridge, the best players were competent but the literature of the game never reflected the best practices; in contract bridge, the most popular systems, if strictly followed, have produced nearly 90% efficiency.

The factors in the systems of contract bridge bidding and play are: (1) Valuation. The player who bids accepts danger; if unable to fulfill his contract he will be subject to penalties. Therefore he must be able to estimate the trick-taking power of his hand. (2) Information. Bridge is essentially a partnership game. Each partner must inform his partner as to the nature and strength of the hand he holds. Assuming such information has been given and received, one partner should be able to decide the best contract for the combined hands. (3) Strategy. A bid defeats its own purposes if the information it gives is more valuable to the opponents than to the bidder's partner. Therefore, ideally, each bid should be designed to inform the bidder's partner only to the extent necessary, while withholding information from the opponents.

Only a few general principles can be stated for the play of the cards, but to the extent possible they have been exhaustively treated in the literature of the several bridge games (see Bibliography, below). The ethics of the game permit information to be given only by the card led (see Leads, below) or the card played to a trick. Convention has endowed certain plays with meanings generally understood.

A. BIDDING SYSTEMS

Bidding systems have preoccupied the student of bridge since the earliest appearance of contract bridge. The first system proposed was that of Harold S. Vanderbilt, who created the game that became successful as contract bridge (see The Development of the Game, above). The Vanderbilt Club system provided that a player with a strong hand bid one club, the lowest bid; his partner with a weak hand would bid one diamond and with a strong hand would make some other bid. Despite its technical excellence, the Vanderbilt Club system was not widely accepted. The most successful system of the first twenty years of contract bridge was devised by Ely Culbertson of New York and was called the Culbertson system or approach-forcing system. This system required a player to value his hand by a schedule of high-card combinations called honour tricks and then to bid in accordance with established requirements based on the number of honour tricks held and the length of the player's suits.

Despite competition from other systems advanced by those who had been the principal authorities in auction bridge (the official system), by leading players such as P. Hal Sims (the Sims system), and by leading teams such as the Four Aces (the Four Aces system), all during the early 1930s, the Culbertson system was paramount throughout the world until the late 1940s.

In 1949, Charles H. Goren of Philadelphia proposed a method of valuation called the point count, an extension of similar methods proposed as early as 1904 but not previously made applicable to more than a fraction of the many hands a bridge player might hold. In other respects Goren's system was similar to or identical with the methods advocated by Culbertson and the Four Aces.

(A. H. Md.)

B. THE GOREN SYSTEM

1. Valuation. — Each player counts for the high cards in his hand: Ace, 4 points; king, 3; queen, 2; jack (knave), 1. In all there are 40 points among the four hands. A hand with 11 or more points is above average. In the combined hands of a partnership, 26 points will normally produce a game; 33 points a small slam; 37 points a grand slam.

To points for high cards add: for opening bids, 3 for a void suit, 2 for a singleton in any suit, 1 for a doubleton. When raising partner's suit, 5 for a void suit, 3 for a singleton, 1 for a doubleton.

Opening bidder adds 1 for all four aces, deducts 1 for an ace-

less hand. Player raising partner's bid adds 1 to the value of each honour in partner's suit unless he has already counted 4 or more for honours in that suit. Player rebidding when his partner has raised adds 1 for a fifth card in his trump suit and 2 for the sixth and each subsequent card in the trump suit.

Player raising deducts 1 point if he has only three cards in his partner's suit or if he has 4-3-3-3 distribution. Any player deducts 1 for an unguarded honour, such as Q-x, J-x, or singleton king, queen or jack (knave).

To open the bidding a player must have, besides the required number of points, at least 2 quick tricks, counted: A-K of the same suit, 2 quick tricks; A-Q, 1½; K-Q, 1; Ace, 1; K-x, ½.

2. Biddable Suits. — To name a suit in opening the bidding, a player must have a four-card suit including 4 or more points (permissible exception: Q-J-10-x), or any five-card suit. To name a suit in responding or rebidding a player must have at least Q-10-x-x, K-x-x-x, or better (four-card suits) or any five-card suit.

To rebid a suit a player must have at least a five-card suit, Q-J-9-x-x, K-Q-x-x-x, or A-J-x-x-x, or better, or any six-card suit.

3. Opening Suit Bids. — (1) 14-point hands must be opened. (2) 13-point hands may be opened if a good rebid is available, as a rebiddable suit or a second biddable suit. (3) All opening hands must contain 2 quick tricks. (4) An opening in third position (after two passes) is permitted with 11 points if the hand contains a good suit. All the foregoing are one bids.

Two Bid in a Suit. — An opening two bid in a suit is forcing to game; partner may not let the bidding die before game has been reached or the opponents have been doubled. (1) 25 points with a good five-card suit; 1 point less with two good five-card suits. (2) 23 points with a good six-card suit. (3) 21 points with a good seven-card suit.

Three, Four or Five Bid in a Suit. — Any of these is a pre-emptive bid, an intentional overbid to interfere with the opponents' bidding, even though the contract undertaken may be defeated. Usually it indicates no more than 10 points in high cards, but ability to win within two tricks of the contract (without help from partner) if the bidder is vulnerable and within three tricks if he is not vulnerable. Usually it is based on a good seven-card or longer suit.

4. Opening No-trump Bids. — These usually are based on 4-3-3-3, 4-4-3-2 or 5-3-3-2 distribution, with no doubleton weaker than Q-x.

One no-trump, 16 to 18 points
Two no-trump, 22 to 24 points
Three no-trump, 25 to 27 points

5. Choice of Suits. — Usually bid the longest suit first. With two five-card suits bid the higher-ranking first. With two or more four-card suits bid the four-card suit next lower in rank to the shortest suit (for this purpose, bid spades if the shortest suit is clubs). Examples:

♠ 5 ♡ K-8-4-3-2 ♦ A-7-5 ♣ A-K-Q-9
Bid one heart, the longest suit.
♠ 7 ♡ K-J-10-6 ♦ K-Q-5-3 ♣ A-K-J-3
Bid one heart, the suit immediately below the singleton.
♠ A-Q-J-5 ♡ 3-2 ♦ A-10-5 ♣ K-J-6-5
Bid one club, the first biddable suit below the doubleton. (The diamonds are not biddable.)

6. Responses. — The requirement for most game contracts is 26 points. Partner's opening bid promises at least 13 of these, but he may have more. Therefore every effort should be made to keep the bidding open so that he will have a second chance to bid. A response should be made with as little as 6 points.

One-round Forcing Bids. — The bid of a new suit by the responding hand is forcing on the opening bidder. Each time the responder bids a new suit, the opener must bid again. If responder makes a jump bid (one more than necessary), the bid is forcing to game.

Game Bids. — Assuming a satisfactory fit can be found, game (four odd tricks) in a major suit is easiest to make. The next-easiest game is three no-trump. The most difficult is game (five odd tricks) in a minor suit, requiring 28 to 29 points.

With a mediocre hand (fewer than 10 points), worth only one constructive bid, responder should prefer to raise his partner in a major suit but to bid one in his own suit, if possible, rather than raise a minor-suit bid.

With 11 or 12 points, responder can make two bids without being forced but should not force to game. With 13 points or more he should see that the bidding does not stop before a game contract is reached. With 19 points he should make a strong effort to reach a slam.

7. Responses to Suit Bids of One.—Raise.—To raise partner's suit responder must have adequate trump support. This consists of J-x-x, Q-x-x or x-x-x-x, or better, for a non-rebid suit; and Q-x, K-x, or x-x-x for a rebid suit. Points required are: Raise to two: 7 to 10 points and adequate trump support. Raise to three: 13 to 16 points and four trumps. Raise to four: no more than 9 high-card points plus five trumps and a short suit (singleton or void).

Bid of a New Suit.—At one-level: 6 points or more (this response may be made on anything ranging from a weak hand to a very powerful one). At two-level: 10 points or more. Jump in a new suit: 19 points or more. (This jump shift is reserved for hands that make a slam very likely. Responder should hold an independent suit or strong support for opener's suit.)

No-trump Responses.—One no-trump: 6 to 9 points in high cards. Two no-trump: 13 to 15 points in high cards, all suits not bid by partner stopped (the hand can eventually win a trick in any unbid suit led by the opponents), and a balanced hand. (Forcing to game.) Three no-trump: 16 to 18 points in high cards, all unbid suits stopped, and 4-3-3-3 distribution.

8. Responses to Suit Bids of Two.—An opening bid of two in a suit is unconditionally forcing to game and responder may not pass until game is reached, no matter how weak his hand may be. With 6 points or less he bids two no-trump, regardless of his distribution. With 7 points and one quick trick or 8 points and $\frac{1}{2}$ quick trick he may show a new suit or raise opener. With 8 or 9 points and a balanced hand, responder bids three no-trump.

9. Responses to Pre-emptive Bids.—A pre-emptor has overbid his hand by two or three tricks, depending on vulnerability. Primary tricks—aces and kings—and potential ruffing (trumping) values are the only factors for responder to consider when contemplating a raise. One or two trumps is sufficient support.

10. Responses to a One No-trump Bid.—Balanced Hands.—Raise to two no-trump with 8 or 9 points, or 7 points and a good five-card suit. Raise to three no-trump with 10 to 14 points. Raise to four no-trump with 15 or 16 points, to six no-trump with 17 to 18 points, to seven no-trump with 21 points.

Unbalanced Hands.—With fewer than 8 points plus a five-card suit in diamonds, hearts or spades, bid two in that suit. With 8 points or more and a four-card major suit, bid two clubs. This is an artificial bid asking opener to show a major suit if he has one. (See *Stayman* Convention, below.) With 10 points and a good suit, bid three of that suit. With a six-card major suit, and fewer than 10 points, in high cards, jump to game in the suit.

11. Responses to a Two No-trump Bid.—Balanced Hands.—Raise to three no-trump with 4 to 8 points; to four no-trump with 9 or 10 points; to six no-trump with 11 or 12 points; to seven no-trump with 15 points.

Unbalanced Hands.—With a five-card major suit headed by an honour, plus 4 points, bid three of the suit. Show any six-card major suit.

12. Responses to a Three No-trump Bid.—Raise to four no-trump with 7 points, to six no-trump with 8 or 9 points, to seven no-trump with 12 points. Show any five-card suit if the hand contains 5 points in high cards.

13. Rebids by Opening Bidder.—When bid was one in a suit the opener's rebid is frequently the most important call of the auction. It gives him his first opportunity to reveal the exact strength of his opening bid. His opening is valued according to the following table:

13 to 16 points, minimum hand
16 to 19 points, good hand
19 to 21 points, very good hand

Minimum Hand—13 to 16 Points.—If partner has made a weak response (one no-trump or a single raise) opener should pass, as game is impossible. If partner bids a new suit at the one level, opener may offer a single raise with good trump support, bid one no-trump if lacking trump support, or rebid his own suit or a new suit if he does not go past the level of two in his original bid.

Good Hand—16 to 19 Points.—If partner has made a weak response (one no-trump or a single raise) opener should bid again. If responder has bid a new suit, opener may make a jump raise with four trumps, jump in his own suit if he has a six-card suit or bid a new suit.

Very Good Hand—19 to 21 Points.—If partner has made a weak response (one no-trump or a single raise) opener may jump to game in either denomination, according to his distribution. If responder has bid a new suit, opener may make a jump raise to game in a major suit with four trumps, or jump to game in his own suit if it is solid. With a balanced hand and 19 or 20 points he should jump to two no-trump, and with 21 points to three no-trump. With 22 points and up he should jump in a new suit, forcing to game and suggesting a slam.

14. Rebids by Opening No-trump Bidder.—*Stayman* Convention.—When the responder bids two clubs, the opening bidder must show a four-card biddable major suit if he has one.

With four spades, he bids two spades.
With four hearts, he bids two hearts.
With both majors, he bids two spades.
With no major, he bids two diamonds.

Opening No-trump Bidder Must *Pass*.—When responder raises to two no-trump and opener has a minimum (16 points). When responder bids two diamonds, two hearts or two spades and opener has only 16 or 17 points and no good fit for responder's suit. When responder bids three no-trump, four spades or four hearts.

15. Defensive Bidding.—Overcalls.—An overcall is a defensive bid made after the opposing side has opened the bidding. Overcalls are based not on a specified number of points but rather on a good suit. The overcaller should be able to win in his own hand within two tricks of his contract if vulnerable and within three tricks if not vulnerable.

One No-trump Overcall.—An overcall of one no-trump is similar to a one no-trump opening bid and shows 16 to 18 points with a balanced hand and with the opening bidder's suit stopped.

Jump Overcall.—Any jump overcall is pre-emptive and shows a hand weak in high cards but with a good suit that will produce within three tricks of the contract if not vulnerable and within two tricks if vulnerable.

Take-out Doubles.—When a defender doubles and: (1) his partner has made no bid; (2) the double was made at the doubler's first opportunity; (3) the double is of one, two or three of a suit; the double asks partner to bid his best (longest) suit. This defensive bid is employed on two types of hand: (1) a hand of opening-bid strength where the doubler has no good or long suit of his own but has good support for any of the unbid suits; and (2) where the doubler has a good suit and so much high-card strength that he fears a mere overcall might be passed out and a possible game missed. The high-card strength required is usually 13 or 14 points and may be more.

Overcall in Opponent's Suit (Cue Bid).—The immediate cue bid (example: opponent opens one heart; defender bids two hearts) is the strongest of all defensive bids. It is unconditionally forcing to game and shows approximately the equivalent of an opening two bid. It normally announces first-round control of the opening bidder's suit (ace or void) with very fine support in all unbid suits.

Action by Partner of Overcaller.—The overcall is usually based on a good suit. Less than normal support is required to raise (Q-x or x-x-x). A raise should be preferred to bidding a suit of one's own, particularly when the overcaller has bid a major. The partner of the overcaller should not bid a weak hand.

Action by Partner of Take-out *Doubler*.—The doubler requests his partner to bid, so the only justification for a pass is the expectation of defeating the doubled contract. Partner's response

guarantees no specified number of points. Preference is normally given to a major suit.

Action by Partner of *the* Opening Bidder.—When the opening bid has been overcalled, the responder is no longer under obligation to keep the bidding open. Every bid shows strength. A bid of one no-trump or a raise should be based on a hand of about average strength (10 points). Over a take-out double, the responder has only one way to show a good hand—a redouble. Any other bid, while not indicative of weakness, shows only mediocre high-card strength. (C. H. G.)

C. SLAM BIDDING

When a partnership has been able to ascertain that it has at least 33 points in the combined hands plus an adequate trump suit, the only thing that remains is to make certain that the opponents are unable to cash two quick tricks. For this purpose control-showing bids are used. Three are most popular: Blackwood, Gerber and cue bidding.

1. Blackwood Convention.—In this convention, devised in 1934 by Easley Blackwood of Indianapolis, Ind., a bid of four no-trump asks partner to show his total number of aces. A response of five clubs shows no aces (or all four aces); five diamonds shows one ace; five hearts shows two aces; five spades shows three aces. After aces have been shown, the four no-trump bidder may ask for kings by bidding five no-trump. The responder now shows kings as he showed aces in response to the four no-trump bid, by bidding six clubs with no king, six diamonds with one king, etc.

2. Gerber Convention.—This was devised in 1938 by John Gerber of Houston, Tex. An unnecessary bid of four clubs, when the bid could not possibly have a natural meaning (such as, opener bids one no-trump, responder bids four clubs) asks partner to show the number of his aces. A response of four diamonds shows no ace; four hearts shows one ace, etc. If the asking hand desires information about kings he bids the next higher suit over his partner's ace-showing response. Thus if the responding hand has bid four hearts over four clubs to show one ace, a call of four spades would ask him to show kings and he would reply four no-trump to show no king, five clubs to show one king, etc.

3. Cue Bidding.—The individual method of ace showing (cue bidding) is used when both partners have shown strength or when the trump suit has been agreed on. For example, opener bids two spades, responder bids three spades; a bid of four clubs by opener now would show the ace of clubs (or a void) and would invite responder to show an ace if he had one.

4. Four-Five No-trump Convention.—Cue bids were the first control-showing method, devised about 1930. In 1933 Ely Culbertson proposed wholesale control showing. A bid of four no-trump showed two aces and the king of the trump suit, or three aces; a response of five no-trump showed the other two aces in the partner's hand. The Blackwood and derivative conventions were based on this. In the United States, Blackwood supplanted the Culbertson convention; in Great Britain and parts of Europe the Culbertson convention continued to be played.

5. Asking Bids.—Another Culbertson innovation (1936), this method permitted a player to ask his partner about second-round controls (kings and singletons). For example: Opener bids one spade; responder bids three spades; opener bids four clubs. The four-club bid asks the responder to show an outside ace if he has at least the king or a singleton in clubs. Without any club control the responder must sign off at four spades. The asking bids have many and complex ramifications. They never became popular in the United States but were played in Europe, especially in Scandinavian countries.

D. OTHER BIDDING SYSTEMS

Hundreds of different bidding systems have been proposed for contract bridge and at all times several dozen systems are in use. Some of these are modifications of the Goren system, described above, or are substantially the same as the Goren system with the addition of a few special bidding conventions; others are radically different. Bidding systems can be divided into two main groups, natural systems, in which the bidder usually has strength in any

suit he bids, and artificial systems, in which most bids are signals designed to show the general strength of the bidder's hand but do not necessarily promise any strength in the suit bid. In the late 1950s the conspicuous success of European teams in world-championship play directed international attention to the various systems used by British, French and Italian teams. The most popular systems in those years were:

1. Two-club System.—An opening bid of two clubs is forcing to game but is artificial, showing a hand usually of 23 or more points but not necessarily a club suit. The partner of the player who bids two clubs must respond two diamonds if he does not hold at least an ace and a king or three kings, but responds naturally if he holds at least that much high-card strength. Other opening two bids are weak bids, showing a six-card suit in a hand of 7 to 10 points. Most American champion teams since 1950 have used this system. (A. H. MD.)

2. British (Acol) System.—While British players, in common with the rest of the world, first played systematic bridge "according to Culbertson," they later developed a style of their own. The Coren method, with its reliance on a point count at almost every stage of the bidding, has never been accepted. The best-known system in Great Britain is Acol. This system—or one that is similar in most respects—is played by almost all the leading tournament players. The system derives its name from a London club frequented by some of the best British players in the middle 1930s.

The strong bid in Acol is a conventional two clubs. This is forcing to game except when the opener, following a minimum response of two diamonds, rebids two no-trump. The two-club opener should have five quick tricks. In this type of valuation, an A-K in the same suit counts as 2 quick tricks, A-Q as $1\frac{1}{2}$, A or K-Q as 1, K as $\frac{1}{2}$.

The responder to a two club opening bids two diamonds on a valueless hand. With one quick trick and a suit that can be bid at the range of two, he can respond two of the suit. For a response at the range of three, generally $1\frac{1}{2}$ honour tricks are required. Two no-trump shows a balanced hand with upwards of 9 points or so.

The other strong call is the Acol two bid—an opening two spades, two hearts, or two diamonds. This call shows a hand of power and quality, generally with $3\frac{1}{2}$ to 5 quick tricks and good playing strength. The bid is forcing for one round, the weakness response being two no-trump.

The usual 4-3-2-1 point count is used for no-trump bidding only. Not vulnerable, one no-trump shows 12 to 14 points; vulnerable, 15 to 17. Two no-trump is not so strong as in America: generally 20 to 22 points (rather than 22 to 24 points). An opening bid of three no-trump is a tactical maneuver generally based on a long minor suit. On strong no-trump hands, two clubs is opened.

For slam bidding, Acol traditionally uses the Culbertson four-five no-trump convention, though many players prefer the simpler Blackwood. Cue bids are freely used.

The main difference between Acol and the American systems lies not in the conventional bids mentioned above, but in the general style and approach. Acol is an attacking system in which the tactical plan is to come into the bidding early and bid high as soon as a fit has been found. Thus, opening bids are freely made on 10 or 11 points when a good six-card suit is held. A response of two no-trump shows 11 to 13 points and is not forcing. A double (jump) raise—one spade to three spades—is not forcing, and a raise to four is stronger than a raise to three.

To afford protection to the weaker opening bids, there are more sign-off bids in Acol than in the American systems. One heart—two no-trump—three hearts is discouraging and will normally be passed.

While a reverse by responder (one club—one heart, two clubs—two spades), or a new suit at the range of three, is forcing, other changes of suit are not forcing. In general, Acol bidding is direct and leans less heavily on the approach style than does Goren. An aphorism that may be taken as expressive of the Acol outlook is: "You bid what you think you can make, and you pass when you feel like it."

3. Italian Systems.—The Italian team that won the world

championship three years running used two systems—the Neapolitan club and the Roman. In the Neapolitan club opening bids of one diamond, one heart and one spade show the suit named and bidding proceeds normally, though on the basis that the opening hand is limited in strength. All strong hands, with 17 points or more, are opened with a bid of one club. Responder shows his values by a step system. Counting a king as one control and an ace as two controls, he responds one diamond with no control, one heart with one control, one spade with two controls, one no-trump with three controls, and so on. Thereafter the bidding proceeds normally.

Hands containing a club suit that are not good enough for the conventional one club are opened one no-trump. An opening bid of two clubs shows the equivalent of a weak no-trump. Other two bids are similar to the American weak two—a good suit and less honour strength than is required for an opening bid of one.

Two no-trump is a conventional opening that promises a long, solid suit. Responder bids three clubs and then the opener shows his suit. An opening of three in a suit shows a long, broken suit.

The Roman club system is more complicated. The opening bid of one club is conventional but may be one of three different types of hand: a minimum opening, a club suit, or a very strong hand. The weakest response to one club is one diamond. One heart or one spade shows the suit and fair values; one no-trump is stronger.

An opening bid of two clubs shows a moderate hand with at least four clubs and four hearts. Two spades and two hearts are the weak two. Two diamonds is a special bid denoting 5-4-4-0 or 4-4-4-1 distribution. If partner has no suit to show he responds two hearts. An opening one no-trump is normal. Two no-trump shows a hand containing nine cards in the minor suits.

In short, the Roman club system has a conventional bid for practically every type of hand. In defense, also, there are many artificial bids that show distribution and have no relation to the suit named. (J. T. R.)

4. French System.—French, and to a certain extent Italian and other continental, bidding methods were influenced by the original ideas of Pierre Albarran of Paris, who proposed that the bidder begin with a relatively weak suit and rebid in his strongest suit. This approach to bidding is called canape.

5. Roth-Stone System.—Most radical of the popular bidding systems was that proposed by Alvin Roth of Washington, D.C., and Tobias Stone of New York city. In this system any opening bid in spades or hearts promises at least a five-card suit, a one no-trump response to an opening bid is forcing, opening bids and overcalls are stronger than in other systems, and there are other points of difference. The Roth-Stone system has influenced many other popular systems.

E. LEADS

The card led against declarer is selected so as to give information to the leader's partner. Certain conventional meanings of leads were establishing during the bridge whist period and with slight changes persisted in contract bridge. The conventional meanings of leads in contract bridge are indicated in the table.

The lead of the fourth-best card from a long suit permits use of the "rule of eleven" (see WHIST).

In winning or attempting to win a trick to which some other player led, a defender plays the lowest equivalent of his highest card; as, the 10 from Q-J-10-8.

A standard defender's signal is the high-low, or come-on: the play or discard of an unnecessarily high card, followed if possible by a lower card of the same suit on a subsequent trick. This denotes a desire to have that suit led.

There are many other signals and conventions in defender's play. These do not violate the spirit of the game if they are known to the opponents. Not even the opponents of bidding conventions object to signals in the play.

Declarer need not observe any system in the selection of cards, for he has no partner to inform.

VIII. BRIDGE PROBLEMS

Proficiency at the play of the cards in bridge is enhanced by

Contract Bridge Leads

Holding	Lead	
	At Suit Bids	At No-trump
A-K-Q-J	K, then J	A
A-K-Q-4-3	K, then Q	K, then Q
A-K-6	K	K
A-K alone	A, then K	K (but avoid)
A-K-J-10	A	A
A-K-J-3	K, then A	A
A-K-J-7-4-3-2	K	7 (fourth-best)
A-K-J-7-2	K	5 (fourth-best)
A-K-10-9-2	K	5 (fourth-best)
A-K-6-5-4	K	5 (fourth-best)
A-Q-J-4-3	A	A
K-Q-J-7-5	K, then J	K, then Q
K-Q-10-7-3	K	3 (fourth-best)
K-Q-7-5-4	K	5 (fourth-best)
Q-J-10-3-2	Q	Q
Q-J-9-4-2	Q	Q
Q-J-6-5-4	Q	5 (fourth-best)
10-9-8	10	10
A-Q-10-9-5	A	10*
A-Q-8-5-4	A	5 (fourth-best)
A-J-10-7-5	A	J
A-10-9-7-5	A	10
K-J-10-4-3	J	J
K-10-9-7-5	10	10
Q-10-9-6-4	10	10
A-5-3	A	3
K-5	7	7
Q-9	7	7
J-8-6	7	7
7-6-3	7	7
Any other four-card or longer suit	Fourth-best	Fourth-best

Leads in Partner's Suit		
Any two cards.		
K-Q-4; Q-J-4-5; J-10-9-5; 8-6-3	Highest	Highest
A-J-4; A-9-7	A	Lowest
K-7-5; Q-8-6; J-6-3; 10-7-6	Lowest†	Lowest
K-Q-7-6; Q-J-8-7; J-10-7-6	Highest	Highest
A-7-6-4	A	Lowest
Any other four-card or longer suit	Lowest	Lowest

*The queen is led when leader suspects that the king is in dummy.
 †The highest may be led when it may win the first trick and the leader wants to hold the lead.

study of double-dummy problems (in which the location of all unplayed cards is known). Putting such knowledge to practical use has been much better accomplished in contract bridge than in any of its predecessor games. For example, a prime problem at whist was the Great Vienna coup, with which the expert whist players had difficulty even when they could see all four hands. Execution of this and similarly difficult plays is commonplace among contract-bridge players far below the highest rank.

Most double-dummy problems embrace the squeeze (so named by Sidney S. Lenz of New York, because it reminded him of a play so-called in baseball), in which a player has winning cards in two or three suits but is forced to discard one of them. The throw-in play and the trump pickup (generic term for the group of plays which included the grand coup of whist) are other favourite themes of problem constructors.

1. The Whitfield Six.—The most famous of all double-dummy problems was proposed by W. H. Whitfield in 1885 and is called the Whitfield six because each hand has six cards. Whist players of the day could make nothing of it, and despite the advancement in the science of cardplaying it would cause trouble even to most experienced contract-bridge players.

Hearts are trumps; South leads and must win all six tricks.
 Trick 1: South leads ♦ K; west ♦ 7; north ♦ J; east ♦ 6.
 Trick 2: South leads ♠ 10; west ♠ 7; north, ♥ 7; east ♠ 6.
 Trick 3: North leads ♥ 8; east ♣ 8; south ♣ 10; west ♠ Q.
 West cannot discard a club or north's ♣ A-2 would both win tricks.

West cannot discard \diamond Q or north, after taking \clubsuit A, could lead \diamond 5 and south could win two tricks with \diamond A-9 by a finesse against east's \diamond 10-8.

Trick 4: North leads \clubsuit A. East is squeezed. If he plays \heartsuit J, south plays \diamond 9, if east plays \diamond 8 or 10, south plays \heartsuit 9. In either case south wins both remaining tricks.

2. Vienna Coup.—The characteristic of the Vienna coup is that a high card must be played early, apparently establishing a card in an opponent's hand but actually subjecting him to a squeeze that could not have been effected had the high card remained unplayed.

<p style="text-align: center;">WEST</p> <p>\heartsuit —</p> <p>\heartsuit 8-5-2</p> <p>\diamond 9-2</p>	<p style="text-align: center;">NORTH</p> <p>\heartsuit 5</p> <p>\heartsuit A-3</p> <p>\diamond A-J</p>	<p style="text-align: center;">EAST</p> <p>\heartsuit Q J</p> <p>\heartsuit K-Q</p> <p>\diamond K-Q</p>
<p style="text-align: center;">SOUTH</p> <p>\heartsuit Q-10</p> <p>\heartsuit J-6</p> <p>\diamond 3</p>		

Spades are trumps; south leads and must win all five tricks. The key is: south leads \heartsuit 6 and north wins \heartsuit A. This gives east the highest heart. North leads \heartsuit 3 and south wins \heartsuit Q and \heartsuit 10, north discarding \heartsuit V 3 on the latter. East cannot discard a heart without making South's \heartsuit J good, nor a diamond without making North's \diamond J good. If the \heartsuit A had not been taken first, east could have discarded a heart on this trick since south could never have returned to his hand to win the \heartsuit J.

BRIDGEND (PEN-Y-BONT AR OGWR), a town and urban district of Glamorgan, Wales, on the river Ogmere (Ogwr) at the northern edge of the vale of Glamorgan, 19 mi. N.W. of Cardiff by road. Pop. (1961) 15,156. This residential and market town, which is divided by the river into Newcastle on the west bank and Oldcastle (the main part) on the east, grew steadily after the 1930s, chiefly because of the large industrial estate on the outskirts and the steel works at nearby Margam. Bridgend owed its initial growth to the erection of the old stone bridge across the river (c. 1435) which linked the village of Newcastle with the hamlet of Nolton. The ruins of a 12th-century castle rise above the church of St. Illtyd in Newcastle, below which is a 15th-century building, the Old Hospice, owned by the Order of St. John. Also in the vicinity is the Unitarian chapel, founded about 1702. Ewenny priory, 1½ mi. S., founded by Maurice de Londres, lord of Ogmere, in 1131, is an early Norman building of both monastic and military character. This is apparent from its crenellated central tower (12th–13th century), portcullis, and the *meurtrières* (apertures)

in its surviving gateways. The ruins of Ogmere castle are in the neighbourhood, and the castle of the Turbervilles (12th–13th century) is at Coity, 2¼ mi. N.E. by road. Bridgend is on the main line railway from London to Fishguard and the civil airport of Rhoose, near Cardiff, is 18 mi. away. (Jo. S. B.)

BRIDGE OF ALLAN, a small burgh of Stirlingshire, Scot., lies 3 mi. N. of Stirling on the Allan water, a tributary of the Forth, in wooded country at the foot of the Ochil hills. Pop. (1961) 3,312. Until 1820 it was a village with fewer than 200 inhabitants. Then the erection of a well house beside a mineral spring gave it a reputation as a spa. Bridge of Allan is still a watering place and a residential town and a centre for tourists. The industries include a factory for bottle-tops and plastic containers.

BRIDGEPORT, a city in southern Connecticut, U.S., about 65 mi. N.E. of New York city. It is the hub of the New York city-New England area and an important industrial centre. Pop. (1960), Bridgeport city, 156,748; standard metropolitan statistical area, comprising Bridgeport and Shelton cities and Fairfield (*q.v.*), Stratford, Monroe, Trumbull and Milford towns, 334,576.

It was settled in 1639 by residents of Fairfield and Stratford and was first known as Newfield and later as Stratfield. In 1800 it was incorporated as a borough and named Bridgeport for the first drawbridge over the Pequonnock river. In 1821 it was incorporated as a town. Because of its advantageous geographical location, situated around an excellent harbour on Long Island sound, the early settlers turned from agrarian to mercantile and manufacturing pursuits. After its incorporation as a city in 1836 Bridgeport grew from a shipping community of 3,000 persons to a world-famous industrial centre, attracting thousands of immigrants from central-eastern Europe at the turn of the 20th century. In politics, the election of Jasper McLevy as Bridgeport's first and only Socialist mayor won international attention; he began a 24-year reign as the nation's most publicized mayor on Nov. 13, 1933, at a time when the dispirited, bankrupt city was in the throes of corruption and despair. In the election of Nov. 5, 1957, at the age of 79, he was defeated by Samuel Tedesco, a Democrat. Another well-known mayor was the showman P. T. Barnum (*q.v.*), whose residence is now a dormitory of the University of Bridgeport and whose memory is commemorated annually by the Barnum festival. Manufactures include electrical supplies, machinery, corsets, hardware, sewing machines, silverware, brake linings, brass goods, valves, ammunition, aircraft, drugs, steel products, machine tools, asbestos products, plastics, home appliances, meters, automotive parts and accessories and steel.

Bridgeport has an airport and good rail service; the 129-mi. long Connecticut turnpike from New York to Rhode Island, completed in 1958, runs through the heart of the city. The University of Bridgeport (1947) continues the work instituted by the Junior College of Connecticut, the oldest legally chartered junior college (1927) in the 11 northeastern states. The Bridgeport Engineering institution presents engineering courses on the college level. The city operates a number of parks and other recreational facilities. (J. S. Ro.)

BRIDGES, CALVIN BLACKMAN (1889–1938), U.S.

geneticist who devoted much work to the chromosome theory of heredity and sex determination, was born at Schuyler Falls, N.Y., on Jan. 11, 1889. In 1912 he graduated from Columbia university, where in 1916 he received the degree of doctor of philosophy and was research assistant to T. H. Morgan during 1910 to 1915. From 1917 to 1919 he continued his research under grants from the Carnegie institution, of whose staff he became a member in the latter year. He died in Los Angeles, Calif., on Dec. 27, 1938. His publications include (with T. H. Morgan and others) *The Mechanism of Mendelian Heredity* (1915); *Sex-Linked Inheritance in Drosophila* (1916); *Genetics of Drosophila* (1925); a number of papers; and (with K. S. Brehme) *Mutants of Drosophila Melanogaster* (1944).

BRIDGES, ROBERT SEYMOUR (1844–1930), English poet laureate, who won permanent fame as a lyrical poet, and is remembered also as a student of prosody and a champion of "pure English." was born at Walmer, Oct. 23, 1844. He was sent to Eton in 1854. Going up to Corpus Christi college, Oxford, in

1863, he met Gerard Manley Hopkins (*q.v.*) who became a life-long friend and whose poems he edited in 1918. From 1869 until 1882 Bridges worked as a medical student and physician in London hospitals. In 1873 he published a volume of verse which he later tried to suppress, and in 1879 printed privately the first of a series of collections of his poems. He retired from medical practice in 1882; two years later he married Mary Monica Waterhouse, and he spent the rest of his life in practically unbroken domestic seclusion, first at Yattendon in Berkshire, then at Boar's Hill, Oxford. Though he knew the leading literary and other figures of his time, and was keenly interested in new developments in science, art and thought, Bridges devoted his life almost religiously to poetry, contemplation and the study of prosodical and phonetic problems.

Bridges published several long poems and poetic dramas (*Prometheus the Firegiver*, 1883; *Eros and Psyche*, 1885; Eight Plays, 1885-94; *Demeter*, 1905) which, though they contain passages of great beauty, are mainly interesting as exercises in poetic method; his reputation rests rather upon the lyrics collected in *Shorter Poems* (Bks. I-IV, 1890; Bk. V, 1894), of which A. E. Housman said "probably no single volume of English verse has ever maintained such perfection." Always interested in the technique of verse, Bridges had published (1893) a study of Milton's prosody and a critical essay on Keats when in 1895 he was asked to stand for the professorship of poetry at Oxford; he declined, for he did not feel that criticism was his *métier*, though his *Collected Essays* (1927-36) contain many shrewd and bold judgments about poetic technique and inspiration and reveal his deep sensitiveness to the quality of poetry. Though his *Collected Poems* had appeared, in six volumes, between 1898 and 1905, Bridges was little known to the public when he was appointed poet laureate in 1913, and he published little official laureate verse. His wartime anthology, *The Spirit of Man* (1916), achieved wide popularity. *New Verse* (1925) contained experiments in "neo-Miltonic syllabics," and this was the metre of the long philosophical poem, *The Testament of Beauty*, which was published on his 85th birthday and brought him fame almost upon his deathbed. He had already (June 3, 1929) been awarded the Order of Merit. He died on April 21, 1930.

Bridges was in every sense a distinguished figure, and the serenity and aristocratic refinement of his work reflect like qualities in its author. (J. Sp.)

BRIDGES. A bridge is a structure surmounting an obstacle such as a river, road or railway without entirely blocking the way beneath. In this article the development of bridge design and construction is dealt with chronologically from early times. Consideration is given to the wide variety of foundations required, the superstructures of all types of bridges (*i.e.*, girder, arch, suspension and combinations thereof), the different materials available for construction and their strengths and properties, advances in theory and methods of calculation, and the evolution of erection techniques. In conclusion, the latest developments and trends are discussed. The article is divided into the following sections and subsections:

- I. Early History
- II. Roman Bridges
- III. The Middle Ages
- IV. The Renaissance and Transitional Period
- V. Iron Bridges and the Railway Age
- VI. Early Steel Bridges
- VII. Reinforced-Concrete Bridges
- VIII. Long-Span Bridges
 1. Cantilever Bridges
 2. Arch Bridges
 3. Suspension Bridges
 4. Toll Bridges
- IX. Modern Developments: General
 1. Loadings and Forces
 2. Aerodynamic Stability
 3. Foundations
 4. Aesthetics
- X. Modern Developments: Steel
 1. High-Tensile Steel
 2. Shop Fabrication and Erection
 3. Brittle Fracture
 4. Fatigue
 5. Protection of Steelwork
 6. Battle Decks and Composite Construction

7. Box Girders
- XI. Modern Developments: Concrete
 1. Prestressed-Concrete Bridges
 - Quality of Concrete
 - Systems of Prestressing
 - Types of Bridges
 - Methods of Construction
 2. Modern Reinforced-Concrete Bridges

For considerations of the theory of structures and other aspects of engineering science upon which modern bridge design is based, reference should be made to the articles ELASTICITY; MATERIALS, STRENGTH OF; and ARCHITECTURAL ENGINEERING. For information on pontoon bridges and other military types, see BRIDGING, MILITARY.

I. EARLY HISTORY

The earliest bridges were natural, such as the huge pointed arch of rock that spans the Ardèche river at Ardèche, France, or the rock bridge near Lexington, Va. The first primitive man-made bridges may have been flat stones or tree trunks laid across a stream to make a girder bridge or possibly festoons of creepers hung across in suspension.

Three types of bridge, beam (or girder), arch and suspension, have all been known and built from the earliest times. The essential differences between the varieties are that whereas the ends of beam or girder bridges simply rest on the ground, arch bridges are in compression and thrust outward at the ends and the cables of suspension bridges are in tension and pull inward on their anchorages (fig. 1). The type of bridge to be preferred at any site depends on the nature of the ground, the span of the bridge, the kind of traffic it has to carry and the materials of construction available. For some of the early bridges in Persia, where the river bed was stony and no timber was available, a site was selected where there were outcrops of rock across the river on which to build the piers. The resulting structures, such as the Shustar bridge over the Karun river, were not straight but wound across from outcrop to outcrop. Alternatively, mounds of stone could be built up on the river bed or, if the ground was not too hard, timber piles could be driven through the water to form trestles, as in Caesar's bridge over the Rhine. It is said that in the construction of some of the early bridges, such as that over the Euphrates at Babylon, the river was diverted so that the piers could be built on the dry river bed. It is doubtful, however, whether this would have been practicable in those days, unless the flow of the river dwindled to a trickle in the dry season.

Another form of girder bridge is the bridge of boats, such as that built by Xerxes in 481 B.C. to carry his army over the Hellespont. Pontoon bridges, however, are short-lived and costly and it is not surprising that their use is first heard of in a military campaign.

Superstition played its part in early bridge building. Iron was taboo in construction even in Roman times, no doubt because the Romans at heart still lived in the Bronze Age. Human sacrifice was also practised in order to propitiate the gods of the river.

II. ROMAN BRIDGES

Perhaps the three most important contributions the Romans made to the art of bridge building were the discovery of a natural cement, the development of cofferdams, in which the cement could be used to make concrete foundations under water, and their magnificent exploitation of the circular masonry arch. The cement,

FIG. 1.—PRINCIPAL TYPES OF BRIDGES: (A) SIMPLE GIRDER; (B) CANTILEVER; (C) ARCH; (D) SUSPENSION. ARROWS SHOW FORCES BRIDGE EXERTS ONTO OR AWAY FROM FOUNDATIONS

FIG. 2.—ROMAN CIRCULAR ARCH AS SEEN IN THE ORIGINAL PONS FABRICIUS, ROME; 62 B.C.

called *pozzuolana*, was mixed in the ratio of two parts by weight to one of lime (*see* CEMENT). Their cofferdams were made by driving timber piles to enclose the site of the pier and then pouring in concrete through the water. Alternatively, if the river bed was very soft, they drove a double row of sheathing piles and filled in the space between with clay to make the cofferdam watertight. They could then empty the cofferdam with water wheels, dig out the greater part of the soft ground inside it, and concrete the pier in the dry. The Sant' Angelo bridge in Rome stands on cofferdam foundations built in the Tiber river 1,800 years ago. Nevertheless, the Roman underwater foundations were rarely built deep enough or given sufficient protection against scour to enable them to survive long. Most of the Roman bridges that remain were built on solid rock.

The superstructure of many Roman bridges, such as the emperor Trajan's famous bridge built by Apollodorus of Damascus over the Danube in A.D. 104–105, was of timber on stone piers; none of these bridges has survived. The fame of the Roman bridge builders rests on their majestic masonry bridges, built on the grand scale, always with circular arches, which perhaps reached the peak of achievement in the mighty bridge over the Tagus at Alcantara, Port. Built by Caius Julius Lacer for Trajan, the tall granite piers and 98-ft.-wide arches that carry the roadway at a height of 170 ft. above the river have stood for nearly 2,000 years. The huge voussoir stones forming the arch weigh up to eight tons each and were so accurately shaped that no mortar was needed in the joints. The arches must have been built on temporary timber structures supported at the springings. The heavy arch stones were no doubt lifted by a system of pulley blocks, operated by means of a winch, probably based on the principle of the treadmill. Tools used by the Roman masons included saws, chisels, bevellers, wedges and trowels; they also used plumb bobs and levels.

Roman bridges required for a military campaign, such as that over the Danube, were built by legionnaires and financed by the treasury, but the more usual practice was to employ forced labour and to rely for finance on contributions by townships. Engineers and skilled workmen formed into semimilitary guilds were dispatched throughout the empire to supervise the work. By this means knowledge was spread abroad and interchanged and the basis laid down for schools in which professional standards were formulated. Out of these beginnings were evolved the laws of the art of building as drawn up by Vitruvius.

III. THE MIDDLE AGES

In the state of chaos that prevailed after the fall of the Roman empire, bridge building in Europe languished, except for a brief upsurge in the reign of Charlemagne, for some eight centuries. Its revival was marked by the spread in popularity of the ogival or pointed arch westward across the continent from Egypt and the middle east, where it originated. Medieval workmanship could not rival that of the Romans and the pointed arch may have been preferred not only on account of its attractive shape, but also because it demanded less precision than the circular form. Any tendency to sag at the crown is less dangerous, and there is less thrust on the abutments.

Medieval bridges had other functions besides carrying traffic. Chapels, shops, tollhouses and customhouses were built on them, and they were used for fairs and tournaments. Fortified bridges, such as the Pont Valentré at Cahors, France, the bridge over the Gave de Pau at Orthez, France, or the bridge over the river Monnow at Monmouth in Wales were defended by means of draw-

bridges, ramparts and tall towers with arrow slits and machicolations. The upkeep of bridges was considered a pious work, for which money was obtained by alms, by endowment, or from tolls levied on both road and river traffic.

One of the most famous medieval bridges in France is the Pont d'Avignon over the Rhône, which was begun under the direction of St. Bénézet in 1177 and completed ten years later. The bridge spanned the river by means of about 20 lofty, elliptical arches, each 100 ft. wide. St. Bénézet, who is said to have been divinely inspired to build the bridge, died before its completion and was buried in a chapel on one of the piers. Because of the ravages of war and damage from ice in the river, only two or three arches at the Avignon end of the bridge, and the chapel, which has since become a place of pilgrimage, remain standing.

A year before the commencement of the Pont d'Avignon, Peter of Colechurch undertook a far more formidable task—the building of the old London bridge (fig. 3). This was the first stone bridge to be built with masonry foundations in a swift-flowing river having a large tidal range. The bridge was to consist of 19 pointed arches of about 28-ft. span, built on piers 20-ft. wide, with a drawbridge at one end. The foundations were built inside cofferdams made by driving timber

FIG. 3.—ARCHES OF OLD LONDON BRIDGE

and served to hold the pier stones in place. Obstructions encountered in pile driving resulted in variations in the span of the arches of from 15 ft. to 34 ft. Moreover, the width of the protective "starlings," which consisted of loose stone filling enclosed by piles at the base of each pier, was so great that the waterway was reduced to a quarter of its original width and the tide flowed under the narrow archways like a millrace. Nevertheless, the bridge was completed in 1209 and survived together with its famous tunnel-like street of shops and houses for more than 600 years.

Beyond the confines of Europe other fine medieval bridges were built, such as the Red bridge, which consisted of four pointed arches, on the road from Tiflis (Tbilisi) to Tabriz in Persia. In the province of Fukien in China, according to H. Fugl-Meyer's *Chinese Bridges*, an extraordinary stone bridge 1,100 ft. long was built over the Dragon river at Poh Lam. The spans, up to 70 ft. in length, were comprised of three huge stones, two of which rested on top of the piers at each end, while the third spanned the gap between them. How stones of such a size, weighing up to 200 tons, were quarried and transported in medieval times is not known.

IV. THE RENAISSANCE AND TRANSITIONAL PERIOD

The confidence and unbounded enterprise of the Renaissance is typified by Leonardo da Vinci's offer in 1502 to build a masonry arch bridge with a span of 905 ft. (centre to centre of the arch rib) over the Golden Horn at Istanbul. The clear span was to be 787 ft. Moreover, his design appears to have been adequate except for the difficulty of supporting the centring (temporary wooden supports) on which the arch would have had to be built. This period saw the completion of some of the most famous bridges in the world, such as the Pont Notre Dame and the Pont Neuf in Paris, the Rialto in Venice and the Santa Trinità bridge in Florence. Engineers had learned much more about bridge foundations. They were still rarely able to excavate deep enough, *i.e.*, down to rock or really hard strata, but they had learned to spread the base of the pier over a wide area and to lay the foundation stones on a timber grillage supported, if necessary, on bearer piles. In the foundation of the Rialto bridge, for example, Antonio da Ponte, the designer, had 6,000 timber piles driven under each abutment and so placed the masonry on the grillages that the bed joints of the stones were perpendicular to the thrust of the arch. So well were these foundations built that, although they have to support in soft alluvial soil a wide arch carrying a street of shops, they are still standing.

In his beautiful Santa Trinità bridge in Florence, which was built during 1567–69 and stood until blown up during World War

II, Bartolommeo Ammanati, working on scientific principles, evolved a new type of arch. He adopted the ogival shape with the angle at the crown concealed and the curves of the arches starting vertically from the springings. This shape of arch, in which the rise-to-span ratio was as low as one-seventh, became known as "basket-handled" and has been widely adopted since. After the war, the Santa Trinità bridge was rebuilt exactly as it was and (so far as possible) with the original materials, which were dredged from the bed of the river.

In the 17th and 18th centuries, bridge building in Europe developed into a science. The Corps des Ingénieurs des Ponts et Chaussées, by whom plans of all bridges in central France had to be approved, was established in 1716. Jean Perronet, builder of some of the finest bridges of his day, including the Neuilly bridge over the Seine, the Pont Ste. Maxence over the Oise and the beautiful Pont de la Concorde in Paris, was appointed director of the first engineering school in the world. This was the famous *École des Ponts et Chaussées*, founded in 1747. Early in this period scientists such as Galileo and Robert Hooke had investigated the theory of beams and framed structures and before the end of the period bridge builders were required to work to detailed specifications. In 1750 or 1755, William Edwards built what many people consider the most beautiful arch in the British Isles—the Pontypridd bridge, with its lofty span of 140 ft. In London, a few years before, C. Labelye had completed the first bridge at Westminster, which survived for only 100 years.

Meanwhile, in distant parts of the world construction had developed along very different lines. In China, masonry arch bridges that had to stand in the spongy, plastic silt of the river valleys were built of thin curved slabs, jointed so that they could yield to considerable deformation before failure. In Persia, bridges such as the Allah Verdi Khan and the Pul Khajoo were designed as cool, shaded retreats, where the traveler could find rooms for rest and refreshment after crossing the hot desert sands. The two-storied Pul Khajoo at Isfahan (1642-67) is comprised of 24 pointed arches that carry an 85-ft.-wide roadway, with walled passageways above it, along the top of a pierced dam. Flanked by tall hexagonal pavilions and watch towers, the bridge constitutes a magnificent example of engineering and architectural harmony.

Working with another material, Johannes and Hans Ulrich Grubenmann, two Swiss carpenters, built the famous covered timber bridge with spans of 193 ft. and 171 ft. over the Rhine at Schaffhausen in 1756-58. This was followed by a similar timber bridge of 240-ft. span at Reichenau. In North America many outstanding timber truss bridges were built, the first being Enoch Hale's framed bridge over the Connecticut river at Bellows Falls, Vt., in 1785. Louis Wernwag's "Colossus" bridge of 340-ft. span over the Schuylkill river at Fairmount, Pa., was constructed in 1812. The "Burr truss," developed by Theodore Burr, set a new pattern for wooden covered bridges in the United States. His McCall's Ferry bridge (1815) had a record-breaking span of 360 ft.

V. IRON BRIDGES AND THE RAILWAY AGE

It was not until late in the 18th century that iron came to be generally employed in structures, so that bridge builders were no longer limited to the use of timber, brick and stone. Because of the genius of such engineers as Thomas Telford, Robert Stephenson, I. K. Brunel and John A. Roebling, the possibilities opened up by the new material were quickly exploited and by 1860 numerous iron arches, suspension bridges and girders had been built. This period also witnessed the first use of compressed air in the construction of bridge foundations below water.

The first all-iron bridge in the world was the semicircular arch of 100-ft. span designed by Thomas Farnolls Pritchard and built over the river Severn at Coalbrookdale in 1779, although iron had been used for many years in the cables of suspension bridges. Pritchard's bridge carried roadway traffic for more than 170 years. It was followed by a number of cast-iron arches designed by Telford, of which the first was the Buildwas bridge, Shropshire, of 130-ft. span, and the most ambitious his design for a high-level 600-ft. span (which was never built) to replace old London bridge. John Rennie, who built London's Waterloo bridge of masonry

arches (replaced by a modern bridge in 1935-42), was also responsible for old Southwark bridge (1814-19), which consisted of three cast-iron arches with spans up to 240 ft., and the new London bridge of multiple masonry arches completed in 1831, after his death, and subsequently widened.

In his design of the Menai suspension bridge (1820-26) of 580-ft. span in north Wales, on which his fame as a bridge builder undoubtedly rests, Telford adopted chains of wrought-iron links for which Sir Samuel Brown had taken out a patent in 1817. After all the links had been tested and pinned together, the chains were laid out full length, towed across the waterway and hoisted up into place; then the deck was suspended beneath. The roadway was only 24-ft. wide and, in the absence of any kind of stiffening girders or storm bracing, it was highly vulnerable to damage by wind and had to be rebuilt at least twice before the whole bridge was reconstructed in 1940. Nevertheless, in view of the fate of most of the early suspension bridges both in Europe and the United States, it was a credit to Telford that the Menai bridge survived for 115 years. The lack of rigidity of these early examples and their inability to stand up to wind, storms or rhythmic loads had been extreme. Nevertheless, a few survived, including the Fribourg bridge (1834) of 870-ft. span in Switzerland and, until World War II, William Tiernay Clark's fine old 666-ft.-span chain bridge over the Danube at Budapest, which was completed by his brother Adam in 1849.

The credit for designing and building the first suspension bridge that was rigid enough to withstand not only wind action but also the impact of railway traffic belongs to John A. Roebling, an immigrant from Germany to the United States. In his Grand Trunk bridge of 820-ft. span below Niagara falls, there were two decks one above the other, for rail and road traffic respectively, with stiffening trusses 18 ft. deep between them. In addition to this, the deck was braced by means of inclined wire stays overhead and others below anchored to the sides of the gorge. To span the gorge initially, Roebling hit upon the expedient of offering a prize of \$10 to the first boy who could fly a kite across and fasten the string on the opposite side; the string then was used to haul across heavier cords that could support a wire. For the four main cables, instead of the separate stranded or twisted ropes that had been used for cables in Europe, Roebling used parallel wrought-iron wires, spun in place, bunched together and wrapped, a process for which he had taken out a patent in 1841; each cable was of 10-in. over-all diameter. Completed in 1855, the bridge survived for 42 years, although not without considerable repairs and reconstruction necessitated by the wear and tear of traffic.

In 1840, W. Howe patented his timber truss, widely used on the railways in North America, in which the verticals consisted of iron ties; this was followed by numerous other trusses including the Pratt and Warren types, the last of which is frequently used today. The first major iron truss bridge, with pin connections, was built in the United States in 1851; and the earliest iron cantilever girder, which consisted of alternate cantilever and continuous spans, was built by H. Gerber over the Main river at Hassfurt, Ger., in 1867.

The Britannia railway bridge (1845-50) across the Menai strait, north Wales, was designed by Robert Stephenson and William Fairbairn. It employed the prototype of the box girder or plate girder of the kind now used throughout the world, and was originally intended to be a stiffened suspension bridge. There are four spans, each consisting of two wrought-iron tubes side by side through which the trains run; the two spans over the water are each 459 ft. long and the shore spans are 230 ft. long. In spite of the fact that C. L. M. H. Navier's lectures on the theory of elasticity and structures had been published some years earlier, so little was known of theoretical design that Stephenson had to proceed empirically by testing, modifying and retesting a series of models. Workshops were built at the site to fabricate the wrought-iron plates and sections (of the kind that had recently been produced for shipbuilding), which were handled by means of overhead gantries and riveted mostly by hand but in part by hydraulic machines designed by Fairbairn. During erection of the bridge it was found possible to dispense with the suspending

chains altogether, and the tubes for the spans over the water, each of which weighed 1,285 tons, were floated out on pontoons and raised to their final level by means of huge hydraulic jacks located on the piers. Still in service, the Britannia bridge carries locomotives 12 times as heavy as those in use when it was designed.

Up to the middle of the 19th century cofferdams were the only means by which bridge foundations could be properly constructed below water. But because of the limited length of the sheet piling and the difficulties caused by obstructions or by very hard or soft ground, cylinders or wells were employed and sunk either by dredging or under compressed air. The first use of pneumatic caissons for bridgework was on the foundations of the Rochester bridge over the Medway at Rochester, Kent, Eng., in 1851 by Sir William Cubitt and John Wright. Subsequently, I. K. Brunel used this method for sinking the cylinders of Chepstow bridge, Monmouth, Wales, and on a much greater scale for the Royal Albert bridge at Saltash, Cornwall, Eng. (1855-59). Brunel designed a wrought-iron cylinder 35 ft. in diameter for the central pier, which had to be sunk through 70 ft. of water and 16 ft. of mud onto a rock bottom. It was built on the foreshore, towed out and sunk in the position required. By means of compressed air, the water was then expelled from the working chamber at the bottom of the cylinder; workers entered the chamber through the air lock, excavated the mud, dressed the rock and securely plugged the bottom of the foundation with concrete (see SHAFT SINKING).

Many early tragedies in the use of compressed air were caused by men working excessively long shifts or coming out of the air lock and decompressing too quickly, thus being afflicted by caisson disease, or "bends." In 1876, the French physiologist, Paul Bert, discovered that this illness was caused by the liberation of bubbles of nitrogen in the blood or tissues. With the limiting of the length of the working shift according to the air pressure, and with slow

decompression in the air lock, the incidence of caisson disease was reduced. Further investigations made by Leonard Hill at the beginning of the 20th century robbed the disease of its more severe terrors (see CAISSON DISEASE).

Brunel was also the designer of the Maidenhead railway bridge at Berkshire, Eng. the 128-ft. spans of which are the flattest and boldest arches ever carried out in brickwork. The longest masonry arch yet built is that at Plauen, Ger. (1903), which has a span of 295 ft.

VI. EARLY STEEL BRIDGES

The last 30 years of the 19th century saw the introduction of steel plates and rectangular rolled-steel sections, which came to be mass-produced and fabricated in shops by standardized methods. This inevitably led to an enormous output of steel truss and plate-girder bridges for use throughout the world and to spans of ever-increasing size. Arch and cantilever bridges were favoured for long spans in the railway era because they could better withstand the impact of heavy railway traffic than could suspension bridges. It is a curious fact that whereas the catastrophic effect of aerodynamic wind forces on suspension bridges had been frequently experienced, no attempt was made to investigate their character until a much later date, but the collapse of the high-level girders of the Tay bridge, Scot., in 1879 at once prompted research by Benjamin Baker and others into aerostatic wind forces.

This period was also outstanding for the advances made in the theory of design and knowledge of the strength of materials. As a result of the work of such scientists as Karl Culmann and James Clerk Maxwell, graphic methods of structural analysis were developed and engineers were able to draw stress diagrams, influence lines (*i.e.*, curves showing, for one component part of a beam or truss, the shearing force, bending moment, stress, deflection or similar function for all positions of a moving load) and to calculate the deflections and bending moments in trusses and beams. Credit must be given to W. J. M. Rankine, who compiled a comprehensive series of textbooks which gave publicity to important work in Europe and the United States in subjects as varied as strut formulas, earth pressures and shear in beams.

The change from iron to steel took place gradually. Two fine iron arches, the Maria Pia bridge (1877) and the Dom Luis I bridge (1885), were built over the Douro at Oporto, Port., the first being designed by A. G. Eiffel and T. Seyrig and the second by Seyrig. In southern France, two magnificent railway bridges were built—the graceful Garabit viaduct (1885) with a central arch of 540 ft. over the Truybre river and the Viarur viaduct at Aveyron (1898). The latter had an arch 721-ft. long, flanked by cantilever spans of 311 ft., and was the first big bridge in France to be built of steel. The Eads bridge over the Mississippi river at St. Louis, Mo., built by James B. Eads in 1867-74, is of importance on account of the difficulties surmounted in sinking the piers in midstream to a depth never before attempted under compressed air and the fact that it was the first major bridge to be erected by the cantilever method.

The Clifton arch (span 840 ft.), completed in 1898 below Niagara falls, stood for 40 years until the ends of the steel ribs were wrecked by a huge ice jam in the river. In 1905, the Victoria Falls bridge, a flat-topped, spandrel-braced arch of 500-ft. span designed by Sir Ralph Freeman, was built to carry the Cape-to-Cairo railway projected by Cecil Rhodes across the 400-ft. deep gorge of the Zambezi river.

The famous Brooklyn bridge (1869-83; span of 1,595 ft.), designed by John A. Roebling and erected under the direction of his son, Washington Roebling, has four cables with an over-all diameter of $15\frac{3}{4}$ in. built up of parallel wires of cast steel with an ultimate strength of 71.5 tons per square inch. The method of cable spinning devised by Roebling (fig. 5) was so essentially simple and effective that it has been used in principle, although now much elaborated, for all the big suspension bridges subsequently built in the United States. The wire, about 0.19 in. thick, is delivered to the site in reels from which loops are carried over the span one after another by means of grooved traveling sheaves attached to an endless hauling cable. The loops of wire are carried

FIG. 4.—PNEUMATIC CAISSON

FIG. 5.— DIAGRAM ILLUSTRATING METHOD OF SPINNING PARALLEL WIRE CABLES ON A SUSPENSION BRIDGE: (A) ELEVATION; (B) PLAN

over the tops of the towers to the far anchorage, where each loop is pulled off the sheave and placed around a strand shoe by which it is anchored.

In one or two of the early suspension bridges, notably the Point bridge at Pittsburgh (1877), an attempt was made to stiffen the eyebar-chain cables instead of the deck, but the latter system has proved more satisfactory. Two more suspension bridges, built over the East river in New York, were the Williamsburg bridge (1903), which has straight backstays, and the Manhattan bridge (1909). For the latter, the cable wire used was cold-drawn and had an ultimate strength of 93.6 tons per square inch, and the "deflection theory," by means of which substantial economy is achieved in the design of the cables, was employed for the first time.

For the design of the Forth bridge (1882–90; two main spans of 1,710 ft. each) in Scotland, Benjamin Baker conducted an extensive series of wind pressure tests, using gauges installed at the site, over a period of two years. As a result, he was satisfied that the pressure of 56 lb. per square foot specified for the design by the committee set up after the Tay bridge disaster was "considerably in excess of anything likely to be realized" and so it has proved. The two main spans of the bridge each consist of two 680-ft. cantilever arms with a 350-ft. suspended span between them. About 54,000 tons of Siemens-Martin open-hearth steel, which has a substantially higher ultimate strength than modern commercial mild steel, were used. The biggest compression members were designed as tubular struts 12 ft. in diameter, and all the steelwork was fabricated in shops built for the purpose at South Queensferry. The spans were built out as balanced cantilevers from each main pier, the tubular members being erected plate by plate by means of two-ton hydraulic cranes.

The latter half of the 19th century witnessed the construction in India of a large number of multi-span railway bridges more than 1,000 ft. long. Their British builders learned how to utilize the simplest kind of equipment and unskilled labour; they had to study and develop the use of guide banks to keep the rivers under the bridges and prevent them from meandering; and, sinking brick wells by dredging in the sand, they built the deepest foundations ever constructed, as a safeguard against undermining when the sand of the river beds was scoured away in the flood seasons.

In 1896 the first Vierendeel truss, in which the bracing consisted of a series of framed portals with rigid verticals and no diagonal members, was built for the Brussels exhibition.

Apart from a few small cast-iron swing bridges built in London early in the 19th century, the three main kinds of movable bridge, *i.e.*, bascules, swing spans and the vertical-lift type, were evolved in the latter half of the century. The Tower bridge in London (1886–94) is a double-leaf simple trunnion bascule which provides an opening 250-ft. wide and is operated by hydraulic power derived from steam (fig. 6). The Kincardine bridge (1936) over the river Forth in Scotland has a balanced swing span of 364 ft. in its overall length of 2,696 ft. The world's longest vertical-lift bridge, over the Arthur Kill between Staten Island and New Jersey, was completed in 1959 (*see* Table I). The lifting span of 558 ft. weighs

2,000 tons. Transporter bridges, such as that at Middlesbrough over the Tees, on which traffic is carried on a moving platform suspended from an overhead structure, cannot cope with the demands of modern traffic and are now obsolete.

VII. REINFORCED-CONCRETE BRIDGES

Among the engineers to whom credit must be given for appreciating and demonstrating the possibilities of reinforced concrete as a new structural material are Robert Maillart of Switzerland and François Hennebique and Eugène Freyssinet of France. Visualizing the entirely novel forms of structure that could now be molded, with concrete resisting the compressive forces and steel bars taking the tension, Hennebique designed his bridges in sweeping curves and Maillart showed how the basic element in reinforced concrete, which was the slab, replaced the beams, posts and ties associated with steelwork design. From the start, Switzerland, France and the Scandinavian countries took the lead and the longest and most impressive reinforced spans were to be found in those nations.

The first notable reinforced-concrete arch, the Pont de Châtelerault (1898) designed by Hennebique, had a span of 172 ft. Maillart, who was Hennebique's pupil, was the protagonist of "the structure as a whole." The first of his famous three-hinged arches,

*Railway bridge. †Combined length including both arms.

in which he combined the deck and the rib to produce closely integrated structures, was the Tavanasa bridge, a span of 157 ft. over the Vorder Rhein, Switzerland, which was unfortunately swept away by a landslide in 1927. In these bridges, Maillart recaptured the beauty of the fine old pointed arch of medieval times. He then developed arches of very thin reinforced-concrete slabs, typified by the Schwandbach bridge (1924) near Schwarzenburg, Switz., which was curved in plan and carried a roadway across a deep ravine.

One of the biggest reinforced-concrete bridges in the United States, the Tunkhannock Creek viaduct, Pa., was completed in 1915. Its over-all length of 2,375 ft. comprises ten semicircular arches of 180-ft. span which carry a double-track railway at a height of 240 ft. In Great Britain, the first major reinforced-

CANTILEVER BRIDGES IN EUROPE AND AMERICA

1. View of the Quebec bridge, crossing the St. Lawrence river nine miles west of Quebec. This bridge, having a channel span of 1,800 feet between pier centres, was completed on September 20, 1917, when the 640-foot suspended span was hung on the cantilevers and bolted into its final position. Two serious accidents which occurred in 1907 and 1916, during the process of construction, necessitated changes in the original design and delayed the completion of the bridge
2. The Poughkeepsie railway bridge, crossing the Hudson river at Poughkeepsie, New York. This reverse cantilever bridge, 2,260 feet long and 200 feet above the water, carries the trains of the Central New England railroad across the Hudson. It was completed in 1889 and rebuilt in 1904
3. The Queensboro cantilever bridge, which crosses the East river between Second avenue, Manhattan, and Long Island City, with sustaining towers on Blackwell's Island (now called Welfare Island)
4. The Forth bridge, crossing the Firth of Forth, in Scotland, at a point where the channel is divided by the island of Inchgarvie. The two main spans of this cantilever bridge, opened March 4, 1890, are 1,700 feet each, the length is 5,330 feet, and the extreme height of the towers above high water is 361 feet
5. The Outerbridge crossing from Tottenville, Staten Island, to Perth Amboy, New Jersey, opened for traffic on June 29, 1928. The main span, centre to centre of piers, is 750 feet; the total length, plaza to plaza, is 10,140 feet, and the over-all width of the bridge is 55 feet

ARCH SPAN BRIDGES

1. Bayonne bridge, crossing the Kill van Kull from Bayonne, New Jersey, to Port Richmond, Staten Island, U.S.A. The length of the arch span is 1652 feet, of the main structure 5780 feet. Completed in 1931.
2. Sydney Harbour Bridge, New South Wales, was completed in 1932. The length of its arch span is 1650 feet, of the main structure, 3770 feet.
3. The Old Trails Highway, opened to traffic in 1916, single span arch across the Colorado river connecting California with Arizona, on the route of the Old Trails Highway near Topock, Arizona.
4. Hell Gate bridge, single span steel-arch four-track railroad bridge across the East river, New York, U. S. A., opened in 1917. From railing to railing it is 93 feet wide. The towers at each end rise 95 feet above the track level.
5. The Newcastle-upon-Tyne bridge, steel arch, constructed in 1925-28 to carry the Great North Road across the Tyne at Newcastle. The total length of the bridge is 1254 feet.
6. The Royal Tweed road bridge, a huge ferro-concrete structure crossing the river Tweed at Berwick, opened on May 16, 1928. To the left is the old stone bridge.
7. Stony Creek bridge, over the gorge of that name, on the Selkirk range in British Columbia, erected in 1893, has a span of arch of 336 feet and is 300 feet high.
8. The International (toll) Peace bridge, Buffalo, New York, connecting the United States with Canada at Fort Erie, Ontario. It was opened August 7, 1927.

BRIDGES OF THE UNITED STATES

1. The George Washington bridge over the Hudson river, connecting 179th street, New York city, and Fort Lee, N.J., was the longest suspension span at the time of its completion (1931). It took four and one-half years to construct it at a cost of about \$60,000,000 and was opened to traffic Oct. 25, 1931. There are four roadway lanes and two pedestrian sidewalks. Length of river span, 3,500 ft.; height of roadway above river, 250 ft.; height of towers, 600 ft.; diameter of each cable, 36 in.; number of wires in each cable, 26,474
2. Aerial view of the Triborough bridge which connects the boroughs of Manhattan, the Bronx and Queens, New York city. The three arms of the giant bridge meet on Randall's island
3. Golden Gate bridge, San Francisco, completed in 1937. Length of main span, 4,200 ft., the longest

in the world at the time of its completion; height of tower 746 feet. This bridge has six highway lanes and a footbridge on each side of the roadway

4. Western section of the \$77,000,000 San Francisco-Oakland bridge. The two suspension bridges have 2,310-ft. main spans. The west half of the bridge is a suspension structure comprising twin suspension bridges anchored into a huge concrete monument in the centre. A double-deck tunnel pierces Yerba Buena island, and the double-deck bridge continues over a 1,400-ft. cantilever span, 5 through truss spans, and 14 deck truss spans before it lands on a fill extending out from the Oakland shore. The 51 piers of this bridge go deeper below water than any previous substructure ever built, some as far as 237 ft. below low tide

concrete structure was the Royal Tweed bridge at Berwick, completed in 1928, which has four arch spans varying from 167 ft. to 361 ft. This was followed in 1935-42 by the new Waterloo bridge in London, designed by the firm of Rendel, Palmer and Tritton in association with Sir Giles Gilbert Scott, which is considered by many people because of its slender simplicity and absence of decoration to be the finest bridge over the Thames. Of the five spans, four are continuous girders and the centre span consists of two cantilever arms and a suspended span. A pioneer attempt was made in this bridge to eliminate hairline cracks in the concrete. The measures adopted, which were very successful, included welding reinforcing bars at their intersections, careful control of the mix, vibrating the mix while pouring, and slow curing of the concrete.

In France, Freyssinet had built a record span of 430 ft. over the Seine at St. Pierre du Vauvray (1923), which he surpassed seven years later with the Albert Louppe bridge near Plougastel. The latter had three arch spans of 567 ft. The centring for this bridge consisted of a timber arch 500 ft. long and 90 ft. high, the ends of which were tied together by cables. It was built on shore, floated out on pontoons and secured in place for concreting each arch rib in turn. Freyssinet also endeavoured, by jacking the arch ribs at the crown, to eliminate internal stresses that would otherwise be produced by shrinkage of the concrete.

In 1934 Sweden took the lead with the Traneberg bridge in Stockholm, which has an arch of 593 ft. This was surpassed by the Esla bridge in Spain with a 672-ft. span completed in 1942; but a year later Sweden regained the lead with the 866-ft. span of the Sando bridge, designed by C. R. Kolm, over the Angerman river (see Table II). In 1939, during the concreting of the rib, the centring—a timber-framed tied arch of 810-ft. span—collapsed, its failure being ascribed to persistent damp weather and the long loading period. New centring had to be built in the form of huge timber trestles supported on 13 groups of piles 130-ft. long, and the bridge was successfully completed in 1943. The working stresses permitted in the concrete and steel were 1,550 lb. per square inch (p.s.i.) and 21,200 p.s.i. respectively, which are about $1\frac{1}{4}$ times those adopted in the Waterloo bridge at about the same date.

Precast-concrete girders are sometimes used for economy and speed of construction in multiple short-span bridges. A typical example is the San Mateo bridge across San Francisco bay, which has 1,054 precast spans of 30 ft. and 116 spans of 35 ft. One of the main advantages claimed for reinforced-concrete bridges is that, if they are well designed and the construction is thoroughly supervised, they should be maintenance-free and not require cleaning and painting every few years, as do steel bridges. To achieve this, the concrete must have a solid weather-resisting surface free from cracks and honeycombs or, alternatively, it must be stone-faced. Facing is costly, but it obviates the risk of the appearance of the concrete deteriorating with age. A most successful example is the Waterloo bridge in London, which is faced with slabs of Portland stone.

VIII. LONG-SPAN BRIDGES

For a given ratio of strength to weight of materials, there is a maximum span for each type of bridge beyond which it would have an insufficient margin of strength to support the weight of

traffic in addition to its own weight and any other forces to which it might be subject. For cantilever bridges built with modern high-tensile steel, the maximum span would approach 2,500 ft., and for arch bridges, 3,000 ft. On account of the much higher strength-to-weight ratio of steel-wire cables, as compared with structural steel, suspension bridges can be built with much longer spans. In a period of 50 years, the maximum span was increased from 1,500 ft. to 4,200 ft. (see Table III), thus bearing out predictions made by Roebling in 1855. There is little doubt that with modern materials engineers could build a suspension span two miles long.

I. Cantilever Bridges.—In 1904 work began on the first Quebec bridge, which was to carry two railway tracks on a span of 1,800 ft. As the southern end of the suspended span was being erected, however, the whole of the structure on that side, some 9,000 tons of steel, collapsed. It was found that the failure was caused by buckling of the web plates of the compression chords, in which the lacing was too weak, and also by the connections being allowed to remain open and unriveted. Other grave disclosures, however, were that the specification was inadequate, the weight of the bridge was underestimated and the working stresses were unwarrantably high. For the new design, made after an exhaustive series of tests on structural members and riveted joints, high-

tensile nickel steel (at working stresses 40% higher than those for mild steel) was used for the main trusses and the width of the bridge was increased from 67 ft. to 85 ft. All went well until the time came to lift the suspended span, which was 640 ft. long, weighed 5,000 tons and had been floated out and attached to lifting links at the four corners of the cantilever arms. Suddenly one of the cross-shaped castings at the end of a lifting link failed and the span tilted, broke its back and fell into the water. Within a year a new span had been made and successfully erected. Opened to traffic in Aug. 1918, the bridge remains the longest cantilever span in the world. (See Table IV.)

Another great cantilever is the Howrah bridge (1936-43) over the Hooghly river at Calcutta, which has a span of 1,500 ft. (fig. 7). This bridge is notable for the huge monolith foundations measuring 180 by 81 ft. in plan, the biggest ever sunk on land, required for the main piers. Each reinforced-concrete monolith was divided into 21 wells 20 ft. square and was sunk by open excavating. The monolith on the Calcutta side was set at a depth of 103 ft. under compressed air. This technique was applied to each well in turn after a temporary air deck was fitted near the bottom of the well to form a working chamber—a method devised by H. J. Fereday and successfully used on a number of major bridges in

FIG. 7.—ERECTION OF HOWRAH BRIDGE, CALCUTTA, INDIA: (A) ANCHOR ARMS ERECTED ON STAGING; (B) ERECTION OF CANTILEVERS; (C) ERECTION OF SUSPENDED SPAN

India and Burma and also on the huge Lower Zambezi bridge in Mozambique. An interesting innovation on the Howrah bridge was that the high-tensile steelwork was prestressed during erection in order to obviate dead load secondary bending stresses that would otherwise have occurred at the riveted connections.

2. Arch Bridges.—The Sydney Harbour bridge (1924–32), New South Wales, Austr., designed by Sir Ralph Freeman, may be

considered the world's greatest steel arch because of its immense carrying capacity and the difficulties overcome in erecting such a huge span across a deep harbour in which no temporary supports were practicable. It has a span of 1,650 ft. and was built to carry four interurban rail or streetcar tracks, in addition to a roadway 57 ft. wide and two footpaths. The two-hinged arch, flanked by granite-faced pylons, is spandrel-braced, with the deck suspended below at a height of 172 ft. above the water. Most of the 38,390 tons of riveted steelwork in the arch is of high-tensile silicon quality, the steel being made in Britain and fabricated in shops built for the purpose in Sydney. The four-webbed, 11-ft.-wide chords of the arch, built up of 2-in.-thick plates and 12 by 12 in. angles, are the heaviest steelwork of this kind ever constructed. The two halves of the arch were built out as cantilevers, temporarily held back by means of wire-rope anchorages, until they met and were joined in the middle. All the steelwork was assembled by two creeper cranes of 120 tons capacity, which moved out along the upper chords of the arch until it was complete and then erected the hangers and the deck as they retreated (fig. 8).

Another fine steel arch, the Bayonne bridge over the Kill van Kull between Staten Island and Bayonne, N. J. (see Table V), was designed by O. H. Ammann after the commencement of Sydney Harbour bridge and completed a few months before. It carries roadway traffic and was built over a shallow waterway which en-

abled the arch, which is 25 in. longer than that at Sydney, to be erected on temporary trestles.

3. Suspension Bridges.—In the series of suspension bridges of ever-increasing span built in the United States between World Wars I and II, cables of parallel wires were invariably used. Although the ultimate strength of wire increases as it is drawn thinner, it is found most economical to use wire of about 0.19 in. diameter. Moreover, the thicker the wire the less length there is to be spun to make up a cable of the necessary diameter. Parallel-wire cables are generally economical for spans over 1,500 ft., particularly in the United States, where the specialized spinning equipment, including unreeling, compacting and wrapping machines, is available. In Canada, cables of stranded-wire ropes have been adopted, notably on the Island of Orleans bridge at Quebec (1935) and the 1,550-ft.-span Lions Gate bridge at Vancouver (1939). A third variant, known as "locked-coil" cables, in which the outer wires of each strand are specially shaped so as to form a smooth circumference, was used in the Cologne-Miilheim bridge over the Rhine.

In the 1,750-ft. span of the Philadelphia-Camden bridge (1926) on the Delaware river, cold-drawn parallel wire was used in the cables, and cellular construction (widely adopted subsequently) was employed for the first time in the design of the towers. In the endeavour to increase the allowable stress in the cables, heat-treated wires with a yield point 31% higher than that of cold-drawn wire were used in the Mount Hope, R.I. bridge and the 1,850 ft.-span Ambassador bridge over the Detroit river, both completed in 1929. During erection of the cables, however, a number of broken wires were detected at the bends around the strand shoes at the anchorages. Investigation showed that the fine-grained, heat-treated wires could not withstand the alternating stresses to which they were subject; they had to be replaced by cold-drawn wire which has a tough, fibrous structure and can resist such stresses.

The next advance was O. H. Ammann's George Washington bridge (1927–31), with a span of 3,500 ft., which was designed to carry two roadways one above the other, sufficient for four to eight lanes of traffic respectively. Four cables 36 in. in diameter, each built up of 26,474 parallel galvanized wires with an ultimate strength of 98 tons per square inch, were used at a maximum working stress of 36½ tons per square inch. A unique feature of the bridge was that initially there were no stiffening trusses; at first, only the upper roadway was built (and that in two stages), but in

FIG. 9.—CABLE ANCHORAGE ON GEORGE WASHINGTON SUSPENSION BRIDGE, NEW YORK CITY

1959 the construction of the lower deck and of stiffening trusses between the two decks was begun. The great mass of wire in the cables (a total of 105,000 mi.) prompted a higher degree of mechanization in the cable erection than had ever been achieved before. Fig. 9 shows one of the cable anchorages.

In 1933, work began in San Francisco on two big suspension bridges, the double-decked Transbay bridge designed by C. H. Purcell, which has an over-all length of $4\frac{1}{4}$ mi., and the huge Golden Gate bridge designed by J. B. Strauss, which has a span of 4,200 ft. across the entrance to the harbour and is the longest single span

yet built. The foundations of these bridges, which had to be sunk through deep, swift-flowing water, some of them to a depth far greater than that at which men could work in compressed air, presented formidable difficulties. A new method of pier construction devised for the Transbay bridge consisted of groups of dome-capped steel cylinders, which were sunk by the controlled release of air pressure inside them. The excavation for one of the piers was carried to a depth of 242 ft. below sea level. For the Golden Gate bridge, the south pier was built inside a huge reinforced-concrete cofferdam placed on the bed of the ocean.

The Mackinac bridge (1954–57), designed by D. B. Steinman, which has a span of 3,800 ft. across the Mackinac straits in Michigan, is the second-longest suspension span yet built.

The Tancarville suspension bridge (completed in 1959) across the Seine estuary near Le Havre has a span of 2,010 ft., which is the longest in Europe (see Table VI). Novel features include reinforced-concrete towers, stiffening trusses continuous over the towers and main cables built up of 56 separate stranded-wire ropes. These are anchored to the deck at mid-span by means of special collars in order to provide extra stiffness against aerodynamic forces.

4. Toll Bridges.—Long-span bridges are costly, and experience has shown that the most practicable manner in which they can be afforded is to build them as financially self-liquidating projects by charging tolls on the traffic using them. By this means, about 30 bridges varying in span from 1,000 ft. to 4,200 ft. were built in the United States during 1920–60, but not one in Britain, where it was hoped to build them out of public funds.

The promotion of a new bridge project and its design, construction and operation are probably best controlled by a bridge authority established by legislation. The necessary capital is raised by the issue to the public either of government-guaranteed bonds or of revenue bonds serviced by the proceeds from tolls. The toll charges for each type of vehicle are fixed by the authority and are generally less than the charges previously made on the ferries. New crossings tend not only to attract but also to generate traffic, and the majority of the U.S. toll bridges have paid their way handsomely from the start; none of them has experienced financial difficulties; on some the toll charges have been successively reduced; and a few have been freed altogether. Examples of toll bridges outside the United States are the Auckland Harbour bridge in New Zealand and the Tancarville bridge in France.

IX. MODERN DEVELOPMENTS: GENERAL

1. Loadings and Forces.—The most important loadings and forces to which a bridge is subject are: its own weight; the weight of the traffic and its dynamic effects; natural forces set up by wind, changes in temperature, snow loads, earthquakes, etc.; and stresses arising temporarily during erection. As regards railway loadings, the bridge has to withstand not only the weight of the locomotives and rolling stock, but also the impact and effects of lurching and lateral motion of the locomotive. The severity of these loadings depends not only on the motive power but also on the quality of the track. On the highways of several countries, vehicles weighing up to 200 tons are not uncommon, and new bridges must be designed to support them.

Considerable research has been carried out on wind forces, which can now be closely estimated, but wind-tunnel tests on a model are still advisable in assessing the effects of wind forces on a long-span suspension bridge. Although no bridge could be expected to withstand an earthquake of catastrophic force, bridges in India and New Zealand are designed to resist a horizontal force equal to one-tenth, and in Japan, Italy and the U.S.S.R. to one-fifth, of the weight of the superstructure. The Golden Gate and Transbay bridges in San Francisco, the Auckland Harbour bridge, and the Howrah and Ganga bridges in India mere all calculated to resist earthquake shocks. It remains for the engineer to exercise his judgment in assessing future traffic developments and deciding what combinations of loading and forces should be adopted and the factor of safety applicable in each case.

2. Aerodynamic Stability.—The collapse of the Tacoma Narrows bridge at Puget sound, Wash, in 1940, only four months after its completion and after more than 50 years of immunity from failure of this kind, brought the study of aerodynamic stability sharply to the fore. This bridge was by far the most flexible among its contemporaries. It had a span of 2,800 ft. with a width of only 39 ft., and the deck was stiffened throughout its length by means of plate girders 8-in. deep. Under quite moderate winds, the deck not only swayed sideways but was subject to severe torsional vibration and ultimately, in a wind of only 42 m.p.h., the vibrations became so violent that the deck was torn away and crashed into the water. Other fine U.S. suspension bridges have also shown undesirable aerodynamic action. D. B. Steinman has calculated a "co-efficient of rigidity," from which it appears that all suspension bridges stiffened with plate girders in which this coefficient is less than 15 and all those stiffened with lattice girders in which it is less than 6 have been adversely affected.

In spite of tests in wind tunnels of models of bridges and their components, the explanation of aerodynamic instability is a matter of theory on which conflicting opinions are held; but a number of general requirements for avoiding it have now been established. These include opening the structure to the wind wherever possible by employing latticed stiffening trusses and cross girders and leaving longitudinal slots along the deck between the dual roadways and the girders. Rigidity can also be increased by providing upper and lower lateral systems in the deck, by employing diagonal cable stays from the towers, and even by anchoring the main cables to the deck at the centre of the span. Comprehensive tests made by R. A. Frazer and C. Scruton in 1946–51 in a specially built 60-ft.-wide wind tunnel, in connection with the design of the proposed

suspension bridge over the Severn, showed the advantages of the above-mentioned features. All of them, except the diagonal stays and the central anchorage of main cables to the deck, were adopted for the second Tacoma Narrows bridge, completed in 1950, in which width and rigidity were considerably increased as compared with those of its predecessor, and for the Mackinac bridge.

3. Foundations.—The most significant trend in foundation design is the tendency to support bridge piers on groups of large-diameter piles where possible in preference to using pneumatic caissons. In the foundations of the Narrows bridge, completed in 1959 over the Swan river at Perth, Western Australia, 180 long piles nearly 3 ft. in diameter were used. These were driven as hollow cylinders by means of a hammer running inside the pile and striking near its foot, and they were subsequently reinforced and concreted. For the huge Wu-Han double-deck rail and road bridge built in 1955–57 over the Yangtze river in China, a new system of "colonnade" foundations on large-diameter piles was designed by the Soviet specialist A. I. Silin-Bekchurin. This bridge consists of nine riveted steel trusses, each of 418-ft. span, which were erected by the cantilever method. The piers were built on top of groups of reinforced-concrete tubular piles up to 5 ft. in diameter, which were bored into the bedrock at a depth of 131 ft. below water level, reinforced inside with steel and concreted below water. (See FOUNDATIONS.)

4. Aesthetics.—Throughout the ages there have been engineers who achieved beauty in their bridges, but in spite of their example vast numbers of purely utilitarian structures have been built. Today it is accepted that economy and function are not the only criteria but that any new bridge should be a work of art, designed to harmonize with its surroundings and to give satisfaction to the eye of the engineer and layman alike. To this end, a number of societies are active, such as the American Institute of Steel Construction, which gives awards for the most beautiful steel bridges built each year. In Britain, the public authorities have a considerable degree of control, and designs for new bridges of importance have to be approved also by the Royal Fine Art commission. Express-highway construction entails the building of many bridges, the design of which largely determines the architectural character of these highways and the way in which they blend with the surrounding countryside.

X. MODERN DEVELOPMENTS: STEEL

Research in steelwork has concentrated on the commercial production of structural steel of high-tensile quality that is also suitable for electric-arc welding and for fabrication by flame cutting. Other important qualities sought include notch ductility and resistance to fatigue and corrosion. New forms of connection include welding, which reduces the weight of the structure, and the use of friction-grip bolts. Steel trusses may be built of all-welded mild or high-tensile tubular members; hollow rectangular sections up to 13-in. square and 1-in. thick, which are seamless and rolled, can now be obtained. For bearings of bridges, Meehanite, a form of cast iron, is increasingly used and expansion joints may be built up of layers of rubber bonded between steel plates. The destruction of bridges in Europe and elsewhere during World War II gave bridge builders a great opportunity for the development of new forms. In Germany this led to the construction of many fine box-girder bridges over the Rhine and elsewhere, in which remarkable savings in material were achieved, and later to the evolution of the cable-braced girder. A new form of stiffened steel-plate deck known as a "battle deck" was evolved, and composite construction in steel and concrete came into general use. Attention has also been paid to the mechanical cleaning of steelwork and methods to be used for its protection.

1. High-Tensile Steel.—For girder bridges of span greater than 300 ft., steel should be the most economical material to use; for arches, the critical span is longer. As the length increases, low-alloy or high-tensile steel is preferable to mild steel (see STEELS, ALLOY). The saving in weight on long spans is shown by the fact that, for example, on the Sydney Harbour bridge every ton of steel in the arch requires 0.7 tons to support it. With their yield

point of 23 tons per square inch, low-alloy steels can be used at substantially higher working stresses than mild steel, which has a yield point of 16 tons per square inch. Among low-alloy steels suitable for welding are St 52–3 (west German), A 52 (Belgian), A 242–55 (U.S.) and steel manufactured to British standard 968. They cost little more to produce than mild steel but are not usually so readily available. Other special steels, such as the U.S. T-1, which has a yield point of over 40 tons per square inch, have been produced, but their cost is double that of mild steel. Nevertheless, about 3,000 tons of weldable quality T-1 steel were used in the second Carquinez bridge (1958) near San Francisco, the allowable working stresses being 20 tons per square inch in tension and 16 tons per square inch in compression.

Laminations in steel plates become a much more serious defect in welded than in riveted work, and a system of ultrasonic tests has been evolved whereby laminations can be detected before fabrication. Light alloys such as aluminum may play a greater part in bridge construction when they become less costly. They have been used to make light service spans required for the erection of bridges, and also to reconstruct the decks of old bridges at reduced weight.

2. Shop Fabrication and Erection.—Shop fabrication now includes the use of profile burners by means of which steel can be flame-cut and the edges beveled for welding, if required; rotary jigs are used for assembly of members and automatic submerged-arc machines, which give complete penetration, for welding the seams of columns or girders. The quality of the welds can be determined by means of X-ray and gamma-ray photographs.

For erection on the site, welding may be used for plate girders but is not usually suitable for trusses. Riveting has been largely superseded by the use of friction-grip bolts, which can be used in clearance holes and act as high-tension clamps. Pneumatic wrenches are used to tighten the bolts and calibrated torque wrenches to check their tension. This system is quicker, cleaner, more efficient and more economical than riveting, and modern workmen much prefer it. It was used in the erection of Auckland Harbour bridge, the Mackinac and Carquinez bridges in the United States and the Volta bridge in Ghana. The method in which these bolts were used in the 805-ft. steel arch of the Volta bridge represents a major advance in bridge-building technique. At the connections between the chord members, four friction-grip bolts were used longitudinally as pretensioned ties, so arranged as to interconnect pairs of plates welded across the corners of the section. During erection of the two halves of the arch as cantilevers, therefore, the stability of the structure depended on these groups of bolts acting in tension in the connections of the upper chords.

3. Brittle Fracture.—The catastrophic failure of the all-welded Duplessis bridge at Three Rivers, Can., at a temperature of –30° F. on Feb. 1, 1951, following the failure of some all-welded Liberty ships built during World War II, drew attention to the liability of steel to brittle fracture. The 2-in.-thick flange plates of the 180-ft. plate girders that failed proved to be of poor-quality steel that was abnormally notch-sensitive even at ordinary temperatures. The risk of brittle fracture is enhanced by welding because welding not only tends to cause changes in local stress ratings, which may initiate failures, but also increases the critical temperature at which they may occur. Moreover, it encourages the use of single, thick flange plates, which are more susceptible to fracture than the multiple thin plates used in riveted work. The fracture of a single thick plate is obviously much more serious than the failure of one of a number of thin plates; furthermore, in riveted work, cracks may be arrested by rivet holes. To obviate the risk of brittle fracture, notch-ductile steel has been evolved in a number of countries; four grades (of mild-steel quality) are now manufactured to British standard 2762, and high-tensile notch-ductile steels are rolled in Sweden and west Germany (St 52).

4. Fatigue.—Fatigue in metal is the lowering of the ultimate strength of the metal and the formation of cracks as a result of continual reversals of stress. Its degree is dependent on the intensity of the stress and the number of reversals. As might be expected, fatigue of steel represents a major problem to railway engineers

responsible for the design and maintenance of railway bridges and their decks. Research has been directed to obtaining all possible data as to the number and nature of the stress cycles to which bridges are subject and to the production of types of construction and a quality of steel that can best withstand them.

5. Protection of Steelwork.

—Until structural steel of stainless quality can be produced economically, protection is of first importance. The old method of cleaning by wire brushing to remove rust and loose mill scale has now been largely superseded by the use of pickling in acid, flame cleaning or blasting with metal grit or sand. It is important that protective coatings of paint or metal should be applied immediately after this treatment, while the surface of the steel is clean and dry. If metal spraying is adopted, zinc or aluminum is generally applied, the thickness of the coat varying from 0.002 in. to 0.006 in.; although this metal coat will protect the steelwork, it is usually protected in turn by painting. Satisfactory maintenance of steelwork further depends on the care taken in designing the details so as to avoid pockets, slots or traps of any kind in which water can lodge and in insuring that no part is inaccessible for cleaning or painting (except, of course, the interior of wholly enclosed box members).

6. Battle Decks and Composite Construction.—"Battle decks," first used in ships but adapted for bridges after World War II, consist of decks made of flat steel plates welded together and stiffened by means of flats, angles or some other section welded on the underside (fig. 10). Further economy can be achieved by making the deck act integrally with the main members, becoming in effect the top flange of a box girder. Battle decks are economical on long spans, where their saving in weight is important, but they require more maintenance than do reinforced-concrete slabs.

In "composite" construction, the concrete roadway slab is anchored by means of shear connectors to the steel girders and made to act in conjunction with them. This form of deck was used on an all-welded steel highway bridge with a span of 334 ft. over the Moscow river in the U.S.S.R. (1956). In the 1,240-ft. Cologne-Rodenkirchen bridge over the Rhine (1954), the concrete deck was prestressed; it not only carries the traffic but also acts as part of the upper chord of the stiffening trusses and provides lateral bracing for the main span. On both steel and concrete decks, waterproofing and wearing surfaces have to be provided. These are frequently of asphalt with granite chips, but experiments have been made involving the application of a very thin layer of rubber compound as protection for a steel battle deck.

7. Box Girders.—The Cologne-Deutz bridge (1947-48), the first of the big postwar box-girder spans over the Rhine, showed what major advances in appearance span and economy could be made by taking full advantage of modern techniques. In the triple

box girders of this bridge, stiffened web plates 25 ft. deep over the piers and only $\frac{3}{8}$ in. to $\frac{3}{4}$ in. thick were first employed. Much of the 5,760 tons of steelwork is high-tensile (St 52), and its weight is only 61% of the steelwork in the old bridge it replaces. Three years later: the Diisseldorf-Neuss bridge, with its 675-ft. span and steel battle deck, was completed (see Table VII). Both these bridges were erected in heavy pieces, each weighing 200 to 300 tons; the pieces were assembled on the river bank, floated out, and lifted by cranes which had been used to clear away the debris of the old bridges. The longest box-girder bridge built through 1960

*Not standing. †Railway bridge.

was the 40-ft.-wide roadway bridge across the Sava river at Belgrade, completed in 1957, which has a span of 856 ft. and replaces the King Alexander suspension bridge. Designed by a west German firm: it consists of an inverted U-shaped girder of high-tensile steel. The new autobahn bridge over the Wupper valley (1959) in west Germany, with seven spans varying from 144 to 239 ft., has a reinforced-concrete deck slab in composite construction with steel box girders of novel trapeze-shaped section and inclined webs. It is interesting to note the basic similarity of these modern box girders to the Britannia tubular bridge first conceived by Robert Stephenson more than a century before.

A further development, in which the girders are supported by groups of prestressed cables passing over the tops of towers on the main piers, was first introduced in the Stromsund highway bridge in Sweden (1956). This method was adopted in the North bridge (1957) over the Rhine at Diisseldorf, which has a main span of 853 ft. The two box girders, of shop-welded St 52 steel, are supported by three parallel tiers of cables that were prestressed during erection. In the Severin bridge (1959) at Cologne, there is a cable-braced span of 991 ft. supported by three sets of cables which pass over the top of an A-shaped tower built on a pier near the east bank (fig. 12). For spans of more than 1,000 ft. on the Rhine, suspension bridges, such as the Rodenkirchen and Miilheim bridges at Cologne, are found the most economical. For spans of less than 650 ft. box girders are cheapest, and for intermediate spans cable bracing shows economies.

XI. MODERN DEVELOPMENTS: CONCRETE

1. Prestressed-Concrete Bridges.—The process of prestressing concrete, which consists of putting it into a state of compression

FROM "STAHLBAU-TASCHENKALENDER"

FIG. 12. — SEVERIN BRIDGE AT COLOGNE, GER.

by tensioning steel wires or bars which pass through it, was conceived at the beginning of the 20th century and undoubtedly represents the most important advance in bridge construction since reinforced concrete came into general use. The economies in material which prestressing rendered possible led to its rapid development in the period of shortages during and after World War II. To obtain the full benefits of the process, concrete of high quality and strength is necessary. Rapid advances in concrete technology have resulted in its strength being doubled and its surface greatly improved since World War II. The use of precast sections, often of substantial size, supported on novel systems of cantilevered and suspended centring and thereafter prestressed, have led to a marked increase in the length of simple or continuous spans, which can be built economically up to lengths of 400 ft. or more.

Quality of Concrete.—Concrete can be made with an ultimate compression strength of 8,000 to 12,000 p.s.i. This permits working stresses in the range of 2,000 to 3,000 p.s.i., but the upper limit must not be exceeded because, beyond it, the rate of creep (*i.e.*, nonelastic deformation resulting from stress) of the concrete increases too quickly. This improvement in quality was achieved by making further refinements in the mix, the water-to-cement ratio and the grading of the aggregate, by improvements in vibrating and by innovations such as steam curing. Because of the thinness of the wire used in prestressed work, it is essential that it should be completely protected against corrosion. The necessity for elimination of cracks in the concrete and the production of a dense, flawless surface therefore become of first importance. The compression induced in the concrete tends to eliminate cracks; and new materials for forms, such as hardboard, have enabled the surface of the concrete, whether flat or curved, to be of good texture, free from imperfections, easy to clean and pleasing to the eye.

Systems of Prestressing.—By 1938 E. Hoyer of Germany had developed a process of having factory-made prestressed concrete reinforced by very thin steel wires of 0.08 in. diameter and under, positioned and tensioned in the forms before the concrete was poured. When the concrete had set and the forms were removed, the ends of the wires were freed so that they compressed the concrete by bond. During World War II, when shortages of timber for forms and steel for reinforcement precluded the use of conventional reinforced-concrete design, Eugène Freyssinet reconstructed bridges in Tunisia by designing them to be built of precast blocks subsequently assembled on site and prestressed. This was done by threading steel wires through holes left open in the blocks, tensioning the wires and grouting them in. Various systems of

TABLE VIII.—Prestressed-Concrete Bridges

prestressing have since been evolved, but the most usual procedures are those outlined below. For reinforcement, high-tensile steel reinforcing bars with an ultimate strength of 64 to 72 tons per square inch are used at a working stress of about 45 tons per square inch. The bars are usually $\frac{1}{2}$ to $1\frac{1}{4}$ in. in diameter: they have rolled threads on the ends and may be smooth or ribbed. Alternatively, cables made up of 12 parallel steel wires 0.276 in. or 0.196 in. in diameter, with an ultimate strength of 90 to 110 tons per square inch (similar to those used in the parallel wire cables of suspension bridges), may be used at a working stress of about 70 tons per square inch. Another development has been the use of stranded-wire ropes from $\frac{3}{8}$ in. to $1\frac{1}{4}$ in. in diameter. There is always a loss of about 15% in the working stresses due to shrinkage and creep of the concrete and relaxation (reduction in stress intensity) of the steel.

Before the concrete is cast, thin-gauge flexible sheathing is fixed permanently in position in the molds for the bars or wires to pass through; alternatively, inflated rubber ducts may be used for this purpose and withdrawn after the concrete has set. When the bars or wires have been placed in position they are tensioned; in reinforcing bars the tension is held by screwing nuts on the ends of the bar against steel anchor plates; if wires are used, the tensioning is done by means of double-acting hydraulic jacks, after which the wires are held by wedges. Colloidal cement is then forced into the sheaths under pressure to grout in the wires or bars and prevent corrosion or slip.

FIG. 13. — (A) FIRST PRESTRESSED-CONCRETE LATTICED TRUSS, MANGFALL VALLEY BRIDGE, WEST GERMANY: (B) DETAIL OF TRUSS

The amount of prestress is usually made greater than the tension stress that would otherwise be induced under full dead and live load. The method can be applied to concrete whether it is poured in situ or precast. On account of the great saving in material, which amounts to at least one-third of the volume of concrete, and three-quarters of the weight of reinforcement that would otherwise be used, prestressed-concrete bridges are striking in their slender proportions. They are also economical in cost, provided the necessary trained labour is available, and in favourable circumstances may be competitive with structural steel designs for spans up to about 500 ft. Because of the very high stresses employed, skilled supervision is, of course, essential throughout the work. Moreover, any fracture or accidental damage to the highly stressed concrete in a critical place may precipitate failure of the structure.

Types of Bridges.—A wide variety of designs, including simple or continuous beams, cantilevers, arches, bowstring or latticed girders and single or multiple portals, can be made with prestressed concrete. For spans of less than 140 ft. simply supported beams are generally the most economical. Examples of these are the Wilhelmsburger railway bridge (1950) in Hamburg, which has a span of 143 ft. (see Table VIII) and the Vauban highway bridge (1956) in Strasbourg, with four spans of 120, 135, 120 and 69 ft. respectively. The Wilhelmsburger bridge is comprised of five box girders, but the Vauban bridge consists of eight beams of I-section, prestressed by 17 cables each having 12 wires 0.276 in. in diameter.

As the span increases, continuous beams, preferably with alternating long and short spans and maximum rigidity at the supports,

become economical. Cantilever bridges can be used instead of continuous girders; the former have similar limits of span length but pose a problem in aesthetics when it comes to concealing the hinges at the ends of the suspended spans. A bridge built over the Moscow river, U.S.S.R., in 1957 has three continuous prestressed-concrete spans of 144, 485 and 144 ft. respectively. In the Casalmaggiore cantilever bridge (completed in 1958) over the Po river in Italy, which is subject to violent flooding, there are eight main spans of 214 ft. and 25 flood spans of 82 ft. The main spans are supported on double piers set on groups of bored piles 5 ft. in diameter and 110 ft. long. The Worms bridge over the Rhine (longest span 374 ft.) and the Coblenz bridge over the Moselle, both completed in 1953, each have three centrally hinged cantilever spans more than 328 ft. long.

Concrete arch bridges are rarely prestressed, because an arch is normally in a state of compression by virtue of its shape and little is gained by supplementary prestressing. Nevertheless, the Dillingen bridge (1952) over the river Saar and its tributary is made up of three continuous prestressed concrete arch spans of 212, 175 and 146 ft., with short cantilevers at each end. Bowstring bridges appear inexpensive because they require the least amount of concrete and reinforcement, but they give little ultimate saving because of the high cost of the centring required during erection. An example is the 250-ft. span Gunthorpe aqueduct in Nottinghamshire, Eng., which was assembled on the river bank to reduce the cost of centring and moved into place by towing the leading end over on a barge.

Portal bridges and multiple portals with either vertical or sloping legs simply represent an angular type of arch and are so shaped that prestressing can be usefully employed to modify the line of thrust due to the external load, so that the resultant thrust is kept within allowable limits. The Hinckeldey bridge (1952) over the Hohenzollern canal near Berlin is an interesting vertical-legged, two-hinged portal bridge with a span of 237 ft. A fine example of a multiple portal with sloping legs is the St. Michel bridge (1957) at Toulouse, France, which has one span of 197 ft. and five of 214 ft. each.

Bridges of latticed construction are economical in material, but the unit costs are high; the saving in weight, however, makes it possible to achieve longer spans. The first prestressed-concrete latticed-girder bridge constructed was the Mangfall valley bridge (1958-60), with three spans of 295, 354 and 295 ft., over the Munich-Salzburg highway in west Germany (fig. 13).

The first self-anchored suspension bridges with continuous stiffening trusses of prestressed concrete were built by M. D. Vandepitte of Belgium. These are the Merelbeke (fig. 14) and Mariakerke bridges near Ghent, with main spans of 185 ft. and 328 ft. respectively. A novel method adopted for prestressing the girders on the Merelbeke bridge consisted in jacking them up 14½ in. simultaneously over the piers by means of hydraulic jacks,

FROM "REPORT OF THE FIFTIETH ANNIVERSARY CONFERENCE, 1958" PUBLISHED BY THE INSTITUTION OF STRUCTURAL ENGINEERS

FIG. 15. — PROPOSED MARACAIBO BRIDGE. VENEZUELA

which were then replaced by permanent steel castings.

In his design (fig. 15) for an international competition for a bridge 5.6 mi. long over the Maracaibo lagoon in Venezuela, R. Morandi of Italy put forward an entirely novel form of construction in steel cables and prestressed concrete that would surpass the span of the longest concrete arch previously built. The 11 navigation spans included one of 1,300 ft., with side spans of 551 ft. The 1,300-ft. span was designed as two prestressed-concrete cantilever arms 574 ft. long, supported near their ends by cables which passed over hinged concrete towers 210 ft. high, the far ends of the cables being attached near the extremities of the anchor arms. The concrete beams were to be prestressed for full dead load by means of the cables, and the gap between the ends of the cantilever arms was designed to be closed by a short suspended span.

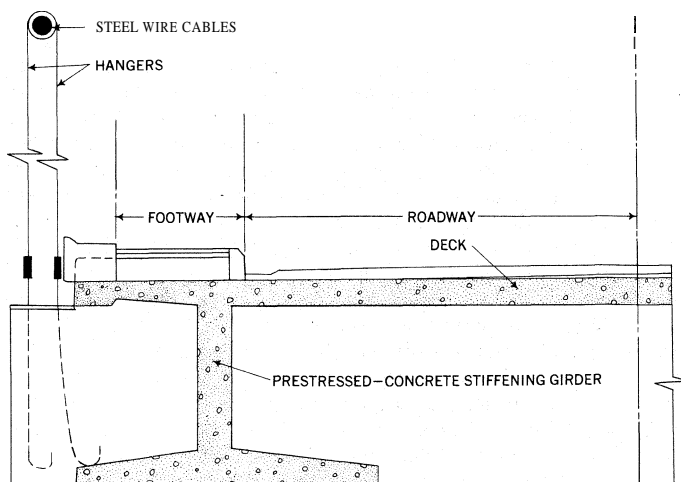

Methods of Construction. — Prestressed-concrete bridges can be built in three ways: (1) by assembly of precast units at the site; (2) by casting in situ; and (3) by a combination of precasting and casting in situ.

The Narrows bridge (1959), which has five spans of 160, 230, 320, 230 and 160 ft. and carries a 76-ft.-wide roadway over the Swan river at Perth in Western Australia, is a fine example of a bridge built up of precast units and subsequently prestressed after assembly at the site. The world's longest precast structure is the 23-mi. Lake Pontchartrain bridge (1956) in Louisiana. This consists of a series of spans 56 ft. long and 28 ft. wide, supported by beams resting on hollow prestressed-concrete piles. Each span, made up of seven beams and the roadway slab, was precast in one piece and erected by means of a floating crane. So well was the work organized that eight spans weighing 180 tons each and comprising 448 ft. of bridge were placed each day.

Precasting has been widely adopted in the U.S.S.R., an outstanding example being the huge two-level bridge (1959) over the Moscow river at Luzhniki which, with its approaches, measures 6,650 ft. over-all and carries a six-lane roadway on the upper deck and interurban railways below. The three spans of 147, 354 and 147 ft. over the river were assembled in halves longitudinally on the foreshore from large precast units, floated out on barges, and set on the piers. In the U.S.S.R., standardization developed to such an extent that by 1958 reinforced-concrete designs were automatically adopted for new railway bridges under 80-ft. span and prestressed-concrete designs for spans of 50 to 90 ft. Methods of heating that would enable concrete to be poured safely in freezing weather were actively investigated.

Casting in situ is more likely to be economical where there is little, if any, repetition work; this technique was adopted for the three magnificent arches of 498, 479 and 452 ft. respectively, designed by Freyssinet in 1953 for the new Caracas-La Guaira highway in Venezuela. In these bridges the decks were prestressed longitudinally and laterally, and prestressing cables were used temporarily to relieve the arch ribs during erection. Cantilevered centring was built out from each springing for a quarter of the span length to support the forms. To concrete the remaining half span in the middle, timber forms shaped as a tied arch of 165-ft. span were built in the valley below and hoisted into place.

A combination of precast and in situ construction may be economically used for continuous and cantilever bridges, the ends of the span near the piers being concreted in situ and the central parts precast. In the 214-ft. spans of the Casalmaggiore bridge, for example, the lengths over the piers and the cantilever arms were concreted in situ, but the 118-ft. suspended beams, each weighing

FROM "REPORT OF THE FIFTIETH ANNIVERSARY CONFERENCE, 1958" PUBLISHED BY THE INSTITUTION OF STRUCTURAL ENGINEERS

FIG. 14. — CROSS SECTION OF MERELBEKE SUSPENSION BRIDGE. BELGIUM

65 tons, were precast and erected by means of floating cranes.

2. Modern Reinforced-Concrete Bridges.—In spite of the evolution of prestressed concrete, it is sometimes preferable, particularly in arch bridges, to use conventional reinforced-concrete design, and many fine bridges have resulted. Examples of these are the 2,360-ft. Birecic bridge (1956) over the Euphrates and the Meric bridge (1954–58), with 35 spans in its over-all length of 2,635 ft., on the new international highway between Greece and Turkey. Two fine bridges in Portugal are the low, slender arch over the river Tua at Abreiro (1957), which has a rise-to-span ratio of only one-tenth; and the 885-ft. fixed arch of the Arrábida highway bridge over the Douro river. See also references under "Bridges" in the Index volume.

BRIDGET (BIRGITTA, BIRGIT), **SAINT**, OF SWEDEN (c. 1303–1373), the foundress of the Brigittine order and a mystic whose revelations were influential in the middle ages, was the daughter of Birger Persson, governor of Uppland. From an early age she had remarkable spiritual favours, including a vision of Christ crucified which influenced her whole life and outlook. In 1316 she married Ulf Gudmarsson, later governor of the province of Nericia. They had eight children, one of whom was St. Catherine of Sweden.

On Ulf's death in 1344, Bridget retired to a life of penance and prayer near the Cistercian monastery of Alvastra on Lake Vetter. To the prior, Peter Olafsson, she dictated the revelations that came to her, and he translated them into Latin. One of these revelations was a command to found a new religious order. This after long waiting, she was eventually able to do (see BRIGITTINES), receiving the necessary papal permission in 1370. She went to Rome for the Holy Tear of 1350, and remained there for the rest of her life, save for making several pilgrimages, the last of which was to the Holy Land in 1372. In Rome she exercised a wide apostolate among rich and poor, sheltering the homeless and sinners, giving God's messages of warning in times that were full of unrest and corruption. She worked untiringly, like St. Catherine of Siena after her, for the return of the pope from Avignon to Rome.

Bridget died on July 23, 1373, and was canonized Oct. 7, 1391. Her feast day is Oct. 8. St. Bridget's revelations were first published in 1492; some of them were edited by L. Hollman in *Den heliga Birgittas Reuelaciones extrauagantes* (1956). A 15th-century English version was edited by W. P. Cumming (1929).

(HN. L. R.)

BRIDGETON, a city in New Jersey. U.S., 40 mi. S. of Philadelphia at the head of navigation on the Cohansey river, the seat of Cumberland county. By 1686 a few Quaker families had settled in the vicinity and in 1716 a bridge was built across the river, which gave the hamlet the name of Cohansey Bridge. From this evolved Bridge Town and later, Bridgeton. In 1748, Cumberland county was separated from Salem county and the following year Bridgeton was made the county seat. Less than 12 families were there in 1754 when Daniel Elmer made a survey and laid out streets.

During the American Revolution a stage route was opened to Philadelphia and in 1799 the old bridge was replaced by a draw-bridge. The river served as the important means of transporta-

tion until 1362 when the railroad reached Bridgeton from Camden.

Among the first local industries was a woolen mill, constructed in 1811. Three concerns which later became important contributors to Bridgeton's growth were a nail and iron works, originating in 1815; the first glass factory, built in 1830; and the first canning establishment, opened in 1860. In later years enterprises of these types continued to be among the main sources of employment.

Among the exhibits of the Cumberland County Historical society in the county courthouse is Bridgeton's liberty bell, cast in 1763, which was rung to help celebrate the signing of the Declaration of Independence. For comparative population figures see table in NEW JERSEY: Population. (H. F. WI.)

BRIDGETOWN, capital and only port of entry of the British West Indian colony of Barbados (*q.v.*), lies mainly on the wide curve of Carlisle bay in the southwestern part of the island. The population of the town in 1956 was estimated at 18,500. A built-up coastal strip under various names stretches for several miles on each side of the town proper.

Founded in 1628 and originally called Indian Bridge, Bridgetown is a crowded and often picturesque mixture of old and new. Two blocks of public buildings, made of coral stone and opened in 1874, face each other in an attractive shady square. Across the larger, and very busy, Trafalgar square lies the careenage, a narrow inlet in which schooners are still sometimes careened or hove down onto one side so they can be cleaned underneath. Broad street, nearby, contains some excellent shops. St. Michael's Anglican cathedral, also of coral rock, was built—largely from the proceeds of a lottery—to replace a building destroyed in the great hurricane of 1780. The dignified Government house, which stands inland in a magnificent garden, represents the beginning of the 18th-century, and the large and successful "ministerial buildings" by the shores of Carlisle bay, the mid-20th century. The Savannah, once the garrison parade ground, is a fine open space used for race meetings and other gatherings; Queen's park contains tropical trees and shrubs.

For centuries ships had to anchor in Carlisle bay and load and discharge by launch and lighter. An artificial harbour adjoining the bay, protected by a large breakwater and with berths for eight ocean-going vessels, was put into operation in 1960.

(P. H.—MY.)

BRIDGING, MILITARY. In the course of most military operations it is necessary to cross rivers at places where no bridges exist or where they have been demolished by the enemy. It is the duty of the engineers of an army to provide the means for such crossings. For small detachments, ferrying with boats or rafts is resorted to; but for forces of any size accompanied by artillery and tanks, bridges must be built.

Military bridges differ from civilian bridges (see BRIDGES) in being designed for speedy construction and in making use of temporary pinned or bolted connections to permit ready assembly, dismantling and reassembly. Military bridges are of two primary types: pontoon (or ponton in U.S. army usage) bridges in which a roadway is laid on floating supports; and fixed bridges, normally used over dry gaps or narrow streams, consisting of a roadway extending from one bank to the other, with or without intermediate supports. In terms of tactical use, military bridges fall into three classifications: assault bridges for use by front-line infantry troops, combat support bridges for use by supporting troops with heavy equipment, and line of communications bridges of more or less permanent construction in rear areas.

Floating or pontoon bridges may be speedily built and are most frequently employed by assault troops. Of the many types of fixed construction the most important are trestle bridges, in which the roadway is supported by a series of timber trestles; cribwork bridges, in which the supports consist of timber cribs usually filled with stone; pile bridges, suspension bridges and steel girder or truss bridges. As long as wagons and guns were drawn by animals the weight of vehicles was limited and the strength required of military bridges remained approximately constant until the beginning of the 20th century. With the introduction of motor vehicles and tanks, however, weights increased enormously and all bridging standards had to be reconsidered.

HISTORY AND DEVELOPMENT

From time immemorial floating bridges of vessels bearing a roadway of beams and planks were employed for the passage of rivers and arms of the sea. Xerxes crossed the Hellespont on a double bridge, one line supported on 360, the other on 314, vessels anchored head and stern with their keels in the direction of the current. Darius threw similar bridges across the Bosphorus and the Danube in his war against the Scythians, and the Ten Thousand employed a bridge of boats to cross the Tigris river in their retreat from Persia. Floating bridges were repeatedly constructed over rivers in Europe and Asia, not merely temporarily for the passage of an army, but permanently for the requirements of the country; and many of the great rivers in India were crossed by floating bridges, for the most part supported on boats such as those employed for ordinary traffic on the river. Alexander the Great is said to have carried his army over the Oxus by means of rafts made of the hide tents of his soldiers stuffed with straw when he found that all the river boats had been burned. Cyrus crossed the Euphrates on stuffed skins. In the 4th century the emperor Julian crossed the Tigris. Euphrates and other rivers by bridges of boats made of skins stretched over osier frames.

In later times bridges were supported on floating piers made of barrels lashed together. During World War I light footbridges for the assaulting infantry were frequently supported by floats composed of cork or empty gasoline tins held together in light crates.

Principles of Pontoon Equipments.—The devices mentioned above gradually passed out of use in military bridging, although the occasional use of light bridges and rafts buoyed up by empty oil drums and similar devices was recorded during World War II. A notable exception was the use of Rhine river barges as floating piers with a steel truss superstructure. Since these expedient bridges depended on materials to be found on the spot, no assurance could be had that suitable materials would be available, especially in sufficient quantities. Furthermore, in rapid-moving warfare, the collection of such materials took valuable time. For these reasons, special pontoon bridging was introduced, which had the added advantage of being adapted to rapid erection by a minimum number of trained troops. Transported by trucks and trailers or by trucks alone, the equipment could accompany an army and be available for use wherever required.

In the standard types of floating bridges at mid-20th century were two essential sections: the floating supports, or pontoons, and the superstructure. The pontoons, located at regular intervals along the bridge with their main axis parallel to the stream current, provide the buoyancy necessary to prevent the structure from sinking under the crossing loads. The superstructure serves as the roadway for the crossing vehicles and tanks and is designed to act as one piece when all parts are connected. By this continuity, the superstructure is stiff enough so that the weight of a go-ton tank is actually transferred to as many as seven pontoons, the farthest of which may be 45 ft. from the centre of the tank. Thus, a floating bridge having pontoons capable of supporting only about 18 tons each can be used to support go-ton tanks. By such means the weight of the bridge is held to a minimum.

The superstructure of military bridges may generally be divided into three types: the "balk and chess" type, the treadway type and the truss type. The first type, particularly adapted to hand erection, employs wooden or steel beams called balk spanning the intervals between pontoons and supporting the wooden transverse deck planking technically known as chess. Pre-World War II bridges were generally of this type. The second type, a product of World War II, was a bridge type suited to erection by mechanical equipment only, and had a superstructure consisting of pairs of steel treadways placed lengthwise across each pontoon to form trackways for the wheels or tracks of the crossing vehicles. The third type, generally resulting from the adaptation of equipment developed for dry-gap bridging to floating-bridge purposes, could be either a through truss or deck truss arrangement. Because of the high stiffness required, articulating connectors were placed at frequent intervals so that the trusses would not be overstressed before full displacement of the pontoons was realized.

The pontoons, in turn, are of two general types: rigid and

pneumatic. The rigid pontoons are usually flat bottomed with scow-shaped bows and either with or without a deck. With the deck, the pontoon can be loaded to lesser freeboards but its interior is inaccessible for repair, is less convenient for use as a boat, and the pontoons cannot be nested to reduce transportation space. The pneumatic pontoon, or float, generally has three rubberized fabric main tubes which are inflated prior to use. A saddle placed on top of, and the full length of, the pneumatic float and tied to it by straps serves to stiffen the float and provides for the connection with the superstructure. The float has numerous bulkheads to form separate air compartments, so that effect of float damage on flotation will be minimized. The float is deflated for transport to reduce the space required, a feature that was chiefly responsible for the rise in popularity of the pneumatic pontoon.

In the design of the bridge as a whole, there are several important considerations. The parts, including pontoons, that make up the bridge must be of a size and weight that can be transported readily by standard trucks and trailers. In earlier designs they also had to be capable of being manhandled, but development and use of erection equipment during World War II virtually eliminated consideration of this requirement. In spite of light weight, the parts must be strong enough to withstand rough usage.

Too close a spacing of pontoons may obstruct floating debris and result in loss of the bridge. But as the interval between pontoons increases, the strength required in the superstructure and the size of the pontoon required also increases. The final design is therefore a compromise to produce a structure requiring minimum transportation, offering maximum capacity with minimum weight, and being capable of rapid assembly with a reasonable number of troops.

Since the bridge, once in place, must remain in place, the anchorage system is an important feature in floating bridge construction. In streams with slow currents, kedge anchors mooring each pontoon in place can be used. For medium and high currents a suspended cable anchor system must be used. In this system a wire cable called the anchor cable is suspended across the stream: to the cable are connected individual rope lines, called bridle lines, from each pontoon. Good construction practice requires adequate anchorage downstream as well as upstream to maintain bridge alignment although it is not considered necessary to provide a tie to each pontoon.

History of Pontoon Equipment.—Alexander the Great occasionally carried with his army vessels divided into portions which were put together on reaching the banks of a river, as in crossing the Hydaspes (mod. Thelum river). The practice of carrying skins to be inflated when the troops had to cross a river was adopted by the Greeks: the Romans and the Mongols. In the wars of the 17th century pontoons were taken as regular components of the trains of armies, the Germans using a leather, the Dutch a tin and the French a copper skin over stout timber frames. In the middle of the 18th century the Russians introduced a collapsible pontoon consisting of a tarpaulin stretched on a wooden frame. For transport the frame was dismantled and the tarpaulin rolled up.

No armies had more experience in pontooning than the French; during the wars of the Revolution and the empire they constructed pontoon bridges over most of the principal rivers of Europe. They experimented with many types ranging from large wooden boats weighing about 2 tons to small copper ones weighing 7 cwt.; the heavy wooden type, the Gribeauval, was discarded in 1805 since it could not keep up with the movements of the armies: in 1853 they adopted a flat-bottomed open wooden boat 31 ft. long and weighing 1,450 lb., which appears to have been successful. The northern states during the American Civil War used this type extensively as heavy equipment, and used dismountable wooden frames covered with canvas as light equipment.

During the Peninsular War the British employed open pontoons, but the experience gained during that war induced them to introduce the closed form. Then Gen. Sir Charles Pasley introduced demipontoons, called sectional pontoons in the U.S., that resembled decked canoes with pointed bows and square sterns. A pair, attached sternwise, formed a single pier of support for the roadway;

they were constructed of light timber frames covered with sheet copper and decked with wood. Each demipontoon was divided into watertight compartments and provided with means for pumping out water; for transport, a pair of demipontoons and the superstructure for one bay of bridge were loaded on a single wagon. The Pasley was superseded by the Blanshard pontoon, a tin-coated cylinder with hemispherical ends for which great mobility was claimed, two pontoons and two bays of superstructure being carried on one wagon. The Blanshard pontoon was long used in the British army, but was ultimately discarded, and British engineers reverted to the open pontoon to which engineers of the continental armies had meanwhile constantly adhered.

In 1889 Lieutenant Clauson, R.E., invented a two-section pontoon coupled with easily manipulated couplings of phosphor bronze. For light bridges the sections could be used independently; for heavy bridges three sections could be coupled together end to end. Except for minor modifications this equipment was retained in the British service until 1924. During World War I it was much used in Mesopotamia and during the early and final stages in France; it was found unsuitable in the rapid current of the Piave on the Italian front.

Historically, the most important equipment was that introduced in the Austrian army by Colonel Birago in 1841; it was either adopted or copied by many other armies. The Birago pontoon was a flat-bottomed open boat constructed in sections, two or more of which could be coupled together end to end to form piers of the buoyancy required. This idea had first been proposed by Col. Pompei Floriani about the middle of the 17th century but had not previously been fully developed; it was later adopted in British Pasley equipment. The Birago pontoons were in the first instance made of wood; later they were made entirely of iron and later still of steel.

An interesting type of equipment was introduced into the U.S. army in 1846. The pontoons were made entirely of India rubber and each consisted of three parallel pointed cylinders 20 ft. long, joined together side by side by an India-rubber web. When the pontoon was required for use, these cylinders were inflated through nozzles by means of bellows; for transport the entire pontoon was folded up and packed in a box. But, after considerable experience during the American Civil War the engineers of the northern states much preferred the French equipment which was of the balk and chess superstructure type with wooden rigid pontoons. It was retained with little or no change up through World War I. Between World War I and World War II the equipment was modernized by making the pontoons of aluminum.

With the introduction of blitz warfare by the Germans in World War II, rapid construction of bridges and ready portability of equipment for rapid movement became of paramount importance. This brought about the reintroduction of a vastly improved pneumatic pontoon and the development of the steel treadway floating bridge by the U.S. army. The use of motorized air compressors solved the problem of inflating the pneumatic pontoons while the single-unit treadways placed in pairs by bridge erection trucks or singly by truck cranes speeded bridge erection and reduced personnel requirements. Meanwhile, the British, with the development of the panel truss bridge by Sir Donald Bailey for fixed bridging requirements, also adapted it for floating bridge purposes by designing special connectors and articulating members. This bridge became commonly known as a floating Bailey.

Methods of Bridge Building With Pontoon Equipment. — There are four recognized methods of building pontoon bridges; the choice depends partly upon the actual equipment in use and, more upon the site of the bridge and nature of the river.

1. Successive pontoons. The pontoons are added successively to the head or far end of the bridge and the roadway added on top of them; this is perhaps the simplest method and is used primarily on narrow streams.

2. By rafts. Complete sections of the bridge are built in convenient positions by the near bank, floated into position and joined together; this method is used primarily on the wider streams and invariably results in quicker assembly than is possible by the other methods.

3. Booming out. pontoons are added successively at the tail or shore end and the whole bridge pushed out; this saves carrying all the stores for the roadway to the far end of the bridge.

4. Swinging bridge. The entire bridge is built alongside the near bank, that is, at right angles to its final position; when complete it is allowed to swing round with the current on its near end as a pivot, anchors are dropped in their appropriate positions as it swings and the entire bridge is checked by the anchor cables as it reaches its correct alignment. On a suitable site this method is extremely rapid, but in fast streams the operation is risky and the bridge often is lost or severely damaged.

The successive-pontoons and by-rafts methods at mid-20th century were the commonest methods used. The booming-out method was generally restricted to the light bridges while the introduction of power utility boats as auxiliary bridge erection equipment virtually eliminated the need for the swinging-bridge method.

Trestle Bridges. — It is not always feasible to construct a floating bridge, as pontoons may not be available, the water may be too shallow or the gap may be entirely dry. In such cases timber trestles have frequently been used to replace pontoons as supports for the roadbearers. Such trestles consist essentially of a horizontal bottom piece, or ground sill, two or more legs which are vertical or slightly inclined inward at the top and a horizontal top piece, or transom, on which the ends of the roadbearers rest as they would on the saddle of a pontoon; the whole is stiffened by diagonal braces. The size of the timber used varies with the nature of the bridge, ranging from light army signal poles used for the trestles of infantry assault bridges during World War I to timber barks 12 in. square or even larger used for railway bridges during the American Civil War and the Boer War and for heavy road bridges during World Wars I and II. Trestles are usually constructed on shore, carried into position and upended either by manpower or mechanical equipment.

Cribwork. — Timber cribs were formerly used instead of trestles for railway and heavy road bridges when timber was plentiful and the height required small. Timber crib construction was very convenient since no skilled labour was required, but cribs are wasteful of material. When placed in water, they were usually spiked together and filled with stone. An instance occurred in 1918 in the crossing of the Selle where, under the nose of the enemy holding the opposite bank, a crib causeway for tanks, built of railway sleepers (ties), bolted together and sunk in the bed of the river, was constructed during the nights immediately preceding the attack and kept concealed from view and from aerial photography by being completed just below water level.

Pile Bridges. — Trestles or cribwork are often not feasible in rapid currents because of the scour and if pontoon equipment is not available pile driving has to be resorted to, but it is a slow method. In 1809, before the battle of Wagram, Napoleon's engineers under Gen. Henri Bertrand constructed a pile bridge 800 yd. long across the Danube at Vienna in 20 days; upstream, piles were driven to form a boom to protect the bridge from floating bodies sent down by the enemy.

The provision of truck cranes with pile-driving equipment by the U.S. army during World War II permitted fairly rapid erection of pile bridges for line-of-communication usage. A number of vital bridges in the Allied supply lines were produced by this method, including several railway bridges across the Rhine river.

Girder or Truss Bridges. — Where bridges must be built across deep ravines or where the foundation is unsuitable, it is necessary that the bridges span clear gaps of 100 ft. or more without intermediate support. In such cases, the superstructure is supported by field assembled trusses. The bridges are made in panels of interchangeable parts; and the total length of any bridge can be that of any multiple of the fixed panel. The total practicable length depends upon the material used. Metal girders, generally limited to spans of less than 100 ft., are also used for dry-gap bridges, often in combination with trestle or pile piers. The standard girders are similar to ordinary commercial girders except that bolts are used instead of rivets, so that the girders may be taken apart for transportation.

(E. W. AN.; R. D. D.; W. A. M.; H. C. T.)

WORLD WAR II BRIDGING

Footbridge.— Attempts to construct any major bridging are suicidal until a foothold has been gained on the enemy-held shore so that direct small-arms fire on the proposed crossing is eliminated. It is usually necessary that the assaulting troops cross the stream in boats under cover of darkness and in secrecy to secure such a foothold. Once across these troops must be rapidly reinforced, a task that can best be done by providing a footbridge.

Since time is of the essence, a footbridge particularly adapted to fast simple erection is necessary for the purpose. The rubber plank footbridge used during World War II by the U.S. army fulfilled such requirements. This bridge is normally constructed from sections consisting of a timber duckboard or footwalk, supported by two floats each. The footwalk sections are provided with interlocking spring catches so that the mere act of pushing the end of one treadway into the end of the adjoining treadway makes the connection. The floats consist of a frame containing a number of very light expanded rubber planks and are provided with handles at each end. Spring catches also serve to attach the treadway to the float.

Footbridge sections are assembled at a convenient spot on shore and carried to the stream by men lifting the section by the handles provided on the floats. The booming-out method of construction is employed and in this case rapid erection times are achieved.

Pontoon Equipment.— While it had been generally anticipated in the interval between World Wars I and II that pontoon equipment had to be strengthened to carry heavy artillery pieces and heavier tanks, the extent and rapidity of increase in weight which occurred early in World War II were not foreseen. Therefore, the redesigned bridges soon became obsolete or were limited in use.

U S SIGNAL CORPS PHOTOGRAPH

FIG. 1.— FIXED BAILEY BRIDGE UNDER CONSTRUCTION IN ITALY DURING WORLD WAR II. THIS IS A "DOUBLE-DOUBLE" BAILEY LAUNCHED OVER A CENTRE BAILEY CRIB PIER

For this reason the principal floating bridges employed during World War II were developed during the war with the exception of the 25-ton pontoon bridge of the U.S. army. This bridge was the product of refinements in basic bridge design adopted by the U.S. from the French in 1869. It exemplified the maximum that could be attained with the wooden balk and chess type of superstructure and only by the addition of reinforcing floats between pontoons was it able to carry all tanks used by the U.S. army during World War II. The bridge served its purpose well even though it appeared to be the last of its line in modern military usage.

Steel Treadway Bridge.— Treadway bridging differs from all other types of floating bridging in that it does not have a solid decking. The vehicles it carries run on a pair of parallel steel runways or treadways, wide enough to take the tracks of a tank, or spaced close enough to take the wheels of a truck. The parallel treadways are supported by pneumatic pontoons or floats. The principal advantage of this bridge is the simplicity of its construction and the transportability of its components, and for these reasons the bridge was the one used most often and most successfully in World War II.

The steel treadway bridge has three main components—the pneumatic float, a float saddle and the individual steel section

U. S. ARMY PHOTOGRAPH: BY COURTESY OF THE CORPS OF ENGINEERS

FIG. 2.—M4 FLOATING BRIDGE UNDER CONSTRUCTION. TROOPS ARE PLACING THE DOWNSTREAM ANCHOR CABLE. AFTER WHICH CONSTRUCTION WILL BE COMPLETE

known as the treadway. In construction, the floats are inflated and placed in the water, after which the float saddles are placed and secured. The treadway pairs to complete one bay of bridge are then placed on the saddles by a special bridge-erection truck, which is a long-bed, six-ton cargo truck fitted with a hydraulically operated boom at the rear end of the truck bed. The boom is used in unloading and loading as well as for placing the treadways. As each bay is completed, it is usually connected to another bay by interlocking the mating ends of the two pairs of treadways. Additional sections are then moved into place successively by power utility boats and connected to each other in a similar manner until the bridge is complete. The first bridge produced, the M1 treadway bridge with narrow treadways and flat-nosed 12-ton floats, was effective in slow-moving streams but suffered disastrous failures in the fast currents of the Colorado river in service tests in 1942 and in the flood-swollen Volturno river in Italy in 1943. It was replaced by the M2 bridge, with wider treadways and 18-ton floats, that was used effectively in World War II and the Korean War.

The M4 Floating Bridge.—Late in World War II the U.S. army corps of engineers unveiled an all-aluminum floating bridge with a normal capacity of 60 tons. This bridge was a slight variation of the balk and chess type of bridge in that it included a deck member that served both purposes and was therefore called a deck balk. Whereas in the 25-ton pontoon bridge previously described, the balk are spaced on about 16-in. centres leaving about an 11-in. space between balk, the balk of the M4 bridge are placed side by side so that when all balk are placed, a complete road surface is provided; therefore, no planking is required. This bridge, designed for erection by manpower, did not see combat usage in World War II but proved its value in the Korean War. At mid-20th century the M4 bridge had the widest roadway of any of the standard floating bridges and, whenever necessary, could be widened even further by the addition of lines of deck balk outside the lines normally furnished. Reinforcing pontoons could also be added between the normal pontoons for added capacity.

The Floating Bailey.—While the U.S. army engineers developed and used floating bridges designed for the purpose, the British turned to the ubiquitous Bailey bridge and adapted it to floating bridge usage. Although it served to reduce the number of bridging types used by their field armies, as well as to provide the necessary capacity, erection of the floating Bailey bridge was not so fast or so easy as was erection of the U.S. bridges. It did, however, employ long Bailey truss hinge spans from the stream bank to the floating bridge proper which allowed for considerably more rise and fall in the stream elevation than did the trestle spans of the U.S. bridges.

The flotation element of the floating Bailey is a tripartite ply-

FIG. 3.— MEDIUM TANK AND BRIDGE TRUCKS CROSSING A CLASS 60 FLOATING BRIDGE

wood pontoon composed of two 20-ft. end sections and one 20-ft. centre section. The complete pontoon is about 60 ft. long, 5 $\frac{1}{4}$ ft. wide and 24 ft. deep. The superstructure is standard dry-gap Bailey bridge equipment, except for a few additional special parts. These parts are primarily the distributing girder, which stiffens the pontoon groups at the ends of the bridge, on which the shore hinge spans rest, and the articulating connectors, which connect the various bays of bridge. These connectors prevent the occurrence of excessive stresses in the Bailey trusses before full use is made of the flotation of the pontoon.

In construction of 40-ton tank capacity bridges, 32-ft. spans of single-truss Bailey bridge are supported by pontoon piers at each end. or 52-ft. spans can be used with an additional pontoon in the centre of the span. For 70-ton tank loads a 32-ft. span of double-truss Bailey bridge supported on three pontoons, one at each end and one near the centre, form a floating bay. Bays are connected one to another by the articulated connectors.

The Bailey bridging used for the end spans is placed in the same manner as would be employed for bridging dry gaps; that is, by cantilevering the span out from shore.

Truss Bridging.— For dry-gap bridging, and also line-of-communication usage over streams for which use pontoon equipment cannot be spared, truss bridges are used. Here again, as in the case of pontoon equipment, much pre-World War II standard bridging was made obsolete by the rapid increase in weight of armoured vehicles. The British in particular were concerned over the inadequacy of their then standard box-girder and Inglis tubular-steel bridges! which reportedly could not be increased beyond 26 tons in capacity. The answer was quickly produced however by Sir Donald Bailey, whose design proved to be the most versatile military bridge of World War II. The Bailey bridge was designed essentially as a heavy, through-type fixed bridge built up of panels rather than the previously conventional box-girder sections. All components were designed to be handled and placed by manpower, and trusses could be combined in multiple to carry loads up to 100 tons over spans from 30 to 220 ft. in length. This adaptability to a wide range of lengths and loads was the greatest advantage of the Bailey bridge. The U.S. army adopted it and made extensive use of it in the European theatre of operations (1944-45).

The roadway in the Bailey bridge is supported by two main trusses composed of sections called panels pinned together to form a continuous truss. Each ten-foot section of bridge, consisting of two parallel truss sections which support cross members called transoms on which the stringers and decking chess are laid, is known as a bay.

The capacity of the bridge may be increased, by adding one or two extra trusses alongside the first, by adding extra trusses on

top of the first two or three to make a second story or by both means. Thus, a single-truss single-story bridge is known as a single-single, a double-truss single-story is a double-single and a double-truss double-story is a double-double and so on up to a triple-triple maximum. In the heavier constructions, the number of transoms in each bay is also doubled.

Still another bridge type appeared in World War II, the short-span assault bridge that could be erected under fire. In this category both the British and U.S. armies developed scissors-type bridges for which standard tank chassis served as transporter-launchers. These bridges could be unfolded over a gap by a mechanism powered from inside the tank. Another type, favoured more by the British than the Americans, was the so-called Ark bridge in which a tank, usually of an obsolescent type, was equipped with top-mounted treadways and attached ramps. When driven into a gap and the ramps dropped, the vehicle itself served as a bridge support.

POSTWAR DEVELOPMENTS

After World War II, when the performance of all equipment was reviewed, it was apparent that nothing further could be achieved with traditional balk and chess bridging. Accordingly, the U.S. 10-ton and 25-ton pontoon bridges and their variations were declared obsolete. The M2 treadway bridge, while still effective for tanks in being, was not suitable for some new designs still on the drawing board. In addition, the centre gap between treadways of the M2 had proved undesirable for supporting multi-wheeled vehicles.

The U.S. army therefore adopted, in 1953, the class 60 floating bridge with a flush deck treadway and centre filler. It consisted of a steel superstructure supported by 24-ton pneumatic floats and was capable of carrying any U.S. army vehicle. During the Korean War this bridge, designed for truck crane erection, replaced the treadway bridge although the latter was retained for divisional use.

In 1953 the deck balk of the M4 floating bridge was adapted to the 24-ton float of the class 60 bridge to produce a floating bridge particularly suited to U.S. marine corps use as it did not require a special bridge truck for transport nor a truck crane for erection. This bridge was also adopted by the U.S. army. It had high potential capacity and great flexibility. Though its normal capacity was only 60 tons, it could be strengthened by placing the aluminum pontoons closer together and adding lines of deck balk to bring its capacity up to 100 tons.

The British army, meanwhile, also recognized a need for an improved floating bridge, particularly in the 30-ton capacity range, that could be speedily erected by a small crew and would replace the standard Bailey pontoon bridge and light-folding boat equipment. The need was met by adoption of the class 30 light-assault floating bridge in the decade following World War II.

Even the successful Bailey bridge was not excepted from review and modernization. Both the British and U.S. armies attempted to develop a bridge that would retain the basic principles of the Bailey but would be more suitable for erection by mechanical equipment. The British evolved the heavy girder bridge with steel panels while the U.S. engineers brought forth an aluminum panel bridge. The

FIG. 5.— SCISSOR-TYPE ASSAULT BRIDGE CARRIED ON A TANK CHASSIS AND LAUNCHED HYDRAULICALLY. 60 FT. SPAN

latter gained only limited acceptance and the M₂ Bailey continued as the standard U. S. bridge. The wider M₃ Bailey with 13 ft. 9½ in. roadway remained standard in the British army.

Interest in mobile short-span assault bridges continued in the postwar period with the U. S. army experimenting with two types—a scissors bridge carried and launched by a tank chassis and a wheeled assault bridge that could be put in place by a fighting tank. The former had superior mobility while the latter was cheaper and required no special transporter-launcher.

Unlike the floating and fixed bridge types in which development had been aided by review of performance under combat conditions in World War II and Korea, development of short-span assault bridging was handicapped by its novelty and by lack of troop experience.

In 1953 the U. S. army adopted an aluminum footbridge to replace the M1938 rubber-plank footbridge used in World War II. It consisted of 80-lb. aluminum footwalk sections supported by 100-lb. aluminum pontoons. Each pontoon had a double bottom filled with plastic foam to make it unsinkable. The bridge could be speedily erected by the booming-out method. It was not vulnerable to small arms fire and presented a difficult target for enemy aircraft. The new bridge had greater carrying capacity than the 1938 model and was intended to provide a means for small units to cross rivers in support of the first landing parties.

(E W AN.; H C T)

BRIDGMAN, FREDERIC ARTHUR (1847–1928), U. S. painter, noted for his sentimental scenes of north Africa in the French academic manner, was born at Tuskegee, Ala., on Nov. 10, 1847. He began as a draftsman in New York city for the American Bank Note company in 1864–65, and studied art in the same years at the Brooklyn Art school and at the National Academy of Design, but he went to Paris in 1866 and became a pupil of J. L. Gérôme. Paris then became his headquarters.

A trip to Egypt in 1873–74 resulted in pictures of the east that attracted immediate attention, and his large and important composition "The Funeral Procession of a Mummy on the Nile," in the Paris salon (1877), bought by James Gordon Bennett, brought him the cross of the Légion d'Honneur. Other paintings by him were "An American Circus in Normandy" and "Procession of the Bull Apis."

Bridgman was an officer of the Légion d'Honneur and of the order of St. Michael of Bavaria, and was made a member of the National academy in 1881. He was the author of *Winters in Algeria* and of *Anarchy in Art* and also composed orchestral music. He died on Jan. 13, 1928, in Rouen, France.

BRIDGMAN, LAURA DEWEY (1829–1889), the first blind deaf-mute person in whom systematic education proved successful, a pupil of Samuel Gridley Howe (q.v.), was born on

Dec. 21, 1829, at Hanover, N.H. At the age of two she had an attack of scarlet fever that permanently destroyed her sight and hearing. Her case was brought to the attention of Howe, head of the Perkins institution for the blind at Boston, Mass., and in Oct. 1837 Laura entered the school. Howe at once set himself to teach her the alphabet by touch. He first pasted on several common articles, such as keys, spoons and knives, little paper labels with the names of the articles printed in raised letters. As soon as she had learned all the names in this fashion she was taught the individual letters, and gradually learned the alphabet and the ten digits. In Jan. 1842 Charles Dickens visited the institution, and afterward wrote enthusiastically in *American Notes* of Howe's success with Laura. Except for short visits to her home, Miss Bridgman lived at the school for the rest of her life, eventually helping with the teaching and household work. In 1887 her jubilee was celebrated at the institution, and she died there on May 24, 1889.

Miss Bridgman's importance in the history of the education of the deaf occasioned several biographies, including those by Mary S. Lamson (1878), Maud Howe and Florence Howe Hall (1903), and Laura E. Richards (1928).

BRIDGMAN, PERCY WILLIAMS (1882–1961), U. S. physicist noted especially for his research on materials at high pressures and their thermodynamic behaviour, was born in Cambridge, Mass., April 21, 1882. He received the Ph.D. degree from Harvard university in 1908, and joined its faculty the same year, becoming Hollis professor of mathematics and natural philosophy in 1926 and Higgins university professor in 1950. He was awarded the 1946 Nobel prize in physics for his extensive investigations on the properties of matter at pressures up to 100,000 atm., considerably higher than had been employed previously. The properties studied included electrical and thermal conductivity, compressibility, tensile strength and viscosity in more than 100 different compounds. Bridgman also contributed extensively to the philosophy of physics, publishing a number of volumes in this field, such as *The Logic of Modern Physics* and *Reflections of a Physicist*. In these writings Bridgman supported the operational point of view—that it is meaningless to interpret physical concepts except as they are capable of observation. He died in Randolph, N.H., on Aug. 20, 1961. (J. H. V. V.)

BRIDGNORTH, a market town and municipal borough in the Ludlow parliamentary division of Shropshire, Eng., 21 mi. S.E. of Shrewsbury by road, on a high red sandstone rock bounded on the east by the river Severn. Pop. (1961) 7,552. The early history of Bridgnorth is connected with Aethelflaed, lady of Mercia, who rebuilt a fortress there in 912 against the Danes. William I granted the manor to Earl Roger of Shrewsbury, whose son built a castle on the rock in 1101 and in 1102 rebelled against Henry I who captured the castle after a three-month siege. The castle was also besieged in 1155 and 1321 and was all but destroyed in the Civil War; the tower (this leans 17° from the perpendicular) is the only remaining fragment. Castle and grounds were presented to the corporation in 1897. The town was incorporated in 1157; the borough returned two members to parliament from 1295 to 1867.

Bridgnorth is divided into Low Town and High Town. The former lies at the foot of the cliff beyond the Severn, there crossed by a bridge which is the successor of others dating back probably to Saxon times. Communication between Low and High Town is by several flights of steps, the best known being Stoneway steps, about 200 in number, and by the Castle Hill railway (1891), the steepest in England. The name of the town refers to the former existence of another bridge at Quatford to the south. There are many half-timbered buildings, including the birthplace of Bishop Thomas Percy (q.v.), dating from 1580 and now a boys' club, and the town hall; several houses have cellars cut in the rock. The chief industries are carpet weaving and the making of electrical equipment and aluminum foil. Bridgnorth lies in a productive agricultural area and holds weekly auctions and monthly sales of livestock; this market dates from 1226. The town was also a rival of Shrewsbury in the cloth and hide trades. Of the two parish churches, St. Mary Magdalene's was built by Thomas Tel-

ford in 1792-94 and St. Leonard's dates from the 12th century.

BRIDGWATER, FRANCIS EGERTON, 3RD DUKE OF (1736-1803), the founder of British inland navigation, was born May 21, 1736, the younger son of Scroop (1681-1745), 1st duke of Bridgwater. His father, who was created duke in 1720, was the great-great-grandson of Lord Chancellor Ellesmere. Francis Egerton succeeded to the dukedom on the death of his brother, the 2nd duke, in 1748. Shortly after attaining his majority he became engaged to the beautiful, widowed duchess of Hamilton, but her refusal to give up the acquaintance of her sister, Lady Coventry, led to the breaking off of the match. Thereupon the duke broke up his London establishment and, retiring to his estate at Worsley, devoted himself to its management and to the making of canals. The navigable canal from Worsley to Manchester, which he projected in 1759 for the transport of the coal obtained on his estates, was (with the exception of the Sankey canal) the first great undertaking of the kind executed in Great Britain in modern times. The construction of this work, with its famous aqueduct across the Irwell, was carried out by James Brindley, the celebrated engineer. In 1762 Bridgwater obtained parliamentary powers to provide an improved waterway between Liverpool and Manchester by means of a canal, which was completed in 1772. The difficulties were still more formidable than those of the Worsley canal, involving, as they did, the carrying of the canal over Sale Moor Moss.

Bridgwater died unmarried in London on March 8, 1803, when the ducal title became extinct, but the earldom of Bridgwater passed to a cousin, John William Egerton, who became 7th earl. By his will the duke devised his canals and estates on trust under which his nephew, the marquess of Stafford (afterward 1st duke of Sutherland), became the first beneficiary, and next his son, Lord Francis Leveson-Gower (afterward 1st earl of Ellesmere), and his issue. The trust did not expire until Oct. 19, 1903, when the whole property passed under the undivided control of the earl of Ellesmere. The canals, however, had in 1872 been transferred to the Bridgwater Navigation company, by which they were sold in 1887 to the Manchester Ship Canal company for £1,710,000.

(A. AL.)

BRIDGWATER, a seaport and municipal borough in the Bridgwater parliamentary division of Somerset, Eng., 11 mi. N.N.E. of Taunton by road. Pop. (1961) 25,582. It lies in the level country east of the Quantock hills on the right bank of the Parret, 10 mi. from its mouth in the Bristol channel; its two portions are connected by an iron bridge. Once a fortified town with a castle and a Franciscan house, there are still traces of medieval architecture. It became a free borough, having a Saturday market and an annual fair (September), by a charter of 1200; there is also an annual carnival (October-November). A number of charters were granted between 1200 and the 18th century and from 1295 until 1870 Bridgwater returned two members to parliament. Fairs for the sale of wool and wine were important in medieval times. The church of St. Mary Magdalene dates from the 14th century. The town was the birthplace of Adm. Robert Blake (1599-1657) and his house became a museum in 1924. The trade of the port revived after the construction of the new dock in 1841 and still continues, the river being navigable to the town for vessels of 300 tons though liable to a bore which sometimes attains four feet. Industries include the manufacture of Bath bricks, bricks and tiles, cellulose film, shirts and collars, preserves, heavy engineering and electrical equipment, furniture, brewing and malting.

Five miles to the southeast is Sedgemoor, a marshy tract where the Monmouth rebellion was crushed in 1685.

BRIDLINGTON, a seaside town and municipal borough (1899) in the Bridlington parliamentary division of the East Riding of Yorkshire, Eng., 17 mi. S.S.E. of Scarborough by road. Pop. (1961) 26,007. The ancient market town lies about one mile from the coast, while the modern houses of Bridlington Quay, the seaside town, fringe the sandy shore of Bridlington bay. After 1867 sea walls were built and maintained against the encroaching sea. Southward the coast becomes low, but northward it is steep and very fine, where the great spur of Flamborough head (*q.v.*), owned by the corporation since 1939, projects eastward. Bridling-

ton seems to have been a borough before the Conquest; its medieval history is linked up with its markets and fairs, first mentioned in a grant of 1200, and with its port. The church of St. Mary and St. Nicholas consists of the fine Decorated and Perpendicular nave of the priory church of an Augustinian foundation of Walter de Gant in 1113 which flourished until 1537. There remains also the Perpendicular gateway. Bridlington was an early centre of non-conformity, and a Congregational society was founded in 1662. In the 20th century developments as a resort were extensive; they include the Spa Royal hall (1932), a promenade (1931), a pavilion (1937) and the Sewerby pleasure gardens. The town hall was opened in 1932. The town is used as a conference centre. Yachting takes place in Bridlington bay and the town is the headquarters of the Royal Yorkshire Yacht club.

Six miles from Bridlington is Burton Agnes hall (1598), a perfect example of Tudor architecture. The Old Manor house in Burton Agnes was probably built about 1170.

BRIDPORT, ALEXANDER HOOD, 1ST VISCOUNT (1726-1814), British admiral, who served with distinction in the French Revolutionary wars, was born on Dec. 2, 1726, the younger brother of Samuel (afterward 1st Viscount) Hood. He entered the navy in 1741 and served as a lieutenant under Capt. Charles Saunders in the Mediterranean and under Sir Edward Hawke at the battle of Quiberon bay in 1759, as captain of the "Minerva." In the same ship he later recaptured the "Warwick" line-of-battle ship. In 1758 he married Mary West, from whose fortune and connections with the Grenville family his career benefited. As captain of the "Robust" he was at the battle of Ushant in 1778 and gave evidence against Viscount Keppel in the court martial which followed. He became rear admiral in 1780 and served under Lord Howe in the relief of Gibraltar in 1782. On the outbreak of war with France in 1793 he was Howe's second-in-command and for the part he played at the battle of the Glorious First of June in 1794 he was made Baron Bridport. From that date until 1800 he was, in effect, in command of the Channel fleet, though only nominally so from 1797. In an attack on the French fleet off Lorient in 1795 he personally took charge of the ship when the pilot refused to sail closer in shore. In 1797 he was criticized for failure to intercept the Hoche expedition to Ireland, and later that year he was in command of the fleet which mutinied at Spithead. In 1800 he retired from active service, his conduct of the blockade of Brest having been criticized by Lord St. Vincent, and was created a viscount. In his old age he was described as "penurious and rich," though the Spithead mutineers called him their "father and friend." He died on May 2, 1814.

See D V. Hood, *The Admirals Hood* (1942).

(C. C. L.)

BRIDPORT, a market town and municipal borough in Dorset, Eng., 15 mi. W. of Dorchester by road. Pop. (1961) 6,517. It takes its name from the small river Brit and is the Port Bredy of Thomas Hardy's Wessex novels. The main part of the town is about a mile inland, but is connected by a winding street with the fishing village of West Bay. A museum and art gallery were opened in 1932. Bridport was of some importance before the Conquest but the town is first mentioned as a borough in the Pipe Roll of 1189. The earliest charter was granted in 1253 by Henry III, when it became a royal borough, and markets and fairs were granted by Elizabeth I. It was incorporated by James I in 1619. The Royal Navy procured its hawsers from Bridport in the 16th century and as early as 1213 the town was noted for the manufacture of ropes and cables. Sailcloth, cordage linen, fishing nets and lines are still made there. There is agriculture and horticulture in the district and some import trade in timber, but the harbour is accessible only to small vessels. Bridport returned two members to parliament from 1295 to 1868 and one until 1885, prior to the formation of the West Dorset parliamentary division.

BRIE, a rich farming district in northern France, east of Paris, lies between the valleys of the Seine and Marne. It includes most of the *département* of Seine-et-Marne, as well as portions of adjacent *départements*. Geologically the district consists for the most part of a platform of Tertiary limestone dissected by left-bank tributaries of the Marne and terminating southeastward in the escarpment known as the Falaise de l'Île de France. There are

some sand cappings that carry forest, and the surface layers of the limestone have commonly been decalcified to furnish damp clay areas. Fertile *limon* soil makes it generally an important area of corn and sugar-beet cultivation, and Brie cheese is well known.

(AR. E. S.)

BRIEF. In the United States, a brief is a written legal argument presented to a court to aid it in reaching a conclusion on issues of law presented by a case. It is used primarily in appellate courts and is of the utmost importance where no oral argument is made. It is less frequently used at the trial level. The usual procedure calls for the party seeking the relief asked for in the brief to present his written argument to his opponent and to file it with the court. The opponent then files and serves an answering brief. Usually, the first counsel will then have an opportunity to file a reply brief. Ordinarily the briefs are not distributed to the judges until each party has had the opportunity, specified by rules or statutes, to file his brief. Most courts have very specific rules governing the format and content of the briefs to be presented to them. The courts differ in the treatment of this written argument; some read it before the oral argument, some after, and in some courts only the judge assigned to prepare the opinion reads the briefs. Occasionally, the court may ask for further briefs after oral argument. On unusual occasions, most effectively in constitutional cases, counsel will include extensive economic and sociological data in his brief. Such a brief has become known as a "Brandeis brief," after the justice of the U.S. supreme court who is generally credited with initiating, or at least of making the most effective use of, such a document. When a court allows an outsider to file a brief in a case to which he is not a party, it is generally called a brief *amicus curiae* (*q.v.*).

In England, the word brief has a different meaning and can be understood only when it is recognized that there, unlike in the United States, the legal profession is separated into two groups: barristers and solicitors. Only the former is eligible to appear before the high court, but he cannot act on behalf of a litigant except pursuant to instructions from a solicitor. These instructions to counsel are known as a brief. In it, among other things, the solicitor will report on the evidence and proof available and will include statements and interviews, or summaries thereof, of witnesses. A barrister who receives such instructions is said to be briefed by the solicitor. The brief will carry on it a notation of the fee offered, though in fact this will have earlier been negotiated between the solicitor and the barrister's clerk. In Scotland, this form of instruction to counsel is known as memorial. A "watching brief" in England is an instruction to counsel to attend hearings on behalf of a person who is not a party to the proceedings so that he can then offer advice relating to the hearings.

A papal brief is an edict from the pope on a matter of discipline directed to an individual or community, similar to a papal bull (see DIPLOMATIC: *Papal Chancery*). (P. B. K.)

BRIERLEY HILL, an urban district (1894) in the Brierley Hill parliamentary division of Staffordshire, Eng., lying 12 mi. W. of Birmingham by road. Pop. (1961) 56,377. The district includes Wallheath, Kingswinford, Pensnett and Brierley Hill.

Thirteenth-century records tell of local "sea-coal" mined in the area, and ironstone was extensively mined in Elizabethan times. Though nailing and scythe making were the chief specialized industries by the 16th century, there was considerable glass-making, which is still a major industry; some of the well-known Stourbridge glass comes from the Brierley Hill area. Coal mining, iron- and steelworking, the making of ceramics and food products (especially hams) are the other main occupations. In the reference section of the library is a large collection of fine glasswork.

In the 1950s and 1960s Brierley Hill underwent extensive redevelopment, including the construction of a new civic centre.

BRIEUX, EUGÈNE (1858–1932), French dramatist whose plays combined dramatic skill and didactic purpose, aiming at exposing social abuses, was born in Paris on Jan. 19, 1858. Beginning as a journalist, Brioux, after several unsuccessful attempts, at last found a producer in André Antoine (1890). *Lu Robe rouge* (1900), dealing with professional deformation in the law, is his

best play. The dramatist yields to the moralist in *Les Remplaçantes* (1901). *Les Avariés* (1902) is a lecture on the dangers of syphilis, censored in France and (as *Damaged Goods*) banned in England until World War I. In his later plays, *Simone* (1908), *La Femme seule* (1912) the balance is held more evenly. Brioux died at Nice on Dec. 6, 1932.

See *Three Plays by Brioux*, with preface by Bernard Shaw (1911); A. Renoist, *Le Théâtre d'aujourd'hui*, vol. i (1911). (D. Ks.)

BRIG (FR. BRIGUE, Ital. BRIGA), a town in the canton of Valais, Switz., whose population (1960 est.) of 3,900 is largely Roman Catholic and German-speaking. It is the junction of the road leading up the narrow Rhône valley to the Grimsel and Furka passes and beyond to eastern Switzerland, and of the road to Italy through the Simplon/pass (*q.v.*), opened in 1807. Brig also owes its prosperity to the tourist industry in the upper Valais and to its position as frontier town and embarkation station for motor vehicles traveling to Italy on railroad flatcars through the Simplon tunnel. The tunnel was opened to traffic in 1906 and is one of the longest in the world (20 km., or 12.4 mi.). Another tunnel contributes to Brig's importance: the Lotschberg tunnel, opened in 1913. This gives direct rail communication between the Bernese Alps, Bern and Milan.

Brig's medieval name was Briga Dives. Its most prominent buildings date from the 17th century, when K. J. von Stockalper, a rich merchant, built there a graceful castle whose bulbous towers and three-storied arcades are landmarks at the entrance of the Simplon road. Also notable is the nearby Glis church, the largest in Switzerland, and the 17th-century ossuary at Naters across the Rhône. (R. M. An.)

BRIGADE, a unit in military organization commanded by a major general, brigadier (*q.v.*) or colonel, and composed of two or more subordinate units such as regiments or battalions.

In World War I the "square" division consisted of two brigades, each commanded by a brigadier general and including two infantry regiments with their components of artillery and other supporting arms (see ARMY). During the postwar period, when the "triangular" division with its three infantry regiments came into being, the infantry brigade was abolished as a standard administrative or tactical unit in the British and U.S. armed forces. The term remained in use during World War II and the Korean war to designate a task force raised for some specific mission. In the summer of 1950, for instance, the U.S. 1st provisional marine brigade in Korea included a marine infantry regiment, four aircraft squadrons and a battalion of artillery, plus smaller units of tanks, engineers and other supporting arms. This brigade was, in effect, a self-sufficient little army of about 6,500 men who were employed effectively as a mobile reserve at a time when the United Nations forces were outnumbered. The British commonwealth division in Korea was composed of four brigades, each consisting of three infantry battalions, headquarters groups and appropriate components of artillery, tanks and engineers.

In 1961 the U.S. army revived the brigade as a tactical unit consisting of a headquarters to which would be attached administrative and combat support elements and from two to five combat maneuver battalions. See also DIVISION. (Ln. Ms.)

BRIGADIER, a military rank conferred by Louis XIV upon the commander of several regiments. The British copied it from the French very early and a royal warrant of 1699 states that "the Major General of Our Ordnance within our Kingdom for the time being shall have rank and precedence as Brigadier," evidence that the title was stabilized at that date.

In both the British and U.S. armies of World War I a brigadier general commanded a brigade (*q.v.*) composed of two infantry regiments with artillery and other supporting arms. When the brigade was abolished after the adoption of the "triangular" infantry division, the British discontinued the rank of brigadier general but revived it as plain brigadier in 1928. In the U.S. military service a brigadier general ranks just above a colonel as the lowest officer of star rank. The ADC, or assistant division commander, is customarily a brigadier general. (Ln. Ms.)

BRIGANDAGE: see BANDITRY.

BRIGANTES, a people of northern Britain, who inhabited

the country from the Humber estuary on the east and that of the Mersey on the west. northward to the Antonine wall. Their chief town was Isurium (Aldborough) and later Eburacum (York), and they had forts at Cataractonium (Catterick), Olicana (Ilkley) and Vinovium (Binchester). They were first defeated by the Romans during Claudius' reign (c. A.D. 50). Under Vespasian they submitted to Petillius Cerealis (c. 71) but were not finally subdued until the time of Antoninus Pius (c. 155).

BRIGGS, CHARLES AUGUSTUS (1841-1913), U.S. Old Testament scholar and theologian, vigorous exponent of "higher criticism," was born in New York city on Jan. 15, 1841, and educated at the University of Virginia, the Union Theological seminary and the University of Berlin. After a pastorate in the Presbyterian church of Roselle, N.J., he went to the Union Theological seminary, where he held successively three different professorships. His inaugural address, on becoming professor of biblical theology in 1891, led to his being tried for heresy by the presbytery of New York. He was acquitted, but the general assembly, to which the case was appealed, suspended him in 1893. He was ordained a priest of the Protestant Episcopal Church in 1900. With S. R. Driver and Francis Brown, Briggs prepared a revised *Hebrew and English Lexicon* (1891-1905), and with Driver edited the *International Critical Commentary*. His publications were numerous, and he was for ten years (1880-90) editor of the *Presbyterian Review*.

Briggs died in New York on June 8, 1913.

BRIGGS, HENRY (1561-1630), English mathematician, famous for his logarithmic tables, was born at Warley Wood, near Halifax, in Yorkshire. He graduated from St. John's college, Cambridge, in 1581, and obtained a fellowship in 1588. In 1592 he was made reader of the physical lecture founded by Thomas Linacre, and in 1596 first professor of geometry in Gresham house (afterward college), London. In his lectures at Gresham house he proposed the alteration of the scale of logarithms from the hyperbolic form that John Napier had given them to that in which unity is assumed as the logarithm of the ratio of ten to one. In conferences with Napier the alteration proposed by Briggs was agreed upon; and on his return from his second visit to Edinburgh in 1617 he accordingly published the first thousand of his logarithms. (See *NAPIER, JOHN*.) In 1619 he was appointed Savilian professor of geometry at Oxford. In 1622 he published a small tract on the *North-West Passage to the South Sea*, *Through the Continent of Virginia and Hudson's Bay*; and in 1624 his *Arithmetica Logarithmica*, in folio, a work containing the logarithms of 30,000 natural numbers to 14 places of figures besides the index. He also completed a table of logarithmic sines and tangents for the hundredth part of every degree to 14 places of figures besides the index with a table of natural sines to 14 places, and tangents and secants for the same to ten places; all of which were printed at Gouda in 1631 and published in London in 1633 under the title of *Trigonometria Britannica* (see *MATHEMATICAL TABLES*). Briggs died on Jan. 26, 1630.

His other works include: *A Table to Find the Height of the Pole, the Magnetical Declination Being Given* (1602); "Tables for the Improvement of Navigation," printed in the second edition of Edward Wright's treatise entitled *Certain Errors in Navigation Detected and Corrected* (1610); *A Description of an Instrumental Table to Find the Part Proportional, Devised by Mr. Edward Wright* (1616 and 1618); *Euclidis Elementorum VI, libri priores* (1620); *A Treatise on the North-West Passage to the South Sea* (1622), reprinted in Purchas's *Pilgrims*, vol. iii, p. 852; *Mathematica ab Antiquis minus cognita*. Some other works, as his *Commentaries on the Geometry of Peter Ramus* were not published.

BRIGHOUSE, a municipal borough (1893, considerably enlarged 1937) in the Brighouse and Spenborough parliamentary division of the West Riding of Yorkshire, Eng., 6 mi. E.S.E. of Halifax. Pop. (1961) 30,783. Area 12.3 sq.mi. The chief industries are textile: mainly carpetmaking, also silk spinning and the manufacture of yarns and fabrics. But there is also considerable engineering of all kinds, especially the manufacture of radio and television equipment. In the grounds of Kirklees hall, 2 mi. S.E.,

are remains of a Cistercian priory, founded in 1155, and the traditional grave of Robin Hood.

BRIGHT, SIR CHARLES TILSTON (1832-1888), English telegraph engineer, who superintended the laying of the first Atlantic cable, was born on June 8, 1832, at Wanstead, Essex. Educated at the Merchant Taylors' school, at the age of 15 he became a clerk under the Electric Telegraph company. In 1852 he was appointed engineer to the Magnetic Telegraph company, and had charge of the laying of lines in various parts of the British Isles, including in 1853 the first cable between Great Britain and Ireland, from Portpatrick to Donaghadee. His experiments convinced him of the practicability of an electric submarine cable connection between Ireland and America; and having in 1855 already discussed the question with Cyrus Field, who with J. W. Brett controlled the Newfoundland Telegraph company on the other side of the ocean, Bright organized with them the Atlantic Telegraph company in 1856 for the purpose of carrying out the idea, himself becoming engineer in chief for the laying of the first Atlantic cable (see *TELEGRAPH*). In 1858, after two disappointments, Bright successfully accomplished what to many had seemed an impossible feat. Within a few days of landing the Irish end of the line at Valentia he was knighted in Dublin. Subsequently Bright supervised the laying of submarine cables in various regions of the world, and took a leading part as pioneer in other developments of the electrical industry. As a partner with Josiah Latimer Clark from 1861, he invented improved methods of insulating submarine cables. A paper on electrical standards read by them before the British association in the same year led to the establishment of the British Association committee on that subject, whose work formed the foundations of the system still in use. From 1865 to 1868 he was Liberal M.P. for Greenwich. He died on May 3, 1888, at Abbey Wood, near London.

See *Life Story of Sir C. T. Bright*, by his son Charles Bright, rev. ed. (1908).

BRIGHT, JOHN (1811-1889), British statesman and prototype of Victorian radicalism, the friend and associate of Richard Cobden (*q.v.*), was born at Rochdale on Nov. 16, 1811, of Quaker stock. His father, Jacob Bright, had opened a cotton mill at Rochdale in 1809; his mother, Martha Wood, Jacob's second wife, was a woman of great strength of character and refined taste. He was educated first at a boarding school near his home, then at a Friends' school at Ackworth, finally at small schools at York and Newton, near Clitheroe. Through this somewhat mixed and fragmentary education he learned, he himself said, only little Latin and Greek, but acquired a lasting love of English literature. In his 16th year he entered his father's mill, and became a partner in 1839. Rochdale, a growing hive of industry, was the centre of all his activities until the late 1830s; its political controversies and social institutions provided Bright with his first interest in public affairs. In 1833 he helped to found the Rochdale Literary and Philosophical society; for seven years, 1834-41, he was the leader of the antichurch party in a prolonged struggle concerning local church rates; his first speech against the Corn laws (*q.v.*), the issue on which his national reputation was to be founded, was made at Rochdale in 1838.

Anti-Corn Law Agitation.—As a Quaker and a millowner Bright was naturally drawn into the radical agitations of the 1830s, but he went further than most Quakers in concerning himself directly with problems of party politics and he soon stood out among his fellow millowners as a brilliant natural orator. It was almost inevitable that he should join in 1838 the Manchester provisional committee which a year later founded the Anti-Corn Law league. After the death in Sept. 1841 of his young wife (formerly Elizabeth Priestman) whom he had married 22 months before, he gave up all his energies to the league. In his famous words Richard Cobden urged him "when the first paroxysm of your grief is past, . . . come with me, and we will never rest till the Corn law is repealed." Bright accepted his invitation, and, in his own words, "from that time we never ceased to labour hard on behalf of the resolution which we had made."

Bright became the leading orator of the league just as Cobden was its leading organizer. He was soon renowned for the bitter-

ness of his attacks on the landed aristocracy and for the appeal he made to the working classes as well as to the millowners. Although he had no sympathy with the demand of factory operatives in the north of England for a shortening of the working day and was one of the most consistent supporters of the principle of *laissez faire*, he knew how to appeal to the feelings of his large audiences on the cheap food question. "The iron hoof of monopoly would no longer trample on the impotent millions," he argued, if the Corn laws were repealed. "The needy shall not always be forgotten. The expectation of the poor shall not perish for ever." In 1843 he stood as a free trade candidate at a by-election at Durham. He was defeated, but his successful competitor was unseated on petition and at the second contest Bright was returned. His talents were now on display in the house of commons as well as the public platform. but he was slower in establishing his reputation there than he was in the country. It was only after 1845 that he began really to impress his fellow members. Along with Cobden, whom he encouraged to continue the national agitation in face of many difficulties, he saw the league's efforts crowned with success in the summer of 1846 when Sir Robert Peel abolished the Corn laws. At a meeting in Manchester on July 2, 1846, Cobden moved and Bright seconded a motion dissolving the league and subsequently a library of 1,200 volumes was presented to Bright as a memorial of the struggle.

Parliamentary Reform.—Bright's national political career was, in fact, only just beginning. In June 1847 he married Margaret Leatham, of Wakefield, by whom he had seven children. His happy family life provided an ordered background to his public career. A month after his marriage he was elected for Manchester, the mecca of the league, without a contest. In the new parliament, as in the previous session, he opposed legislation restricting the hours of labour and as a nonconformist spoke against clerical control of national education. But he was anxious to direct the fervour which the league had aroused in the cause of parliamentary reform. In 1848 he voted for Joseph Hume's household suffrage motion and he tried to persuade Cobden, who was more interested in financial than parliamentary reform, to join him in a campaign to extend the franchise. He had only limited success in his endeavour to win over Cobden, but never himself abandoned the battle for parliamentary reform until the last stage in the process had been realized in 1884.

Before parliamentary reform became the leading question of the day. Bright went through a period of loneliness and unpopularity which contrasted sharply with the excitement and acclamation of the early 1840s. He had joined with Cobden in attacking Lord Palmerston's foreign policy, in his view, a policy of glory and gunpowder. He maintained that traditional diplomacy was merely a form of "outdoor relief for the landed aristocracy," and resolutely supported the peaceful business ideals which lay behind the Great Exhibition of 1851. When Britain became involved in the Crimean War in 1854, Bright was Palmerston's most eloquent and persistent opponent. On Feb. 23, 1855, he delivered the greatest speech he ever made in the house of commons. with its famous image, "the angel of death has been abroad throughout the land. You may almost hear the beating of his wings." The speech moved the house as it had never been moved within living memory; his political opponent, Benjamin Disraeli, who frequently went out of his way to discuss politics with Bright, for whom he felt a curious sympathy, remarked that he would have given his all to have made the speech. Influence at Westminster, however, did not imply popularity in Manchester. The same crowds who had pressed for repeal were now prepared to identify themselves with Palmerston's policy. to brand Bright as a "Russian" and to burn his effigy in the Manchester streets. At the general election of 1857 Bright and his radical colleague lost their Manchester seats.

The next year, however, he was returned as representative for England's second city. Birmingham, which had a longstanding reputation for radicalism and which was glad to welcome him without a contest. He remained member for Birmingham for the rest of his life, finding its political atmosphere much more congenial than that of Manchester. He soon had the satisfaction of seconding a

motion which led to the defeat and resignation of Palmerston in Feb. 1858. Although Bright had few sympathies with the new minority Conservative government, he warmly supported two of their measures, which he had long advocated—the admission of Jews to parliament and the transfer of the government of the East India company to the crown. He was less enthusiastic about Disraeli's projected suffrage bill which he regarded as "the product not of the friends but of the enemies of reform."

In all the many parliamentary debates on franchise reform between 1859 and 1867, Bright was a regular speaker. "I am told . . .," he said after 1867, "that I have with more labour, with greater pertinacity, with more elaborate speeches, urged the enfranchisement of my country than any other man." He had the satisfaction of seeing W. E. Gladstone, chancellor of the exchequer in a new liberal coalition formed under Palmerston in 1859, become a supporter of the cause and gave him frequent advice and encouragement. Above all he had the satisfaction of seeing public opinion swing toward reform ideas again in the middle 1860s after many earlier signs of lack of interest and excitement. Bright believed in public opinion as the key to change; his first speech in Birmingham had stressed the need for a new agitation to press for parliamentary reform. but there was relatively little enthusiasm in the country until 1864, the year when Gladstone announced his conversion.

The death of Palmerston in 1865; the growth of new political organizations of which the most important were the National Reform union (1864) founded in Manchester and backed by Bright, and the Reform league (1865) with its headquarters in London; and a trade depression in 1866 and 1867, which did as much as the diffusion of ideas to stir working class opinion. all led to a genuine revival of agitation. Bright more than any other man pulled together the threads of organization and worked for "a combined and friendly movement" in London and the provinces. In parliament Lord John Russell, who had succeeded Palmerston, was unsuccessful in carrying a reform bill in 1866, largely because of the opposition of a section of his own party led by Robert Lowe. However, Lowe and his friends, whom Bright named "the Adullamites" (*q.v.*), were unsuccessful in holding back the tide. Lord Derby and Disraeli, who formed a new Conservative minority government after Russell's defeat, introduced a reform bill of their own. It fell far short of Bright's demands, but Disraeli frequently yielded to the pressure of the opposition, and the Reform bill of 1867 as it finally passed the house was a radical measure, aptly described by the prime minister as a "leap in the dark." One Conservative critic of the government's surrender maintained that "if the adoption of the principles of Mr. Bright be a triumph, then the Conservative party, in the whole history of its previous annals, has won no triumph as signal as this."

Other Interests.—Parliamentary reform was not Bright's only interest between 1858 and 1867. In 1860 he warmly supported Cobden in the negotiations for the treaty of Commerce with France, which he regarded as a model instrument of healthy international relations. When Cobden died in March 1865, Bright told the house of commons that he dared not even attempt to express the feelings which oppressed him, and sat down overwhelmed with grief. "I little knew how much I loved him till I had lost him," he remarked, reviewing a friendship which had lasted more than 20 years.

While supporting the efforts not only of Cobden but also of Gladstone for extension of the principles of free trade, Bright was one of the most active advocates of the side of the North in the American Civil War. He had profound admiration for Abraham Lincoln, with whom he frequently corresponded; and he believed that the battle against slavery was the greatest crusade the Americans had embarked upon. He shared with Cobden a belief that American authority in world economic and political life would increase, but he went further than Cobden in acquainting himself with the immediate as well as the distant problems of U.S. politics. He was sometimes accused, unfairly, of trying to "Americanize" the British constitution. In the long run, he looked forward to the day when "from that point of land which is habitable nearest to the Pole, to the shores of the Great Gulf, the whole

of that vast continent might become one great confederation of States—without a great army and without a great navy, not mixing itself up with the entanglements of European politics, without a custom-house inside, through the whole length and breadth of its territory and with freedom everywhere, equality everywhere, law everywhere, peace everywhere—such a confederation would afford at least some hope that man is not forsaken of Heaven, and the future of our race may be better than the past." This speech, delivered at Rochdale in Nov. 1861, is a good example of his extended oratory; he was, however, equally powerful in coining new pithy phrases. The slogan "a free breakfast table" was first used by him; and he also coined the sentence, "Force is not a remedy."

Until 1868 Bright had never been in office, and indeed throughout the whole of his life he preferred to remain in what he called the "common rank of simple citizenship." He was never interested in administration. The formation of a Liberal government after the general election of 1868, however, provided him with his first opportunity of office. When Gladstone urged him to accept the post of president of the board of trade, he accepted, and gave powerful support to the program of reform, particularly Irish re-furn of church and land, a matter which had long been among his chief interests. A severe illness compelled his retirement in Dec. 1870, but he returned to office in Aug. 1873 as chancellor of the duchy of Lancaster. Although the Conservatives gained a majority at the general election of 1874 Bright was returned unopposed for Birmingham. He gave his continued support to Gladstone when the latter came out of his retirement in 1877 to thunder against Disraeli's policy in the near east. Following the same line of argument which he had pursued during the Crimean War he now found himself backed by the united moral indignation of the whole Gladstonian party. When Gladstone returned to power after the general election of 1880, Bright once again became chancellor of the duchy of Lancaster.

His conduct between 1880 and 1886 showed that he put the claims of office far below the claims of principle. For two sessions he spoke and voted with his colleagues, supporting for example W. E. Forster's Irish Coercion bill in 1881, but after Gladstone had intervened in Egypt and the British navy had bombarded Alexandria, Bright left the ministry (July 15, 1882) and never held office again. Although he gave continued general support to Gladstone between 1880 and 1886, he disagreed with the policy of Home Rule for Ireland and played a central part in the Liberal split of March 1886, presiding over the crucial meeting in the house of commons. He had never believed in political violence and had attacked the Irish members of parliament for having "exhibited a boundless sympathy for criminals and murderers." He was therefore able to associate himself without inconsistency with his fellow radical member for Birmingham, Joseph Chamberlain, whose version of radicalism in many other ways contrasted sharply with his own. The breakup of the Liberal party, however, filled Bright with gloom. He was unhappy also in his last years about the revival of protectionist doctrines, the new interest in the expansion of the empire and the talk of imperial federation, which he dismissed as a "dream" and an absurdity. Dogged by ill-health, he died at Rochdale on March 27, 1889, and was buried in the graveyard of the meetinghouse of the Society of Friends there.

Bright and the Liberal Movement.—Bright's importance in 19th-century British history was that he helped to clarify the operative Liberal ideal of "peace, retrenchment and reform" and to popularize it among large sections of the population. The "robust, powerful and vigorous style" of his oratory, as the third marquis of Salisbury described it, was not his only weapon; in addition, he had great courage and consistency, unbounded confidence and a basic humility. As Joseph Chamberlain put it, "the foundation of his political faith was confidence in the people . . . he placed the happiness of the many before the interests of the few." His belief in the people and his attack on vested interests, particularly agricultural interests, led his opponents to brand him as an agitator who fomented class antagonisms; his unlimited confidence caused his more sophisticated critics to claim that he lacked subtlety and depth. Both these qualities, however, contributed to

his influence within the Liberal movement, which he always regarded as something more than a party. If Gladstone was the official leader of that movement, Bright was for long its chief guide and inspiration. In the house of commons Bright's role was parallel to his role in the country. "The supreme eulogy which is his due," Gladstone claimed, "is that he elevated political life to a higher elevation, and to a loftier standard, and that he has thereby bequeathed to his country the character of a statesman, which can be made the subject not only of admiration and of gratitude, but of reverential contemplation." When the reverence is stripped away, Bright remains as an outstanding figure, although he has had many critics among historians just as he had in his lifetime. "The history of the last forty years of this country," he told his Birmingham constituents in 1873, "is mainly a history of the conquests of freedom. It will be a grand volume that tells the story, and your name and mine, if I mistake not, will be found in some of its pages."

BRIGHT, RICHARD (1789–1858), English physician, the first to describe the clinical manifestations of the kidney diseases called after him Bright's disease (*q.v.*), was born on Sept. 28, 1789, at Bristol. After an expedition to Iceland and a short period of study at Guy's hospital, London, Bright took his M.D. at Edinburgh in 1812. From 1814 to 1815 he visited continental hospitals, and then became assistant physician to the London fever hospital. In 1820 he was made assistant physician at Guy's and four years later full physician. The results of his researches first appeared in *Reports of Medical Cases Selected With a View of Illustrating the Symptoms and Cure of Disease by a Reference to Morbid Anatomy* (1827), a work which described dropsical cases and showed that they involved a diseased condition of the kidney. "Bright's disease" soon became world-known, and its discoverer's reputation was ensured by subsequent papers on renal disease in the second volume of reports in 1831 (this also contained studies of the central nervous system and of diseases of the brain, meninges and cord) and in the important first volume of *Guy's Hospital Reports* of 1836. To these latter reports, from 1836 onward, Bright contributed many papers on abdominal tumours, fever, diseased arteries of the brain, etc. He resigned his post at Guy's in 1843. He died in London on Dec. 16, 1858.

See *Guy's Hospital Reports, Bright Centenary Number* (1927); Arturo Castiglioni, *History of Medicine*, ed. by E. B. Krumbhaar, pp. 703–704 (1958).

BRIGHTLINGSEA, a seaport and urban district in the Harwich parliamentary division of Essex, Eng., on a creek of the Colne, 10 mi. S.E. of Colchester by road. Pop. (1961) 4,788. Brightlingsea was a limb of the Cinque Port of Sandwich (*q.v.*) long before 1442. A 14th-century house, Jacobs, still stands. The oyster fishery is the chief industry; there are also some shipyards. It is a yachting and holiday resort.

BRIGHTON, a parliamentary and county borough and seaside resort of East Sussex, England, 51 mi. S. of London by road or rail. Pop. (1961) 162,757; area 19.6 sq.mi. The borough, which returns two members to parliament, was extended in 1923, 1928 and 1952 and includes Patcham, Rottingdean, Ovingdean and part of Falmer and Saltdean. It is bounded by the South Downs on the north, and also on the east, where the chalk cliffs rest on traces of a raised beach at Black Rock beyond Kemp Town, and by Hove (*q.v.*) which continues the urban development without interruption along the flat shore line to the west. In 1930 big sea defense schemes were undertaken between Black Rock and Saltdean, including an undercliff promenade and sea wall.

The first mention of Brighton is in Domesday where it appears as Bristelmestune (Bryghneston in 1324, Brighthempston in 1514, Brighthelmston in 1816) and comprised three holdings, from one

of which a rent of 4,000 herrings was due to Earl Godwin. Its early history is one of the vicissitudes of its fishing community, living largely at the foot of the cliff amid the hazards of sea storms, cliff erosion and marauding Frenchmen. In the time of Elizabeth I, disputes between fishermen and neighbouring landmen led the queen to order the establishment of the "Society of Twelve"—eight fishermen and four landmen—to assist the constable, and this body was for long the local government. From the 17th century the community declined until in 1750 Richard Russell published his work on the medical uses of sea water and settled in Brighton (1754) to carry his theories into practice, thereby initiating the era of sea bathing. Its popularity received a new impetus from the arrival, in 1783, of the prince of Wales, afterward the prince regent and King George IV. His poverful patronage, extending almost continuously to 1827, gave Brighton its most splendid period and one which stamped the town with the distinguished character imparted by its regency squares and terraces. Mrs. Fitzherbert, recognized as his wife, is buried in St. John's Roman Catholic church. His palace, the Royal pavilion, designed in Indian style with fantastic Chinese interior decorations, was built on the Old Steine (where fishing nets were dried) at a cost of more than £376,000 for land and buildings alone. It was sold to the town by Queen Victoria in 1850 and now, furnished in the style of that period, including some of the original furnishings, is open to the public during the summer. The Dome, originally the royal stables, accommodates 2,000 and is used for concerts, conferences and social functions, and the Royal pavilion estate houses the museum and art gallery. With the opening of the London to Brighton railway in 1841, the future popularity of the resort was assured. It was granted a charter of incorporation in 1854.

The heart of Brighton—the old town of narrow "lanes"—lies west of the Old Steine, and its seaward side is the main promenade, between the Palace and West piers. The Chain pier (1.134 ft.), built in 1823 in the form of four suspension bridges, was destroyed in a storm in 1896. The oldest church, St. Nicholas, originally dated from Norman times. Brighton has more than 7 mi. of sea front above the pebbly beach where there is sand at low tide. There in 1887 Magnus Volk established the first electric railway in Great Britain (1½ mi. in length), which still carries holiday-makers in open coaches. The town has several theatres; the Booth museum of birds; Preston manor, a Queen Anne house bequeathed for a museum and public park; a racecourse of 122 ac. on a crest of the downs overlooking the sea near Whitehawk hill, where are Neolithic earthworks; two open-air swimming pools; an aquarium; five golf courses; an ice stadium; a sports arena of 14 ac.; and about 28 sq.mi. of land within and without the borough, a large part of which, including the Devil's dike, was bought to form a green belt. The municipal airport is at Shoreham-by-Sea. University College of Sussex was established at Brighton in 1961 and the first phase for development provided for 1,000 students by 1963. Of many schools the biggest are Brighton college (1845) and Roedean girls' school; there are also a technical college, a college of arts and crafts and a teachers' training college. Sussex county hospital is the largest of numerous hospitals and sanatoria.

The town has industrial estates covering 45 ac., and the making of office machinery, jigs and machine tools, time recording equipment, electrical apparatus, vacuum cleaners, shoes, paint, medicinal preparations, street name plates, brushes and beer are among its varied industries.

BRIGHT'S DISEASE is named after Richard Bright, an English physician, who described the clinical manifestations of certain kidney diseases now known as glomerulonephritis and hypertensive contracted kidney. Subsequently others enlarged Bright's conception to include essentially all forms of kidney disorders of the glomeruli, the vascular tree and those of a degenera-

tive type. See BRIGHT, RICHARD; EDEMA; KIDNEY, DISEASES OF; UROLOGY.

BRIGIT (BRIDGET, BRIGIDA, BRIDE). **SAINT, OF IRELAND** (d. c. 524–528), abbess of Kildare, is one of the patron saints of Ireland. Little is known of her life but legend, myth and folklore. According to these, she was born at Fochart, in the present County Louth, of a noble father and a slave mother. As a child she was sold with her mother to a druid, whom she later converted to Christianity. On being set free she returned to her father, who tried to marry her to the king of Ulster, but the latter, impressed by her piety, removed her from parental control. She gathered other virgins around her, and obtained ecclesiastical recognition of their privileged status. They lived as a community at Kildare, which became a double abbey, for monks and nuns, under an abbess who ranked above the abbot. St. Conlaed, bishop, was honoured there with Brigit from the earliest times. She seems to have been active in founding other communities of nuns. Brigit died on Feb. 1, which is kept as her feast day.

BRIGITTINES (*Ordo Sanctissimi Salvatoris*), a religious order founded by St. Bridget (*q.v.*) of Sweden about 1346, though the mother house at Vadstena, Swed., was not begun until 1371. Among the 79 pre-Reformation houses of the order (mostly in northern Europe) was that of Syon at Isleworth, Eng., dating from 1415. On Aug. 5, 1370, Pope Urban V approved the Brigittine rule but required the use also of the rule of St. Augustine. The modern Sisters of the Most Holy Saviour of St. Bridget, founded at Rome in 1911 by Mother Elisabeth Hesselblad, were recognized by the Holy See on Sept. 12, 1942, as an offshoot of the ancient order.

(H. G. J. B.)

BRIHASPATI (BRHASPATI or "Lord of Prayer," equated with the planet Jupiter), a deity in the Vedic Hindu mythology, an ally of Indra in his conquest of the cloud demon. In the Rig-veda he is identified with Agni (*q.v.*). Offspring of heaven and earth, he inspires prayer and protects the pious. Depicted as having 7 mouths, 100 wings and sharp horns, he is armed with bow and ax, and his chariot is drawn by red horses. In the epics he is merely a priest or sage.

BRIL (BRILL), **PAUL** (1554–1626), Flemish artist, was the most popular landscape painter in Rome in the late 16th and early 17th centuries, a time when the Flemings were still considered the leading specialists in this field. His early forest landscapes have a twisted, exaggerated appearance; their style derives partly from the Mannerist painters of his native Antwerp. After 1600 he disciplined and simplified his compositions under the influence of Adam Elsheimer (*q.v.*). His latest work is classical in character and forms part of the background which helps to account for Claude Lorrain. He died in Rome on Oct. 7, 1626.

Several fresco cycles by Bril survive (Vatican, Palazzo Rospigliosi, etc.) and numerous individual works on panel and canvas.

See A. Mayer, *Das Leben und die Werke der Brüder Mattheus und Paul Brill* (1910); R. Baer, *Paul Brill* (1930).

(M. W. L. K.)

BRILLAT-SAVARIN, ANTHELME (1755–1826), French lawyer, politician and writer, who was the author of the celebrated work on gastronomy, *Physiologie du goût*. Born at Belley on April 1, 1755, he followed the family profession of lawyer. A deputy of the third estate at the states-general of 1789, he was forced to flee the country during the Terror and went to Switzerland and the United States. He returned to France in 1796 and became a judge of the court of cassation during the consulate. He published several works on law and political economy before his work on gastronomy appeared in 1825 (Eng. trans., *The Physiology of Taste*, 1925). He died at Paris on Feb. 2, 1826.

See M. des Ombiaux, *La Physiologie du goût de Brillat-Savarin* (1937).

BRINDISI, a city of southeast Italy, Apulia region, and capital of Brindisi province, is a major Adriatic port situated on the Italian "heel," 113 km. (70 mi.) S.E. of Bari by road. Pop. (1957 est.) 66,301 (commune). It lies between the arms of a

Y-shaped sea inlet which admits ocean-going ships. Much of the city is modern, with wide streets and spacious buildings. Two columns are the chief Roman relics, but other remains include vestiges of a water-supply system and public baths. The church of S. Benedetto (1080) has a cloister and a carved portal, that of Sta. Lucia, a crypt with Byzantine frescoes. The 11th-century circular baptismal church of S. Giovanni al Sepolcro is now a museum. The 12th-century cathedral was almost entirely rebuilt in 1749. The Church of Christ has a 13th-century façade and 14th-century frescoes by Rinaldo da Taranto. The castle of Frederick II overlooks the western arm of the inner harbour. Brindisi is on the main coastal railway from Ancona to Lecce, with a branch to Taranto, and from its port ships ply to the near and far east. There is an airport 3 mi. N., at Casale. The chief industry is the import and export of merchandise, but wine and preserved fruit are produced.

Legend attributes the city's foundation to Diomedes, the companion of Ulysses, and its original Greek name, *Brentesion*, changed by the Romans to Brundisium (meaning "Stag's head" from the antler-shaped inner harbour), shows its Illyrian origin. It was made a Roman town in 266 B.C. and with Tarentum (Taranto) formed a base of resistance to Hannibal half a century later. In the 2nd century B.C. it was joined to Rome by the Apian way and after the Social wars became a municipium. Octavian (Augustus) and Antony were reconciled there in 40 B.C. and in 19 B.C. Virgil died there. Brindisi had various rulers during the early middle ages. It regained importance after conquest by the Normans (1071) and was the embarkation port for many crusaders. Its prosperity continued under the first Angevin, but the town was damaged in the struggles over the succession at the end of the 14th century, and by an earthquake in 1456. In common with the rest of the kingdom of Naples, Brindisi changed hands several times in the 18th and early 19th centuries, but from 1815 the restored Bourbons began to make it an important commercial centre. The opening of the Suez canal in 1869 increased its prosperity. In World War I it was the centre of naval operations in the Adriatic and in World War II was captured by the Allies on Sept. 10, 1943.

The province of Brindisi, formed in 1927 with Brindisi as capital, is shaped roughly like a flat triangle, with its base on the Adriatic 47 mi. long. Its greatest width is 28 mi. and its chief river the Canale Reale. Pop. (1957 est.) 337,125; area 709 sq. mi. The province is mainly flat or undulating, rising to the westward. Chief towns are Fasano, Ostuni and Francavilla Fontana. The emphasis in agriculture is on cereals, olives, vines and vegetables.

(M. T. A. N.)

BRINDISI, a term used for drinking songs in 19th-century Italian opera, from *brindisi*, "a toast." Typical examples are the aria "Libiamo" ("let's drink") in Verdi's *La Traviata* and "Viva il vino" in Mascagni's *Cavalleria Rusticana*. The genre reached its height in the dramatic drinking song by Iago, accompanied by Cassio, Roderigo and a choir, in act 1 of Verdi's *Otello*.

BRINDLEY, JAMES (1716–1772), co-founder with John Smeaton of the civil engineering profession, was born at Thornsett near Buxton, Derbyshire, in 1716. Of humble origin, he became a millwright. In 1752 he designed and set up an engine for draining coalpits at Clifton, Lancashire. In 1759 his genius and skill led to his being called by the duke of Bridgewater to advise on his project of a canal from Worsley to Manchester. His solution of the problems, including the Barton aqueduct carrying the canal over the river Irwell and the many miles of underground communications in the Worsley coal mines, established him as the foremost canal engineer of his day. The success of this canal encouraged similar projects; the Grand Trunk canal, penetrating the central ridge of England by the Harecastle tunnel, the Staffordshire and Worcestershire, the Coventry, the Oxford, the old Birmingham and the Chesterfield canals were all designed and, with one exception, executed by Brindley. By his labours a network totaling 360 mi. of canals was laid out and constructed. The communications of the country were so improved that the way was paved for the industrial revolution of the 19th century. Brindley left no record of his works, which he undertook without written

calculations or drawings. He died on Sept. 30, 1772, at Turnhurst, Staffordshire.

See S. Smiles, *The Lives of the Engineers*, vol. i (1864).

(A. McD.)

BRINELL, JOHAN AUGUST (1849–1925), Swedish metallurgist, devised the Brinell hardness test (see **HARDNESS TESTING**). Born in Bringetofta in the district of Jonköping, on Nov. 21, 1849, he attended the technical school at Borås. He rose to a leading position in the iron and steel industry. In 1875 he became the engineer for the Lesjöfers ironworks and in 1882 was appointed chief engineer of the Fagersta ironworks, a position he held until 1903. From 1903 to 1914 at the Järnkontoret works he carried on research in steel handling and the crystallization of steel. He retired in 1914.

About 1900 he developed the rapid test for steel that bears his name, by which the hardness and other properties are determined by the imprint made by a hardened ball under a given pressure. He won many awards including the Bessemer medal of the Iron and Steel Institute of London. Brinell died at Stockholm on Nov. 17, 1925.

(S. C. HR.)

BRINK, BERNHARD TEN (1841–1892), German philologist, of Dutch origin, best known for his studies of early English literature, was born at Amsterdam on Jan. 12, 1841, and educated at Dusseldorf, Munster and Bonn. In 1870 he became professor of modern languages at Marburg, and in 1873 professor of English at Strasbourg university. In 1874 he began to edit, in conjunction with W. Scherer, E. Martin and E. Schmidt, *Quellen und Forschungen zur Sprache und Kulturgeschichte der germanischen Völker*. In 1877 he published *Chaucer: Studien zur Geschichte seiner Entwicklung und zur Chronologie seiner Schriften*; in 1884, *Chaucers Sprache und Verskunst*. He also published critical editions of the *Prologue* and the *Complaynte to Pité*.

Brink's work stimulated a revival of Chaucer study in the United Kingdom as well as in Germany, and to him was indirectly due the foundation of the English Chaucer society. His *Beowulf-Untersuchungen* (1888) proved a hardly less valuable contribution. His best known work is his *Geschichte der englischen Literatur* (1889–93; English trans. by H. Kennedy in Bohn's *Standard Library*), which was never completed, and broke off just before the Elizabethan period.

Brink died at Strasbourg Jan. 29, 1892.

BRINON, FERNAND DE (1887–1947), a leading French supporter of Nazism and collaborator under the Vichy regime, was born at Libourne, Gironde, on Aug. 16, 1887, and graduated at the École Libre des Sciences Politiques in Paris. A journalist, he became a vigorous supporter of Franco-German reconciliation and founded the Comité France-Allemagne and the Cercle du Grand Pavois, which exercised great influence in political and business circles. Heavily financed by Germany through his friend Otto Abetz, J. von Ribbentrop's chief agent in France, he played an important part in the final demoralization of the third republic and in the establishment of the Vichy regime.

In Nov. 1940, by agreement with the Germans, the Vichy government appointed Brinon its ambassador in Paris and then its delegate general for German-occupied France also; in April 1942 he became a junior minister. In Sept. 1944, after the Allied invasion had caused the collapse of the Vichy regime, he, Marcel Déat and other collaborators formed in Marshal Pétain's name a pseudo government which was, however, devoid of effective authority. Eventually captured by the Allies, Brinon was tried by the high court and sentenced to death for treason. He was executed on April 15, 1947. His services to Germany had been so great that his Jewish wife was recognized by the *Reich* as an "honorary Aryan."

(P. W. C.)

BRINVILLIERS, MARIE MADELEINE MARGUERITE D'AUBRAY, MARQUISE DE (c. 1630–1676), French poisoner, was the eldest daughter of Antoine Dreux d'Aubray, civil lieutenant of Paris. In 1651 she married a young army officer, Antoine Gobelin de Brinvilliers. Vivacious, attractive and pleasure-loving, she became the mistress of a friend of her husband's, J. B. Godin, called de Sainte-Croix. On her father's intervention, Sainte-Croix was arrested and sent to the Bastille on March 19.

1663. Released two months later, he plotted with his mistress to take revenge on her father by poisoning him. With the assistance of Glaser, one of the king's apothecaries, he obtained poisons which she tested on patients in hospitals. Eventually she was thus enabled to procure the death of her father (Sept. 10, 1666) and then of her two brothers (1670), but an attempt on her husband failed. Then Sainte-Croix died suddenly (July 31, 1672) and among his belongings documents were found incriminating Madame de Brinvilliers and her valet, as well as some phials of poison. The valet was condemned to death and was broken on the wheel in the Place de Grève (Feb. 23, 1673). The marquise, having escaped and taken refuge in England and later in the Low Countries, was condemned to death in her absence. Arrested at Liège (March 25, 1676) and taken to France, she was tried by the *parlement* of Paris and condemned to be beheaded. Having admitted her crimes under torture and expressed her repentance, she received the consolations of the church and was executed in the Place de Grève on July 16, 1676. Her body was burned and the ashes scattered.

During her interrogation Madame de Brinvilliers had declared: "Half the people of quality are involved in this sort of thing, and I could ruin them if I were to talk." The people whom she refused to name were those who were later to be compromised in the "affair of the poisons" (see LA VOISIN).

Stokes, *Madame de Brinvilliers and Her Times* (1912; 2nd ed., 1924); G. Mongrédien, *Madame de Montespan et l'affaire des poisons* (1953). (G. Mo.)

BRIOSCO, ANDREA: see RICCIO (ANDREA BRIOSCO).

BRISBANE, ARTHUR (1864–1936). C.S. newspaper editor and writer, was best known for his work on the Hearst newspapers. He was the son of Albert Brisbane (1809–1890), U.S. social reformer, whose European study and travels led him to adopt the principles of François Marie Charles Fourier (*q.v.*), and after his return to the U.S., to organize, write and lecture for their implementation. Arthur was born in Buffalo, N.Y., Dec. 12, 1864. Educated in the U.S. until the age of 13, he then, like his father, studied in France and Germany. Returning to the U.S. in 1883, he worked first on Charles A. Dana's *New York Sun* and then on Joseph Pulitzer's *New York World*. In 1889, William Randolph Hearst (*q.v.*) made him managing editor of the *New York Journal*, and, with his salary tied to circulation rises, Brisbane became the highest paid U.S. newspaper editor of his day. Master of the big, blaring headline and of the atrocity story, he played a large part in the *Journal's* promotion of the Spanish-American War (see **NEWSPAPER: Yellow Journalism**). His editorial column, "Today," written from 1917 to the day of his death in New York city, Dec. 23, 1936, was widely syndicated, often as a front page feature.

See Oliver Carlson, *Brisbane: a Candid Biography* (1937).

BRISBANE, SIR THOMAS MAKDOUGALL (1773–1860). Scottish soldier and astronomical observer who is mainly remembered as a patron of science, was born on July 23, 1773, at Brisbane house, near Largs, Ayrshire. He entered the army in 1789 and served in Flanders, the West Indies, Canada and Spain. He developed an interest in astronomy and built an observatory at Brisbane house. In 1821 he was appointed governor of New South Wales and, although generally a poor administrator, he introduced grapevines, sugar cane and tobacco plants into the colony. He established an observatory at Paramatta in 1822 and after his return to Scotland constructed a combined observatory and magnetic station at Makerstoun in Roxburghshire. He was awarded the gold medal of the Royal Astronomical society in 1828, and the results of magnetic observations at Makerstoun gained him the Keith prize of the Royal Society of Edinburgh in 1848. He was elected president of that society in 1833 in succession to Sir Walter Scott. Brisbane was made a baronet in 1836 and a general in 1841. He died at Brisbane house on Jan. 28, 1860.

See *Mon. Not. R. Astr. Soc.*, vol. 21 (1860).

(O. J. E.)

BRISBANE, city, seaport and capital of Queensland, Austr., is situated in the southeastern corner of the state on the Brisbane river, 14 mi. from its mouth in Moreton bay. Pop. (1954) 82,251. Metropolitan area 502,320, (1959 est.) 567,000, making it the third city of Australia. The area of greater Brisbane is 385 sq.mi.,

BY COURTESY OF BRISBANE CITY COUNCIL

VIEW OF BRISBANE FROM WICKHAM TERRACE. THE CITY HALL (WITH CLOCK TOWER) STANDS IN THE CENTRE

the third largest local authority area in the southern hemisphere. The city lies astride the river which winds through wooded, hilly country and is there crossed by four bridges and several ferries. The Brisbane and Logan basins give access to the uplands of the Darling downs and of northern New South Wales, while northward lowlands, crossed by hill ranges, lead toward the central coastal basins. The climate is subtropical with temperatures varying from a mean maximum of 59.9° F., an average daily sunshine of 7½ hr. and an average annual rainfall of 40.1 in., falling mainly from December to March.

One of the city's most splendid buildings is the city hall, erected in Renaissance style in 1929 at a cost of nearly £A1,000,000 and covering 2½ ac. on the site of Brisbane's original water hole. The University of Queensland at St. Lucia has excellent modern buildings and there are a fine parliament house (1869), the Queensland museum (1855), a National Art gallery (1895) and an Anglican and a Roman Catholic cathedral. The main thoroughfares are Queen street and Adelaide street. There are three race tracks—Eagle Farm, Doomben and Albion park—and many public recreation grounds, besides beautiful parks and gardens, such as the Botanic gardens (51 ac.). The Easter yachting classic, the Brisbane-Gladstone race, attracts entries from all the states and from overseas.

Brisbane is the outlet for a vast and rich agricultural and pastoral hinterland stretching west to the Eastern highlands, the Darling downs and beyond. It is also becoming increasingly important as an industrial centre, its industries including heavy and light manufacturing, shipbuilding, food processing, sawmilling, tanning and the manufacture of cement, clothing and motor cars. The city is supplied with water from Lake Manchester and the Somerset dam.

Railways link Brisbane with Sydney and the southern states, one via Toowoomba and Warwick and the other via Kyogle and the coast. There are also rail links with the northern sugar and mining areas and with the vast pastoral plains to the west. Coal from the West Moreton coal field centring on Ipswich is transported by river to the port of Brisbane. This has a 400-ft.-wide dredged channel, a maximum tidal rise of 7 ft. and berths for ships up to 750 ft. in length and with a draft of 28 ft. right up to the heart of the city. The total wharfage is 34,000 ft. and there are two graving docks. Most of the state's exports of wool, meat,

sugar, minerals, butter and general dairy products pass through the port, which grows in importance yearly. Brisbane has two civil airports—Eagle Farm, 6 mi. N. E., provides services to the main cities of Australia and also to London and other major cities overseas, and Archerfield, 8 mi. S., is an auxiliary airport.

The site of the city was discovered by Lieut. John Oxley in 1824 when he "landed to look for water" and it was first used for the penal settlement of Moreton bay. Land was thrown open for sale in 1842, after transportation to New South Wales had been abolished. In 1859, when Queensland was created a colony, the place became its capital and was officially renamed in honour of Sir Thomas Brisbane, governor of New South Wales. At this time Brisbane had a population of about 5,000; in the 1950s it was growing at the rate of 12,000 a year.

See Gordon Greenwood and John Laverty, *Brisbane, 1859-1959* (1959). (D. B. W.)

BRISSON, (EUGÈNE) HENRI (1835-1912), French statesman of strong anticlerical views, twice premier, was born at Bourges on July 31, 1835. He studied law and practised as a barrister in Paris. He contributed articles to *Le Temps* in the days of the second empire. One of the deputy mayors of Paris after Sept. 4, 1870, he was elected on Feb. 8, 1871, to the national assembly, as a deputy of the extreme left. He was the first to propose a general political amnesty—to include the condemned Communards—but this was rejected. Brisson sat as a deputy for Paris from 1876 to 1902 and for the Bouches-du-Rhône from 1902 until his death. He was president of the chamber from Nov. 1881 to March 1885. He succeeded Jules Ferry as premier on April 6, 1885, but resigned on Dec. 29 on obtaining a bare majority for the vote of credit required for the Tongking expedition. He was president of the committee of inquiry into the Panamá scandal. He stood unsuccessfully as a candidate for the presidency of the republic in June 1894 and again in Jan. 1895. Having been president of the chamber again from Dec. 1894, he formed his second cabinet on June 28, 1898. The two main problems with which he had to deal were the Dreyfus affair and the Fashoda incident. He was forced to resign on Oct. 25, when his war minister, Gen. Jules Chanoine, contrary to the cabinet's agreed policy, declared in the chamber that he believed in Dreyfus' guilt and so provoked a vote of no confidence in the government.

Brisson actively supported René Waldeck-Rousseau and Émile Combes (*qq.v.*), particularly in regard to the separation of church and state. In 1906 and in 1912 he was re-elected president of the chamber. He died in Paris on April 13, 1912.

BRISSOT, JACQUES PIERRE (BRISSOT DE WARVILLE), (1754-1793), a leader of the Girondins (Brissotins) during the French Revolution, notable particularly for his war policy, was born at Chartres on Jan. 15, 1754, the 13th son of an eating-house keeper. He began to work as a clerk in lawyers' offices, first at Chartres, then in Paris. His pamphlet *Testament politique de l'Angleterre* (1780) brought him to the notice of the English editor of *Le Courrier de l'Europe*, and Brissot worked for this journal for a year. He then tried to resume his former career, but the legal profession's resentment at his *Théorie des lois criminelles* (1781) made this impossible. Taking an interest in science, he went to London (Feb.-Nov. 1783) and not only sent literary articles to *Le Courrier* but also founded two scientific periodicals, which failed. Returning to France, he was imprisoned in the Bastille for pamphlets against the queen and the government, but was released in Sept. 1784.

Inspired by the English antislavery movement, Brissot founded the Société des Amis des Noirs in Feb. 1788. He left for the United States in May, but returned when the states-general were convened in France and launched a newspaper, *Le Patriote français* (May 1789). Elected to the first municipality of Paris, he took delivery of the keys of the Bastille when it had been stormed.

At first Brissot concentrated on the struggle for the emancipation of slaves, demanding from the Jacobins (May 11, 1791) that Negroes should enjoy all the rights of ordinary citizens. After Louis XVI's flight to Varennes, however, he attacked the king's inviolability in a long speech to the Jacobins (July 10, 1791), which contained all the essentials of his future foreign policy. Elected

12th deputy for Paris to the legislative assembly, he at once concerned himself with foreign affairs, joining the diplomatic committee. He argued that action must be taken against the king's *émigré* brothers (Oct. 20, 1791) and that war could only consolidate the Revolution by unmasking its enemies and inaugurating a crusade for universal liberty (speeches of July 10, Dec. 11 and 30, 1791, and Jan. 20, 1792). Only Robespierre dared to oppose him, and war was declared (April 1792). The early defeats suffered by the French, however, gave fresh impulse to the revolutionary movement, which Brissot and his friends meant to check. Having tried in vain to prevent the suspension of the monarchy, Brissot was denounced by Robespierre in the Paris commune as a "liberticide" on Sept. 1.

No longer acceptable to Paris, Brissot represented Eure-et-Loir in the Convention. Expelled from the Jacobins (Oct. 12, 1792) and attacked by the Mountain (extreme revolutionary faction), he was still influential in the diplomatic committee: his report led to war being declared on Great Britain and the Dutch (Feb. 1, 1793). Having voted for suspension of the death sentence on Louis XVI, he later maintained in a pamphlet that the execution had halted the course of French victories. On April 3, 1793, Robespierre accused him of being the friend of the traitor Gen. C. F. Dumouriez and of being chiefly responsible for the war. Brissot replied denouncing the Jacobins and calling for the dissolution of the municipality of Paris. He was not conspicuous in the struggle between the Girondins and the Mountain (April-May), but on June 2, 1793, his arrest was decreed with that of his Girondin friends. He fled, but was captured at Moulins and taken to Paris. Sentenced by the revolutionary tribunal on the evening of Oct. 30, he was guillotined the next day. His *Mémoires*, written in prison, were edited by C. Perroud, two volumes (1912).

See E. Ellery, *Brissot de Warville* (1915); also H. A. Goetz-Bernstein, *La Diplomatie de la Gironde* (1912). (A. So.)

BRISTLE, the supple, resilient hair of the wild or semiwild boar or hog, one species of which is found in Europe, Siberia and China; three other distinct types are native to India, Tibet and Japan respectively. Bristle has a broad base and a tapered tip split into several filaments or "flags." Its surface is slightly rough or ridged. Because of its form, bristle has been a brush material of prime importance for centuries.

The chemical basis of bristle is keratin, a protein-type substance, the molecular structure of which is a chain formation. Nylon bristles are produced by the chemical construction of similar molecular chains. The nylon compound is melt spun, forced through the holes of a spinning-jet and solidified as filaments by contact with air. They are then mechanically processed as segments of filament having a broad base and tapered "flagged" tip so that they closely resemble the natural product. Untapered nylon bristles are also produced. See BRUSH. (E. L. Y.)

BRISTOL, EARLS AND MARQUESSSES OF. The English title earl of Bristol was first held, between 1622 and 1698, by members of the Digby family (see BRISTOL, GEORGE DIGBY, 2nd earl of; BRISTOL, JOHN DIGBY, 1st earl of). It was revived in 1714 in favour of John Hervey and has been held continuously by members of his family since that date. From 1826 the earls of Bristol have also borne the titles marquess of Bristol and Earl Jermyn.

JOHN HERVEY (1665-1751), 1st earl of Bristol (in the Hervey line), was born on Aug. 27, 1665, the son of Sir Thomas Hervey (d. 1694) and the nephew of John Hervey (1616-79), treasurer to Catherine of Braganza, queen consort of Charles II. He was educated at Clare hall, Cambridge, and became member of parliament for Bury St. Edmunds (March 1694). He was created Baron Hervey of Ickworth in March 1703 and earl of Bristol in Oct. 1714, through the influence of the duchess of Marlborough. By his first marriage he had only one son, Carr, who died unmarried on Nov. 14, 1723, and is thought by some to have been the father of Horace Walpole (1717-97). The 1st earl died on Jan. 20, 1751. His eldest son by his second marriage, John (1696-1743), gained some renown as a writer and politician (see HERVEY OF ICKWORTH, JOHN HERVEY, Baron).

The 1st earl was succeeded by his grandson GEORGE WILLIAM

HERVEY (1721–75), 2nd earl, who was born on Aug. 31, 1721. He became Baron Hervey of Ickworth in 1743 and succeeded to the earldom in 1751. He served in the army (1739–42), was sent to Turin as envoy extraordinary in 1755, and was ambassador at Madrid from 1758 to 1761. Appointed lord lieutenant of Ireland in 1766, he never visited that country during his short tenure of office. After having served for a short time as keeper of the privy seal, he became groom of the stole to George III in Jan. 1770. He died unmarried on March 18, 1775, and was succeeded by his brother AUGUSTUS JOHN HERVEY (1724–79), 3rd earl.

Augustus John was born on May 19, 1724. He entered the navy in 1736, served under Adm. John Byng in the Mediterranean and gave evidence at his trial in 1757. He was of great assistance to Adm. Edward Hawke in 1759. Having served with distinction in the West Indies under George Rodney, his active life at sea ceased with the peace of Paris (Feb. 1763). Hervey was, with one short interval, member of parliament for Bury St. Edmunds from 1757 until he succeeded his brother in the peerage (1775). Having served as a lord of the admiralty (1771–75) he won some notoriety as an opponent of the Rockingham ministry and a defender of Admiral Keppel. He had married in 1744 Elizabeth Chudleigh (1720–88), later well known in many European courts. The marriage was kept secret as she wanted to retain her position as maid of honour to the princess of Wales. In 1769 she denied having been married and married the duke of Kingston. On his death she was prosecuted for bigamy, and convicted, and spent the rest of her life on the continent. The earl died in London on Dec. 24, 1779, leaving no legitimate issue and having, as far as possible, alienated his property from the title.

He was succeeded by his brother FREDERICK AUGUSTUS HERVEY (1730–1803), 4th earl, who was born on Aug. 1, 1730, and educated at Westminster school and Corpus Christi college, Cambridge. He became a royal chaplain and was made bishop of Cloyne in 1767, and of Derry in 1768. He did much to improve agriculture and communications within his diocese, often at his own expense, and he opposed the penal laws, the tithes system and Roman Catholic disabilities. He became earl of Bristol in 1779. In 1782 he threw himself ardently into the Irish volunteer movement. He was a member of the volunteer convention at Dublin in 1783 and probably wanted to be elected chairman. But his ideas, which included votes for Catholics, were too radical and republican for loyal Protestants, and more moderate parliamentarians like Henry Grattan gained control of the movement. Discouraged, the bishop retired abroad and died at Albano, Italy, on July 8, 1803. He was buried at Ickworth.

Frederick Augustus was succeeded by his younger son, FREDERICK WILLIAM HERVEY (1769–1859), 5th earl and 1st marquess, born on June 2, 1769. He was created marquess of Bristol and Earl Jermyn in 1826, and died on Feb. 15, 1859. He was succeeded by his son, FREDERICK WILLIAM (1800–64), M.P. for Bury St. Edmunds, 1826–59, as 2nd marquess, by the latter's son FREDERICK WILLIAM JOHN (1834–1907), M.P. for West Suffolk, 1859–64, as 3rd marquess. FREDERICK WILLIAM FANE HERVEY (1863–1951), 4th marquess, nephew of the 3rd marquess, served with distinction in the Royal Navy and was M.P. for Bury St. Edmunds in 1906–07. His brother HERBERT ARTHUR ROBERT HERVEY (1870–), 5th marquess, succeeded to the title in 1951, after a career in diplomacy.

BRISTOL, GEORGE DIGBY, 2ND EARL OF (1612–1677), English royalist, who was an ambitious and impetuous minister of Charles I and for a short time, in exile, of the future Charles II, was born in Madrid in Oct. 1612, the eldest son of John Digby, 1st earl of Bristol. He was educated at Magdalen college, Oxford. In 1638–39 he attacked Roman Catholicism in a series of letters to Sir Kenelm Digby. He bore resentment to the court for his imprisonment for dueling in Whitehall palace in 1634, and so when he was elected member of parliament for Dorset in 1640 he supported John Pym and John Hampden, and was one of the committee for the impeachment of the earl of Strafford. But in 1641 he voted against the earl's attainder and opposed the bill whereby the Puritans unsuccessfully tried to abolish the episcopacy and the hierarchy of the church "root and branch." To save

him from the attacks of the house of commons, the king raised him to the peerage in his father's barony of Digby (June 1641), and he became one of Charles's advisers. He urged the arrest of the five members in Jan. 1642, and was soon after forced to escape impeachment by fleeing abroad. He returned to fight for the king at Edgehill, the first battle of the English Civil War (1642), but threw down his commission after a quarrel with Prince Rupert. He was made secretary of state in 1643, and lieutenant general of the king's forces north of the Trent in 1645. On Oct. 15, 1645, he was defeated at Sherburn in Durham, his correspondence, disclosing royal intrigues with Ireland, Scotland and foreign powers, was captured, and he was forced to escape to Ireland, where he worked with the marquess of Ormonde, and was unjustly blamed for the intrigues of the earl of Glamorgan. Finally he fled to France where he served Louis XIV in the Fronde. He was reappointed secretary of state by the future Charles II in 1657, but he became a Roman Catholic in 1658 and, to his surprise, was forced to resign office. His estrangement from Edward Hyde, afterward earl of Clarendon, also occurred at this time.

Digby, who had inherited the earldom of Bristol in 1653, returned to England after the Restoration but was excluded from office because of his religion. He adopted an attitude of violent hostility toward Clarendon and on July 10, 1663, brought a charge of high treason against him. The charge was dismissed and Bristol expelled from court. On the fall of Clarendon, however, Bristol was again welcomed at court and resumed his seat in the house of lords (July 1667). In March 1673, though still a Roman Catholic, he spoke in favour of the Test act, describing himself as a "Catholic of the Church of Rome, not a Catholic of the court of Rome." He died at Chelsea on March 20, 1677.

The 2nd earl had two sons, Francis, who was killed in a naval engagement on May 28, 1672, and John, the elder, who died without legitimate issue in 1698, when the barony of Digby and the earldom of Bristol became extinct.

See D. Townshend, *George Digby, Second Earl of Bristol* (1924).

BRISTOL, JOHN DIGBY, 1ST EARL OF (1580–1653), English diplomat and statesman, who as a moderate royalist advocated conciliation and reform in the struggle with parliament, was born in Feb. 1580 and educated at Magdalen college, Oxford. Between 1611 and 1624 he was constantly employed as ambassador of James I, notably in the negotiations with Spain, and he was created Baron Digby in 1618, and earl of Bristol in 1622. During 1621 he was sent to Brussels and Vienna to advocate the cause of the king's son-in-law, Frederick V, elector palatine. In 1623 when the negotiations for a marriage between Prince Charles (afterward Charles I) and a Spanish princess were wrecked by the behaviour of Charles and the duke of Buckingham in Madrid, Bristol incurred Buckingham's resentment by sending to England an account of the true state of affairs. On his arrival at Dover in March 1624 he was ordered to be confined to his home at Sherborne in Dorset. After the death of James he was removed by Charles I from the privy council and ordered to absent himself from Charles's first parliament (March 1626). Bristol applied to the lords, who supported his right either to take his seat in parliament or to be given a fair trial, and Charles sent him his writ, accompanied by a letter desiring him not to use it. Bristol, however, took his seat and demanded justice against Buckingham. The king endeavoured to obstruct his attack by causing Bristol, on May 1, to be himself brought to the bar, on an accusation of high treason by the attorney general. The lords, however, ordered that the charges against Bristol should be investigated simultaneously with the charges against Buckingham. Charles could only prevent further proceedings by the dissolution of parliament on June 15, and he ordered that Bristol should be prosecuted in the Star Chamber. Bristol was sent to the Tower of London, where he remained until March 17, 1628, when the peers, on the assembling of Charles's third parliament, insisted on his liberation and restoration to his seat in the house of lords.

In the discussions on the Petition of Right, Bristol supported the use of the king's prerogative in emergencies, but, when the compromise based on this principle was rejected by the commons, he joined in the demand for a full acceptance of the petition by

the king. He was now restored to favour, but took no part in politics until the outbreak of the Scottish rebellion (1639) when he warned Charles of the danger of attacking with inadequate forces. He was a leader in the great council held at York and a commissioner to negotiate with the Scots at Ripon in 1640, and he strongly advised the summoning of a parliament. In Feb. 1641 he advocated reforms in the administration and received a seat in the council. Though no friend to the earl of Strafford, he endeavoured to save his life, desiring only to see him excluded from office. Bristol was declared an evil counselor by the house of commons on Dec. 27, 1641, and Oliver Cromwell moved an address to the king to dismiss him from his councils, on the plea that he had advocated the bringing up of the northern army to overawe parliament in the preceding spring. There is no evidence to support the charge but Bristol was regarded by the parliamentary party with unreasonable hatred and distrust. He was sent to the Tower on March 28, 1642, for having failed to disclose to parliament the Kentish petition. Liberated in April, he joined Charles at York, and became his councilor at Oxford. He was named in the propositions for peace of Feb. 1643 for removal from the court and public office forever, and in those of Nov. 1644 was excepted from pardon. In January he had endeavoured to instigate a breach of the Independents with the Scots. Bristol, however, was not in favour of continuing the war, and withdrew to Sherborne, moving in the spring of 1644 to Exeter and, after the surrender of the city, retiring abroad (July 11) by order of parliament. He published in 1647 *An Apology* defending his conduct during the English Civil War. He spent the rest of his life in exile, dying in Paris on Jan. 16, 1653, when he was succeeded by his eldest son (see BRISTOL, GEORGE DIGBY, 2nd earl of). (G. Ds.; X.)

BRISTOL, a city, parliamentary and county borough and seaport of England on the boundaries of Somerset and Gloucestershire, a separate county of itself, 114 mi. W. of London by road, with its own sheriff, court of quarter sessions, civil court (the Tolzey court) and assizes, returning six members to parliament. Pop. (1961) 436,440; area 41.2 sq.mi. The nucleus of the city is at the confluence of the Avon and Frome rivers, whence the Avon flows through a limestone gorge, crossed by the Clifton suspension bridge, to join the Severn estuary at Avonmouth, the western extremity of the city. Main lines of the Western and Midland regions of British railways connect the city with London, with south Wales via the Severn tunnel, with Birmingham and the midlands via Gloucester and with Exeter and Plymouth via Taunton. The municipal airport at Lulsgate 6½ mi. S. of Temple Meads railway station, provides flights to Ireland, the Channel Islands and the European mainland.

History.—The ancient city of Bristol (Bricgstowe, Bristou, Bristoll) was situated on a 20-ac. mound of land at the junction of the Avon and the Frome, thus providing a sheltered tidal harbour capable of defense.

It differs from other large English cities in that it was from the beginning a strictly commercial place and has remained such to this day. The early history of Bristol is shrouded in obscurity. At Clifton, on the heights commanding the portion of the Avon gorge close to the suspension bridge, are three camps of British origin, but there is no evidence of a settlement at the confluence of the Avon and Frome until the 10th century, when Saxon coins of the reign of Aethelred the Unready (978–1016) minted in Bristol prove that the place had become sufficiently important to have a mint. At the time of the Norman Conquest, Bristol was part of the royal manor of Barton, paying to the king 110 marks of silver and 33 marks of silver to Geoffrey, bishop of Coutances, France, who built the first castle. This was enlarged and completed by Robert of Gloucester in 1122 and was wholly destroyed in the 17th century.

The growth of trade which followed the Conquest put Bristol in the forefront of ports outside London. The first of the city's long series of charters, granted by Henry II in 1155, freed the burgesses from all tolls and customs throughout England, Normandy and Wales. Another, dated 1171, granted the town of Dublin to the men of Bristol as a trading colony. In the early 13th century a better harbour and quays were provided by diverting

THE TIMES

GOthic TOWER OF MAIN BUILDING OF UNIVERSITY OF BRISTOL, DESIGNED BY SIR GEORGE OATLEY, 1925. SITUATED ON THE UPPER SLOPES OF ST. MICHAEL'S HILL. OVERLOOKING CENTRE OF CITY

the Frome and by building a stone bridge over the Avon, and this led to the expansion of the town and the inclusion of the parishes of Temple and Redcliffe within its walls. During the reign of Edward III the manufacture of woolen cloth developed in Bristol, being marketed in Ireland, Spain and Portugal, and Bristol was made one of the staple towns.

Until 1216, when Adam le Page was elected the first mayor of Bristol, the constitution of the town was manorial rather than municipal. In 1373 Bristol was made a county and separated from Gloucestershire and Somerset, being the first provincial town to receive this honour. The boundaries were extended to include a large water area of the Avon and Severn to Steep Holme and Flat-holm Islands. The town had its own sheriff, controlled its own legal affairs and elected a common council.

In the 15th and 16th centuries, Bristol, port and manufacturing town, was a great collecting and distributing centre not only for overseas, but also for inland trade. The city also played a notable part in maritime history. From its quays sailed such famous men as John and Sebastian Cabot, Martin Pring and Capt. Thomas James. It was the age of the merchant princes and in 1552 the Society of Merchant Venturers was incorporated. Bristol was a royalist stronghold during the Civil War until it was captured by parliamentarians under Lord Fairfax in 1645.

During the 17th and 18th centuries, trade with the new colonies, based on tobacco and sugar, stimulated the growth of new industries, such as pottery, glass, textiles, leather goods, sugar refining and tobacco manufacture. Bristol was a famous centre for glass manufacture; no fewer than 14 glassworks were active in the 18th century. In 1768 Richard Champion set up a pottery making the finest porcelain. The manufacture of chocolate was first developed in the city. Bristol also played a large part in the prosperous African slave trade, which was, however, vigorously opposed by the Quakers, who were an influential body in Bristol, and John Wesley, of whose activities Bristol was the centre.

It was in the 18th century that Bristol became a spa as a result of the opening up of springs (70° F.) at Hotwells, which led to the development of Clifton, to the west, where fine terraces and crescents were laid out.

Toward the end of the 18th century Bristol began to lose its importance, and the decline continued into the 19th century. For this there were a number of reasons: (1) the rise of Liverpool and loss of the West Indies trade; (2) failure to improve the port

facilities; (3) the abolition of the slave trade; and (4) heavy rates levied by the Bristol Dock company, formed in 1803, to pay for the floating harbour built in 1809. Nevertheless, it was from the Bristol area that J. L. McAdams's idea of road construction spread throughout the country, and the "Great Western," one of the first steamships to cross the Atlantic, and the "Great Britain," the first iron ship, were both built in Bristol. In an attempt to restore the trade of the city, a chamber of commerce was established in 1823, and in 1848 the corporation took over the control of the docks, making many improvements and reducing the dock rates. By mid-20th century Bristol was again a flourishing seaport and the great distributive centre of the southwest of England.

But while its greatness has always been based on industry and commerce, Bristol has made notable contributions to practical progress in other ways: one of the first free libraries was established there in 1613, the first newspaper outside of London (1704) and the first savings bank in England (1812).

Great names connected with Bristol are those of the poets Thomas Chatterton and Robert Southey, who were born there, and S. T. Coleridge, who met Southey there in 1794 after which the Bristol bookseller, Joseph Cottle, published poems of both Coleridge and W. Wordsworth. Sir Thomas Lawrence, the artist, was the son of a Bristol innkeeper, and W. G. Grace, the cricketer, was born at Downend, 3 mi N.E. of the town.

In 1899, the mayor of Bristol received the title of lord mayor.

Architecture.—Although the city suffered badly from air attack in World War II and a number of buildings of architectural or historic interest were destroyed or seriously damaged, the city still retains a large number of interesting and picturesque buildings. The Cathedral Church of the Holy and Undivided Trinity, seat of the Anglican bishop and situated in College green, was once the abbey of St. Augustine, founded by Robert Fitzhardinge in 1142. The Norman gateway of the abbey and the rectangular chapter house remain. The see was founded by Henry VIII in 1542 and in 1836 was united with that of Gloucester until 1897 when it was again separated. On the north side of College green is St. Mark's or the Lord Mayor's chapel, probably the only municipally owned church in the world. Formerly part of the Gaunt's hospital, it was founded in 1220 by Sir Maurice de Gaunt. The chantry of Sir Robert Poyntz, with its fan-tracery roof, is a beautiful example of late Perpendicular architecture: the hospital was purchased by the corporation from Henry VIII and the chapel has since been maintained by the corporation for worship and is unique in this respect in England.

Other conventual remains are the Dominican priory which has associations with William Penn and the early history of the Friends (the priory with the adjoining Regency Friends' meetinghouse was restored for use as the central register office); the Benedictines' church of St. James (c. 1130) and the gateway of St. Bartholomew's hospital. The church of St. Mary Redcliffe is the most striking ecclesiastical building in Bristol for grandeur of proportion and elaboration of design and is one of the most celebrated parish churches in England. Rebuilt in the 14th century by William Canynge the elder, whose grandson completed the work a century later, it is planned like a cathedral with aisled choir, ambulatory and transepts. Of St. Thomas' in the vicinity only the tower (15th century) remains of the old structure.

All Saints' church, rebuilt in the 15th century, retains much Norman work. The New Room in Broadmead, the first Methodist chapel in the world, was the headquarters of John Wesley after 1739. There is an equestrian statue of Wesley in front of the building. Broadmead Baptist church has associations with the early days of nonconformity in Bristol. The Roman Catholic pro-cathedral is at Clifton.

Notable examples of secular architecture are the Red lodge, which was built in 1590 and contains fine carved woodwork; the Llandoger Trow, a 17th-century inn; the Georgian house, now used as a museum for the display of Georgian furniture; the Theatre Royal, the oldest theatre in the country still in use, which was built in 1766 by James Paty and received a royal licence in 1778; and the Exchange, built by John Wood of Bath in 1743. A new council house on College green, opened by Queen Elizabeth

II in 1956, holds most branches of the city administration and the city archives and insignia. The museum and art gallery contains china, pictures and other works of art.

Among the buildings destroyed during World War II were St. Peter's hospital, a gabled building mainly Jacobean, with a fine courtroom and carved timber front; the Dutch house, an early 17th-century timbered building; and the Hall of the Merchant Venturers. Of the churches of St. Mary-le-Port (Perpendicular), St. Peter (15th century) and the Temple (Decorated and Perpendicular) only the towers remain. The 11th-century crypt of St. Nicholas (18th century) remains intact.

The destruction of a large part of the city centre in World War II by air raids provided an opportunity for replanning. Postwar reconstruction resulted in the building of a new shopping centre in Broadmead.

Education.—The University of Bristol was founded as University college, Bristol in 1876 and its charter was granted in 1909. Its growth has been rapid as a result of much generosity notably from the Wills family, and by the mid-20th century it had more than 3,000 full-time students. The main building, designed by Sir George Oatley and opened in 1925, is situated on the upper slopes of St. Michael's hill, overlooking the centre of the city.

There are flourishing colleges of advanced science and technology, art and commerce provided by the corporation, which serve the many and various industries of the city and its neighbourhood. Among the schools of the city may be mentioned the grammar school, Queen Elizabeth's hospital (a bluecoat school for boys) and the Cathedral school, all founded in the 16th century; Colston's school (1708); and the Red Maids school (1627). The Baptist college was founded in 1679 and the Western college (Congregational), founded in Plymouth (1752), was transferred to Bristol in 1901. Other colleges include Didsbury (Methodist; 1842), Tyndale Hall (1925) and Clifton (1862).

Open Spaces.—Bristol possesses about 3 000 ac of parks and open spaces. The most extensive is the Ashton Court estate acquired by the corporation in 1960; the best known are the Durham and Clifton downs, which adjoin the Avon gorge near the point at which the gorge is spanned by Isambard Kingdom Brunel's suspension bridge (1831-64); and Blaise Castle estate with a folk museum and a park. Close to Clifton down are the zoological gardens. Brandon hill, near the centre of the city, commands a fine view of Bristol and the surrounding countryside and on the summit of the hill is the Cabot tower erected to commemorate the 4th centenary of the voyage to North America made by John Cabot.

The Port.—The port of Bristol comprises three dock systems: the City docks, Avonmouth docks and Portishead dock, administered as one undertaking (The Port of Bristol authority) by the corporation.

Until the early years of the 19th century the Avon and Frome rivers were tidal, but in 1809 three miles of tidal river were converted into a floating harbour with a constant depth of water. In 1884 the docks at Avonmouth and Portishead, which had been constructed by private interests, were acquired by the corporation. In 1908 the Avonmouth docks were considerably extended by the construction of the Royal Edward dock, and subsequently they were again enlarged.

The entrance lock of the Royal Edward dock measures 875 ft by 100 ft, with 46 ft. of water on the outer sill (high-water ordinary spring tides) and is capable of admitting, with few exceptions, the largest type of vessel. There are good facilities for the repair and reconditioning of vessels, including a graving dock 875 ft. over-all in length.

Well-equipped modern transit sheds are available both at the Avonmouth and City docks, and there is extensive warehouse accommodation, including a cold store, silo granaries, tobacco warehouses and a bonded warehouse for wine. All general cargo berths are amply furnished with cranes, and specialized equipment such as floating and shore elevators is available. In general the port is highly mechanized and most of the equipment was installed after World War II.

The City docks are mainly concerned with coastwise and Euro-

pean traffic, whereas the Avonmouth docks enjoy a world-wide trade and provide accommodation for the largest cargo vessels. The principal imported commodities are grain, petroleum, animal feeding stuffs, zinc concentrates, meat, dairy produce, fruit, timber, phosphates, metals, tobacco, wines and cocoa. Export commodities include cars, tractors, machinery, clay and chemicals. About 7,000,000 tons of cargo are handled in the port annually and on the sterling value of its imports it occupies fifth place among the ports of Great Britain and is the largest municipally owned port.

Liner services link the port with most European countries trading with the United Kingdom and with Canada, the United States, Africa, Australia, New Zealand, India and Pakistan, Japan and far eastern countries, including Malaya and Burma. The Avonmouth docks are connected with the centre of the city by a magnificent roadway, known as the Portway, $5\frac{1}{2}$ mi. long and for the most part 100 ft. wide. Just below New Passage pier ($11\frac{1}{2}$ mi. N.W.), the railway crosses the Severn estuary via the Severn tunnel (4.33 mi. long).

Industries.—Bristol has a large variety of industries, of which aircraft design and construction at Filton is the most important. Other significant industries are tobacco, papenaking, printing and flour milling and their allied trades, pottery and metallurgical and chemical processes of various kinds, shipbuilding and engineering. Bristol is also a market centre for a rich agricultural area.

BRISTOL, a city of Hartford county, Conn., U.S., 19 mi. S.W. of Hartford on the Pequabuck river. The area was first settled in 1727 as part of Farmington and a Congregational parish (called New Cambridge) was organized in 1744. Bristol was organized as a town in 1785, incorporated as a borough in 1893 and chartered as a city in 1911. During the American Revolution it was the centre of considerable Tory activity, and Chippens hill with its cave known as the "Tories' den" was a meeting place for Connecticut Loyalists. The Rev. James Nichols, the Anglican rector, was tarred and feathered by the Patriot party; Moses Dunbar, also an Anglican, was hanged by the Connecticut authorities for recruiting soldiers for the British army.

Bristol has always been a manufacturing centre. During the colonial period there were gristmills and sawmills, tanneries, tinware shops and woodworking establishments. In the late 17th and early 18th centuries Bristol supplied the "Yankee peddlers" with the tinware which was sold throughout the Atlantic seaboard. The presence of workers in both metal and wood led to Bristol's pre-eminence in the manufacture of clocks. With the introduction of metal wheels and interchangeable parts Bristol clockworkers turned to the production of low-priced clocks and pocket watches and later to such other metal products as bicycle and automobile parts, springs, machinery, tools, cutlery and sporting goods. For comparative population figures see table in CONNECTICUT: *Population*. (GL. W.)

BRISTOL, a town of Rhode Island, U.S., and the shire town or seat of Bristol county, is 12 mi. S.E. of Providence on a peninsula between Narragansett bay and Mt. Hope bay. On the south it is connected to Aquidneck Island by Mt. Hope bridge. Capacious Bristol harbour was an active centre of privateering and the triangular trade in rum and slaves in the 18th century but is now used largely by pleasure craft. Until its closing in 1945 the Herreshoff Manufacturing company, builders of the America's cup defenders, made Bristol a renowned yacht building centre.

It is an important suburban residential area for Providence (*q.v.*) and has large manufactures of rubber goods. The Rhode Island soldiers' home, established in 1890, is located in Bristol.

The town was created in 1680 by Plymouth colony out of land acquired in 1676 at the close of King Philip's War, and named after Bristol, Eng., in anticipation of a commercial future. It came under the jurisdiction of Massachusetts in 1692 and in 1747 was annexed to Rhode Island. During the American Revolution it was twice attacked by the British and partially destroyed, Oct. 7, 1775, and May 25, 1778. It is governed by a town meeting and a mayor. It has many fine homes of historic interest, is the site of Brown university's Hafienreffer Museum of the American Indian and is noted for its scenic location.

For comparative population figures see table in RHODE ISLAND: *Population*. (W. D. Mz.)

BRISTOL, an urban unit on the Virginia-Tennessee (U.S.) state line. Physically and culturally unified, it consists of two politically separate bodies, each with its own government, public schools, utilities and post offices. In 1903, to equalize maintenance, Tennessee legislatively re-established the state line, previously slightly off centre of the main business street. Bristol is between the Cumberland and Holston ranges at 1,800 ft. elevation but in a valley, the extension of the Shenandoah. The site was originally an Indian village. In mid-18th century a trading post was built there to serve the frontiersmen moving west over the Wilderness trail blazed by Daniel Boone. Eight miles east stands the centuries-old Pemberton oak, where assembled the mountaineers who defeated the Loyalists in the battle of King's mountain during the American Revolution. On a Scotch-Irish pioneer stock have been grafted many cultural branches, but emphasis on education and religion, characteristic of the first settlers, continues to be a vital force. More than 50 churches and 3 colleges, dating from the 19th century, attest this fact. King college (1867), offering a four-year course, is Presbyterian and coeducational. Sullins college (1870), originally Methodist but now nondenominational, and Virginia Intermont college (1884), a Baptist institution, are both junior colleges for women. The trading centre of a rich agricultural valley and home of numerous and diversified manufacturing concerns, the city has a well-balanced and stable economy. The climate and natural beauty of a mountainous region, enhanced by national forests and game preserves and proximity to four Tennessee Valley authority lakes, provide Bristol with uncommercialized facilities for recreation. Bristol, Va., which was known as Goodson before it was chartered as a city in 1890, has a council-manager form of government which became effective in 1919; the city is administratively independent of Washington county. Bristol (Sullivan county) Tenn., has a mayor-commission form of government. For comparative population figures see tables in TENNESSEE: *Population* and VIRGINIA: *Population*. (D. L. ME.)

BRISTOW, BENJAMIN HELM (1832–1896), U.S. lawyer and statesman, was born in Elkton, Ken., on June 20, 1832. He studied law in his father's office and was admitted to the bar in 1853. He was an ardent antislavery unionist, and at the outbreak of the Civil War, helped recruit the 25th Kentucky infantry. He was wounded at Shiloh and upon his recovery helped raise another regiment, the 8th Kentucky cavalry, and became its colonel. Elected to the state senate in 1863 without his knowledge, he reluctantly took his legislative seat, realizing the need for Union men in the government of Kentucky. He worked actively for President Lincoln's re-election in 1864, for ratification of the 13th amendment to the federal constitution and for other Unionist measures.

After the war he served as U.S. attorney for the Kentucky district, 1866–70. By working for the protection of the Negro against the violence of Ku Klux Klan, as well as by prosecuting distillers of illicit whisky, he attracted national attention. Pres. Ulysses S. Grant appointed him as the first solicitor general of the United States and later as secretary of the treasury (1874–76). His greatest service in the latter post was to direct the prosecution of the so-called "whisky ring," a group of western distillers, revenue officers and others who had evaded payment of the federal

whisky tax. An alleged accomplice of the ring was Orville E. Babcock, private secretary to President Grant. Bristow resigned from the treasury under presidential pressure. He was a prominent candidate for the Republican presidential nomination in 1876 with the backing of party moderates, but when it became apparent that he could not win, he gave his support to Rutherford B. Hayes. He took up the practice of law in New York city in 1878 and a year later was elected the second president of the American Bar association. He died in New York on June 22, 1896. (C. F. McL.)

BRITAIN (Gr. *PRETANIKAI NESOI*, *BKETTANIA*; Lat. *BRITANNIA*, rarely *BRITANNIA*), the anglicized form of the classical name of England. Wales and Scotland, sometimes extended to the British Isles as a whole. The Greek and Roman forms are doubtless versions of a Celtic original, which gives modern Welsh *Prydain*. Brittany (Fr. *Bretagne*) in western France acquired its name because of migrations thither from Britain in the 5th and 6th centuries A.D.

The first written evidence of the island came indirectly from Pytheas (*q.v.*), the Greek navigator who explored its coast *c.* 325 B.C.

In this article the archaeological interest of early Britain is dealt with in connexion with the history of Britain in pre-Roman and Roman times; this account being supplementary to the articles *CALEDONIA*; *ENGLAND*; *ENGLISH HISTORY*; *SCOTLAND*, etc.

It is arranged as follows:

I. Pre-Roman Britain

II. Roman Britain

A. The Military System

1. Walls of Hadrian and Antoninus
2. Military Areas
3. Roman Army and Fortifications
4. Roman Roads

B. The Civil Pattern

1. Administration
2. Urban Development
3. Rural Life
4. Religion
5. Art

C. End of Roman Britain

I. PRE-ROMAN BRITAIN

Britain appears to have been first inhabited by sporadic Paleolithic hunters in the latest phases of the Pleistocene, or Glacial, epoch (see *PLEISTOCENE EPOCH*). Much more definitive evidence of settlement is forthcoming for the presence of Mesolithic settlers, who ranged over much of Britain, in nomadic groups. The Scottish coasts, the Pennines, Star Carr in Yorkshire, East Riding, the caves in the Mendip hills, the Peak district and Devonshire or the pit dwelling at Abinger, Surrey, provide useful evidence of active communities of hunters and fishers. Neolithic people, arriving from northwestern Europe about 3000 B.C., introduced not only systematic stock raising, associated with enclosures, but also agriculture, pottery and improved tools of stone and flint, the latter mined on a large scale. Communal burial mounds (long and circular barrows) were introduced in different styles from different regions. Circular religious enclosures, in wood (U'oodhenge) and stone (Stonehenge, *q.v.*), were another new feature, partly connected with the dead. About 1800 B.C. Rhineland folk, styled Beaker folk from their distinctive pottery, introduced gold and copper and exploited the metals of western Britain and Ireland, evolving bronze and trading widely with the continent: amber, tin, gold and Egyptian faience are found, particularly in Wessex. Individual wealth is reflected in individual hamlets and fields and individual or family burials in round barrows. Imposed upon this vigorous and primitive civilization the Iron Age invaders, moving in from about 400 B.C., made little impression at first, but their improved tools increased agricultural and technical possibilities, encouraged family land settlement and, as population increased, led to the organization of the tribe for aggression or defense and of the first hill forts of the 3rd century B.C. This organization of society for self-defense was intensified by the Belgic invasion during the first half of the 1st century B.C. which embraced south-eastern Britain, bringing with it developments in pottery and chariot warfare, and in the extensive fortified chieftain's capital

(*oppidum*), with multiple defenses against chariots and sling fire. In this changing world the tribes known to Roman Britain (see map for names and location) began to emerge and were completed by the influx following the conquest of Gaul by Julius Caesar. The growing complexity of society and the growth of trade was illustrated by the emergence of coinage by 100 B.C., at first in gold and later in silver and bronze. It replaced gradually a currency of iron bars or ingots, attested by Caesar and by surviving examples in the form of sword blanks of standard weights. In religion, the chief feature was the priesthood of Druids, who there, as in Gaul, practised magical arts and barbarous rites of human sacrifice, taught a secret lore and wielded great influence in society (see *DRUIDISM*). In art, these tribes possessed a native late-Celtic fashion, descended from far-off Mediterranean antecedents and more directly connected with the La Tène culture of the continental Celts (see LA TÈNE). Its characteristics were a flamboyant and fantastic treatment of plant, animal and, more rarely, human forms, a brilliant use of curved geometrical forms, and much skill in enameling. Its finest products were in bronze, but the same patterns spread to woodwork and pottery. The Roman conquest of northern Gaul (58-50 B.C.) brought Britain into definite relationship with the Mediterranean. It was already closely connected with Gaul, and when Roman civilization and its products invaded Gallia Belgica they passed on easily to Britain. The British coinage then began to bear Latin legends, and after Julius Caesar's two raids (55, 54 B.C.) the southern tribes were regarded at Rome, though they do not seem to have regarded themselves, as vassals. Actual conquest was, however, delayed. The emperor Augustus planned it. But both he and his successor Tiberius realized that the greater need was to consolidate the existing empire and absorb the vast additions recently made to it by Pompey, Caesar and Augustus.

II. ROMAN BRITAIN

Preparations for the Roman conquest of Britain had been started and then canceled by the emperor Caligula (Gaius Caesar): the invasion was finally undertaken by Claudius in A.D. 43. Two causes coincided to produce the stem 'Claudius desired for political prestige an outstanding conquest.' Cunobelin, probably a philo-Roman prince (known to literature as Cymbeline), had just been succeeded by two sons, Caractacus (*q.v.*) and Togodumnus, who were hostile to Rome. Two immediate reasons for action were the expulsion of Verica, a Roman partisan, by Cunobelin's sons and the raids upon Gaul which were then taking place from across the English channel. So Aulus Plautius, with a well-equipped army of about 40,000 men, landed in Kent and advanced on the Thames, crossing at the site of London (Londinium). Claudius himself appeared there—the one emperor of the 1st century who crossed the ocean—and the army moved through Essex to capture the native capital, Camulodunum (now Colchester). From the bases of London and Colchester three legions and their auxiliaries continued the conquest. The left wing, the 2nd legion (under Vespasian, afterward emperor), subdued the south; the centre, the 14th and 20th legions, subdued the midlands, while the right wing, the 9th legion, advanced through the eastern part of the island. This strategy was at first triumphant. The lowlands of Britain, with a population partly romanized and scanty in parts and with easy physical features, presented no obstacle. Within three or four years everything south of the Humber estuary and east of the river Severn had been either directly annexed or entrusted, as protectorates, to native client princes. Farther north, even the Brigantes (*q.v.*) in the area of the Pennine range came into the sphere of client realms.

The wild hills and wilder tribes of Wales, notably the Silures (*q.v.*), offered fiercer resistance, and there followed more than 30 years of intermittent hill fighting (A.D. 47-79). The precise details of the struggle are not known. Legionary fortresses were established at Gloucester, Wroxeter (until A.D. 66 at least) and Lincoln, Caerleon replacing Gloucester, Chester Wroxeter, and York Lincoln at the close of the period. The method of conquest was the erection and maintenance of small detached forts in strategic positions, each garrisoned by 500 or 1,000 Roman legionaries

FIG. 1.—MILITARY STATIONS, CIVIL SITES AND ROADS OF ROMAN BRITAIN (ROMAN NAMES APPEAR IN PARENTHESES)

and auxiliaries, and it was accompanied by a full share of those disasters which vigorous barbarians always inflict on civilized invaders. Progress was delayed in A.D. 60–61 by the revolt of Queen Boadicea (*q.v.*) and a large part of the nominally conquered lowlands. Her rising was soon crushed, but the government was obviously afraid for a while to move its garrisons forward. Indeed, other needs of the empire caused the withdrawal of the 14th legion in A.D. 69. But the decade A.D. 70–80 was decisive. A succession of three able generals commanded an army which was restored to full strength by the addition of the 2nd legion (*Legio II Adiutrix*) and achieved the final subjugation of Wales and the first conquest of Yorkshire.

The third and best known, and probably the ablest, of these generals, Gnaeus Julius Agricola (*q.v.*), moved on in A.D. 79 to the conquest of the farther north. He built forts in Cumberland and County Durham, began the network of roads: held down the north, and pushed on into Scotland, where he established between the rivers Clyde and Forth, a temporary frontier that was guarded by a line of posts, the most certainly identifiable of which is that at Bar Hill in Dunbartonshire. Presently he advanced into Caledonia and won a notorious victory at Mons Graupius (incorrectly spelled Grampius), the site of which is unidentified, but was not south of the approaches to the county of Banff. He dreamed even of invading Ireland, and thought it an easy task, preparing for it by the conquest of southwestern Scotland with forts at Loudon hill, Ayrshire; Dalswinton, Dumfriesshire; and Glenloch and Gatehouse-of-Fleet, Kirkcudbrightshire. His permanent occupation of Scotland enveloped Strathmore, the large valley in central Scotland stretching from southwest to northeast through the counties of Perth, Angus and Kincardineshire.

A. THE MILITARY SYSTEM

1. Walls of Hadrian and Antoninus. — Before A.D. 90 the Roman garrison in Britain was reduced by the transfer of *Legio II Adiutrix* to Pannonia, a country south and west of the Danube. About this time Strathmore was evacuated and the whole of Scotland was abandoned early in the 2nd century, probably in connexion with Trajan's conquest of Dacia in central Europe. Early in Hadrian's reign the Britons were in revolt, and the 9th legion faded from history. In 122 Hadrian came to Britain, brought the 6th legion to replace the 9th, and introduced the frontier policy of his age. For more than 70 mi., from the Tyne estuary to the Solway firth, more exactly from Wallsend to Bowness, he built a continuous rampart known as Hadrian's Wall. There were outposts in the west to the north of it, and some detached forts, mile-castles and towers guarding the Cumberland coast beyond its west end. His title as builder of the wall is proved alike by literature and by inscriptions. The meaning of the scheme is equally certain. It was to be a wall (comparable with the Great Wall of China) marking the definite limit of the Roman world. The actual works were twofold. First, the stone wall, 10 ft. thick in the east, 6–8 ft. thick elsewhere, and originally 15 ft. high to rampart walk, with a deep ditch in front (*i.e.*, on the northward side) and regularly spaced mile-castles and towers (two to a mile) attached to it for patrols, together with 16 forts for the fighting garrison, was connected by a road behind it. On the high moors between Chollerford, Northumberland, and Gilsland, Cumberland, its traces are still plain, as it climbs from hill to hill and winds along precipices. In the west, the wall was at first of turf, but was gradually replaced in stone, on the same line except for two miles at Birdoswald near Gilsland. Second, to the south of the wall the so-called Vallum (rampart) was in reality no vallum at all, but a broad flat-bottomed ditch out of which the earth was cast up on either side into regular and continuous mounds, 100 ft. apart from crest to crest. The meaning of this ditch has been much discussed. It is now clear that it is a Roman work of Hadrianic date, but an addition to the Wall, intended as a rearward obstacle delimiting the military zone. When the reoccupation of Scotland led to the temporary dismantling of mile-castles the ditch was breached by having a series of causeways laid across it, at 15-yd. intervals. It is further clear that before the Vallum existed the earliest forts associated with the Wall lay behind it (*i.e.*, to the south of it), on the Stanegate road, at such points as Corbridge,

Chesterholm (Vindolanda), Haltwhistle Burn, Throp, Nether Denton, Boothby Castle Hill, Old Church Brampton, and Carlisle. The forts on the Wall itself belong to a rapid strengthening of the frontier, and only after they were built was it possible to devise the rearward obstacle represented by the Vallum. The Hadrianic scheme thus reached final form only after numerous changes of plan. Under Lucius Septimius Severus many elements in the tower system were given up and the outpost forts, hitherto existing only in the west at Bewcastle, Netherby and Birrens, were extended to the east at Risingham (*Habitancum*) and High Rochester, both on Dere Street.

Whether the land beyond Hadrian's Wall became temptingly peaceful or remained in vexing disorder, in 139 Hadrian's successor, ~~Antoninus Pius~~, acting through his general Lollius Urbicus, made a change and was preparing to advance to the narrower isthmus between the Forth and Clyde rivers 36 mi. across, which Agricola had fortified before him. There in 142 he erected a turf wall (the so-called Antonine Wall) fronted by a large ditch, with 19 forts, normally attached to it, and a rearward connecting road. In the central sector the work still survives, in varying preservation, and occasionally, as on Croy hill (near Kilsyth) or at Bonnybridge (about 3 mi. W. of Falkirk), wall, ditch and road can be distinctly traced, while the sites of many forts (some revealed by aerial photography) can be plainly seen by practised eyes. Eight forts have been excavated. In each case the barrack rooms were of wood, and the headquarters buildings, granaries, commandant's house and the baths of stone. In size the forts range from just over one acre to just under seven. The defenses differ. Balmudly, Dunbartonshire, and Castlecary, Stirlingshire, were walled with stone, whereas the ramparts of Old Kilpatrick and Bar Hill, Dunbartonshire, and of Rough Castle, Stirlingshire, were of sods, and those of Mumrills, Stirlingshire, of clay. Besides the 19 forts on the wall, there were outposts at Camelon, Ardoch, Strageath, Carpow and Bertha, along the natural route which runs by Stirling and Perth to Strathmore. On the Firth of Forth, Cramond and Inveresk forts guarded the flank, while the Clyde was watched by a fort at Bishopton near Paisley and by minor posts. The new frontier was reached from the south by two roads. One, known in medieval times as Dere Street, ran northwest from Corbridge on Tyne (*Corstopitum*) through forts at Risingham, High Rochester, Cap-puck, Newstead near Melrose, Inveresk and Cramond, to the eastern end of the Wall. The second, starting from Carlisle, ran to Birrens near Ecclefechan, Dumfriesshire, and thence by Tassiesholm and Crawford in Lanarkshire to Inveresk in Midlothian, with branches to Carzield in the valley of Nithsdale, Dumfriesshire, and to Carstairs in Clydesdale, Lanarkshire, and so to the west end of the Wall. A fort at Lyne near Peebles suggests the existence of an intermediate link between them. There is nothing to suggest that the erection of the Wall of Antoninus Pius meant the complete abandonment of the Wall of Hadrian. At first the latter was held by a garrison in forts only, but later both barriers were fully held together, and the district between them was regarded as a military area.

The Antonine Wall brought no long peace. Less than 20 years after its construction (155–158) disorder broke out in the district between the Cheviot and Derbyshire hills, and was repressed with difficulty. About 180–185 the "northern" Wall according to Dio Cassius, presumably the Antonine Wall, was broken; and civil war which soon raged in Europe (193–197) for the imperial succession gave the Caledonians the opportunity to ravage the north when its garrison was withdrawn to fight on the continent. The lost land was recovered as far as Hadrian's Wall in 197, and in 209 the emperor Lucius Septimius Severus with his son Caracalla conducted a punitive expedition into Caledonia and consolidated the position once more. Then, in 211, the third year of operations, Severus died at York. Amid much that is uncertain and even legendary about his work in Britain, this is plain, that Hadrian's Wall was chosen as the substantive frontier. His successors, Caracalla (sole emperor 212–217) and Alexander Severus (emperor 222–235), accepted the position, and many inscriptions refer to building or rebuilding executed by them for the greater efficiency of the frontier defenses. There was no further advance. The Wall of Ha-

drian remained for nearly 200 years more the northern limit of Roman power. (See also HADRIAN'S WALL; ANTONINE WALL.)

2. Military Areas.—Geographically, Britain consists of two parts: (1) the comparatively flat lowlands of the south, east and midlands, suitable for agriculture and open to the continent; *i.e.*, to the rest of the Roman empire; and (2) the district comprising Devon and Cornwall, Wales and northern England, regions lying more, and often very much more, than 600 ft. above the sea, scarred with gorges and deep valleys, mountainous in character and difficult for armies to traverse. The lowlands were conquered easily and quickly, though the midlands were garrisoned until about A.D. 79. The uplands were hardly subdued completely until the end of the 2nd century. They differ, moreover, in the character of their Roman occupation. The lowlands were the scene of civil life. Towns, villages and country houses were their prominent features; troops were hardly seen in them save in some fortresses on the edge of the hills and in a chain of forts built in the 4th century to defend the south and southeast coast, the so-called Saxon shore. The uplands of Wales and the north presented another spectacle. There civil life straggled into Glamorgan and Pembrokeshire and even touched Brecknockshire, while in the north it penetrated as far as County Durham. But the hills were one extensive military frontier, covered with forts and strategic roads connecting them, and only the trading settlements outside the forts afford any hint of organized Roman communities. This geographical division was not reproduced by Rome in any administrative partition of the province. At first the whole was governed by one imperial legate (*legatus Augusti*) of consular standing. Caracalla made it two provinces, superior and inferior, the former including Caerleon, Monmouthshire and Chester, the latter Lincoln, York and Hadrian's Wall. In the 4th century there were four provinces, Britannia Prima, Britannia Secunda and Flavia Caesariensis, ruled by governors with the title of praesides, Maxima Caesariensis and, after 369, a fifth named Valentia, ruled by *consulares* (governors of consular rank), all under the vicarius Britanniarum (vice-governor of the Britains). Politically, it is known that Britannia Prima included Cirencester. Within the army organization the command was divided between the dux Britanniarum, or "duke of the Britains," responsible for York and Hadrian's Wall, while the comes *litoris Saxonici*, or "count of the Saxon shore," was responsible for the fleet and for coastal defense; in the later stages of Roman rule the comes Britanniarum, or "count of the Britains" commanded the field army.

3. Roman Army and Fortifications.—The army of the province consisted, from the time of Hadrian onward, of (1) three legions, the 2nd at Caerleon (*q.v.*; Isca), the 6th at York (*q.v.*; Eboracum), the 20th at Chester (*q.v.*; Deva), a total of approximately 15,000 heavy infantry; and (2) a large but uncertain number of auxiliaries, troops of the second grade, organized in infantry (cohortes) or cavalry (alae), each 500 or 1,000 strong, and posted in *castella* (or small forts) nearer the frontiers than the legions. The legionary fortresses were large rectangular enclosures of 50 or 60 ac., surrounded by strong walls of which traces can still be seen in the north and east town walls of Chester, at the eastern and western angles of York and on the south side of Caerleon. The auxiliary *castella* were likewise square or oblong in shape but varied from three to six acres according to the size of the regiment and the need for stabling. Of these about 100 are known. The internal arrangements follow one general plan, but while in later forts the buildings are all of stone, in Claudian and Flavian forts wood is used throughout, and in many forts as late as 160 only the principal buildings seem to have been constructed of stone. In the centre of the fort was the headquarters (*principia*), a rectangular structure with a front entrance which gave access first to a small cloistered court, then to a covered hall, bordered by a row of three, five or even seven rooms containing the shrine for official worship, the pay and record offices. Close by was the commandant's house (praetorium), generally built around a cloistered court, granaries (*horrea*) with buttresses and ventilated basements. These filled the middle third of the fort. In the other two thirds were barracks for the soldiers. No space was allotted to private religion or domestic life. The shrines which individual private wor-

shippers might visit, the bathhouse, and the dwellings or shops of camp followers, etc., lay outside the walls. Such were nearly all Roman forts in Britain, differing little from those in other provinces.

4. Roman Roads.—The road system was laid out to meet the strategy of Roman conquest, which was in stages.

Roads in Wales and Northern Britain.—Forts were dotted all along the military roads of Wales and of northern Britain. From Chester a road ran through north Wales past Canovium fort at Caerhun near Conway to a fort at Caernarvon (Segontium), and a similar road ran westward along the south coast from Caerleon past a fort at Cardiff to Neath (Nidum) and Carmarthen (Maridunum). A third, roughly parallel to the shore of Cardigan bay, with forts at Llanio, Trawscoed, Pennal, Tomen-y-Mur near Ffestiniog, Llystyn and Caer Llugwy, connected the northern and southern roads, while the interior was held by roads and forts discernible at Caer-gai on Bala lake in Merionethshire, Caersws in Montgomeryshire, Forde Gaer near Montgomery, Leintwardine (Bravonium) in Herefordshire, Castell Collen near Llandrindod Wells in Radnorshire, Cae Gaer near Llangammarch in Brecknockshire, Y Gaer (Bannium) (caer, or gaer, is the Welsh for fort, or encampment) near Brecon, and Merthyr Tydfil and Gellygaer in Glamorgan.

In the north of Britain there were three principal roads. One led due north from York past forts at Catterick (anc. Cataractonium), Piercebridge, Binchester (Vinovium), Lanchester (Longovicium), Ebchester (Vindomora) in Durham and Corbridge in Northumberland to Hadrian's Wall and to Scotland, while branches through Chester-le-Street in Durham reached the Tyne mouth at South Shields. A second road, turning northwest from Catterick, crossed the Pennines with forts at Greta Bridge and Bowes (Lavatrae) in Yorkshire and at Brough-under-Stainmore (Verterae) in Westmorland, descended the Eden valley with forts at Kirkby Thore, northwest of Appleby, and Broughham in Westmorland, where it joined the third route, reaching Hadrian's Wall near Carlisle by way of Old Penrith (Voreda) in Cumberland, and running on to Birrens (Blatobulgium). The third route, starting from Chester and passing up the western coast, was more complex and existed in duplicate, the result perhaps of two different schemes of road making. Forts in plenty can be detected along it, notably Manchester (Mamucium), Ribchester (Bremetennacum) and Overborough (Galacum) on a western branch, Lancaster, Watercrock near Kendal, Ambleside (Borrans Field), Hardknott (a peak in Eskdale with remains of a Roman camp known as Hardknott Castle) and, on the Cumberland coast, Ravenglass (Glanoventa), Moresby, Maryport (Alauna), and Old Carlisle. In addition, crossroads from Manchester, Ribchester and Overborough maintained communication with Yorkshire.

Roads in Southern Britain.—There were four main groups of roads radiating from London, and a fifth which ran obliquely. One road ran southeastward to Canterbury (Durovernum) and the Kentish ports, of which Richborough (Rutupiae or Portus Ritupis) was the most frequented. A second ran westward to Silchester (Calleva Atrebatum), and thence by various branches to Winchester (Venta Belgarum), Exeter, Bath, Gloucester (Glevum), and south Wales. A third, known afterward to the English as Watling street (*q.v.*), ran by St. Albans and Wall (Letocetum) near Lichfield to Wroxeter (Viroconium) and Chester (Deva). A fourth served Colchester (Camulodunum), the eastern counties, Lincoln and York. The fifth, known to the English as the Fosse Way (*q.v.*), joined Lincoln and Leicester with Cirencester (Corinium), Bath and Exeter. Besides these five groups, a useful road, called by the Saxons Akeman Street, gave alternative access from St. Albans, through Alchester north of Oxford, to Bath; while another road ran south from near Sheffield, past Derby and Birmingham, to Gloucester (Glevum), linking the lower Severn river with the Humber estuary. Ermine Street (*q.v.*) connected London with the north and ran to the Humber via Godmanchester (Durolipons), Ancaster (Causennae) and Lincoln. These roads and their various branches provided adequate communication throughout lowland Britain. Besides these detached forts and their connecting roads, the north of Britain was defended by Hadrian's Wall (see above).

B. THE CIVIL PATTERN

Behind this formidable garrison, sheltered from barbarians and in easy contact with the Roman empire, stretched the lowlands of southern and eastern Britain. There a civilized life grew up, and Roman culture spread. In the lands looking on to the Thames estuary (Kent, Essex, Middlesex) the process had perhaps begun before the Roman conquest. It was continued after that event, and in two ways. To some extent it was encouraged by the Roman government, which founded towns settled with Roman citizens—generally discharged legionaries—and endowed them with franchise and constitution like those of Italian municipalities. It developed still more by its own volition. The coherent civilization of the Romans was accepted by the British tribal notables, as it was by the Gauls, with something like enthusiasm. Encouraged perhaps by sympathetic Romans, spurred on still more by their own instincts, they began to speak Latin, to use the material resources of Roman civilized life and presently to consider themselves not as unwilling subjects of a foreign empire but as British members of the Roman state. The steps by which these results were reached can to some extent be dated. In A.D. 49 a colonia, or municipality of time-expired soldiers, had been planted in the old native capital of Colchester, and, though it served at first mainly as a fortress and thus provoked British hatred, it soon came to exercise a civilizing influence. At the same time the British town of St. Albans (Verulamium) was thought sufficiently romanized to receive the status of a *municipium* (*q.v.*), which at this period differed little from that of a colonia. London became important. Romanized Britons were numerous; in the great revolt of Boadicea (60–61) the rebels seem to have massacred many thousands of them along with actual Romans. Fifteen or 20 years later, the movement increased. Tribal capitals sprang up, such as Silchester, laid out in Roman fashion, furnished with public buildings of Roman type, and filled with houses which are Roman in fittings if not in plan. The hot springs of Bath (Aquae Sulis) were exploited. Another colonia was planted under Domitian (emperor A.D. 81–96) at Lincoln (Lindum), and a third at Gloucester in 96. The fourth, established on the west bank of the Ouse at York, belongs to the early 3rd century and marked the upgrading of an existing town. A series of judicial legates was appointed to attend to the increasing civil business.

After the 2nd century Hadrian and his successors consolidated the achievement, despite the repeated risings in the north, and country houses and farms became common in most parts of the civilized area. By the beginning of the 4th century the skilled artisans and builders and the cloth and corn of Britain were famous on the continent; this probably was the age when the prosperity and romanization of the province reached its height. The town populations and the educated landowning class spoke Latin, and the people of Britain regarded as a Roman land, inhabited by Romans.

The civilization which had thus spread over half the island was identical in kind with that of the other western provinces of the empire, and in particular with that of northern Gaul. But the elements which composed it were smaller, less wealthy and less splendid. It was also uneven in distribution. Large tracts, in particular Warwickshire and the adjoining midlands, were very thinly inhabited. Even densely populated areas like north Kent, the Sussex coast, west Gloucestershire and east Somerset immediately adjoin areas, like the Weald of Kent and Sussex, where Romano-British remains hardly occur.

1. Administration.—The administration of the civilized part of the province, where subject to the governor of all Britain, was practically entrusted to local authorities. Each Roman municipality ruled itself and a territory, perhaps as large as a small county, which belonged to it. Some districts formed part of the imperial domains and were administered by agents of the emperor. By far the larger portion of the country was divided up among the old native tribes or cantons, about 10 or 12 in number, each grouped around a country town where its council (*ordo*) met for cantonal business. This system closely resembles that of Gaul. It is a native element recast in Roman form and well illustrates the Roman principle of local government by devolution.

FIG. 2. — ROMAN PLAN OF SILCHESTER: 2ND CENTURY A. D.

2. Urban Development.—In the general framework of Romano-British life the two chief features were the town and the villa. Apart from Carlisle (Luguvallium) and Corbridge on Tyne, which lay within the military area and became market towns for the soldiers of the frontier garrison, the towns of the province fall into two classes. Five modern cities, Colchester, Lincoln, York, Gloucester and St. Albans, stand on the sites, and four in some fragmentary fashion bear the names of Roman municipalities founded by the Roman government with special charters and constitutions. All of these reached a considerable measure of prosperity. Besides them cantonal capitals developed as market centres or capitals of the Celtic tribes. Such are Aldborough (Isurium Brigantum), capital of the Brigantes, 12 mi. N.W. of York and the most northerly Romano-British town; Leicester (Ratae Coritanorum), capital of the Coritani; Wroxeter near Shrewsbury, capital of the Cornovii; Caerwent (Venta Silurum) near Chepstow; Cirencester (Corinium), capital of the Dobuni; Exeter (Isca Dumnoniorum), the most westerly of these towns; Dorchester (Durnovaria) in Dorset, capital of the Durotriges; Winchester; Silchester, south of Reading; Canterbury; and Caister St. Edmund (Venta Icenorum). Besides these country towns, London was a rich and important trading town, centre of the road system and of the finance officials of the province, while Bath was a spa provided with splendid baths and a richly adorned temple of Sulis, goddess of the hot springs, whom the Romans called Minerva. Many smaller places within the cantons, for example Kenchester (Magna) near Hereford, Rochester (Durobrivae) in Kent, Chesterton near Peterborough, Great Chesterford near Cambridge, or Alchester near Oxford, exhibited some measure of town life and served as markets or centres of tax collection.

A good general idea of life in the cantonal capitals has been depicted through excavations carried out at Silchester, Caerwent, St. Albans, Canterbury and Wroxeter. Public life centred in the forum (market place) and the adjoining basilica (public hall of exchange). There the local authorities had their offices, justice was administered, traders trafficked, citizens and idlers gathered. In the plan of Silchester (see fig. 2), the area of the forum contained the basilica, or great hall for meetings and business, into which opened a row of administrative offices; while many of the rooms on the other three sides of the quadrangle were probably shops. The temples might have been of classical or native type, and at Silchester a small Christian church has been postulated. A suite of public baths was always a prominent feature, and there was usually an amphitheatre and sometimes a theatre as well. The private houses consisted either of a row of rooms, with a corridor along them, and perhaps one or two additional rooms at one or both ends, or of three such units, ranged around three sides of a large square open court or garden. Except in the chartered towns, they were detached houses, standing each in its own garden, and not forming terraces or rows. They differed widely from the town

houses of Italy; their real parallels occurred in Gaul, and they may have been Celtic types modified to Roman use—rather as Indian bungalows were adapted to European use. Their internal fittings—hypocausts, frescoes, mosaics—were everywhere Roman.

The streets varied in width. They intersected regularly at right angles, dividing the town into rectangular blocks, a system usual in both Italy and the provinces, and derived ultimately from Babylon and the east through the Hellenistic cities founded by Alexander the Great and his successors. The walls were often built later than the streets, having been erected when the peace of the province began to be seriously threatened by barbarian inroads. The material romanization suggested by the town planning was confirmed by numerous small objects recovered in the course of the excavations—coins, pottery, window and table glass, bronze ornaments, iron tools, etc. Few were individually notable; traces of late Celtic art were singularly absent; Roman fashions ruled supreme, and inscriptions showed that even the lower classes there spoke and wrote Latin. These towns were thoroughly romanized, peopled with Latin-speaking citizens, furnished with Roman appurtenances and adapted to Roman ways, but were not very large and not very rich, a humble witness to the assimilating power of the Roman civilization.

3. Rural Life.—The country, as opposed to the towns, of Roman Britain seems to have been divided into estates commonly (though perhaps incorrectly) known as *villas*. These represented the landowning upper classes of the cantons. Many examples survive, some large and luxurious, some simple farms, constructed usually on one of the two patterns described in the account of the towns above. The inhabitants were clearly as various—at the top the tribal notables who were wealthy landowners, lower down small farmers or possibly bailiffs. Some of these estates were worked on the true villa system, by which the lord occupied the "great house," and cultivated the land close around it by slaves, while he let the rest to half-free *coloni*, or tenant farmers. But other systems inherited from the Celtic world must have prevailed as well. Among the most important country houses of which remains exist are those of Bignor in west Sussex, Woodchester and Chedworth in Gloucestershire. At the other extreme were the hut dwellings, whose remains can be detected in the Thames valley and else here, and which housed the peasant population.

The wealth of the country was indeed principally agrarian, and the needs of the army of occupation must have helped to stimulate production. Wheat and wool were exported in the 4th century when, as we have said, Britain was especially prosperous. But the details of the trade are unrecorded. More is known of the lead and iron mines which, at least in the first two centuries, were worked in many districts—lead (from which silver was extracted) in Somerset, Shropshire, Flintshire, Derbyshire and Yorkshire; iron in the Weald of west Sussex, the Forest of Dean and to a slight extent elsewhere. Other minerals were less notable. The gold mentioned by Tacitus proved scanty, although there was one large-scale gold mine at Dolau Cothi, Carmarthenshire. Cornish tin, according to present evidence, was worked comparatively little until the 4th century, when Somerset was also producing silver in quantity.

4. Religion.—The religious life of the province was divided into official, imported and native cults. Official worship was represented in the civilian world by the calendared festivals of Roman officials and troops, and by the provincial cult of the emperor. Relics of the worship accorded by Roman government officials have hardly survived, but those of the troops and their officers are abundant, including the rich series of annual parade-ground dedications (from Maryport, Cumberland) to Iuppiter Optimus Maximus and other purely Roman deities, the dedications to the standards by legionary or auxiliary officers and to the imperial discipline, a series which Roman Britain shared with Roman Africa, or to local deities of importance such as Mars Cocidius in Cumberland and Apollo Maponus or Hadrian's Wall. Brigantia, the patron goddess of northern England, appears to be an official creation of the early 3rd century and her personified statue is now in the National Museum of Antiquities, Edinburgh. The official provincial cult was centred under Claudius at Colchester and is

mentioned by Tacitus and, biting, in the *Apocolocyntosis* of Seneca. There in the worship of a living emperor as *divus* (divine) Claudius, provincial zeal, however inspired, had outrun normal convention. The vaulted foundations of the temple, in existence below Colchester castle, attest its large size and underline the burden of the cult on a relatively small number of tribal communities, about a dozen as compared with 64 in Gaul. A comparable early dedication was for the welfare of the *Domus Divina*, or imperial household, by a guild at Chichester set up by the authority of Tiberius Claudius Cogidumnus, *rex et legatus Augusti*, who is also mentioned by Tacitus as a faithful ally and client king. This led on to the religious corporations of cities represented by the *seviri Augustales* at York and Lincoln, whose business was the maintenance of a local imperial cult, and to the innumerable dedications to the *numina Augustorum* ("the imperial spirits") by officials, military officers and private individuals.

Imported cults were represented by many deities brought by auxiliary units, such as Mars Thincsus, worshiped by Frisii at Housesteads, Northumberland; Matres Ollolotae of the Vettones at Binchester, County Durham; Vagdavercustis and Harimella, brought by Tungrians to Birrens, Dumfriesshire; or the Dea Hamia of the Syrian archers at Carvoran, Northumberland. The eastern religions were exemplified by numerous dedications to Iuppiter Dolichenus, and the dedications and shrines of Mithras. Mithraism (q.v.) was not only favoured by the soldiery, as demonstrated by the shrines on Hadrian's Wall at Housesteads, Rudchester and Carrawburgh (this last on public view) but also by traders, as shown by the rich shrine at Walbrook, London: for Mithras was a god not only of valour but also of honest dealing and truth. It should, however, be emphasized that Mithraic communities were never large and that this religion, though widespread, counted relatively few adherents. Individual importations were not uncommon, such as the dedication to Oceanus and Tethys by Demetrius of Tarsus (copying Alexander the Great) at York, that to Sarapis by a legionary legate at York or to Apollo Grannus by a procurator at Inveresk, Midlothian. Dedications in Greek, like that of Demetrius, were rare and principally confined to doctors, with whom it was a professional fashion, or to such exotic figures as the priestess of Tyrian Hercules at Corbridge, Northumberland.

The native cults were numerous and striking, and it is interesting that the dedications in many of them were coupled with the *numen Augusti*, associating loyalty with worship. The most striking was perhaps that of Sulis-Minerva at Bath (in Somerset), where Sulis, the native goddess of the springs, was equated with Minerva. This *interpretatio Romana*, which gave to a native deity perhaps never expressed in human form a classical equivalent whose human guise and attributes were well known, was exemplified at Bath by the statues of Minerva and by the classic form given to the temple, whose architectural order and front pediment still survive. But it led to strange results, as when Mars became a healing deity (an attribute from the Treveri of the Moselle region in Gaul) at Caerwent (in Monmouthshire) where he was *Mars Lenus sive Ocelus*, or where an auxiliary unit must speak of *Mars Militaris* (Maryport in Cumberland). Maponus on Hadrian's Wall is equated with Apollo, Belatucadrus in Cumberland with Mars, as is also Cocidius in north Cumberland. Nodens, the hunter-god at Lydney (in Gloucestershire), is equated with Silvanus, as is also Vinotonus, a local deity of the high Pennines, near Bowes (in Yorkshire). Many shrines remain nameless, for want of inscribed dedications surviving. The striking feature is their ubiquity and their survival to the latest period of Roman Britain, particularly in the southwest.

Christianity.—By mid-20th century archaeological evidence of Christianity had been found, notably the wall-paintings discovered at Lullingstone, Kent, to supplement the isolated literary references of early date (*i.e.*, those of Tertullian and Origen, writing at the beginning and middle of the 3rd century respectively). These point to the beginnings of Christianity in Britain, but the evidence, especially for the period before Constantine I (sole emperor 323–337), remains comparatively meagre and is often difficult to interpret. The traditions reflected in later writers such as Bede (*q.v.*), ascribing the earliest British martyrs, including St.

BY COURTESY OF (1, 2, 3, 4, 6, 7, 8, 9, 11) THE TRUSTEES OF THE BRITISH MUSEUM, (5) THE DIRECTOR OF THE YORKSHIRE MUSEUM, YORK, (10) THE DIRECTOR OF THE NATIONAL MUSEUM OF ANTIQUITIES, EDINBURGH

JEWELLERY AND METAL CRAFTSMANSHIP OF EARLY BRITAIN

1. Glass drinking horn found at Kempston, Bedfordshire. 2. The Franks casket of whale's bone, about 8th century. 3. Silver penannular brooch, about 10th century, found in Cumberland. 4. Gold neck-chain, probably 2nd century, found near Backworth, Northumberland. 5. Embossed Anglian bowl, found in Ormeside, Westmorland, England.

6. Gold ornament, found in Knight's Field, Faversham, Kent. 7. The ring of Aethelwulf, father of Alfred the Great. Front and back views. 8. Frankish bronze ewer, probably 7th century, found at Wheathampstead. 9, 11. Anglo-Saxon gold brooches, designed in enamel and precious stones. 10. Gold staff head, from Cairnmuir, Peebleshire, Scotland

BY COURTESY OF (1, 3, 4, 7, 8, 12, 14, 15) THE TRUSTEES OF THE BRITISH MUSEUM (2, 13, 16) THE DIRECTOR OF THE NATIONAL MUSEUM OF ANTIQUITIES EDINBURGH (5, 6, 9, 11) THE CURATOR OF THE COLCHESTER AND ESSEX MUSEUM (10) THE CURATOR OF THE LETCHWORTH MUSEUM

ARCHAEOLOGICAL SPECIMENS OF ANCIENT BRITISH ART

1. Bronze mirror, found at Disborough, Northamptonshire, probably 1st century. Decorative curves and basket-pattern filling are late Celtic. 2. Silver chain found at Crawfordjohn, Lanarkshire, dating probably from the period of Celtic Christianity. The chain is 18 in. long and on the pen-ular link, at the end, are incised symbols. 3. Bronze shield, ornamented in red enamel, found in the Thames, near Battersea, London. It is an example of late Celtic decoration. 4. Celtic helmets of bronze (early period). Left, helmet with enamelled ornaments found in the Thames near Waterloo bridge, London. Right, helmet found in a chariot-burial at Gorge-Meillet, Somme Tourbe, Marne. 5. Leaden coffins. These specimens are now in the Colchester Museum. 6. Tombstone of Roman cavalry soldier, Colchester. The inscription reads "Longinus, son of Sdapezmatucus; duplicarius of the First Regiment of Thracian Cavalry; from the district of Sardica; aged 40; served 15 years. His heirs made this as directed by his will. He lies here." 7. Tiled tomb found at Old Windsor, dating from the Roman occupation of Britain. It contained an urn for ashes and

a small jar of red pottery. 8. Bronze spear-head, in use in Britain before iron was introduced. 9. Burial urns, examples of castor ware. The centre urn is the "Colchester Vase" with a representation of a gladiatorial display. 10. Roman pottery and glass. The group shows thirty-three vessels of the 1st and 2nd centuries, found in a cemetery at Baldock, Herfordshire. 11. Roman pottery, Rhenish ware, decorated with white or yellow ornament, first imported towards the end of the 2nd century A.D. 12. Bronze vessel for temple use found at Prickwillow, Isle of Ely, bearing the name of the maker, Boduogenus, apparently a Briton. 13. Wrought-iron helmet with visor-mask, found at the Roman fort of Newstead, Melrose. originally encrusted with silver and used in tournaments. 14. Statuette of Osiris Pethempantes, found at Swanscombe, Kent, probably brought to England by the Romans. 15. Roman jug of pale olive-green glass, from a grave of Bayford-next-Sittingbourne, Kent, probably of 1st or 2nd century. 16. Brass helmet, found at the Roman fort of Newstead, Melrose. The embossed design shows a nude winged figure driving a leopard-drawn chariot

Alban (*q.v.*), to the late 3rd or early 4th century may rest on historical fact but it is not clear, for instance, to which persecution St Alban's martyrdom belongs. For the 4th century, there are written references to the presence of British bishops at the Councils of Arles (314) and of Nicaea (325). For the British heresy of Pelagianism see PELAGIUS.

5. Art.—The term Romano-British art embraces objects of varied character and provenance since it includes not only works which were purely British, i.e., made in Britain by British craftsmen, but also works made in Britain by immigrant craftsmen from Gaul, the Mediterranean and even the orient. Imported provincial (e.g., Gaulish and Rhineland) work shows in varying degrees the influence of Greek and Greco-Roman art, as well as a large number of imported objects of actual Greco-Roman workmanship. Art in Roman Britain includes sculpture in the round and relief sculpture (particularly on tombstones, sarcophagi and the like) in marble and stone; sculpture in bronze; fresco painting, mosaics, carved objects in bone, ivory and native shale and jet; ceremonial armour (such as the 1st-century bronze parade masks from Ribchester in the British museum and from Newstead in the National Museum of Antiquities, Edinburgh); vessels of metal and glass for domestic and ceremonial use and pottery; as well as a host of small objects (such as brooches, rings and toilet articles) for personal adornment and other uses.

The best tradition of Greco-Roman sculpture is exemplified in the heads of Mithras and Sarapis probably of the 2nd century A.D. in Italian marble and of Italian manufacture from the Mithraeum excavated at Walbrook, London, in 1954 (now in the Guildhall museum, London). Of approximately the same period are the examples of Roman portrait sculpture from Lullingstone. The naturalism which, having its origins in classical Greek sculpture, animated such works as these often prevailed over the native tendency toward the abstract and the formalized to produce in Britain works showing a high degree of naturalism and classical restraint; at other times it combined with these tendencies to produce works of singular novelty and vitality. The dignified 2nd-century bronze head of Sulis-Minerva at Bath is among the best provincial work showing strong classical influence; other works, such as the fragmentary stone relief depicting figures with stylized drapery from Wellow, Somerset, show the persistence of the native tendency to geometric simplification of forms. The stone head from Towcester, Northamptonshire (in the British museum), with its formalized rendering of the hair and flat, almost linear, treatment of the features, has an expressionistic quality alien to classical art.

Excavation of the sites of Roman villas in Britain has revealed examples of mosaic pavements, many of them depicting figure subjects chosen from classical mythology, such as the 4th-century pavements from Aldborough representing the nine muses and that from Lullingstone, showing the abduction of Europa; a villa at Horkstow, Lincolnshire, yielded notable mosaics including genre scenes of horse racing and chariot racing. In another type of mosaic, often associated with baths, marine deities are surrounded by sea creatures and plants formally rendered: examples of this type are the pavement from Withington, Gloucestershire, representing Oceanus encircled by dolphins, sea monsters and plants, and the damaged pavement from Hemsworth, Dorset, of Venus surrounded by a border of dolphins and mullet. As well as these figurative mosaics derived from Mediterranean models (by whatever processes of copying that can be inferred from the recurrence of classical motives) there were numerous nonfigurative mosaics in which conventional abstract pattern, already a strong element in Celtic art, was developed and enriched by new classical motives. In the decorative arts, although classical influence generally prevailed, the persistence of late Celtic tendencies is to be noted in some Romano-British objects: the predilection for curvilinear design, for foliation and for palmette, pelta and scroll ornament appears in such objects as the enameled altar-shaped plaque (2nd–3rd century) from the river Thames with its colours of the pleasantly low key characteristic of Romano-British decorative colour schemes, and the "dragonesque" enameled brooch from Norton, Yorkshire (both in the British museum). As in other parts of the Roman empire, fresco painting was employed in the

decoration of Romano-British villas although because of the climate it has hardly survived. 4 notable 2nd-century painted plaster frieze was found at St. Albans in 1956 with a remarkable use of the "populated" scroll design familiar from the wall plasters of Pompeii: in this Romano-British version of the motif the spirals terminate in the masks of animals.

The so-called Samian red-glazed ware (with its relief decoration molded and applied) which was common throughout the Roman empire was imported to Britain (mainly from central and southern Gaul) and to a small extent imitated by British potters. As well as a large number and variety of coarse wares from many centres in Britain, notable wares were produced at certain centres such as Castor, Northamptonshire, where pottery decorated in barbotine with foliated designs and animal and human forms was made from the late 2nd century A.D. until the end of the Roman occupation. Other centres which produced their own characteristic wares were New Forest, Hampshire, and Crambeck, Yorkshire.

Bronze objects for furnishings and domestic and other uses were imported in large quantities from Gallia Belgica. The costly silver vessels which were used both for table and for cult use in Roman Britain were for the most part imported from the Mediterranean. Perhaps the most spectacular is the group of tableware discovered near Mildenhall, Suffolk (now in the British museum'), of which the great dish, with its embossed decoration depicting a Bacchanalian scene with Hercules, and the two platters showing Pan and a satyr with maenads, are undoubtedly of Mediterranean and probably of Roman origin; while other pieces, such as a bowl with fluted decoration, may have been made in Britain.

C. END OF ROMAN BRITAIN

About 286 Marcus Aurelius Carausius (*q.v.*), admiral of the Classis Britannica (a well-equipped fleet that secured him command of the English channel and neighbouring seas), quarreled with the central government and proclaimed himself emperor. He remained in control of the island until 293, when he was murdered by one of his own officers, Allectus, who succeeded him for three years. In 296, an expedition under the Caesar and future emperor, Constantius I, successfully recaptured the province. Extensive changes in the distribution of the garrison seem to have followed. Danger threatened, not only from the Picts beyond Hadrian's wall but also from the sea. A special coast defense, reaching from the Wash to Spithead, was established against Saxon pirates: there were forts at Brancaster (Branodunum) in Norfolk; Burgh Castle; and Walton, near Felixstowe, Suffolk; Bradwell, at the mouth of the Blackwater estuary in Essex; Reculver (Regulbium), Richborough, Dover (Dubrae) and Lympne (Portus Lemanis), all in Kent; Pevensey (Anderida) in Sussex; Portchester (Portus Adurni) near Portsmouth; and Carisbrooke on the Isle of Wight. The Irish (Scoti), too, were becoming increasingly aggressive. It is, therefore, not surprising that a new fort should have been erected at Cardiff and a fleet station at Holyhead, Anglesey. These measures were effective and the province prospered, even after a heavy barbarian assault in 367–369. To this date belong the series of stone watchtowers along the Yorkshire coast, from the river Tees to the promontory known as Flamborough head, and the camouflaged scout ships of Valentinian I (*q.v.*)

In 383 Magnus Clemens Maximus, claiming to be emperor, withdrew many troops from Britain and a later pretender did the same. Early in the 5th century the Teutonic conquest of Gaul cut the island off from Rome. This did not mean that there was any great "departure of the Romans." The central government simply ceased to send the usual governors and high officers. The Romano-Britons were left to themselves, but the cantonal authorities carried on, and towns like St. Albans continued. Their position was weak. Their fortresses lay in the north and west, while the Saxons attacked the east and south. Their trained troops, and even their own numbers, must have been few. It is probable that they followed a precedent set by Rome in that age, and hired Saxons to repel Saxons. But they could not command the fidelity of their

mercenaries, and the Saxon peril only grew greater. After the close of the 5th century the Romano-Britons were driven from the east of the island, and the Saxons, though as yet unable to gain a hold on the western uplands, were able to prevent the natives from recovering the lowlands. Half a century later the position was worse: driven from the region of walled cities and civilized houses, into the hills of Wales and the northwest, the provincials underwent an inevitable change. The Celtic element, never extinct and, like most forms of barbarism, reasserting itself in this wild age—not without reinforcement from Ireland—changed the remnants of Roman civilization and in the end absorbed them. The Celtic language reappeared; Celtic art emerged to develop in new and medieval fashions. For Anglo-Saxon Britain see ENGLISH HISTORY; for Scotland see CALEDONIA. See also references under "Britain" in the Index volume.

BIBLIOGRAPHY.—*Ancient Authorities:* the principal references to early Britain in classical writers occurs in Strabo, Diodorus, Caesar, Pliny the elder, Tacitus, Ptolemy, Dio Cassius and Ammianus Marcellinus and in the lists of the roadbook of Augustus Antoninus, *Antonini Itinerarium* (c. 212–216), vol. i ed. by O. Cuntz (1929), vol. ii ed. by J. Schnetz (1940), the *Notitia Dignitatum* (c. A.D. 428), ed. by O. Seeck (1876) and the Ravenna cosmography of the 7th century A.D., derived from an earlier map (see *Archaeologia*, xciii, pp. 1–50 [1949]). The chief passages are printed in H. Petrie, *Monumenta Historica Britannica* (1848). The Roman inscriptions have been collected in *Corpus Inscriptionum Latinarum*, vii (1873), in *Ephemeris Epigraphica*, iii (1877), iv (1881), vii (1892) and particularly ix (1903) and annually in the *Journal of Roman Studies*. *Modern Works: Pre-Roman Britain:* D. BRITAIN, BATTLE OF, the series of air engagements in Aug.–Sept. 1940, during U^oorld War II, which frustrated the German plan for the invasion of Great Britain.

Immediately after the armistice signed with France on June 22, 1940, Hitler and his advisers insisted that the German high command, despite its misgivings, should proceed with plans for the invasion of Great Britain. A massive operation, code-named "Sea Lion," was to convey a large army across the English channel. It was correctly appreciated that the first essential of this operation was the destruction, by daylight air action, of the British air defense system. After extensive preparation of land, sea and air forces, "Sea Lion" was timed for launching during the first two weeks of September.

Air fighting was almost continuous during the summer of 1940, but the destruction of the air defense system was planned to start on Aug. 10 and to finish by Sept. 1. The Germans massed two air formations totaling 980 fighters and 1,620 bombers in France and the Low Countries, *Luftflotte 2* under Gen. A. Kesselring and *Luftflotte 3* under Gen. H. Sperrle, the two fleets working east and west of a line drawn down the centre of England. In addition *Luftflotte 5*, stationed in Norway with a mixed force of 190 aircraft, menaced the thinly guarded north.

Against this threat the Royal Air Force's fighter command, under Air Chief Marshal Sir Hugh Dowding, deployed 620 Hurricane and Spitfire fighters, plus 84 less effective aircraft. Both sides had approximately half again as many aircraft in reserve,

but the British reserves of pilots were much fewer than the German. Fighter command was formed into four fighter groups, of which the two most important were nos. 11 and 12, commanded by Air Vice-Marshal K. R. Park and T. Leigh-Mallory, respectively. The British radar detection system, coupled to a developed reporting and controlling organization, was much more advanced than the German.

The attack proper began on Aug. 12, with the attempted destruction of the radar stations, but was only partly successful. For this reason the massive German daylight attacks against southern and eastern England that followed were countered, day after day, by effective concentrations of fighters. At first the German targets were the elements of the air defense system, but on Sept. 7 Hitler made the fatal mistake of changing them to objectives in London. Although fortunes fluctuated, the German losses became so large that after the widespread battles of Sept. 7 and 15 it became clear to the Germans that they had made little headway, while the last date for launching "Sea Lion" was passing. On Sept. 17 Hitler postponed it indefinitely, and though large-scale air fighting continued into October, the battle of Britain was over. Between July 10 and Oct. 31 (the official British dates for the battle), the Germans lost 1,733 aircraft and the British 915.

The Royal Air Force had won its victory by superior control and tactics and by the supreme and desperate efforts of the pilots and their supporting organizations. The battle may have saved Great Britain from conquest and so changed the course of World War II. It also changed the technique of air warfare, by showing that ground-based control organizations are capable of greatly increasing the effectiveness of air forces. (P. G. W.)

BRITANNIA METAL, a silvery white alloy with bluish tint, consisting essentially of tin and antimony, although bismuth, copper or zinc are occasionally added. The best qualities of this alloy contain 90% of tin and 10% of antimony and may be regarded as tin hardened by antimony. Commoner grades of the alloy may contain 94% of tin, 5% of antimony and 1% of copper. The last mentioned metal increases the ductility and decreases the fusibility of the metal to which, however, it gives a yellowish tint. Britannia metal is used in bearings and is employed in the manufacture of hollow ware (*q.v.*) for table use. It is easily worked into complicated shapes by spinning or stamping and can then be silver-plated (see ELECTROPLATING). (G. T. M.)

BRITANNICUS (d. A.D. 55), son of the Roman emperor Claudius and Messalina, was born in A.D. 41. He was originally called Tiberius Claudius Germanicus, and received the name Britannicus in honour of Claudius' expedition to Britain (A.D. 43). Until his mother's execution in 48 he was looked upon as the heir; but Agrippina, the new wife of Claudius, brought about the adoption of Nero, her own son by a former marriage. After his accession, Nero poisoned Britannicus at a banquet (A.D. 55).

BRITISH ANTARCTIC TERRITORY: see FALKLAND ISLANDS AND BRITISH ANTARCTIC TERRITORY.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, an organization founded in 1831 at York, Eng., "to give a stronger impulse and more systematic direction to scientific enquiry, to obtain a greater degree of scientific knowledge and a removal of those disadvantages which impede its progress, and to promote the intercourse of the cultivators of science with one another and with foreign philosophers."

During the 19th century the association played a notable part in convincing the government and the public that it was in the national interest to foster scientific education and research. After 1831 meetings were held annually, except during World Wars I and II, in various cities in Great Britain and the commonwealth. Annual meetings featured varied programs dealing with all fields of scientific knowledge and activity except the medical sciences. The list of past presidents of the association include nearly all the great names of British science. The annual meeting is the largest scientific gathering of its kind in the year and the only one which members of the general public can join on equal terms with scientists. It not only provides a platform on which scientists can discuss their work with their colleagues in their own language and one on which scientists in separate but related fields can con-

sider the "growing points" of science but also affords an unrivaled chance for the layman to learn something of the progress of science from the scientists concerned. The association made important contributions to advances in basic research (for example, electrical standards), offered awards to encourage individual investigation and spent more than £12,000 to support the Kew observatory in Richmond park, but is now chiefly concerned with making advisory studies on possible fields of research.

The association is also now engaged in a major effort to present science to the public at large throughout the year. It has a central scientific lecture service and a number of area committees which arrange their own scientific programs, including special junior British association meetings, and maintains close relations with sister associations overseas and with other scientific institutions. It also undertakes studies and reports on special problems; e.g., in the 1960s, the implications of a change-over to the metric system by the United Kingdom and the whole problem of scientific education in that country.

See *The British Association: a Retrospect (1922; rev. ed. 1931)*; also the association's periodical, *The Advancement of Science*.

(Jo. M. R.)

BRITISH CARIBBEAN FEDERATION: see WEST INDIES (FEDERATION), THE.

BRITISH COLUMBIA, the westernmost province of Canada, is bounded on the east by the watershed of the Rocky mountains until it, in its northwesterly course, reaches the meridian 120° W. which is followed north to the 60th parallel, which forms the northern boundary. The southern boundary follows the parallel of 49° N. except in the west where it swings southward to include all of Vancouver Island. Westward, the province fronts the Pacific ocean for about 600 mi. and the Alaskan "panhandle" for another 400 mi. Within the provincial boundaries are Vancouver Island and the Queen Charlotte Islands, as well as innumerable smaller islands lying off the west coast of Canada. Total area of the province is 366,255 sq.mi. of which 39% is forested, 5% is suited to agriculture. The area of inland waters is 6,976 sq.mi.

PHYSICAL GEOGRAPHY

Landforms.—British Columbia is essentially mountainous, forming part of that great group of mountain systems known as the North American Cordillera. Within the province (see fig. 1), the Cordillera is divisible into three basic units—a northwestward-trending group of mainland and insular mountains along the coast, a system of scattered plateaus and mountains in central British Columbia, and another northwestward-trending mountain system on the east. In the northeast, the province extends beyond the Cordillera to include a small part of the Great Plains of interior North America. The first of these units may be divided longitudinally into three parts—the Coast mountains (an extension of the Cascade range), an outer mountain area (an extension of the mountains known as the Coast ranges in the United States) and a coastal trough lying between them. (See *CASCADE RANGE; COAST RANGES*.) The Coast mountains in combined height and area represent the greatest mountain mass in Canada. Average elevation is 5,000 to 6,000 ft., but peaks over 10,000 ft. occur, the highest of which is Mt. Waddington whose 13,260-ft. elevation exceeds the highest summit in the Canadian Rocky mountains. The coastal trough, part of a tremendous structural depression extending from Alaska to the Gulf of California, is largely submerged, but its margins form the east coastal plain of Vancouver Island and the lowland into which the Fraser river delta has been built. Its submerged portions, with interconnecting fiords, form that great sheltered waterway, stretching from Puget sound to Alaska, known as the Inside passage (*q.v.*). The outer mountain area includes the ranges of Vancouver Island, Queen Charlotte Islands, the outer islands of southern Alaska and the St. Elias mountains. While the Coast mountains are larger in combined mass, the outer mountain area, in its northern extremity, contains the highest elevations in the province. The St. Elias mountains, containing the largest group of great peaks in North America, extend through Alaska and Yukon Territory

into British Columbia. Though they are considerably higher beyond the provincial boundary, that portion in British Columbia culminates in 15,300-ft. Mt. Fairweather on the Alaskan boundary.

The interior system is comprised of a southern and a northern plateau area, and includes a number of mountains and mountain groups. Among the latter are the rugged and scenic Columbia mountains in southeastern British Columbia. The Southern plateau area, like its U.S. counterpart, the Columbia plateau, is a gently rolling upland in which the major rivers are deeply entrenched. The plateau, mantled with glacial deposits of varying thicknesses and textures, is in most places timber covered and dotted with upland lakes. Though generally unsuited to sedentary agriculture, parts of the southern plateau area contain extensive open range lands, and are the scene of most large-scale ranching in the province. The northern plateau area is generally similar to that in the south. It is however less dissected by streams, and broad plateau surfaces stand like tablelands, separated by wide valleys of the major rivers.

The eastern system is composed of the Canadian Rocky mountains and the Rocky mountain trench. The former stretch in a series of parallel ridges, separated by deep valleys, from the 49th parallel to the Liard river. In the vicinity of the Peace river, summit elevations decline to about 6,000 ft., but north and south of the area the Rockies are high and rugged, with peaks exceeding 10,000 ft. The Rockies interpose a barrier to communication with eastern Canada, but they contain a number of passes, among the more important of which are Pine pass (2,850 ft.), Yellowhead (3,717 ft.), Kicking Horse (5,320 ft.), Vermilion (5,376 ft.) and Crowsnest (4,453 ft.).

On their western flank the Rocky mountains slope abruptly into a remarkably persistent structural depression, the Rocky mountain trench. This feature, lying between 2,000 and 4,000 ft. above sea level, extends from the vicinity of Flathead lake, Mont., northward to the Liard plain. Except near the great bend of the Fraser river, where it opens to the interior plateau, the flat-floored trench is walled by abrupt mountain slopes. It is occupied by the upper courses of several important rivers including the Kootenay, Columbia, Fraser, Parsnip and Finlay rivers and forms a natural route of travel of both historic and modern significance.

Geology.—The Coast mountains consist almost entirely of middle-aged intrusive rocks and the Rocky mountains, of ancient rocks, yet the Rockies were formed in comparatively recent Late Cretaceous and Early Tertiary times when ancient rocks were thrust into folds and heavily faulted (see *ROCKY MOUNTAINS*). Their complex geologic history is important to British Columbia in that mineral deposits occur throughout the province, particularly in the mountain areas.

British Columbia underwent widespread Pleistocene glaciation that left conspicuous surface features and has profoundly affected the nature and distribution of arable soils. Glacial till (unsorted, ice-transported debris) underlies much of the rolling surface of the interior plateaus, while deposits of silt and clay laid down in ice-dammed lakes form the basis of valuable agricultural soils in several interior valleys.

Climate.—Latitudinal extent, rugged terrain and proximity to the Pacific ocean greatly affect British Columbia's climate. The interaction of these climatic controls produces remarkable variations in both precipitation and temperature, often within short distances. Victoria, for example, with an average precipitation of 27 in. a year, is less than 100 mi. S.E. of Henderson lake, the wettest station in Canada, with an annual average of 262 in. Similarly, while Summerland, in the Okanagan valley, has a frost-free season of 198 days, Princeton, 40 mi. W., has less than 100 frost-free days. The over-all pattern of climate can, however, be appreciated by considering the three main air masses that affect the province.

Polar maritime air dominates the coastal region for much of the year, its particular temperature and moisture characteristics determined by its trajectory over the ocean. In general, it brings mild, humid conditions to the entire coast in winter and warmer, drier conditions in summer. Warm, dry weather which characterizes the southwest coast in midsummer is related to the

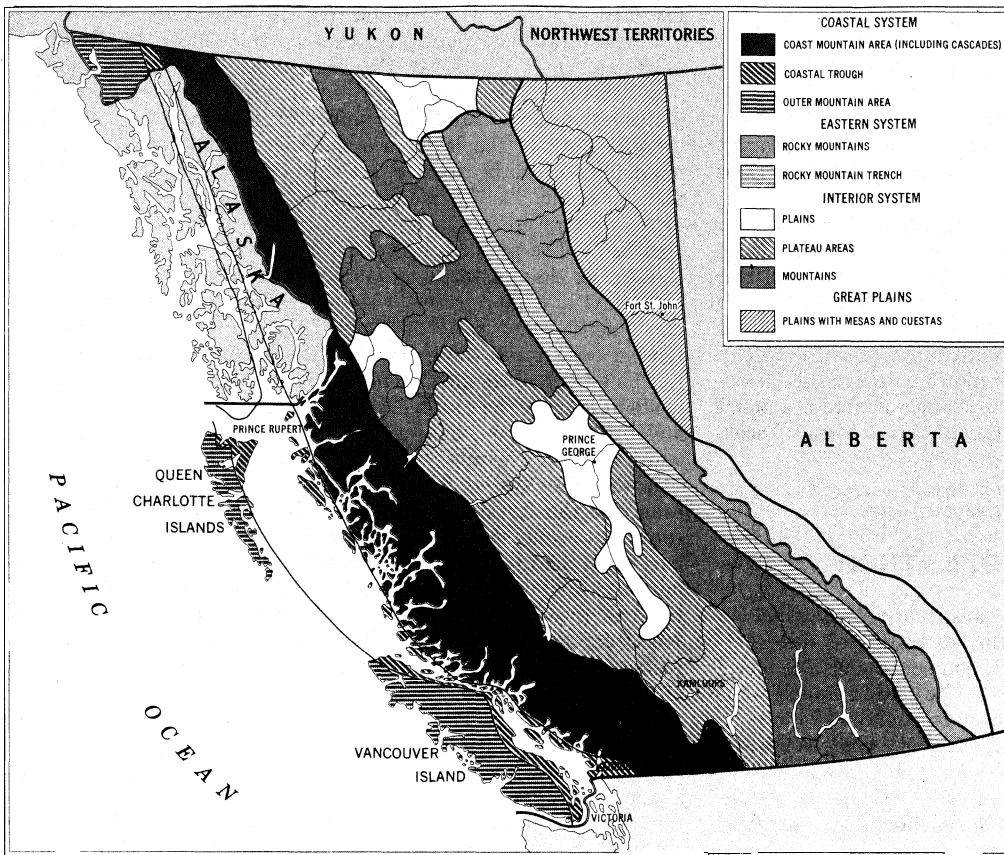

FIG. 1. — LANDFORMS OF BRITISH COLUMBIA WHICH FORM PART OF THE NORTH AMERICAN CORDILLERA

northward extension of the subtropical high-pressure cell (Hawaiian high). Polar continental air, with source regions east of the Rockies in Yukon Territory and Alaska, predominates over northeastern British Columbia but infrequently extends to the coast. In winter it is characteristically cold and dry, in summer, warm and dry. Tropical continental air is less important to the climate than are the polar air masses, although in summer it sometimes extends northward from the American southwest and brings hot, dry conditions to the southern interior valleys.

In general there are strong relationships between climate and physical features. The coast experiences moist mild conditions throughout the year (the mildest winter temperatures in Canada), southeastern Vancouver Island and the adjacent mainland being particularly favoured. The interior plateaus are dry, with precipitation averaging 15 to 20 in. per year. The Columbia and Rocky mountains experience higher precipitation and lower average temperatures than adjacent plateaus and plains. Extreme northeastern British Columbia is typically subarctic, with short, moderately warm summers and long harsh winters.

Plants and Animals.—About 40% of the province is classed as forested, much of the remainder being made up of alpine barrens, snow fields and glaciers. Most of the nonforested land is concentrated in the eastern and western mountain systems and in the northern one-third of the province.

Most of the vegetation consists of coniferous softwood tree species although, especially in the central and northern interior, hardwoods such as birch, aspen and cottonwood are common, either in pure stands or intermixed with conifers. In the southern interior, particularly in the valleys, open grasslands occur, in some places covering extensive areas on the plateaus. In certain southern valleys such dry land species as sage brush, rabbit bush and cactus are common. The most luxuriant vegetation and the largest trees occur on the coast, especially along the southern coast where mild temperatures and abundant rain favour the growth of some of the finest timber stands in the world. Species there include the true firs, hemlock, cedar, spruce and the Douglas fir, or false hemlock. Similar species, but in less prolific stands, occur

in the interior wet belt, the western flanks of the Columbia mountains. Most of the southern plateau area supports dense stands of lodgepole pine and Douglas fir, the latter merging with, open, parklike stands of ponderosa pine on the grassland margins.

Among the larger fauna are game species such as deer, elk, moose and bear as well as sheep and mountain goat. Except for bears, populations of these species depend largely on the availability of winter forage. Since 1900 extensive forest fires and logging operations have improved range conditions in this regard, second growth providing suitable forage for browsing animals. Moose, for example, now range in greater numbers and farther south than formerly. Although not found on the coast, they are widely distributed through the interior. Deer are concentrated on the coast, especially on Vancouver Island, and in the southern interior valleys, while elk are largely restricted to Vancouver Island and to valleys of the Columbia and Rocky mountains. Black bears are common throughout, grizzly bears less so and asso-

ciated with less accessible mountain areas.

Aside from big game, numerous waterfowl and upland game species occur. Grouse, pheasant and partridge are associated with the grasslands and open forests of the southern interior and with cleared land on the coast. Both salt- and fresh-water game fish are abundant, the most sought after being two species of Pacific salmon (*Oncorhynchus*) and rainbow and cutthroat trout (*Salmo*). Fur-bearing animals, including mink, muskrat, marten and beaver are widely distributed and provide the basis of the historically significant trapping industry.

Parks.—Several million acres of parks have been set aside for the use and enjoyment of the public. There are four national parks, in southeastern British Columbia, totaling over 1,000,000 ac. The provincial park system includes more than 150 individual parks, the largest of which are Hamber (2,400,000 ac.), Tweedsmuir (2,300,000 ac.) and Wells Gray (1,300,000 ac.). The park program has shifted from reservation of additional large wilderness areas to the acquisition of numbers of small parks in strategic use areas. The most heavily used park facilities are the attractive public campsites and picnic sites along the more frequently traveled routes. (See also NATIONAL PARKS.)

NATIVE PEOPLES

At the time of European contact British Columbia was inhabited by aboriginal peoples with highly developed cultures and grotesquely beautiful art forms. Seven main linguistic divisions have been recognized—Haida, Tlingit, Athapaskan, Tsimshian, Wakashan, Salishan and Kutenai (Kootenay)—each with several subdivisions. The native peoples had no sedentary agriculture or domestic stock and their distribution and numbers were therefore closely related to the natural food supply. The coast and major rivers supported the main concentrations, for there were bountiful food resources, especially of Pacific salmon, which could be easily taken during the seasonal spawning run to fresh water. There, too, developed the most advanced cultures (see also CANADA: *Native Peoples*). Following white contact the Indian population suffered a severe decline through decimation by introduced diseases and

social demoralization. The decline continued until about 1930 but after that time there has been rapid growth. Populations in the second half of the 20th century reflected essentially the same distribution as in aboriginal times, but the activities had changed from subsistence to wage-earning employment in fishing and logging operations. The Indian population totaled about 35,000 most of them on reserves administered by the federal government.

HISTORY

The discovery of British Columbia was an outcome of the long-continued search for the Northwest passage. The first fleeting contact was made in 1774 by the Spaniard Juan Perez who sailed northward from Mexico. Two years later Capt. James Cook, on his third and last great voyage, established the general outline of northwest North America, though he saw little of what is now the British Columbia coast. While Cook repaired his vessels at Nootka sound, on the west coast of Vancouver Island, a few pelts of sea otter were obtained from the Indians. It was when the expedition, on the return trip to England, stopped at Macao, on the coast of south China, that the fabulous profits that could be made in the sea-otter trade became apparent. Following the publication of Cook's narrative, a veritable armada of trading vessels appeared on the northwest coast. As an outcome, a controversy between England and Spain developed, in the course of which Capt. George Vancouver was instructed to map the area. His surveys, conducted during the period 1792-94 represented the first comprehensive mapping of the coast north of San Francisco.

In 1793 Alexander Mackenzie made the first overland crossing of the continent north of Mexico, reaching the coast at Bella Coola, about 275 mi. N. of Vancouver. He paved the way for occupation of the Pacific slope by the fur traders and trappers of the Northwest company which, in 1821, amalgamated with the Hudson's Bay company. During the following 25 years the Hudson's Bay company ruled that immense territory west of the Rockies and north of the Spanish possessions with beneficent despotism in the interests of the fur trade. Prefaced by the influx of American settlers to the Oregon country, the international boundary west of the Rockies was established in 1846. In anticipation of this, the Hudson's Bay company had moved its western headquarters from Vancouver, Wash., to Victoria. Partly as a bulwark against further American expansion, Vancouver Island was made a British colony in 1849.

In 1858, with the discovery of gold on the Fraser river and, later, on its tributaries in the Cariboo district, and the consequent influx of miners, the mainland territory was proclaimed a colony under the name of British Columbia, and in 1866 it was united with the colony of Vancouver Island. Sir James Douglas, former chief factor in the Hudson's Bay company and an outstanding colonial administrator, was appointed governor.

In 1871 British Columbia became a province of Canada (see CANADA: History). One of the conditions under which the colony entered the confederation was the promise of the speedy construction of a transcontinental railway. Completion in 1885 (through trains, 1886) of the Canadian Pacific railway led to the founding of the city of Vancouver (incorporated 1886) and the initiation of steamship trade with the orient.

Associated with the gold rush were the beginnings of permanent settlement and transport development in the interior. In 1858 a route was established between the lower Fraser valley and Lillooet about 250 mi. upstream, and in the period 1860-65 the Royal Engineers surveyed and helped to build the Cariboo wagon road via the perilous Fraser canyon, connecting with Lillooet and leading northward to Quesnel and the Cariboo diggings. Several farms and ranches were established at way points along the Cariboo road to supply the miners. These "mile houses" were spaced about a day's journey apart along the road and were numbered as distances from Lillooet.

The gold boom soon faded but permanent settlement continued to expand, based on the development of agriculture, forestry and minerals such as the lode metals of the Kootenay country. The Canadian Pacific and the later completed Canadian Northern and Grand Trunk Pacific railways (after 1919, Canadian National rail-

ways) greatly stimulated resource development. The northern branch of the Grand Trunk line led westward to Prince Rupert, created on the coast 500 mi. N. of Vancouver in anticipation of the orient trade. Expectations in that direction failed to materialize and, especially after completion of the Panama canal, which opened in 1914, trade and commerce became centred more and more upon Vancouver, with its fine natural harbour and productive hinterland. By 1900 it had already outstripped Victoria as the largest city in the province, and later became the third largest in Canada.

Since the turn of the 20th century the development of provincial resources, while generally rapid, has been marked by periods of boom and depression. In common with other areas, British Columbia experienced a great expansion in its economy after World War II. Much of this expansion was attributable to increasing utilization of forest and water-power resources and the exploitation of natural gas and petroleum. Hydroelectric power resources increased rapidly after the war, more than 2,500,000 h.p. being added to the province's total within a period of 10 years. In 1960 an international agreement was signed between Canada and the United States providing for co-operative development of the Columbia river with storage projects in British Columbia and power generation projects downstream in Washington and for the sharing of flood control benefits and of increased power production resulting from the program.

Oil and gas reserves in northeastern British Columbia were developed with natural gas production becoming significant in 1956 and crude oil production beginning in 1958. The development of electric power and the construction of oil and gas pipelines made fuel and power available for expanding industry in southwestern British Columbia and the adjacent state of Washington. Prominent among these were the manufacture of aluminum and the refining of petroleum. Transportation facilities, especially truck and air transport, were improved, as were radio communications networks covering wide areas. In 1942 the Alaska highway was completed as a military road linking Dawson Creek with Yukon Territory and Alaska. Following the war it was improved and connected with Prince George (and Vancouver) by the John Hart highway. Later the publicly owned Pacific Great Eastern railway was extended northward from Quesnel to Prince George and Fort St. John, providing a rail link between Vancouver and the rapidly developing (gas and oil) Peace river country. Of minor but growing importance was the tourist industry, based primarily on the excellent hunting and fishing, which reached multimillion dollar proportions.

In political affairs Conservatives and Liberals, who had alternated in power after 1903 when Richard (later Sir Richard) McBride introduced Dominion party politics to the province, formed a wartime coalition in 1941, with the Co-operative Commonwealth federation (C.C.F.) as the chief opposition. The Social Credit party won by a narrow margin in 1952 and established a clear majority in 1953, which it increased in 1956 and retained, but with a reduced majority, in 1960; the opposition was formed by the C.C.F. while the Conservatives and Liberals formed small minorities. (See also CANADA: Administration and *Social Conditions: Political Parties.*)

A school consolidation program reduced the number of school districts to fewer than 100 (formerly there had been several hundred small districts with rural schools) and large schools were constructed in centrally located settlements. The extensive system of health and welfare services provided by the province (in 1927 British Columbia became the first province to provide old-age pensions) were greatly expanded with the assistance of the federal government after World War II, as were those of the other provinces (see CANADA: *Administration and Social Conditions: Welfare Services.*)

GOVERNMENT AND JUDICIARY

The unicameral provincial legislature, composed of 52 elected members, sits for a maximum term of five years. The government is formed by the majority party, from the elected members of which the premier (party leader) selects an executive council or

cabinet The crown is represented by a lieutenant governor, appointed by the governor general of Canada.

Administration is effected by a 10,000 employee provincial civil service. In addition to royalties from provincial resources, public revenue in British Columbia is derived from federal subsidies, succession duties, gasoline taxes and the profits of liquor control. Local government is effected through cities, villages and district municipalities, each with an elected mayor or reeve (president of village or town council) and a council.

In the bicameral federal government British Columbia is represented by 22 elected members and six senators, the latter appointed for life.

The judiciary is composed of both provincial and federal members. Judges of the supreme and county courts are appointed by the federal government and normally hold permanent office. The province appoints a chief justice of British Columbia, who heads the court of appeal, and minor court judges, including justices of the peace, magistrates and juvenile court judges.

POPULATION

The population of British Columbia in 1961 was 1,629,082 (up 38.9% from 1956), about 75% of it concentrated on the east coastal plain of Vancouver Island and along the adjacent mainland. About half the total lives in or near metropolitan Vancouver, and another 18% resides on Vancouver Island, mainly in metropolitan Victoria. In the interior, most people live in the southern valleys or are scattered along the main transportation routes. The largest interior concentration is in the fertile Okanagan valley, especially along the margins of Okanagan lake. Lesser concentrations are found in the Columbia and tributary valleys west of Kootenay lake, and in the valleys of the Rootenay and Thompson rivers. The central interior is sparsely populated, the main settlements being along the northern branch of the Canadian National railways from Prince George to Prince Rupert. The Peace river area has a rather dispersed rural settlement but contains fewer people than the associated area of Alberta. Large sections of northern British Columbia have no resident population.

Over two-thirds of British Columbia residents are of British stock, the remaining one-third primarily of western European origin, notably French (and French-Canadian), Scandinavian, German and Dutch. Among the minorities are Chinese, Japanese and East Indians. Largely because of the importation of indentured labour during early railroad construction and of subsequent federal immigration policy, British Columbia has more Chinese than any other Canadian province. Comprising nearly two-thirds of the 30,000 Asians in the province, the Chinese are primarily urban dwellers, engaged in wholesale and retail trade. Before World War II. Japanese were the most numerous Asian group and were associated with the fishing industry, but as a result of relocation during and after the war, their proportion has declined to about 30% of the total number of Asians. Practically all of the East Indians are of Punjab origin, chiefly Sikhs, and many are associated with sawmilling and retail fuel businesses.

About three-quarters of the provincial population is urban, only 6% being classed as rural farm dwellers. The largest cities (with their 1961 populations) are Vancouver, city 376,808, metropolitan area 777,197, and Victoria, city 53,861, metropolitan area 150,760. Vancouver is the chief commercial and manufacturing centre in the province, and an important deep-sea port. Manufactures include sawmilling, plywood and veneers and other wood processing, canning and other food processing and metal working. Victoria, the provincial capital, is primarily an administrative and residential city although retaining its early function as a deep-sea port and naval and garrison centre. Because of the pleasant climate and attractive setting, Victoria and adjacent southeastern Vancouver Island have become favourite retirement places, especially for people from the Canadian prairies. Other important Vancouver Island cities are Nanaimo (pop. 13,551), formerly a coal mining town but now a wood processing and supply and distribution centre, and the twin cities of Alberni (4,544) and Port Alberni (11,260), associated with sawmilling and pulp manufacture.

In the interior are Penticton (13,481), Kelowna (12,926), and Vernon (9,974), all fruit packing and processing centres in the Okanagan valley; Kamloops (9,725), transport focus at the confluence of the North and South Thompson rivers; Trail (11,242), a smelting centre; and Prince George (13,261), sawmilling, transport and regional commercial centre. The most important coastal settlement north of the Strait of Georgia is Prince Rupert (11,661), port city and north-western terminus of the Canadian National railway (see fig. 2).

EDUCATION

Under the terms of the British North America act, education is under control of the provincial government. Free public schooling to university entrance level is provided and is compulsory to age 15. Generally, school years are divided into seven years elementary, two years junior secondary and three years senior secondary school. Instruction is given by correspondence to those students who do not have access to one of the regularly established schools. School buildings and maintenance and teachers' salaries are financed from municipal revenues, supplemented by government grants. Several private and denominational schools also

provide courses up to university level but receive no municipal or provincial grants. They follow in general, however, a government-approved curriculum to qualify students as candidates for departmental (government) examinations and high school graduation certificates.

Higher education is available at the provincially endowed University of British Columbia, at Vancouver. Faculties include agriculture, arts and science, applied science, commerce and business administration, education, forestry, law, medicine, pharmacy and graduate studies. Annual enrollment is about 13,000. Affiliated with the university is Victoria college, in Victoria, which offers the baccalaureate in arts, science and education.

Aside from municipally owned libraries and local museums there is a Provincial library and archives in Victoria containing a valuable collection of Pacific northwest literature. Also at the legislative buildings is a Provincial museum which includes an interesting collection of Indian artifacts. The Provincial Public Library commission offers mail service to individuals; dispatches boxes of books to outlying settlements; and in the larger settlements operates several branch libraries which also provide book-mobile services.

THE ECONOMY

Industries.—Logging.—Among the primary, or extractive industries, logging holds first place in terms of dollar value. In the second half of the 20th century logging accounted for a net value (*i.e.* value of product less cost of extraction) of about \$200,000,000 annually and employed about 18,000 workers. The chief species cut are Douglas fir, western hemlock, western red cedar, balsam (*Abies amabilis*) and spruce. Of these the Douglas fir is most important both in volume cut and in commercial value. Total annual cut is approximately 1,200,000,000 cu.ft. (7,000,000,000 bd.ft.), more than enough to build 500,000 average-sized frame houses. Although output from interior forests has been increasing, the coast continues to supply most of the annual cut, with the Vancouver forest district (Vancouver Island and adjacent mainland coast) contributing far the greatest share of the coastal cut. After 1947 a sustained-yield program was initiated by the provincial government to regulate the timber harvest.

Mining.—Mining has traditionally held second place among the extractive industries, in the 1950s accounting for a net value approaching \$100,000,000 annually and employing over 10,000 workers. British Columbia is endowed with a variety of metallic and nonmetallic minerals of which zinc, lead, copper, gold, iron ore, coal, asbestos, natural gas and petroleum are economically the most important. Discoveries of coal and placer gold led to early development of the province. Gold (lode) continues to hold a significant place. After 1940 production from the Crownsnest pass coal fields exceeded that from Vancouver Island. As a result of the introduction of the selective flotation process for separating complex silver-lead-zinc ores, the Sullivan mine at Kimberley (Kootenay area) has developed as the largest lead-zinc mine in Canada. The ore moves westward to the smelter at Trail. As by-products of the smelting process, antimony, cadmium, bismuth and other minerals are produced. An asbestos mine, operating on a very large, high quality ore body near McDame (north-central British Columbia) was opened in 1952. Output (about 1,500 tons per day) is milled near the mine and shipped by truck to Whitehorse, Yukon territory, by rail to Skagway, Alaska, and by boat to Vancouver. Substantial reserves of natural gas have been proved and petroleum has been discovered in northeastern British Columbia. In 1957 a pipeline was completed to bring natural gas from the Peace river area to the Vancouver area and adjacent United States. Alberta petroleum is brought to the same region by a pipeline completed in 1953. A pipeline to carry petroleum from the Peace river area to Kaloamps was constructed in 1961.

Agriculture.—Agriculture, which in the second half of the 20th century accounted for a net value of over \$75,000,000 annually, ranks third among the primary industries. It employs nearly twice as many persons as are engaged in logging. Only 5% of the provincial area is classed as agricultural (including open range). Arable land amounts to 6,500,000 ac., about 20% of which is

actually under cultivation. Because of the dry summer climate, supplementary irrigation is commonly practised on Vancouver Island and in the lower Fraser valley. In the dry valleys of the southern interior, water is a necessity for cultivated crops. About 200,000 ac. are under irrigation, the concentration being in the Okanagan, Thompson and Nicola valleys.

In spite of the limited crop acreage, the diversity of climate, soils and terrain conditions in the province has made possible a diversity of farm types, ranging from horticultural specialty to livestock ranching. The lower Fraser valley, including the Fraser river delta, contains the heart of British Columbia agriculture. Nearly half the total value of agriculture production comes from this area of diverse enterprises. The Okanagan valley is next in importance, contributing about 17%. followed by Vancouver Island, with about 10%. Each of the other agricultural areas accounts for 7% or less. Nearly 90% of the cultivated acreage is devoted to field crops (hay and pasture, small grains and forage seed); horticulture (growing of fruit and vegetables) occupies the remaining 10%. The value of field crops is largely reflected in returns to the livestock industry which constitutes the most valuable phase of agriculture in British Columbia with dairying, the most important single element, accounting for nearly half the livestock income. Poultry follows, contributing about one-third of the livestock value. Both these enterprises are concentrated in the lower Fraser valley and on Vancouver Island. Beef production on the other hand is associated with the open grasslands and nonirrigated benchlands of the central and southern interior. In crop production, the lower Fraser valley, Okanagan valley, Peace river area and Vancouver Island are the most important regions, the first two accounting for about 70% of the provincial crop value. Most of the cereal grains are grown in the Peace river area while about 75% of the tree fruits (apples, peaches, pears and apricots) come from the Okanagan valley. Because of the long frostless season and mild winters, specialty horticulture in the lower Fraser valley and on Vancouver Island takes the form of small fruits (strawberries, raspberries and loganberries), market vegetables, greenhouse horticulture, nursery stock and flower production. The Saanich peninsula, north of Victoria, is particularly favoured in this regard and most of the greenhouse crops, bulbs and cut flowers come from that area.

Fisheries.—Fisheries follow agriculture in order of economic importance, accounting for a landed value of \$28,000,000 to \$51,000,000 a year in the 1950s (approximately 40% of the total value of Canadian fisheries) and employing an average of about 7,000 full-time and 6,000 seasonal or part-time workers. In contrast to the fisheries of eastern Canada, over two-thirds of the value of British Columbia's fisheries comes from the five species of Pacific salmon—sockeye, pink, chum, coho and spring. They are easily taken by nets and by trolling when they congregate in coastal waters during the annual spawning run. Gill nets are commonly used in the larger estuaries and at river mouths. Purse seine operations involve more expensive equipment and are usually carried on farther afield than is the case with gill-netting. The salmon catch taken by trollers is almost entirely limited to spring (king, Chinook or tye) and coho (silver or blueback), since these are the only species that readily take an artificial lure. For the same reason, and because of their spectacular fighting qualities when hooked, spring and coho form the basis of the salt-water sport fishery in British Columbia. Because of their vulnerability during the spawning run, commercial salmon fishing is carefully regulated by an international (Canada-U.S.) commission. About three-fourths of the catch is canned, largely for export. The landed value of sockeye far exceeds that of the other salmon species individually amounting to an annual average of about \$8,000,000. Herring and halibut follow salmon in economic importance, the distribution of the latter being closely related to shallower areas along the narrow continental shelf. The halibut catch, like that of salmon, is regulated by an international commission.

Trapping.—Trapping is the least important of the extractive industries. In the second half of the 20th century it accounted for a net value of about \$1,000,000 annually and employed approximately 300 persons. Since 1926 the industry has been regulated

by a registered trap line system, thus ensuring maintenance of the fur resource. Most of the trap lines are in the north, about half of them owned by native Indians.

Hydroelectric Power.—The generation of hydroelectric energy may be grouped among the primary industries. By 1960, on the basis of power generated for sale, the annual net value of hydroelectric power approximated \$80,000,000. British Columbia is well-endowed with water resources, having an estimated potential of 30,000,000 h.p. (about $\frac{1}{3}$ of the national total). The larger streams are snow-fed and, though inclined to be "flashy," have considerable flows and gradients and offer numerous sites for hydroelectric development. The largest drainage basin lying within the province is that of the Fraser river, embracing an area larger than Great Britain. It contains large water-power potentials but their development hinges largely on a satisfactory solution to the problem of developing power installations without destroying the salmon, because the Fraser is also British Columbia's most important salmon-spawning stream. Most of the developed power in the province comes from hydroelectric installations, but a large (100,000 h.p.) thermo-electric plant is located on southeastern Vancouver Island and the first unit of a second, larger plant near Vancouver, using Peace river natural gas as fuel, was placed on test in 1961. The largest single hydroelectric development before 1960 was that at Kemano, built to supply the large aluminum refinery at nearby Kitimat (70 mi. S.E. of Prince Rupert). This development, with an ultimate capacity of over 2,000,000 h.p., diverts the impounded waters of the upper Nechako system via a 10-mi. tunnel through the Coast mountains and drops it to the powerhouse at tidewater. Other large installations are at Campbell river on Vancouver Island, on the Bridge river near Lillooet, and on the Kootenay and Pend Oreille rivers near Trail. Aside from general utility sales, most of the rapidly increasing output is consumed by mining and smelting and pulp and paper industries.

Manufacturing.—Industrially, British Columbia is a producer of raw and semiprocessed goods which are mainly exported to foreign markets, principally in the United States and United Kingdom. The processing of wood, mineral, fish and agricultural products, based on provincial resources, constitutes the bulk of manufacturing activity.

Forest Products.—Over half the net value of all manufacturing is contributed by the forest-based industries, which have a net value of about \$350,000,000 and employ 50,000 persons. Primary among these is sawmilling, which uses about three-fourths of the annual cut and makes British Columbia the leading Canadian lumber producer. Most of the mills are scattered through the interior, but the large stationary plants, the largest capable of turning out over 300,000 bd.ft. in an eight-hour day, are typically located on the coast, on Vancouver Island and the southwestern mainland. Logs are transported by tug-towed rafts, log-carrying barges and trucks to feed these large mills. Former waste products of logging and sawmilling are utilized in the second major forest industry, pulp and paper milling, which has seen tremendous expansion after World War II. Pulp and paper mills, consuming about 15% of the annual timber cut, are concentrated on the coast. Output is mainly in the form of sulfate pulp, newsprint and sulfite pulp. British Columbia supplies about 10% of the Canadian newsprint export and about 20% of the wood pulp export. Veneer and plywood mills utilize only 5% of the annual log cut but account for two-thirds of the Canadian production of these materials, primarily Douglas fir plywood.

Mineral Refining and Processing.—Mineral refining and processing ranks next in economic importance to the forest-based manufacturing industries, with a net value of about \$100,000,000. Most of this value comes from the smelting of nonferrous metals which is carried on at two very large plants in Trail and Kitimat. The former produces the major share of Canada's lead and zinc along with many valuable by-products. Although foreign ores are smelted, most of the raw material is supplied by the Sullivan mine, operating on the huge Kimberley ore body, near Cranbrook. Large blocks of power are required and are supplied by company-owned plants on the Kootenay and Pend Oreille rivers. The

Kitimat plant, which depends upon alumina imports, principally from Jamaica, is located at the head of Douglas channel, a deep fiord. Its location is governed by tidewater access and availability of large quantities of cheap electric power, supplied by the company's installation at Kemano. Ultimate annual capacity of the Kitimat smelter is 550,000 tons of aluminum ingots.

Agricultural and Fish Products.—Processed agricultural products and fish products are other important manufactures. A large share of the raw materials for the former are imported (e.g. grains and beef animals from the prairie provinces, sugar from overseas), but fish processing utilizes local resources. Until 1940 fish canning and reduction plants were widely distributed along the coast. Since that time, because of more rapid and efficient transport and integrated operations, there has been a trend toward concentration in the Vancouver and Prince Rupert areas.

Transportation and Communication.—**Railways.**—The railway system has three components—the privately owned Canadian Pacific (C.P.R.), the federally owned Canadian National (C.N.R.), and the provincially owned Pacific Great Eastern (P.G.E.R.) railways. The C.P.R. main line enters the province via Kicking Horse pass and crosses the Selkirk and Monashee mountains to Fraser river drainage, which it follows to Vancouver. The C.P.R. Kettle Valley line follows a devious route from the Crowsnest pass near Fernie to Brodie (connecting the main line north through Merritt at Spences Bridge), and serves the southern valleys and "boundary country" of British Columbia. The C.N.R. main line crosses the Rockies via Yellowhead pass, well to the northward of the C.P.R. line. At Tête Jaune Cache, in the Rocky mountain trench, a northern branch line extends westward to Prince Rupert. The main line follows the North Thompson to Kamloops whence, like its C.P.R. counterpart, it parallels the Thompson and Fraser rivers to the sea. Short branch lines of both the C.P. and C.N. railways extend along Vancouver Island's east coastal plain, northward from Victoria. The P.G.E.R. line follows a historic route from Vancouver through the Coast mountains, emerging at Lillooet. From there it extends northward to Prince George and Fort St. John and Dawson Creek in the Peace river country. The link between Prince George and the Peace river area, where it connects with the Northern Alberta railways, was completed in 1958.

Highways.—The highway pattern, although less-strongly valley-oriented, is similar to that of the railroads. In many sections following historic routes, the road system includes seven major highways—the Island highway, along the east coastal plain of Vancouver Island; the Trans-Canada highway, extending from Vancouver to Hope, Kamloops and Revelstoke, to Golden and on into Alberta; the southern transprovincial highway, following a circuitous route between Hope and Crowsnest pass, and with northward links to the Trans-Canada highway; the Cariboo highway extending from Vancouver to Prince George; the northern transprovincial highway extending westward from Prince George to Prince Rupert; the John Hart highway leading northward from Prince George and crossing the Rockies to the Peace river country; and the Alaska highway, winding across northern British Columbia from Dawson Creek to the Yukon and terminating at Fairbanks, Alaska.

Air.—Air transport in British Columbia has seen remarkable development since World War II, and Vancouver's international airport is the focus of all air traffic in the province, multiple daily flights connecting that city with Victoria and with points in eastern Canada. Daily flights serve Penticton, Nelson and Cranbrook in the south; Kamloops, Quesnel, Prince George, Fort St. John and Fort Nelson to the north; and the Smithers-Terrace-Kitimat area, Queen Charlotte Islands and western Vancouver Island. International service originating in Vancouver includes flights to Seattle, Japan, Hawaii, Fiji and Australia, as well as to Central and South America and Europe. The stately Canadian Pacific "Empress" liners which, until World War II, connected Vancouver and Victoria with the orient and Australia have been replaced by less luxurious but vastly speedier aircraft. Apart from scheduled air services, a large number of charter operations link the more isolated logging and fishing camps with the Victoria-Vancouver area.

Water.—The same terrain characteristics which make land travel difficult, enhance the possibilities of water transport. Aside from the Strait of Georgia area, most coastal points are accessible only by boat or, in good weather, by air. The deeply fiorded coast line and intersecting channels provide a sheltered, natural waterway most important in exploiting the abundant resources of sea and forest. Fine natural harbours exist, capable of holding the largest ships, and these figure prominently in the export of British Columbia's products. In the second half of the 20th century about 12,000,000 tons of incoming and outgoing freight was handled annually by deep-sea vessels and about half that amount by coastwise shipping. Three foreign markets, the United States, the United Kingdom and Japan, take nearly three-fourths of British Columbia's exports. Two of these, the United States and United Kingdom, supply three-fourths of British Columbia's imports.

BRITISH COMMONWEALTH: see COMMONWEALTH OF NATIONS.

BRITISH COUNCIL OF CHURCHES, "a fellowship of churches in the British Isles which accept our Lord Jesus Christ as God and Saviour." Formed in 1942, it has the same basis as the World Council of Churches (*q.v.*). All the main British churches except the Roman Catholic belong to it. Its main objects are common action, co-operation in study and the promotion of Christian unity. Its committees deal with education, evangelism, faith and order, international affairs, social responsibility and youth work. Its department of interchurch aid and service to refugees raises money for the relief of those in need throughout the world. (H. M. W.)

BRITISH DRAMA LEAGUE, an organization created in 1919 for the encouragement of the art of the theatre, both for its own sake and as a means of intelligent recreation among all classes of the community. Its founder, Geoffrey Whitworth, was its first secretary and later became its first director and chairman of the council. From its inception its work has been mainly among amateur groups, helping them by advice, information, tuition and the loan of books to improve their standards of production. Most groups borrow acting copies of every play they perform from the league. Its success would not have been possible without its library, started with a gift of books from Annie E. F. Horniman and now one of the principal theatrical collections of the world, containing more than 100,000 books. The journal *Drama* was founded in July 1919.

However, it was always the intention of its founder that the league's activities should not be limited to amateurs, and it has urged the following matters on the attention of successive governments: the establishment of a national theatre policy adequate to the needs of the people; the establishment of drama departments at the universities; a place for drama in the school curriculum; and the abolition of entertainment duty in respect of live entertainment. The league also organizes an annual one-act play competition and sends officials to adjudicate at local drama festivals.

The main outlines of the league's work are established through annual conferences, of which the first was held at Stratford-upon-Avon, Warwickshire, in 1919, and the annual national festivals of community drama, first organized in 1927. A successful conference for professional producers was arranged by the league in London in 1960.

The membership of the league, which has its headquarters in London, at the beginning of the 1960s was about 5,500. One-third of these were individuals and the rest organizations, including amateur societies of all kinds, professional repertory companies, the British Broadcasting corporation and Independent Television authority.

See Twenty-Five Years of *the British Drama League*, MCMXIX-MCMXLIV (1944). (I. K. F.)

BRITISH EAST AFRICA, is the name given to Uganda,

Kenya, Tanganyika and Zanzibar. Early proposals to amalgamate Kenya and Uganda were abandoned at the beginning of the 20th century but after World War I the comparative poverty of the east African territories suggested that Tanganyika, Germany's former dependency, might profitably be linked with other British east African possessions. The possibility of creating some form of closer union was borne in mind when the terms of the Tanganyika mandate were drafted, and between 1924 and 1929 a number of commissions considered the problem. In east Africa itself they met with little support for the proposal. Kenya's European settlers, intent upon achieving responsible government, feared that union might find them overwhelmed by the predominantly African populations of the neighbouring territories. The Africans in all the territories feared domination by the European settlers of Kenya as too did the Indians, while even Europeans were suspicious of the pre-eminence of Kenya. Gradually, however, European and Asian communities outside Kenya came to favour some form of economic co-operation. But the Africans remained suspicious and all that emerged from the investigations was a conference of the governors of some of the territories, first held in 1926 and repeated in 1930 from which date it met annually; representatives from Nyasaland and Northern Rhodesia attended less frequently.
